This definition has been broadly accepted although actual wording differs somewhat[3]. Because omitting the name “Interstitial Cystitis” might cause serious problems in different health systems by affecting reimbursement and disability determinations, the name Bladder Pain Syndrome/ Interstitial Cystitis (BPS/IC) could be used in parallel with BPS for the time being. **In this chapter, as in the 2008 Consultation, the term Bladder Pain Syndrome largely replaces the older Interstitial Cystitis term, but the two are essentially interchangeable as there is no accepted definition that clearly delineates the interstitial cystitis syndrome from bladder pain syndrome. The Consultation believes the latter term more appropriately describes the disorder.**

Historically, definitions of IC have moved from a severe inflammatory bladder disease to a condition described primarily by symptoms (**Table 1**) [3].

The International Continence Society [13] (ICS) used the term Painful Bladder Syndrome (PBS) defined as “ the complaint of suprapubic pain related to bladder filling, accompanied by other symptoms such as increased daytime and night-time frequency, in the absence of proven urinary infection or other obvious pathology”. ICS reserved the diagnosis Interstitial Cystitis (IC) to patients with “typical cystoscopic and histological features”, without further specifying these. It has however been shown,

Table 1: Historical definitions of interstitial cystitis.

1887 Skene [4]: An inflammation that has destroyed the mucous membrane partly or wholly and extended to the muscular parietes.

1915 Hunner [5]: A peculiar form of bladder ulceration whose diagnosis depends ultimately on its resistance to all ordinary forms of treatment in patients with frequency and bladder symptoms (spasms).

1951 Bourque [6] : Patients who suffer chronically from their bladder; and we mean the ones who are distressed, not only periodically but constantly, having to urinate at all moments of the dav and of the night suffering pains every time they void.

1978 Messing and Stamey [7]: Nonspecific and highly subjective symptoms of around-the-clock frequency, urgency, and pain somewhat relieved by voiding when associated with glomerulations upon bladder distention under anesthesia.

1990 Revised NIDDK Criteria: Pain associated with the bladder or urinary urgency, and, glomerulations or Hunner's ulcer on cystoscopy under anesthesia in patients with 9 months or more of symptoms, at least 8 voids per day, 1 void per night, and cystometric bladder capacity less than 350cc [8].

1997 NIDDK Interstitial Cystitis Database Entry Criteria [9]: Unexplained urgency or frequency (7 or more voids per day), OR pelvic pain of at least 6 months duration in the absence of other definable etiologies.

2008 European Society for the Study of Bladder Pain Syndrome (ESSIC)[10]: Chronic (>6 months) pelvic pain, pressure, or discomfort perceived to be related to the urinary bladder accompanied by at least one other urinary symptom such as persistent urge to void or frequency. Confusable diseases as the cause of the symptoms must be excluded.

2009 East Asian Guideline [11]: A disease of the urinary bladder diagnosed by 3 conditions: lower urinary tract symptoms, bladder pathology, and exclusion of confusable diseases. The characteristic symptom complex (hypersensitive bladder syndrome) includes bladder hypersensitivity, usually associated with urinary frequency, with or without bladder pain.

2011 American Urological Association [12]: An unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than 6 weeks duration, in the absence of infection or other identifiable causes.

that only a fraction of patients believed by experts to have BPS fulfil this definition [14].

In the remainder of this chapter the condition will be referred to as bladder pain syndrome (BPS). Some of the older literature may be discussed using the original terminology in the interests of clarity. Logically "interstitial cystitis" should include some form of demonstrable inflammation in the bladder wall, while "bladder pain syndrome" should include pain in the region of the bladder. The diagnosis of BPS is based on exclusion of other diseases in the bladder, urethra, and other pelvic organs including the musculoskeletal system. As with other diseases without clear objective diagnostic criteria or pathophysiological explanation, countless theories have been put forward without adding much to the delineation or understanding of the disease.

In practice, patients with symptoms of BPS are screened to exclude other relevant diagnoses or confusable diseases[2], and a focused evaluation is performed at the discretion of the physician or centre. This evaluation might include cystoscopy under local or general anaesthesia, bladder distension with registration of bladder capacity and/or the presence of glomerulations and Hunner's lesion. Bladder wall biopsies might be obtained and evaluated for inflammation, ulcer, fibrosis, mast cells etc. The evaluation might also include urodynamics with registration of bladder capacity, compliance and bladder stability[15]. One view of the relationship of BPS with OAB is graphically depicted in **Figure 1** [16]. The 14% incidence of urodynamic detrusor overactivity in the BPS [17] patients is probably close to what one might expect in the general population if studied urodynamically [18].

In the end, these investigations might prove to be normal and the patients are identified as having BPS as a diagnosis of exclusion. The relevance of urodynamic, cystoscopic and histological findings is limited by a lack of consistency in technique, and it is therefore recommended to use the standardisations described by ESSIC [2].

II. HISTORY/NOMENCLATURE/ TAXONOMY

1. HISTORICAL NOTES

Recent historical reviews confirm that interstitial cystitis was recognized as a pathologic entity during the 19th century.[19,20] In his textbook Practical Observations on Strangulated Hernia and Some Diseases of the Urinary Organs, Joseph Parrish, a Philadelphia surgeon, described 3 problematic cases of recurrent, severe lower urinary tract symptoms in which he made repeated attempts to locate a bladder stone, which was the most common source for these symptoms in early 19th century America. [21] As Teichman et al have convincingly argued,

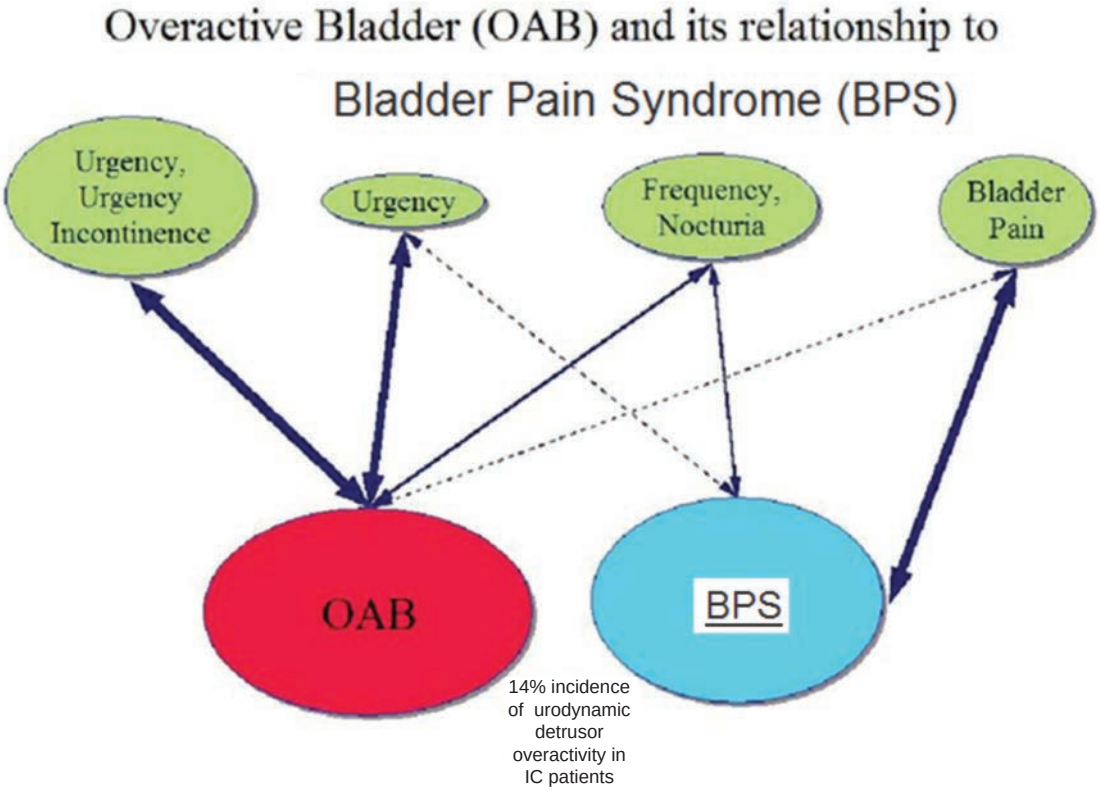

Figure 1: Overactive Bladder (OAB) and its relationship to Bladder Pain Syndrome (BPS). Abrams, P., Hanno, P., and Wein, A.: Neurourol Urodyn, 24: 149, 2005.

these patients displayed all of the clinical hallmarks of IC including chronic frequency, urgency, dysuria and pelvic pain in the absence of demonstrable pathology.[22] Although he used the term repeatedly in his manuscript, Parrish did not elaborate upon the clinical definition of "tic douloureux," likely because contemporaneous physicians would have been familiar with the concept. However, Parrish attributed the term Tic doloreux to his mentor, Dr. Phillip Syng Physick, who had applied it to patients with severe lower urinary tract symptoms with no discernible etiology, with the most common etiology during the 19th century being bladder stones.

A review of archival material from the Philadelphia College of Physicians indicates that by 1808 Physick had developed a concept of bladder inflammation, a "bladder ulcer," that produced lower urinary tract symptoms in the absence of bladder stone.[19] Tic douloureux at its time represented a neurological irritation, most often associated with the trigeminal nerve but applicable to other sensory distributions as well, which produced pain and discomfort in the absence of injury or other specific physical findings. In applying the concept of tic douloureux to bladder sensation Parrish was ascribing the paroxysmal lower urinary tract symptoms occurring in patients to an idiopathic process affecting the nerves of the bladder. This sophisticated concept continues to be a prominent component of modern theories of BPS pathogenesis. Furthermore, Tic douloureux allowed him to formulate a diagnosis for those patients who chronically manifested the symptoms caused by a stone (severe frequency, urgency, dysuria and pelvic pain) but had no stone that could be detected. That is, he considered a neuropathic etiology in the absence of any other tangible causes of bladder pain. Clearly, this experience strongly resonates with the contemporary diagnosis of BPS.

50 years after Parrish's first publication on the condition, Skene used the term interstitial cystitis to describe an inflammation that has "destroyed the mucous membrane partly or wholly and extended to the muscular parietes".[4] Early in the 20th century, at a New England Section meeting of the American Urological Association, Guy Hunner reported on 8 women with a history of suprapubic pain, frequency, nocturia, and urgency lasting an average of 17 years.[5,23] He drew attention to the disease, and the red, bleeding areas he described on the bladder wall came to have the pseudonym "Hunner's ulcer". As Walsh observed, this has proven to be unfortunate.[24] In the early part of the 20th century,

the very best cystoscopes available gave a poorly defined and ill-lit view of the fundus of the bladder. It is not surprising that when Hunner saw red and bleeding areas high on the bladder wall, he thought they were ulcers. For the next 60 years, urologists would look for ulcers and fail to make the diagnosis in their absence. The disease was thought to be a focal, rather than a pancystitis.

Hand authored the first comprehensive review about the disease, reporting 223 cases.[25] Many of his epidemiologic findings have held up to this day. His description of the clinical findings bears repeating. “I have frequently observed that what appeared to be a normal mucosa before and during the first bladder distention showed typical interstitial cystitis on subsequent distension”. He notes, “small, discrete, submucosal hemorrhages, showing variations in form…dot-like bleeding points…little or no restriction to bladder capacity.” He portrays three grades of disease, with grade 3 matching the small-capacity, scarred bladder described by Hunner. Sixty-nine percent of patients were grade 1 and only 13% were grade 3. Walsh later coined the term “glomerulations” to describe the petechial haemorrhages that Hand had described.[24] But it was not until Messing and Stamey discussed the “early diagnosis” of IC that attention turned from looking for an ulcer to make the diagnosis to the concepts that 1) symptoms and glomerulations at the time of bladder distention under anesthesia were the disease hallmarks, and 2) the diagnosis was primarily one of exclusion.[7,24] However, this description was not suitable for defining this disease in a manner that would help physicians make the diagnosis and set up research protocols.

The National Institute of Diabetes, Digestive, and Kidney Disorders (NIDDK) held a major meeting in 1987 with researchers and clinicians from around the world[26]. This ultimately resulted in the **1990 Revised NIDDK Criteria**: Pain associated with the bladder or urinary urgency, **and**, glomerulations or Hunner’s ulcer on cystoscopy under anesthesia in patients with 9 months or more of symptoms, at least 8 voids per day, 1 void per night, and cystometric bladder capacity less than 350cc.[8]

In order to validate the criteria, which were designed not for clinical diagnosis, but rather to ensure that patients enrolled in research trials could be agreed upon to have the disease, a database with broad entry criteria was created. The **1997 NIDDK Interstitial Cystitis Database Entry Criteria**: Unexplained urgency or frequency (7 or more voids per day), **OR** pelvic pain of at least 6 months duration in the absence of other definable etiologies[27] Urgency was not defined in the protocol. Participants were given a 10 point scale, and those who scored 2 or higher on self report satisfied the urgency criteria. The protocol was written in 1992, a time when the definition of “urgency” was not a particularly controversial topic. When a comparison of the NIDDK revised criteria with the database entry criteria was performed, it was apparent that up to 60% of patients clinically believed to have interstitial cystitis by experienced clinicians were being missed when the NIDDK research criteria were used as a definition of the disease. [28] With the demise of the NIDDK criteria as an appropriate clinical definition of the disorder, the last decade became an active one from an international standpoint in terms of wrestling with the issues of nomenclature, taxonomy and diagnosis.[3,29,30]

2. NOMENCLATURE AND TAXONOMY

The literature over the last 170 years has seen numerous changes in description and nomenclature of the disease. The syndrome has variously been referred to as tic doloureux of the bladder, interstitial cystitis, cystitis parenchymatosa, Hunner’s ulcer, panmural ulcerative cystitis, urethral syndrome, and painful bladder syndrome.[4,6,20,22,23,31,32] The term ‘‘interstitial cystitis,’’ which Skene is credited with coining and Hunner for bringing it in to common usage, is a misnomer; in many cases not only is there no interstitial inflammation, but also, histopathologically, there may be no inflammation at all.[33-36] By literally focusing exclusively on the urinary bladder, the term interstitial cystitis furthermore does not do justice to the condition from both the physician’s and the patient’s perspective. The textual exclusiveness ignores the high co-morbidity with various pelvic, extra-pelvic and non-urological symptoms[37] that frequently precede the onset of the bladder condition.[38]

With the formal definition of the term ‘‘painful bladder syndrome’’ by the ICS in 2002, the terminology discussion became an intense international focal point.[13]

- In Kyoto at the ICICJ in March 2003, it was agreed that the term ‘‘interstitial cystitis’’ should be expanded to ‘‘interstitial cystitis/chronic pelvic pain syndrome’’ when pelvic pain is at least of 3 months duration and associated with no obvious treatable condition/pathology[39].

- The European Society for the Study of Interstitial Cystitis (ESSIC) held its first meeting in Copenhagen soon after Kyoto. Nomenclature was discussed, but no decision was reached, as the meeting concentrated on how to evaluate patients for diagnosis[15].

- At the 2003 meeting of the NIDDK titled, ‘‘Research Insights into Interstitial Cystitis,’’ it was concluded that ‘‘interstitial cystitis’’ will inexorably be replaced as a sole name for this syndrome. It will be a gradual process over several years. At the meeting it was referred to as ‘‘interstitial cystitis/painful bladder syndrome’’ in keeping with International Continence Society nomenclature.[40]

- At the 2004 inaugural meeting of the Multinational Interstitial Cystitis Association in Rome, it was

concluded that the syndrome should be referred to as ''painful bladder syndrome/interstitial cystitis'' or ''PBS/IC'' to indicate an intellectual and taxonomical hierarchy within the acronym.[40]

- The International Consultation on Incontinence in 2004, cosponsored by the ICS and Societe Internationale d'Urologie in association with the World Health Organization, included the syndrome as a part of its consultation. The chapter in the report was titled, ''painful bladder syndrome (including interstitial cystitis),'' suggesting that the IC formed an identifiable subset within the broader syndrome. Because such a distinction is difficult to define, within the body of the chapter, co-authored by nine committee members and five consultants from four continents, it was referred to as PBS/ IC (one inclusive entity).[41]

- In June 2006 Abrams and colleagues published an editorial focusing on the nomenclature problem.[42] They noted that: "It is an advantage if the medical term has clear diagnostic features that translate to a known pathophysiologic process so that effective treatment may be given. Unfortunately, the latter is not the case for many of the pain syndromes suffered by patients seen at most pain, gynecological, and urological clinics. For the most part these ''diagnoses'' describe syndromes that do not have recognized standard definitions, yet imply knowledge of a pathophysiologic cause for the symptoms. Unfortunately the terminology used to describe the condition may promote erroneous thinking about treatment on the part of physicians, surgeons and patients. These organ based diagnoses are mysterious, misleading and unhelpful, and can lead to therapies that are misguided or even dangerous." The editorial went on to note that a single pathologic descriptive term (interstitial cystitis) for a spectrum of symptom combinations ill serves patients. The umbrella term ''painful bladder syndrome'' was proposed, with a goal to define and investigate subsets of patients who could be clearly identified within the spectrum of PBS. It would fall within the rubric of chronic pelvic pain syndrome. Sufferers would be identified according to the primary organ that appears to be affected on clinical grounds. Pain not associated with an individual organ would be described in terms of the symptoms.

One can see in this the beginnings of a new paradigm that might be expected to change the emphasis of both clinical and basic science research, and that removes the automatic presumption that the end-organ in the name of the disease should necessarily be the sole or primary target of such research.

•At the major biannual IC research conference in the fall of 2006, held by the National Institute of Diabetes, Digestive, and Kidney Disorders (Frontiers in Painful Bladder Syndrome/Interstitial Cystitis), the ESSIC group was given a block of time in which to present their thoughts and conclusions. Because PBS did not fit into the taxonomy of other pelvic pain syndromes such as urethral or vulvar pain syndromes, and because IC is open to different interpretations, ESSIC suggested that Painful Bladder Syndrome be redesignated as Bladder Pain Syndrome (BPS), followed by a type designation. BPS is indicated by two symbols, the first of which corresponds to cystoscopy with hydrodistention findings (1, 2, or 3, indicating increasing grade of severity) and the second to biopsy (A, B, and C, indicating increasing grade of severity of biopsy findings) (**Table 2**). Although neither cystoscopy with hydrodistention nor bladder biopsy was prescribed as an

essential part of the evaluation, by categorizing patients as to whether either procedure was done, and if so, the results, it is possible to follow patients with similar findings and study each identified cohort to compare natural history, prognosis, and response to therapy [2].

- As Baranowski et.al. conceived it in early 2008[43], BPS is thus defined as a pain syndrome with a collection of symptoms, the most important of which is pain perceived to be in the bladder. IC is distinguished as an end-organ, visceral-neural pain syndrome, whereas BPS can be considered a pain syndrome that involves the end-organ (bladder) and neuro-visceral (myopathic) mechanisms. In IC, one expects end-organ primary pathology. This is not necessarily the case in the broader BPS.

A didactically very demonstrative way to conceptualize the dawning shift in conception of the condition is with the drawing of a target (**Figure 2**). There may be many causes of chronic pelvic pain. When an aetiology cannot be determined, it is characterized as pelvic pain syndrome. To the extent that it can be distinguished as urologic, gynecologic, dermatologic, and the like, it is further categorized by organ system. A urologic pain syndrome can sometimes be further differentiated on the site of perceived pain. Bladder, prostate, testicular, and epididymal pain syndromes follow. Finally, types of BPS can be further defined as IC, or simply categorized by ESSIC criteria. Patient groups have expressed their concerns with regard to any nomenclature change that potentially drops the term ''interstitial cystitis'' because the U.S. Social Security Administration and private insurances recognize IC but not the term BPS, and benefits potentially could be adversely affected. Whether the term "interstitial cystitis", as difficult as it is to define and as potentially misleading as it is with regard to aetiology and end-organ involvement, should be maintained, is a subject of ongoing controversy.

Taxonomy and nomenclature in Japan, Korea, and Taiwan use the umbrella term of "frequency/urgency syndrome" characterized by frequency (frequent voiding) and urgency (strong desire to void). It is an inclusive term incorporating overactive bladder syndrome (OAB), hypersensitive bladder syndrome (HSB), and other conditions that are associated with frequency and urgency. Urgency in OAB is characterized by sudden onset and/or fear of leakage, while urgency in HSB is of a persistent nature and is associated with the fear of pain. OAB-wet is a subgroup of OAB. Painful bladder syndrome (PBS) is a subgroup of HSB with pain. Interstitial cystitis is one of the diseases manifest by frequency/urgency and overlaps with HSB and PBS.[11,44,45] (**Figure 3**).

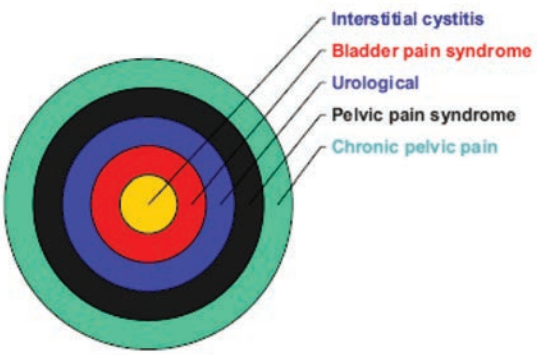

Figure 2: Conceptual Diagram of Pelvic Pain.

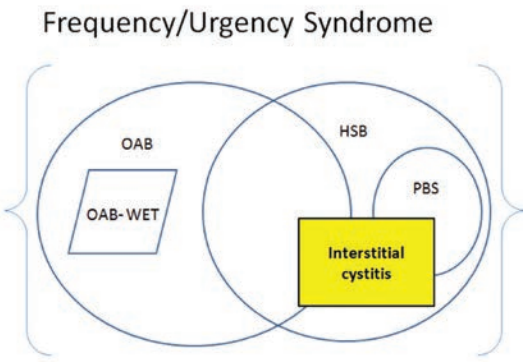

Figure 3: East Asian View of Taxonomy adapted from Homma[44] (see text for explanation).

The American Urological Association refers to the syndrome under consideration as "interstitial cystitis/bladder pain syndrome" (IC/BPS) and considers the terms synonymous [12].

The International Association for the Study of Pain (IASP) has dropped the terms interstitial cystitis, painful bladder syndrome, and PBS/IC or BPS/IC and now recognizes the term "bladder pain syndrome" as the occurrence of persistent or recurrent pain perceived in the urinary bladder region accompanied by at least one other symptom, such as pain worsening with bladder filling and day-time and/or night-time urinary frequency. www.iasp-pain.org The reader is referred to the IASP website for an in depth discussion of pain taxonomy. This work was spearheaded by Dr. Andrew Baranowski and the Pain of Urogenital Origin (PUGO) group that is associated with IASP and contributed to advancement of nomenclature and taxonomy over the last 5 years [42].

The Consultation will continue to refer to the symptom complex as "bladder pain syndrome".

III. EPIDEMIOLOGY

Since the clinical diagnosis of BPS remains controversial, epidemiology studies of BPS have been

problematic [46]. The lack of an accepted definition, the absence of a validated diagnostic marker, and questions regarding etiology and pathophysiology make much of the literature difficult to interpret. Overlapping patterns of bladder pain, lower urinary tract symptoms and pelvic pain are common and present challenges for clinical practice and research [47]. The other major difficulty in evaluating various prevalence trials is that some are based on unverified self report, others by physician diagnoses (with or without some type of verification) or by identification of BPS symptoms (with or without exclusion of other confusable conditions). This confusion becomes apparent when one looks at the variation in prevalence reports in the United States and around the world. These range from 4.5 per 100,000 females in Japan [48], to a questionnaire based study that suggests a figure in 20,000 per 100,000 in US women [49]. Studies, however, have consistently shown that bladder pain symptoms are more common than suggested by coded physician diagnoses [50]. Therefore it is important to realize when examining epidemiological data in BPS, that the prevalence of this enigmatic condition can be estimated from patient self-reports, physician diagnoses and/or symptom based surveys, all of which will give a different figure. A Conceptual diagram of the various manifestations of pelvic pain illustrates the problems in determining prevalence data. (**Figure 2**)

1. EARLY EPIDEMIOLOGICAL STUDIES:

One of the first population-based studies [51] included "almost all the patients with interstitial cystitis in the city of Helsinki". This superb, brief report from Finland surveyed all diagnosed cases in a population approaching 1 million. The prevalence of the disease in women was 18.1 per 100,000. The joint prevalence in both sexes was 10.6 cases per 100,000. Ten per cent of cases were in men.

Another early population study, this in the United States, first demonstrated the potential extent of what had been considered a very rare disease [52]. The following population groups were surveyed: 1) random survey of 127 board-certified urologists 2) 64 IC patients selected by the surveyed urologists and divided among the last patient with IC seen, and the last patient with IC diagnosed 3) 904 female patients belonging to the Interstitial Cystitis Association and 4) random phone survey of 119 persons from the US population. This 1987 study reached the following conclusions (interestingly, most of these conclusions have stood the test of time and many further epidemiological studies described later in this section)::

1. 43,500 to 90,000 diagnosed cases of IC in the USA (twice the Finnish prevalence)
2. Up to a five-fold increase in IC prevalence if all patients with painful bladder and sterile urine had been given the diagnosis, yielding up to half million possible cases in the USA
3. Median age of onset 40 years
4. Late deterioration in symptoms unusual
5. 50% temporary spontaneous remission rate, mean duration 8 months
6. 10 times higher incidence of childhood bladder problems in IC patients vs controls
7. 2 times the incidence of a history of urinary tract infection vs. controls
8. Lower quality of life than dialysis patients
9. Costs including lost economic production in 1987 of $427 million.

2. PATIENT SELF REPORT SURVEYS:

As mentioned earlier, the prevalence of BPS can be estimated from patient self-reports, physician diagnoses and/or symptom based surveys. Jones and Nyberg [53] obtained their data from unverified self-report of a previous diagnosis of IC in the 1989 National Household Interview Survey. The survey estimated an overall prevalence of 500 per 100,00 populations (0.5% of the population), or >1,000,000 people in the United States with a self-reported diagnosis of IC. For women this prevalence figure was 865 per 100,000. As part of the third National Health and Nutrition Examination Survey (NHANES III), patients were answered yes to two questions (pain in the bladder/frequent urination and a diagnosis of IC or PBS) and the figures were remarkably similar with an estimated prevalence of 470 per 100,000 (850 per 100,000 women) [54]. These numbers must be viewed with caution because of inaccurate patient recall or confusion with other pain or bladder related conditions. However these patient-reported diagnoses figures certainly suggest that BPS is a common occurrence.

3. PHYSICIAN DIAGNOSES STUDIES

Estimations of prevalence based on physicians' diagnoses may be thought to produce more accurate estimates, and while they do provide different figures, these are in part based on the local or geographic diagnostic criteria employed. Bade et al [55] used a physician questionnaire-based survey in the Netherlands yielding an overall prevalence of 8-16 per 100,000 females, with diagnosis heavily dependent on pathology and presence of mast cells. The Nurses Health Study I and II [56] showed a prevalence of IC between 52 and 67 per 100,000 in the USA. This report was based on self-reports with validation using data from medical records. The prevalence of a physician based diagnosis of BPS in men and women in a managed care population in the US Northwest[57] was 197 per 100,00 women and 41 per 100,000 men. However these rates decreased to 99 per 100,000 women and 19 per 100,000 men

if the definition of the condition was limited to individuals who had undergone cystoscopy. Nickel, et al [58] performed a prospective practice audit in outpatient urology practice populations of 65 urologists and noted that the prevalence of IC and IC diagnosis in urology outpatient practice, confirmed by both investigation and symptom scoring, was determined to be 2.8%. This of course does not represent in any way the burden of this condition in the general population, but rather reflects the national referral and practice traditions. There are other limitations using physician diagnoses to determine prevalence. Studies that utilize physician diagnoses to define the presence of BPS will likely underestimate the true prevalence, primarily because they do not identify patients with undiagnosed disease or they may not assign a diagnosis when the symptoms are present (reluctance to label a patient with the condition or alternatively are not familiar with diagnosing it).

4. SYMPTOM BASED SURVEYS

Another and possibly more sensitive method to examine prevalence and incidence of BPS is to assess the presence of symptoms that suggest BPS. A follow-up study utilizing the Nurses' Health Study (NHS) cohort) [59] used a mailed questionnaire followed by a detailed supplementary questionnaire if the participant responded "yes" to a bladder or pelvic pain question. They observed that the prevalence of PBS symptoms was 1.7% in women younger than 65 years and increased progressively to 4.0% in women aged 80 years or older. This study suggested that the prevalence of BPS increases with age. Warren, et al [60] combined a mail-in survey with randomly selected telephone surveys to determine the prevalence of BPS amongst first degree relatives in comparison to that of the general population. They concluded that adult female first degree relatives of patients with BPS may have a prevalence of BPS 17 times that found in the general population. This suggests but does not prove a genetic susceptibility to BPS. The Boston Area Community Health (BACH) 0Survey [61], a population based cross-sectional survey of individuals in the Boston area which included an in person interview, determined the prevalence of painful bladder symptoms to be 0.83% to 2.71% in women and 0.25% to 1.22% in men depending of the definition used.

The O'Leary Sant (OLS) and the Pelvic Pain and Urgency/Frequency (PUF) questionnaires were compared by Rosenberg and Hazard [62] in the same general practice population of 1218 patients. The prevalence of BPS with the OLS was determined to be 0.57%, with the PUF the prevalence was determined to be 12.6%. Leppilahti and colleagues [63,64] estimated the prevalence of BPS in the general Population of Finland using a rather robust definition based on the OLS to be 0.68%. However, when a sample of those women was examined by one of the urologists, the more accurate prevalence was 0.3%.

Clemens et al employed [65] 3 different definitions of BPS related symptoms. The first included only self reported pelvic pain with voiding symptoms. The second included increasing pain with bladder filling and relief with urination. The third included a score of 12 or more on the OLS, including 2 episodes of nocturia and a pain score of 2 or greater. The prevalence estimates based on these definitions were 11,200 per 100,00 women and 6,200 per 100,000 men for definition 1; 3,300 per 100,00 women and 1,400 per 100,00 men for definition 2; and 6,200 per 100,000 women and 2,300 per 100,00 men for definition 3. Using a similar methodology, [66] concluded that the prevalence of BPS-like symptoms in South Korean women appear to be lower than in Europe [67] and the United States, similar to Japan and higher than in China [68]. It is conceivable that the acknowledgement by individual patients of these specific IC/BPS symptoms may be influence by cultural differences.

The most comprehensive and probably most accurate estimation of the prevalence of BPS symptoms involved population based symptom prevalence estimate using 2 validated case definitions to identify bladder pain syndrome/interstitial cystitis in 131,691 adult females [69]. Based on a high sensitivity definition, 6.5% (6,500 per 100,000) of women met the symptoms criteria, while 2.7% (2,700 per 100,000) of women met the criteria for a high specificity definition. These percentages translated into 3.3 to 7.9 million US women over 18 years of age with symptoms of bladder pain and/or interstitial cystitis. But only 9.7% of these identified women reported being assigned a bladder pain syndrome or interstitial cystitis diagnosis. A further study compared 3,397 women identified in this RAND Interstitial Cystitis Epidemiology (RICE) survey [46]with urinary symptoms consistent with a diagnosis of IC/BPS to 277 women with an actual BPS diagnosis recruited from specialist practices in the USA [70]. The two cohorts showed remarkably similar demographics, symptoms and quality of life measures, confirming that BPS is a very prevalent condition that is very likely under diagnosed and undertreated in the USA.

Conclusion:

Based on these studies, it is impossible to determine an accurate estimation of the prevalence of BPS, but a review of studies done in the US shows that this is a very prevalent medical condition (**Figure 4**). It is clear that the most inaccurate prevalence figures are derived from patients self-reported recollection, while the prevalence of BPS symptom complexes are more common than those based on physician diagnoses. It is apparent that there has been no standardized method of determining the prevalence of BPS, with wide variation of estimates in the same study employing different definitions or criteria for identifying the condition. Many factors including bias, cultural differences, methodology,

geographic variations in diagnostic criteria and/or possibly real differences in different populations lead to further variations between countries.

Recommendation:

A reasonable prevalence estimation for patients diagnosed with BPS would be about 100-200 per 100,000 women with a male prevalence of 10% to 20% of the female estimate. The prevalence of women and men with symptoms suggestive of BPS could be as much as 10 to even a 100 times more. (**Figure 4**) Level of **Evidence: 1 Grade of Recommendation: A**

5. INCIDENCE:

Only a few estimates of Incidence have been reported. The annual incidence of new female cases in Oravisto et al, 1975 study[51] was 1.2 per 100,000. The overall age- and sex-adjusted incidence rate of physician assigned diagnoses of BPS in Olmstead county [73] was 1.1 per 100,00 per year (1.6 per 100,00 per year for women and 0.6 per 100,000 for men. Another review of physicians' diagnoses identified a much higher yearly incidence of 21 per 100,000 women and 4 per 100,000 men [57]. A physician-coded diagnosis supplemented with chart review of the Kaiser Permanente database [74] suggested a BPS incidence rate of 15 per 100,000 women per year. The mean average age of patients was 51 years. With such a wide variation between two similar studies in the same country, it is evident that we really do not have an accurate estimation of BPS incidence.

Recommendation:

The available data suggests that the incidence of BPS diagnoses is somewhere between 1 and 15 per 100,000 per year. This does not include the women who have developed symptoms but have not been diagnosed with the condition.

Level of Evidence: 1 Grade of Recommendation: A

6. OTHER CONSIDERATIONS

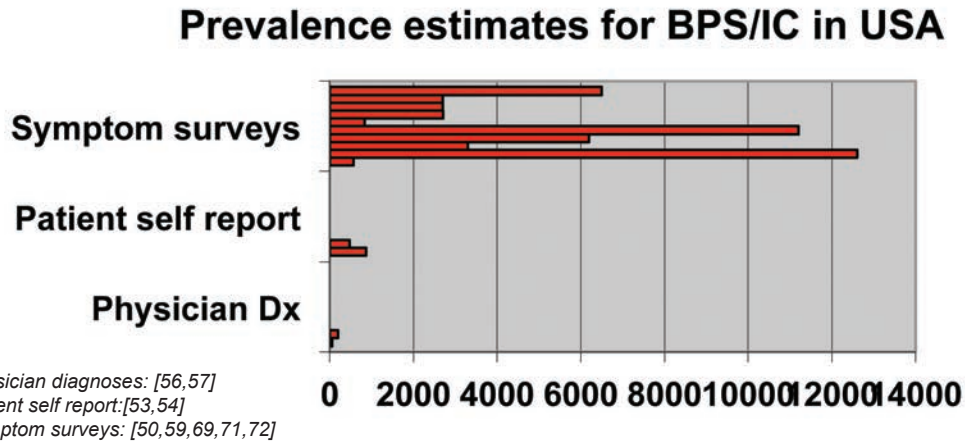
a) Children

Geist and Antolak [75] reviewed and added to reports of disease occurring in childhood. A childhood presentation of BPS is extremely rare and must be differentiated from the much more common and benign-behaving condition variously called the urinary frequency syndrome of childhood or dysfunctional elimination syndrome, a self-limited condition of unknown etiology. Nevertheless, there is a small cohort of children with chronic symptoms of bladder pain, urinary frequency, and sensory urgency in the absence of infection who have been evaluated with urodynamics, cystoscopy, and bladder distention and have findings consistent with the diagnosis of BPS. In Close and colleagues' review [76] of 20 such children, the median age of onset was younger than 5 years, and the vast majority of patients had long-term remissions with bladder distention. Rakow et al [77] assessed 28 women aged 13 to 25 with chronic pelvic pain syndrome and confirmed that 39% had a diagnosis of IC while a further 25% had both IC and endometriosis. The relationship between dysfunctional voiding and bowel symptoms in early life was suggested in a mail based questionnaire study in 215 BPS patients and 823 controls [78]. Another study examining early childhood events [79] showed that early childhood trauma, in particular sexual trauma was more common in IC/BPS patients than asymptomatic control subjects. While not proven in these studies, it may be possible to link early childhood events to the eventual development of BPS symptoms.

Recommendation:

C/BPS should be evaluated in young women with complaining of chronic pelvic pain.

Level of Evidence: 1 Grade of Recommendation: A



Physician diagnoses: [56,57]
Patient self report:[53,54]
Symptom surveys: [50,59,69,71,72]

Figure 4: Prevelence estimates for BPS/IC in USA

b) Men

Most studies show a female to male preponderance of 5:1 or greater [41,57,80]. In the absence of a validated marker, it is often difficult to distinguish BPS from the chronic pelvic pain syndrome (nonbacterial prostatitis, prostatodynia) that affects males [81,82], and the percentage of men with BPS may actually be higher [83,84]. Men tend to be diagnosed at an older age and have a higher percentage of Hunner's lesion in the case series reported.

Recommendation:

The Male to Female ratio of BPS cases is 1:5-10

Level of Evidence: 1 Grade of Recommendation: A

c) Overlapping Non bladder syndromes

Observations have shown that BPS patients are more likely than controls to have syndromes manifesting symptoms beyond the bladder and even the pelvis. In 1997, Clauw, et al [37] reported on the symptom overlap between two cohorts of patients, one with fibromyalgia and one with BPS. In the same year an analysis of a survey by Alagiri, et al [85] of over 6,700 persons who had a physician diagnosis of Interstitial Cystitis reported that individuals with IC were 100 times more likely to have inflammatory bowel disease, and that allergies, irritable bowel syndrome, sensitive skin, and fibromyalgia also have an increased association with IC. The presence of non-bladder syndromes (NBSs) and BPS has further complicated the interpretation of epidemiological studies. Investigators have subsequently compared BPS patients to controls on multiple NBSs. Wu et al. [86] compared 749 cases with BPS them to 1498 randomly selected and matched controls. Significantly more cases had FM, IBS, chronic pelvic pain (CPP), endometriosis, depression, anxiety and vulvodynia. Clemens et al.[87] compared 239 women with ICD-coded BPS to 717 matched controls and showed that cases significantly exceeded controls in myalgias, gastrointestinal symptoms, gynecologic pain, headache, back disorders, depression, and anxiety. Warren et al. [88] demonstrated that significantly more BPS cases than matched controls had 11 antecedent syndromes: FM, CFS, IBS, sicca syndrome, Chronic pelvic pain, migraine, allergies, asthma, depression, panic disorder, and vulvodynia. Nickel et al. [89] found significantly higher prevalence of self-reported FM, CFS, IBS, migraine and tension headaches, vulvodynia, temporomandibular disorder and low back pain in 207 female BPS cases than in 117 controls as well as significantly more with depression and anxiety [90] in a study in several urology practices in 3 continents. A recent review confirmed that fibromyalgia (FM), chronic fatigue syndrome (CFS), and and irritable bowel syndrome (IBS) were associated with IC/BPS [91]. The etiological and epidemiological questions that remain unanswered is how are these NBSs associated with BPS, do these NBSs precede or follow IC/BPS and do multiple NBSs increase the risk of BPS. Warren and colleagues [92] have introduced a number of hypotheses, however the studies to validate these have not yet been done.

One other NBS that is sometime neglected or forgotten in these epidemiological associations is the association of BPS with sexual dysfunction. Multiple studies have shown that women with BPS diagnoses or symptoms experience very high levels of sexual dysfunction [93-96].

Recommendation:

Overlapping Non-bladder syndromes are common in patients with a diagnosis of BPS.

Level of Evidence: 1 Grade of Recommendation: A

d) Progression:

The disease onset is generally described as subacute rather than insidious, and full development of the classic symptom complex occurs over a relatively short time. It appears that BPS does progress continuously, but usually reaches its final stage rapidly (within 5 years) [97] and then continues without significant change in symptomatology. Subsequent major deterioration is unusual[51]. The duration of symptoms before diagnosis was 3-5 years in the Finnish study [51] while a very early American study quoted 7-12 years [25]. The Interstitial Cystitis Database Cohort (ICDB) of patients has been carefully studied, and the findings seem to bear out those of other epidemiologic surveys [98]. Patterns of change in symptoms with time suggest regression to the mean and an intervention effect associated with the increased follow-up and care of cohort participants. Although all symptoms fluctuated, there was no evidence of significant long-term change in overall disease severity. The data suggest that BPS is a chronic disease and no current treatments have a significant impact on symptoms over time in the majority of patients. There is some data [89] to suggest that some patients undergo a phenotypic progression over time from a purely organ specific (eg. bladder) condition to a regional pain syndrome (eg. IBS, vulvodynia) to a more generalized pain syndrome (eg. FM, CFS). Long term longitudinal studies examining progression issues in BPS are lacking.

Recommendation:

Epidemiological data required to describe progression patterns of BPS is lacking.

Level of Evidence: 1 Grade of Recommendation: A

IV. ETIOLOGY

The etiology of BPS is still an enigma. Quite often hypotheses abound with sparse evidence to support

them and some quickly are found to be untrue. For example disturbed nitric oxide metabolism has been proposed to contribute to BPS, but later controlled studies using L-arginine therapy did not show therapeutic effect and failed to support the hypothesis. It is highly possible that BPS is induced by a variety of causes. Symptoms of urinary frequency and bladder pain are likely the final common presentation of bladder injury resulting from single or a combination of etiologies.

1. MAST CELL ACTIVATION

Mast cells are thought to have a role in the etiology and/or pathogenesis of BPS. They are multifunctional immune cells that contain highly potent inflammatory mediators such as histamine, leukotrienes, serotonins, and cytokines.[99] These cells are the repositories of many potent inflammatory factors. Many of the symptoms and findings in ulcerative BPS such as pain, frequency, oedema, fibrosis, and the production of new vessels in the lamina propria, could possibly be ascribed to the release of mast cell-derived factors. Hence, the mast cell-IgE system and its interaction with other inflammatory cells and the nervous system[100] seems to be of importance when it comes to pathogenesis. There is a ten-fold increase in mast cell count in bladder tissue from patients with ulcerative BPS as compared to controls. In non-ulcer BPS, however, the mast cell count is normal or only slightly increased. [99,101,102]

Other mechanisms have also been put forward. Bouchelouche[103] compared the urinary excretion of leukotrienes E4 and eosinophil protein X in patients in BPS and noted detrusor mastocytosis and both increased urinary leukotrienes E4 and eosinophil protein X.

Level of Evidence: 1 - Grade of Recommendation: A

2. INCREASED PERMEABILITY OF THE UROTHELIUM DUE TO UROTHELIAL DYSFUNCTION/GAG-LAYER DEFECTS

The bladder urothelium plays a key barrier to keep low and high molecular weight solutes in the urine from leaking into bladder interstitium. The barrier includes a dense layer of glycosaminoglycans on the luminal surface and intercellular junctions. Intracellular junctions consist of tight junction, adherence junction, demosome and gap junction in the order of location from the luminal layer to the basal layer. Studies have shown impaired function of intercellular junctions of bladder urothelium of BPS patients. Zhang et al demonstrated significantly increased paracellular permeability, decreased expression of the tight junction proteins ZO-1 and occludin, and increased expression of the adhesion protein E-cadherin from patients with BPS.[104] Shie et al further showed that in the urothelium of the BPS bladder a reduced E-cadherin expression was associated with a higher level of apoptosis.[105] A defect in the glycosaminoglycan (GAG) layer has been proposed by Parsons and co-workers.[106] With such a defect the sub-mucosal nerve filaments might become accessible to noxious substances in the urine and this might explain bladder pain and urinary frequency. In ulcerative BPS there is granulation tissue indicating a reparative process following repeated disruption of the mucosa.[107] Widened tight junctions and increased permeability have been demonstrated by scanning electron microscopy and other techniques.[108,109]

A study by Parsons et al[110] has shown that Tamm-Horsfall protein is quantitatively different in BPS patients as compared to controls. Tamm-Horsfall protein is synthesized in the kidney and excreted into the urine. It has been suggested to have a role in immune defense and in preventing damage to the urothelial cells by injurious urinary constituents.

Level of Evidence: 2 - Grade of Recommendation: B

3. INHIBITION OF UROTHELIAL BLADDER CELL PROLIFERATION

One explanation of the bladder epithelial dysfunction might be the fact that the cells produce an inhibitor of heparin-binding epidermal growth factor-like growth factor in BPS.[111] It was shown that explanted urothelial cells from BPS patients differ from controls not only as to production of epithelial growth factors but also in the rate of proliferation and the production of an antiproliferative factor (APF). Keay and co-workers[112] studied gene expression patterns in normal bladder urothelial cells treated with APF and with mock APF as compared to patterns expressed by BPS urothelial cells. The results indicate that the mechanism of APF inhibition of urothelial cells may involve both down-regulation of genes that stimulate cell proliferation along with up-regulation of genes that inhibit cell growth. The same group of researchers has indicated that APF seems to be specifically elevated in the urine of patients with BPS but not in normals or patients with confusable diseases. These findings might open up new avenues for identification and development of urine markers for BPS.[113] There has not yet been confirmation of the importance of antiproliferative factor by other laboratories.

Level of Evidence:2 - Grade of Recommendation: B

4. AUTOIMMUNE MECHANISMS

There are numerous reports on autoantibodies in patients with BPS.[114-117] The precise identity of these of autoantibodies has yet to be determined. Some of the common clinical and histopathological characteristics present in BPS patients show certain similarities with other known autoimmune disturbances. Studies on autoantibodies in BPS have shown that these mainly consist of antinuclear antibodies[116] and these findings are in turn similar to the autoantibody profiles in some systemic diseases like Sjögren syndrome, which is known to be of

autoimmune origin.[118-120] Only a portion of BPS patients have auto-antibodies. It has been proposed that the presence of auto-antibodies in these patients could be a reflection of disease severity.[121]

Vascular immunopathology with immune deposits in the bladder wall was found by Mattila.[122] Further studies also suggest activation of complement.[123] By means of immunophenotyping and flow cytometric analyses of the bladder mucosa and peripheral blood, differences between ulcerative and non-ulcer BPS patients have been demonstrated. In the former group intense T-cell infiltrates and B-cell nodules were seen, compared to far less T-cell infiltrates in non-ulcer BPS.[124] Involvement of the immune system is one feature found in some individuals with BPS, but findings are conflicting and have not been helpful in explaining the etiology. The lack of thorough descriptions of patients in many published studies has made classification and comparison between series impossible.

Level of Evidence: 2 - Grade of Recommendation: C

5. INFECTION

No microorganism has ever been revealed as the cause of BPS. Lynnes and coworkers did not find any evidence of recent or remote Gram negative or Gram positive infections in patients with BPS, nor did they find increased urinary IgA and IgG elevation.[125] This makes infection by an untested organism unlikely. Warren et al[126] in a case control study of women with recent onset of BPS symptoms, reported that documented evidence of UTI at symptom onset was found in only a minority of patients. Polymerase chain reaction techniques to amplify bacterial 16S rRNA genes that would be present if there were bacteria in bladder tissue or urine in BPS patients despite negative cultures have been without success.[127] Contrary to what was demonstrated for chronic gastritis, there is no evidence for helicobacter in BPS patients.[128] However, Zhang et al showed that a high prevalence (11 in 27 patients) of nanobacteria (NB) was observed in female BPS patients, and anti-NB treatment effectively improved the symptoms, suggesting that some BPS might be caused by nanobacteria.[129] Nevertheless, the possibility of a microbial contribution to the etiology of BPS remains an open question.

Level of Evidence: 1 - Grade of Recommendation: C

6. NEUROBIOLOGY/PELVIC CROSS-TALK

Several authors have described autonomic nerve changes[130-132], but the findings are far from uniform. An increase of sympathetic innervation and activation of purinergic neurotransmission has been reported. The S-100 family of proteins appear in Schwann cells of the peripheral nervous system.[133,134] Decreased levels of S-100 protein in the non-ulcer group as compared to controls has been found[135], which is consistent with a decreased nerve content in patients with non-ulcer BPS, a finding conflicting with the results of Hohenfellner [131] who used polyclonal antihuman protein gene product 9.5 antibody and found the overall nerve content increased in BPS patients as compared to controls. However, their study did not include subtyping of the disease into ulcerative and non-ulcer type. A distinctive utrastructural appearance of specimens from patients with non-ulcer BPS prompted Elbadawi and Light to propose neurogenic inflammation as a trigger to a cascade of events taking place in this disease.[136] In this context it should be noted that afferent nerves release transmitters like substance P which could activate immune cells, or vasoactive intestinal polypeptide. These events may constitute a link to the immune cell system and promote a decrease of lymphocyte proliferation.

A prominent increase of tyrosine hydroxylase immunoreactivity in bladder tissue of BPS patients, as compared to controls, has been described.[137] This can presumably be interpreted as a sign of generally increased sympathetic outflow. This lends support to the notion of a neurogenic aetiology and or pathogenesis.

Malykhina and others[138-142] have demonstrated in innovative animal studies that there is a bidirectional neural cross-sensitization of the colon and lower urinary tract. Acute colitis sensitized lumbosacral spinal neurons receiving input from the urinary bladder result in spinal neuronal hyperexcitabiity that may be involved in central cross-organ sensitization of visceral nociception between the colon and urinary bladder. This provides information which not only supports a neurogenic etiology but also may account for the substantial overlap of BPS with other chronic pelvic pain disorders, especially the inflammatory bowel disorders.[85] Rudick and Colleagues have shown in a murine model organ cross talk in pelvic pain and modulation of pain responses by visceral inputs distinct from the inflamed site.[143]

Level of Evidence: 2 - Grade of Recommendation: B

7. TOXIC AGENTS

There are a few publications which have suggested that toxic substances in the urine may cause injury to the bladder resulting in symptoms consistent with BPS. One published hypothesis is that heat labile, cationic urine components of low molecular weight may exert a cytotoxic effect.[144] Another group of investigators has suggested that defective constituent cytokine production may decrease mucosal defense to toxic agents.[145]

Level of Evidence: 3 - Grade of Recommendation: D

8. HYPOXIA

Decreased microvascular density has been reported to be a feature of bladders from some individuals with BPS.[146] One group of investigators

has reported that bladder perfusion decreased with bladder distension in some BPS patients compared to the opposite effect in control subjects.[147] The hypoxic hypothesis is further supported a report by Lee et al, who found an increased expression of hypoxia-inducible factor-1(HIF-1) alpha in bladder tissue obtained from BPS patients.[148] However, it is still unknown why the BPS bladders would become hypoxic.

Level of Evidence: 4 - Grade of Recommendation: D

9. THE ROLE OF GENETICS IN BPS

Warren et al[149] report findings from a small cohort of twins which demonstrated a greater concordance of BPS among monozygotic that among dizygotic twins. A later study by the same research group[60] suggested that adult female first-degree relatives of patients with BPS may have a prevalence of IC 17 times that found in the general population. This coupled with the previously reported twin data suggests, but does not prove, a genetic component adds to the susceptibility for BPS. Another study on more than 25,000 twins, Altman et al found that in female twins genetic factors contributed less than one-third of the total variation in susceptibility to BPS, suggesting that there could be a genetic susceptibility to BPS, although environmental factors might also be substantial in the development of BPS. [150]

The report by Weissman et al[151] of the increased frequency of BPS in patients and their first degree relatives with panic disorder and other seemingly disparate disorders, has suggested that there is a familial syndrome consisting of BPS and other disorders of possible autonomic or neuromuscular dysfunction. More recent studies by the same group[152] from a case control study, suggested that this syndrome might include other anxiety disorders as well, and that families with and without this collection of symptoms were genetically distinguishable on chromosome 13.

Level of Evidence: 1 - Grade of Recommendation: B

10 . CONCLUSIONS:

There have been no significant conclusive advances made in understanding either the etiology or pathogenesis of BPS. It is now believed that the etiology of BPS is more complex than has been previously envisioned.[37,85,87,153-155] The consideration of BPS as a part of a generalized somatic disorder should open new pathways to the study of BPS. Investigators should continue to explore central neurological mechanisms of pathogenesis, as well as genetic/familial, immunological and infectious etiologies of this puzzling, complex disorder.

An algorithm that attempts to illustrate an etiologic schema is presented (**Figure 5**).

V. PATHOLOGY

One can have pathology consistent with the diagnosis of BPS, but there is no histology pathognomonic of this syndrome. The role of histopathology in the diagnosis of BPS is primarily one of excluding other possible diagnoses. One must rule out carcinoma and carcinoma-in-situ, eosinophilic cystitis, tuberculous cystitis, as well as any other entities with a specific tissue diagnosis[107,156,157].

Level of Evidence: 1 Grade of Recommendation: A

While earlier reports described a chronic, edematous pancystitis with mast cell infiltration, submucosal ulcerations and involvement of the bladder wall and chronic lymphocytic infiltrate[158,159], these were cases culled from patients with severe disease and not representative of the majority of cases currently diagnosed. The pathologic findings in BPS are not consistent. There has been a great variation in the reported histologic appearance of biopsies from BPS patients, and even variation among biopsies taken from the same patients over time[26].

Lepinard and colleagues[160] reported a pancystitis affecting the 3 layers of bladder wall. In nonulcerative disease the vesical wall was never normal, epithelium being thinned and muscle being affected. Johansson and Fall[107] looked at 64 patients with ulcerative disease and 44 with nonulcerative IC. The former group had mucosal ulceration and hemorrhage, granulation tissue, intense inflammatory infiltrate, elevated mast cell counts and perineural infiltrates. The nonulcer group, despite the same severe symptoms, had a relatively unaltered mucosa with a sparse inflammatory response, the main feature being multiple, small, mucosal ruptures and suburothelial hemorrhages that were noted in a high proportion of patients. As these specimens were almost all taken immediately after hydrodistention, how much of the admittedly minimal findings in the nonulcer group were purely iatrogenic is a matter of speculation.

One can see completely normal biopsies in the nonulcerative BPS group[161]. Transition from nonulcerative to ulcerative BPS is a rare event[101], and pathologically the two types of IC may be completely separate entities. While mast cells are more commonly seen in the detrusor in ulcerative BPS[162], they are also common in patients with idiopathic bladder instability[163]. Mastocytosis in BPS is best documented by tryptase immunocytochemical staining[164]. Larsen and colleagues recommend taking biopsies from the detrusor of patients with suspected BPS and examining them with tryptase-stained 3 micron thick sections, with every seventh section used for quantification. They consider 27 mast cells/mm2 indicative of mastocytosis.[165] Despite attempts to develop a diagnostic algorithm based on the detrusor to mucosa mast cell ratio and

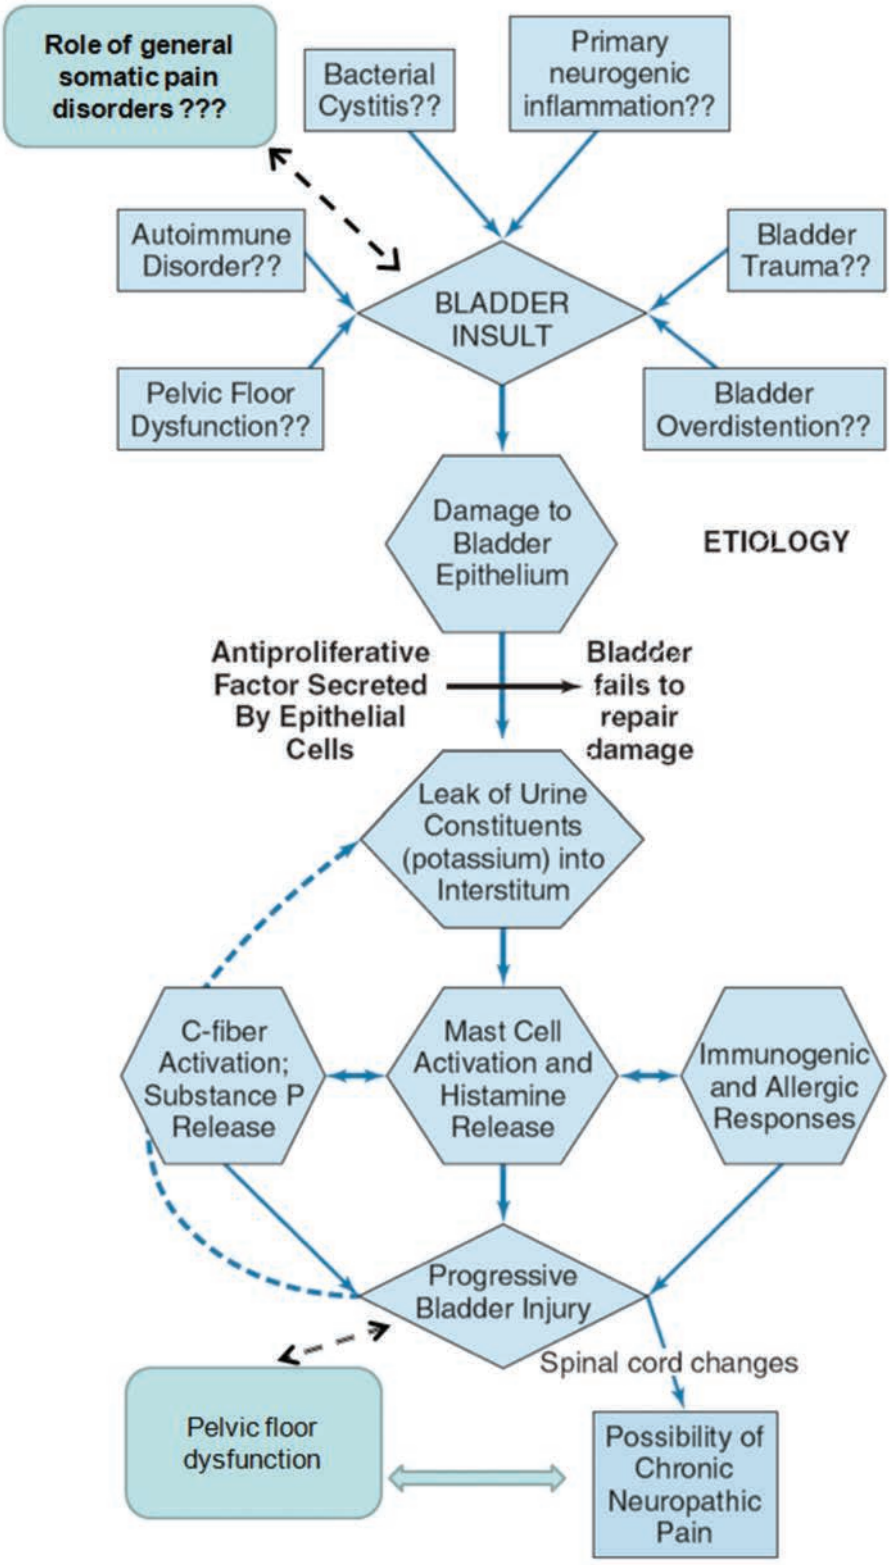


Figure 5: Theories of Etiology.

nerve fiber proliferation[100], mast cell counts per se have no place in the differential diagnosis of this clinical syndrome.

Mast cells could be valuable in clinical phenotyping, but as yet that is unproven. Mast cells trigger inflammation that is associated with local pain, but the mechanisms mediating pain are unclear. In a murine model of neurogenic cystitis, Rudick and colleagues[166] demonstrated that mast cells promote cystitis pain and bladder pathophysiology through the separable actions of histamine and tumor necrosis factor respectively. Therefore, pain is independent of pathology and inflammation, and histamine receptors may represent direct therapeutic targets for the pain of BPS and other chronic pain conditions.

Lynes and coworkers[35] concluded that biopsy specimens are often not helpful in confirming the diagnosis. Although BPS patients in his study had a higher incidence and degree of denuded epithelium, ulceration, and submucosal inflammation, none of these findings was pathognomonic. In addition, these "typical" findings occurred only in BPS patients with pyuria or small bladder capacity. Epithelial and basement membrane thickness, submucosal edema, vascular ectasia, fibrosis, and detrusor muscle inflammation and fibrosis were not significantly different in the BPS and control patients.

Attempts to definitively diagnose BPS by electron microscopy have also been unsuccessful. Collan's group[167], in the first such study, wrote that the similarity of the ultrastructure of epithelial cells in controls and IC patients makes it improbable that the disease process originates in the epithelium. Other investigators found no differences in the morphologic appearances of the glycocalyx and of urothelial cells in patients with IC when compared with controls[168]. Anderstrom and colleagues[109] saw no surface characteristics specific for IC, but believed that the mucin layer covering the urothelial cells seemed reduced in IC compared with controls, a fact disputed by Nickel in a very elegant paper[169]. Elbadawi and Light[136] observed ultrastructural changes sufficiently distinctive to be diagnostic in specimens submitted for pathologic confirmation of nonulcerative interstitial cystitis. Marked edema of various tissue elements and cells appeared to be a common denominator of many observed changes. The wide-ranging discussion of the etiology of IC in his paper is fascinating, but the pathological findings are potentially marred by the methodology, in that specimens were obtained after diagnostic hydrodistention[170].

So what is the place of pathologic examination of tissue in BPS? Attempts to classify the painful bladder by the pathoanatomical criteria described by Holm-Bentzen[171] are of questionable value. There is a group of patients with what she describes as "nonobstructive detrusor myopathy"[172]. In her series, these patients with degenerative changes in the detrusor muscle often had residual urine, a history of urinary retention, and an absence of sensory urgency on cystometry with bladder capacities over 400cc. Most would not be clinically confused with BPS. A similar English series[173], however, included patients who met NIDDK research criteria and associated detrusor myopathy with diminished detrusor compliance and ultimate bladder contracture.

The Interstitial Cystitis Database (ICDB) study worked backwards from symptoms to pathology, and concluded that certain symptoms are predictive of specific pathologic findings[33,174]. Denson et. al.[36] analyzed forceps biopsies from 65 females and 4 males with BPS. Ten per cent of specimens showed vasodilatation or submucosal edema. Inflammation was absent in 30% of patients, and mild in another 41%. Cystoscopic changes did not correlate with degree of inflammation. Hanus and colleagues[175] studied 84 biopsies from 112 BPS patients and reported a linear relationship between the mean bladder capacity under anesthesia and severity of glomerulations. They did not find a correlation between severity of symptoms and histopathological changes observed by light or electron microscopy.

Richter and the Danish group showed studied 349 consecutive BPS patients and concluded that nocturia, detrusor mastocytosis, and detrusor intrafasicular fibrosis are associated with multiple treatments and presumed failure of standard urological therapy while bladder capacity and glomerulations are not.[176] In a Belgian study, cystoscopic parameters (glomerulations, bleeding, mucosal tears, bladder capacity) showed no correlations with the histological features of bladder biopsies. No correlations were found between inflammatory infiltrate and detrusor mastocytosis. In fact, detrusor mastocytosis was more elevated in biopsies with normal urinary epithelium than in those with damaged epithelium. The study concludes that the clinical significance of pathological findings awaits future research findings. [177]

Rosamilia reviewed the pathology literature pertaining to BPS in 2 recent publications and presented her own data[34,41]. She compared forceps biopsies from 35 control and 34 PBS/IC patients, 6 with bladder capacities less than 400cc under anesthesia. Epithelial denudation, submucosal edema, congestion and ectasia and inflammatory infiltrate were increased in the BPS group. Submucosal hemorrhage did not differentiate the groups, but denuded epithelium was unique to the BPS group and more common in those with severe disease. The most remarkable finding in her study was that histological parameters were normal and indistinguishable from control subjects in 55% of BPS subjects. Method of biopsy can be important in interpreting findings, as transurethral resection biopsies tend to show mucosal ruptures, submucosal hemorrhage and mild inflammation[107], while

histology is normal approximately half the time with cold-cup forceps biopsies [34,35,178].

Histopathology plays a supportive diagnostic role at best[179]. Major reconstructive procedures appear to have better outcomes in patients with pathology consistent with Hunner's lesions.[180] Inflammatory features can be seen in 24% to 76% of patients without a visible Hunner's lesion.[181] While recent studies suggest that a severely abnormal pathology may be associated with poor prognosis[182,183], this is not necessarily the case [184].

At this point in time, excluding other diseases that are pathologically identifiable is the primary utility of bladder biopsy in this group of patients.[185,186]

VI. DIAGNOSIS

Much work has been put into the attempt to define objective diagnostic criteria based on, among other factors, cystoscopy under local or general anesthesia, bladder distention with registration of bladder capacity and/or possible presence of glomerulations and Hunner's lesion, bladder wall biopsies evaluated for inflammation, ulcer, fibrosis, mast cells, etc. and urodynamics with registration of bladder capacity, compliance and bladder stability. Results have, however, been frustrating. It is more fruitful to establish a broad clinical diagnosis, mainly on the basis of symptoms and exclusion of other diseases, and then stratify patients by urodynamic, cystoscopic, histological, and other tests on the basis of the significance of these findings for results of treatment and prognosis of disease. Current efforts to phenotype the disorder by the presence or absence of associated syndromes and diseases may also prove useful in the same way.

What follows is based solely on expert opinion.

Level of Evidence: 4 Grade of Recommendation: C

It is hoped that future Consultations will have the data to base such suggestions on a firmer foundation.

1. HISTORY

A general thorough medical history should be taken.

Special emphasis should be given to:

- Previous pelvic operations
- Previous UTI
- Bladder history/urological diseases
- Location of pelvic pain (referred pain) and relation to bladder filling/emptying.
- Characteristics of pain: onset, correlation with other events, description of pain
- Previous pelvic radiation treatment
- Autoimmune diseases

2. PHYSICAL EXAMINATION

A common physical examination should be performed including palpation of the lower abdomen for bladder fullness and tenderness:

- Standing: kyphosis, scars, hernia
- Supine: abduction/adduction of the hips, hyperaesthetic areas

In **females** physical examination should include a vaginal examination with pain mapping of the vulvar region and vaginal palpation for tenderness of the bladder, urethra, levator and adductor muscles of the pelvic floor. Tenderness might be graded as mild, moderate or severe.

3. PAIN MAPPING

Inspection:

- Vulva
  - exclusion of vulvar/vestibular diseases (vulvitis, dermatosis etc.)
  - evaluation of introital area (endometriosis)
  - tenderness of vestibular glands or vulvar skin (Touch Test: use wet cotton stick or finger tip)
- Vagina
  - tenderness during insertion and opening of speculum
  - cervical pathology
  - vaginal fornices (endometriosis)
- Bimanual physical examination
  - tenderness of urethra, trigone and bladder
  - superficial/deep vaginal tenderness
  - tenderness of pelvic floor muscles (levator, adductor)
  - tenderness in adnexal areas

In **males** digital rectal examination (DRE) should be performed with pain mapping of the scrotal–anal region and palpation of tenderness of the bladder, prostate, levator and adductor muscles of the pelvic floor and the scrotal content.

4. LABORATORY TESTING

- Urine dipstick (ABS, pH, leucocytes, nitrate), urine culture in all. If sterile pyuria culture for tuberculosis.
- Urine cytology in risk groups.
- Investigations for vaginal Ureaplasma and Chlamydia in females and prostatitis in men are optional.

5. SYMPTOM EVALUATION

- Voiding diary with volume intake and output for 3 days at initial evaluation. Patient sensation at voiding might be recorded (see chapter outcome assessment, Hanno).
- At follow-up only number of voidings during day and night time is necessary. Morning volume might be recorded as a help to monitor highest functional capacity.
- The O'Leary–Sant Symptom Score supplemented should be used as basic symptom score supplemented with the Quality of Life Score from the International Prostate Symptom Score (see chapter symptom scales, Hanno3).

Pain should be recorded using a Visual Analogue Scale (VAS) for pain during the last 24 hours (to fit with the voiding diary). Separate scores for the average, mildest and worst pain should be obtained (see symptom scales)

6. URODYNAMICS

Level of Evidence:4 Grade of Recommendation:C

The NIDDK criteria excluded patients with detrusor overactivity at filling cystometry in order not to confuse the picture in clinical trials.[8] This does not however mean that detrusor overactivity can not coexist with bladder pain syndrome. In the interstitial cystitis database approximately 14% of BPS patients had overactive bladders[17]. Whether these patients respond better to antimuscarinics than BPS patients with stable bladders has never been systematically investigated. If so, a rationale for routinely employing urodynamics as a part of the evaluation would follow. In males, infravesical obstruction might be a differential diagnosis[187], and it is recommended to do flowmetry in all males and pressure-flow studies in men with a peak flow rate below 20ml/seconds.

There are no data to support the following recommendations:

In females, flowmetry, post void residual urine volume and pressure- flow study are optional. In males, a flowmetry should be done in all, and if maximum flow rate <20 ml/s a pressure-flow study and measure of residual urine volume should be done. It is recommended to perform filling cystometry with a filling rate of 50 ml/s (to comply with the revised Potassium Test - see below) to look for overactivity, volume at first desire to void and cystometric capacity.

7. POTASSIUM TESTING

Level of Evidence:1 Grade of Recommendation: -A (not recommended)

Parsons has championed an intravesical potassium chloride challenge, comparing the sensory nerve provocative ability of sodium versus potassium using a 0.4 M potassium chloride solution. The test has proved controversial [188]. Pain and provocation of symptoms constitutes a positive test. Whether the results indicate abnormal epithelial permeability in the subgroup of positive patients, or hypersensitivity of the sensory nerves is unclear. Normal bladder epithelium can never be absolutely tight, and there is always some leak, however small[189]. The concentration of potassium used is 400meq per liter, far exceeding the physiologic urinary concentrations of 20-80meq/liter depending upon dietary intake[190]. Healthy controls can distinguish KCl from sodium chloride, though they don't experience severe pain[191]. The hope is that this test may stratify patients into those who will respond to certain treatments (perhaps those designed to fortify the glycosaminoglycan layer) [192].

Used as a diagnostic test for bladder pain syndrome, the potassium chloride test is not valid[193]. The gold standard in defining BPS for research purposes has been the NIDDK criteria. These criteria are recognized to constitute a set of patients that virtually all researchers can agree have BPS, though they are far too restrictive to be used in clinical practice[28]. Thus, this group of patients should virtually all be positive if the KCl test is to have the sensitivity needed to aid in diagnosis. Up to 25% of patients meeting the NIDDK criteria will have a negative KCl test[194]. In the group it should perform the best in, it is lacking in sensitivity. When we look at the specificity side of the equation, in the universe of asymptomatic persons, it performs relatively well and is rarely positive, although a recent study reported a 36% false positive rate in asymptomatic men[195]. It is in the patient population with confounding conditions for which we would want help in sorting out BPS from other disorders. Sixty percent of patients with overactive bladder test positive[196] and virtually all patients with irritative symptoms from radiation cystitis and urinary tract infection test positive[194,197]. The results with chronic prostatitis / chronic pelvic pain syndrome in men are variable, but 50-84% of men have been reported to test positive[195,198,199]. In women with pelvic pain results are similar[200], and based on these findings, Parsons has expressed the view that BPS may affect over 20% of the female population of the United States[201]! Others have reported prevalence in unselected female textile workers in Turkey using similar methods at 32.8%[202]. Another way to interpret the findings would be that the KCl test is very nonspecific, missing a significant number of BPS patients and over-diagnosing much of the population.

Prospective and retrospective studies looking at the KCl test for diagnosis in patients presenting with symptoms of BPS have found no benefit of the test in comparison with standard techniques of diagnosis[193,203,204]. A later modification of the test

using 0.3 molar potassium chloride for potential differentiation between patients with IC and detrusor overactivity (DO) showed that the 0.3 M KCl reduces maximum cystometric capacity in BPS and DO, the effect being more pronounced in DO. Urothelial hyperpermeability was not specific to IC. Comparative cystometry using NS and 0.3 M KCl does not help to differentiate BPS from DO [205,206].

The development of a painless modification of the potassium chloride test[207] using cystometric capacity and a 0.2M solution may improve acceptability among patients. The so-called revised or Comparative Potassium Test has shown prognostic value in bladder irrigation studies[208] but is considered optional by ESSIC. If performed it should be performed according to Daha et al.[207]: A Foley balloon catheter (14F) is inserted and the bladder drained. Instill into the bladder 500 ml saline (0.9%) at a rate of 50 ml/min via an infusion set until the maximum capacity is reached. Drain the bladder and measure the saline filling volume. Repeat the instillation and measurement with 500 ml 0.2 M potassium chloride at a rate of 50 ml/min (taking care that filling lines are emptied of all saline before KCl instillation), and calculate the filling volume difference. A difference in bladder capacity > 30% is considered positive. Besides reduction of bladder capacity with 0.2 M KCl there is a stronger feeling of urgency in IC patients compared to the saline filling, which is also clinically relevant.

8. CYSTOSCOPY AND HYDRODISTENSION

Level of Evidence:2 Grade of Recommendation:B

The classic cystoscopic picture of BPS as an "elusive" bladder ulcer with a corresponding cystoscopic appearance of patches of red mucosa exhibiting small vessels radiating to a central pale scar was described by Hunner in 1915 [5]. (**Figures 6, 7 & 8**) courtesy of Jorgen Nordling)

After 1978, glomerulations, described as punctuate petechial hemorrhages and observed after hydrodistention, became the primary cystoscopic feature of BPS[7]. (**Figures 9 and 10**, courtesy of Tomohiro Ueda)

But not all patients with symptoms of BPS have glomerulations[9,28,36,176], and not all patients with glomerulations have symptoms of BPS [196,209-212]. Neither presence nor severity of glomerulations correlate with any of the primary symptoms of BPS [33], although the presence of a Hunner's lesion is significantly associated with bodily pain and urinary urgency [211]. The finding of a Hunner's lesion or glomerulations has been somewhat subjective. Some researchers find a Hunner's lesion in 50% of their BPS patients [213], while others rarely see one [214].

No study comparing individual perceptions and variations in reporting or classifying glomerulations has ever been reported. Bladder capacity during hydrodistention has not drawn much attention, although it is strongly associated with increased urgency [215].

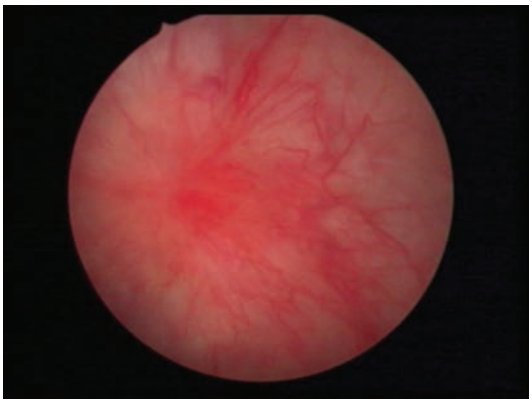

Figure 6: Hunner's lesion prior to bladder distention.

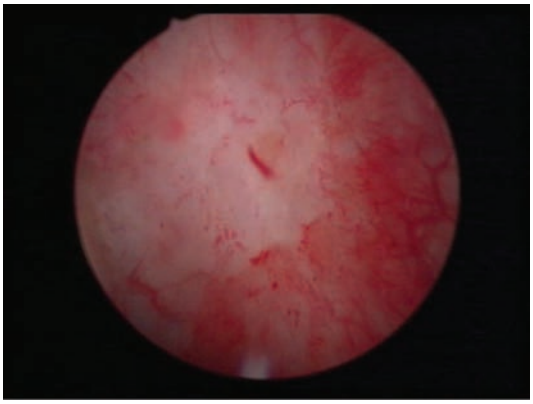

Figure 7: Hunner's lesion at bladder distention to 80cm pressure.

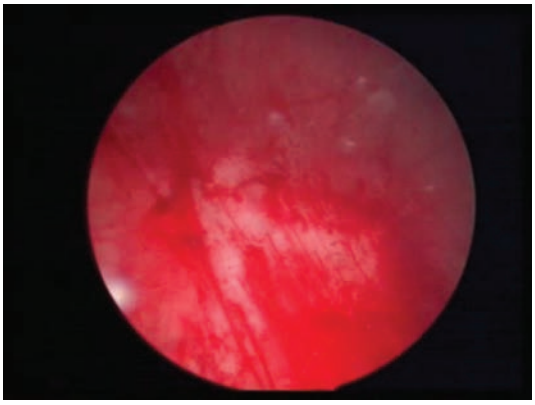

Figure 8: Hunners lesion after distention and release of fluid.

Because considerable variation in the duration of distension, repetition of distension, the pressure used for distension, and the measurement of bladder capacity have been described [216]}, the ESSIC

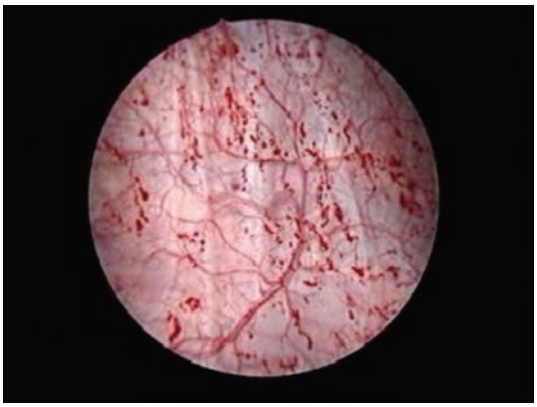

Figure 9: Glomerulations at 80cm water pressure.

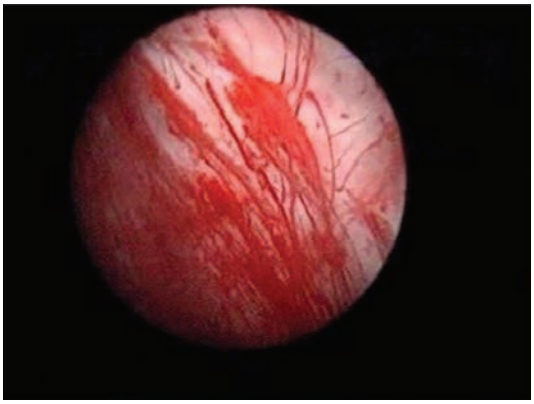

Figure 10: Typical waterfall after release of bladder pressure.

has suggested a standardized procedure for cystoscopy and **hydrodistension** [15]:

A rigid cystoscope is preferred to facilitate taking of adequate biopsies. Glycine or corresponding filling fluid should be used to allow for coagulation after biopsies. Infusion height should be approximately 80 cm above the Symphysis Pubis. **(note: some would recommend a pressure of only 60cm to minimize risk of bladder perforation and in the absence of data that a higher pressure is beneficial)**. A dripping chamber is used and the bladder is filled until fluid dribbling stops. If necessary, a digital block is applied around the urethra to prevent leakage. Pre-distension inspection includes observation for radiating vessels, coagulum or fibrine deposits, white spots, hyperaemia, oedema, cracks, scars or any other mucosal changes. Continuous inspection while filling the bladder is advised. When maximum capacity is reached, the distension is maintained for 3 minutes. The bladder is emptied and the colour of the fluid checked for the degree of bleeding. The total volume drained is the measured maximum bladder capacity. During a second filling, the bladder is filled to approximately 1/3rd to 2/3rd of the bladder capacity to achieve optimal vision for inspection and biopsies. The bladder should not be filled to maximum capacity or distended again to avoid further provocation of changes with doubtful reproducibility.

a) Inspection

Describe lesions in anterior wall, posterior wall, lateral quadrants and fundus. At the fundus one should be alert for possible artefacts if there is blind introduction of the scope. Bladder mapping by drawing is mandatory. Photographs are recommended but optional.

b) Classification

Grade 0 = normal mucosa

Grade I = petechiae in at least two quadrants

Grade II = large submucosal bleeding (ecchymosis)

Grade III = diffuse global mucosal bleeding

Grade IV = mucosal disruption, with or without bleeding/oedema

The importance of the finding of the finding of glomerulations after hydrodistension is however as mentioned been questioned since 45% of asymptomatic females, 20% of males with LUTS suggestive of BOO and 85% of females with OAB and no bladder pain demonstrates typical glomerulations after hydrodistension[196,210,212] and 10-34% of patients with BPS do not [9,176]

c) How useful is hydrodistention?

Hydrodistension results fail to identify any statistically significant differences in post-distention objective findings (anesthetic capacity, glomerulations) or therapeutic benefits when patients are categorized according to presenting symptoms[217]. Cystoscopy with hydrodistention may provide little useful information above and beyond the history and physical examination findings. In one study, 56% of 84 patients reported symptom improvement, but the duration was short lived with a mean of 2 months[218]. It is necessary to distinguish between short term hydrodistension (2-10 min.) for classification of BPS and long term hydrodistension (20-30 min.) for treatment[219]. Many reports on the therapeutiv effect of hydrodistension are from Asia and from patient material with IC based on the Asian definition[45], where up to 2/3 of the patients have frequency-urgency and no pain.

Lamale and colleagues examined the relationships between symptoms and cystoscopic findings in 12 women newly diagnosed with BPS who had not previously received treatment. Pain symptoms had consistent positive correlations with the cystoscopic findings. An increase in pain with bladder filling was associated with inflammation ($P = 0.011$), ulceration, and smaller bladder capacity. Pain relief after voiding correlated with smaller bladder capacity ($P = 0.019$), hematuria, and total cystoscopic score. Pain

intensity in the urethra was related to ulceration and hematuria, and pain in the lower abdomen was related to a smaller bladder capacity (P = 0.047), glomerulations, and a larger total cystoscopic score. Daytime frequency correlated negatively with most cystoscopic findings, and nocturnal frequency had a positive relationship with most cystoscopic findings and was significantly associated with a smaller bladder capacity (P = 0.010). Urgency showed no strong associations with any cystoscopic findings. The results of this study contradict those of previous studies that found no relationship between symptom reports and cystoscopic findings suggesting possible effects of treatment on pain perception and therapeutic influence on cystoscopic findings[220] .

It is important to keep in mind that the cystoscopic appearance of the bladder wall after hydrodistention may not be constant over time, and the absence of initial findings of glomerulations or terminal hematuria does not preclude further development of these findings of the disease on subsequent evaluation [221]. Rare cases of hydrodistension induced bladder necrosis have been described [222].

9. MORPHOLOGY

Pathological changes in light microscopic and electron microscopic features in patients with BPS have been described including infiltration with inflammatory cells in all or specific parts of the bladder wall. Although these findings are important in our attempt to understand the disease and perhaps as an aid to stratification of patients, there are at this time no pathognomonic findings on biopsy in terms of diagnosis[33]. Expert opinion as per the ESSIC suggests the following procedures when biopsy is planned for BPS evaluation[15]:

a) Biopsies

During cystoscopy the bladder is distended to full capacity. After draining the bladder, bladder biopsies are taken at roughly half full bladder capacity: Biopsy procedures should be performed by using large forceps and include detrusor muscle; alternatively double punch biopsies or resections of lesions can be used.

b) Number of biopsies

At least 3 biopsies from the two lateral walls and bladder dome should be taken in addition to biopsies from visually abnormal areas. The biopsies are to be immediately fixed in neutral buffered 4% formalin.

c) Biopsy handling

Biopsies are treated conventionally. Six adjacent 3 mm sections are cut and placed with 3 specimens on each of two specimen slides. The first slide is stained with H&E, the next with a connective tissue stain suitable for the individual institute. Twenty-four 10 mm sections are then cut and every third section is mounted on a specimen slide for mast cell counting. The specimens are stained by Lederstain (naphtolesterase) according to routine procedures. Finally, a 3mm section is obtained to ensure the presence of detrusor muscle in the specimens.

d) Mast cell counting

The use of a measuring grid (e.g. Leitz periplan 6F 10_N ocular containing a standardized grid) is necessary. Only mast cells containing nucleus are included. When counting the cells those covering or touching the bottom should be excluded whereas those covering the upper and left line are included. At least 3 biopsies must be the subject of mast cell counting and if possible one including a lesional area. Biopsies for mast cell counting should contain detrusor muscle.

e) The pathology report

- Epithelium
  - Not present
  - Present
  - Dysplasia with grading
  - Abnormal but no dysplasia: description is mandatory.
- Propria
  - Normal
  - Inflammation: description with a grading
  - Other findings are described
- Detrusor muscle. Abnormal muscle cells: describe
- Intrafascicular fibrosis
  - Not present
  - Present
- Mast cell count: At least three biopsies should be included in the counting. Only the biopsy with the highest number of mast cells per mm2 should be reported

The enzymatic (naphtolesterase) staining is, for the time being, recommended since standardized values are available:

- less than20mast cells/mm2:no detrusor mastocytosis;
- between 20 and 28 grey zone!
- more than 28 mast cells/mm2: detrusor mastocytosis.

Larsen recommends examining the detrusor biopsies with tryptase-stained 3 micron thick sections, with every seventh section used for quantification; 27 mast cells/mm2 is considered indicative of mastocytosis[165].

These guidelines have been reported to be easy to follow. A statistically significant correlation was found between the cystoscopic aspect and inflammatory infiltration, mast cell count in the detrusor muscle and stromal edema. Maximum bladder capacity was negatively correlated with inflammation, detrusor mast cell count, hemorrhages and the overall cystoscopic aspect[223]. Correlations have also been demonstrated between urothelial damage and inflammatory infiltrates and between normal epithelium and detrusor mastocytosis suggesting either 2 different types of BPS or different stadiums in the pathophysiological process of BPS [177]. Also in a large retrospective study of 349 patients with BPS, it was found that treatment intensity ranging from hydrodistension only to major surgery correlated positively to detrusor mast cell count, detrusor fibrosis and nocturia, but not to maximum bladder capacity or glomerulations after hydrodistension [224].

10. BIOMARKERS

The lack of universally accepted clinical diagnostic criteria for BPS affects all aspects of making progress in understanding this disease. Insights into risk factors, pathogenesis, trials for effective therapy, prognosis, and outcome criteria for treatment are all affected by this lack of diagnostic criteria. A major factor affecting the controversy over accepted clinical diagnostic criteria is that the current criteria are predominantly symptom specific. An objective biomarker would advance the establishment of reproducible diagnostic criteria for BPS and also aid in monitoring effects of treatment.

A biomarker for any disease needs to demonstrate high sensitivity and high specificity. In addition, the marker assay needs to be reproducible in many laboratories and should be suitable for use in a clinical diagnostic laboratory.

Many of the published studies on biomarkers for BPS have been on biomarkers isolated from urine. Erickson et.al has published excellent reviews of urine markers for BPS [225,226]. The most thoroughly investigated marker is antiproliferative factor (APF). This factor has been identified and characterized by Dr. Susan Keay and her colleagues at the University of Maryland [227,228]. Control subjects for this study included asymptomatic individuals, patients with bacterial cystitis, and patients with vulvovaginitis. APF is found in urine from the bladder and not from the renal pelvis [229-231]. Treatment of symptomatic BPS by either hydrodistention or neurostimulation normalized the APF levels concurrent with symptom relief [232]. It is not known if other forms of treatment will affect APF levels. Preliminary studies in 58 women with documented BPS demonstrated a sensitivity value of 91.4% and a specificity of 90.6%[233]. A later study with 219 symptomatic BPS patients and 325 controls with and without other urological disorders documented the sensitivity as 94% and the specificity at 95%[234]. APF has been isolated from urine and found to be a frizzled 8 protein-related sialoglycopeptide which interacts with the epithelial cell receptor CKAP4/p63[235,236]. Keay et al have suggested that APF might inhibit cell proliferation by the downregulation of genes that stimulate cell proliferation along with the upregulation of genes that inhibit cell growth[112]. Cell growth inhibition of human urothelial cells appears to be mediated by p53[237]. APF treatment caused significant increases in the paracellular permeability of normal bladder epithelial cell monolayers and the attenuation of tight junctions compared to mock APF, similar to changes seen in IC cells. APF treatment also decreased expression of the tight junction proteins zonula occludens-1 and occluding [236].

APF seems an ideal candidate for a biomarker for symptomatic BPS. There need to be additional studies to determine if it can serve as a BPS marker for patients in remission or for those who have not yet become symptomatic. As of 2008, the findings on symptomatic patients have yet to be replicated by laboratories around the world, and the biologic assay has not proven suitable for commercial development as it currently exists. The ultimate fate of APF as an important biomarker and etiologic factor remains to be determined.

GP-51 is a glycoprotein present in both the transitional epithelium and urine of humans and other mammals. Moskowitz et. al have shown that bladder biopsies of BPS patients had decreased staining for GP-51[238] The same laboratory also demonstrated that although GP-51 demonstrates a high specificity for BPS, it is not as sensitive as APF[239].

There have also been many published studies on heparin-binding epidermal growth factor-like growth factor (HB-EGF)[112,230,231,240,241]. HB-EGF is a growth factor found in normal urine. It has been shown that APF inhibits the production of HB-EGF. There have been no large population studies focusing solely on HB-EGF as a biomarker for BPS.

11. CONFUSABLE DISEASES

Criteria for a diagnosis are needed only if the target disease may be confused with other diseases (confusable diseases) because of overlapping features[242]. For a diagnosis, the target disease has to be recognized in a pool of confusable diseases in one of two ways: by recognition of the specific combination of features of the target disease or by exclusion of confusable diseases. For the diagnosis of BPS both methods might be used because:

- Confusable diseases are more common than BPS, so recognition is mandatory because many can be treated.
- Failure to diagnose a confusable disease would automatically incorrectly yield a diagnosis of BPS.
- Patients may have a confusable disease plus BPS.

The diagnosis of BPS can thus made on the basis of exclusion of confusable diseases and confirmation by the recognition of the presence of the specific combination of symptoms and signs of BPS. If the main urinary symptoms are not explained by a single diagnosis (confusable disease or BPS), the presence of a second diagnosis is possible. Symptoms and signs for use in diagnostic criteria do not need to be specific for the target disease. On the contrary, if a specific symptom or sign existed for the target disease, a diagnosis would only require the presence of the specific feature and diagnostic criteria would not be necessary.

In evidence-based medicine, diagnoses are based on medical history, physical examination, and appropriate clinical investigations to eliminate diseases from a list of differential diagnoses (confusable diseases) and to confirm the final diagnosis. BPS may occur together with confusable diseases such as chronic or remitting urinary infections or endometriosis. Cystoscopy with hydrodistention and biopsies might in this situation document positive signs of BPS thereby making a double diagnosis more probable. For therapeutic studies it makes sense to exclude patients who also have a confusable disease because symptoms and signs may be caused by BPS, the confusable disease, or by both. For prevalence studies of BPS, on the other hand, all cases with BPS should be included, also those with a confusable disease. This approach eliminates the need for separate diagnostic criteria for clinical practice and scientific studies. **Table 3** summarizes confusable diseases related to BPS and their mode of exclusion based upon the aforementioned diagnostic proposals and procedures [15,243].

VII. CLASSIFICATION

Interstitial cystitis was originally described as bladder disease with severe inflammation of the bladder wall described by Hunner as an ulcer[5]. The lesion is however not an ulcer but an inflammatory infiltrate that can crack upon distention, and the name of the bladder lesion has consequently been changed to "Hunner's lesion[243]". The finding of a Hunner's lesion could therefore originally be regarded as a diagnostic criterion for IC. Messing and Stamey introduced glomerulations as another typical finding for IC and this was included in the NIDDK criteria[8]. Magnus Fall proposed, that patients with Hunner's lesion (classic IC) and patients with glomerulations (non-ulcer type) represented two different subtypes [101] with different clinical pictures, different outcomes, and different responses to treatment [213] meaning that patients fulfilling the NIDDK criteria represents at least two different patient populations. Moreover up to 60% of patients clinically believed to have BPS by experienced clinicians do not fulfil the NIDDK criteria [28] and whether or not these patients are comparable to the patients fulfilling the NIDDK criteria is unknown. Finally Japanese urologists con-

Table 3: Differential Diagnosis of Bladder Pain Syndrome.

Carcinoma and carcinoma in situ	Cystoscopy and biopsy
Infection with	
Common intestinal bacteria	Routine bacterial culture
Chlamydia trachomatis, Ureaplasma urealyticum	Special cultures
Mycoplasma hominis, Mycoplasma genitalium	
Corynebacterium urealyticum, Candida species	
Mycobacterium tuberculosis	Dipstick; if "sterile" pyuria culture for *M. tuberculosis*
Herpes simplex and human papilloma virus	Physical examination
Radiation	Medical history
Chemotherapy, including immunotherapy with cyclophosphamide	Medical history
Anti-inflammatory therapy with tiaprofenic acid	Medical history
Bladder-neck obstruction and neurogenic outlet obstruction	Uroflowmetry and ultrasound
Bladder stone	Imaging or cystoscopy
Lower ureteric stone	Medical history and/or hematuria: upper urinary tract imaging such CT or IVP
Urethral diverticulum	Medical history and physical examination
Urogenital prolapse	Medical history and physical examination
Endometriosis	Medical history and physical examination
Vaginal candidiasis	Medical history and physical examination
Cervical, uterine, and ovarian cancer	Physical examination
Incomplete bladder emptying (retention)	Postvoid residual urine volume measured by ultrasound scanning
Overactive bladder	Medical history and urodynamics
Prostate cancer	Physical examination and PSA
Benign prostatic obstruction	Uroflowmetry and pressure-flow studies
Chronic bacterial prostatitis	Medical history, physical examination, culture
Chronic non-bacterial prostatitis	Medical history, physical examination, culture
Pudendal nerve entrapment	Medical history, physical examination, nerve block may prove diagnosis
Pelvic floor muscle-related pain	Medical history, physical examination

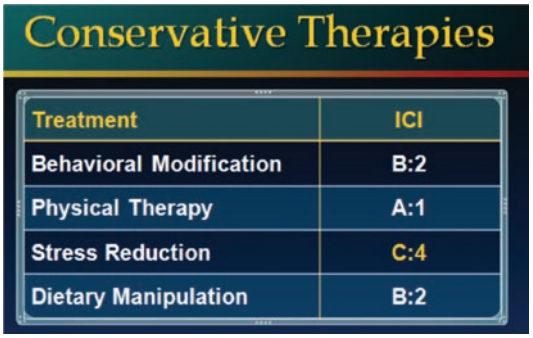
Van de Merwe J, Nordling J, Bouchelouche P, Bouchelouche K, Cervigni M, Daha LK et al. Diagnostic criteria, classification, and nomenclature for Painful Bladder Syndrome/Interstitial Cystitis: An ESSIC proposal. Eur. Urol. 2008;53:60.

sider that “interstitial cystitis” should be preserved as a disease name for patients with urinary symptoms and cystoscopic findings of glomerulations or Hunner’s lesion as outlined in the NIDDK criteria [45].

In an attempt to unite these different philosophies into a coherent schema, ESSIC proposed a classification of BPS based on findings during cystoscopy with hydrodistension and morphological findings in bladder biopsies[243] (**Table 2**) . The classification includes groups not having had cystoscopy with hydrodistension (group X) as well as groups not having had morphological investigation of bladder biopsies (group XX). By using this classification future research will be able to identify if findings of glomerulations and/or Hunner’s lesion as well as morphological changes in bladder biopsies does have significant importance for disease prognosis and/or treatment outcome.

VIII. CONSERVATIVE TREATMENT (TABLE 4)

Table 4: conservative therapies graded by Oxford Criteria



1. BEHAVIORAL MODIFICATION

Behavioral therapy for BPS includes education, timed voiding (scheduled voiding time and interval), controlled fluid intake, pelvic floor muscle training and bladder training (gradually extending voiding interval).

Chaiken et al [244] reported that when they conducted behavioral therapy consisting of frequency-volume chart, timed voiding, controlled fluid intake and pelvic floor muscle training for the treatment of 24 female patients, 50% of the patients showed improvement in the number of urinations and bladder capacity. At the same time, they considered that as the data was collected from 12 weeks’ intensive therapy conducted by skilled therapists for selected patients whose main symptom was urinary frequency, it should not be generalized. Parsons and Koprowski [245] reported that when 21 patients with the main symptom of urinary frequency underwent bladder training using a frequency-volume chart, 15 patients showed improvement. In 15 patients, the mean voided volume after one month increased by 65cc, whereas a persistent sensation of bladder fullness remained unchanged.

Participants in both arms of a large NIH funded randomized placebo controlled trial evaluating amitriptyline in BPS [246] received a standardized education and behavioral modification program (EBMP) .Adherence to the EBMP at 6 weeks was assessed in 4 categories of 1) symptom management, 2) fluid management, 3) diet modification and 4) bladder training. For each of these EBMP categories adherence was defined as the overall percentage of participants who reported adhering to each component of the EBMP at each telephone contact or clinic visit. For the 241 subjects evaluable for EBMP adherence, the rate at 6 weeks was 75% (181 of 241) for symptom management, 83% (201 of 241) for fluid management, 82% (196 of 240) for diet modification and 71% (172 of 241) for bladder training. The overall GRA response rate was approximately 57% for adherers in any of the 4 EBMP categories, whereas it was lower for nonadherers. This rate neared statistical significance for diet modification, which demonstrated only a 41% response rate among nonadherers (p = 0.051).

Recommendation:

Behavioral therapy should be a cornerstone of treatment for patients with BPS.

Level of evidence: 2 Grade of recommendation: B

2. PHYSICAL THERAPY

Women with BPS may have associated pelvic floor dysfunction [247]. Physical therapy for the pelvic floor is said to be effective for genitourinary and anorectal disorders[248]. Biofeedback and soft tissue massage may stimulate the relaxation of the pelvic floor muscles [249,250]. Lukban et al [251] conducted a direct myofascial release treatment on 16 BPS patients with high-tone pelvic floor dysfunction and sacroiliac dysfunction. The treatment was effective for urinary frequency and suprapubic pain. Fifteen patients (94%) showed improvement in the O’Leary & Sant symptom score. Coital pain relief was observed in 15 of 16 patients, with 9 patients becoming able to resume sexual intercourse [252]. Transvaginal Theile massage was also reported to be effective for 9 of 10 patients of the same group [253]. Mendelowitz et al [250] showed a 69% success rate when treating 16 patients using electromyographic biofeedback. However, it was suggested that a placebo effect may have occurred because the effect did not correlate with the improvement in patient’s awareness of the pelvic floor muscle movement and position before and after the therapy. Weiss [254] reported that 70% of 10 patients with IC showed symptomatic improvement, rating from “effective” to “remarkably effective”.

An NIH study[255] to determine the feasibility of conducting a randomized clinical trial was undertaken to compare 2 methods of manual therapy (myofascial physical therapy and global therapeutic massage) in patients with urological chronic pelvic pain syndromes. The global response assessment response rate was 57% in the myofascial physical therapy group compared

to 21% in the global therapeutic massage treatment group. This statistically significant difference (P=0.03) was primarily driven by the response seen in women (24 women) compared to the men (24 men) enrolled in this small pilot study. A follow-up randomized trial comparing similar treatments [256] but only in women with BPS and demonstrable pelvic floor pathology showed a clear benefit of directed myofascial physical therapy.

Recommendation:

Physical therapy of selected and motivated patients with BPS, particularly those with demonstrable pelvic floor dysfunction, is indicated.

Level of evidence: 1 Grade of recommendation: A

3. STRESS REDUCTION

It is long been observed that mental stress is one of the factors which aggravate the symptoms of BPS. Koziol et al [97] reported, in a survey of 374 patients, that more than half of the patients experienced intensified pain due to stress. Rothrock et al [257] reported that when comparing patients with BPS and healthy people, increased pain and urgency caused by stress were observed only in patients with BPS. Case-cohort studies have confirmed that patients diagnosed with IC/BPS experience considerably more stress than patients without the condition [90]. Stress was shown to correlate with both the severity of symptoms and quality of life. In another study of patients with BPS identified in urology tertiary care clinic populations [258], mental health disorders were identified in 23 % of IC/BPS female cases compared to 3% of female control subjects. Medications for anxiety, depression or stress were taken by 37% of patients with IC/BPS compared to 13% of female controls.

It is believed that exercise and bathing favorably influence the quality of life by reducing stress [259] however, the effect of such nonspecific therapies are difficult to assess and have not been proven in clinical trials. It would seem reasonable to suggest, when possible, to shorten working hours, choose a job with less stress or create a less stressful home environment. Involvement in patient education programs and patient support groups are considered by most practitioners to be beneficial [259,260]. Worldwide patient support groups, including the Interstitial Cystitis Association (ICA) [261], http://www.ichelp.org/ , the International Painful Bladder Foundation, http://www.painful-bladder.org/, are important sources of information for patients with BPS. Patients with BPS frequently suffer depression, which may negatively impact upon the quality of life [90] and perhaps symptoms. Effective self-care strategies taught by psychiatric nurses are considered to be useful [262,263].

Recommendation:

Stress and depression are related to poorer quality of life and increase in severity of symptoms. **Level of evidence: 1 Grade of recommendation: A.** Reduction of stress and depression may contribute to an overall improvement in quality of life and perhaps even symptoms. **Level of evidence: 4 Grade of recommendation: C.**

4. DIETARY MANIPULATION

Acidic beverages, coffee, spicy food, and alcohol may aggravate the symptoms of most patients with BPS [97,259,264,265]. The symptoms of the majority of BPS patients are generally believed to be improved by dietary manipulation [259,264,266,267]. However this has proven difficult to document and Nguan et al [268] reported that there was no statistically significant difference in pain and other symptoms, when they evaluated the influence of the changes in urinary pH on the symptoms of 26 patients with BPS by instilling pH5.0 and pH7.5 saline solutions into the bladder. One of the best studies designed to determine the effect of particular foods, beverages and/or supplements (comestibles) on IC/BPS symptoms was undertaken by Shorter et al [269]. One hundred and four patients with IC/BPS were asked to indicate on a validated questionnaire whether each of 175 individual items worsened, improved or had no effect on symptoms. Of the patients surveyed, 90% indicated that the consumption of certain foods or beverages caused symptom exacerbation. The comestible items that had the most effect were caffeinated, carbonated and alcoholic beverages, certain fruits, artificial sweeteners and spicy foods.

Dietary manipulation was ranked in the top five frequently used treatments in a cohort study of the Interstitial Cystitis Data Base (ICDB).[270]. As the influence of diet is variable with regard to food, beverage, and patient, there is no reason for patients to be uniformly on a strict diet. It is advised that each patient experiment to find out the foods that tend to aggravate their symptoms and avoid them. The ICA home page, (http://www.ichelp.org/) introduces the foods often avoided by patients with BPS.

Recommendation:

Personalized dietary manipulation should be part of the therapeutic strategy for patients with IC/BPS.

Level of evidence:2 Grade of recommendation :B

IX. ORAL THERAPY (TABLE 5)

Several categories of medication have been used in the management of patients with bladder pain syndrome including analgesics, antidepressants, antihistamines, Immunosuppressants, and glycosaminoglycans. Many

of these drugs are used empirically. Only a few of them have been studied in randomized controlled trials and none have a grade A recommendation.

1. ANALGESICS

Grade of Recommendation: C - Level of Evidence: 4

The long-term, appropriate use of pain medications is indispensible in the treatment of bladder pain syndrome. Many nonopioid analgesics including acetaminophen and the nonsteroidal anti-inflammatory drugs (NSAIDs) and even antispasmodic agents [271] have a place in pain therapy. Patients with more severe symptoms can often be helped with medical pain management using medications commonly used for chronic neuropathic pain syndromes including antidepressants, anticonvulsants, and opioids.

Gabapentin, introduced as an anticonvulsant, has found efficacy in neuropathic pain disorders including diabetic neuropathy [272] and postherpetic neuralgia [273]. It demonstrates synergism with morphine in neuropathic pain[274]. Two patients with IC showed improved functional capacity and received adequate pain control when gabapentin was added to their regimen [275]. Sasaki et al reported that 10 of 21 male and female patients with refractory genitourinary pain had subjective improvement of their pain following treatment with gabapentin[276]. Recently gabapentin was one compound of a triple mix including amitriptyline and etodolac, a NSAID. The interpretation of the observed efficacy in 74 patients is hampered by an uncontrolled open lable study protocol that additionally allowed uptitration of gabapentin and amitriptyline. The impact and contribution of amitriptyline, whose exclusive efficacy for BPS has been proven better than for any other oral drug, on the reported amelioration was not discussed[277].

Pregabalin has similar structure as gabapentin and also has been shown to reduce the pain of diabetic neuropathy [278]. Pregabalin was proved effective for treating pain associated with fibromyalgia [279]. Pregabalin might be worthwhile to try for bladder pain syndrome, particularly for those with concurrent fibromyalgia, though studies are lacking.

Opioids are seldom the first choice of analgesics in chronic pain states, but they should not be withheld if less powerful analgesics have failed [280]. Chronic opioid therapy can be considered as a last resort in selected patients, who have disabling pain and often receive inadequate doses of short-acting pain medications, which put them on cycles of short-term relief, anxiety, and pain.

The major impediment to the proper use of opioids when they are prescribed for long-term nonmalignant pain is the fear of addiction. Some studies suggest the risk is low [281], but not zero. [282] Using opiates is a difficult decision that requires much thought and discussion between patient and urologist, and a pain specialist. They are best administered in a pain clinic setting, requiring frequent reassessment by both patient and physician [283].

In addition to narcotics, concurrent usage of nonsteroidal anti-inflammatory drugs, cyclooxygenase inhibitors, acetaminophen, and tricyclic antidepressants may provide better pain control [284]. The common side effects of opioids include sedation, nausea, mild confusion, and pruritis. These are generally transient and easily managed. Respiratory depression is extremely rare if they are used as prescribed. Constipation is common and a mild laxative is generally necessary. The long-acting narcotic formulations that result in steady levels of drug over many hours are preferable.

2. ANTIDEPRESSANTS

a) Amitriptyline

Grade of Recommendation: B - Level of Evidence: 2

Amitriptyline is a tricyclic antidepressant with the property of blocking H1-histaminergic receptors [285]. It stabilizes mast cells and inhibits mediator stimulated vascular leakage. It inhibits synaptic reuptake of serotonin and norepinephrine, thus inhibiting painful nociception from the bladder at the level of the central nervous system. Its nighttime sedation can be therapeutic in the BPS population and its purported beta-adrenergic receptor sti¬mulation in the bladder may facilitate urine storage [286].

Using a dose titration of up to 75mg taken before bed, Hanno and Wein reported success in about half of 20 patients who could tolerate the medication. Twenty percent of the initial 25 patients dropped out because of fatigue, weight-gain, or dry mouth. In a follow-up report [287], 18 of 28 patients who could tolerate the drug had major relief of symptoms within 3 to 6 weeks of onset of therapy with a mean follow-up of 14.4 months. However, about one-third of patients initially placed on the drug could not continue on it because of side effects. Kirkemo et. al [288] treated 30 patients and 90% had subjective improvement in 8 weeks. Pranikoff and Constantino [289] reported improvement in 16 of 22 patients with urinary frequency and pain who did not have a diagnosis of interstitial cystitis, noting that 5 of the 22 could not tolerate the drug.

van Ophoven et al performed the first prospective, double-blind, placebo-control¬led study of amitriptyline. Fifty patients were randomized to placebo or a titrated dose of ami¬triptyline up to 100mg daily. Forty-two per¬cent of amitriptyline patients had greater than 30% decrease in O'Leary/Sant symptom and problem scores at 4 months compared to 13% in the placebo group[290]. They subsequently reported a long-term follow-up of amitriptyline for patients who can tolerate the side effects and continued the medication. With a mean follow-up of 19 months, 64% of 94 patients had response [291].

Foster and Hanno reported a second multicenter, randomized, double-blind, placebo controlled clinical trial of amitriptyline in subjects with interstitial cystitis/painful bladder syndrome who were naïve to therapy. Study participants in both treatment arms received a standardized education and behavioral modification program. Only of the subgroup of 207 subjects who achieved a drug dose of at least 50 mg, a significantly higher response rate was observed in the amitriptyline group (66%) compared to placebo (47%) ($p = 0.01$). When all randomized subjects were considered, amitriptyline plus an education and behavioral modification program did not significantly improve symptoms in treatment naïve patients with interstitial cystitis/painful bladder syndrome. However, amitriptyline may be beneficial in persons who can achieve a daily dose of 50 mg or greater[246].

b) Doxepin, desipramine, duloxetine

Other tricyclic antidepressants that have been used for bladder pain syndrome are doxepin and desiprami¬ne. Wammack et al used the combination of doxepin and piroxicam, a cox-2 inhibitor. Twenty-six of 32 patients (81%) experienced remission of symptoms [292]. One study reported satisfactory outcome with desiprami¬ne. [293] Duloxetine, a serotonin-norepinephrine reuptake inhibitor has also been tried but without therapeutic effects [294]

3. ANTIHISTAMINES

Grade of Recommendation: D - Level of Evidence: 1

Simmons first proposed use of antihista¬mines in 1955 [295]. His findings of mast cells in the wall of a normal bladder and the edema and increased vascularity seen in the IC bladder suggested that histamine may be responsible for the development of interstitial cystitis. He reported on 6 patients who had some improvement with pyribenzamine for limited periods [296].

a) Hydroxyzine

Hydroxyzine is the most widely used antihistamine for bladder pain syndrome. Its ability as an H-1 receptor antago¬nist, to inhibit bladder mast cell activation, along with its anticholinergic and anxiolytic

properties and good safety profile, have made it a reasonable candida¬te for use as a therapeutic agent for bladder pain syndrome.[297]In 1933, Theoharides first reported significant benefits of hydroxyzine in reducing pain and urinary symptoms. [298] His two subsequent reports of totally uncontrolled series further suggested the therapeutic effects of hydroxyzine. [299] [300] However, in an NIDDK randomized controlled trial, the global response rate for hydroxyzine was only 31% compared to a 20% response to those not treated with hydroxyzine. When looked at by itself the response was 23% vs. 13% on placebo. None of the results in this under-powered trial reached statistical significance [301].

b) Cimetidine

Grade of Recommendation: C - Level of Evidence: 3

Cimetidine, a H2 histamine receptor antagonist, has been explored for treatment of bladder pain syndrome. In a pilot study [302], 9 patients were treated with a dose of 300mg orally twice daily for one month. At follo¬wup 26 to 42 months later, 4 patients had complete relief of urinary symptoms and suprapubic pain. Lewi [303] reported 31 patients given 200mg three times daily with mean follow up of 6.6 months. Seventy-one per cent experienced varying degrees of symptomatic relief, 45% were pain free, and 26% went into remission of all symptoms. In a later report [304] of 69 patients treated over a 4 year period, 67% of patients had complete relief of all symptoms.

A small, prospective, placebo-controlled RCT studied 36 patients who either received oral cimetidine or placebo [305]. Median supra¬pubic pain and frequency scores improved signifi¬cantly, but the publication does not state exactly how many patients in each group improved.

4. IMMUNOSUPPRESSANTS

a) Cyclosporine

Grade of Recommendation: C - Level of Evidence: 3

Cyclosporine, a widely used immunosuppressive drug in organ transplantation, was the subject of a novel bladder pain syndrome trial. [306] Eleven patients recei¬ved cyclosporine for 3-6 months at an initial dose of 2.5-5 mg/kg daily and a maintenance dose of 1.5 to 3mg/kg daily. Micturition frequency decreased, and mean and maximum voided volumes increased significantly. Bladder pain decreased or disappeared in 10 patients. After cessation of treatment, symp¬toms recurred in the majority of patients.

In a lon¬ger-term follow-up study, 20 of 23 refractory IC patients on cyclosporine therapy followed for a mean of 60.8 months became free of bladder pain. Bladder capacity more than doubled. Eleven patients subsequently stopped the¬rapy, and in 9, symptoms recurred within months, but responded to reinitiating cyclosporine [307]. Sairanen et al further found that cyclosporine A was far superior to sodium pentosanpolysulfate in all clinical outcome parameters measured at 6 months. [308] Patients who responded to cyclosporine A had a significant reduction of urinary levels of epidermal growth factor (EGF) [309].

b) Suplatast Tosilate

Grade of Recommendation: D - Level of Evidence: 3

Suplatast Tosilate (IPD-1151T) is an immunoregulator that selectively suppresses IgE production and eosinophilia via suppression of helper T cells that produce IL-4 and 5. It is used in Japan to treat allergic disorders including asthma, atopic dermati¬tis, and rhinitis. Ueda et al reported a small study in 14 women with interstitial cystitis. [310] Treatment for one year resulted in a significantly increased bladder capacity and decreased urinary urgency, fre¬quency, and lower abdominal pain in 10 women. Concomitant changes occurred in blood and urine markers suggesting an immune system response. Larger, multicenter, randomized controlled trials in the United States and Japan have been completed and results are unpublished. Further studies with this drug for bladder pain syndrome are not planned and approval for this indication is not expected.

c) Azathioprine and Chloroquine derivatives

Grade of Recommendation: D - Level of Evidence: 4

In a single report in 1976, Oravisto et al used azathioprine or chloroquine derivatives for BPS patients not responding to other treatments.[311] About 50% patients responded.

d) Corticosteroids

Reports on outcome with corticosteroid therapy have been both promising (131) and discouraging (132). Soucy et al. (133) have suggested a trial of prednisone (25 mg daily for 1–2 months, afterwards reduced to the minimum required for symptom relief) in patients with severe ulcerative IC, which is otherwise unresponsive to conventional treatment. The side effects of steroids can be very serious, making it difficult to justify their use[312-314].

5. SODIUM PENTOSANPOLYSULFATE

Grade of Recommendation: D - Level of Evidence: 1

Sodium pentosan¬polysulfate (PPS), a synthetic sulfated polysaccharide, is available in an oral formulation, 3-6% of which is excreted into the urine and theoretically may replenished the damaged glycosaminoglycan (GAG) layer overlying transitional epithelium of the urinary bladder of BPS patients. An intact urothelial GAG layer has been proposed to be essential to keep the urothelium impermeable to urinary components. A defective bladder GAG layer is hypothesized to be one important cause for BPS. [315]

PPS's mechanism of action has been attributed not only to correction of a putative defect in the GAG layer, but also its ability to inhibit histamine release from mast cells, [316] and a pos¬sible effect mediated by nonspecific binding of the molecule with the inflammatory stimulants of uro-thelial activation, an action that would occur in the urine rather than at the mucosal membrane [317].

PPS is the most intensively studied treatment ever proposed for BPS. It is the only medication approved by the Food and Drug Administration for the pain of interstitial cystitis. Parsons initially administered the drug at a dosage of 50mg 4 times daily or 150mg twice daily in an open trial involving 24 patients. [318] Twenty-two of 24 patients experienced a good or excellent response within 8 weeks. In a subsequent randomi¬zed, placebo-controlled trial using a dose of 100mg three times daily in 62 patients, pain and urgency improved in 44% vs. a placebo response of 15%. Urgency improved by 38% vs. 18% on placebo. The average number of daily voids was unchanged [319].

Five randomized controlled trials for pentosan polysulfate have yieled conflicting results of efficacy. Holm-bentzen et. al[320] reported the first multicenter double-blind placebo controlled trial in 1987 looking at 115 patients with bladder pain syndrome. Patients were randomized to a dose of 200mg twice daily vs. placebo for 4 months. The results showed no difference between pre and post trial values with regard to symptoms, urodynamic parameters, cystoscopic appearance, or mast cell counts in the two groups. The study concluded that the drug had no clinically significant effect.

The first of two pivotal studies for the FDA was per¬formed in the United States in 1990.[321] A total of 110 patients in 5 medical centers were studied for 3 months on a dosage of 100mg three times daily. Twenty-eight per cent of patients on PPS reported "more than slight improve¬ment" versus 13% of those on placebo. Pain and pressure to urinate were the main parameters to show benefit with PPS.

The FDA asked for a second study which was reported 3 years later. [322] In a multi¬center, placebo-controlled RCT 148 patients were randomized to 100mg three times daily of pentosan-polysulfate vs. placebo. In the primary endpoint of patient self-evaluation of global improvement, 32% of those on PPS reported 50% or more overall impro¬vement vs. 16% on placebo at 3 months. Pain, urgen¬cy, and pressure showed significant improvement with drug. Frequency, nocturia, and volume voided showed no significant changes between study groups.

The NIDDK performed their own 2 X 2 factorial study to evaluate PPS and hydroxyzine. [301] Each drug was used alone and in combination and compa¬red to a placebo group. Patients were treated for 6 months. There were 121 participants in 7 centers. No statistically significant response to these medi¬cations was documented. A non-significant trend was seen in the PPS treatment groups (34%) compa¬red to non-PPS groups (18%). Of the 29 patients on PPS alone, 28% had global response (primary end¬point) of moderately or markedly improved vs. 13% on placebo, very similar in this 6-month study to improvement rates in the 3-month pivotal studies, though not reaching statistical significance in the longer study.

In summary

Of 5 RCTs 2 had unfavorable and 3 had favorable results for PPS. Most recent non randomized studies showed a complex heterogenity in efficacy as well[323-326]. Such conflicting results might suggest that a minority of patients do respond to PPS, but currently there is no reliable method to identify such patients.

Long-term, open-label studies with PPS have been reported. Populations of patients receiving extended treatment for up to 90 months or more in the com¬passionate use program showed no further improve¬ment in symptoms after 1-2 years, though there seemed to be little tachyphylaxis [301,327]. A total of 2809 patients had begun treatment with a 3 month supply of PPS and 21% continued with treatment beyond this point and reordered medication. This seems to cor¬relate with the 28-32% improvement rate previously reported. The dropout rate in the first 6 months was extraordinarily high with only 178 active patients out of 1742 who initially ordered the drug. There was an overall improvement in symptoms in 62% of the patients who did remain in treatment for 6-35 months.

PPS appears to be a very well-tolerated medi¬cation [327] with no common central nervous sys-tem side effects, and appears to be beneficial with regard to improving the pain associated with inter-stitial cystitis in up to one-third of patients, a stan¬dard often expected with a placebo. A 3-6 month course is required to see an effect in most patients. Claims suggesting greater efficacy and claims urging its use in patients who do not meet the standard defi¬nition of bladder pain syndrome should be regarded with caution.

6. OTHER ORAL MEDICATIONS THAT HAVE BEEN USED FOR BPS

a) L-arginine

Grade of Recommendation: -A - Level of Evidence: 1

Foster and Weiss were the original proponents of L-arginine in the therapy of interstitial cystitis [328]. Eight patients with IC were given 500mg of L-arginine 3 times daily. After one month, urinary nitric oxide synthase activity increased 8-fold and 7 of the 8 patients noticed improvement in IC symptoms. An open-label study of 11 patients showed improvement in all 10 of the patients who remained on L-arginine for 6 months [329].

An open-label study of 9 women in Sweden failed to find any change in symptom scores or in nitric oxide production in the bladder [330]. A placebo-control¬led randomized controlled trial of 53 IC patients could find no difference on an intention to treat analysis between drug and pla¬cebo-treated patients [331]. A smaller randomized placebo-controlled crossover trial of 16 IC patients found no clinically significant improvement with L-arginine and concluded that it could not be recom¬mended for IC treatment [332].

Data does not support the use of L-arginine for the relief of symptoms of interstitial cystitis.

b) Quercetin

Grade of Recommendation: D - Level of Evidence: 4

Quercetin, a bioflavenoid available in many over-¬the-counter products, may have the anti-inflammato¬ry effects of other members of this class of com¬pounds found in fruits, vegetables, and some spices. Katske et. al [333] administered 500mg twice daily to 22 BPS patients for 4 weeks. All but one patient had some improvement in the O'Leary/Sant symptom and problem scores as well as in a global assessment score. Further studies are necessary to determine efficacy.

c) Antibiotics

Grade of Recommendation: D - Level of Evidence: 4

Warren et. al [334] randomized 50 patients to recei¬ve 18 weeks of placebo or antibiotics in-cluding rifampin plus a sequence of doxycycline, erythromy¬cin, metronidazole, clindamycin, amoxi-cillin and ciprofloxacin for 3 weeks each. Intent to treat ana¬lysis demonstrated that 12 of 25 patients in the anti¬biotic and 6 of 25 patients in the placebo group reported overall improvement while 10 and 5 respec¬tively noticed improvement in pain and urgency. The study was complicated by the fact that 16 of the patients in the antibiotic group un-derwent new BPS therapy during the study as did 13 of the placebo patients. There was no statistical signi¬ficance reached. What was statistically sig-nificant were adverse events in 80% of participants who received antibiotic compared to 40% in the pla-cebo group. Nausea and/or vomiting and diarrhea were the predominant side effects. Most patients on antibio¬tics correctly guessed what treatment arm they were in, and those that guessed correctly were significant¬ly more likely to note improvement after the study. No duration in improvement after comple-tion of the trial of antibiotics was reported.

Burkhard et.al [335] reported a 71% success in 103 women presenting with a history of urinary urgen-cy and frequency and chronic urethral and/or pel-vic pain often associated with dyspareunia and/or a his¬tory of recurrent urinary tract infection. This was a large, inclusive group and one that is prob-ably broa¬der than the bladder pain syndrome we are focu¬sing on. Nevertheless, he recommended empiric doxycycline in this group. The overwhelm-ing majo¬rity of BPS patients have been treated with empiric antibiotics prior to diagnosis. The role of tetracyclines to eradicate nanobacteria in urine of BPS patients has recently been addressed in small Chinese open label study, leaving the significance of nanobacterias as a reasonable pathogen or trig-ger of the condition open [129,324-326].

At this time there is no evidence to suggest that an-tibiotics have a place in the therapy of BPS in the absence of a culture-documented infection [336].

d) Methotrexate

Grade of Recommendation: D - Level of Evidence: 4

Low dose oral methotrexate significantly improved bladder pain in 4 of 9 women with BPS, but did not change urinary frequency, maximum voided vol-ume, or mean voided volume [337]. No placebo-controlled, RCT has been done with this agent.

e) Montelukast

Grade of Recommendation: D - Level of Evidence: 4

Mast cell triggering releases 2 types of proinflamma¬tory mediators, including granule stored pre-formed types such as heparin and hista-mine, and newly syn¬thesized prostaglandins, and leukotriene B4 and C4. Classic antagonists, such as montelukast, zafirlukast and pranlukast, block cys-teinyl leukotriene 1 recep¬tors. In a pilot study,[338] 10 women with IC and detrusor mastocytosis re-ceived 10mg of montelukast daily for 3 months. Fre-quency, nocturia, and pain improved dramatically in 8 of the patients. Further study would seem to be warranted, especially in patients with detrusor mas-tocytosis, defined as >28 per mm2.

f) Nifedipine

Grade of Recommendation: D - Level of Evidence: 4

The calcium channel antagonist nifedipine inhib-its smooth muscle contraction and cell-mediated immu¬nity. In a pilot study, [339] 30mg of an ex-tended release preparation was administered to 10 female patients and titrated to 60mg daily in 4 of the patients who did not get symptom relief. Within 4 months five patients showed at least a 50% de-crease in symptom scores, and 3 of the 5 were as-ymptomatic. No further studies have been reported.

g) Misoprostol

Grade of Recommendation: D - Level of Evidence: 4

The oral prostaglandin analogue misoprostol was studied in 25 patients at a dose of 600 micro-grams daily [340]. At 3 months 14 patients were signifi¬cantly improved, and at 6 months 12 patients still had a response. A cytoprotective action in the urina¬ry bladder was postulated.

h) Tanezumab

Grade of Recommendation: D - Level of Evidence: 1

A recent randomized, double-blind, placebo controlled phase two 64 patient study investigated tanezumab, a humanized monoclonal antibody that specifically inhibits nerve growth factor as a treatment for BPS pain[341]. At week 6 tanezumab produced a significant reduction from baseline in average daily pain score vs placebo . A significantly higher proportion of patients on tanezumab responded as improved in the global response assessment and tanezumab also significantly reduced urgency episode frequency vs placebo. Studies with this drug have been suspended by the Food and Drug Administration because of the occurrence of osteonecrosis in nonurologic trials.

X. INTRAVESICAL / INTRAMURAL THERAPY (TABLE 5)

Intravesical therapies form one of the staples of BPS therapy, though regulatory approvals and availability throughout the world differ from nation to nation. What follows are treatments that have been reported in the recent literature, some of which are commonly used. Older therapies that are rarely used now include silver nitrate[80,344-347] and chlorpactin WCS90.[7,348-352] These have not been included in this current edition of the Consultation, but have level 3 evidence to support a grade C recommendation based on original reports.

1.DMSO (DIMETHYL SULFOXIDE)

Grade of Recommendation: B - Level of evidence 2

A small number of significant side effects. Not approved in Japan.

DMSO is believed to reduce inflammation, relax muscles, eliminate pain, dissolve collagen, and degranulate mast cells. It has long been used as a therapeutic agent for BPS. Its mechanism of action, however, has not been clarified. Ten articles on DMSO for the treatment of IC were retrieved. Peeker et al[353] reported that in a randomized study, frequency and pain were improved in ulcer-type IC patients, although no improvement was observed in maximum bladder capacity. Perez-Marrero et al[354] reported that in a non-randomized controlled study, 53% of the patients showed remarkable improvement in subjective evaluation (placebo 18%), and 93% in objective evaluation (placebo 35%). Around an 80% improvement rate has been reported in case series and retrospective studies.[355-362]

With regard to side effects after instillation of DMSO, most patients recognize a garlic-like odor, which disappears within a day, and about 10% of patients report bladder irritative symptoms which resolve with or without symptomatic treatment.[363] It is hypothesized that these transient exacerbations occur as the result of mast cell degranulation. The number of significant side effects is considered to be small[362]. Cataracts have been reported in animal studies,[364,365] though not in humans. Negative effects on bladder compliance have been noted in rat detrusor.[366] DMSO may accelerate the absorption of other drugs instilled simultaneously, which could be a source of side effects.

The instillation method has not been standardized. Generally, 50cc of a solution of medical grade 50% DMSO is instilled into the bladder. If pain occurs immediately following instillation, local anesthesia (e.g. 20ml of 2% lidocaine solution) may be instilled. Average retention time is considered to be 10 to 20 minutes.[363] The instillation is performed weekly for 6-8 weeks. After an initial course, treatment is suspended until symptoms recur. If a good result was obtained, another 6 week course (often followed by monthly maintenance) can be initiated. The long-term effect is unknown, although there is no upper limit for the duration of the treatment. DMSO is medically approved in the US, while it has not been approved yet in Japan.

2. HEPARIN

Grade of Recommendation: C - Level of Evidence: 3

Side effects primarily related to effects intravesical catheterization and slight chance of bladder hemorrhage.

The glycosaminoglycan (GAG) layer on the bladder urothelium is a kind of muco-polysaccharide, working as a non-specific defense mechanism. It is believed that a deficiency or abnormality of GAG secondarily causes inflammation of the bladder by increasing the permeability of the bladder mucosa, leading to the pathologic cascade of BPS. Heparin has similarities to the GAG layer of the bladder. When instilled into the bladder, theoretically it might replace the damaged GAG layer. Kuo[367] reported that the International Prostate Symptom Score, as well as bladder capacity at initial desire to void and maximum bladder capacity, improved significantly. According to the report by Parsons et al[368] symptoms were reduced in 56% of patients treated 3 times weekly for 12 weeks. These reports suggest the efficacy of heparin, however, there is no randomized comparative study to give conclusive evidence. One study indicated that intravesical heparin instillations may prolong the response to dimethyl sulfoxide treatment.[369]

No significant side effects have been reported, as it does not affect systemic coagulation parameters. In the case of patients with hematuria, however, it may exacerbate local hemorrhage.

The instillation method has not been standardized. Generally, 10,000-40,000 units of heparin are instilled. It is unusual to have pain or irritation as a

result of instillation, and retention times can be 30 minutes or more. Instillation frequency can be up to every other day and is often administered at home by the patient. Parsons et al[370] recently reported that when 40,000 units of heparin combined with 1 to 2% lidocaine was instilled 3 times a week for 2 weeks, about 80% efficacy was obtained. There is no upper limit for the duration of the treatment, but a long-term effect is unknown. A bleeding tendency may occur. Heparin for intravesical use is not approved by drug regulatory authorities.

3. HYALURONIC ACID

Grade of Recommendation : D - Level of Evidence: 1

No significant side effects.

Hyaluronic acid, like heparin, is a muco-polysaccharide, that could theoretically repair a damaged GAG layer of the bladder mucosa. Seven reports have indicated efficacy.[371-376] In the summer of 2003 Bioniche Life Science Inc http://www.medicalnews-today.com/articles/112053.php and in the spring of 2004 Seikagaku Corporation reported double-blind, placebo-controlled, multicenter clinical studies of their hyaluronic acid preparations (40mg or 200mg per cc respectively) and neither showed significant efficacy of sodium hyaluronate compared to placebo. These negative studies have not been published in peer reviewed literature. Neither preparation has been approved for use for BPS in the United States. At the same time, no significant side effects were observed.

A non-placebo-controlled study has demonstrated a favorable effect of hyaluronic acid on pain reduction [192]. Forty-eight patients with typical symptoms and a positive potassium (0.4 M) sensitivity test were treated with weekly instillations of 40 mg hyaluronic acid for 10 weeks. Visual analogue scale scores showed symptom relief due to hyaluronic acid therapy, irrespective of bladder capacity. The improvement was particularly evident in patients with a reduction in Cmax < 30% compared to patients with a reduction of < 30% with 0.2 M KCl solution (P = 0.003). Long-term effects were investigated in a study of 70 patients previously treated with hyaluronan [377]. Of the initial 70, 48 improved. Of these, 50% reported complete remission with no further therapy. Another 41.7% of patients with symptom recurrence improved after retreatment

A recent interventional study from China suggested a prolonged effect of bladder distension when combined with instillation of hyaluronic acid [378]

4. CHONDROITIN SULFATE

Grade of Recommendation: D - Level of Evidence: 4

No significant side effects.

Chondroitin sulfate is another mucopolysaccharide. Its efficacy was suggested for the first time 2002 when used alone [379]and in another trial when used in combination with hyaluronic acid (364). Intravesical chondroitin sulphate demonstrated beneficial effects in patients with a positive potassium stimulation test in two non-randomised, uncontrolled, open-label pilot studies. Steinhoff (363) treated 18 patients with 40 mL instilled intravesically once weekly for 4 weeks and then once monthly for 12 months. Thirteen of 18 patients were followed for the entire 13-month study. Twelve of these patients responded to treatment within 3–12 weeks. A total of 6/13 (46.2%) showed a good response, 2/13 (15.4%) had a fair response, 4/13 (30.8%) had a partial response, and 1/13 (7.7%) showed no response. In a second trial [380] 24 refractory patients with BPS/IC were treated with high-dose (2.0%) chondroitin sulphate instillations twice weekly for 2 weeks, then weekly with 0.2% solution for 4 weeks, and monthly thereafter for 1 year. The average symptom improvement reported in 20 patients completing the trial was 73.1% (range: 50–95%). The time to optimum response was 4–6 months. A more concentrated 2.0% solution was needed in eight patients to maintain results. Chondroitin sulphate instillation was effective and well tolerated in the therapy of various chronic forms of cystitis associated with a possible GAG layer deficit including BPS in a large multicenter but open srudy [381].

Sixty-five patients with IC/BPS were treated in a prospective, randomized, double-blind, inactive vehicle-controlled, 12-week study (6 weeks treatment, followed by 6 weeks follow-up) . At the primary endpoint analysis (week 7), 22.6% of the vehicle control group were responders compared with 39.4% of the active therapy group, however, the difference was not significant [382]. A follow up randomized placebo-controlled trial with 98 female patients showed only minor improvements in IC/BPS symptoms and pain and failed to demonstrate a statistically significant drug effect vs. placebo [383] . The authors concluded that the study did not support the use of intravesical chondroitin sulfate as a monotherapy for this condition.

5. PENTOSAN POLYSUFATE

Grade of Recommendation: D - Level of evidence: 4

No significant side effects are considered to be present.

Pentosan polysufate (PPS) is a mucopolysaccharide similar to heparin, with a similar postulated mode of action when used locally. Like other muco-polysaccharides, it has not been well-studied clinically. Bade et al in a randomized controlled trial found benefit in 4 patients out of 10 on PPS versus 2 of 10 on placebo.[384] A more recent placebo-controlled study of 41 patients found the addition of a 6 week course of intravesical PPS to a regimen of oral PPS significantly improved results.[385]

6. VANILLOIDS (CAPSAICIN, RESINIFERATOXIN)

Grade of Recommendation: -A (ineffective) - Level of Evidence: 1

Significant side effects: local irritation possible

It would seem reasonable that capsaicin, a C-fiber afferent neurotoxin, could alleviate the pain of BPS by desensitizing bladder afferents. Resiniferatoxin (RTX) is considered to have a stronger action than capsaicin, by desensitizing C-fibers more quickly, and causing less initial irritation. Efficacy was indicated in five relatively small clinical trials.[386-390] No severe side effects were reported. A randomized multicenter placebo-controlled clinical trial of RTX failed to demonstrate benefit over placebo.[391]

7. BACILLUS CALMETTE-GUERIN (BCG)

Grade of Recommendation: -A (ineffective) - Level of Evidence: 1

Potential serious complications

Seven articles reported on a BCG instillation therapy. Zeidman et al first reported that 5 patients who did not respond to other therapies showed symptomatic improvement.[392] Peters et al conducted a randomized double blind study showing a 60% improvement compared to 27%[393] placebo response with good long-term results at 27 months.[394] Sixty-five percent of the patients experienced burning sensation, 41% irritation of the bladder, and 35% pelvic pain. One patient was reported to have dropped out due to joint pain.

Peeker et al conducted a randomized double blind study comparing intravesical BCG and DMSO and failed to find any efficacy with BCG.[353] A very large, multicenter randomized placebo controlled trial conducted by the National Institute of Diabetes, Digestive, and Kidney Disorders failed to identify benefit from BCG, although the side-effect profile was surprisingly similar to that of placebo.[395]

8. OXYBUTYNIN

Grade of Recommendation D - Level of Evidence: 4

Side effect profile is unknown

Barbalias et al observed significant improvement when combining intravesical instillation of oxybutynin with bladder training.[396] Randomized trials are lacking.

9. LIDOCAINE

Grade of Recommendation: C - Level of Evidence: 2

No significant side effects.

Lidocaine is a local anesthetic that relieves pain by blocking sensory nerves in the bladder. Four articles[397-400] reported on the electromotive drug administration (EDMA) of lidocaine. Using EMDA, ionized lidocaine is actively introduced into the bladder using an electrical current. Three articles reported that lidocaine and dexamethasone were instilled following hydrodistention. According to the report by Rosamilia et al[400], 85% of the patients had a good result, with the effect persisting for 6 months in 25%. There are two other case reports.[401,402] A report on a pharmacokinetic effect, demonstrated safe levels of lidocaine absorption into the bladder.[403] 102 adult patients (99 women) with a clinical diagnosis of BPS were randomised from 19 centres in the USA and Canada to receive a daily intravesical instillation of alkalinised lidocaine or placebo (double-blind), for 5 consecutive days. Treated patients had significant sustained symptom relief for up to 1 month [404]. However, further randomized, placebo-controlled trials are needed to ascertain efficacy, optimal treatment parameters, and length of response to intravesical lidocaine preparations.[405] Advantages seem to be immediate response, low-cost of generic medication, and ability of patients to self-administer at home.

10. BOTULINUM TOXIN (INTRAMURAL)

Grade of Recommendation: A - Level of Evidence: 1

• Side effects include dysuria, incomplete emptying

Botulinum toxin type A (BTX-A) acts by binding to the nerve endings within muscles, blocking the release of acetylcholine, and probably other neurotransmitters, to modulate muscle contraction and reduce the sensitization of sensory nerve endings. There is increasing evidence for an additional, direct effect on the sensory bladder pathways and subsequent modulation of the efferent overactivity or hyperexcitability involved in the pathophysiology of the detrusor and other muscle dysfunction.[406]

Thirteen BPS patients were injected with 100–200 IU of BTX-A (abobotulinumtoxin A or onabotulinumtoxin A) into 20–30 sites submucosally in the trigone and floor of the bladder. Overall, nine (69%) patients noted subjective improvement, and ICSI scores improved by 70% ($P < 0.05$). There were significant decreases in daytime frequency, nocturia and pain, and a significant increase in first desire to void and maximal cystometric capacity. However .dysuria occurred in a majority of patients and persisted in a minority for several months after initial injection. Three patients required clean intermittent catheterization for 2-3 months following therapy.[407]

To ascertain effect of repeat injections a total of 13 patients were followed up for 2 years, while 58 injections were administered with a mean of 4.8 ± 0.8 injections per patient. The mean interval between two consecutive injections was 5.25 ± 0.75 months. At 1 and 4 months follow-up, 10 patients reported a subjective improvement. Mean VAS scores, mean daytime and night-time urinary frequency decreased significantly. The three non-responders to

the first intravesical treatment session underwent further treatment 3 months later with satisfactory results. At 1 and 2 years follow-up, the beneficial effects persisted in all patients [408]

These results are in contrast with those in another study from Kuo of BTX-A (onabotulinumtoxin A) in 10 patients with BPS. One hundred units were injected suburothelially into 20 sites in five patients, while 100 U were injected into the trigone in the remaining five. None of the patients became symptom-free; two showed only limited improvement in bladder capacity and pain score.[409]

However in an RCT, Kuo and Chancellor analysed the difference between hydrodistension and hydrodistension plus intravesical, sub mucosal BTX-A (onabotulinumtoxin A).[410] Of the 67 patients, 44 were divided in two groups: one received 200 U and the other 100 U, and cystoscopic hydrodistension was performed after 2 weeks. The remaining 23 patients received hydrodistension only. There was symptomatic improvement in all groups. However, in the hydrodistension group, 70% had returned to their previous symptoms after the first month, while in the BTX-A-treated groups, there was improvement of VAS, functional bladder capacity and cystometric bladder capacity at 3 months. At 12 and 24 months, the results in the active group were 55 and 30% versus 26 and 17% in the hydrodistension group

Trigonal-only injection seems effective and long-lasting since 87% of patients (n = 23) reported improvement after a 3-month follow-up period in a study by Pinto et al.[411] Over 50% referred continuity of the beneficial effect 9 months after the first treatment. When retreatment was needed, similar results were obtained. No cases of urinary retention were reported. The authors concluded that this treatment is safe, effective and can be repeated.

Further studies will be needed to obtain conclusive evidence for its efficacy, duration of effect, and side-effect profile.

XI. NEUROMODULATION

Grade of Recommendation: B - Level of Evidence: 1

Sacral nerve stimulation (SNS) involves implanting permanent electrode(s) to stimulate S3 or S4 roots. As early as 1989, Tanago et al showed that stimulation of S3 may modulate detrusor and urethral sphincter function [412]. FDA approved the usage of sacral neuromodulation for treating refractory detrusor overactivity in 1997 and for urinary urgency and frequency in 1999. Although the effectiveness of SNS for detrusor overactivity is largely confirmed by a goodnumber of papers, only a few papers report the effect of SNS in treating BPS.

Zerman et. al reported significant improvement in a 60-year-old woman treated for severe BPS pain using sacral nerve stimulation implant. Pain and accompanying bladder dysfunction were improved by temporary and permanent sacral nerve stimulation for up to six months [413]. Maher et al [414] showed that temporary stimulation was effective in 73% of 15 women with refractory BPS. Mean voided volume during treatment increased and mean daytime frequency, nocturia and pain decreased significantly. As indicated by the Short Urinary Distress Inventory and SF-36 Health Survey, the quality of life parameters of social functioning, bodily pain and general health significantly improved during the stimulation period.

Chai et. al[230] found that percutaneous S3 nerve root stimulation improves symptoms and normalizes urinary HB-EGF levels and antiproliferative activity in patients with BPS. In their report in 2003, Comiter et al[415] prospectively investigated the effect of SNS on a series of 17 patients with refractory BPS. At an average of 14 months follow-up mean daytime frequency, nocturia and mean voided volume improved significantly. The average pain decreased from 5.8 to 1.6 points on a scale of 0 to 10 and Interstitial Cystitis Symptom and Problem Index scores (ICSI and ICPI) decreased from16.5 to 6.8 and 14.5 to 5.4, respectively. Of the 17 patients 16 (94%) with a permanent stimulator demonstrated sustained improvement in all parameters at the last postoperative visit. Whitmore el al [416] applied percutaneous sacral nerve root stimulation on 33 patients with refractory interstitial cystitis. Statistically significant improvements were seen in pain and urinary symptoms. Significant improvements were also seen in ICSI and ICPI scores.

Peters et al [417] reported a reduction of narcotic usage in 18 BPS patients following SNS for a mean of 15.4 months, although the dose reduction was modest (36%) and only 4 of 18 discontinued the narcotics. However, Elhilali and colleagues [418] found that both of two patients with interstitial cystitis reported no improvement following sacral neuromodulation. Zabihi et al [419] more extensively stimulate S2-S4 by implanting electrodes into epidural space through sacral hiatus. 23 of 30 (77%) patients had successful trial stimulation and were permanently implanted. Among these patients, the symptom score was improved by 35% (p=0.005). The pain score improved by 40% (p=0.04). Patients reported an average of 42% improvement in their symptoms.

In the first prospective, single-blind, crossover trial of sacral nerve stimulation (SNS) versus pudendal nerve stimulation (PNS) for patients with BPS (n = 22), PNS gave an overall 59% improvement in symptoms, whereas SNS gave an overall 44% improvement (P = 0.05). Most patients who tested both a sacral and pudendal electrode chose PNS as the better site. Follow-up showed marked improvements in voiding variables

and validated BPS symptom questionnaires. Over 90% of patients treated with neuromodulation stated that they would undergo implantation again [420].

Long-term results were verified in a retrospective study of 78 patients treated from 1994 to 2008. Permanent sacral neuromodulation implantation was performed in patients who showed at least 50% improvement in their symptoms with a temporary peripheral nerve evaluation test. Median follow-up was 61.5 ± 27.7 months. Good long-term success of sacral neuromodulation was seen in 72% of the patients. The explantation rate was 28%. The most frequent reason for explantation was poor outcome (54% of the failed patients). The revision rate was 50% [421] In another observational, retrospective, case-controlled review (January 2002–March 2004), 34 female patients underwent permanent device implants . Mean pre-/postoperative pelvic pain and urgency/frequency scores were 21.61 ± 8.6/9.22 ± 6.6 ($P < 0.01$), and mean pre-/postoperative visual analogue pain scale (VAPS) scores were 6.5 ± 2.9/2.4 ± 1.1 ($P < 0.01$). Mean follow-up was 86 ± 9.8 months. Sacral neuromodulation showed adequate improvement for the symptoms of refractory BPS. Reoperation rate was 25%.[422]

Sacral nerve modulation is still considered an investigational procedure for BPS by the Consultation. Pudendal nerve stimulation has shown better results. Therapeutic benefits of both appear to be significant in selected cases. Strict patient selection and detailed discussion with patients prior to surgery is mandatory. Long-term results should be collected and reported, and trial results discussed with patients before employing this treatment modality.

XII. PAIN EVALUATION AND TREATMENT

1. EVALUATION OF PAIN:

The first premise that all physicians treating patients diagnosed with BPS is that they deserve to have their chronic pain assessed and treated. It is now recognized that successful management of BPS is only possible using a multidisciplinary and multimodal treatment approach which must include management of the associated chronic pain. This includes evaluation of the whole patient, not just the urology related symptoms. As described in previous sections, this will involve assessment of clinical symptoms, physical signs and history to best define the underlying diagnosis and overlapping conditions, while not ignoring the problems of mood, sleep and sexual problems. The patient's self report should be the primary source of assessment. Clinicians should assess pain with easily administered rating scales and should document the efficacy of pain relief at regular intervals after starting or changing treatment. Systematic evaluation of the pain involves the following:

- Evaluation of severity
- Detailed history of the pain including assessment of pain intensity and character
- Evaluation of the psychological state of the patient, including assessment of mood and coping responses
- Physical examination emphasizing the neurologic examination
- Diagnostic workup to determine the cause of the pain
- Re-evaluation of therapeutic strategy and response.

The initial evaluation of pain should include a description of the pain, **PQRST** has been described for this purpose:

P: Palliative or Provocative factors, 'what makes it less intense?'

Q: Quality, 'what is it like?'

R: Radiation, 'does it spread anywhere else?'

S: Severity, 'how severe is it?'

T: Temporal factors, 'is it there all the time, or does it come and go?'

Pain measurement

A number of different rating scales have been devised to attempt to methodically measure pain and to allow patient follow-up. These have been used in research, audit and in clinical practice. They all rely on a subjective assessment of the pain and therefore make inter-individual comparisons difficult. Additionally, pain is a multidimensional complex phenomenon and is not adequately described by one-dimensional scales, however there is value in making some sort of an assessment to aid clinical practice.

- Categorical scales e.g., verbal rating scales: mild, moderate, severe pain
- Visual analogue, Likert or Numerical Rating scale (VAS)
- Complex pain assessment compendiums e.g., Brief Pain Inventory (BPI), McGill Pain Questionnaire [423-425]

The BPI consists of several visual analogue scales grouped together assessing pain at rest, on movement, and other aspects of the pain including interference with function and effect on work. The McGill Pain Questionnaire measures pain quality by asking patients to rate the intensity of 15 verbal descriptors of pain on a 0 to 3 rating scale. The pain rating index is composed of 2 scores, including a sensory pain score and an affective pain score. Some versions also use a standard pain intensity VAS.

2. PHARMACOLOGIC MANAGEMENT OF CHRONIC PELVIC PAIN

Physicians using pharmacologic measures to control BPS pain must be committed to the following principles [426]:

1. drugs are prescribed and monitored with knowledge of the patient's history and risks,

2. patients understand potential benefits and harms and participate in reducing harms

3. clinicians assess outcomes for both effectiveness and harms.

a) Non-acidic antipyretic analgesics

Acetaminophen (paracetamol) is the main representative of this group. It has antipyretic activity and is a simple analgesic. There is very little evidence about its role in chronic pelvic pain [427,428]. Acetaminophen should be considered for only mild pain. Acetaminophen is a common cause of hepatotoxicity [429,430] and risk increases with alcohol use [431].

b) Acidic antipyretic analgesics

The classical non-steroidal anti-inflammatory drugs (NSAIDs) fall into this group and include salicylic acid. They are known to act on the cyclooxygenase (COX) enzyme. The early NSAIDs tended to have little selectivity for COX2 over COX1, and are therefore said to be associated with more side effects than the newer COX2 selective inhibitors [432]. The COX1 enzyme is mainly involved in normal 'housekeeping' functions, such as mediating gastric mucosal integrity, and renal and platelet function. Blocking the COX1 enzyme is the cause of the platelet, gastric and renal complications that can occur with NSAIDs. It has been suggested that the COX2 enzyme is inducible as a result of tissue damage, and that it is the main enzyme involved in inflammation and peripheral sensitization of nociceptors [433]. As a result, the analgesic efficacy of COX2 selective drugs should be as good as that of the nonselective drugs, however the benefit is primarily seen in acute inflammatory type pain The selective COX2 agents should not be prescribed in patients with increased risk of cardiovascular disease including congestive cardiac failure [434]. There is very little evidence for a role of NSAIDs in the management of chronic pelvic pain and even less evidence for a role for the COX2 selective drugs. Most of the analgesic studies have investigated dysmenorrhoea in which NSAIDs have been found to be superior to placebo and possibly paracetamol [428,435]

For practical purposes the NSAIDs may be divided into:

1. Non-selective, low potency (e.g. salicylic acid, ibuprofen).

2. Non-selective, high potency (e.g. ketoprofen, diclofenac, ketorolac).

3. COX2 selective drugs (e.g. celecoxib).

Non-selective, low potency NSAIDs can be used as first-line analgesics [436]. They are most likely to be of help if there is an inflammatory component to the pain. More potent NSAIDs should be reserved for those conditions in which the low potency drugs have been tried and failed to produce significant benefit. COX2 selective drugs should be used with caution as an alternative to the non-selective drugs where there is an increased risk of gastric complications. They should be avoided in patients with known cardiovascular disease. NSAIDs should be taken with food and consideration must be given to the use of gastric protective agents. The benefits of the NSAIDs must be demonstrated to outweigh the risks. All NSAIDs are contraindicated in active gastrointestinal ulceration/bleeding and renal disease. They may seriously exacerbate asthma and produce fluid retention. Even if stronger analgesics such as opioids are added, the NSAIDs can be continued as they are likely to have a synergistic action improving pain control above and beyond that obtained with opioids alone [437]

c) Neuropathic analgesics

1. Tricyclic Antidepressants

Tricyclics have a definite analgesic effect on neuropathic pain compared with placebo [438]: 30% of patients should obtain more than 50% pain relief; 30% will have minor adverse effects; and 4% will have to stop treatment because of side effects. Tricyclics are said to work in doses that are too low to affect mood. They may work by increasing levels of norepinephrine and/or serotonin. They also have actions at sodium channels. They are extensively used for pelvic pain and good evidence exists to justify their usage [290,439]. A recent randomized placebo controlled study sponsored by the US National Institutes of Health [246] evaluated increasing doses of amitriptyline with or without standardized education and behavioural modification in treatment naïve patients with IC/PBS. While this study did not confirm the overall benefit of amitriptyline plus education and behavior modification was superior to only the education and behavioral changes, they did show that amitriptyline may be beneficial in persons who can achieve a daily dose of 50 mg or greater.

2. Serotonin Reuptake Inhibitors

Selective serotonin reuptake inhibitors appear to be less effective for the management of pelvic pain [440]. Fluoxetine can increase plasma levels of amitriptyline and induce toxicity, and therefore care must be exercised if the drugs are combined.

Anticonvulsants have been used in the management of pain for many years.

3. Anticonvulsants

Gabapentin and pregabalin have recently been introduced for pain management. There is evidence to show that both compounds are effective in chronic neuropathic pain [441,442]. Whereas

there is little evidence to support the use of anticonvulsants in the management of genitourinary pain, they should be considered if there is a suggestion of neuropathic pain or central sensitization [275,443-445].

N-methyl-D-aspartate (NMDA) antagonists. Ketamine is thought to act primarily at the NMDA receptor, though it may also have actions at sodium channels, as well as opioid (kappa and mu) receptors [446]. Ketamine has been shown in both human [447] and animal models [448] of neuropathic pain to reduce central sensitization and wind-up. Ketamine has been found to be useful in a number of chronic pain states including: peripheral neuropathies with allodynia, stump and phantom pain, central pain, as well as fibromyalgia [449-453] However it has become evident that ketamine should only be used with caution (or not at all) by an experienced practitioner trained in its use. Ketamine is a street drug of addiction and has recently been associated with disastrous bladder consequences, the so-called ketamine bladder. [454]

4. Opioids

There is now a general acceptance that opioids have a role in the management of chronic non-malignant pain [455]. While the use of opioids in urogenital pain is poorly defined, they should be considered for patients with BPS in whom all other treatments to reduce pain have failed. Opioid use does present very real risks and potential harms [284] and include overdose, addiction, and opioid diversion and prescribers have an obligation to assess risks and minimize harms. Unfortunately, not enough is known about the long-term benefits, risks, and side effects of opioid therapy, not only in IC/PS, but other chronic non-cancer pain conditions. More research is needed in this area. The following guidelines for the use of opioids in chronic/non-acute urogenital pain are suggested by the European Association of Urology [436].

1. All other reasonable treatments must have been tried and failed.
2. The decision to instigate long-term opioid therapy should be made by an appropriately trained specialist in consultation with another physician (preferably the patient's family doctor).
3. Where there is a history or suspicion of drug abuse, a psychiatrist or psychologist with an interest in pain management and drug addiction should be involved.
4. The patient should undergo a trial of opioids.
5. The dose required needs to be calculated by careful titration.
6. The patient should be made aware (and possibly give written consent):

I. that opioids are strong drugs and associated with addiction and dependency

II. the opioids will normally only be prescribed from one source

III. the drugs will be prescribed for fixed periods of time and a new prescription will not be available until the end of that period

IV. the patient will be subjected to spot urine and possibly blood checks to ensure that the drug is being taken as prescribed and that non-prescribed drugs are not being taken

V. inappropriate aggressive behaviour associated with demanding the drug will not be accepted

VI. hospital specialist review will normally occur at least once a year

VII. the patient may be requested to attend a psychiatric/psychology review

VIII. failure to comply with the above may result in the patient being referred to a drug dependency agency and the use of therapeutic, analgesic opioids being stopped.

- *Morphine*. There is no compelling evidence that one opiate is better than another. Morphine has, however, become the traditional gold standard. Morphine is the first-line drug, unless there are contraindications to morphine or special indications for another drug. The drug should be prescribed in a slow release/modified release form. Short-acting preparations are undesirable and should be avoided where possible. Parenteral dosing is undesirable and should be avoided where possible. In an acute situation, the daily morphine requirement may be calculated by titration of the drug with progressively increasing doses of 4-hourly rapid-release morphine. However, in most cases, starting with a low dose of slow-release morphine and confining the increments to occur at intervals of no less than 3 days to 1 week is adequate. Chronic non-cancer pain can be managed effectively in most patients with dosages at or below 200 mg/day of morphine or equivalent.
- A *fentanyl patch* can be used when oral absorption is restricted or when the patient suffers from nausea and vomiting. Patches are generally changed every 72 hours. The problem with the currently available patches is that the dosing increments between patches are large. Care needs to be exercised when increments in dose are undertaken. Fentanyl has contributed to numerous overdose deaths [456,457].
- *Methadone* is a strong analgesic which has a long track record [458]. While it may have a useful role in the management of urogenital pain, there is very little science to support this. Methadone has the

tendency to accumulate with repeated dosing and cause delayed respiratory arrest. Therefore, whereas it may be a very useful drug, it should only be prescribed by a practitioner familiar with its use as an analgesic. Methadone as an analgesic is usually prescribed 6 hourly as its analgesic action is relatively short-lived compared with the longer benefits seen from using the drug in drug addiction.

- *Meperidine* (Demerol) 300 mg intramuscular (i.m.) is about as effective as morphine 30 mg i.m.(conversion factor 0.1). Its oral bioavailability is, however, poor. Meperidine has a short duration of action, can accumulate with multiple dosing and is therefore not recommended for use in chronic, non-acute pain [459].

- *Oxycodone*, *hydromorphone* and *hydrocodone* are available as slow/modified-release preparations. They may be useful for opiate rotation if side effects or tolerance is a problem. They are powerful opioids and should be used with the same caution as morphine. 20 mg of oxycodone and 6 mg hydromorphnone is equivalent to 30 mg of Morphine (1.5 and 5 X conversion factor). Oxycodone, hydromorphone and hydrocodone may have a higher abuse liability than morphine [460].

- *Codeine* is a less potent opioid than morphine and the other opioids discussed and could be useful in mild to moderate pain. 20 mg of Codeine is equivalent to 30 mg of morphine (conversion factor 0.15). Tramadol produces analgesia by two mechanisms: an opioid effect; and an enhancement of serotoninergic and adrenergic pathways [461,462]. It has fewer of the typical opioid side effects (notably, less respiratory depression, less constipation and less addiction potential) [463]. Morphine dose equivalences with tramadol has not been reliably established. Codeine and tramadol may have a lower abuse risk than more potent opioids [460,464].

Opioid Recommendation:

A stepped approach to opioid selection should be based on a patient's clinical profile and individual characteristics and should proceed in a stepwise fashion. First line therapy for mild to moderate pain would include codeine or tramadol while second line therapy for mild to moderate pain could include morphine, oxycodone or hydromorphone. First line therapy for severe pain would include these same agents, morphine, oxycodone or hydromorphone while second and third line therapy for severe pain could include fentanyl and methodone respectively. It is important to determine the optimal dose, i.e., a dose that will improve function or reduce pain intensity by at least 30% without causing major adverse effects or complications. It is recommended to start the opioid trial with a low dose and increase the dose in small quantities over several days or weeks carefully monitoring for effectiveness (or plateauing of response) and adverse effects or complications. Opioids produce a graded analgesic response: the patient experiences the greatest benefits at lower doses and a plateauing of analgesic response and adverse effects at higher doses.

Recommendation Pain Treatment

BPS patients deserve to have their chronic pain treated. There are few well controlled long term pain therapy studies in this area, therefore most of our recommendations must come from studies in other non-cancer pain conditions. As discussed in the previous sections, management of symptoms of BPS, including the chronic pain must start with conservative therapies along with BPS condition-specific treatments. For those whose chronic pain is refractory to these therapies including standard analgesics, therapy for the chronic pain should normally start with a tricyclic and/or gabapentinoid (gabapentin or pregabalin), followed by addition of an opioid such as codeine, tramadol, morphine or oxycodone as a last resort. **Level of Evidence: 4 Recommendation: C**

XIII. SURGICAL THERAPY

Bladder Pain Syndrome (BPS) is a chronic and debilitating disease. Major surgical options should be considered only when all conservative treatment has failed (**Table 6**) The patient should be informed of all aspects of surgery and understand consequences and potential side effects of surgical intervention. An experienced surgeon familiar with the particular surgical technique should perform the procedure.

Table 6: surgical therapies rated according to the Oxford System

Surgical Therapies: ICI

Neurostimulation	B:1
Cysto Hydrodistention	C:3
Hunner's Directed Rx	C:3
Cystolysis	-A:3
Sympathetic Deinervation	-A: 4
Parasympathetic Deinervation	-A: 4
Augmentation Cystoplasty +/- partial cystectomy	C: 3
Diversion +/- cystectomy	C:3

1. HYDRODISTENTION

Bladder distension has been used for many years [465] not only as a diagnostic/ classification tool but also for treatment of BPS. In 1957 Franksson reported on a retrospective series of 33 patients, with symptom improvement in all, and lasting up to 1 year in 7 patients[466]. Reports from the seventies were contradictory. Using the Helmstein method [467] Dunn reported complete absence of symptoms in 16 of 25 patients[468], while Badenoch found no improvement in 44 of 56 patients[312]. More recent literature reports poor results with only a minority of patients reporting a small improvement in symptoms for a relatively short period of time[217,218,232,469]. Most studies are retrospective and uncontrolled.

Level of evidence 3; recommendation C

2. TRANSURETHRAL RESECTION

In his first papers Hunner described open resection of the bladder ulcer in the treatment of patients with IC[5]. He later abandoned this treatment due to operative morbidity and recurrence of symptoms. Results of transurethral resection were originally reported by Greenberg et al.[470] and Fall[471]. The retrospective results of this treatment in 116 patients with Hunner's lesion from Fall's Swedish clinic was later reported by Peeker et al.[472]. Hunner's lesion was first recognized by bladder distension under general anesthesia. All lesions were then resected including at least half of the underlying muscular coat. Large areas of the bladder might be treated to resect all diseased tissue. Ninety-two of the 116 patients experienced amelioration of their symptoms. Average duration of symptom alleviation was 23 months ranging from 0-180 months. Up to 16 reresections were performed if symptoms recurred. This is the only center having reported a large clinical series of patients with BPS treated in this manner. Shanberg and Malloy reported in 1987 on laser fulgeration of 39 patients with BPS[473]. Nineteen of 39 had Hunner's lesion. Of the 19 patients with Hunner's lesion 17 reported good pain relief lasting between 6 and 18 months. In the 20 patients without Hunner's lesion, reddened areas in the bladder were photocoagulated with the Neodynium:Yag laser. Thirteen felt marked improvement of symptoms but time to symptom recurrence was not reported. Small bowel perforation in 2 patients was the most important complication in this series. This series was extended to 76 patients [474] where 21 of 27 patients with Hunner's lesion (BPS ESSIC type 3X) experienced symptom improvement; 12 had relapse within 18 months. Of patients with BPS ESSIC type 1 or 2, 20 of 49 improved but 10 required further therapy within 1 year. Rofeim et al. [475] reported on Nd:YAG laser ablation of Hunner's lesion in 24 patients with BPS type 3X. All had symptom improvement within days without complications. Pain, urgency, nocturia, and frequency were improved after 23 months, but relapse in 11 patients required up to four additional treatments.

Payne et al. reported on 14 patients with Hunners lesion treated by cystoscopic ablation. Eight became symptom free and 4 improved symptomatically more than 50%. Four had symptomatic recurrence with improvement after repeat ablation[476]. Intravesical, submucosal injection of triamcinolone has in uncontrolled studies been reported to have as good symptomatic effect as resection/fulgeration[477].

Transurethral resection, coagulation, or laser ablation of Hunner's lesions is a recommended treatment for patients with BPS type 3X.

Level of Evidence: 3 Grade of Recommendation: C

3. CYSTOLYSIS – PERIPHERAL DENERVATION

Hunner [5] simply dissected bladder from surrounding tissue. Initial results were encouraging, however after 3 years of follow-up, symptoms reoccurred. Worth and Turner-Warwick [478] attempted to do more formal cystolysis and were more successful with regard to symptoms. Worth [479] followed patients up to 7 years and found bladder areflexia to be a significant complication of this procedure. Patients had to use Credé technique or even be on intermittent self-catheterisation. Albers & Geyer [480] reported symptom recurrence after 4 years in most of the patients.

- **Cystolysis – peripheral denervation is not indicated for BPS; Level of Evidence: 3 Grade of Recommendation: -A (not recommended)**

4. SYMPATHETIC DENERVATION

Visceral pain is transmitted in most cases by the sympathetic nervous system. Gino Pieri [481] applied this principle to the bladder pathology and suggested resection of the superior hypogastric plexus (presacral nerves), paravertebral sympathetic chain, and gray rami from S1-3 ganglia (Level 4). This was repeated by Douglass [482] a few years later . Immediate results were very good; however Nesbit [483] showed that the long term results were short lived.

- **Sympathetic denervation is not indicated for BPS**

Level of Evidence: 4 Grade of Recommendation: -A (not recommended)

5. PARASYMPATHETIC DENERVATION

Based on the contribution of S2-S4 segments to bladder innervation, Moulder and Meirowsky [484] used S3 neurectomy in 3 patients with good long term follow-up. Larger series were reported by Milner [485] and Mason[486] but results after five years were not encouraging. To improve results selective dorsal sacral root neurectomy, unilateral or bilateral, was introduced by Bohm and Franksson[487]. The outcomes of this procedure were unclear.

• Parasympathetic denervation is not indicated for BPS;

Level of Evidence: 4 Grade of Recommendation: -A (not recommended)

6. BOWEL SURGERY

a) Bladder augmentation-cystoplasty has been commonly used for refractory BPS for 50 years. First reports of ileocystoplasty from 1958 were very promising[488]. Later publications were less sanguine with good results varying from up to 100% [489,490] to 25%[312,491]. Cystoplasty is usually done with or without bladder resection.

Cystoplasty alone was reported as early as 1967 by Turner-Warwick and Ashken[492], advocating augmentation with removal of the diseased tissue. Several subsequent studies indicated that cystoplasty with subtrigonal cystectomy offers better results than without subtrigonal cystectomy[490,493-495]. These were all retrospective studies and conclusions should be taken with reservation. Cystoplasty with partial or total removal of the bladder requires bowel tissue substitution. Different bowel segments are used to enlarge the bladder. It is the general consensus that the intestine segment used for bladder augmentation should be detubularized[496]. Experiences with different bowel segments have been reported in numerous articles with level 4 evidence:

- Ileum [312,489,490,495,497-501]
- ileocecum [344,490,491,493,502,503]
- cecum [489,504]
- right colon [312,490,505]
- sigmoid colon [493,495,499,502]
- gastric segments [506,507]

There is no significant different between different bowel segments with regard to outcome except for gastric tissue substitution which is associated with dysuria and persistent pain due to production of acids.

b) Cystoplasty with Supratrigonal Resection (i.e. trigone-sparing) has been reported in various studies. Von Garrelts[489] described excellent results in eight of 13 patients with a follow-up of 12-72 months. Bruce et. al [495] reported satisfactory relief of BPS symptoms by ileocystoplasty and colocystoplasty in eight patients. Dounis and Gow [508] reported improvement in pain and frequency in seven BPS patients after supratrigonal cystectomy with ileocecal augmentation. Kontturi et. al [493] used segments of colon and sigmoid colon in 12 cases with 100% symptom-free outcome in five patients augmented with sigmoid colon over 4.7 years of follow-up. Two of seven cases augmented with colon required ileal conduit and cystectomy. Linn et. al [509] followed six BPS patients for 30 months, and reported that all were symptom-free and voided spontaneously. The report by Nielsen et. al [491] was less favorable. Six out of eight patients had good results. Van Ophoven et. al [510] reported the long-term (mean 5 years) results of orthotopic substitution enteroplasty in 18 women with BPS, using ileocecal (n = 10) or ileal (n = 8) segments with only two failures. In the group [511] augmented with ileum, three patients required self-catheterization and one a suprapubic catheter. Peeker et. al [512] found that patients with end-stage ulcerative BPS had excellent results following ileocystoplasty but not so the patients with non-ulcer disease. A follow up on this paper was recently published [180] with the same conclusion for the patients with end stage BPS ESSIC type 3C, while both continent diversion and iliocystoplasty were unrewarding in patients with type 2X BPS. Patients with low cystoscopic capacity (<200 ml) under general anaesthetic have achieved better results [7,25,513,514].

There is some weak evidence that cystoplasty with supratrigonal resection may benefit some selected patients with end stage ESSIC type 3C BPS.

Level of Evidence: Level 3; Grade of Recommendation: C

c) Cystoplasty with Subtrigonal Cystectomy — orthotopic continent bladder augmentation (i.e. with trigone removal but preservation of the bladder neck) in the management of BPS has been reported less often[511,515-517]. Because of the need of ureteral reimplantation, it is associated with some risks of urine leakage, urethral stricture and reflux[516]. Linn et. al [509] had three failures in 17 patients and half of the patients with good symptomatic response required self catheterization. Nielsen et. al [491] had better results following orthotopic substitution with low bladder capacity (200 mL versus 525 mL, respectively). Orthotopic continent bladder augmentation, particularly when removing the trigone, may cause incomplete voiding requiring intermittent self-catheterization. Therefore patients considering such procedures should be advised accordingly and must be considered capable of performing, accepting and tolerating self catheterization. Nurse suggested that the decision on whether to due a subtrigonal or supratrigonal cystectomy be based on the results of trigonal biopsy, with the former procedure indicated in the patient with trigonal inflammation[518].

There is no compelling evidence that subtrigonal cystectomy with cystoplasty has any outcome advantage over supratrigonal cystectomy but it tends to be associated with more complications and poorer functional bladder rehabilitation. Level of evidence: 3; Grade of Recommendation: C

7. URINARY DIVERSION WITH OR WITHOUT TOTAL CYSTECTOMY AND URETHRECTOMY

This is the ultimate, final and most invasive option. It should be used as a last therapeutic resort in selected

patients. Techniques include simple or continent urinary diversion. Continent diversion may be preferable for cosmetic reasons in younger patients.

Simple urinary diversion with formation of an ileal conduit is the most common surgical treatment for BPS [519]. Initially, diversion can be done without cystectomy and only when bladder pain is persistent, cystectomy may be considered. Bladder defunctionalization alone produced symptom-relief in several reports. [7,25,312,520,521]

Often diversion is performed as a next step after unsuccessful bladder augmentation. To avoid further bowel resection, a bowel segment used for cystoplasty can often be converted to a conduit[522] In some patients chronic inflammatory changes have been seen in the cystoplasty pouch resembling interstitial cystitis[7,312,523,524], preventing one from using this technique. Similar bowel changes however have been described when cystoplasty is performed for pathology other than interstitial cystitis, suggesting that these pathologic findings are not a direct result of the exposure of bowel to BPB urine [525]. Relatively good responses to diversion without cystectomy have been reported in small series. [491,526]

Urinary diversion with and without cystectomy may be the ultimate option for refractory patients. Continent diversion may have better cosmetic and life style outcome but recurrence of pain in the pouch is a real possibility. Level of Evidence: 3; Grade of Recommendation: C

XIV. CLINICAL SYMPTOM SCALES

Symptom scales have enabled patients to be categorized by symptom severity and have also served to follow results of treatment in patients with bladder pain syndrome. Their future development may enable a presumptive diagnosis of the syndrome but at this time that is not possible. A brief survey that reliably segregates BPS from other urologic disorders would make the ability to diagnose the syndrome reliable, inexpensive, and available to all healthcare providers. It would aid in epidemiologic studies as well. Currently such work sponsored by NIDDK is ongoing. www.mappnetwork.org

A process for development of a case definition for BPS has been developed by adapting the RAND/University of California, Los Angeles Appropriateness Method.[46] This involves a panel consisting of nine experts with experience in BPS and related diseases, literature review of case definitions of BPS, initial ratings of symptoms as indicators of the BPS diagnosis, and discussion and a second set of ratings to establish criteria for diagnosis through patient reports. Symptom questionnaire development, based on the results of the case definition exercise, and validation have been successful in establishing a population-based estimate for disease prevalence using both high specificity and high sensitivity models.[69] If this could be adapted for use in screening by primary care physicians, the potential benefits in early diagnosis of BPS are evident.

Questionnaires and symptom scales are currently utilized to measure treatment outcome and are especially valuable in clinical research studies as well as for guiding therapy for individual patients.

There are 3 published BPS symptom questionnaires: the University of Wisconsin IC Scale (**Figure 11**), the O'Leary-Sant IC Symptom Index (ICSI) and IC Problem Index (ICPI) (**Figure 12**), and the Pelvic Pain and Urgency/Frequency (PUF) Scale (**Figure 13**).

The University of Wisconsin IC Scale includes 7 BPS symptom items and has not been validated for identification or diagnosis of BPS. It captures severity of symptom expression [527,528]. Unlike the other two instruments, it addresses some quality-of-life issues, and this is an advantage when such issues are subject of investigation. Its most attractive aspects are its clinically apparent face validity and its ease of implementation.

The O'Leary-Sant indexes are validated questionnaires that were originally developed by focus groups, subjected to test-retest reliability analysis, and validated by administration to BPS patients and asymptomatic controls[529,530]. The questionnaires center on 3 questions related to urgency/frequency and one on bladder-associated pain. It does not address generalized pelvic pain or symptomatology associated with sexual activity. This is not because these questions were not considered in the formulation of the questionnaire. Of 73 questions in the preliminary instrument covering domains of urinary symptoms, pain, sexual function, menstrual variability, and general health, only the four questions now in the instrument were needed to reliably and validly describe the illness experience of those with IC and distinguish these patients from those without the disorder[531].

The Pelvic Pain, Urgency, Frequency (PUF) questionnaire[201] was specifically designed to include questions that directly reflect a wide variety of the symptoms experienced by patients who are affected by this disorder. One-third of the questions address pelvic pain, including pain anywhere in the pelvis: the vagina, labia, lower abdomen, urethra, perineum, testes, penis, or scrotum.

The PUF is marred by the fact that patients were not included in its development. If used to monitor outcomes, question 4 regarding sexual activity may worsen the score as the outcome improves. These and other problems make its use highly dubious.[532]

A large study utilizing the PUF questionnaire has concluded that up to 23% of American females have BPS[201]. This makes one wary as to the utility and

face-validity of the PUF[533]. A total score of 10-14 =74% likelihood of positive potassium test (PST); 15-19=76%; 20+=91%. To the extent that the PST is suspect, the reliability of PUF data comes into question.

Neither the PUF nor O'Leary Sant questionnaires have been shown to be of value in diagnosis of the individual patient[534]. In an interesting epidemiologic study in Finland, Leppilahti and colleagues randomly selected 2000 participants from the Finnish population registry and administered the O'Leary Sant IC symptom and problem index[64]. Women with symptom scores 7 or higher with no history of urinary tract infection in the preceding month were invited to undergo clinical examination. Of these 32 women, 21 underwent examination of whom 3 had probable interstitial cystitis and 4 had possible interstitial cystitis. Based on this specificity, a population prevalence in Finnish women of 230/100,000 probable interstitial cystitis and 530/100,000 possible interstitial cystitis was calculated. Thus, one can get some idea as to O'Leary Sant specificity. For probable BPS it would be about 14% using a parameter of 7 or greater on the symptom index.

The O'Leary-Sant and University of Wisconsin instrument correlate strongly in a large population of patients with BPS.[535] Clemons and co-workers administered the ICSI to 45 patients scheduled to undergo laparoscopy for pelvic pain. Seventeen were diagnosed with BPS based on the finding of glomerulations on bladder distention associated with urgency, frequency, or nocturia. A score of 5 on the ICSI had a 94% sensitivity and a 93% negative predictive value in this enriched population of patients with pelvic pain[536]. However, Clemens and colleagues have found a high degree of overlap in International Prostate Symptom Scores, the O'Leary Sant Symptom Index, and the Chronic Prostatitis Symptom Index in a random sample of over 1400 men and women with urologic symptoms, underscoring that we should be cautious in using these questionnaires as a basis for diagnosis in epidemiologic studies[537].

Rosenberg and Hazzard[62] surveyed 1218 consecutive patients presenting to their primary care office and found 7 (0.6%) who had a 7 ICSI score. Likely BPS was noted in 12.6% of patients on the PUF scale, a **Figure 21** times higher, suggesting that either the PUF drastically overestimates BPS, or the ICSI lacks sensitivity. Based on the correlation of the potassium sensitivity test and the PUF questionnaire, Parsons[49] stated that 30.6% of 3'rd year female medical students at his California institution had probable BPS. Sahinkanat and co-workers[202] in Turkey administered the PUF questionnaire to all 442 female textile workers in two local factories. Eighty-six per cent of those with a PUF score 7 or greater had an 86% positive rate of PST testing verses 9% positive in the group with PUF less than 7. They extrapolated that bladder epithelial permeability dysfunction was present in 32.8% of these unselected women. The ICSI estimate seems much more in line with current epidemiologic data.

While perhaps not ideally suited for epidemiologic studies, these questionnaires can reveal important

Interstitial Cystitis Symptoms Index During the past month:

How often have you felt the strong need to urinate with little or no warning:
0. __ Not at all
1. __ Less than 1 time in 5
2. __ Less than half the time
3. __ About half the time
4. __ More than half the time
5. __ Almost always

Have you had to urinate less than 2 hours after you finished urinating?
0. __ Not at all
1. __ Less than 1 time in 5
2. __ Less than half the time
3. __ About half the time
4. __ More than half the time
5. __ Almost always

Interstitial Cystitis Symptoms Index During the past month:

How often did you most typically get up at night to urinate?
0. __ Not at all
1. __ Once per night
2. __ 2 times per night
3. __ 3 times per night
4. __ 4 times per night
5. __ 5 or more times per night

Have you experienced pain or burning in your bladder?
0. __ Not at all
1. __ A few times
2. __ Fairly often
3. __ Usually
4. __ Almost always

Figure 13: Pelvic Pain, Urgency, Frequency Scale

epidemiologic data. Porru and colleagues[538] compared University of Wisconsin scores including both urinary and non-urinary symptoms, for 30 BPS female patients and 30 female controls. While the IC group had significantly higher scores for the urinary symptoms, they did not appear to indiscriminately report higher scores than controls for different somatic and general complaints, as might be expected if this disease is a manifestation of a more generalized disorder. Diggs and colleagues[539] used the ICSI to investigate how interstitial cystitis patients interpret urgency. The ICSI question regarding: "the strong need to urinate with little or no warning" consistently underestimated the response to the International Continence Society definition of urgency: "the compelling urge to urinate that is difficult to postpone.

Treatment outcome studies have also used the Global Response Assessment (**Figure 14**); a balanced patient self-report on overall response to therapy, developed for NIDDK sponsored multicenter therapeutic trials[301]. The O'Leary Sant and University of Wisconsin questionnaires are responsive to change over time in patients with BPS and have been recommended as secondary endpoints in future clinical trials of the disorder. Propert and colleagues in the Interstitial Cystitis Clinical Trials Group determined that a 1.2 point change in the O'Leary Sant indexes and a 3.1 point change in Wisconsin IC inventory corresponded to a one-category change in the GRA. Individual symptoms were also responsive [540].

A self-report measure that reliably identifies moderate to severe bladder pain syndrome patients for inclusion into clinical trials was recently reported by Pfizer Inc. [532]. Whether it will have value in diagnosis of the syndrome or following patients' clinical course remains to be seen. A quality of life scale for women with BPS has also been developed for use in clinical trials and reportedly can be used to examine the effects of psychosocial and treatment interventions on quality of life.[541]

Conclusions

The three commonly employed clinical symptom scales include the O'Leary Sant, the University of Wisconsin, and the Pelvic Pain, Urgency, Frequency scales. None of the questionnaires have the sensitivity or specificity to be used in the clinical diagnosis of patients. The O'Leary Sant and University of Wisconsin indexes have been validated as reliable instruments for following the course of the disease and results of treatment interventions. All have shown some value in assessing the severity of disease. The Global Response Assessment has become one of several primary endpoints used in judging the response to specific therapies.

XV. OUTCOME ASSESSMENT

1. THE PROBLEM

BPS/IC has been a difficult condition for which to assess therapeutic impact. There is a 50% inci-

-3:	Markedly worse
-2:	Moderately worse
-1:	Slightly worse
0:	No change
+1:	Slightly improved
+2:	Moderately improved
+3:	Markedly improved

Figure 14: Global Response Assessment (GRA)

dence of temporary remission unrelated to therapy, with a mean duration of 8 months [52]. A somewhat surprising finding from the Interstitial Cystitis Database was that although there was initial improvement in symptoms partially due to regression to the mean[542] and the intervention effect, there was no evidence of a long-term change in average symptom severity over the four year course of follow-up[98]. In a chronic, devastating condition with primarily subjective symptomatology, no known cause, and no cure, patients are desperate and often seem to respond to any new therapy. A skeptical view of outcomes is essential (**Figure 15**), as patients can be victims of unorthodox health care providers using unproven forms of therapy, some medical, some homeopathic, and some even surgical.

2. THE PLACEBO ISSUE

Where possible, the results of randomized controlled studies should be used for decision making. Placebo, double-blind studies are optimal in this disorder for which there is no generally effective standard therapy.

Placebo effects influence patient outcomes after any treatment which the clinician and patients believe is effective, including surgery. Placebo effects plus disease natural history and regression to the mean can result in high rates of good outcomes, which may be misattributed to specific treatment effects.[98,543-545] Unfortunately, few BPS treatments have been subjected to a placebo-controlled trial. This is not to say that what seems effective is not, but rather that a high index of skepticism is healthy, even in treatments tested in controlled trials.[546]

While in many diseases an argument can be made against using a true placebo control as opposed to an orthodox treatment of approved or accepted value[547], a good case for true placebo comparison can readily be made for BPS. The vagaries of the natural history, the general lack of progression of symptom severity over time, and the fact that it is not life threatening, mean that there is little to lose and much to gain by subjecting new treatments to the vigorous scrutiny of placebo control. Many patients who volunteer for such trials have already run the gamut of accepted (though generally unproved) therapies. It has long been recognized in protocols that use subjective criteria for assessment that “improvement” may be expected in up to 35% of placebo-treated patients[548]. As the spontaneous remission rate (though temporary) for BPS is 11%[311] to 50%[52], combined with the placebo improvement it can be difficult to prove efficacy.

Even in placebo controlled trials, it is reasonable to surmise that some degree of unblinding may occur as a result of somatic or psychological side effects of the active arm, impairing the validity of the trial results and giving the active arm a slight edge over placebo.[549,550] Failure to recognize unblinding can easily bias results of a study and has not been routinely measured in clinical trials.[551] When occurring late in a study after one would expect onset of a therapeutic effect, unblinding could be the result of side effect profile or drug efficacy. Early in the trial it reflects poor placebo or study design. The degree of blinding needs to be ascertained throughout the trial. This is of specific concern in BPS and any disorder where primary outcomes may be subject to patient-specific psychological and physiological factors.

The ethics and necessity of placebo-controlled trials have been questioned, especially in situations in which an effective treatment exists and also where delay in treatment has been shown to result in disease progression[552-554]. However, there are methodological concerns with equivalence and non-inferiority active agent comparison trials[555]. These include an inability to determine if the treatments are equally good or equally bad, and the possibility that successive non-inferiority trials can lead to a gradual decrease in treatment efficacy. Although the use of placebo-controlled trials raises ethical concerns when proven effective treatment exists for the condition under investigation, they are ethically justified, provided that stringent criteria for protecting research subjects are satisfied [556].

The value of placebo-controlled trials is aptly illustrated by the recent decisions by pharmaceutical manufacturers not to pursue FDA approval in the United States for seemingly promising intravesical therapies for BPS[557,558] after placebo-controlled trials failed to establish efficacy. These include low concentration hyaluronic acid (Bioniche, Canada), high concentration hyaluronic acid (SKK, Tokyo), and resiniferatoxin (ICOS, Bothell, Washington, USA). Nalmefene, an initially promising oral therapy in the 1990’s,[559] also failed phase 3 trials (IVAX, Miami). Placebo trials are impractical in surgery and it can be difficult to evaluate surgical reports. The many older medications currently used off-label might not meet success if tested in the stringent manner in which new molecular entities are tested. The expense of testing therapies currently used off-label often requires dependence on the largesse of government agencies like the National Institute of Health [301,395,560].

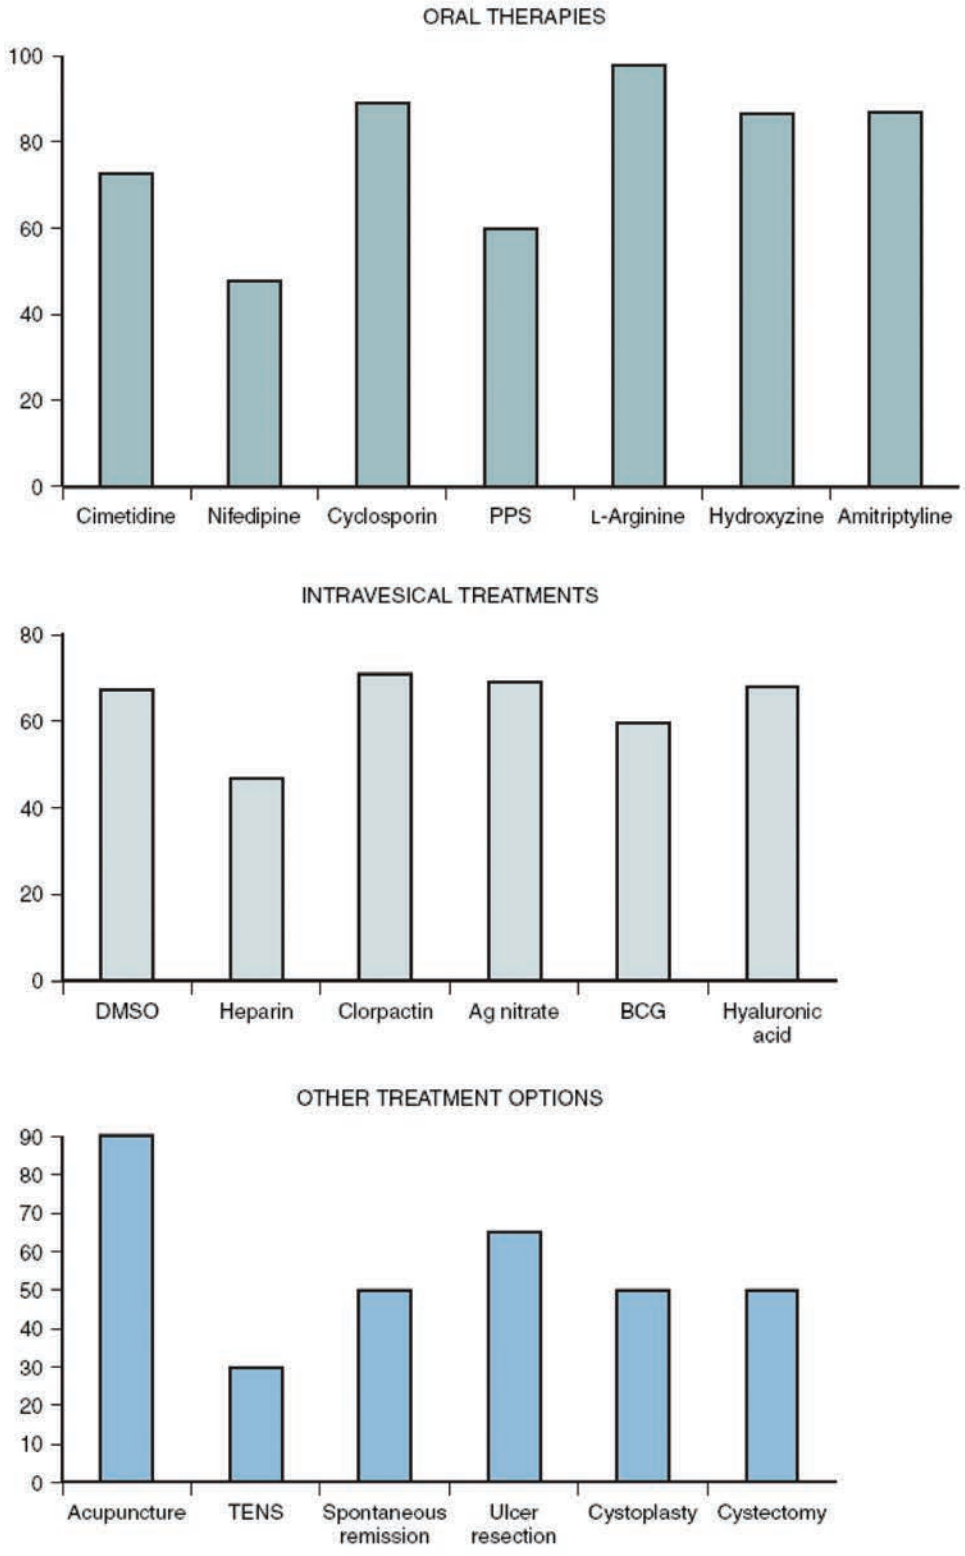

Figure 15: Selected reported treatment outcomes in uncontrolled studies in IC literature: Percentage of patients initially improved.

3. OUTCOME INTERPRETATION

As has been discussed with regard to rheumatologic disorders[561], the interpretation of measurements of physical functioning in clinical trials should consider the composition of the study sample, with attention to the stage of disease and the heterogeneity in disease duration. Patients with long-standing disease or compromised bladder capacity or central sensitization can be expected to be less responsive to treatments directed toward the bladder itself. Finally, when considering objective changes, the concept of statistical versus clinical significance is paramount. Investigators should, but rarely do, point out differences between statistical improvement and what they consider to be clinically significant improvement[562]. As Gertrude Stein reportedly stated, "A difference, to be a difference, must make a difference". An increase in bladder capacity of 30cc may be statistically significant but clinically irrelevant. Number needed to treat and number needed to harm data[563] may be particularly important in BPS and have not typically been included in efficacy analysis.

4. IMMPACT RECOMMENDATIONS

The core outcome domains for chronic pain clinical trials have been published.[423,564] The Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials (IMMPACT) recommendations indicate that core outcome domains should be considered in all clinical trials of the efficacy and effectiveness of treatments for chronic pain. These domains include:

1. Pain
2. Physical functioning
3. Emotional functioning
4. Participant ratings of improvement and satisfaction with treatment
5. Symptoms and adverse effects, participant disposition

CONCLUSIONS:

Currently for BPS/IC there are no accepted biologic disease markers that can be used for the assessment of response to therapy. The O'Leary Sant, University of Wisconsin, and Global Response Assessment are well-validated questionnaires to follow disease progression and response to therapy. The IMMPACT recommendations suggest that, as well as symptoms scores, any future study on a pain syndrome must involve more general assessments of psycho-physical functioning. There is limited experience in BPS/IC for the use of well-validated measures available for the study of chronic pain. Future NIDDK research initiatives may help to rectify this. http://www.mappnetwork.org

International recognition of an agreed upon definition and inclusion and exclusion criteria of BPS/IC will help future studies to fulfill the highest standards available, and placebo-controlled, double blind, randomized controlled trials, where possible, will provide the highest level of evidence to move the field forward.

LEVEL 2 GRADE C RECOMMENDATIONS

XVI. PRINCIPLES OF MANAGEMENT

The information currently available in the literature does not lend itself to easily formulating a diagnostic or treatment guideline. Different groups of "experts" would undoubtedly create different "best practices".[565] The compromise approach devised by an experienced cross-section of urologists and gynecologists from around the world at the International Consultation on Continence 2004 meeting in Monaco[41] and subsequently modified at the 2008 meeting in Paris[1] has been reviewed and updated by the committee and allows for significant latitude to reflect varying individual practice patterns and to account for patient preference.

An underlying principle is that, where possible, decisions on the treatment of bladder pain syndrome should be evidence based[566]. Unfortunately, high level evidence of efficacy is lacking for many common treatments, either because such studies have not been done, or were done and failed to demonstrate efficacy.[343,567,568]

Another principle is that we should be guided by patient perceived and driven outcomes for bladder pain syndrome, which is, after all, diagnosed on the basis of symptoms after exclusion of confusable diseases. Many patients prefer noninvasive therapies[569], and it would seem reasonable to start with physical therapy and/or oral therapies if conservative non-medical interventions (i.e. education, diet, behavioral modification, stress reduction) fail to result in significant symptom amelioration. Use of surgical therapies should be approached with some caution. It has been reported that women with BPS have had significantly more pelvic surgeries than controls, and the majority were performed prior to diagnosis of BPS, possibly for pain related to undiagnosed BPS.[570,571]

1. HARMONIZATION

With representatives from Asia, Europe, and North America, the Consultation has attempted to create a document that is harmonious with guidelines developed around the world in the last several years, many since the last meeting of the Consultation. The Canadian Urological Association[572], the International Society for the Study of Bladder Pain Syndrome (ESSIC)[2,15], the European Association of Urology[342], the Japanese Urological Association[45], East Asian countries[11], and the American Urological Association[12] all have published

consensus guidelines, many of which have been reviewed in a recent publication[565].

In the Japanese and Asian view, urinary frequency/urgency is the primary symptom, with overactive bladder (OAB) and hypersensitive bladder (HSB) listed as subgroups (with painful bladder syndrome (PBS) as its extreme form)[44]. (**Figure 3**)

In the European view as reflected in European Association of Urology and ESSIC guidelines, pain is the key symptom, with frequency being secondary to pain, while urgency basically represents a different pathology. American and Canadian guidelines are concordant with the European view. They emphasize pain, pressure, and discomfort perceived by the patient to be related to the bladder and associated with urinary frequency or urgency.

Pathologic afferent activity is a feature in overactive bladder as well as BPS, making the philosophy of the Asian guidelines conceptually attractive. But the knowledge gaps on lower urinary tract sensory functions are tremendous and from a neurophysiologic point of view it may be premature to link the conditions.

As a disorder based on symptoms, it is remarkable that we do not know if sensations described by the patient as pain, urge, or pressure are physiologically different or identical, if they represent various grades of the same pathology, or if this set of terms merely represents linguistically different ways of presenting the same problem. Do cultural differences play a part? Are Asian patients more reluctant to use the word pain to describe the same symptoms?

Cystoscopic and pathologic findings have a more important role in Asia and Europe than in North America, but nowhere do guidelines now recommend invasive procedures like endoscopy with or without biopsy as essential to make a diagnosis of BPS.

The latest algorithms from the European Association of Urology, American Urological Association, and East Asian nations are presented below and illustrate different approaches to a difficult problem. (**Figures 16, 17, 18)** Opportunities for future harmonization are apparent.

XVII. RECOMMENDATIONS OF INTERNATIONAL CONSULTATION ON INCONTINENCE:

1.HISTORY / INITIAL ASSESSMENT

Men or women with ***an* unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than six weeks duration, in the absence of infection or other identifiable causes** should be evaluated for bladder pain syndrome[12] The initial assessment consists of a frequency/volume chart, focused physical exam, urinalysis, and urine culture. Cytology and cystoscopy are recommended if clinically indicated.

Patients with infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and/or hematuria are evaluated with appropriate imaging and endoscopic procedures, and only if findings are unable to explain the symptoms are they diagnosed with BPS.

2.INITIAL TREATMENT

Patient education and support, dietary manipulation, stress reduction, nonprescription analgesics, and pelvic floor relaxation techniques comprise the initial management of BPS. **It is important at every stage to address the patient's pain, and understand that at some point in the progression of treatment, referral to a pain specialty clinic may be desirable.** When the conservative approach fails, or symptoms are severe and conservative management unlikely to succeed, oral medication, physical therapy, and/or intravesical treatment can be prescribed.

3.SECONDARY ASSESSMENT

If oral or intravesical therapy fails, **or before beginning such therapy at the discretion of the clinician**, it is reasonable to consider further evaluation which can include urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anesthesia. Laparoscopy may be indicated if there is a suspicion of gynecologic disease. Findings of bladder overactivity suggest a trial of antimuscarinic therapy. Findings of a Hunner's lesion suggest therapy with transurethral fulguration or resection of the ulcer. Distention itself can have therapeutic benefit in up to one-third of patients, though benefits rarely persist for longer than a few months.

4.REFRACTORY BPS

Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive modalities. These might include neuromodulation, intradetrusor botulinum toxin, or cyclosporine. At any stage of the treatment algorithm, experimental pharmacologic protocols of promising new treatments are reasonable to consider if symptoms warrant and the risk-benefit ratio is acceptable.

The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urine stream. Augmentation (substitution) cystoplasty and urinary diversion with or without cystectomy have been used with good results in very well selected patients.

A treatment algorithm by the Consultation is presented in **Figure 19**.

Assessment	Treatment	
Urine culture	Grade A recommended	Standard: Hydroxyzine, Amitriptyline, Pentosanpolysulphate
Uroflowmetry		Limited data: antibiotics, cyclosporin A,
Cystoscopy with hydrodistension		Intravesical: PPS, DMSO,
Bladder biopsy	Grade B recommended	Oral: Cimetidine
Micturition diary		Intravesical: hyaluronic acid, chondroitin sulphate,
Pelvic floor muscle testing		Electromotive drug administration for intravesical drugs
Phenotyping		Sacral nerve stimulation, bladder training, physical therapy ,
ICSI score list		Psychological therapy
	Not recommended	Bacillus Calmette Guerin
		Intravesical Chlorpactin
	Other comments	Data on surgical treatment are largely variable.
		Coagulation and laser only for Hunner's lesions

Figure 16: European Association of Urology guidelines 2012/2013.

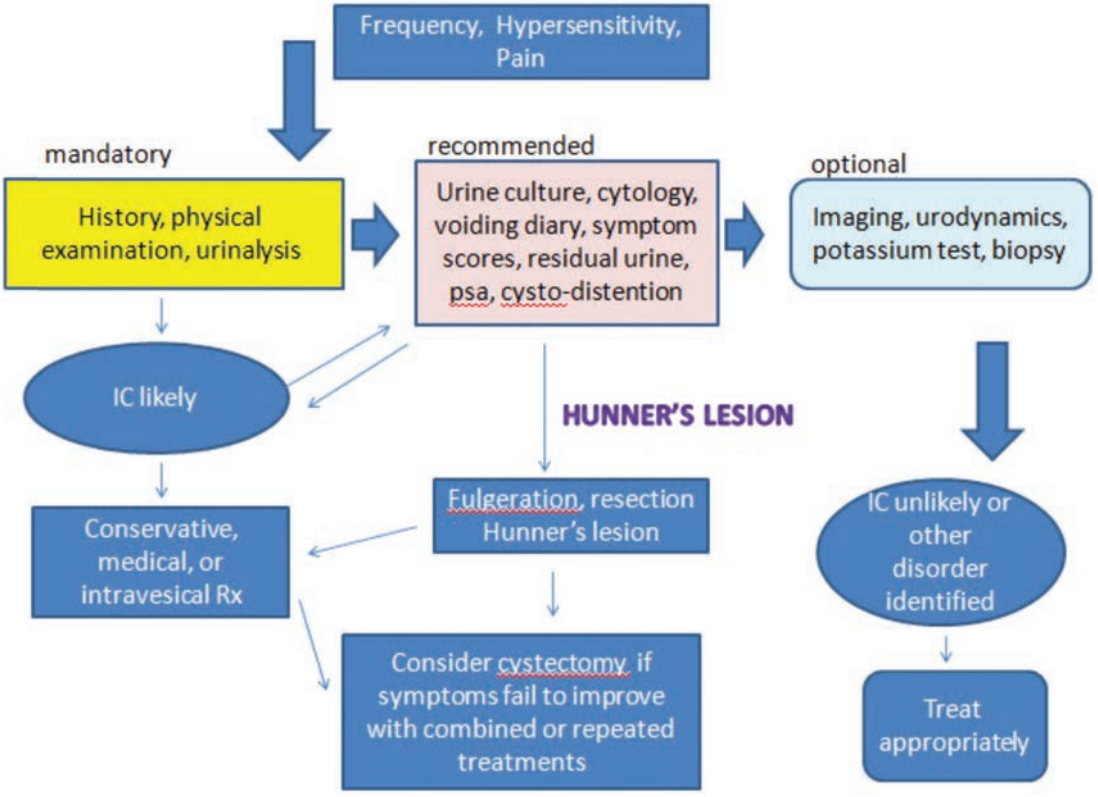

Figure 17: Management proposed by Japanese Urological Association and urologists in Taiwan and Korea, modified from Homma[573].

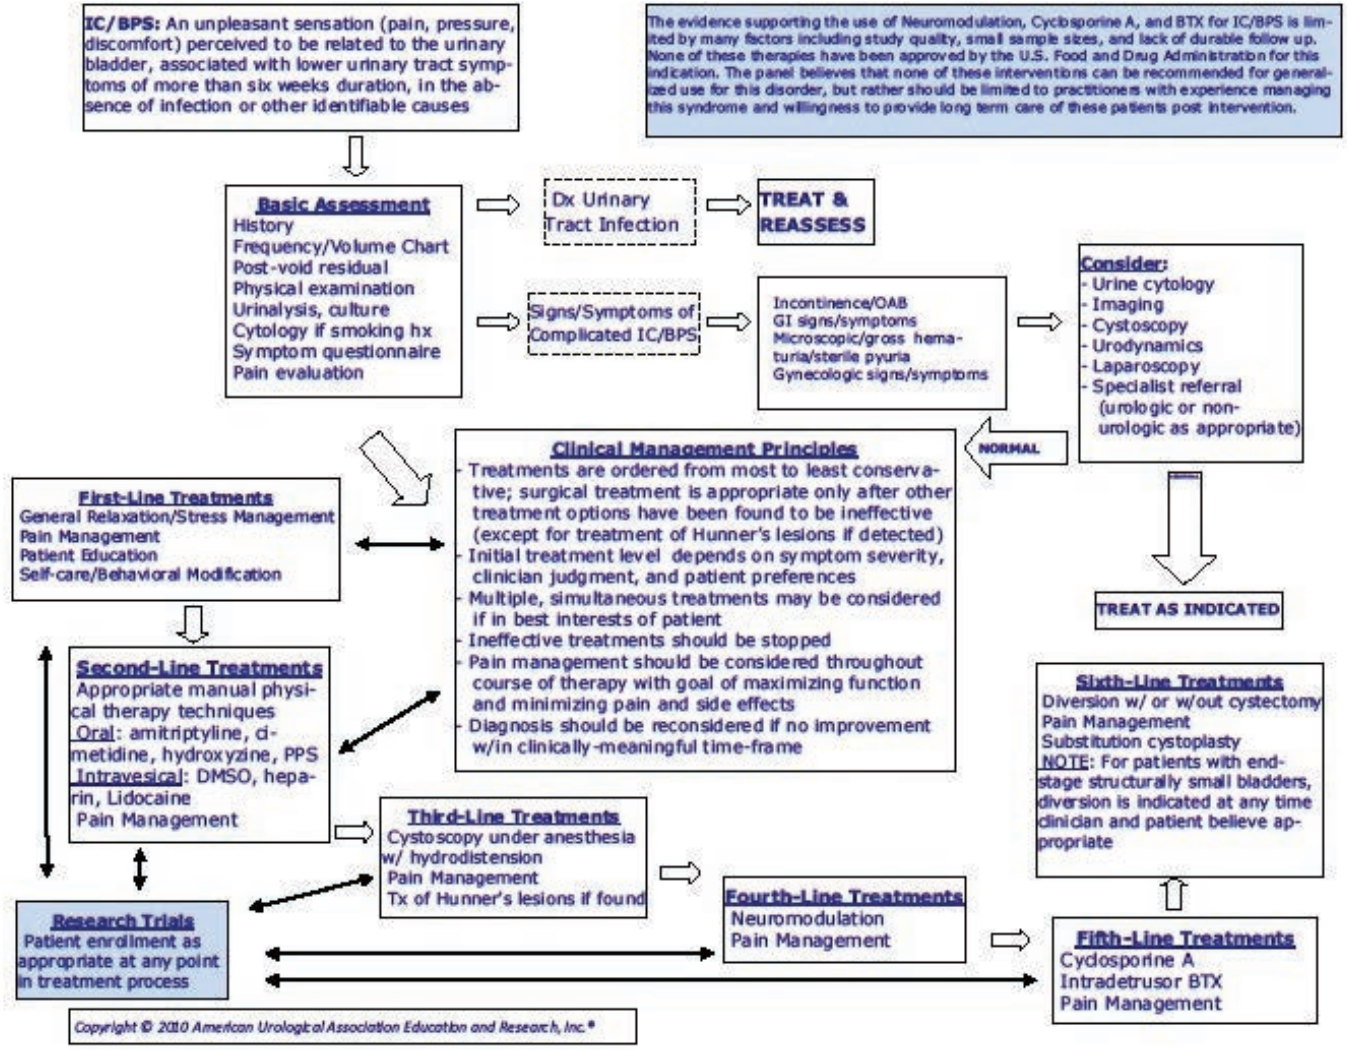

Figure 18: Management Guideline of American Urological Association[12].

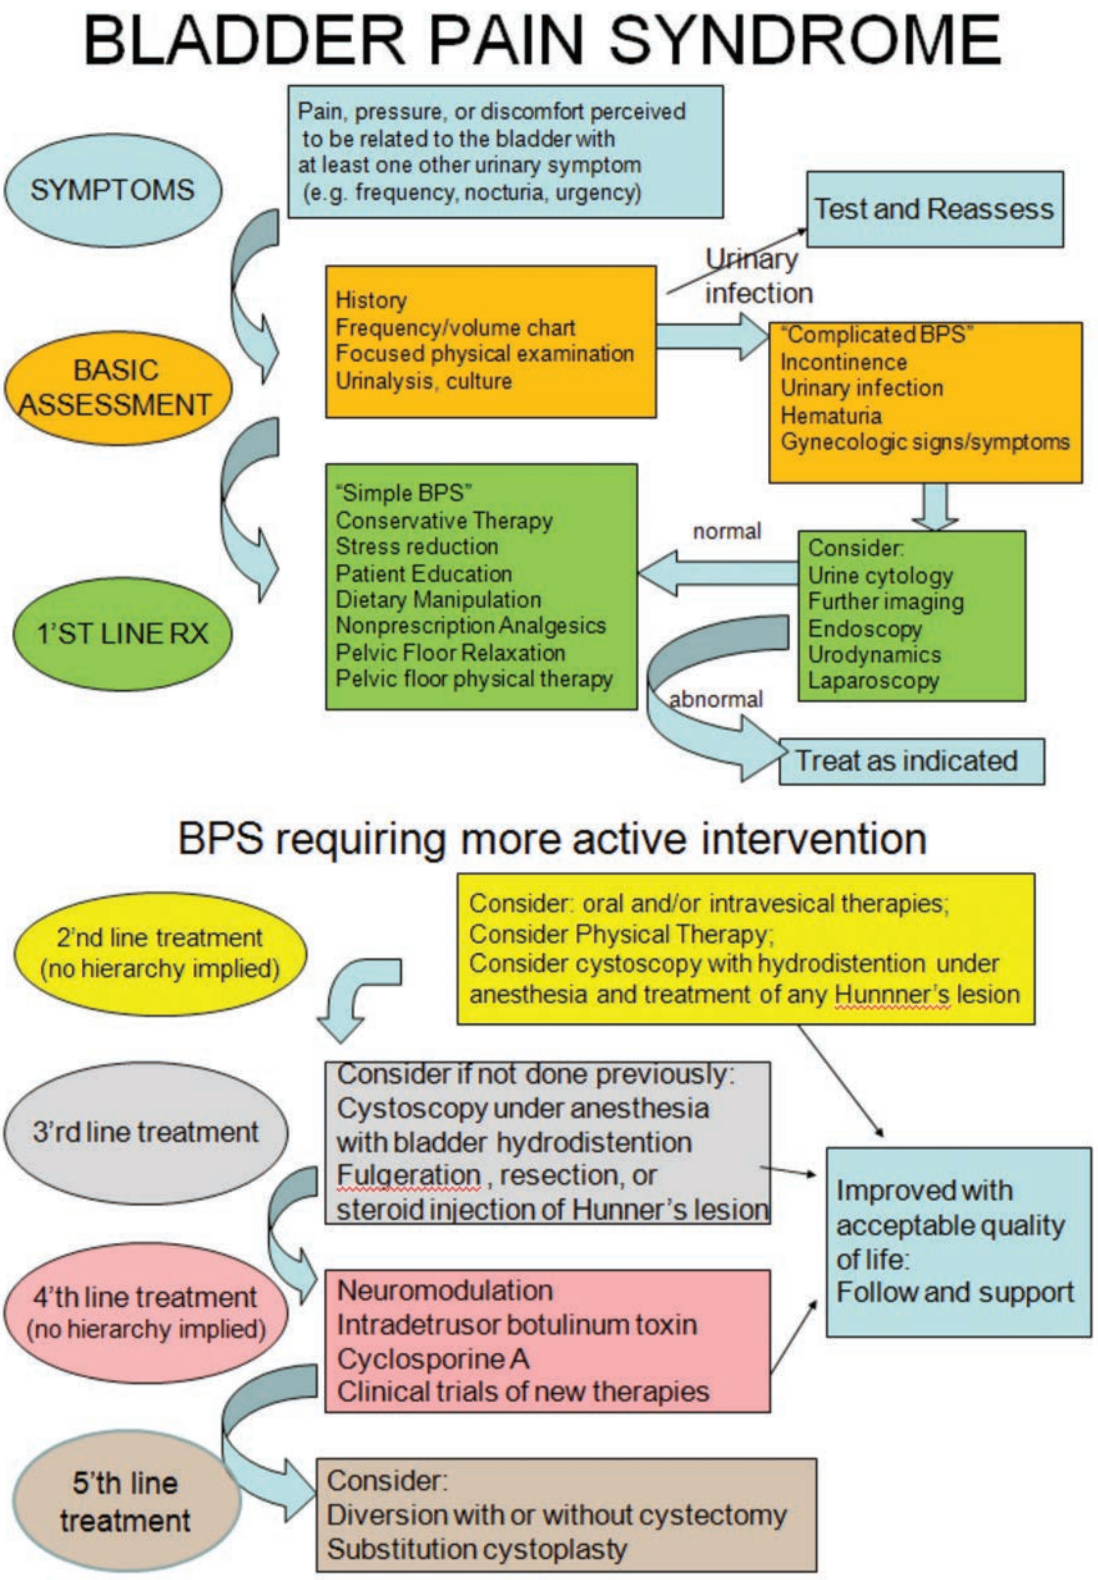

Figure 19: Algorithm for Diagnosis and Treatment: 2012 International Consultation on Incontinence.

It is the opinion of the committee that, because of the natural history of the disorder, it is best to cautiously progress through a variety of treatments. Whereas the shotgun approach, starting newly diagnosed patients on a variety of simultaneous medications, seems to have many adherents, employing one treatment at a time makes the natural history of the disease itself an ally in the treatment process. If a treatment has no efficacy, it should be stopped. It a treatment results in modest improvement, it should be continued and another treatment option employed in an attempt to further improve symptoms. The goal is to maximize quality of life and dispense with ineffective treatments in a somewhat controlled fashion. The patient and clinician must remember that "perfect is the enemy of good" and expectations should be realistic. One should encourage patients to maximize their activity and live as normal a life as possible, not becoming a prisoner of the condition. Although some activities or foods may aggravate symptoms, nothing has been shown to negatively affect the disease process itself. Therefore, patients should feel free to experiment and judge for themselves how to modify their lifestyle without the guilt that comes from feeling they have harmed themselves if symptoms flare. Dogmatic restriction and diet are to be avoided unless they are shown to improve symptoms in a particular patient.

Level 4 Grade C

XVIII. FUTURE DIRECTIONS IN RESEARCH

The committee believes that further research is needed in the following broad areas:

1. The recent American Urological Association guideline[12] points out numerous areas for which there was not enough information to allow an evidence basis for recommendations, and these areas require further study.
2. Pathology of BPS
3. Biomarker development
4. Immunology of BPS
5. Neurological aspects with particular attention to the relationship of BPS to overactive bladder
6. The relationship of bladder pain syndrome to chronic pelvic pain syndrome (nonbacterial prostatitis)

The majority of current treatments options are still targeting the bladder. However, as said in the AUA guideline, IC/BPS, which was originally considered to be a bladder disease, has now been recognized as a part of chronic pain syndromes. There is a growing body of literature demonstrating that different visceral pain syndromes, as well as pain syndromes in other body regions, and other systemic diseases often occur together in the same patient. Thus, the efforts to understand the pathophysiology and to design therapeutic modalities have recently shifted from an organ-based approach to a more global approach. Therefore, "phenotyping" of the disease conditions would be important to identify "bladder-related" and "non-bladder" (=outside the bladder) components that contribute to the symptoms for improving the treatment efficacy.

For this purpose, following issues require major research initiatives:

1. To improve symptom-based classification to identify the degree of bladder and non-bladder symptoms, for example, based on the responses to local treatment such as lidocaine intravesical application.
2. To identify bladder-specific pathology (urothelial changes, ulcer, hypervasculization, and the potential role of narrow band imaging[574], Neurometer[575] etc.
3. To identify bladder-specific biomarker (NGF or other neurotrophic factors, angiogenic growth factors, urothelial markers such as antiproliferative factor, cytokines/chemokines profile, uroplakin [antibody, splice variant]) .
4. To identify bladder-specific or systemic immunological process (cytokines/chemokines profile) Identification of these factors could also identify the difference in the disease process between IC/BPS and OAB (=LUTS with and without pain, respectively)

Finally, if we can identify the "bladder-related" and "non-bladder" (=outside the bladder) components that contribute to the symptoms, we should be able to develop the agent(s) to control bladder pain based on its pathology.

Major recommendations of the last Consultation for future directions in research on BPS still have pertinence today. They include:

A) Epidemiological study

i. Develop a reliable screening tool with adequate sensitivity and specificity to conduct epidemiologic research in the general population to study the incidence, prevalence and identify risk factors for the development of BPS.

ii. Establish patient data bases in different regions and conduct longitudinal follow up to understand the natural history of the disease and to examine the differences in disease natural history among regions.

B) Sub-grouping/phenotyping patients.

Patients who have or develop additional pain syndromes, such as vulvodynia, temporomandibular disorder, irritable bowel syndrome, fibromyalgia and

chronic fatigue syndrome, or autoimmune diseases such as lupus erythematosus and Sjögren's syndrome might have different pathophysiology, natural history and treatment response from those patients without co-morbidities. Sub-grouping patients not only allows us to develop better treatment strategy but also may answer the question: Is BPS an end-organ disease of the bladder or a systemic condition? [37,576] [87] However, to properly phenotype patients, it is necessary to develop an easy-to-use tool for non-specialists to identify those with co-morbidities. It is also important to validate the concept that categorizes all types of pelvic pain into one "chronic urological pelvic pain syndrome", as some patients' symptoms involve multiple pelvic organs, concurrently or sequentially along with other body systems.

C) Developing a simple, non-invasive diagnostic test for BPS.

This will most likely involve urinary markers. Urinary markers may help to sub-classify various types of BPS. This test will determine the diagnosis of BPS in the female population, as well as determine the subset of men currently diagnosed with non-bacterial chronic prostatitis/chronic pelvic pain syndrome who may actually have BPS.

D) Develop a practical multi-disciplinary care model.

In addition to physical morbidities (urinary frequency, pain), many BPS patients have associated psychological co-morbidities. [577] These can often be managed by psychological intervention. BPS patients also need help from dietitians and physiotherapists. A practical multi-disciplinary care model, which includes physicians, dietitians, physiotherapists, pain specialists, psychologists, psychiatrists and patient support groups, should be developed and tested in various settings.

XIX. SUMMARY

1. DEFINITION

Bladder Pain Syndrome (in the absence of a universally agreed definition, the European Society for the Study of Interstitial Cystitis –ESSIC definition is given along with the definition of the American Urological Association

ESSIC: *Chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent urge to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.*

American Urological Association Guideline Definition: *An unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than 6 weeks duration, in the absence of infection or other identifiable causes.*

2. BLADDER PAIN SYNDROME (BPS)

a) Nomenclature

The scientific committee of the International Consultation voted to use the term "bladder pain syndrome" for the disorder that has been commonly referred to as interstitial cystitis (IC). The term painful bladder syndrome was dropped from the lexicon. The term IC implies an inflammation within the wall of the urinary bladder, involving gaps or spaces in the bladder tissue. This does not accurately describe the majority of patients with this syndrome. Painful Bladder Syndrome, as defined by the International Continence Society, is too restrictive for the clinical syndrome.

Properly defined, the term Bladder Pain Syndrome appears to fit in well with the taxonomy of the International Association for the Study of Pain (IASP) (see below), and focuses on the actual symptom complex rather than what appears to be long-held misconception of the underlying pathology.

Bladder Pain Syndrome (XXIII-2) (per IASP)

Bladder pain syndrome is the occurrence of persistent or recurrent pain perceived in the urinary bladder region, accompanied by at least one other symptom, such as pain worsening with bladder filling and day-time and/or night-time urinary frequency. There is no proven infection or other obvious local pathology. Bladder pain syndrome is often associated with negative cognitive, behavioral, sexual, or emotional consequences as well as with symptoms suggestive of lower urinary tract and sexual dysfunction.

b) History / Initial Assessment

Males or females whose symptoms meet the requirements of the definition of bladder pain syndrome should be evaluated. The presence of commonly associated disorders including irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia in the presence of the cardinal symptoms of bladder pain syndrome also suggests the diagnosis. Abnormal gynecologic findings in women and well-characterized confusable diseases that may explain the symptoms must be ruled out.

The initial assessment consists of a frequency/volume chart, focused physical examination, urinalysis, and urine culture. Urine cytology, cystoscopy, and urodynamic evaluation are recommended if clinically indicated and/or the diagnosis is in doubt. Patients with urinary infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and microscopic or gross hematuria are evaluated with appropriate imaging and endoscopic procedures, and only if findings are unable to explain the symptoms, are they diagnosed with BPS. **Grade of recommendation: C**

c) Initial Treatment

- Patient education,
- dietary manipulation,

- nonprescription analgesics,
- stress reduction,
- pelvic floor relaxation techniques comprise the initial treatment of BPS. In the patient with findings suggesting pelvic floor dysfunction, pelvic floor physical therapy with myofascial trigger point release and intravaginal Thiele massage is often an effective therapeutic intervention. The treatment of pain needs to be addressed directly, and in some instances referral to an anesthesia/pain center can be an appropriate early step in conjunction with ongoing treatment of the syndrome.

When conservative therapy fails or symptoms are severe and conservative management is unlikely to succeed,

- oral medication or
- intravesical treatment can be prescribed. It is recommended to initiate a single form of therapy and observe results, adding other modalities or substituting other modalities as indicated by degree of response or lack of response to treatment. Grade of recommendation: C

d) Secondary Assessment

If initial oral or intravesical therapy fails, *or before beginning such therapy based on clinician judgment*, it is reasonable to consider **further evaluation** which can include Urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anesthesia.

- Findings of bladder overactivity suggest a trial of antimuscarinic therapy.
- The presence of a Hunner's lesion suggests therapy with transurethral resection, fulguration of the lesion, or direct steroid injection into the lesion.
- Distention itself can have therapeutic benefit in 30-50% of patients, though benefits rarely persist for longer than a few months. **Grade of recommendation: C**

e) Refractory BPS

Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive modalities. Many of these are best administered within the context of a clinical trial if possible. These may include

- neuromodulation,
- intradetrusor botulinum toxin,
- oral cyclosporine A, or
- clinical trials of newly described pharmacologic management techniques. At this point, most patients will benefit from the expertise of an anesthesia pain clinic.

The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urinary stream.

- Urinary diversion with or without cystectomy has been used as a last resort with good results in selected patients.
- Augmentation or substitution cystoplasty seems less effective and more prone to recurrence of chronic pain in small reported series.

Grade of recommendation: C

- Pain management is a primary consideration at every step of algorithm
- Patient enrollment in appropriate research trial is reasonable option at any point
- Evidence supporting neuromodulation, cyclosporine A, and botulinum toxin for BPS indication is limited. These interventions are appropriate only for practitioners with experience treating BPS and willing to provide long-term care post-intervention.

I. INTRODUCTION

Not all incontinence can be cured completely and even those who are ultimately successfully treated may have to live with incontinence for a time, for example, whilst they wait for surgery or for pelvic floor muscle training to yield its benefits. Still others – depending on their frailty, severity of incontinence and personal priorities – may not be candidates for treatment or may choose management over attempted cure. For all such people, the challenge is to discover how to deal with their incontinence so as to minimise its impact on their quality of life. This usually involves using some kind of continence product(s) to control or contain leakage of urine and / or faeces, and /or to manage urinary retention. In short, the possible role of continence products should be considered at each stage of patient assessment and treatment and, if treatment is not available, appropriate, acceptable or (fully) successful – subsequent management. Managing incontinence successfully with products is often referred to as contained incontinence, managed incontinence or social continence, in recognition of the substantial benefits it can bring to quality of life even though cure has not been achieved [1].

This chapter is aimed primarily at healthcare professionals seeking to make informed decisions as they choose – or help their patients to choose - between continence product categories and then select a specific product within their chosen category. We have also aimed to make this information accessible to the user, particularly in the summary and recommendation sections. The chapter includes a section for each of the major product categories, each section reviewing published data and – where possible - identifying evidence-based recommendations for product selection and use. Products designed to deal with skin and odour problems caused by incontinence are also addressed.

The sections on the major product categories are preceded by two others. The first provides overall guidelines for product selection, describing the key elements of patient assessment and suggesting a classification of people with incontinence into a number of broad groups based on gender, age (adult or child) and the nature and severity of their incontinence. A table is provided for each group summarising the user characteristics, priorities and contexts which commonly favour or discourage the use of each of the major product categories available to them. Following these overall guidelines and preceding the sections on the major product categories, a review is provided of the methodological challenges of conducting continence product evaluations and interpreting the results.

Much of the evidence base for product selection and effective use is patchy and so, where there is little published data to provide confident evidence-based advice on an issue commonly raised by patients and caregivers, an expert opinion is offered as the best advice available. The hope is that highlighting knowledge gaps in this way will help stimulate the research necessary to provide more robust evidence-based advice in the future.

To accompany this chapter, the International Consultation on Incontinence and the International Continence Society have collaborated to make the material more generally available via a new web site hosted by the International Continence Society at http://www.continenceproductadvisor.org/. The hope is that this will help people with incontinence and their caregivers to make informed choices in selecting appropriate products, and provide them with accessible, evidence-based advice on how to use them effectively.

The literature search strategy to identify material for this chapter additional to that reviewed for the third consultation [2] was conducted as follows. MEDLINE and CINAHL databases were searched from 2008 – 2011 for English language publications. Detailed search strategies were developed for each electronic database searched. Consideration was given to variations in terms used and spellings of terms in different countries so that studies were not missed. Relevant abstracts were examined and then pertinent articles were retrieved and reviewed, and the reference lists searched for further studies.

For product categories associated with little or no research literature, analysis relied on expert opinion from clinical practice papers.

The following main search terms were used: incontinence AND device*, toilet* AND facilities, female, male, urinal*, commode*, bedpan*, urin* AND sheath, condom AND catheter*, incontinence OR absorbent pad*, urinary AND catheter* (in title), urinary AND leg bag* OR legbag* OR drainage bag, faecal OR fecal AND incontinence AND plug OR pouch OR bag OR device, OR manage* system, incontinence OR perineal AND dermatitis OR inflammation OR skin damage.

II. OVERALL GUIDELINES FOR SELECTING CONTINENCE PRODUCTS

Selecting suitable continence products is critical for the well-being and quality of life of patients and carers. The ability to contain and conceal incontinence enables individuals to protect their public identity as a "continent person" and avoid the stigma associated with incontinence [3]. Failure to do so can result in limited social and professional opportunities, place relationships in jeopardy and detrimentally affect emotional and mental wellbeing [4]. The ability to contain and conceal incontinence enables carers to feel confident that the person(s) they care for will not be embarrassed publicly. It reduces the level of care required in relation to maintaining hygiene, skin care and laundry for the person who is dependent upon continence products [5].

Fortunately there is a diverse range of different products to choose from. However, without comprehensive and current information on the products available, this plethora of choice can be overwhelming and confusing [5]. Furthermore, the range of products actually accessible to users can vary enormously between and within countries, depending on the funding available, healthcare policy and the logistics of supply [5].

The choice of appropriate products for an individual with incontinence is influenced by the resources and care available and patient / carer preference, as well as assessment of specific client characteristics and needs [6] [7].

The stigma associated with incontinence means that another measure by which the success of products is judged is their ability to conceal the problem [8]. Such concealment may involve compromises: for example, in order to prevent leakage from a product, those with a larger capacity than strictly necessary may be preferred but this can in itself introduce issues to do with discretion when the product is worn. The intimate and stigmatised nature of incontinence means that issues relating to self-image can affect some patients' preferences. This may be especially marked in younger people for whom body-image may be particularly important and for whom disruption to normal social and interpersonal development may result in isolation or lack of access to normal experiences [9] [10].

1. PRODUCT CATEGORIES

The continence products considered in this chapter may be divided into those that are intended to assist with toileting and those to manage urinary retention and / or contain incontinence (urinary and / or faecal) (**Figure II-1**).

All toileting products can be useful for dealing with urine and / or faeces except for handheld urinals which are just for urine. Containment / control products are subdivided into three overlapping classes: those for urinary retention, urinary incontinence, and faecal incontinence. So, for example, someone with urinary retention is most likely to benefit from one of the products in the red ellipse, while someone with urinary incontinence will most likely benefit from one in the blue ellipse. A patient experiencing both problems will need two products (one from each ellipse) or one product from the intersection of the two ellipses.

2. IDENTIFYING THE NEEDS

The algorithms below (**Figures II-2 and II-3**) are designed to provide guidance for determining broadly which product(s) is likely to be of benefit to a particular patient. There are three main questions:

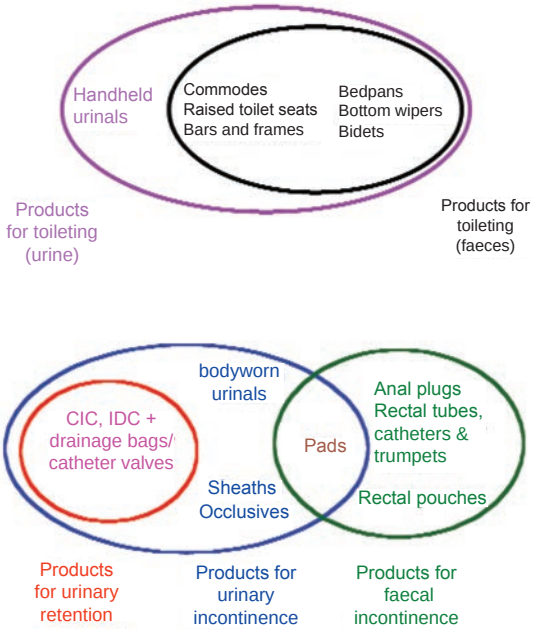

Figure II-1: Products for toileting (top) and for managing incontinence and / or urinary retention (bottom). CIC= Clean intermittent catheterisation; IDC= Indwelling catheter

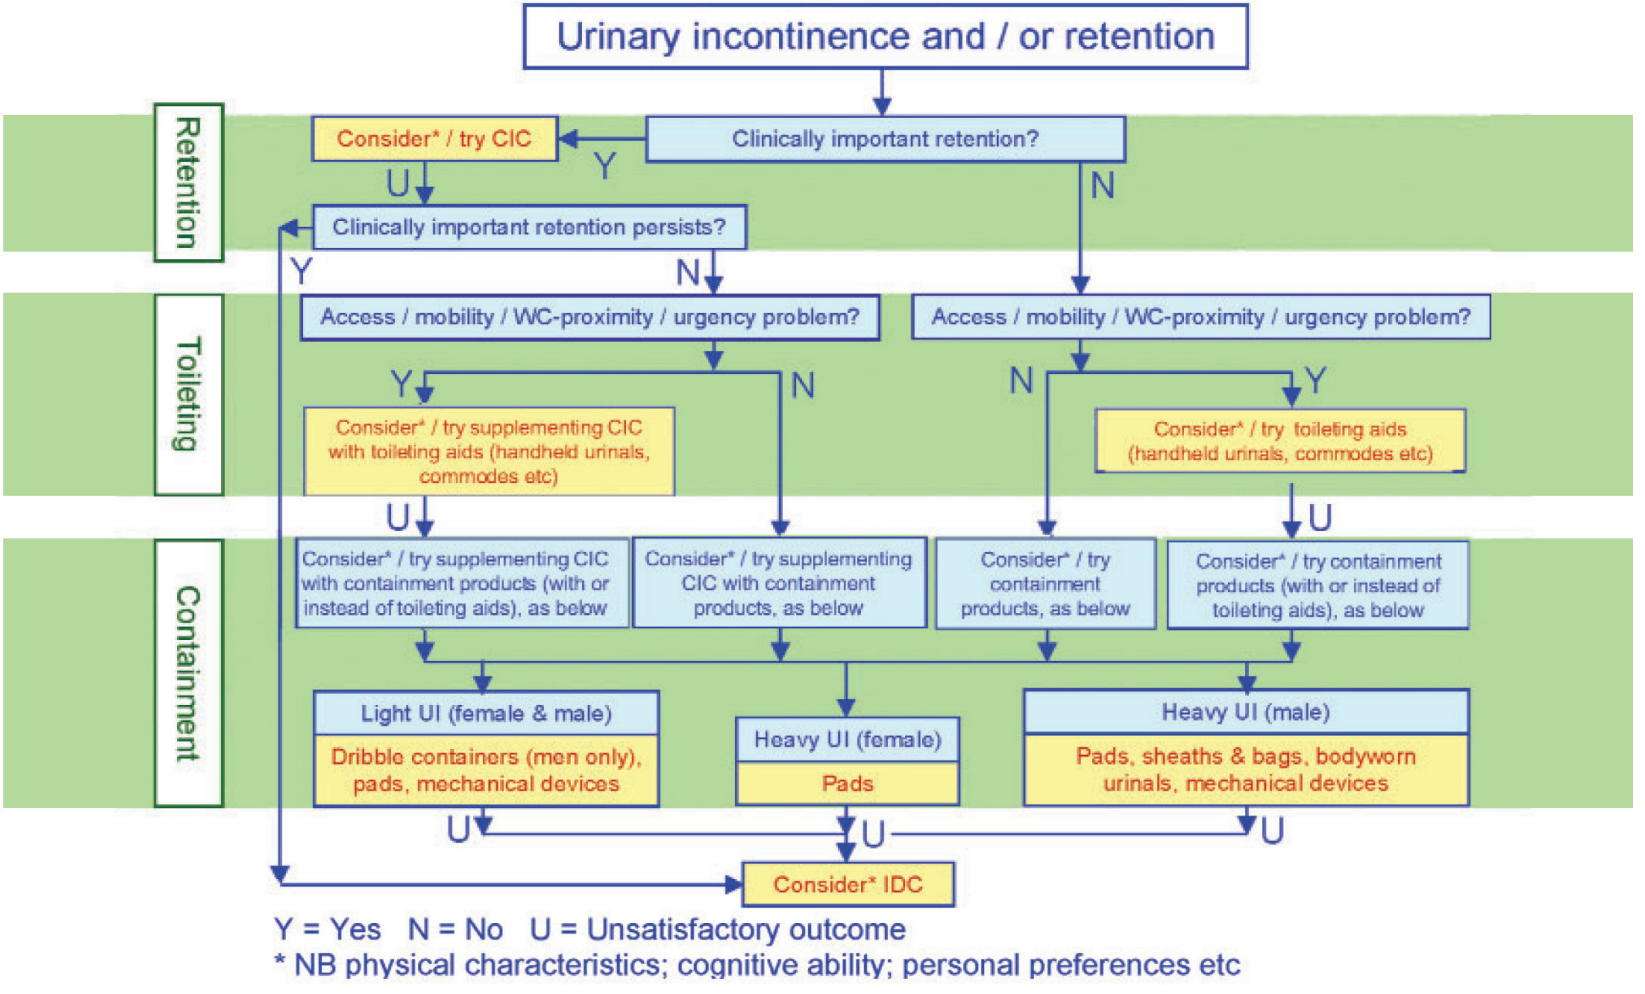

Figure II-2: Algorithm to help identify the category(s) of products most likely to help a patient with urinary incontinence and / or urinary retention. (Y = Yes; N = No; U = unsatisfactory ie considered and deemed unsuitable or tried and found not to work satisfactorily). * Consideration should be based on assessment of the patient's physical characteristics, cognitive ability and personal preferences, as well as the nature of their incontinence. (CIC = Clean intermittent catheterisation; IDC = Indwelling catheter).

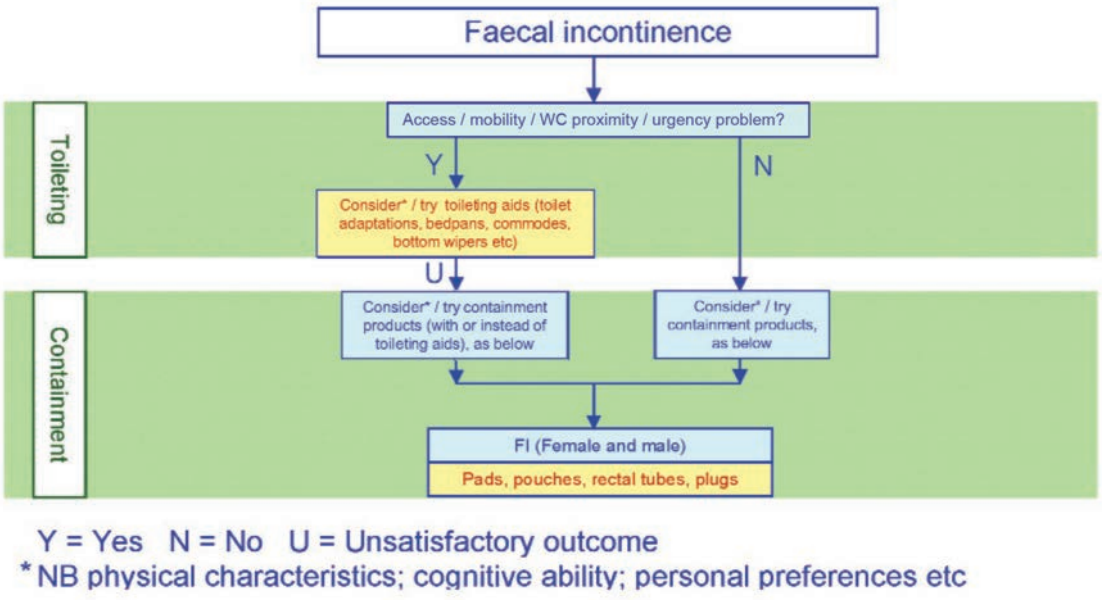

Figure II-3: Algorithm to help identify the category(s) of products most likely to help a patient with faecal incontinence. (Y = Yes; N = No; U = unsatisfactory ie considered and deemed inappropriate or tried and found not to work satisfactorily). * Consideration should be based on assessment of the patient's physical characteristics, cognitive ability and personal preferences, as well as the nature of their incontinence.

- Is there urinary retention (with or without incontinence)?
- Are there problems with toilet access (e.g. the proximity or design of the toilet; mobility or urgency problems for the patient)?
- Is there urinary incontinence or faecal incontinence or both?
- Answers to these questions will determine which one (or both) of the algorithms is most appropriate for an individual and help identify the category(s) of products most likely to help.

3. PATIENT ASSESSMENT FACTORS

A careful patient assessment is an important part of the process of product selection and **Table II-1** summarises the key elements to be considered.

The choice of appropriate products for an individual with incontinence is dependent upon the resources and care available. It must also be influenced by patient and carer preference as well as assessment of specific client characteristics and needs [6] [7].

Assessment of physical characteristics such as anthropometrics, level of independence, mobility and dexterity, mental acuity and the nature of the incontinence will determine which products may be appropriate. In addition to these factors, successful product choice and effective use involves other practical and psychosocial considerations. Product effectiveness depends upon the same factors as any assistive device intended to address a disability or impairment: patient participation in device selection [11] provision of adequate instructions for use [12] and the need for products to fulfil their function reliably and not be difficult to use [12] [9] [13].

While **Table II-1** provides general guidance on patient assessment relating to product selection, later sections in the chapter provide further discussion on assessment issues specifically related to the various product categories.

In addition to selection of appropriate and effective products following patient assessment, education and training of users or carers in the correct use of the devices is of importance if product use is to be optimal. This may be a simple matter of instruction in the effective fitting and changing of absorbent products, or may involve more in-depth training in the ongoing care of, for example, a suprapubic catheter.

Table II-1: Key elements of assessing a patient and his / her environment

Element	Rationale
Nature of the continence problem	The frequency, volume and flow rate of the incontinence influences product suitability.
Gender	Males may consider and prefer sheaths as a more masculine option to pads. Females may be attracted to products that are more feminine in design and presentation. Some 'unisex' products such as absorbent pads have different designs that work better for men (or women).
Physical characteristics	Anthropometrics (e.g. height and waist, thigh, penile circumference) will influence the comfort and effectiveness of a product.
Mental acuity	Mental impairment can affect the person's ability to manage the product. Products that resemble usual underwear (e.g. some absorbents) may be easiest to manage. Products which have health implications if used incorrectly (e.g. mechanical devices or catheter valves) should be avoided if mental impairment is likely to preclude correct and safe use.
Mobility	Impaired mobility may make some product choices impractical or require toilet or clothing modification to allow effective use of the product.
Dexterity	Problems with hand or finger movement can make it difficult to use some products (eg taps on leg bags, straps with buttons).
Eyesight	Impaired eyesight limits effective application and management of some products.
Leg abduction problems	Difficulty with abduction can make the use of some products impractical or ineffective.
Lifestyle and environments	Daily activities and environments can influence the choice of product and a mixture of products may provide optimum management. Different products may be most satisfactory for daytime and going out (when discreetness may be a priority) and night- time or staying in (when comfort may be a priority), for holidays (when laundry and / or large quantities of disposables may be a problem) or for use at work. The proximity and accessibility of a toilet in the various environments may be a key factor.
Independence / assistance	If a caregiver is required to apply or change the product then it may be important to involve them in the selection of the product and to establish their willingness and ability to use it.
Laundry facilities	Washable pads and bed linen may be very heavy when wet and take a long time to dry. It is important to check that the person doing the laundry has the ability and facilities to cope.
Disposal facilities	Ability to appropriately, safely and discreetly dispose of the selected products needs to be considered.
Storage facilities	Some products - notably, pads for heavy incontinence - can be bulky. Adequate space to store supplies between deliveries / purchases needs to be available.
Personal preferences	Different people like different products and where possible patients should be given a choice of products with which to experiment to determine the most satisfactory product.
Personal priorities	Everyone wants to avoid leakage but other factors such as discreetness may be more or less important to individuals.

Incontinence is often a long term condition and so monitoring and periodic reassessment is essential to maintain effective management with products.

4. MAIN USER GROUPS

Although needs, priorities and preferences vary between people with incontinence it is useful to divide patients into major user groups to help identify the category(s) of products most likely to benefit an individual. Seven primary groups are identified in this chapter:

- People with urinary retention.
- People who need help with toileting / toilet access.
- Females with light urinary incontinence.
- Males with light urinary incontinence.
- Females with moderate / heavy urinary incontinence.
- Males with moderate / heavy urinary incontinence.
- People with faecal incontinence.

An individual may belong to more than one group. Each group includes children and young people: the products available for them are broadly similar to those for adults.

5. CHOOSING BETWEEN PRODUCT CATEGORIES

- **Figures II-4 to II-9** summarise the user characteristics, priorities and contexts which favour or discourage the use of each of the categories of products available for six of the seven user groups identified in section II.4. Assistance with choosing appropriate products for the first group (people with urinary retention) is given in the section on catheters (**Table XII-1**) as all the product options for these people are in the same category (catheters).
- The recommendations given in these charts are based on the evidence presented in the sections of the chapter dedicated to different product categories and they are intended to help identify which product category (categories) are most likely to help an individual. However, it should be remembered that the same product will not suit all people, even if they have very similar assessment outcomes on the factors summarised in Table II-1. Different people prefer different products and where possible patients should be given access to a range with which to experiment to determine the most satisfactory product(s) for them. Similarly, the balance of priorities varies between users; for example, some pad users will opt for a bulky and, therefore, less discreet product to achieve an acceptably low risk of leakage while others will see the balance differently. It should also be noted that a mix of products from different categories may provide the best solution; for example, needs may vary between day / night and home / away. Once a product category of interest has been identified the corresponding chapter section should be consulted for further help.

6. SUMMARY

In conclusion, continence products can play an important role in enhancing the quality of life and reducing the stigma of incontinence of those who: are awaiting treatment; are waiting for treatment to take effect; elect not to pursue cure options; are unable to be fully cured and are living with an ongoing bladder / bowel problem.

7. RECOMMENDATIONS

- Incontinence should be actively managed with products to minimise the impact of incontinence on quality of life (**Grade of Recommendation C**).
- Patients should be carefully assessed (and reassessed periodically) to select the most appropriate products (**Grade of Recommendation C**).

III. PRODUCT EVALUATION METHODOLOGY

This section aims to assist those planning clinical trials of products. There have been relatively few large clinical trials of continence products (with the exception of urinary catheters) and for most product categories research evidence to guide the selection of individual products / designs / features is limited and in some cases absent.

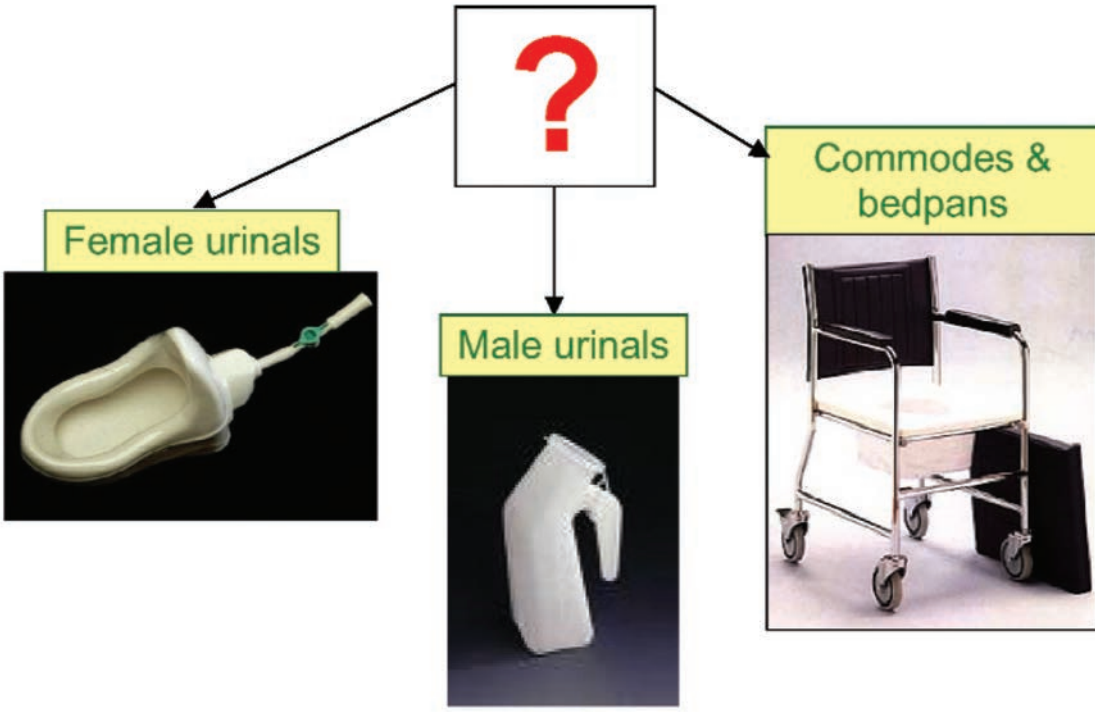
Measuring the performance of continence products is methodologically challenging. Manufacturers modify and change their products regularly - in terms of both materials and designs - and this limits the long-term validity of research results. There are also complex issues regarding research questions, study design, product representation, blinding and sample size [14] which are discussed below.

It is common for practitioners to be asked (by their employers or by companies) to do a small evaluation or trial – sometimes to 'test out' a new product and sometimes to help choose between competing brands for bulk-buying. Such trials should be approached with caution; they can be very demanding but their results may be of very limited value, even for local use. The methodological challenges identified below still apply but are compounded by small sample size and restricted product selection. These studies are likely to be helpful only for identifying gross product short-comings or benefits.

1. RESEARCH QUESTIONS

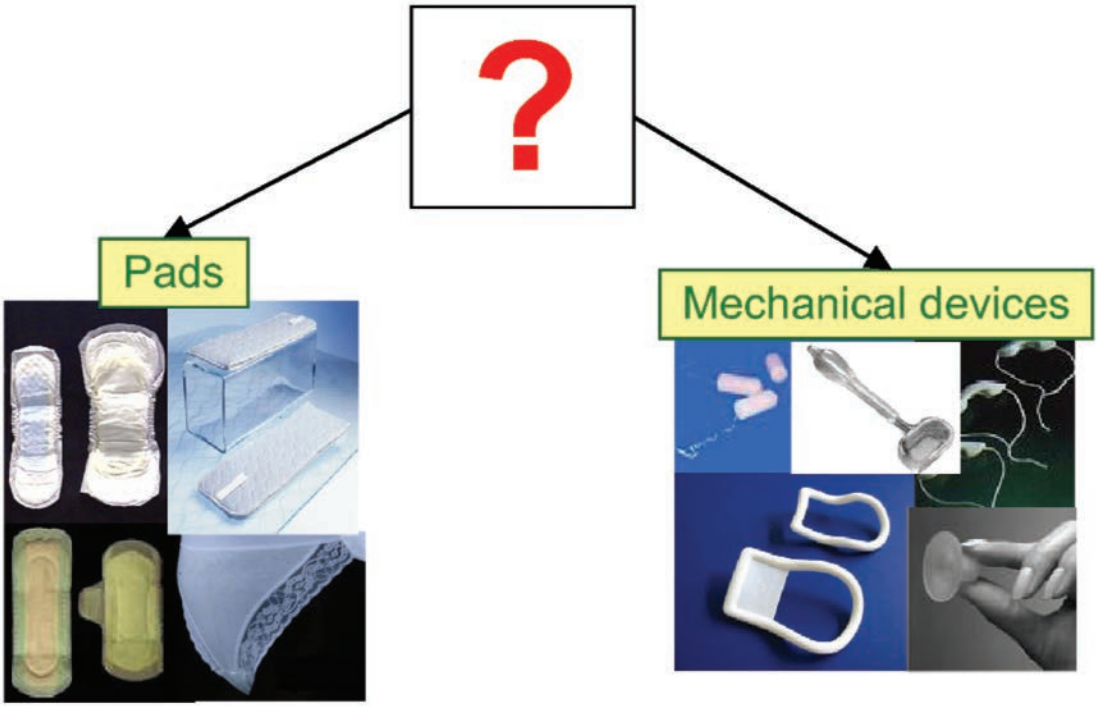
a) Comparisons

Part of the complexity of product evaluations stems from the sheer number and type of products available, meaning that many different comparisons could be made. **Table III-1** illustrates the problem



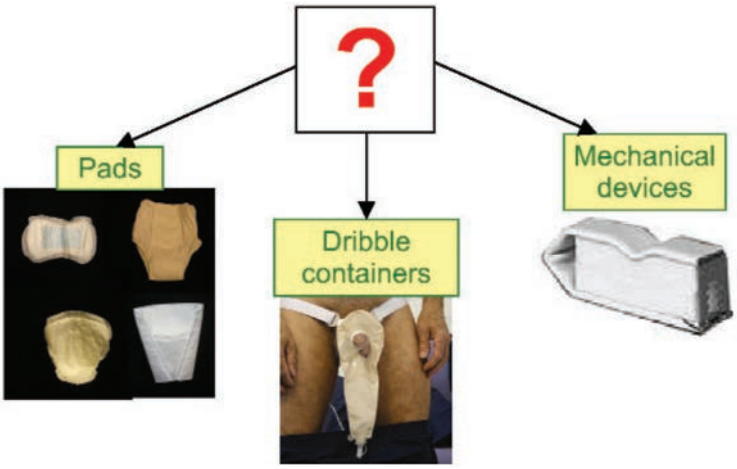
Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Female handheld urinals (Section IV.1)	• Any woman with mobility/urgency/access problems (C) • Able to stand or crouch (B/C) • Able to move to edge of chair (B/C)		• Many urinals: experiment using a library of urinals. • Urinals are less likely to succeed if woman needs to lie down or sit back in a chair.
Male handheld urinals (Section IV. 2)	• Any man with mobility/urgency/access problems (C) • Some manual dexterity (C) • Design concept acceptable (C)	• Inability to empty urinal independently (C) • Poor balance (C) • Impaired forward arm reach and wrist function (C) • Impaired cognition (C)	• Clothing adaptation may be needed. • NB Non-spill adaptors. • NB Flat-pack urinals for travel.
Commodes (Section V)	• Anyone with mobility/urgency/access problems (C)	• In rooms used by others (C) • Institutional settings (shower chairs preferred) (C) • Where there is a safety risk.	• Ensure privacy and dignity.
Bedpans (Section V)	• Unable to use toilet or commode / shower-chair (C)	• In general (C)	• Ensure privacy and dignity.

Figure II-4: Products for people who need assistance with toileting.(Grade of recommendation in brackets)



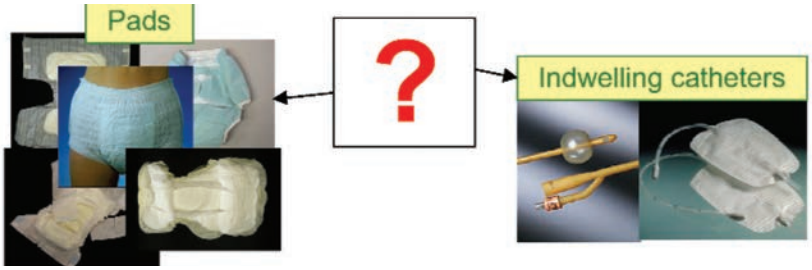
Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Pads (Section VI.5)	• In general (C)		• See Fig VI-16 for details.
Mechanical devices (Section X)	• Incontinence is predominantly stress (C) • Manual dexterity is good (C) • Sound cognition (C) • Device concept is acceptable / preferred (C) • Preventing leakage rather than containing it is attractive (C)	• Incontinence has a significant urgency component (C) • Concerns over risks of UTI are high (intra-urethral device) (C)	

Figure II-5: Products for females with light urinary incontinence (Grade of recommendation in brackets)



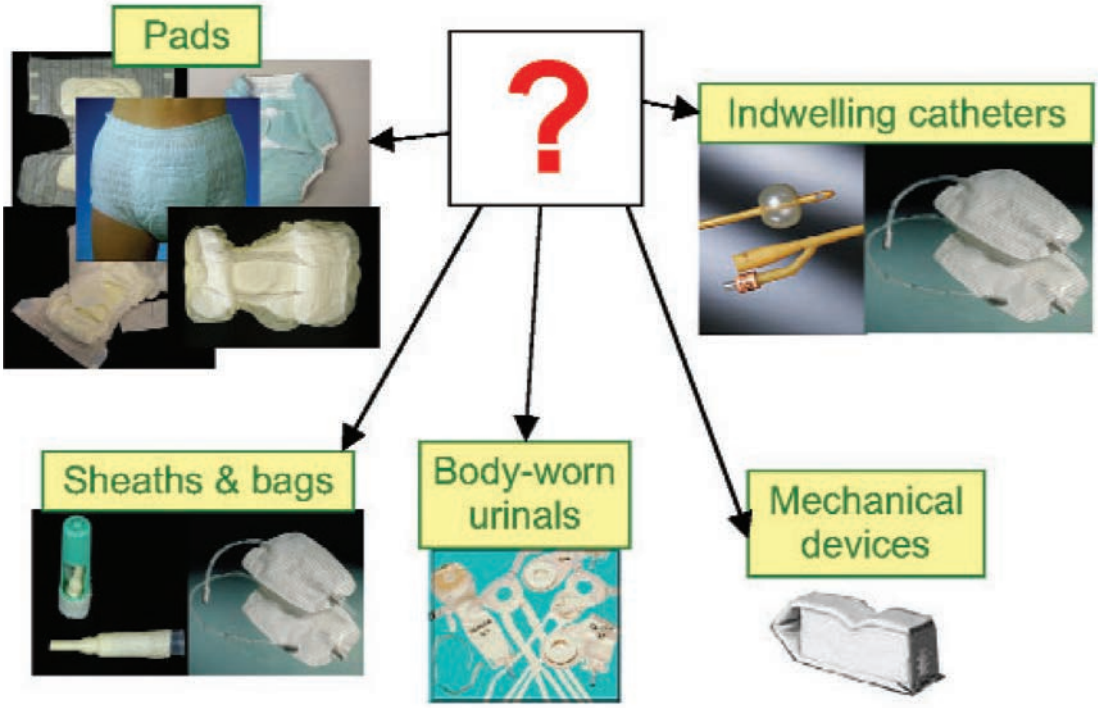
Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Pads (Section VI.6)	• In general		• See Fig VI-17 for details.
Dribble containers (Section IX.2)	• Device concept is acceptable / preferred (C)	• Unknown	
Mechanical devices (Section XI)	• Highly motivated (C) • Periodic / intermittent use (C) • Incontinence is predominantly stress (C) • Device concept is acceptable / preferred (C) • Preventing leakage rather than containing it is attractive (C)	• Incontinence has a significant urgency element (C) • Doubtful level of cognition (C) • Risk of skin / tissue damage (C) • Bladder sensation poor (C) • Poor dexterity (C)	• Skilled fitting by a professional is needed.

Figure II-6: Products for males with light urinary incontinence (Grade of recommendation in brackets)



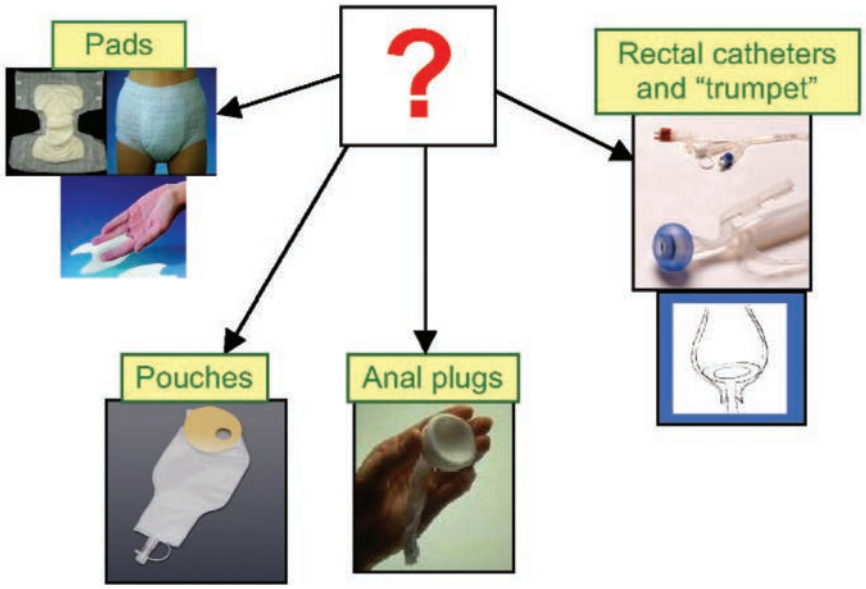
Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Pads (Section VI.7)	• In general (C)	• Skin is severely damaged (C)	• See Fig VI-18 for details.
Indwelling Catheters (Section XII.2)	• Retention / voiding problem (if no alternative) (C) • Skin is severely damaged (C) • Pads (or other products) unsuccessful / inappropriate (C) • Unable to perform CIC (C)	In general (A), but particularly if: • History of urethral trauma • Cognitive impairment (danger of interfering with catheter) • Avoidance of UTI is a priority	• See Table XII-1 for details.

Figure II-7: Products for females with moderate / heavy urinary incontinence. (Grade of recommendation in brackets)



Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Pads (Section VI.7)	• In general – particularly if active (C)	• Skin is severely damaged (C)	• See Fig VI-18 for details.
Sheaths & bags (Sections VII & VIII)	• Less risk of bacteruria, recurrent UTI's or death than indwelling catheters (C) • More comfortable than indwelling catheters (C) • Acceptable / preferred to pads (C) • Minimal physical intervention is a priority (C) • Good dexterity (C) • Sound cognition (C)	• Local skin breakdown (C) • Bacteruria, UTI (C) • Carer / user unable / reluctant to apply (C)	• Sheaths with integral adhesive are more popular than sheath with separate adhesive strip. • Sheath applicators are often ineffective and unpopular.
Body-worn urinals (Section IX.2)	• Desire to avoid pads (C) • Concept acceptable/preferred (C) • Mobile (not wheelchair user) (C)	• Latex / materials allergy (C)	
Mechanical devices (Section XI)	• Highly motivated (C) • Periodic / intermittent use (C) • Incontinence is predominantly stress (C) • Device concept is acceptable / preferred (C) • Preventing leakage rather than containing it is attractive (C)	• Incontinence has a significant urgency element (C) • Doubtful level of cognition (C) • Risk of skin / tissue damage (C) • Bladder sensation poor (C) • Poor dexterity (C)	• Skilled fitting by a professional is needed.
Indwelling catheters (Section XII.2)	• Retention / voiding problem (C) • Skin is severely damaged (C) • Pads (or other products) unsuccessful / inappropriate (C) • Unable to perform CIC (C)	In general (A), but particularly if: • History of urethral trauma • Cognitive impairment (danger of interfering with catheter) • Avoidance of UTI is a priority	• See Table XII-1 for details.

Figure II-8: Products for males with moderate / heavy urinary incontinence. (Grade of recommendation in brackets)



Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Pads (Section VI.11)	• In general (C)	• Skin problems (C)	• Few pads are specifically for faecal incontinence. • Dressing between buttocks favoured by some men for minor faecal incontinence
Pouches (Section XIII.6)	• Acute situations (C) • Liquid stool (C) • Post-surgical / enema drainage (C) • Immobile / in bed (C) • Risk of skin problems (C)	• Skin problems (C)	• Skin problems may depend on adhesive material.
Anal plugs (Section XIII.3)	• • Children tolerate better than adults (C) • After using enemas or rectal irrigation (C) • Spina bifida, anorectal malformation, rectal sphincter damage / tear (C) • Periodic use (eg sports or special occasions) (B/C)	• Possibly if there is bowel/rectal disease • Spinal cord patients with autonomic dysreflexia (C) • Device concept unacceptable (C) • Disruptive of successful established routines (B/C)	• Discomfort / pain influenced by plug design. • Discomfort and frequent expulsion are common cause of rejection. • Leakage around plug may occur.
Rectal trumpets (Section XIII.4)	• Acutely ill (C) • Liquid stool (B/C) • Post-surgical enema drainage (C) • Immobile / in bed (C) • Risk of skin problems (C)	• Skin problems (C)	
Rectal catheters (Section XIII.5)	• Acutely ill (C) • Liquid stool (B/C) • Immobile / in bed (C) • Skin problems or skin at high risk (B/C) • Wound contamination due to faecal incontinence (B/C)	• Possibly if there is bowel disease, large haemorrhoids, stricture / stenosis • Recent rectal surgery / injury (C) • Long term use	

Figure II-9: Products for people with faecal incontinence. (Grade of recommendation in brackets)

using a hierarchy of questions relating to absorbent products. So, in this example, once the decision is made to choose an absorbent product in response to question 1, successive further questions can be used to narrow down the choice to a specific product brand. Questions at any of these levels may form the basis for research projects.

Table III-1: Levels of questions

• Which product category (eg catheter, sheath, absorbent pad)?
• Which design of product design (eg pull-up or diaper design of pad)?
• Which material type (eg reusable or disposable)?
• Which features (eg with / without elastic gathers)?
• Which product brand?

In the field of absorbent products the practitioner and / or patient wishes to know whether to use an underpad or a bodyworn product, a reusable or a disposable, a diaper or an insert (if they select a bodyworn), a diaper with internal elastication (standing gathers) or without and, finally, which of the many diaper brands is likely to be most effective. Attempting to answer this final question is the most pertinent question for the practitioner (who may already have made decisions about questions 1-4, Table III-1) but is particularly problematic because of the high rate of product change. By the time the results of a clinical trial of product brands are known many of the test products will have been modified and the results will have limited value for product selection. However, these 'single design' studies do have value in demonstrating the range of performance within the group of product brands, and where objective measurements can be made (for example, of leakage performance) can allow for comparisons between groups of products. Single design studies are also helpful in promoting product improvement by revealing common problems experienced by patients and exposing particularly poor products or poor product features which are amenable to change by manufacturers.

Basic product designs, features and materials change much less frequently and attempting to answer questions 1-4 (Table III-1) is therefore likely to lead to more long-lasting results. Such studies have been attempted by many researchers, but these have frequently been confounded by problems with product representation.

b) Product representation

The single greatest (and most frequently overlooked) threat to the validity of clinical trials of products is the selection of the products entered into the study. Evaluations of a number of product variants of a similar design (eg different brands) have shown that patient 'overall opinion' scores can vary by as much as 70 percentage points between apparently similar products [15]. Accordingly, in an evaluation to compare different designs, the selection of one or more products to represent each design, is crucial. Studies that have purported to compare different designs or materials have often included a small number (most often just one) of arbitrarily selected product(s). Generalizing the results of such studies to whole product groups (e.g reusable underpads, or disposable bodyworns) is meaningless and misleading. It is perfectly possible to select (either by accident or design) a particularly 'good' product from one group and a particularly 'poor' product from another. A well-designed study will therefore be seriously flawed if there is no clear process or pilot study to determine and justify the choice of particular products. Even with a systematic process of product selection (or preferably a pilot study) it is unwise to select a single product to represent a whole group of products and selection of a small group of products (e.g. three) is preferable. This allows for any 'within group' differences to be detected and helps to demonstrate the 'representativeness' of the products selected.

The most controlled method of testing different designs, materials or features of products is to make up experimental batches which differ only in the aspect of interest (e.g. the material or the feature) and a small number of studies have attempted this [15] [16]. However, experimentally made products are not usually identical to those available on the market which impairs the validity of such studies.

2. RESEARCH DESIGN

A randomized controlled trial is not possible for clinical trials of products in most categories simply because a 'control' product does not usually exist. Nor is there a 'standard or reference' product to act as a control and comparisons with 'standard practice' (i.e. the product currently in use) are prone to bias.

Although it is methodologically simpler (and more robust) to compare only two different product groups, it is more clinically relevant to compare several competing groups, using a multiple cross-over design, where there are valid comparisons. For example, there are four main design groups of disposable bodyworn pads for moderate / heavy incontinence (inserts, diapers, pull-ups and T-shaped). Evaluation of all four groups together is much faster (and therefore gives more long-lasting results) and more cost-effective than several serial studies. Cross-over trials are vulnerable to order effects and randomization of the order of testing should be carried out using Latin squares [17] to ensure balance.

It is important that clinical trials of single designs of products (which aim to enable selection of particular product brands) are comprehensive (i.e. cover all the available products) because otherwise manufacturers

can justifiably claim that although their product may be similar to one of those tested even subtle distinctions may lead to clinically important differences.

A further problem with research design is the blinding of products. Different products have different appearances and it is impossible to blind subjects or staff to the product in use. Products can be repackaged to assist anonymising but this may have unwanted effects on the products and is expensive.

Previous product experience can also affect study results, particularly if a substantial proportion of subjects are currently using a product included in the study. It is therefore important to record which products are in current use in order to add this data to the model used in the analysis.

a) Sample size and study power

Studies that include more than two products (or two small groups of products) will need to be powered so that multiple comparisons can be made. As the number of products included in the study increases the number of possible comparisons of pairs of products rises. This requires a corresponding reduction in the significance level (e.g. by using the Bonferroni method) for each pair-wise comparison to retain the overall level of significance (usually $p<0.05$). Thus as the total number of pair-wise comparisons increases the likelihood of a type 2 error (accepting the null hypothesis when it is false) also increases.

Sample sizes therefore need to be calculated to allow for each pair-wise comparison. Sample size requirements rise rapidly if each subject does not test each product and the number of products entered into a study must therefore be limited by subject fatigue. As an example, a clinical trial of four product groups where the primary outcome variable will be binarised (e.g. satisfactory / unsatisfactory) will require a sample size of approximately 80 subjects with an alpha of < 0.05 and d (difference) of 20%.

b) Outcome variables

Studies of product performance have most frequently used self-report questionnaires at the end of the product test period to assess participant ratings of product performance. Diaries of product-related events such as leakage, laundry generation and product consumption are also commonly included. Subjects in some absorbent pad studies have been asked to identify and prioritise items of product performance [18] [19] [20] to inform questionnaires and **Table III-2** shows the most common items of high priority to women with light urinary incontinence identified by Getliffe and colleagues [19].

Outcome variables in studies designed to compare catheterisation strategies and / or catheter materials or other design features commonly encompass measures of urinary tract infection, tissue trauma and recurrent catheter encrustation leading to blockage (see Section XII-2).

Questionnaire items vary depending on the products being tested and for product groups where few studies have been carried out it is particularly important to tailor questionnaires to patient needs by asking study subjects to prioritise items and to assess final questionnaires for content and face validity. One study [21] has measured the test re-test reliability of a questionnaire to assess sheath performance and found moderately good Kappa scores (around 0.7) when assessing the same sheath twice with four weeks between assessment periods.

Skin health, urinary tract infection, pain or discomfort are the main physical health consequences of containment products and skin health (which can be rated by self-report or by skin inspection) has sometimes been used as the primary outcome variable (e.g. [22]). Urinary tract infection is an important outcome for invasive devices such as catheters.

Although leakage performance is most frequently

Table III-2. Most common items of high priority to women with light incontinence using absorbent products. Getliffe et al. [19]

Daytime:	% women (N =99)	Nightime:	% of women (N=81)
Hold urine without leaking	83.8	Hold urine without leaking	93.8
Contain smell	75.8	Stay in place	77.8
Stay in place	54.5	Contain smell	54.3
Discreetness	41.1	Comfortable when wet	54.3
Comfort when wet	40.4	To keep skin dry	48.1

rated as the top priority for users, good leakage performance is not adequate as a sole measure of patient satisfaction with performance. A single (or multiple) fatal flaw such as poor comfort, bulkiness, or poor fit may cause a product that performs well for leakage to be unacceptable to the patient. For this reason aggregate measures - which assumes that the overall performance of a product can be calculated using a weighted sum of the scores for specific aspects of performance (like comfort and freedom from leakage) - are ill-advised. Patient overall opinion or satisfaction with the product should therefore be used as the primary outcome variable [21].

There are no quality of life measurement tools specifically designed for clinical trials of products, but there is a need for such tools to measure the impact that good or bad product performance has on people's lives. Existing incontinence-specific quality of life tools are designed to measure change after interventions to improve incontinence and include urinary symptoms. These tools are therefore likely to be insensitive to changes in quality of life brought about by products which are designed to contain incontinence rather than reduce or prevent it. The first stage in the development of a quality of life tool for absorbent product users has been reported by Getliffe et al. [19] and a similar tool for catheter users is known to be under development.

3. SUMMARY AND RECOMMENDATIONS

There is little published evidence on which to base summary and recommendations regarding methodology and so the following summary points / recommendations are all **Level of Evidence 3 / Grade of Recommendation C.**

- Evaluation of continence products is methodologically complex and many attempts at providing robust evidence for product selection have been hampered by methodological weaknesses.
- Product representation is critical to providing robust and generalisable data. Selection of products for inclusion in a study needs to be transparent and systematic and several products should preferably be included to represent a product group. In particular, care should be taken not to select a particularly good or a particularly poor product to represent a whole class of products.
- Multiple crossover designs are likely to be more efficient than randomised controlled trials for many products (eg pads) and therefore sample sizes estimation needs to take into account the multiple comparisons that will be made.
- Outcome variables should include patient (or carer) questionnaire including items that have been established as important to patient users.
- Diary data should be included to determine leakage performance, skin health, laundry and product consumption.
- Incidence of urinary tract infection should be included when testing invasive devices such as catheters, but "significant" UTI/ bacteriuria needs to be carefully defined (see Section 12.2.8).
- The primary outcome variables should be patient overall opinion / satisfaction and patient preference.
- Health economics should be measured alongside product performance

4. RESEARCH PRIORITIES

- The development of Quality of Life tools for users of continence products.

IV. HANDHELD URINALS

Handheld urinals are portable devices designed to allow a person to empty their bladder when access to a toilet is not possible or convenient, often due to limited mobility, hip abduction or flexibility. They can be especially helpful for those suffering from frequency and / or urgency.

An effective hand held urinal must enable its user to empty his / her bladder in comfort and be confident of no spillage. It should not require excessive physical effort on their part and should be easy to empty without spillage.

General guidelines on patient assessment for product selection are discussed in Section 2. Aspects of patient assessment particularly important for handheld urinals are user postures (in bed, on side of bed, back in chair, on edge of chair, standing/ crouching/kneeling), leg abduction, approach of urinal (from front, side, behind, above), ability to initiate void, dexterity and strength to position and remove urinal, level and availability of assistance, user preference.

There has only been one clinical trial [23] of female urinals and there are no published trials of male urinals. However, much helpful guidance and expert opinion has been published [24] [25] [26] [27].

1. FEMALE HANDHELD URINALS

Female handheld urinals come in a variety of shapes and sizes (**Figure IV-1**). Most are moulded in plastic but they may be made from metal or (for single use items) cardboard. Some are designed for use in particular postures, like standing, sitting or lying down – (see below). Some have handles to facilitate grip and positioning. Some are intended to empty into a drainage bag during or after use.

Although female handheld urinals are often described and discussed in general nursing articles on continence products they have only been the subject of one published (cross-over) evaluation. Fader

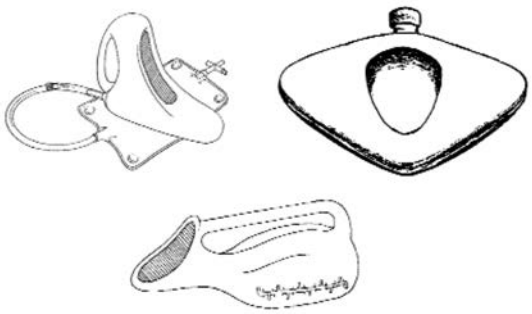


Figure IV-1: A variety of female handheld urinals.

et al. [23] carried out a multi-centre study in which each of 37 community-based women (age range 33-89y; mean age 61y) was invited to evaluate all 13 products on the UK market in 1997. No product suited everybody but each was successful for at least some subjects. The key requirements for success were that the user should be able to position the urinal easily and feel confident that it would catch urine without spilling (Level of Evidence 2). Many products were successful when used in the standing / crouching position or when sitting on the edge of a chair / bed / wheelchair. Fewer worked well for users sitting in a chair / wheelchair. Only one worked even reasonably well when users were lying / semi-lying (Subaseal), In general, subjects with higher levels of dependency found fewer urinals to be suitable for their needs.

Recently the development of a powered urinal designed to pump urine into a reservoir has been described [28]. The aim of the device was to provide active removal of urine without leakage and without the need for gravity-assisted drainage. The urinal was tested by 80 women from six countries. Although evaluated as 'good' or 'okay' by more than three-quarters of the women, nearly half the women found the device 'poor' for weight and size. Problems with reliability of the device were also common and the authors concluded that the current device needed further refinement but may have potential as an alternative to conventional urinals. Although this device is not currently on the market, at least one other powered device is available. However, there are no published reports on efficacy.

2. MALE HANDHELD URINALS

Most handheld urinals for men are somewhat similar, involving a narrowed neck opening into which the penis is placed. Some products come with a detachable or integral non-spill adaptor containing a flutter valve to impede back-flow of urine from the urinal. There are no published trials of such products.

A review paper by Vickerman [27] makes recommendations for selecting suitable urinals for men. A flat bottom urinal may be more stable (and less likely to spill) for those using a urinal in bed. Urinals made from soft plastic (jug-style or with a funnel) may be easier to grip for those with poor manual dexterity. Urinals designed to be attached to a drainage bag (for emptying the urinal) may also be helpful to men living at home with limited support.

Vickerman also suggests that home-made devices (such as empty wide-mouthed containers with a handle and lid (for example, those used for clothes-washing liquid or conditioner) may be a practical (and cheap) option for some men. For those with a retracted penis female urinals may be easier to use than male products.

3. GENERAL POINTS FROM THE LITERATURE, INCLUDING EXPERT OPINION

The literature [24] [25] [26] [27] suggests that successful use of urinals depends on many factors which are summarised below.

- Experimentation is often needed to find the optimum urinal for an individual. A 'library' of urinals (i.e. a collection of different types of urinals to be lent out to users for experimentation) has therefore been recommended [26] but rigorous cleaning methods are needed (see below).
- Clothing alterations can aid quick and easy use of a urinal. For men, extending the fly opening of trousers or replacing zips with Velcro can be helpful, as can boxer shorts. For women drop-front pants may be needed, particularly if mobility is limited.
- Disposable and reusable 'travel' hand-held urinals are available for both men and women. These urinals fold away to fit into a pocket and may therefore be more discreetly portable than conventional urinals.
- Some disposable urinals include superabsorbent polymer in their reservoirs which turns urine into a gel and help to prevent spillage. Sachets of superabsorbent polymer may also be added to reusable urinals.
- Use of a urinal is not always free from leakage and provision of absorbent chair or bedpads to protect bedding, clothes and furniture (particularly when testing out urinals) may be necessary.
- The limited range of urinal options in acute settings, where often only bedpans are available, has been criticised and the process of introducing hand-held urinals to hospital services has been described and recommended [29].
- When used by one individual in the home, urinals can be cleaned with soap and water between uses. But where urinals are shared (i.e. cleaned and used by others), or if a library of urinals is used then robust methods are necessary. Some urinals can be cleaned in a bedpan washer but cleaning methods vary with different designs and

materials and compliance with local infection control procedures will be needed.

4. RECOMMENDATIONS

- There is a wide range of female urinals and experimentation is likely to be necessary to identify the best one for an individual (dependent on their individual needs and abilities) (Grade of Recommendation C).
- A library of female urinals (used with robust cleaning methods) will help to facilitate experimentation (Grade of Recommendation C).
- Male urinals are less varied than female urinals, but may be supplemented by use of less conventional receptacles (e.g. jugs, home-made devices); experimentation will help to identify best options (Grade of Recommendation C).
- Section IV.3 addresses other more general recommendations regarding urinal use.

5. PRIORITIES FOR RESEARCH

- Further development of female urinals is encouraged, particularly for supine users and those unable to move to the edge of a chair.
- The range of male and travel urinals need to be evaluated to provide guidance for users and carers.

V. COMMODES AND BEDPANS

Toilets can be difficult to use by people with mobility problems and other disabilities. Toilet adaptations such as raised toilet seats, padded seats, and grab rails can be very helpful in enabling individuals to access the toilet easily and comfortably. Bottom wipers and bidets can also be useful. However, if access to the toilet is impossible, commodes and other toileting receptacles should be considered.

Commodes are devices that comprise a frame supporting a toilet seat with a pan (disposable or washable) beneath to receive urine and faeces. They are used independently of a toilet and may be static or mobile. Mostly, they are used by people with reduced mobility who find it difficult to access a conventional toilet. Bedpans are portable receptacles that may be used for passing urine or faeces while in bed or chair. Some female urinals (see section 4) may also be used to collect faeces.

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important regarding commodes and bedpans begin with appropriate indications for their use since Matsumoto and Inoue [30] reported that incontinent elderly persons or their caregivers misunderstand indications of commode use for incontinence. Other patient assessment elements include: a) physical characteristics of the person with incontinence (e.g. can an obese person fit on a commode and use its handrails?); b) mental acuity (e.g. will a person with dementia recognize a commode or bedpan as a device to be used for defecation?); c) need for supervision or foot supports whilst on the commode (what is the risk of falling?); d) mobility (e.g. does the person need a commode or bedpan?), ability to transfer and method of transfer to the commode (e.g. hoist, carer help, independent with transfer board), need for static or mobile commode (particularly when considering using commode over a toilet), postural stability and need for supportive commode, e) level of assistance needed and physical burden to caregiver involved; and f) personal preferences (e.g. comfort of bedpan type) including need for 'non-commode-like' appearance (e.g., particularly when used in own room, particularly the living room). Patient assessment findings need to be evaluated in terms of the safety and stability properties of a commode. The proximity of the area for waste disposal, storage facilities (i.e., the location / visibility of the commode in the household), the availability of privacy during defaecation, and length of time likely to remain on the commode (is there a need for a pressure-relieving commode cushion?), are additional factors to be considered.

Commodes (or better still toilets) are preferable to bedpans (which are relatively difficult to use and do not permit appropriate posture for passing urine/faeces). Bedpans are generally reserved for people who are confined to bed (e.g. post-operatively) and for whom safety (risk of falling) is an important assessment issue.

1. RESULTS

Fader [31] has reviewed the little work that has been done to evaluate existing commodes and bedpans and to identify the needs of users. An investigation of commode design by Nazarko [32] highlighted the problem of commodes providing poor trunk support for elderly and disabled people. Prolonged periods of sitting alone (for privacy) to enable defecation resulted in a risk of falls. Nazarko worked with a manufacturer to produce a design specification for a commode. Consultation with patients indicated that many would prefer to use a toilet. As a consequence, attention was focused in designing a shower chair which could also be used as a commode or could be wheeled over a toilet.

An evaluation of the four main types of commodes (standard; with adjustable height; with removable / drop-down arm; with adjustable height and removable / drop-down arm combination) was published by the UK Medical Devices Agency [33] [34]. One third of the 150 commodes on the UK market at the time were found to have backwards instability, and most of them scored poorly for aesthetics and comfort. A discussion of the results of this evaluation and its application to nursing was subsequently published by Ballinger et al. [35].

The maintenance of hospital commodes can be a problem and Gillan [36] complained about the poor condition of commodes in wards for elderly people. Commode cleaning has also been found to be poor [47] and a recent audit by Bucior and Cochrane [37] showed visible traces of faecal contamination on cleaned commodes. The authors concluded that it was necessary for ward staff to have clearly defined roles and responsibilities for commode cleaning. New commodes have been designed to overcome such problems by being easier to clean (e.g. design-bugs-out commode www.designcouncil.org.uk/our-work/challenges/Health/Design-Bugs-Out/Case-studies/Commode).

Naylor & Mulley [38] investigated the use of commodes in community-dwelling patients and the attitude of carers and users towards them (115 subjects and 105 carers). The main reasons for commode use were impaired mobility, difficulty climbing stairs and urinary incontinence. Main concerns were lack of privacy and embarrassment about using the commode, unpleasant smells and the poor physical appearance of the commode. Carers tended to view them negatively, particularly with regard to cleaning. Where commodes were used for defecation in a living area the authors highlighted the problem of odour that lingered even after a commode had been emptied, and recommended the use of a chemical toilet.

Thorough cleaning of commodes or bedpans after every use is necessary for hygienic purposes and to eliminate odours. Naylor & Mulley [38] report that typically a caregiver rather than the commode user empties and cleans a commode. No recommendations for cleaning a home commode or bedpan were found in the published literature. In institutional settings, large sinks with spray hoses or special sanitizing equipment are available. The size and shape of a bedpan or commode receptacle may be difficult to fit under a standard sink basin in the home. Whether certain commode cleaning products reduce any residual odour more than others is not known. Toilet bowl cleaning products are suitable for cleaning a commode or bedpan; many contain bleach or antibacterial ingredients but their effect on reducing odour of commodes or bedpans has not been studied. Gel formulations are advertised by manufacturers as being better able to cling to hard-to-reach surfaces than liquid agents. Use of a deodorizer can be considered (Level of evidence 4).

Nelson and colleagues [39] surveyed 147 spinal cord injured patients regarding their satisfaction and safety with the shower chairs (used for bowel care) used in the home. They found that around a half of patients were dissatisfied with their chairs and concerns expressed related to lack of hand access to the perianal area, difficulty in turning and rolling the chair and problems with keeping the chair clean. One third of patients experienced chair related falls and nearly a quarter reported pressure ulcers. Two-thirds of subjects felt that their safety was compromised.

The same group of researchers evaluated three shower chairs using video-taping, photography and questionnaires and produced performance criteria for the design of an optimal shower chair [40]. Pressure mapping devices were used to measure seat pressures on three subjects who tested all three bowel / shower chairs to inform seat design [41].

These researchers [42] then set about designing a more advanced commode-shower chair. It had lockable, swing-away armrests and lever activated brakes to facilitate transfers. To prevent pressure ulcers a chair frame and padding combination was designed to facilitate a seating position that distributed body weight and reduced pressure on pressure points. Cupped edgeless footrests were designed to reduce the risk of heel ulcers. An adapted version of this chair is now commercially available in the USA.

Matsumoto and Inoue [30] examined whether use of a commode in the home might prevent or delay nursing home admission of elderly people who were incontinent. A five-year follow-up of multiple predictors of institutionalization in elderly people in a rural town in Japan showed that 40% of incontinent men and only 17% of incontinent women used a commode. Use of a commode was not associated with institutionalization. The authors suggested several possible reasons: misunderstanding of appropriate indications for a commode based on the type of incontinence; physical burden in assisting a care recipient to use a commode that seemed no different than for cleansing after an incontinence episode; and inadequate muscle strength of the elderly for using either a Japanese-style or Western commode.

Bedpans and other portable receptacles are not well described in the literature. Wells and Brink [43] describe three general shapes of bedpans: concave, cutaway, and shovel. The concave pan has a rounded triangle shape that slopes back to front and a curved seat. The cutaway has a rounded triangle shape with a flatter seat and rolled edges that allow for handgripping. The shovel shape, commonly called a “fracture pan” is a wedge or rectangle shape that has a flattened end that goes under the individual and a handle at the distal end. Generally bedpans are considered to be unsuitable for defecation for safety and acceptability reasons. However, for individuals with specific needs (e.g. frequency and urgency of defecation) a portable receptacle may be beneficial. Although many portable urinals are now available for both men and women, very few are recommended for defecation [44] and they have yet to be formally evaluated.

Privacy and dignity need to be given high priority when patients need to use a bedpan or commode, in particular in institutional settings. Care needs to be taken when transporting patients on a shower

chair to maintain dignity and avoid revealing the patient's bottom.

Bottom wiping and cleaning can be difficult for people with disabilities, particularly manual dexterity problems, or caregivers. Simple moist wipes may be helpful and are widely available. Devices designed to assist with bottom wiping problems are on the market and portable bidets are also available, however there are no published trials of these products. Bedpans have other disadvantages including difficulty removing the bedpan from under an individual without spilling (particularly if the individual is obese), risk of spilling and odour when transporting the contents for disposal since none have lids, and lack of privacy during use.

2. SUMMARY

- There are major defects in most of the current designs of commodes, especially: poor aesthetics; poor trunk support; instability (i.e. a tendency to tip over easily); poor comfort; difficult to clean; poor pressure relief (**Level of Evidence 3**).
- If direct transfer to a toilet is impossible or unsafe a sani-chair / shower chair is usually preferable to a commode (**Level of Evidence 3**).
- The main concerns of users about commodes and bedpans are: lack of privacy; embarrassment over use; odour; poor aesthetics; poor perineal cleansing accessibility; and inadequate facilities for cleaning the devices in the home (**Level of Evidence 2**).
- Defecation on a bedpan or other portable receptacle presents problems of safety and unacceptability to users (**Level of Evidence 2**).

3. RECOMMENDATIONS

- If at all possible, access to a toilet should be made available for defecation (**Grade of Recommendation C**).
- If direct transfer to a toilet is impossible or unsafe, a sani-chair / shower chair should be offered in preference to a commode wherever possible (**Grade of Recommendation C**).
- If a commode is used, care should be taken to ensure good trunk support; that the chair is stable; and that methods of reducing noise and odour are offered (**Grade of Recommendation C**).
- With commodes and sani-chairs / shower chairs, the user's bottom should never be visible to others and transportation to the toilet and use of the toilet or commode should be carried out with due regard to privacy and dignity (**Grade of Recommendation C**).
- Bedpans and other portable receptacles should be avoided for defecation purposes (**Grade of Recommendation C**).
- Patients vulnerable to pressure ulcers should not sit on a commode / sani-chair / shower chair for prolonged periods (**Grade of Recommendation C**).
- The person should be given a direct method of calling for assistance when left on the toilet / commode / sani-chair / shower chair (**Grade of Recommendation C**).
- Cleaning of bedpans and commodes should be carried out after each use following local infection control policies (in institutional settings) (**Grade of Recommendation C**)
- There are no evidence-based published guidelines regarding frequency of cleaning or type of cleaning product. However, thorough cleaning after bowel evacuation (to avoid odour and maintain aesthetics) is important, together with rinsing after urine has been passed. Cleaning needs may vary according to personal hygiene standards and offensiveness of urine/faecal smells (**Grade of Recommendation C**).

4. PRIORITIES FOR RESEARCH

- Studies are needed to determine how to make toilets accessible to as many users as possible. These may lead to improved designs for toilets and associated equipment and / or strategies for toileting.
- Studies are needed to determine which commode / sani-chair / shower chair designs best meet performance and safety requirements.
- Development of better commodes designed to overcome the limitations identified

VI. ABSORBENT PRODUCTS

1. INTRODUCTION

Absorbent products (commonly known as pads) are available in a wide range of sizes and absorbencies encompassing light through to very heavy incontinence. Most pads are bodyworn but some are used on the bed or chair (underpads, see Section 6.2); in this section the term 'pad' refers to bodyworn absorbent products. Broadly speaking, absorbent products can be divided into two main sub-groups: those suitable for light incontinence (usually smaller products) and those suitable for moderate-heavy incontinence (usually larger products). Manufacturers generally indicate the severity of incontinence that each product is designed to accommodate, but see the discussion in Section VI.4. Although absorbent pads are most commonly used for urinary incontinence they are also used by individuals for both faecal and urinary / faecal incontinence; however, there have been no published studies which specifically address this issue.

Incidental findings from evaluations of products indicate that absorption capacity alone does not

determine whether a user will choose to use a product. Some users may have frequent, low flow-rate loss of small volumes of urine ("dribble"), whilst others may be dry for days but then have a higher volume, higher flow-rate incontinence incident ("gush" or "flooding". Both may prefer to use pads for light incontinence. Mobile and independent community-dwelling women of all levels of incontinence are reported to generally prefer small pads and are often willing to change them frequently rather than use larger products and change them less often [45]. Conversely, dependent, immobile individuals may prefer the security of larger products despite relatively low urine volumes due to their dependence on others for pad changing.

More recently studies have focused on the use of pads by men. Teunnissen and Lagro-Jansson [46] interviewed 56 men with UI of which only nine used absorbent pads. They concluded that men use pads less frequently than women, have little knowledge about purpose-built pads, are more likely to construct their own pads out of absorbent materials such as towels and are less satisfied with pads than women. Furthermore there are indications that men may prefer other devices such as urinary sheaths [47] (see Section VII Sheaths).

Studies that have collected and weighed used pads to measure urine volume have found overlap between the quantities contained by pads from different sub-groups of users; thus in a study of insert pads for moderate-heavy incontinence used by older people in residential care around 15% of insert pads for moderate-heavy incontinence contained less than 100g of urine [48] and in a study of older women with light incontinence living in the community about 10% of insert pads for light incontinence were found to contain more than 100g of urine [49].

It might be speculated that the number of pads used per day might be a good measure of degree of urinary incontinence, but this has not been found to be the case in nursing home residents in Norway [50]. Pads were collected and weighed from residents in six homes, but a poor correlation was found between the number of pads used and the mass of leaked urine measured over 48 hours. The authors concluded that this was due to pad changes being carried out at routine times by healthcare assistants.

It is possible that a proportion of patients are simply provided with inappropriate products that exceed or fall short of the absorption capacity they require. One study investigated this issue [51] and found that patients were more satisfied with their products once their urine loss had been determined by pad weighing and appropriately absorbent products were provided. But many of these patients were using inadequate products to start with (such as pads comprising tissue paper) and firm conclusions could not be drawn. In practice, it is probably hard to justify the need for pad weighing to determine which absorbents should be provided and if there is doubt about which group a patient falls into then the patient should be offered small pads for light incontinence in the first instance and the size of pad titrated upwards as necessary.

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important regarding absorbent pads are frequency / severity of leakage, day / night incontinence, gender (some products are designed for, or are better for, men / women than others), ability to change pad independently / need for carer, pad changing position (standing / lying), laundry / drying facilities, individual priorities (e.g. need for discreetness), personal preference for design / materials (washable / disposable), lifestyle (at home / travel / work etc).

Aspects of absorbent pad performance have been identified and prioritised (during interviews) by men and women taking part in a series of clinical trials of such products [19]. There was considerable consistency across patient groups (light / heavy, men / women) with the ability of a product to hold urine without leakage being the top priority, and the following aspects also being considered to be of high priority: discreetness, containment of smell, ability to stay in place, comfort when wet and ability to keep skin dry.

2. ABSORBENT PRODUCT CATEGORIES

Absorbent products may be classified into two broad categories - disposable (single-use) and washable (reusable) - with each category dividing into two sub-categories: bodyworn products (worn on the person) or underpads (placed under the person). Within each sub-category are different design groups such as diapers and pull-ups which are subdivided by size (to fit users of different sizes) and / or absorbency (to cater for different severities of incontinence). Some designs are further subdivided into those intended for men, women or children. This classification is shown in **Table VI-1**.

- ***Bodyworn*** absorbent products can be divided into four main design groups:

- ***Inserts*** (sometimes called liners or, in the case of small pads, shields) are held in place by close-fitting underwear or stretch mesh briefs (**Figure VI-1**). Some patients experience problems with keeping pads in place using the commonly supplied net pants. As a result, many use more robust stretch pants purchased privately (e.g. cotton / Lycra, etc). Many disposable inserts (**Figure VI-2 and Fig VI-3**) have an adhesive strip on the back to help secure them and may have an indicator that changes colour when the pad is wet to signal the need for a change. They may have longitudinal, elasticated standing gathers of hydrophobic material intended to impede lateral leakage of urine and faeces. They

Table VI-1. Classification of absorbent continence products

Categories:	Disposable (single use)		Washable (reusable)	
Sub-categories:	Bodyworns	Underpads	Bodyworns	Underpads
Design groups*	Inserts Diapers Pull-ups Pouches	Bedpads Chairpads	Inserts Diapers Pull-ups Pouches	Bedpads Chairpads
Sub-groups	Groups sub-divide according to the severity of incontinence (light or moderate / heavy) and the gender of the intended users (M, F or unisex).			
* The products within a given design group may vary considerably in their features and their constituent materials.				

are sometimes rectangular but are more usually shaped to fit the body more snugly. Elastication at the legs may also be used to enhance fit. Washable inserts (**Figure VI-4**) are usually more simply designed than disposable inserts, with no elastication and are either shaped or a simple rectangle. Inserts are made in a wide range of sizes suitable for light through to very heavy urinary incontinence. For light faecal incontinence, the liner may be a small cotton gauze dressing placed against the anus and held in place by the cheeks of the buttocks (**Figure VI-5**).

- ***Diapers*** (sometimes called all-in-ones or briefs) are adult-size versions of babies' diapers. Disposable diapers (**Figures VI-6**) usually have elasticated waist and legs and self-adhesive tabs (usually resealable), and often a wetness indicator and standing gathers. More recently modified diapers have been introduced that fasten round the waist before the front is pulled into position and secured, to enable users to apply the diaper whilst standing (**Figure VI-7**). Washable diapers are usually elasticated at the waist and legs and are fixed with Velcro or press-studs (**Figure VI-8**). Diapers are intended for moderate to very-heavy incontinence.

- ***Pull-ups*** are similar in construction to trainer pants for toddlers. The absorbent material is built into a pull-up pant and is either limited to the crotch area or distributed throughout the pants (**Figures VI-9 to VI-11**). Disposable pull-ups (**Figure VI-9**) are usually elasticated throughout the pants to give a close fit. Both disposable and washable pull-ups have versions for different levels of incontinence. Washable pull-ups for light incontinence are often known as pants with integral pad (**Figure VI-11**).

Some people use less conventional or home-made systems either instead of or as well as the designs described above. In particular terry-towelling squares may be used by those with heavy incontinence. These may be formed into briefs by folding into different configurations and fastening with pins and covered with plastic pants as a waterproof barrier. It is known that such pants may also be worn over more conventional designs in an attempt to reduce leakage and / or odour.

"Body" garments (like vests which have a crotch section which opens and closes with snap fasteners, much like those manufactured for babies) may be helpful to hold pads in place well and may reduce the rustling noise from plastic backing materials.

- Male ***pouches*** (sometimes called shields, guards or leaves) are for lightly incontinent men and are designed to fit around the penis and sometimes the scrotum too (**Figures VI-12 and VI-13**). All are worn with close-fitting underwear or stretch mesh briefs. An adhesive strip is often provided on the disposable versions to help hold them in place.

- ***Underpad*** absorbent products are usually simple rectangles of different sizes to be used on the bed or chair (**Figure VI-14**). Washable underpads (**Figure VI-15**) may have a high friction backing or have 'wings' for tucking beneath the mattress of single beds to help keep them in place. Underpads vary widely in absorbency with less absorbent products being used as 'back-up' with bodyworn absorbents and more absorbent products being used as sole protection on the bed at night.

3. ABSORBENT PRODUCT MATERIALS

Absorbent products – disposable or washable – usually comprise three main layers: an absorbent core sandwiched between a water-proof backing beneath and a water-permeable coverstock (or topsheet) next to the wearer's skin.

The main component in disposable absorbent cores is invariably some kind of fluffed wood pulp fibres, but most also contain some powdered superabsorber (sometimes referred to as SAP (superabsorbent polymer) or AGM (absorbent gelling material)), which is often concentrated in the crotch region. Superabsorbers hold much more urine – weight for weight – than fluff pulp and retain it far more tenaciously under pressure. They are usually based on cross-linked salts of polyacrylic acid whose chemistry can be varied according to the balance of properties such as absorption capacity and absorption speed desired. Some thermoplastic fibres are also sometimes included in absorbent cores to reduce core break up and the collapse of the structure when wet. It is increasingly common for absorbent cores to comprise two or more layers, each designed to perform a different function. For example, an upper layer might comprise low absorbency fibres engineered to receive and distribute urine efficiently and maintain a dry layer next to the skin, while lower layers provide absorption capacity. Some disposable products have 'breathable' plastic backings designed to reduce skin occlusion.

Washable absorbent cores are usually made from a needlefelt or knitted fabric comprising rayon and / or polyester fibres. A variety of polymers are used for the water-proofing. In general, the thicker, stiffer materials are more durable (the durability of the plastic backing often determines the lifetime of the product) but less comfortable. Topsheets are usually made from either cotton – which is hydrophilic and intended to have good dry comfort – or polyester – which is hydrophobic and intended to have good wet comfort.

Concern for the environment and also for controlling costs has led to an increase in the number of washable products available on the market. An important consideration in the comparison of washable and disposable designs is the relative environmental cost, particularly disposal (landfill) costs of disposable designs and energy costs associated with laundering the washables. A recent report on baby diapers concluded that there was no significant difference in environmental impact between three diaper systems (disposables, home and commercial laundered washables) although the types of impacts did vary [52].

4. ABSORBENT PRODUCT CAPACITY AND USER REQUIREMENTS

Pads come in a range of absorbencies to cater for users with different levels of urinary incontinence and, understandably, purchasers wish to know how much urine available pads will hold. But there is no simple answer: a pad does not have a volume of urine below which it is guaranteed not to leak; rather, the probability of success decreases as the volume of the urine increases. However, for higher absorbency pads the performance falls away more slowly with increasing urine volume than it does for lower absorbency products.

This is a complex concept to communicate in sales literature and product packaging and so companies commonly quote a simple absorption capacity figure. Some use the volume of fluid a pad will hold in a laboratory test - usually international standard ISO 11948-1[53] - but this figure can be very misleading. Although it has been show to correlate well with the leakage performance of pads for some groups of users (see Section VI.7.2), the volume of urine which a pad will hold when tested with ISO 11948-1 is enormous compared with how much it will hold in real use. For this reason, some companies prefer to quote a "working capacity", which might be calculated as some proportion (companies vary in the proportion they use) of the capacity in the laboratory. However, this is still misleading as it implies that the pad will not leak until the working capacity is exceeded. A simple, valid and widely accepted solution to this problem has yet to be devised.

It is equally difficult to determine the needs of users in terms of the volume of urine they need their pads to hold. Not only can different users leak widely differing volumes from each other but also a given user may leak widely differing volumes on different occasions. This means that, like pad performance, users' needs cannot be easily quantified. However, a number of studies have been published on work with pad users described as being lightly incontinent of urine in which the median and 90th percentile urine volumes in used pads have been of the order of 15ml and 100ml, respectively [54]. Similarly, a number of studies of pad users described as having moderate-heavy urinary incontinence have yielded corresponding figures of about 250ml and 600ml [54]. Accordingly, in this chapter the material is divided – somewhat simplistically – into that which relates to light incontinence and that which relates to moderate-heavy.

But the published work also makes it clear that some products work better for users whose inconti-

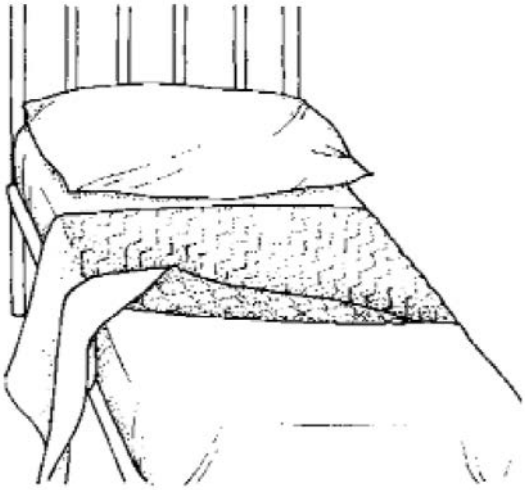

Figure VI-15: A reusable underpad.

nence is towards the lighter or the heavier end of the spectrum within each of these two groups and so, where necessary in the text and tables that follow, these distinctions are made by dividing light incontinence into "light LIGHT" and "heavy LIGHT"; and moderate-heavy incontinence into "light HEAVY" and heavy HEAVY".

5. ABSORBENT PRODUCTS FOR WOMEN WITH LIGHT URINARY INCONTINENCE

There are four main product designs for women with light incontinence (**Table VI-2**). In addition menstrual pads are known to be frequently used for light urinary incontinence. The disposable pull-up group are relatively expensive, single-use items and are seldom used for light incontinence except as 'emergency' items. Underpads are not commonly used for light incontinence.**(Figure VI-16)**

Aspects of assessment that are particularly important regarding pads for women with light incontinence include frequency / severity of leakage, day / night incontinence individual priorities (e.g. need for discreetness), personal preference for washables / disposables, lifestyle (home / travel / work).

a) Quality of data

A small number of robust comparative evaluations of absorbent pads for lightly incontinent women have been published and there has been a Cochrane review [55]. A recent study has compared the most common designs: disposable inserts, menstrual pads, washable inserts and washable pants with integral pad. One study has compared a range of disposable inserts and menstrual pads and there have been comprehensive single group studies of disposable inserts and washable pants with integral pads. A further study has compared specially made experimental products that have differed from one another in carefully controlled ways enabling more specific questions about product materials and design to be addressed.

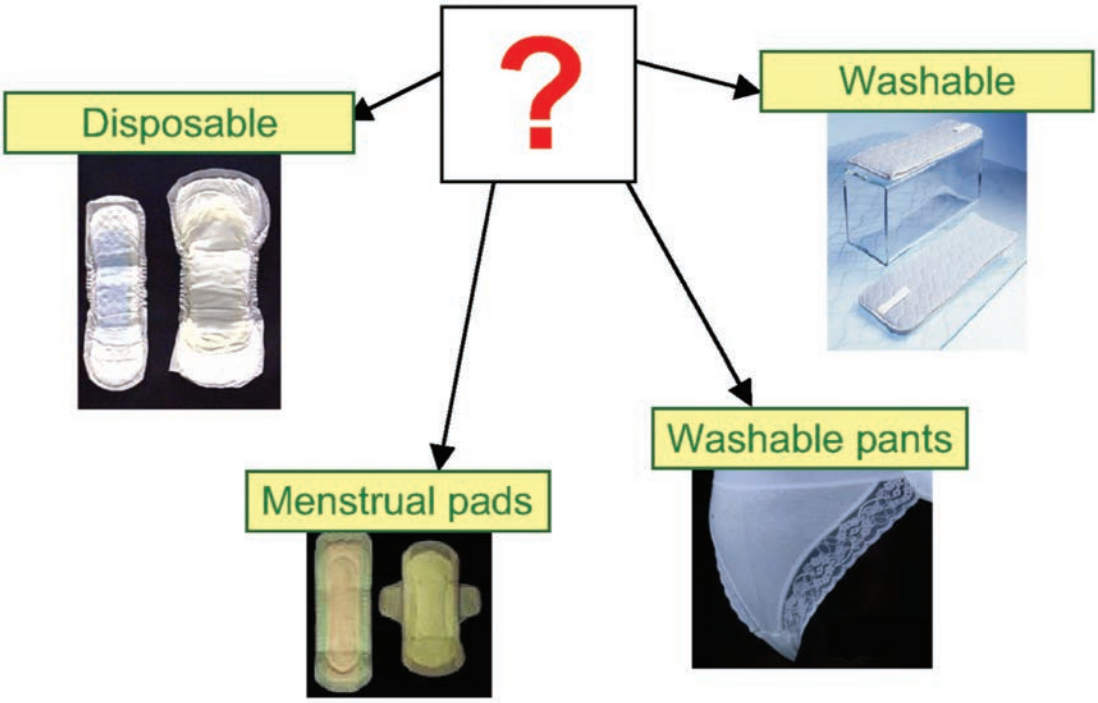
b) Results

Using a crossover design, Fader et al [54] compared disposable inserts, menstrual pads, washable pants with integral pad, and washable inserts. Three products were selected (based on previous study results) to represent each design and each product was tested for one week (three weeks for each design block, total 12 weeks). Order was randomised. Product performance was characterised using a validated questionnaire to evaluate pad performance (leakage, discreetness etc) with a five point scale (very good – very poor) at the end of each week of product testing. A pad change and leakage diary was used to record severity of leakage from pads (three-point scale: a lot, a little, or no leakage), and numbers of laundry items and pads used were recorded to estimate costs. Skin health changes were recorded weekly. At a final interview preferences were ranked (with and without costs), acceptability of the design recorded (highly acceptable – totally unacceptable) and overall opinion marked on a visual analogue scale (VAS) of 0-100 points (worst design – best design). This VAS score was used to estimate cost-effectiveness.

Eighty-five women (mean age 60) completed the study and 8691 used pads were weighed. The disposable insert was significantly better than the other designs on most variables except for discreetness. For leakage prevention, overall acceptability and preference, disposable inserts were found to be significantly better than menstrual pads, which were better than washable pants with integral pad, which were better than washable inserts. There was no clear benefit for skin health using either washable or disposable designs. Most women preferred the disposable insert pad but some preferred the other cheaper designs (6/85 preferred menstrual pads;

Table VI-2: Bodyworn absorbent products for women with light urinary incontinence

	Disposable	***Washable***
Design groups	Inserts (Fig VI-2)	Inserts (Fig VI-4)
	Pull-ups ie pants with integral pad (Fig VI-8)	Pull-ups ie pants with integral pad (Fig VI-10)
	Menstrual pads	



Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Disposable inserts	• Reliable leakage prevention is a priority (B)	• Low cost is a priority (B) • Discretion is a priority (B)	• Some users prefer a mix of products eg using different products at home / when out; or during the day / night.
Disposable menstrual / sanitary pads	• Low cost is a priority (B)	• Incontinence is heavy LIGHT (B)	
Washable pants	• Low cost is a priority (B) • The design concept is acceptable / preferred (B) • Incontinence is light LIGHT (B/C)	• Adequate laundry facilities are not available (C) • The design concept is unacceptable (C) • Carrying used pads when out is an issue (C) • Incontinence is heavy LIGHT (B/C)	
Washable inserts	• As for washable pants, but prefer separate pad (B/C)	• As for washable pants (B/C)	

Figure VI-16: Designs of pads for women with light urinary incontinence. For definitions of light LIGHT and heavy LIGHT, see Section VI.4. (Grade of recommendation in brackets)

13/85 preferred washable pants), both of which were >50% cheaper to use than disposable inserts. Washable inserts were significantly worse than the other designs (72/85 found them unacceptable). Overall there were generally more practical problems with washables, particularly when away from the home (**Level of Evidence 1**).

The authors concluded that allowing women to choose their preferred design of absorbent product (or combination of different designs for different circumstances) would be more cost-effective and provide better patient satisfaction than provision of disposable insert pads (the most expensive product) alone.

Clarke-O'Neill et al. [18] compared the range (12 products) of disposable inserts for lightly incontinent women available in the UK in 2000. Products were tested by 60 community-based women aged 50 years or older who currently used products similar to those to be evaluated. Products were evaluated using a pad performance questionnaire and a pad leakage diary. As a group, the products performed well in terms of their ability to hold urine without leakage. However, the 'overall opinion' scores of the testers showed large differences between products with 88% of subjects scoring the most successful insert as Good or OK compared with 51% for the least successful product ($p<0.001$) (**Level of Evidence 2**).

A similar study by the same research group [56] compared all 10 washable pants with integral pad for lightly incontinent women available in the UK in 1999. Seventy-two community-based women who usually used absorbent products for light incontinence tested each product for one week each. Leakage performance was found to be disappointing with 69% (CI: 59-78) of the best performing product not leaking at all with 10g of urine, compared to 40% (CI: 29-51) for the least successful product. Again subjects' 'overall opinion' scores showed wide differences between products with the best performing product scoring 85% Good or OK compared with 34% for the least successful product (**Level of Evidence 2**).

Baker and Norton [57] evaluated six small disposable inserts and two menstrual pads (available in the USA in 1991) with 65 community dwelling women. The products were rated using an evaluation questionnaire and daily diary of pad use. The two menstrual pads (which were the least expensive pads in the study) scored significantly higher than many of the incontinence products although neither was the most popular pad. The authors concluded that women should try a 'maxi' menstrual pad first and then move onto a higher capacity (incontinence) pad if this was inadequate. However, this study was carried out more than 10 years ago and products have changed considerably since then (**Level of Evidence 2**).

Thornburn et al. [16] studied 'wet comfort' using small disposable pads that had been experimentally made using different combinations of materials in an attempt to reduce 'wetback' (the tendency of pads to allow urine to escape back on to the wearer's skin). Twenty women tested the pads. Whenever differences in wet comfort, absorbency or overall performance were found they were in the expected order but differences were small and few reached statistical significance. The clinical value of including technically superior materials was not strongly supported. However, this was a small study and may have had insufficient power to detect significant differences (**Level of Evidence 2**).

More recently Erekson and colleagues [58] measured the wet-back performance of a range of 10 different branded products. This was a laboratory experiment involving two patients (of different BMIs) sitting on pre-wetted pads. Results showed that neither size nor price of the pads had any effect on the measured product performance. However it is difficult to determine how much such measurements reflect clinical performance.

c) Summary

There is robust evidence that disposable inserts are more effective in terms of leakage and more acceptable than menstrual pads, washable pants and washable inserts (**Level of Evidence 1**). Menstrual pads are cheaper and washable pants cheaper still (on a per-use basis) and are acceptable to many, particularly those with lighter incontinence and particularly when used at home. Washable inserts are not acceptable to most women. The user characteristics, priorities and contexts which favour or discourage the use of the different product designs are summarised in **Figure VI-16**.

d) Recommendations

- Disposable inserts are recommended as the most effective and preferred absorbent product for women with light incontinence (**Grade of Recommendation B**).
- Menstrual pads or washable pants may be sufficient for some patients with very light incontinence and are cheaper (**Grade of Recommendation B**).
- Washable inserts are not recommended (**Grade of Recommendation B**).
- Combinations of designs for different situations (e.g. disposable inserts for going out, washable pants with integral pad for staying at home) are likely to provide optimum management in terms of patient needs and cost-effectiveness, and product advice and provision (where purchased by institutions / services) should reflect this (**Grade of Recommendation B**).
- See also the general recommendations relating to pad selection in Section VI.11 and to washable pads in Section VI.12.

e) Research priorities

- Because the performance of washables is generally poor (particularly for leakage) compared to disposables, the development of better washable products is a priority.
- The use of combinations of designs for different situations needs to be evaluated.

6. ABSORBENT PRODUCTS FOR MEN WITH LIGHT URINARY INCONTINENCE

There are five main product designs for men with light urinary incontinence (**Table VI-4**). However, disposable and washable insert pads are often unappealing to men as they are frequently marketed specifically at women and bear a strong resemblance to menstrual pads. Anatomical differences are also likely to mean that they are less effective for men. Pouch, shield and leaf products (**Figures VI-11 and VI-12**) are designed to be more suitable for men by containing the penis or penis and scrotum.

Aspects of assessment that are particularly important regarding pads for men with light incontinence include frequency / severity of leakage, day / night incontinence, retraction of penis, individual priorities (e.g. need for discreetness), personal preference for washables / disposables, and lifestyle (home / travel / work).

Only one study has been published which has evaluated absorbent products for men with light urinary incontinence (59]. It compared the four main absorbent designs of products available in the UK in 2003: disposable insert pads, pouches and leafs and washable pants with integral pad. All six leaf products (five disposable and one washable) and all six pouches (all disposable) on the UK market in 2003 were evaluated, together with a selected disposable insert pad and a selected washable pant with integral pouch (chosen to represent their respective designs). Seventy men with light urinary incontinence completed the 14 week study and filled out product performance questionnaires at the end of testing each product for a week. Products were supplied in random order within their design group and the design group order was also randomised. Pad leakage diaries were used to record product performance and used pad weight. At the end of testing each design a design performance questionnaire was completed. 'Overall opinion' was used as the primary outcome variable. Results showed that the pouch design performed significantly worse than the leaf and the insert design. The most common problems with the pouch were staying in place and difficulties re-inserting the penis in the pouch once the pouch was wet. The leaf designs had the best leakage scores, but one product was significantly better than the other leafs (Tena). The disposable insert was also effective for leakage prevention and was substantially cheaper than the leaf designs. The washable leaf was the least successful of the leaf designs. The washable pants with integral pad received polarised overall opinion scores (loved or hated) and scored well for staying in place but poorly for leakage (Level of evidence 2). The user characteristics, priorities and contexts which favour or discourage the use of the different product designs are summarised in **Figure VI-17**.

a) Recommendations

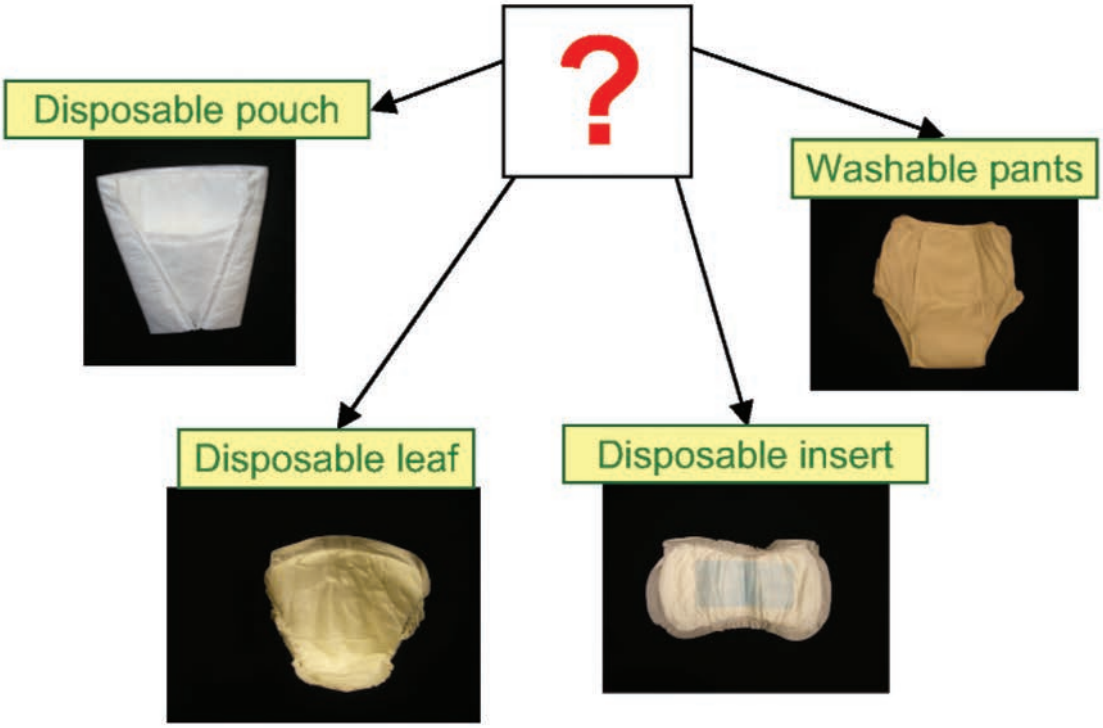
- Disposable leafs are recommended as the most acceptable and effective design for men with light incontinence, but some men prefer other designs which should be considered as alternatives (**Grade of Recommendation B**).
- Simple insert pads are cheaper and may be acceptable to some men (**Grade of Recommendation B**).
- Washable pants with integral pad are likely to be most suitable for men with very light incontinence who have difficulties keeping an insert or pouch in place (**Grade of Recommendation B**).
- See also the general recommendations relating to pad selection in Section VI.11 and to washable pads in Section VI.12.

b) Research priorities

Because the performance of washables was generally poor (particularly for leakage) compared to disposables, the development of better washable products is a priority.

7. ABSORBENT PRODUCTS FOR MEN AND WOMEN WITH MODERATE-HEAVY URINARY INCONTINENCE

There are at least 12 absorbent product designs for men and women with moderate-heavy urinary incontinence (**Table VI-5**). The most commonly used products are disposable bodyworn inserts and diapers (**Figures VI-3 and VI-6**). More recently, modified diapers (T-shaped diapers, **Figure VI-7**) have been introduced which can be applied by the wearer whilst standing. Pull-ups are also a relatively new innovation and comprise an absorbent pad integrated into a disposable elasticated pant (Figure VI-9). Washable counterparts to most disposable bodyworn designs are available but they have a much smaller market, where they are available. They are made from a variety of natural and synthetic materials. Disposable and washable bedpads are used on the bed at night with or without the support of a bodyworn product. Disposable and washable chairpads are used either without a bodyworn product (in which case the individual must sit directly on the pad with no underpants on) or in combination with bodyworn products to protect chairs from any leakage from the bodyworn. Both practices place an underpad on display and mark the individual as being incontinent and are therefore to be discouraged.



Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Disposable pouches	• Discretion is a priority (B/C) • Using a specifically male product is important (C)	• Penis is retracted (C) • Incontinence is heavy LIGHT (B/C)	
Disposable leafs	• In general (B/C)		• Appropriate whether or not penis is retracted
Disposable inserts	• Low cost is a priority (B/C) • Male specific product unimportant (C)		
Washables	• Incontinence is light LIGHT (B/C) • Low cost is a priority (B/C) • Design concept is acceptable / preferred (C) • User is mobile and active (B/C)	• Adequate laundry facilities are not available (B/C) • Design concept is unacceptable (B/C) • Carrying used pads when out is an issue (B/C) • Incontinence is heavy LIGHT (B/C)	

Figure VI-17: Designs of pads for men with light urinary incontinence. For definitions of light LIGHT and heavy LIGHT, see Section VI.4. (Grade of recommendation in brackets)

Table VI-4: Bodyworn absorbent products for lightly incontinent men

	Disposable	***Washable***
Design groups	Inserts (Fig VI-2)	Inserts (Fig VI-4)
	Pouch (Fig VI-11)	Pouch (Fig VI-12)
		Pull-ups ie pants with integral pad (Fig VI-10)

Aspects of assessment that are particularly important regarding absorbent pads for moderate / heavy UI are frequency / severity of leakage, day / night incontinence, gender (some products are better for men/women than others), ability to change pad independently / need for carer, pad changing position (standing / lying), laundry / drying facilities, individual priorities (e.g. need for discreetness), personal preference for design / materials (washable / disposable) and lifestyle (at home / travel / work etc).

a) Quality of data

There have been two recent clinical trials comparing the main designs of disposable bodyworn pads (one also included washable designs) which are included in a Cochrane review [55]. There have been no trials of underpads for the last 15 years. There have also been a large number of comparative studies of absorbent products for moderate-heavy incontinence but most are more than 10 years old and evaluated products that are no longer available. Furthermore, changes in materials and design features mean that it is impossible to generalise any particular findings to products of today. Brink [60] identified 30 studies of absorbent products published between 1965-1990. Some robust multi-centre international studies have examined the correlation between laboratory testing and the leakage performance of products clinically.

b) Results

1. Evaluations comparing different designs of disposable and / or washable bodyworn absorbent products for urinary incontinence

Fader et al. [54] carried out two clinical trials of absorbent products for moderate-heavy incontinence; one involving subjects in the community and the other subjects in nursing homes. In the community-based trial 85 moderate / heavily incontinent adults (urinary or urinary / faecal) living in their own homes [49 men and 36 women) were enrolled, and tested three (or two) products from each of five design categories (total of 14 test products): disposable inserts (with mesh pants); disposable diapers; disposable pull-ups; disposable T-shape diapers; and washable diapers. All products were provided in a daytime and a (mostly more absorbent) night-time variant. Products were selected based on having similar scores for absorbency across the designs (Rothwell scores, [53] see below) and performance data from pilot studies. In the nursing-home-based trial 100 moderate / heavily incontinent adults (urinary or urinary / faecal) living in a total of 10 nursing homes (27 men and 73 women) evaluated one product from each of the four disposable design categories above. Products were selected on the basis of product performance from the community-based trial and, again, day and night-time variants were provided.

Product performance was characterised using validated questionnaires which asked the participants (in the community-based trial) or carers (in the nursing home based trial) to evaluate various aspects of pad performance (leakage, ease of putting on, discreetness etc) using a five point scale (very good – very poor) at the end of the week (or two weeks for the nursing-home-based trial) of product testing. In addition, participants / carers were asked to save individual used pads in bags for weighing and to indicate the severity of any leakage from them on a three-point scale (none, a little, a lot). These data were used to determine differences in leakage performance. Numbers of laundry items and pads used were recorded to estimate costs, and skin health changes were recorded by the participant or by the researchers. At the end of testing participants were interviewed and ranked their preferences (with and without costs), stated the acceptability of the design (highly acceptable – totally unacceptable) and recorded their overall opinion on a visual analogues scale (VAS) of 0-100 points (worst design – best design). A pad changing experiment was conducted with 12 women from the nursing home based trial to determine any differences between product designs. Under idealised conditions the different designs were applied (by the same carers) in random order for each patient and the speed of pad changing was timed using a stop-watch.

Findings from the community-based and nursing home trials were broadly similar. The leakage performance for the disposable inserts was worse than the other designs for day and night and disposable pull-ups were preferred over inserts for the daytime. The new T-shape diaper was not better overall than the traditional disposable diaper. But there were important differences in performance and preference findings between men and women from both trials

Table VI-5: Absorbent products for moderate-heavy adult incontinence

	Disposable (single use)		Washable (reusable)	
Type	Bodyworns	Underpads	Bodyworns	Underpads
Design groups	Inserts Diapers T shaped diapers Pull-ups	Bedpads Chairpads	Inserts Diapers T shaped diapers Pull-ups	Bedpads Chairpads

and the men (in the community) had more severe urinary incontinence than the women - mean daytime urine mass in a pad 375 g for men and 215g for women (difference148g, CI: 80, 218).

Pull-ups (the most expensive design) were better overall than the other designs for women during the day and for community-dwelling women during the night too. Although disposable diapers were better for leakage than disposable inserts (the cheapest), women did not prefer them, but for men (in the nursing homes and the community) the diapers were better both overall and for leakage and were the most cost-effective design. No firm conclusions could be drawn about the performance of designs for faecal incontinence and there was no firm evidence that there were differences in skin health problems between designs (Level of Evidence 1).

In the nursing home trial the carers found pull-ups and inserts significantly easier to apply (in the standing position) and significantly quicker in the pad change experiment (mean time 35.2 and 37.9 seconds for inserts and pull-ups respectively and 53.2 and 62 seconds for diapers and T-shaped diapers respectively) and ability to stand was associated with preference for pull-ups or inserts. Despite being designed for ease of changing the T-shape diaper was not found to be easier or quicker to change than the diaper.

The washable products (used in the community-based trial) gave diverse results. Two of the products were made from cotton terry-towelling (one a simple square, folded and pinned in a diaper shape; the other a shaped diaper-like design, both worn with plastic pants) while the third product had a felt absorbent core, with an integral plastic backing and was fixed by poppers. This third product performed significantly worse for leakage than the other two washables and was therefore excluded from the final data analysis. The terry-towelling washables were better for leakage at night than the disposable designs, but were less popular overall for daytime use than the disposable designs. Three quarters of the women (27/36) found them unacceptable, but nearly two thirds of men (31/49) found them highly acceptable at night. Findings from the community-based trial showed that there were many practical problems dealing with washable products particularly when out of the house, but that they were more acceptable at home.

Macaulay et al, [20] carried out a pilot study of 19 washable products with 14 community dwelling subjects. The products included a mixture of washable insert and brief designs and two disposable bodyworn products. Product performances varied widely: the most popular was rated as good (for overall performance) by 78% of testers, while the least popular scored 22%. Although most of the washable products performed poorly for leakage, one washable product made of cotton towelling (used with plastic pants), scored better than both the other washable and disposable products (Level of Evidence 3).

Eight older trials have compared disposable with washable bodyworn products for moderate-heavy incontinence [61] [62] [63] [64] [65] [66] [67] [68]. The trials varied in size and design from a large controlled trial with 276 subjects [61] to a small trial of eleven subjects [64]. In addition some trials have compared disposable and washable bedpads and body-worns. Brown [22] [69] undertook a large trial of this kind. The fact that no systematic method of product selection was used for these studies limits the utility of the results since particularly good or poor products may have been selected to represent the disposable or washable groups.

Skin condition was used as an outcome measure in five of the above trials. However, only three used an experimental design and statistical methods of analysis. Beber [61] and Grant [62] both reported that they did not find statistically significant differences between their washable and disposable products in terms of an adverse change in skin condition. But Hu et al. [70] reported a statistically significant improvement in the skin condition of their disposable product users as compared to their users of washable products (See Section XIV).

Other parameters frequently investigated in these studies were staff preference, product leakage and laundry. Overall, the disposables in the studies were considered to have performed better than the washable products in terms of preventing leakage (often measured by quantity of laundry) and staff preference.

Four studies attempted to measure costs [63] [62] [71] and [69]. Of these, three used statistical methods of analysis. Hu et al. [71] and Brown [69] reported that although there were no statistically significantly differences in terms of per-day product costs of washable and disposable products, the laundry costs associated with the disposable product (ie for laundering soiled bed linen and clothes) were significantly lower than those associated with the washable product (ie for laundering the products as well as soiled bed linen and clothes). Brown [69] found no significant differences between daily costs of the washable and disposable products. However, statistically significant differences were found between the groups in terms of incontinence-related laundry, with the disposable group producing less laundry than the washable group. Grant [62] reported that the cost of washable products was significantly lower than that of disposables, but laundry costs were not taken into account.

2. Disposable absorbent products for urinary incontinence: studies of single designs, laboratory tests and studies of materials

Clancy and Malone-Lee [15] compared versions of the same pad experimentally engineered to have differ-

ent combinations of fluff pulp and topsheet materials. Forty-five heavily incontinent older adults participated. The main valuable finding from this study was that pads were more likely to leak if they were not held in place by pants ($p<0.0001$) and that, if there was any leakage from a pad, this tended to be less severe if the supplied mesh pants were worn than if normal pants were worn ($p<0.05$) (Level of Evidence 2). The mesh pants probably held pads more firmly to the body.

There have been two single design group studies of bodyworn products for moderate-heavy incontinence [72] [73], both carried out in nursing homes. A study of shaped insert pads involved 228 subjects from 33 nursing / residential homes who tested 20 ranges of insert pads [74 products in total). A similar study of diapers involved 192 subjects from 37 nursing / residential homes who tested a total of 36 products. These studies showed the wide range of product performance that can exist within single product groups. For example, the least successful diaper (based on 'overall opinion') was found to be unacceptable to 100% of the test subjects while the most successful was unacceptable to only 6% (Level of Evidence 2).

In addition, there have been a number of studies on the impact of wet pads on skin health and these are reviewed in Section XIV.

Because clinical evaluations are expensive and time-consuming, laboratory evaluation procedures are in widespread use. Few have been clinically validated but there is a clinically-validated International Standard (ISO 11948-1) relating to the leakage performance of disposable bodyworn pads for moderate-heavily incontinent adults in institutions [53]. It describes a simple method for measuring the absorption capacity of pads in the laboratory that was shown to correlate well with the leakage performance of 18 different products evaluated in an international multi-centre clinical study involving 112 heavily incontinent adults [74]. The strength of the correlation between technical and clinical data data depended on the exact parameters being compared, but typically $r = 0.9$ (Level of Evidence 2). This laboratory test (the Rothwell method) is now in common use in the UK, Sweden and other countries and provides a basis for selecting similar products with which to make direct comparisons (for cost purposes) or to select promising pads for inclusion in clinical trials.

The ability of ISO 11948-1 to predict the leakage performance of more recent bodyworn pads (138 diapers and inserts) for heavy incontinence was investigated by Cottenden et al. [75]. Correlations were poorer than in the original 1993 study ($r<0.87$ compared with $r<0.95$) but still strong enough to make the method useful. For a given Rothwell capacity, the leakage performance of diapers was far superior to inserts, but no evidence was found for any other design feature of the test products (inserts and diapers) having a significant impact on their leakage performance (Level of Evidence 2).

The repeatability and reproducibility of the ISO 11948-1 was investigated by Cottenden and co-workers [76] in three laboratories (UK, Spain and Sweden). Repeatability (precision between repeats in the same laboratory) was found to be very good with the co-efficient of variation for five repeats rarely exceeding 5%. However, the reproducibility (precision between laboratories) was poorer, revealing systematic differences: results from the Swedish and Spanish laboratories typically exceeded those from the English laboratory by 13% and 8%, respectively. Efforts to identify the source(s) of this poor reproducibility have so far been unsuccessful but it seems likely that minor variations in interpretation of the standard when constructing the apparatus and / or executing the test are to blame (Level of Evidence 2).

c) Summary

Results from these studies indicate that there is no single best design (i.e one design that is significantly better than all other designs for all users) (**Level of Evidence 1**).

There is evidence that different designs are better for men and women, and that men leak substantially higher volumes of urine than women (**Level of Evidence 1**).

Of the disposable designs, the more expensive pull-up and T-shaped diaper designs are not better overall than the cheaper diaper for men, indicating that the diaper is the most cost-effective design for men. For women pull-ups are better overall than the other designs (except for night-use in those living in nursing homes), but they are expensive (**Level of Evidence 1**).

Unlike men, women in the community do not favour diapers over insert pads and of these cheaper designs, inserts may be preferred for women. There is also evidence that the leakage performance of inserts is worse than other designs, but that they leak significantly less if they are held in place by mesh pants than by ordinary pants, and using no pants at all is associated with significantly more leakage than if either kind of pant is worn (**Level of Evidence 3**).

There is evidence that pads containing superabsorber leak less, are more comfortable, and keep the skin drier than those without (**Level of Evidence 2**).

The leakage performance of inserts and diapers for heavy incontinence can be predicted with reasonable precision using an international standard laboratory tests (**Level of evidence 2**).

This test has been shown to have very good repeatability and adequate reproducibility (**Level of Evidence 2**).

Washable products are very varied in design and materials, and also in performance. There is evidence that terry-towelling products (used with plastic pants) have good leakage performance, however they have limited acceptability - confined mainly to some men at night. There is no firm evidence regarding the perfor-

mance of different designs for faecal incontinence and no firm evidence that any particular design or type of material (washable or disposable) is better or worse for skin health.

The user characteristics, priorities and contexts which favour or discourage the use of the different product designs are summarised in **Figure VI-18**.

d) Recommendations

- Gender should be considered when products are prescribed / purchased for users. As men often have substantially higher incontinent urine volumes than women, men may require more products and / or more absorbent products than women (**Grade of Recommendation B**).
- Gender should also be considered when products are prescribed / purchased for users because men and women are likely to prefer different designs. Men generally prefer disposable diapers to inserts (**Grade of Recommendation B**).
- Women generally prefer disposable pull-ups to other designs, but these are expensive. Disposable inserts are a cost-effective alternative (**Grade of Recommendation B**).
- Caution is recommended if washable designs are being considered. Heavy bulk confines their use mainly to the night-time (where they may be particularly useful for users who lie on their side). They are unacceptable for most people during the daytime and for most women at any time and for this reason a blanket policy of health services providing washables alone is not recommended. If washables are being considered refer to points below (**Grade of Recommendation B**).
- Freedom from leakage: Where possible, international standard laboratory tests should be used to rank the likely leakage performance of different pads for heavy and light incontinence (Grade of Recommendation B). In general, diapers should be selected in preference to inserts to minimise leakage (**Grade of Recommendation B**).
- Carer application: When products are applied by a carer to a patient who can stand for pad changing, disposable inserts or pull-ups are easier and quicker to change than diapers or T-shaped diapers. If the patient is lying down (e.g. at night) pull-ups should be avoided (**Grade of Recommendation B**).
- Combinations of designs for different situations (e.g. disposable inserts for staying in, disposable pull-ups for going out, washable diapers at night) are likely to provide optimum management in terms of patient needs and cost-effectiveness (**Grade of Recommendation B**).
- See also the general recommendations relating to pad selection in Section VI.12 and recommendations specific to washable pads in Section VI.13.

e) Research priorities

- Comparison of absorbent products (disposable and washable) when used by carer-dependent users in the community.
- Development of more effective and aesthetically acceptable washable products, particularly for nighttime use and for women.
- Development of more effective and acceptable disposable designs specifically for men.

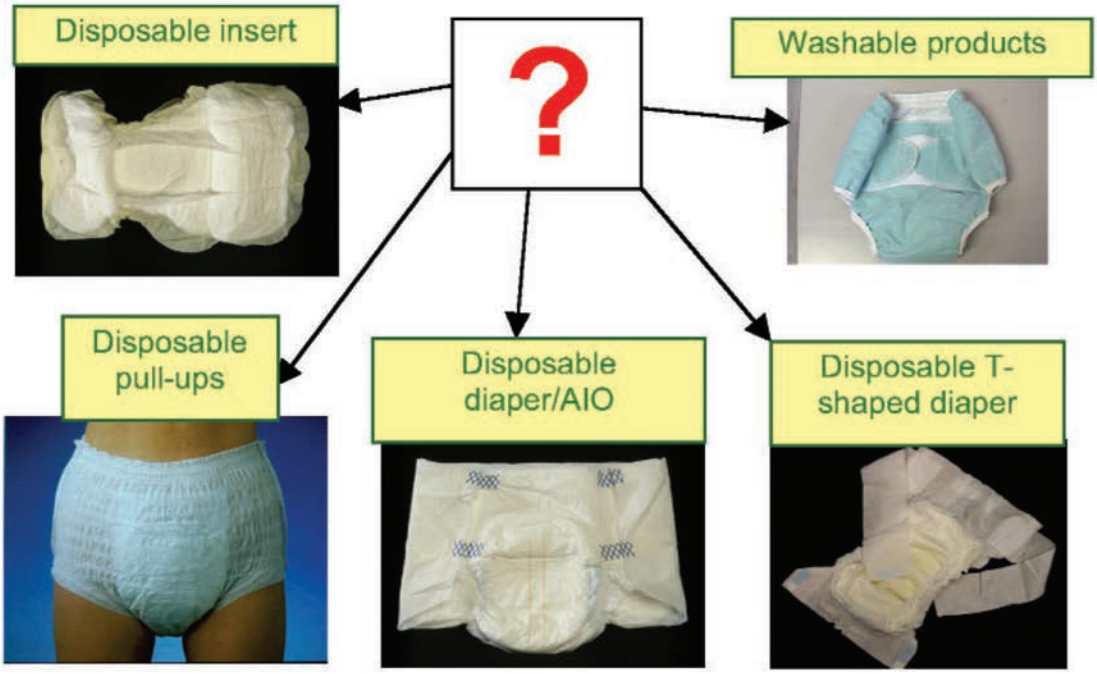
8. DISPOSABLE UNDERPADS

There have been no published studies examining the use of bedpads during the last 15 years. This probably reflects the recognition of their limited role in long-term management of incontinence. Disposable underpads on chairs declare their user to be incontinent and require clothes to be pulled up (or absent) which is unacceptable for dignity. In the bed disposable underpads easily become displaced, folded and creased under the patient which inhibits their performance and comfort, and may potentially be a threat to skin health. Large disposable underpads with wings to tuck into the bed may have a role as bed protection 'back-up' to bodyworn pads. The main role of disposable underpads should be confined to temporary bed or chair protection such as during clinical procedures (e.g. enemas) or when using a urinal.

Published trials comparing different disposable bedpads are few [77] [78] [22] and it is not possible to draw firm conclusions from them on the effectiveness of different product design features and materials. Some useful work has been done to highlight the risks of infection from disposable bedpads and to validate clinically some laboratory tests to assist with product selection by predicting pad leakage performance.

Bedpads are generally supplied as non-sterile items and Bradbury [79] has drawn attention to the risk of infection, particularly from products containing recycled paper. Leigh and Petch [80] and Sprott et al. [81] have conducted microbiological tests on a range of products. Both studies identified low levels of bacterial contamination but concluded that the risk to patients was minimal unless they were immunocompromised in some way. More recently, Stansfield and Caudle [82] reported an outbreak of wound colonization on a surgical orthopaedic hospital ward which they attributed to the use of disposable underpads containing virgin wood pulp.

Due to the paucity of published clinical data many technical tests have been devised to evaluate products in the laboratory. The only tests with published clinical validations are described by Cottenden et al. [74] who subjected six different bedpads to a variety of laboratory tests and to a multi-centre clinical evaluation in which 95 incontinent subjects tested each product in turn for a week, in random order.



Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Disposable inserts	• Carer is needed for pad change and user can stand (B/C) • Discretion is a priority (B/C) • Ease of putting on is a priority (B/C) • Female (B/C)	• Incontinence is heavy HEAVY (B/C) • Mobile and active (C)	
Disposable pull-ups	• Carer is needed for pad change and user can stand (B/C) • Reliable containment of leakage is a priority (B/C) • Ease of putting on is a priority (B/C) • Discretion is a priority (B/C) • Female (B/C)	• Removal of clothing for pad changing is an issue (B/C) • Low cost is a priority (B/C) • Night time use, with a carer (B/C)	
Disposable all-in-ones	• Incontinence is heavy HEAVY (B/C) • User can not stand for a pad change (B/C) • Male (B/C)	• Discretion is a priority (B/C)	
Disposable T-shaped pads	• Reliable containment of leakage is a priority (B/C) • Male (B/C)		
Washable bodyworns	• At night, if incontinence is heavy HEAVY (B/C) • Male (B/C)	• Adequate laundry facilities are not available (B/C) • The concept is unacceptable (B/C) • Discretion and appearance are a priority (B/C)	

Figure VI-18: Designs of pads for adults with moderate-heavy urinary incontinence. For definitions of light HEAVY and heavy HEAVY, see Section VI.4. (Grade of recommendation in brackets)

A combination of two laboratory tests (one to measure the absorption capacity and the other the absorption time of bedpads) gave a strong correlation with the percentage of subjects finding the leakage performance of a product acceptable when used as their sole protection (r = 0.94) and predicted the acceptability scores of all six products accurate to within ± eight percentage points. A different absorption capacity test produced a strong correlation for the leakage performance of bedpads used as back-up to bodyworn products (r = 0.96) and predicted the acceptability scores of all six products to within ± five percentage points.

a) Summary

No robust data are available on the effectiveness of current disposable bedpads or of their various design features or constituent materials. There is a risk of infection from bedpads made from recycled paper for immunocompromised users (**Level of evidence 2**). The leakage performance of bedpads (used alone or as back up to bodyworn pads) can be predicted with reasonable precision using clinically-validated laboratory tests (**Level of Evidence 2**).

b) Recommendations

- Disposable underpads should not be used for long-term management of incontinence, but have a useful role as temporary protection for chairs and beds during clinical procedures (**Grade of Recommendation C**).
- Immunocompromised people should not use bedpads made from recycled paper because of the risk of infection (**Grade of Recommendation B**).
- Where possible, clinically-validated laboratory tests should be used to rank the likely leakage performance of different products (**Grade of Recommendation B**).

c) Research priorities

Disposable underpads have a limited role in continence management but are known to be widely used. An exploration of patient views regarding their use may help demonstrate their limitations.

9. WASHABLE UNDERPADS

Aspects of assessment that are particularly important regarding washable underpads are patient acceptability and preference, particularly with regard to willingness to be naked below the waist (if sole use intended) and availability of laundry and drying facilities.

Cottenden [83] has reviewed comparative evaluations of different washable bedpads up to about 1990. Leiby and Shanahan[84] have since published a study. Some evaluations have found significant differences between products relating, for example, to leakage performance and impact on skin health but none of the products evaluated is still available in the variant tested. In addition, compared products always differed from one another in many respects making it impossible to draw reliable generic conclusions relating to the products now available. However, the choice of topsheet material and the presence or absence of features like tuck-in flaps and integral water-proofing appear to be, primarily, matters of personal preference.

In institutional settings washable bedpads are commonly used by multiple patients and questions are often asked about the risk of cross-infection. Cottenden et al. [85] assessed the risk by determining the microbial content of 145 bedpads of five different designs after a night's use by incontinent adults, followed by laundering using a standard foul wash procedure which included heat disinfection at 71^{o}C for three minutes. Laundering destroyed all known pathogenic organisms, although some commensal flora were isolated in small numbers. It was concluded that foul wash laundry had left bedpads safe for multiple patient reuse with no demonstrable risk of cross-infection.

a) Summary

The literature contains insufficient robust data on which to base guidelines for choosing between washable bedpads. Choice of topsheet material and the presence/absence of design features like tuck-in flaps and integral/separate water-proof backing appear to be, primarily, matters of personal preference (**Level of evidence 3**). Provided an approved foul wash procedure is used, the risk of cross-infection between different users of a bedpads is very low (**Level of Evidence 2**).

b) Recommendations

- If considering using washable underpads for sole use (ie without a bodyworn product) the patient will need to be naked below the waist. Patient consultation and approval will therefore be needed (**Grade of Recommendation C**).
- Personal preferences of users with regard to topsheet material, tuck-in flaps and integral waterproof backing should be considered in making product selections (**Grade of Recommendation C**).
- Provided an adequate foul laundry wash cycle is used, the risk of cross-infection between successive users of washable bedpads is low and not a contra-indication for their use (**Grade of Recommendation B**).

c) Research priorities

- Comparison of washable underpads with bodyworn products when used at night.

10. ABSORBENT PADS FOR CHILDREN WITH URINARY AND / OR FAECAL INCONTINENCE

Most children are expected to achieve daytime dryness by the age of three [86]. However, some children take longer to become dry and some (e.g.

children with learning and physical disabilities) may never reach this goal. These children usually require absorbent products to contain leakage.

Aspects of assessment that are particularly important regarding bodyworn products for children are presence of faecal incontinence, day / night incontinence, level of independence with toileting, and use of aids (e.g. callipers).

To date there has been only one study of absorbent products for children and this has compared the diaper design with the newer pull-up design [87]. Sixty-one children with physical and / or learning disabilities tested five diaper products and five pull-up products, each testing each product for one week. The children were randomised to receive either the pull-up or diaper group first and individual products were tested in random order within each design arm. Parents completed a product performance questionnaire and a pad leakage diary to record wet weights and severity of leakage. Parents were asked to state their preference for a design for day and night use.

Findings indicated that generally, the diaper products performed similarly to each other and so did the pull-up products, although there were some statistically significant differences between products within each of the two design groups. Overall diapers were preferred for night-time use by the majority of parents. By contrast, 40% of parents preferred pull-ups for daytime use and these were found to be particularly appropriate for older children and those who were attempting independent toileting, provided they did not have faecal incontinence and did not wear callipers or adapted footwear. Diapers were more suitable for children who were dependent on carers and / or had faecal incontinence, and wore callipers or adapted footwear. The authors recommended that both diapers and pull-ups should be supplied for children, with pull-ups (which are about 50% more expensive than diapers) being provided for selected children during the daytime.

a) Summary and recommendations

Diapers and pull-ups meet different needs of children and both should be made available to children with disabilities, dependent on assessment **(Level of Evidence 3 / Grade of Recommendation C)**.

b) Research priorities

Comparison of washable and disposable bodyworn products.

11. PADS FOR FAECAL INCONTINENCE

Most absorbent products are designed for urinary incontinence. No studies comparing available absorbent products for faecal incontinence were found. Bliss et al. [88] reported preliminary findings of a survey of the use and evaluation and suggested modifications of absorbent products for faecal incontinence by 188 community-living persons with the problem. Forty-five percent of persons used an absorbent product for FI. Ninety-eight percent of those with UI and FI used the same type of product for both. Suggested improvements in product designs included having better odour control, fit, and ability to stay in place; a clearer distinction between the front and back of a pantiliner or pad; adding wings for greater absorbency; and making them flushable, cooler feeling, wider and longer in the rear and more absorbent but less bulky. For mild faecal incontinence, especially when faeces remain between the buttocks without soiling underwear, persons have used a small disposable gauze surgical dressing placed between the buttocks. This product was more acceptable than a pantiliner or pad to some men [88] (**Level of Evidence 2**).

a) Recommendations

- A disposable gauze dressing that can be placed between the buttocks maybe acceptable for men with light faecal incontinence (Level of Recommendation C).

b) Research priorities

- Better designs of products are needed for light and moderate FI (with and without UI).

12. GENERAL RECOMMENDATIONS ON PAD SELECTION

- *Individuality*: No study has ever identified one product that worked best for all testers: needs and priorities vary. Accordingly, users are advised to try a variety of products when possible (**Grade of Recommendation B**).
- *Brand differences*: The individual product brands within a design group often exhibit a wide range of performance and acceptability for individuals, and it cannot therefore be assumed that pads of different brands but broadly similar design will be equally acceptable or effective (**Grade of Recommendation B**).
- *Combinations of designs*: Absorbent products vary greatly in price and performance and suitability for individual needs. Users may therefore find combinations of designs preferable and cost-effective. For example, women might use pull-ups (expensive, but discreet and good for leakage) for going out, and inserts (cheap, less good for leakage) for staying at home. Men might use disposable diapers for daytime, and washable terry-towelling products for night-time (**Grade of Recommendation B**).
- *Freedom from leakage*: In general, pads containing superabsorber should be selected in preference to those without (**Grade of Recommendation B**). Nobody wants their pad to leak but compromises have to be made: the pad needed to contain a person's most severe accident may be substantially more bulky and expensive than is needed most of the time. Some users choose to

tolerate a higher risk of pad leakage in exchange for being able to use cheaper, smaller (more discrete) pads. The balance of priorities for a given user should be investigated in making product selections (**Grade of Recommendation C**).

- *Comfort and skin health*: In general, pads containing superabsorber should be selected in preference to those without (Grade of Recommendation B). Shaped pads should usually be selected in preference to unshaped (**Grade of Recommendation C**).

- *Staying in place*: No product is effective if it slips from position. Inserts should be used with pants, preferably mesh pants (Grade of Recommendation B). Robust, stretch (e.g. cotton / lycra) pants may also help to provide a snug fit and minimise leakage. Shaped pads are preferable to rectangular (**Grade of Recommendation C**).

- *Ease of putting on and taking off*: The ease of putting pads on and taking them off should be considered, especially for caregivers and for incontinent users with reduced mobility or dexterity (**Grade of Recommendation C**).

- *Aesthetics and discretion*: A possible preference for small, more discrete pads (even if they are more likely to leak) should be considered, especially for those wishing to wear close fitting clothing (**Grade of Recommendation C**). The possibility of plastic backing materials rustling noisily should be considered (**Grade of Recommendation C**).

- *Independence and lifestyle*: The ability of a user to change his / her own pad should be considered (**Grade of Recommendation C**): those able to change their own pad can often manage with a smaller (less absorbent) one than those reliant on a caregiver. Users who travel should consider in their choice of product(s) the practicalities of carrying a supply of pads, disposing of used ones, and dealing with laundry (**Grade of Recommendation C**).

- *Costs*: Cost issues should be approached with caution (**Grade of Recommendation C**). Expensive pads do not necessarily work better than cheaper ones. Cheaper pads do not necessarily save money. If pads leak more they may have to be changed more frequently and / or lead to higher laundry costs. More pad changes will mean increased caregiver workload. However, more absorbent pads will not necessarily reduce pad consumption rates: pads are often changed according to ward or personal routine.

13. RECOMMENDATIONS RELATING TO WASHABLE PADS

- Laundry issues: Access to good, reliable washing and drying facilities should be checked before washable products are introduced (Grade of Recommendation B). Laundry – especially of bedpads – can be heavy work, beyond the capability of frail incontinent people or their caregivers. The number of washable products needed per user depends on laundry turn-around times. Drying times for washables can be long and expensive, especially for bodyworns for heavy incontinence and for bedpads.

- *Personal preferences*: Personal preferences (of both users and caregivers) with regard to choosing between washable and disposable products should be taken into account carefully (**Grade of Recommendation C**). Some users prefer the chore of laundering washables to anxiety over whether their next consignment of disposables will be delivered on time. Washables generally require less storage space than disposables. Discreet disposal of disposables can be a challenge. The possibility of using a mix of disposable and washable products should be considered (**Grade of Recommendation C**). Some users who choose disposables when at home prefer washables when travelling because of the space that disposables occupy in luggage and the possible inconvenience of disposal. Others use washables at home and disposables when away as they see the balance of disadvantages and advantages differently.

- *Personalisation of products*: In institutions, the chore of personalizing washable products and sorting them after each laundry cycle should be considered before they are introduced (**Grade of Recommendation C**). Washable bodyworns are often personalised to particular users. In institutions this means marking products with users' names and sorting them after laundry, an extra task for caregivers. Washable bedpads are not usually personalised.

- *Staining*: Washable products should not usually be used by those with faecal incontinence – beyond occasional light smearing – because of staining (**Grade of Recommendation C**). Skin sprays and ointments may stain washables too.

- *Costs*: Cost comparisons between washable and disposable products should be made with caution (**Grade of Recommendation C**). Key factors are: local arrangements (mostly laundry and transport costs); the durability of the products (which depends on how carefully they are used and the criteria for deciding when they should be replaced); the costs of ordering, transporting and disposing of disposables; and product purchase costs. Much of the cost of washables is encountered with the initial capital outlay for stock. This also represents a commitment to use the products for an extended period and so expensive mistakes can be made if it transpires that a better product was / has become available. It will usually be wise to experiment with samples of a variety of alternative products before committing to major purchases.

VII. SHEATHS

Close-fitting penile sheaths (sometimes called condom catheters, uridomes or external catheters) are commonly used male incontinence devices and they are used in combination with a urine drainage bag. They are suitable for males who are experiencing moderate to heavy urine loss, or have limited mobility and are experiencing frequency and urgency and may even be considered in combination with intermittent catheterisation (IC) for males who are leaking urine as a consequence of bladder emptying problems. Sheaths may not be suitable for males who are experiencing confusion, considered psychologically vulnerable or have decreased sensation through spinal cord injury [89], [90], [91]). There is strong opinion expressed in the literature that suggests assessment, selection and use of penile sheaths and the accompanying urine drainage systems needs to be undertaken with the guidance, education and monitoring of health professionals who have a knowledge of continence products. Failure to do so, according to this expert opinion [[90], [92], [91]], may result in serious penile trauma, impaired penile skin integrity and leakageof urine.

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important in relation to sheaths include: physical, mental, cultural, gender and socio-economic factors. This incorporates assessment of the cognitive and dexterous ability of the male or carer to apply the sheath and empty the drainage bag, the integrity of the penile skin, length and circumference of the penis and whether it is retracted, or retracts on sitting or bending down, history of latex or adhesive allergy and, most importantly, recognition that the assessment from the health professional needs to be ongoing. It is also important to assess factors known to encourage or discourage sheath usage. Expert opinion [[93], [90], [94]] suggests factors that encourage usage include: level of reimbursement, cultural expectation, resonance with masculine image, and ability to keep urine off the skin when the skin integrity is at risk because of incontinence. Factors which they suggest discourage usage include: ignorance of product efficacy by professionals and consumers and embarrassment between carer and client.

An effective sheath is one that stays securely in place for an acceptable period of time, is leak-free, comfortable to wear, easy to apply and remove, avoids skin damage and channels the urine effectively into a urine drainage bag.

1. PRODUCT CATEGORIES AND FEATURES

Sheaths come with a variety of features (**Figure VII-1**) of which the following are the most important to consider in making selections:

- Material: sheaths may be made from latex, silicone rubber or other synthetic polymers. Some men will be allergic to latex.
- Size: most sheaths are supplied in a range of lengths and sizes. Most companies supply them with diameters in the range of about 20 – 40 mm, in 5-10 mm increments.
- Adhesive: the adhesive may be integral to the sheath (one-piece systems) or come as a separate strip or spray (two-piece systems). Some men will be allergic to some adhesives.
- Applicator: some sheaths come with an applicator intended to help users and carers to put the sheath on.
- Anti-kinking / twisting features: some sheaths come with features intended to improve drainage by reducing kinking and twisting at the distal end, near the connection to the drainage bag tube.
- Anti-blow-off features: some sheaths come with features intended to reduce the likelihood of the sheath blowing off at high urine flow rates, for example, at the beginning of a void (eg the distal end of the sheath may be thickened and bulbous to stop the internal walls sticking to one another between voids).
- Connection to the drainage bag: some sheaths come with features intended to increase the ease and security of connection to the drainage tube (eg a push ring or ridge at the end of the outlet tubing)
- Retracted penis features: with or without specific features intended to accommodate a retracted penis (eg a shorter sheath or a wider adhesive seal).
- Durability: some sheaths are intended for use over a limited time period (eg 24 h) while other (generally, more robust) designs are intended for extended wear.
- Transparency: some sheaths are transparent allowing for observation of the condition of the skin along the shaft and glans of the penis.

2. QUALITY OF DATA

Some controlled comparative evaluations of different sheaths have been performed; one extensive market survey to identify the needs and priorities of sheath users; and two studies comparing sheaths with other product categories (versus indwelling urethral catheter, and versus absorbent pads). Other studies report on the problems encountered by various groups of sheath users.

3. RESULTS

Although many men use sheaths successfully, problems have been reported in the literature. In a study on an unspecified number of spinal cord injured men, Golji [95] found that 15% experienced side effects or complications when using sheaths. These were irritative, allergic or compressive in

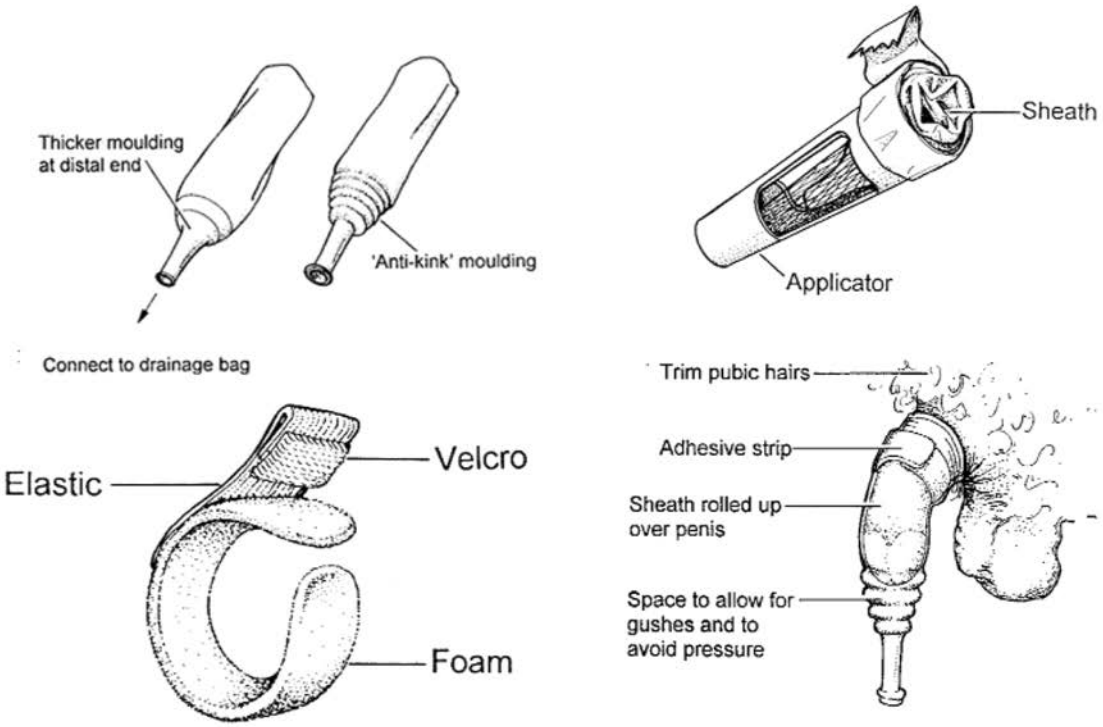


Figure VII-1: A variety of sheaths (top left and bottom right), a sheath applicator (top right) and an external fixation strip (bottom left).

nature. Jayachandran et al. [96] reported similar experiences with six incontinent men of widely varying aetiology and highlighted the importance of ensuring that the sheath does not become twisted near the distal end to avoid stagnation of urine and the risk of UTI. They also stressed the importance of good genital hygiene to avoid problems with infections. In a study of 94 men on medical / surgical wards, Hirsh et al. [97] found that none of the 79 who were judged as co-operative and able to manage their sheaths properly developed UTI (mean period of use, 21.2 days). By contrast, eight of 15 patients who tended to tug and kink the drainage tube attached to their sheath developed UTI within a mean of 9.6 days. In a retrospective study, Johnson et al. [98] compared the frequency of UTI in users (mean period of use, 35 months) and non-users of sheaths amongst 64 elderly men on an extended care unit. He found that 63% of users but only 14% of non-users developed UTI. No difference was found between men who did and did not tug and kink their tubing. Ouslander et al. [99] reported that 40% of 30 nursing home sheath users (mean period of use, 35.9 months) developed at least one UTI. The need for proper fitting of the sheath and regular monitoring of the skin integrity of the penile shaft, glans penis and prepuce of males who are regular sheath users has been highlighted in two articles that report a combined total of eight cases of fibropithelial polyps of the glans penis and prepuce of which six had a history of long term sheath use [92] [100].

A trial to compare sheaths and indwelling catheters in terms of infection, risk and patient satisfaction has been reported by Saint et al [101]. This was a prospective, randomised, unblinded, controlled trial which compared one type of sheath drainage with one type of indwelling urethral catheter using a small group of participants (N=75) across several locations in one hospital. There are important limitations of the study, including the low numbers drawn from a specific population, and the lack of comment on the changing / care routines associated with the sheaths and catheters. After making adjustments for age, mental score, history of UTI and history of catheterisation the conclusions of the study were that for males without dementia the use of sheaths has the potential to reduce infection compared to indwelling catheters and is more acceptable to patients in terms of comfort and pain. For males with dementia no significant difference in infection rates was found.

There has also been a cross-over trial [47] comparing sheaths with absorbent pads when used by men with moderate to severe UI (N=61). Products were used for two weeks each and the Kings Health

Questionnaire was used as the primary outcome measure. Scores for the sheath system were significantly better than for the pads on most domains and the number of men preferring sheaths was significantly higher than for pads.

Nichols and Balis [102] reported the results of a survey undertaken for marketing purposes of an international cohort of 216 men who had used sheaths for at least three years, and their carers. Their responses to 19 brands of sheath were gathered using a questionnaire in the form of a Likert scale. It was found that catheter security (presumed to mean staying in place and freedom from leakage) was the most important issue for both wearers and carers, followed by comfort and ease of application and removal.

There have been a number of comparative evaluations of different sheaths. Peifer and Hanover [103] reported on an evaluation in which 20 men compared a new branded sheath system that consisted of three ed parts: a tubular sheath impervious to urine with a drainage tube connection at one end and a ring at the other; an undergarment with a frontal opening through which the penis is extended; and a ring-like collar which is used to keep the sheath and penis in the correct position, with the variety of external sheaths they had previously been using. The participants were a convenience sample identified through pharmacy medication files. In all, 32 men were approached and 20 consented, all experienced users of urinary sheaths. A questionnaire was developed to test the participants pre and post intervention. The new sheath – which was used for a week - proved more popular with the participants: it was judged to provide superior security (13/20 experienced increased dryness by day; 10/20 by night), and considered easier to apply (19/20) and remove (20/20).

In a multi-centre study involving 35 men (age range 22-87y; mean age, 54y; 34 living in their own homes), the UK Medical Devices Agency [104] compared four latex sheaths: two with integral adhesive; and two in which the adhesive was supplied as a separate strip. They found the products with integral adhesive to be more successful in both overall performance and ease of application. Fader et al. [21] conducted a multi-centre study to compare all six sheaths with integral adhesive on the UK market in 1998. Five were made from latex, one from silicone rubber. Four were supplied with an applicator, two without. Fifty-eight men (age range 26-88y; mean age 53y) were given the opportunity to try each sheath in turn for one week. The silicone rubber sheath was found to be significantly better than four of the other sheaths in overall performance ($p<0.01$). The ease with which a sheath could be put on was found to be the best predictor of overall performance. Surprisingly, sheaths with an applicator were found to be unacceptable to a significantly higher proportion of subjects than sheaths without an applicator ($p<0.0001$). Subjects found that the silicone sheath fell off / blew off significantly less frequently than two of the other products ($p<0.01$).

Pemberton et al [94] report a randomised prospective open crossover design trial to test user preference for an established one-piece silicone rubber self-adhesive sheath with a new one-piece silicone rubber self-adhesive sheath in a study sponsored by the distributor of both products. To be included the males had to be currently using at least one, one-piece urinary sheath, per day. Fifty three males from seven centres participated in the trial and were each given 10 sheaths of each product. Data from the 44 participants who had evaluated at least three of each product were analysed. No reason was given for why nine males did not complete the trial. The data shows that there were some problems with both products, however, it is difficult to understand why the new product was preferred, as the report does not mention any differences in the features of the two products.

Watson & Kuhn [105] describe a crossover study with six male participants that found the choice of leg bags may influence the performance of penile sheaths. Goldyn, Buck and Chenelly [106] conducted an exploratory study on 10 patients in an extended care hospital to consider the efficacy of a brand name external sheath and a hospital constructed sheath. The brand name sheath was found to be more secure and the preferred nursing choice but it was recognised that the hospital-constructed sheath was useful for patients with fragile skin and limited mobility. A study by Saint et al. [107] provided further evidence (although low level) to support the importance of security and comfort to sheath users. Using questionnaires, they interviewed a convenience sample of 104 older men (response rate = 90%) and surveyed 99 nurses (response rate = 92%) about the relative merits and problems of sheaths and indwelling catheters. The study population was drawn from a university-affiliated Veterans Affairs Medical Centre in the USA. The patients using the sheaths were more likely to believe their product was comfortable ($p = 0.04$) and less likely to believe it was restrictive ($p = 0.002$) or painful ($p = 0.008$) than those using an indwelling catheter. This viewpoint was supported by the nurses surveyed, the majority of whom (no numbers given) believed that sheaths were more comfortable and less restrictive than indwelling urinary catheters for male users, but required more care time because they fell off or leaked.

4. SUMMARY

For incontinent males, sheath drainage can provide a good alternative to pads. However, the increased risk for complications such as local skin breakdown, bacteriuria and infection - especially in the frail confused elderly male – should be borne in mind (**Level of Evidence 2**). Also, there is the risk of urinary retention if the condom twists or the external band is

too tight, leading to poor drainage to the urine bag (**Level of Evidence 3**). Sheaths with integral adhesive are more popular with users and easier to apply than those with separate adhesive strip (**Level of evidence 2/3**). Secure fixation and the ease with which a sheath can be put on are the best indicators of its overall performance (**Level of Evidence 2**). Sheath applicators are often ineffective and unpopular (**Level of Evidence 2**). There can be considerable differences in performance between products with somewhat similar designs (**Level of Evidence 2**).

5. GENERAL POINTS FROM THE LITERATURE, INCLUDING EXPERT OPINION

- Prior to applying the sheath, ensure any remaining adhesive or barrier cream is removed from the penis and that it is thoroughly washed with soap and water and thoroughly dried.
- Trim long pubic hairs to prevent them being caught up in the adhesive.
- Protective skin wipes can be used to protect the skin, but make sure the skin has dried properly before applying the sheath.
- Leave a gap at the end of the sheath between the glans penis and the drainage tube to avoid trauma to the glans / prepuce. However, make sure the gap is not too large such as to cause kinking or twisting of the sheath [108].
- After the sheath has been applied, snip any reinforced ring or unrolled section of sheath sitting at the bottom of the shaft of the penis.
- Penile sheath removal should not be rushed and is made easier by gently rolling it off while bathing the penis in warm soapy water.

6. RECOMMENDATIONS

- Since there can be considerable differences in performance between products of similar design, men should be given the opportunity to experiment with different products before making a final selection (**Grade of Recommendation B**).
- The key performance characteristics which should be considered in selecting products are: security (ie ability to keep a leak-proof seal and channel urine to the drainage bag without leakage) and ease of putting the sheath on and taking it off (**Grade of Recommendation B**).
- In general, sheaths with integral adhesive (one-piece systems) should be selected rather than those in which the adhesive is supplied separately (two-piece systems) (**Grade of Recommendation C**).
- It should not be assumed that a sheath applicator will make sheath application easier: often it does not (**Grade of Recommendation B**).
- Potential sheath users should be asked if they have an allergy history and regular users should be routinely checked as their latex allergy status can change over time and with continued use. (Some health settings are moving to reduce or eliminate latex usage whenever possible and some manufacturers have moved to offer non-latex sheaths) (**Grade of Recommendation C**).
- Sheath users should be monitored for skin health, tissue damage and UTI (**Grade of Recommendation C**).
- When possible the external sheath rather than indwelling urethral catheter should be the urinary collection device of choice. (**Grade of recommendation B**).

7. PRIORITIES FOR RESEARCH

- Although products are continually being developed, changed, withdrawn and released, comparison studies that are controlled and use multiple sites to achieve larger numbers are recommended to further evaluate the effectiveness of the variety of sheaths available.
- More comparative studies of the risks of complications between the use of sheaths, pads and catheters are required.
- Since leg bag features may influence the performance of the sheath, further evaluation of design features claimed to reduce twisting and kinking at the drainage bag connection site and increase ease and security of connection to drainage bags is required.
- Well designed studies to generate and validate procedures to help identify the type of sheath most likely to suit an individual are needed.

VIII. URINE DRAINAGE BAGS AND ACCESSORIES

Urinary drainage bags are attached to an indwelling catheter or penile sheath to collect and store urine. Features of effective drainage bag systems include ease of operation of all components (connectors, taps, and support devices), comfort and discreetness.

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important regarding urine drainage bags are patient / carer dexterity [90] [109], and eyesight. Both are necessary to manage the urinary drainage bag system, including using the outlet tap to empty the drainage bag. It is also important to assess the patient's preferred and usual mode of dress [90] [109]; for example, a male whose preferred mode of dress is shorts will want a drainage system that is not visible and allows easy access for emptying,

1. PRODUCT CATEGORIES AND FEATURES

Urine drainage bags fall into two major categories:

leg / body worn bags for day-time usage; and large capacity body-free bags for night-time use (night drainage bag) which are suspended from a stand or bed hook.

Leg / body worn bags come with a variety of features of which the following are the most important to consider in making selections:

- Volume: most bags have a volume in the range of 350-750 ml, but some are bigger.
- Material: most bags are made from transparent PVC (polyvinyl chloride) but PVDF (polyvinylidene fluoride, less noise from rustling), polyethylene or rubber / latex may be used.
- Sterility: bags may or may not be supplied sterile.
- Wear position: bags may be designed for wearing over the knee, across or down the thigh, down the calf, or against the abdomen.
- Attachment / suspension system: most leg bags are attached to the leg with straps, which are usually made from latex or a (usually elasticated) fabric. A variety of hooks, loops, buttons / button holes and Velcro may be used to secure straps and to attach bags to straps. Some bags are designed to be suspended around the waist. Some straps and suspension devices can be bought separately from bags, but they are generally not suitable for use with all bags (**Figure VIII-1**).
- Connecting tube: bags come with a variety of connecting tube lengths (eg the length required for wearing a bag on the calf will be greater than that for the thigh). With some products the tube can be cut to the preferred length.
- Drainage tap: Drainable bags come with a variety of drainage tap designs (**Figure VIII-2**).
- Sampling port: bags may or may not have a sampling port in the drainage tubing for taking urine specimens.
- Comfort features: some bags come with features intended to increase comfort – most commonly, a fabric backing against the skin to reduce sweating.
- Discretion features: some bags come with features intended to increase discretion – most commonly, internal welds between the front and back faces to reduce bulging and / or sounds caused by a large volume of liquid moving about as the user mobilises.
- Anti-kinking / twisting features: some bags come with features intended to improve drainage by reducing kinking and twisting in the connecting tube.
- Infection reduction features: some bags come with features intended to reduce the risk of infection for the self-carer and cross-infection between bag users by care givers. Such features may include; a non-return flap valve, designed to help reduce reflux of urine up the tubing when the bag is moved by users or carers, a sampling port and / or a tap with an outlet sleeve which allows the overnight bag to be connected to the body worn bag. This linkage provides a mechanism to maintain a closed catheter drainage system designed to minimise the risk of cross-infection by reducing the handling of the catheter. Having connected the night bag to the leg bag sleeve, the leg bag tap is opened and urine flows freely from the sheath or catheter through the leg bag into the night drainage bag. Pre-sealed drainage systems to prevent breaking the closed system are also available, and these could be beneficial in reducing time to bacteriuria [110].

Night drainage bags are usually held on a suspension system away from the body. They may be connected directly to the catheter or sheath or they may be connected to the drainage tap of the leg / body worn bag to avoid the need for repeated connections and disconnections with the catheter or sheath (**Figure VIII-3**) ie a closed-link system. They usually have a capacity of 2000-4000 ml and come with a variety of design features many of which are similar to those for leg / body worn bags. Night drainage bags are available as non-drainable bags (NDB) i.e. without a tap for single use as well as with a variety of drainage tap designs for emptying and reuse. Glass bottles are also available for high volume or overnight urine drainage. It has been suggested that current standard drainage tubing / bag designs evacuate the bladder sub-optimally, leading to retention of residual urine. Outflow obstruction can be caused by the development of air-locks in the dependent curls of tubing. A new drainage tubing design which incorporates a coiled downward-spiral-shaped configuration has been reported to eliminate air-lock obstruction [111] in experimental and clinical studies. However the importance of this in relation to infection requires further study.

2. QUALITY OF DATA

Several controlled comparative evaluations of urine drainage bags and suspension systems have been performed, as well as a small number of studies addressing infection and cross-infection issues There are also two case-controlled studies which have investigated the purple urinary bag syndrome.

3. RESULTS

a) Evaluations of urine drainage bags

A randomized cross-over design compared use of a standard latex drainage bag with a cloth covered bag in 42 men with post prostatectomy incontinence [112]. Each bag was tested for about 4-5 days, and complete data were provided by 30 individuals. People with known latex allergy were excluded. Measures included adapted questionnaires for Leg Bag Evaluation and Skin Health. A statistically significant preference was found for the

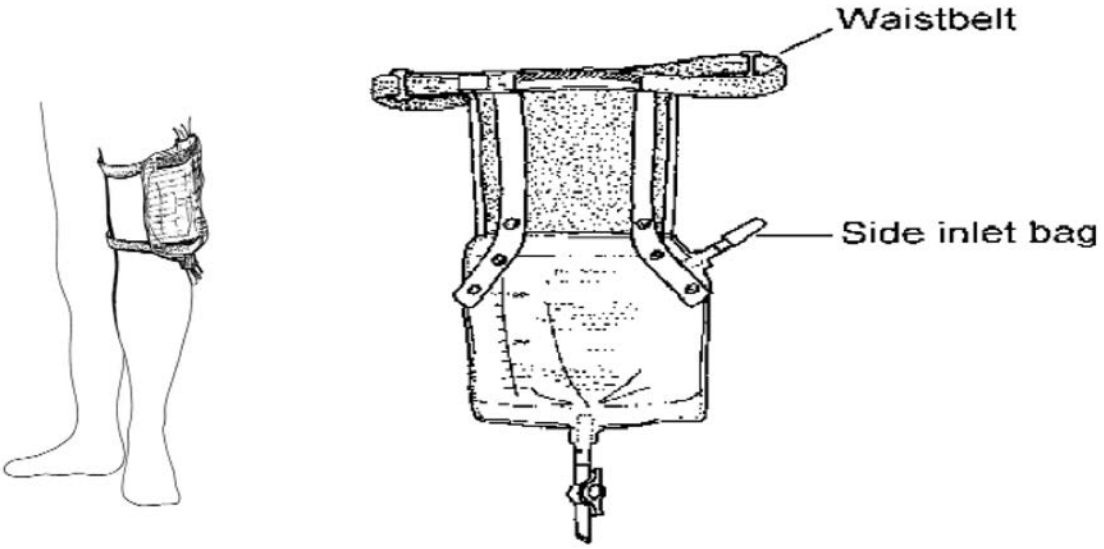

Figure VIII-1: Body worn urine drainage bags held in place using leg straps (left) and a waist band suspension system (right).

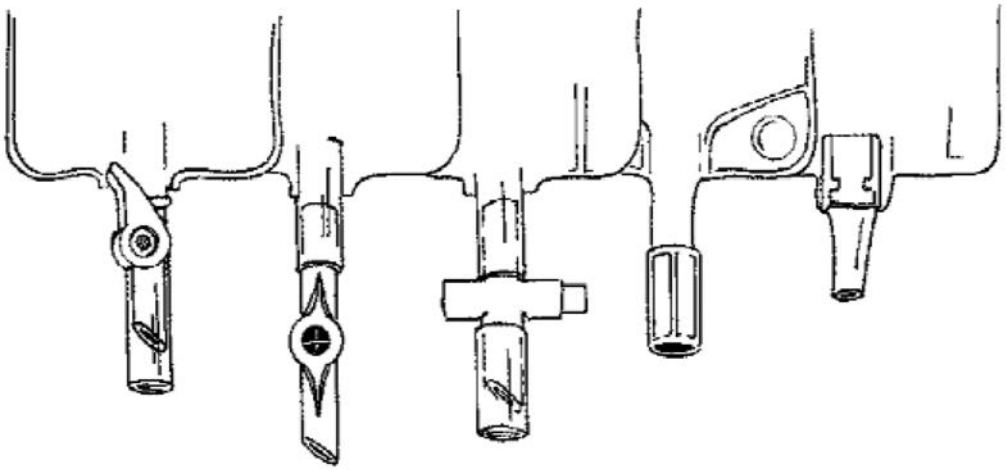

Figure VIII-2: A variety of urine drainage bag tap designs.

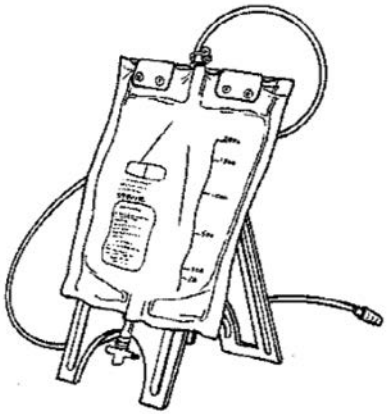

Figure VIII-3: A night urine drainage bag on a stand.

cloth covered bag with a main effect ($F= 36.614$, $df = 1.28$, $p<0.01$) as well as an effect related to the order provided ($F= 8.398$, $df = 1.28$, $p<0.01$). That is, those who used the cloth bag first had a stronger preference for it than those allocated to the latex bag first. The cloth backed bag seemed to have several positive features, including comfort under the bag and cloth straps, flexible adjustable tubing, and taps that did not cause urine spillage on fingers. But these bags had a tendency to slip down and pull on the catheter. Two persons using the latex bags had minor skin irritation, one a rash related to the straps pulling on hairs on the leg and the other minor redness and swelling which resolved within 24 hours.

Kennedy et al. [113] tested the performance of ten different drainage bags in a simulation study involving 40 subjects (mostly health-care staff) which focused particularly on taps. Significant differences ($p<0.05$) were found between many pairs of bags with regard to each of the performance aspects studied: ease of tap opening and closing, ability to empty the bag without urine wetting fingers; and how easy the tap mechanism was to understand. Taps comprising caps or bungs were found to be particularly fiddly and messy to use.

In a study which focused primarily on the cross-infection risks associated with leg bags, Wilson and Coates [114] evaluated four leg bags. Each of ten long-term catheterised patients was invited to try each bag for a week in turn. The authors concluded that no one bag suited every patient; rather, each was liked by some users. The popularity (or otherwise) of many features was a matter of personal preference. Adverse comments mostly related to the tap (difficult to operate, opened accidentally, causing leakage) and the straps.

The UK Medical Devices Agency [115] evaluated all 14 sterile 500 ml leg bags on the UK market in 1995 in a multi-centre study involving 83 test subjects (58 men, 25 women). About half (44) lived in their own homes and almost all the rest in nursing / residential homes. Subjects were divided into pairs matched for sex, mobility, manual dexterity and dependency and each pair was offered each of the 14 bags (seven each) to try for a week in turn. Preferences varied but the main concerns of users consistently focused on taps (many subjects found many taps difficult to operate), straps (discomfort was common) and the minimisation of leakage (through faults in bags and / or connectors; onto the fingers when emptying; or by the tap accidentally opening in use). The most popular bags tended to perform well in these three respects.

In a multi-centre study involving 34 men (age range 27-84y; mean age 55y; all sheath users) Fader et al. [116] evaluated all seven non-sterile 500-700 ml leg bags on the UK market in 1997. Twenty-five of the men lived in their own homes and the rest in residential/nursing homes or long stay wards. Conclusions were substantially similar to those for the earlier MDA study.

Some international standards have been developed which provide general advice on bag performance and test methods [53]. These standards can be useful to laboratories asked to advise on bulk buying choices.

b) Urine drainage bag suspension systems

Little research has been undertaken on urinary drainage bag suspensions apart from a study by Thelwell et al. [117]. Thelwell et al. conducted a cross-over study using 52 subjects (20 men, 32 women). This study compared four suspension systems for fastening leg bags with the leg straps they had used prior to the study. Each subject evaluated each product for a week in turn and recorded their findings on a weekly questionnaire. Again, difficulty of application, comfort, discreteness and cost were key issues. However, there is suggestion in the literature that urinary drainage bag suspensions have an important role to play not only in the comfort and security of the wearer but in the prevention of urinary tract infection regardless of whether the drainage system is connected to a sheath or an indwelling catheter.

Munnings and Cawood [118] report the findings of a pilot study designed to evaluate the use of a belly bag of 1,000ml capacity and worn 24 hours a day, thus eliminating the need to use two separate bags and reducing the number of times the closed system is broken, Twenty-nine patients from a variety of areas from within an acute care setting who were using continuous catheter drainage systems were invited to participate, with 27 of the participants completing the study. All agreed to wear and then compare the belly bag with their previous leg and night drainage bag system. Worn around the waist, the belly bag is not positioned below the bladder: the manufacturers claim that the pressure of the bladder muscles is sufficient to ensure that urine flows through the catheter from the bladder into the bag. The residual pressure of the bladder is reported to be around 10-25cm H_2O, while the manufacturer asserts that a pressure of only 6cm H_2O is necessary to ensure the urine drains into the bag. Following education of how to use the drainage bag, users were given a questionnaire designed to facilitate comparison between the previous drainage system used and the belly bag. This was followed up with a telephone call. All agreed the belly bag was an improvement over their previous system of leg and overnight drainage bags, and found it more convenient, comfortable and less likely to cause pain with movement.

It has been suggested that current standard drainage tubing / bag designs evacuate the bladder sub-optimally, leading to retention of residual urine. Outflow obstruction can be caused by the development of air-locks in the dependent curls of tubing. A new drainage tubing design which incorporates a coiled downward spiral shaped configuration has been reported to eliminate air-lock obstruction [119] in experimental and clinical studies. However the importance of this in relation to infection requires further study.

There is opinion in the literature that positioning standard drainage bags below the bladder in a

manner that averts kinking will prevent reflux of urine, and associated infection [120], [121], [122]. When doing so care must be taken not to increase traction or friction [109]. This can be achieved with the use of supports specially designed to divert accidental pulling on the catheter or sheath. When using these support systems allowance should be made for penile erection and tumescence [109].

The drainage system for indwelling catheters should be positioned off the floor to reduce the risk of cross infection [120], [121], [122]. Some sterile and unsterile leg bags come with a variety of tubing lengths or tubing that can be cut according to the needs of the individual, and leg straps that can be adjusted to allow positioning of the bag on the thigh or calf. Night bags - even if the tubing can be cut - rely on uniform stands or hangers to ensure that they are off the floor. Roe et al [123]) raised the issue of poorly designed support systems for night bags. Expert opinion suggests that this still remains an issue.

c) Infection and cross-infection issues for management of urine drainage systems for indwelling catheters.

Usage of urinary catheters and their drainage systems increases the risk of urinary tract infection and cross infection (See Section XII.2.h). There is evidence to suggest that catheter associated infections are reduced with the use of closed urinary drainage systems. A randomised controlled trial was reported by Platt et al [124]. This trial compared the incidence of infection (measured as 10^5 cfu/ml in catheter urine or drainage bag urine) between patients who were catheterised using sealed junction catheters (i.e. catheters pre-connected to a drainage bag using a sealed junction), and those catheterised using unsealed junction catheters (i.e. unconnected catheters and drainage bags), in a hospital setting with a median period of catheterisation of three days. For subjects not taking antibiotics, sealed junctions showed less infection than unsealed ($p=<0.01$). For subjects taking antibiotics there was no difference in infection rates between sealed junctions and unsealed junctions. The infection rate appeared to be consistently lower in the subjects taking antibiotics than the ones not taking antibiotic but no statistical significance tests of this effect were reported.

Maintaining a 'closed' system has since become an important tenet for avoidance of urine infection both particularly in acute care but also in long-term care. This has led to the introduction of products designed to maintain a 'closed' system. In the UK the 'link' system is advocated whereby legbags are designed with a connector to attach to a night drainage bag, thereby obviating the need to disconnect the legbag from the catheter in order to connect a night bag. Use of non-drainable (single-use) night bags is also recommended in the UK (RCN 2008) presumably to reduce the cost of using a new (and more expensive) drainable night bag every night and also to avoid the practice of cleaning and re-attaching drainable night-time bags. However it should be noted that this 'link' system is not completely 'closed' (because the night bags are still disconnected and reconnected every night – albeit at the legbag tap rather than at the catheter) and the legbag may still be disconnected at the catheter junction for other purposes such as bladder instillations.

If a 'link' system is not in use then whenever a legbag needs to be changed to a nightbag the bag will need to be disconnected at the catheter junction. The bag (leg or night) may then be replaced (or more commonly) will be cleaned and reused. As yet there have been no studies to compare the use of the 'link' system with a conventional disconnection system.

The number of days that a legbag may be safely (or acceptably) left in place before it is replaced is unknown. There is little research to support the common practice of changing drainage bags every five to seven days (or any other particular change regime). The practice appears to be based upon expert opinion, anecdotal evidence and manufacturers' recommendations. The five to seven day practice seems to be challenged by a study by Rogers et al. (1996) [125],of biofilm progression,which showed that it took only four days for colonization in the bladder model to extend all the way to the drainage bag (Royal College of Nursing, 2008).

A prospective study of catheter use in the US, of 43 long-term catheter users, indicated that drainage bags were changed less often than either commonly reported, or Rogers et al. suggest. In that study, drainage bags were replaced an average of every 23.5 (95% CI 21.1-25.9) days, during their six months' participation in the study [126].

Of interest is the study outlined by Keerasuntonpong et al. [127] which was a randomized controlled study that compared the incidence of catheter-related urinary tract infections in a group of 79 hospitalised patients whose catheter bag was changed every three days with that for a group of 74 patients who had their bag changed at the time of the catheter change or if the bag became faulty. A urine sample for culture was obtained for each participant every seven days, on the day the catheter was removed or on the day the participant was suspected of having an infection. The findings suggest that urinary drainage bags could be left for longer than three days but the authors were reluctant to define how long as the sample size was considered too small to rule out a false-negative result. They recommended additional study.

Single use drainage bags, including non-drainable urine bags (NDB), were recommended in England's Royal College of Nursing Catheter Guidelines (2008) for all sites of care (hospital based and community living patients). Only one study was found of this product. Hardyck and Perrinovich (1998) [128] described a retrospective home care trial of a NDB in 63 elderly patients, comparing with the same persons who had used a typical drainable bag (DB) in the previous months. The non-drainable bag was replaced when full, but no information was given about the capacity of the bags, the mean number of bags used per day or how often they were replaced. Fewer UTIs (and hospitalizations) were reported with the NDB, 71 (2) versus 1395 (27) in the DB. Unfortunately the methodology was flawed in several ways. Counts of UTIs were reported though the timeframes were vastly different, with a mean of 44.4 months for DB prior to the intervention period and a mean of 8.8 months for NDB. UTI diagnosis was determined by mailed questionnaires to 82 home care patients and information from nurses, physicians, and patients as well as chart information reviewed by the physicians. Comprehensiveness or completeness of the chart data extraction was not described. Additional analysis comparing matched timeframes of 16 months for a subsample of 15 (and 5 more within 2 months either direction) indicated that the mean number of UTI related hospitalizations in the NDB group was significantly higher: 12.1 (SD 8.87) as compared with 2.8 (SD 4.74) in the DB group (Wilcoxan rank test $p<0.005$). The matched pairs were selected based on whether the NBD was used for at least a month and chart data were available. Given questions on the methodology, it seems that a well designed randomized trial is needed, but no such study was found.

There is no evidence to support the practice of adding in situ antiseptic agents to drainage bags to reduce catheter-associated infection. A paper by Thompson et al. [129] which was primarily looking at the effectiveness of hydrogen peroxide instilled into closed drainage bags in reducing infection in drainage bags and in catheters also raises the question of whether catheters are infected primarily via drainage bags or vice versa. This prospective randomised study in a hospital setting involved daily sampling for bacteriuria (See Section XII.2.h for further discussion of outcome measures for catheter-associated infection) in catheters ($>=10^5$ cfu/ml) and drainage bags ($>= 10^3$ cfu/ml) and identifying the infecting bacteria species. In a sample size of 688, infection was found in 68 catheters and 78 bags. Although bag contamination was 8% in the H_2O_2 group and 16% in the control group ($p<0.001$) there was no significant difference in catheter bacteriuria (11% and 9%, respectively). One of the reasons given in the paper for questioning whether the drainage bag is the main source of catheter infection was that 77 % of the bags in this study were contaminated later than the catheters.

Best practice guidelines to prevent infections associated with short term indwelling urethral catheters are available. The most recent of these, the EPIC 2 guidelines, were revised in 2005 and reported by Pratt et al. [122]. Designed to prevent short term, indwelling urethral catheter associated infection in NHS Hospitals in England, the guidelines are based upon a series of systematic reviews that include the best available evidence (experimental and non-experimental research as well as expert opinion). These guidelines recommend a closed catheter system where drainage bags are changed according to the manufacturer's recommendations (5-7 days) or the patient's clinical need. The guidelines also recommend that antiseptic or antimicrobial solutions are not added to urinary drainage bags.

Recommendations for acute care settings were issued by the Society for Healthcare Epidemiology of America (SHEA) in 2008[130]addressing system wide infrastructure preventive activities. These include use of written guidelines, complete documentation, surveillance for catheter–associated UTI (CAUTI), education and training of personnel related to catheter insertion and management, and appropriate insertion technique. The authors noted that decreasing catheter use and duration are central to preventing bacteriuria and CAUTI. Suggestions were given for organization-wide strategies, such as reminder systems for review of catheter continuation, automatic stop order processes, ward rounds to enhance communication and review, catheter related protocols like post operative duration, and systems for data reporting. Guidelines from SHEA for preventing infection in long-term care facilities were updated also in 2008 [131].

d) Long-term management of urine drainage systems and reuse of components

The quandary for health professionals involved in the education and support of clients, who are self-managing and often financing their long term indwelling catheter drainage systems while living at home, is that they are aware that many of them are leaving the bags on for much longer than the manufacturers recommend and are often washing the bags out with a variety of solutions and reattaching the bags directly to the indwelling catheter. The reuse of drainage bags is often not a matter of choice but necessity in developing countries. In a survey of 28 continence nurses who were members of ICS, a majority (68%) said they advised their community dwelling patients to reuse drainage bags [132]. A number of reasons were given, such as cost of bags, evaluation of risk in the patient, policies, guidelines, and ability to do the procedure. While advice varied, most suggested a solution of water mixed with vinegar, household bleach, or dishwashing detergent.

There is a paucity of studies that have explored long-term self-management of urinary catheter drainage systems in a community setting. Moreover,

practices may vary considerably in parts of the world where catheter supplies are not routinely provided by prescription, as in the UK, or in developing nations where supplies are scarce. More research in this area is needed to provide guidance to clinicians. Implications involve cost, aesthetics, and environmental waste, particularly when single use non-drainable bags are used.

Madigan & Neff [133] undertook a literature review (50 studies) that explored the complications and long term management of long term indwelling catheters used for urinary retention and incontinence. Their recommendation in relation to management of drainage bags was that closed drainage systems were preferred best practice. However they also indicated that leg and bed bags may be used for up to four weeks if the system is broken daily to allow daily bag decontamination with a diluted (1:10) bleach solution This recommendation appears to be based on the following two trials, one of which involved 54 participants sampled from an acute care rehabilitation centre and one involving 14 community dwelling participants.

Dille et al [134] report a randomised group parallel study with a pre-test and multiple post-tests utilised to determine the safety of a four week re-use of vinyl leg and bed bags compared to the usual practice of one week when de-contaminated daily with a procedure that utilised dilute bleach (sodium hypochlorite, 1:10 bleach to water). This study was based on previous research in which daily decontamination of drainage bags was done as compared with replacing with new sterile bags each day [135]. Set in an acute rehabilitation unit, 54 participants (18 female and 36 males) completed the four week data collection period. Randomised by the flip of a coin, 28 participants were in the experimental group and 26 in the control group. All participants had an indwelling catheter and were using a leg bag during the day and a bed bag at night. Both groups received identical daily bag decontamination and weekly bag and urine cultures. A standard of 0 to 100 cfu/mL was used to measure bag decontamination effectiveness and the urine cultures were processed by the Associated Regional and University Pathologists Inc. No significant differences were found between groups and the authors concluded that it is safe and cost effective to reuse vinyl bags for four weeks as opposed to the previous practice of one week, if the protocol for daily decontamination described is used. This study does not compare the practice of washing out the drainage bags with the chlorine solution either weekly or for a period of four weeks with a closed urinary catheter system to determine if that would result in fewer UTI's.

Rooney [136] reported a study of 14 people with neurogenic bladders living at home. They changed from using daily sterile leg bags to non-sterile leg bags which were washed out after use each day with a dilute chlorine solution. Nine participants were on Foley catheter drainage and five were using sheaths. Bedside urine collection bags were used by all participants at night and there was no change made to the standard practice of rinsing the overnight bag with water each morning and recapping the drainage tubing. While the steps of the procedure were described, no information was given on who did the decontaminating, i.e., patients/caregivers or both. The study ran for three months including a preliminary baseline phase of one month. No comment was made on whether the non sterile bags were changed. There were no symptomatic UTI infections during the study and urine samples with bacteriuria (>105 cfu/ml) did not increase. However the sample was very small and no statistical tests were applied to the results.

e) Urinary drainage bag features intended to reduce the risk of cross infection

The cross-infection risks of leg bags (particularly via the tap or sampling port) have been studied by Glenister [137] and by Wilson and Coates [114]. In her study Glenister [137] concluded that designs in which the tap and outlet spouts were most widely separated were most effective at preventing contamination of the hands with urine. Wilson and Coates [114] studied sampling ports and contamination of leg bag spouts. They suggested that the night connector tubing attached to the taps on the four leg bags in their study made decontamination difficult.

A small comparative study of two sets of closed system bags with a double non-return valve and two set of bags with a single non-return valve - all inoculated with Escherichia Coli and using simulated laboratory conditions in two separate microbiological laboratories blinded to each other - found that the colonisation of a simulated bladder was significantly delayed when the double non return valve was used [138].

f) Purple urine bag syndrome

There are occasional reports in the literature of purple discolouration in urine drainage bags – termed, purple urine bag syndrome (PUBS) – and there is considerable debate and diversity of opinion over the cause and significance of the phenomenon. Two case controlled studies were found.Tsumura et al. (2008) [139] compared five persons with PUBS to10 without it.Urine sugar, serum amino acids, and leukocytes were similar, but the PUBS group differed in having a high alkaline urine in combination with bacteriuria. An earlier study had showed similar results with a high urinary pH. Mantani et al [140] conducted a case controlled study on 26 patients in three long-term wards. Fourteen (two men and 12 women) had exhibited PUBS while 12 (four men and eight women) had not. The clinical, microbiological and bacteriological backgrounds of the subjects in the two groups were compared to identify possible causes of PUBS. The findings of both studies suggest that urine that is alkaline and has a high

bacterial yield are most likely to exhibit PUBS. There is no evidence to suggest detrimental effects on patients' health or functioning of the drainage system. However, the smell can be very distressing.

Studies which have compared leg bags and catheter valves are reviewed in Section 12.

4. SUMMARY

Taken together, published studies agree that the main factors to consider in selecting leg bags are the ease of tap operation, the comfort of suspension systems and the minimisation of leakage (Level of Evidence 2). Bags in which the tap and outlet spout are widely separated are most likely to be effective at preventing contamination of the hands with urine and cross-infection (Level of Evidence 3). There is high level evidence from studies – predominantly in acute care settings - to support the use of closed urinary drainage systems (Level of Evidence 2).

5. GENERAL POINTS FROM THE LITERATURE, INCLUDING EXPERT OPINION

Provision of clearly presented information based on the best evidence available is needed for clinicians, carers and patients as many aspects of caring for a urinary drainage bag system are supported by scant or conflicting evidence or by custom.

There is agreement that the hands must be cleansed and clean non-sterile gloves put on prior to caring for the urinary drainage bag system and that, on completion of handling the system, the gloves must be discarded and the hands cleansed again [141], [122].

There is also mention of confusion arising for clinician, patient and carer because of the many different designs of urinary drainage bag taps, and the regularity with which such features are changed [142]. Manufacturers should ensure that the instructions and accompanying literature that they develop for their urinary drainage bag systems are clearly presented and easily understood [142] in a format which is convenient to retain and refer to.

6. RECOMMENDATIONS

In making urinary drainage bag selections particular attention should be focused on: the ability of the user to operate the tap; comfort (especially of the straps); freedom from leakage (especially from the welds and the tap); and discretion (especially visibility beneath clothing) (Grade of Recommendation B).

The patient's individual needs and personal preferences should determine the use of leg / suspension / attachments and position of where the bag is worn (Grade of Recommendation C)

Maintain closed urinary drainage system for indwelling urinary catheterisation where the system is only broken to change the sterile bag according to manufacturer's recommendation or in a shorter period of time if clinically indicated. (Grade of recommendation A).

7. PRIORITIES FOR RESEARCH

Jones, et al [141] identify many of the issues concerning the handling of urinary drainage bag systems that require further research, including the issue that has already been discussed above, of how long a closed urinary drainage system can be left unbroken before the urinary drainage bag is changed. Jones et al [141] also suggest research is needed into:

- How often and how drainage bags should be emptied?
- If a closed urinary drainage bag link system is used, does the night bag that is connected to the leg bag need to be sterile or can it be a reusable one?
- If a reusable night urinary drainage bag can be used, how should it be cared for when not in use?
- What is a reasonable method to dry reusable bags after they have been washed?
- Establishing whether the incidence of UTI is increased in hospital, community or residential aged care settings when urinary drainage bags in closed drainage systems are changed at different intervals (eg the time of catheter change rather than weekly).
- Determining in own home settings whether a closed catheter drainage system is more effective at preventing urinary tract infections than reusable non-sterile urinary drainage.
- Determining which method of cleaning non-sterile urinary drainage systems is most effective and acceptable to patients.

IX. BODYWORN URINALS

1. FEMALE BODYWORN URINALS

Pieper [143] has reviewed the many attempts to design bodyworn urine collection devices for women. The major challenge is in achieving a comfortable and aesthetically acceptable leak-proof seal with the body. Various designs have sought to achieve this by holding a collection device over the urethral meatus with the help of suction, straps, adhesive or close-fitting underwear. While none have found widespread success and usage, they are available commercially in some countries.

2. MALE BODYWORN URINALS AND DRIBBLE CONTAINERS

The urine collection devices most commonly used by men are sheaths (see Section VIII) but a variety of other products such as pubic pressure urinals are available. They comprise a ring-shaped opening or cone-shaped component which is worn around the

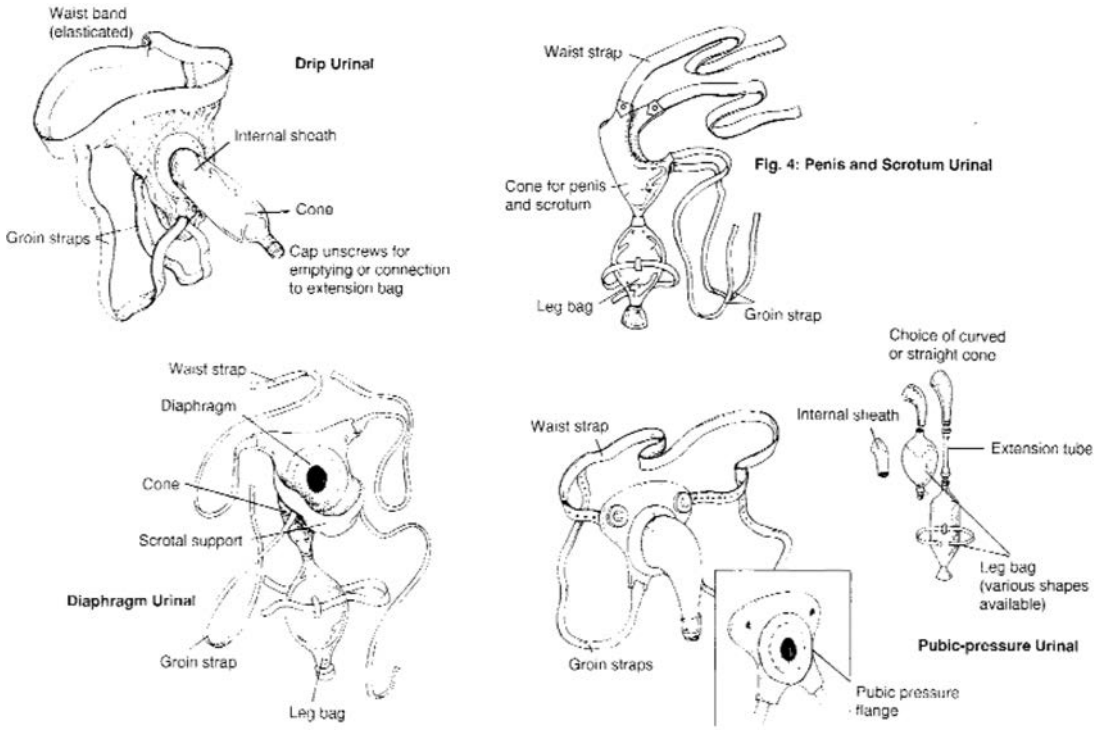

Figure IX-1: A variety of pubic pressure bodyworn urinals for men.

Figure IX-2: A dribble pouch

penis (and held firmly against the pubis by means of a belt and straps) and channels urine to an integral collection bag (**Figure IX-1**). Such devices are not widely used but they can be effective for individuals whose penis is too retracted for a sheath to be suitable. There are no published evaluations of these products.

They should be fitted by a specialist: a good fit is crucial for comfort and to avoid leakage. It is also important that the wearer / carer understands how to use the device and the importance of skin care, The wearer / carer will need good manual dexterity to manage the device. Several urinals will be needed to use in rotation, allowing each to be properly washed and dried between periods of use.

Dribble pouches are also available for light incontinence (**Figure IX-2**) but there are no published evaluations of these products.

3. PRIORITIES FOR RESEARCH

There is a need for leak-free, comfortable and aesthetically acceptable body-worn urine collection devices for women and improved (in these respects) products for men.

X. MECHANICAL DEVICES FOR WOMEN WITH URINARY INCONTINENCE

Female mechanical devices are designed to prevent urinary leakage in different ways and fall into three main categories: those that are applied over the urethra at the external meatus; those that are placed within the urethra (intraurethral devices) and those that are inserted into the vagina (intravaginal devices). Both designs of urethral device are intended to occlude the urethra and the intravaginal devices are intended to provide some support to the bladder neck and possibly some compression to the urethra. These devices are also known as occlusive devices and are primarily used by women with

stress incontinence. There is a recently updated Cochrane review of these devices [144].

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important regarding mechanical devices are high levels of motivation and acceptability of the concept of use, good cognition and good manual dexterity. They should probably be avoided by those with skin sensitivity or if avoidance of urinary tract infection is a priority.

1. DEVICES THAT OCCLUDE AT THE EXTERNAL MEATUS

Urethral occlusion devices have been developed to block urinary leakage at the external urethral meatus (**Figure X-1**). Several devices have utilized either adhesive or mild suction to achieve occlusion. In addition to the simple barrier effect, compression of the wall of the distal urethra has been hypothesized to contribute to continence.

Miniguard (Uromed Inc., but no longer available) is an angularly shaped foam device which utilizes an adhesive hydrogel to adhere to the peri-meatal area. The device is single use, removed prior to voiding, and disposable. FemAssist (InsightTM Medical Corp., but no longer available) is a hat-shaped silicone device, which adheres by applying an adhesive gel to the edge of the device, squeezing the central dome and creating a vacuum. The device is then placed over the urethral meatus and, upon release, the meatal mucosa is drawn up into the device and the urethral lumen is occluded. It may be worn for up to four hours or until voiding, after which the device is washed in hot soapy water and reapplied. The device was reusable for one week. CapSure (CR Bard Inc., no longer available) was applied and retained by suction. A petroleum based lubricant is applied prior to device use. The device is removed for voiding and re-utilized for up to two weeks.

a) Quality of data and results

Miniguard: Eckford et al. [145] studied the efficacy of a single application of this device during a one hour pad test and reported that 25% of patients were continent, 50% were improved, but 25% had worse incontinence. Brubaker et al. [146] enrolled 411 women to their study; 390 used the device, and 346 completed the study. Results showed significant improvement in symptoms. The incontinence impact scores significantly decreased from a mean of 41.0 (out of 300 – high scores worse) to a mean of 10.5 at 17 weeks. Twelve hour pad test showed mean urine loss decreased significantly from 15.8 to 6.9 ml and incontinence episodes from 14.2 episodes per week to 4.9 episodes at week 17. Symptoms of vulvar irritation or lower urinary tract discomfort occurred in a small percentage of subjects but it was generally transient, and only three women discontinued using the device for this reason. There were no statistically significant differences in the proportion of subjects reporting urinary tract infection during device use compared to beforehand. The authors concluded that the device was safe and effective (Level of Evidence 3).

Fem Assist: Versi et al. [147] studied 155 women with stress or mixed incontinence, of whom 133 attempted to use FemAssist and 96 enrolled in a four-week study. Their mean pad test loss fell from 27 g to 9.4 g ($p<0.001$) and 49% were dry. Symptomatic cure was more likely in those with mild incontinence. Of the nine women who had a positive pad test (>2 g) without the device, five were dry (<2 g) with the device ($p<0.05$). VAS scores showed a significant improvement for the symptom of stress incontinence ($p<0.05$). QoL scores improved significantly by 38% ($p<0.05$) for the IIQ and 29% ($p<0.01$) for UDI (Level of Evidence 3).

Moore et al. [148] reported on 57/100 recruited women who completed a one-month trial. Reduction of incontinence was statistically significant on pad testing, which revealed that 47% of the patients became continent and 33% had more than 50% benefit compared to baseline, while 9% had worse leakage. Those with severe baseline leakage were as likely to respond as those with mild or moderate pad test loss. Women with stress, urgency or mixed incontinence appeared to respond equally well. Dropouts included 13% who were unwilling to utilize the device (Level of Evidence 3).

Tincello et al. [149] in a 3-month prospective study involving 27 women with urodynamic stress incontinence found the median (range) loss with and without the device was 4.9 (0-65) ml and 21 (1-94) ml respectively ($p<0.01$); and 20 patients were

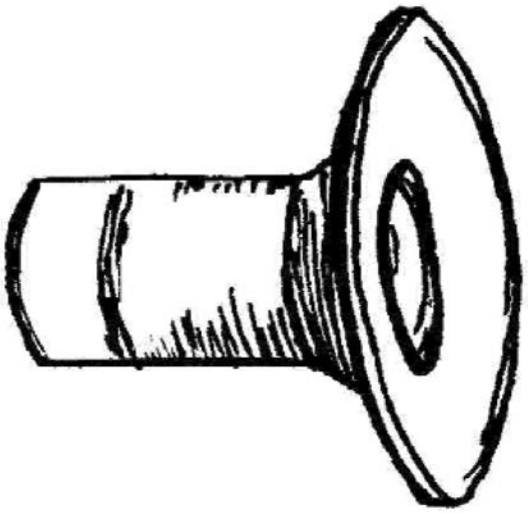

Figure X-1: A female occlusive device that occludes at the external meatus.

less wet when using the device. Discomfort was greater among the women with a greater loss. The acceptability correlated negatively with discomfort (r = -0.53) and negatively with embarrassment (r =-0.39); 15 patients (56%) reported that they would use the device in the long-term (Level of Evidence 3). Tincello et al. [150] later reported on 41 women recruited to use the device over a three month period, but 10 declined to participate, six withdrew before two weeks, 10 failed to attend two week follow-up and 11 did not attend three month follow-up. Only two completed the study. There was no difference in pad test or voiding diary grades. The authors concluded that the device had low acceptability and was ineffective, and could not be recommended for non-surgical management of stress incontinence (Level of Evidence 3).

CapSure: Bellin et al. [151] reported on 88/100 completers after 12 weeks, with 82% elimination of leakage on pad test, 91% continent on provocative stress test (single cough assessment of leakage), and 48% dry and 40% improved on urinary diaries. Pad test leakage decreased from 6.67 g (range 0.55-25.95 g) to 0.19 g (range, 0-2.5 g) by week 12. Five patients withdrew secondary to vaginal irritation and three due to poor device fit (Level of Evidence 3).

Shinopulos et al. [152] carried out a multi-centre study enrolling 100 women with stress incontinence who wore the device for 12 weeks. Eighty-four women completed the study. Mean pad weights reduced from 6.7g at baseline to 0.19 by week 12. Complications affected seven patients, including urethral / vaginal swelling and vulval abrasion, but none of the affected patients withdrew from the study. The IQOL tool showed significant mean improvement from 62.3 to 90.4.

b) Summary

External urethral occlusive devices were found to be of varying efficacy, with minimal morbidity. Efficacy of the combined studies reveals a continence rate of approximately 50% dry and two-thirds of patients improved, but this data is from open studies (typically pre-test / post-test with no control group) and there have been no randomised controlled trials. Devices achieve occlusion either by blocking at the meatus or compressing the distal urethral lumen and adherence to the peri-meatal area is essential to success. However, the method and degree of adherence is also the determining factor for the type and severity of local irritation. Patient selection based on motivation, appropriate anatomy, and manual dexterity, in combination with efficacy and morbidity will determine overall satisfaction. There is no data which compares one extra-urethral device to another, or to other categories of products. Cost comparisons for disposable versus short-term reusable devices are not available. Efficacy for different grades of incontinence has not been established. The objective degree of continence improvement in the clinical laboratory (pad and stress tests) is greater than in community use (diaries). The devices tested in these studies are no longer available and there are no external urethral devices currently on the market.

c) Recommendations

Although these devices have proved effective for some women (limited mainly to those with high motivation, manual dexterity and cognitive function), it appears that they have failed to find popularity with users and clinicians. They are no longer commercially available and so no recommendation on their use can be made.

d) Priorities for research

Further research on the development and role of devices which block urinary leakage at the external urinary meatus, with a focus on improving patient acceptability is recommended. One half of patients utilizing these devices in monitored studies were dry and two-thirds of the patients were improved with minimal morbidity. These devices may have a future role in the algorithm of conservative treatment based on patient acceptance, availability and cost, especially in those patients with mild or moderate stress incontinence, for occasional or intermittent use and/or for those who prefer to avoid pads or surgery.

2. INTRAURETHRAL DEVICES

Urethral inserts are silicone cylinders that are self-inserted or removed at the patient‘s discretion. They are intended for day-time use, especially during vigorous physical exercise. While some women manage exercise incontinence by limiting fluid intake before or during exercise, by choosing sports that allow frequent bathroom access, or wearing absorbent pads, 20% to 40% of women cope with leakage by ceasing exercise [153]. These devices have external retainers or flanges to prevent intravesical migration and proximal balloons to hold the device in place. They act by causing occlusion either in the urethra itself or at the external urethral meatus [154]. (**Figure X-2**)

The FemSoft (Rochester Medical Corporation) is the only urethral insert currently distributed. It has a soft, compressible, mineral oil-filled silicone layer with an insertion probe. Before insertion, the fluid distends the proximal end of the cylinder, as the user pushes the device (guided by the insertion probe) into the urethra, fluid transfers automatically to the distal end, allowing the device to pass through the urethra. Once in place, fluid flows back to the proximal end to hold the device in place. None of these devices are recommended for reuse after removal. The FemSoft Insert is currently packaged in a box of 28 inserts and each box is priced at $49.95. The Viva [155], Reliance and other intraurethral devices mentioned in this sub-section, are not currently marketed.

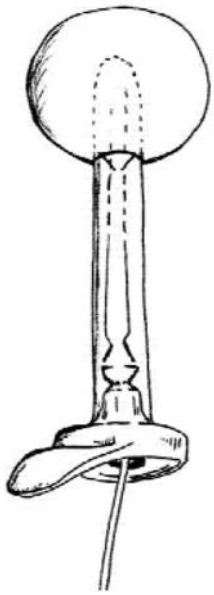

Figure X-2: A female intraurethral occlusive device.

a) Quality of data and results

The objective efficacy measurements utilized were the one-hour pad test, voiding diary and quality of life questionnaires. There have been no randomized control trials.

Nielsen et al. [155] [156] and Peschers [157] studied the Viva device. Peschers et al. screened 53 patients with USI and 21 patients accepted treatment with the two sphere device. During a four month study, the investigators analyzed subjective improvement and performed pad-weight and cough tests. The authors reported that 67% of patients had improvement in symptoms. Nielsen et al. [155] studied forty women who tested two variants of the device (with one or two spheres) each for two weeks in a cross-over study. They then continued with what they judged to be the better plug in period three (two months). Only 45% (18/40) completed this period but almost all (17/18) were reported to be subjectively and objectively continent or improved. Six women developed urinary tract infections and two of these had retained a plug in the bladder.

Staskin [158] reported on a four month study of 135 of 215 patients who utilized a disposable balloon tipped urethral insert made from thermoplastic elastomer, inflated with an applicator on insertion and deflated by pulling a string at the meatal plate for removal during voiding (Reliance, Uromed Corp., but no longer available). Eighty subjects discontinued the device prematurely, mostly because of discomfort and inability or unwillingness to use the device. Miller et al [159] and Sand et al [160] then reported on 63 of the 135 patients from the above cohort who utilized the device for one year.

The Reliance device provided 72% complete dryness with 17% improvement on diary, and 80% complete dryness and 15% improvement on pad weight testing in the study by Staskin et al. [158], and 79% complete dryness and 16% significant improvement on objective pad weight studies consistent with the improvement in subjective diaries ($p<0.0001$) for Miller et al. [159]. In the Miller study the patients reported improved comfort and ease of use over time. Sensation of device presence decreased from 35% at week one to 7% at 12 months. The volume of urine lost during exercise decreased from a median of 20g (range 4.9-80.2g) without the insert to 2.6g (1.3-6.8g) when the insert was worn ($p=0.03$). On a 5-point scale, in which 1 represented very comfortable and 5 very uncomfortable, subjects rated the mean comfort for the sessions performed with the insert in place as 2.1.

Treatment for positive urine cultures was undertaken in 20% of' symptomatic and 11% of asymptomatic patients, 39% of patients had positive cultures which were not treated and 30% had negative cultures at all monthly intervals for the four month study. The main reason for drop-out was discomfort [158]. One or more episodes of gross haematuria (24%), cystoscopic findings of mucosal irritation at four or at 12 months (9%) and asymptomatic bacteruria (30%) on monthly cultures were also documented [159].

Robinson et al [161] carried out a small randomised controlled trial comparing the NEAT device (intraurethral device with expandable tip) with the Reliance device. Twenty-four women (mean age 51 years) entered the study and there were eight withdrawals. Devices were randomly allocated and tested for four months. Improvement was reported for 6/8 women (NEAT) and 5/8 women (Reliance) when compared to baseline. There were no significant differences in the number of women improved, in mean reduction in urine loss, or in leakage scores between the two groups.

Boos et al. [162] reported in an abstract, a randomized prospective parallel group trial comparing the Reliance intra-urethral insert with the FemAssist external meatal occlusive device. Assessments at baseline, one month, and three months included subjective efficacy, seven day diary, and pad test (1 hour). Fifty-three females were randomized to the FemAssist and 49 to the Reliance device. There were some initial problems with sizing the Reliance. Once this was corrected, 40.8% (20) of women were subjectively dry and the remainder improved on completing the trial. Of women using the FemAssist, 28.3% [15] were dry, 60.4% [32] were improved, 9.4% [5] were no better and only one subject was made worse with device use. Problems experienced were few and minor with no serious adverse events. The conclusion was that both devices are efficacious, the FemAssist was more comfortable, but required a greater degree of user skill to achieve control of leakage (Level of Evidence 2).

Recent studies have investigated the efficacy of the FemSoft which is the only intra-urethral device which is currently available. Dunn et al. [153] measured pad weights during four standardized aerobics sessions during which six subjects were randomly assigned to exercise twice with the insert and twice without it. The medians of the averaged pad weights for the two different types of' sessions were compared. Median urine loss during standardized exercise sessions decreased from 20g (range, 4.9 to 80.2g) without the device to 2.6g (range, 1.3 to 6.8g) with the device (p=0.03). Five women used the device at home during unsupervised exercise; one subject had urinary tract infection. At the end of three months, satisfaction and comfort were rated high on a 5-point scale. The conclusion was that the FemSoft urethral device is an effective, safe, and comfortable treatment for exercise incontinence in women (Level of Evidence 3).

Results from a prospective three-year study, (FDA post-approval device safety data submitted by Rochester Medical Corporation, 2002 unpublished), for evaluation of the long term effect of the device involved 41 subjects. Of the group, nine women were 65 years or older (22%, 9/41); 80% were post-menopausal with 24 women (59%) being on hormone replacement. Thirty-eight, (93%) used absorbent products to contain urine leakage prior to enrolment. A total of 66 follow-up visits took place with an average participation period of 4.2 years. Seven patients withdrew in the third year, three due to non-study related health problems and one because of dissatisfaction due to urge symptoms. Two were lost to follow up. There was a significant difference in the rates of incontinence at the three-year follow-up between users and non-users of the device: 0.83 versus 2.64 episodes per day, according to voiding diaries. The difference in urine loss during pad weighing tests was also significant. There were 24 reported adverse events in the 41 subjects enrolled. None of these events required medical intervention except for antibiotic prescription in cases of urinary tract infection. The 24 events included: bacteriuria (11); symptomatic UTI (3); urinary symptoms (3); device performance problems (2); irritation (2); and migration (1).

In 33 women a total of 38 cystoscopies were performed at three years. Only one patient was reported to have an abnormal finding, but this was due to mucosal irritation produced by an indwelling Foley catheter during one hospitalization for a problem unrelated to the device. Patient satisfaction had not changed over the follow-up time interval. The Quality of Life questionnaire (I-QoL) scores at three years were compared to those at 12 months and there was improvement from the baseline of 60.6 to 74.0. No safety concerns concerning urethral integrity were identified after the three years of continuous use. The incidence of urinary tract infections, given the high number of insertions and removals, was considered low risk (Level of Evidence 3).

b) Summary

Intraurethral devices have demonstrated high efficacy, but have been associated with urinary tract infection, hematuria and discomfort. Bacteruria, without symptomatic infection, was similar to extraurethral device use, which approaches screening urinalysis data [146] or may be similar to the rates seen with self catheterization. Device migration into the bladder, which requires endoscopic removal is the most serious reported problem. Long-term results are limited. Patient and clinician acceptance of this form of therapy has also been limited and there is currently only one intraurethral device on the market. High cost is also a factor that probably precludes more widespread application but 'occasional' use, for example during exercise may be helpful and affordable for some patients. Good hand dexterity is necessary to use the device (**Level of Evidence 3**).

c) Recommendations

Intraurethral occlusive devices may be considered for women with stress incontinence but they are invasive devices with high cost and have had limited evaluation. They may be most appropriate for intermittent and occasional use (such as during vigorous exercise) (**Grade of Recommendation C**).

d) Priorities for research

It is important that new devices - particularly invasive ones - are evaluated by randomized trials and comparing to control approved devices. Long-term follow-up results are needed to demonstrate the effects of such devices on the urethra and / or bladder and will determine the real value and safety of devices that initially have been adopted enthusiastically.

Further development and study of the use of intraurethral devices for the treatment of urinary incontinence is recommended. In particular assessment of their cost-effectiveness and effects on quality of life, when used intermittently or for particular activities, is recommended.

3. INTRAVAGINAL DEVICES

Support of the bladder neck to correct urinary stress incontinence has been achieved, with varying success, utilizing traditional tampons, pessaries and contraceptive diaphragms, and intravaginal devices specifically designed to support the bladder neck.

a) Quality of data and results

1. Tampons / pessaries

Nygaard [163] performed a prospective, randomized, single blind, and laboratory based study testing 18 patients (age 33-73) with three 40 minute standardized aerobics sessions, utilizing a Hodge pessary, a super tampon, or no device. Urine loss was determined by a change in the weight of the pad worn while exercising. Statistical analysis of the log of urine loss revealed that women lost

significantly less urine when exercising with either the pessary or the tampon than when exercising with no device. Continence rates were 6/14 cured and 2/14 improved with tampons, 4/10 improved with a diaphragm (Level of Evidence 2).

2. Diaphragms / Pessaries

Realini et al, [164] analyzed the benefit for one week, in 10 selected patients of a coil-type diaphragm ring, which was softer than a pessary, utilizing diaries and a two hour pad test. They also gave an overall subjective evaluation of their experience. Urodynamic findings were essentially unchanged by wearing diaphragm rings. Four of the 10 women experienced clinically significant improvement in the amount of urine lost during pad tests, number of leaks per week, and overall assessment response (Level of Evidence 3).

Suarez et al. [165] included urodynamic testing in his evaluation of a contraceptive diaphragm in 12 patients. Complete resolution of SUI was achieved in eleven of twelve patients (91%) but two of them withdrew from the study because of associated discomfort from the diaphragm, therefore, complete resolution of SUI was achieved in 9/12 patients (75%) (Level of Evidence 3).

Bhatia et al. [166] reported on the urodynamic effects of the Hodge pessary on 30 women aged 29 to 71 with a history of UI. With the pessary, 24 of the 30 patients became continent when tested in supine position with a full bladder, three of the 24 patients lost urine with coughing in the standing position and demonstrated a positive cough profile despite the presence of the vaginal pessary. Uroflowmetry data show that the vaginal pessary did not produce any obstruction to the free flow of urine and suggested this is a modality to predict the outcome for bladder neck support surgery.

Richter et al (2010) [167] compared use of a pessary (ring or dish) with behavioural therapy (pelvic floor muscle training plus strategies for active use of muscles to prevent stress and urgency incontinence), compared with combined treatment in a randomized controlled trial of 446 women with stress incontinence. Outcomes were measured at 3, 6 and 12 months. There were small differences between groups at 3 months with slightly better results in terms of bothersome incontinence symptoms for the behavioural therapy group than the pessary group. Combined treatment was not significantly better than behavioural therapy alone and difference between groups were not sustained at 12 months.

The long-term discontinuation rates of ring pessaries (including the Introl device – see below) was investigated by Sarma et al (2009) [168]. A retrospective review of the notes of 273 women was carried out and found a surprisingly high rate of complications (93 (56%) of the 167 women who were successfully using a pessary at 4 weeks subsequently developed problems such as bleeding, extrusion, discharge and pain). The majority of women discontinued use of the pessary over time. It is therefore important that further studies of pessary use should include long-term follow-up results. Gorti et al (2009) [169] surveyed clinicians about use and follow-up of pessary placement and concluded that patients should be followed up at 6-12 monthly intervals.

3. Intra-vaginal devices designed specifically to support the bladder neck

Included in this category are:

1. Removable reusable intra-vaginal ring, composed of silastic, and constructed with two prongs which are placed behind the symphysis to support the bladder neck (Introl, no current distributor).

2. Single-use disposable devices: (i) A clam-type device composed of polyurethane foam, which is folded up upon its long axis and placed into the sagittal plane in the vagina, and when moistened, its dimensions expand by 30% and create a supportive cushion under the urethrovesical junction (originally called the Conveen Continence Guard, now known as Contrelle Activgard); (ii) A version of the expanding polyurethane design, with similarities to a tampon, (Conveen Continence Tampon, Coloplast, Denmark (no longer available) (**Figure X-3**); (iii) An expanding polyvinyl alcohol sponge (Ladycon, Home Care Engros, Norway); (iv) a simple surgical foam cylinder with drawstring e.g. Rocket stress incontinence device (Rocket Medical PLC)

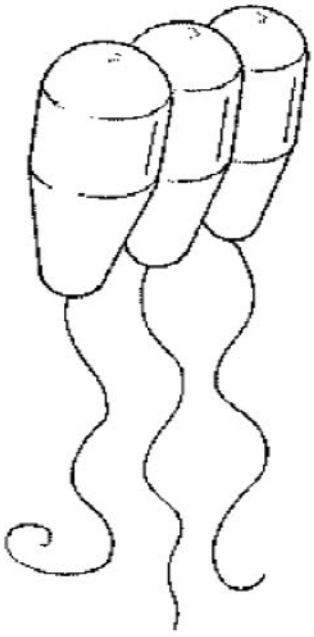

Figure X-3: A female intravaginal occlusive device.

4. Reusable intra-vaginal ring (Introl)

A pilot laboratory study was carried out by Biswas [170], the developer of the device, employed a straining cystogram. Eighty-six percent of the patients were continent with the device in place on cystogram. Following this study, the number of device sizes was increased from eight to 25. Evaluation studies followed examining efficacy, safety and satisfaction. Davila [171] initially demonstrated that 83% of patients were dry on pad weight test. Later [171] the researchers enrolled seventy women (53 completed) aged 24-76, 29 with stress, and 24 with mixed incontinence in a one month study. A statistically significant reduction in incontinence was noted on pad testing (stress mean 46.6-16.6g; mixed, mean 31.9-6.8 g) and in bladder diary (stress, mean 28.6-7.8 losses per week; mixed, mean 30.2-15 losses per week). QoL scores (I-QoL) improved in both groups. With the device in place, urodynamic testing indicated normalization of urethral function without evidence of outflow obstruction. Subjects found the device comfortable, easy to use and convenient. Side effects included five urinary tract infections and 23 cases of vaginal soreness or mild irritation (**Level of Evidence 3**).

Moore et al. [148] detailed problems with both sizing and efficacy. Of the 80 recruits, four could not be fitted, and 11 did not satisfy all entry criteria. Of the 65 participants, 39 (60%) withdrew; 20 for distorted vaginal anatomy which made fitting difficult, five for lack of efficacy, four for constipation, and ten for unrelated patient events. In the remaining 26 patients, pad test weights decreased from a baseline median of 19g to 2g ($p<0.001$), 62% were continent, and 15% were >50% improved, and wished no further therapy. Moore et al. commented that the device was difficult to fit in women who have had multiple vaginal surgeries or were oestrogen deficient. Long-term follow-up showed that 18 of 26 (from the original 65) continued to wear the device at six months (interim dropouts being due to concurrent illness in half, the remainder had declining efficacy). Of these, 78% continued to wear the device for a minimum follow-up of two years (**Level of Evidence 3**).

In a separate study of patients with mixed incontinence by Moore et al. [148], five of 21 recruits never wore the device home, leaving 16 participants. A further two did not reach week four, because of poor efficacy or inability to fit the device. In the 14 who reached week four, the median number of leaks/day declined from 4.3 to 1.0 ($p=0.002$). Median pad weight loss fell from 53g to 7g. ($p=0.012$). Cystometry showed an increase in maximum bladder capacity ($p<0.05$) and a modest reduction in severity of detrusor overactivity, with no evidence of outflow obstruction. Three women discontinued because of poor efficacy or a poorly fitting device, leaving 11 of 16 participants (69%) at week eight, when median pad weight decreased to 2 g (**Level of Evidence 3**).

Kondo,et al. [172] found no urinary flow obstruction with the device in place. Urine loss decreased from 20.6 to 4.8 g per hour ($p<0.001$) on the 60-minute pad weight test. Twenty two patients (29%), reported complete continence, and 39 (51 %) had decreased severity of incontinence by more than 50%. Minor adverse effects occurred in 26% of the patients. According to the global usefulness rating which was employed, 62 patients (81%) had some or maximum benefit (**Level of Evidence 3**).

5. Reusable intravaginal hollow tampon (Contiform)

The Contiform intravaginal device was first tested in 2003 and although significant benefit was shown only 20% of participants were completely dry on 24 hour pad test [173]. In 2007 Allen et al [174] enrolled 65 women to test the device and fitted 52 devices. 37 women completed the protocol (4 weeks testing). Urine loss on pad testing was significantly reduced from a median of 6.6g to 2.2g and there were significant improvements on the Incontinence Impact Questionnaire and Urinary Distress Inventory. Seven patients were unable to insert the device and two were shown to have residual urine over 100ml, but overall the authors concluded that the device was well tolerated.

6. Disposable intra-vaginal devices

Thyssen et al. [175] tested the Continence Guard in 26 women with stress incontinence before and after one month's use: four women discontinued the treatment because of discomfort or difficulties in using the device 9 (41%) were subjectively cured of incontinence, 10 (45%) improved while three (14%) claimed unchanged incontinence. With the device in place all had decreased leakage at the 24-hour pad weighing test and unchanged urodynamic tests. No vaginal or urinary infections were found (**Level of Evidence 3**).

Thyssen et al. [176] reported on 19/22 women with stress incontinence, subjectively and objectively cured or improved in a short-term study, and who then continued the treatment with the device for one year. All 19 completed the study, 13 (68%) were subjectively dry, (26%) were improved and one (5%) reported unchanged incontinence. All but one had decreased leakage at the 24h pad test, and 67% a greater than 50% decrease. Subjectively cure was 41%, and 36% were dry on 24 hour pad test. Overall reduced leakage was statistically significant ($p<0.0005$) No significant changes were found in the other urodynamic measurements, specifically, urinary flow rate.

Sander et al. [177] found subjective cure in 11/55 women (20%) and improvement in 27/55 (49%) was reported. Results of the 24-hour pad test and mean leakage and epi-sodes in the voiding diary significantly decreased. After three months, 58% of the 55 patients desired to continue device usage. There was a highly significant improvement in QoL scores using the IIQ, as well as two additional

incontinence-related quality of life questionnaires. Responses to the SF-36 general health questionnaire showed no significant changes

Hahnet al. [178] reported on 121 women, in a four week study. Patients dropped out because of vaginal irritation (25%), other product-related reasons (6%), lack of time (6%), or failure to complete a user questionnaire. Of the remaining 90 (mean age 47.5), 85 performed a 24 hour pad test, which showed that baseline leakage of 42 ml/24h decreased to 14 ml/24h ($p < 0.001$). Of these, 39 (46%) were continent. The device was considered unpleasant by 8%, and caused some local discomfort in 62% on direct questioning: 75% of these wished to continue using the device. The authors noted that older women (age 56-65) tolerated the device and appeared more motivated to continue. Coexistent atrophic vaginitis and the use of topical oestrogen was not discussed

Thyssen et al. [179] reported on 94 women recruited in a cross-over study, which compared two versions of the same device; the Conveen Continence Guard (CCG) and the Contrelle Continence Tampon CCT. 62 women (66%) completed the study with withdrawals mainly due to discomfort or for unknown reasons. Both devices reduced leakage significantly but the CCT was significantly better than the CCG. Few side-effects were reported. Thirty-two women continued the treatment for one year or more with 63% preferring the “tampon” type design for its ease of use.

The report on the polyvinyl sponge by Glavind [180] was an acute laboratory study of only six women utilizing a pad test measurement during 30 minutes of aerobic exercise Without the vaginal sponge the patients had a mean loss of 7g (range 2-18g) during exercise. With the vaginal sponge in situ there was no leakage.

Two papers have been published recently on the Tipi device (ConTIPI Ltd. Israel) [181] [182]. This device has a resin core with support ‘poles’ covered with a soft nylon mesh that stretches between the arms of the poles to act as a suburethral sling. Ziv et al. [183] recruited 60 women with severe stress incontinence to test the product. A seven day ‘control’ period was followed by a 28 day device usage period. There was no control arm or comparison product. Pre-weighed pads were used during the test period and the primary end point was the percentage of women achieving at least a 70% reduction in pad weight gain from the control period to the last 14 days of usage. Ten women withdrew from the study during the test period, four for device related reasons. Using intention to treat analysis 85% of women achieved at least 70% reduction in pad weight gain. The most common adverse events reported were mild and included genital tract discomfort, pain and spotting with blood; the only report of a moderate event was of candidiasis. The authors conclude that the device is easy to use, well-tolerated and effective.

Farage et al (2011) used a similar evaluation design with 57 women who had at least seven episodes of SUI per week. After a baseline period the women identified the best TIPI among a selection of three device sizes. The fitting period was followed by 14 days of device usage for up to 12 hours daily. The results of the 57 intention to treat population shows that 75% of the patients had at least a 60% reduction in SUI episodes, the subjective perspective of patients with regard to the severity of their incontinence improved and the results show also an improvement in the quality of life (statistically significant for: feeling frustrated, impact on social activities and impact on recreational activities). The authors stated that the device is safety in daily use and a nonsurgical alternative in the therapy for SUI.

b) Summary

Support of the bladder neck resulting in improved continence is possible with intravaginal devices without evidence that they cause significant lower urinary tract obstruction or morbidity, but the evidence is limited (Level of Evidence 3).

Studies performed in the acute setting, regardless of the device type, demonstrate better performance than diary based studies performed over time. Efficacy appears to be higher in patients with minimal to moderate urinary leakage.

Relatively high drop-out rates in monitored studies, during which patient support is provided, indicates the need for proper patient selection’ and patient and provider education, but may also indicate limitations in product efficacy, difficulties in application or other factors such as discomfort (Level of Evidence 3).

c) Recommendations

Intra-vaginal support devices may be considered as a treatment option when managing women with stress urinary incontinence, dependent upon the availability of product, patient ability to manage the product (particularly manual dexterity) patient acceptance, and cost (Grade of Recommendation C).

d) Priorities for research

Long-term results are not available and studies comparing these therapies to other forms of conservative therapy or surgery are needed

4. OVERVIEW OF MECHANICAL DEVICES FOR WOMEN

a) Overall summary

The recently updated Cochrane review of mechanical devices for urinary incontinence in women [144] review found seven trials that met their criteria and concluded that the role of such devices is questionable. The authors state that there are indications

that using mechanical devices might be better than no treatment but that the evidence was weak and that there was insufficient evidence to recommend any specific device or to show that mechanical devices are better than other forms of treatment.

In this section we have attempted to review all available evidence including many trials that did not meet Cochrane criteria. Most trials were open pre-test post-test trials with no comparators and the strength of this evidence is relatively weak. Although most trials showed positive effects on symptoms, this was often combined with relatively high drop-out rates and unwanted effects, such as discomfort, skin irritation or urinary tract infection.

Although many products have appeared on the commercial market, few have stood the test of time and are currently marketed – there are no external urethral devices available and there is only one intra-urethral device. There are at least two intra-vaginal devices available on the market and these may have potential to be more acceptable to women because of their similarities to familiar tampons. The relative lack of market success for these products may indicate low efficacy and unwanted effects, but may also reflect their relatively high cost compared to pads which are the main alternative.

b) Overall recommendations

It is possible that some of the mechanical devices currently marketed are effective and acceptable to a minority of women and, given that they are relatively non-invasive (with the exception of intra-urethral devices), they may be suggested to patients for consideration and testing, particularly for short-term or occasional use.

c) Overall priorities for research

The substantial withdrawal rate and the frequency of unwanted events indicates that that there is a need to establish efficacy of these devices (compared to no treatment) over longer time periods (more than a year), with careful identification of unwanted effects.

There is also a need to compare devices with simple, cheap devices. The Cochrane review recommends an intravaginal tampon as a suitable comparator.

There are indications that the devices may best be used occasionally or intermittently for specific activities and there is a need for this type of use to be tested, possibly compared to the most common alternative - an absorbent pad.

As these devices aim to prevent urine leakage there is also potential for testing their efficacy compared to other treatments such as pelvic-floor exercises or surgery.

XI. MECHANICAL DEVICES FOR MEN WITH URINARY INCONTINENCE

Male mechanical devices aim to prevent urine leakage by compressing the penis. A variety of designs are available but occlusion is usually achieved with either a clamp or a peri-penile strap (**Figure XI-1**). Such devices have the potential advantages of low cost and simplicity compared with a sheath and drainage bag. However there is potential for tissue damage and these devices should be used with caution.

Careful assessment is necessary for use of these devices because there is potential for damage to the penis from ischaemia (restriction of blood to the penis). Such devices should be fitted by a trained health professional and subject to regular review. Use should be limited to men who are assessed as being cognitively intact, are aware of bladder filling, have normal genital sensation and intact penile skin, have sufficient manual dexterity to open and close the device (Moore 2004) and are motivated and willing to use such a device.

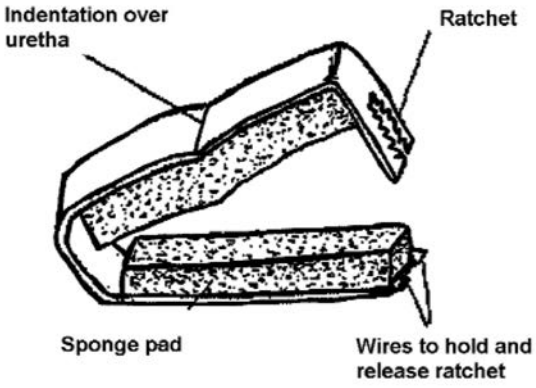

Figure XI-1: A penile clamp.

1. QUALITY OF DATA

The use of penile compression devices is described only rarely in the literature [184] [185] and is usually referred to as a last resort where other forms of management have failed or been judged inappropriate. There has only been one published evaluation [186].

2. RESULTS

Moore et al. [186] evaluated three different devices (Timms C3 penile compression device; Cunningham clamp; and U-Tex male adjustable tension band) in a cross-over study in which twelve men with stress urinary incontinence following radical prostatectomy tried each device in turn. Each of the devices significantly ($p<0.05$) reduced mean urine loss (measured using a 4h pad tests) compared with baseline measurements. There was some objective or subjective improvement in continence for

each of the 12 men with at least one of the devices, although none completely eliminated urine loss when applied at a comfortable pressure.

Ten of the 12 men rated the Cunningham clamp positively; two, the C3; and none, the U-Tex. However, the C3 and U-Tex allowed good cavernosal artery blood flow while the Cunningham clamp significantly reduced it. Overall Moore et al. concluded that, used correctly, the Cunningham clamp can be an effective method of controlling urinary incontinence (although it should be noted that complete control i.e. no leakage, was not achieved) in men with stress urinary incontinence who are cognitively intact and aware of bladder filling, and have normal genital sensation, intact penile skin and sufficient manual dexterity to open and close the device.

Expert opinion and anecdote suggest that penile clamps may be more successful when used for short periods, for example when undertaking activities such as swimming or jogging. Such activities may not only exacerbate incontinence but also preclude the use of bulky and / or absorbent products.

3. SUMMARY

Male mechanical devices can partially control urinary leakage (but not eliminate it at comfortable levels of use) but are likely to lead to reduced cavernosal artery blood flow and therefore care must be taken to ensure regular removal or release (Level of Evidence 2).

4. RECOMMENDATIONS

- Male mechanical devices may be considered for selected men with stress urinary incontinence who are cognitively intact and aware of bladder filling, and have normal genital sensation, intact penile skin and sufficient manual dexterity to open and close the device (B).
- The devices should be fitted by a trained health professional and reviewed regularly (Grade of Recommendation C).
- The devices may be considered for short-term use when undertaking sport or other activities, as an adjunct to management with other products (Grade of Recommendation C).

5. PRIORITIES FOR RESEARCH

- There is a need for mechanical devices for men which are discreet, easy to use and which prevent leakage without risk of tissue damage.

XII. CATHETERS

Urinary catheters can provide an effective way of draining the bladder in either the short-term or long-term, by intermittent or indwelling catheterisation, where alternative strategies are unsuitable or unsatisfactory. However, indwelling catheters are rarely completely trouble-free and the risk of catheter-related complications is high, with substantial detrimental impact on patients, carers and healthcare services. It is generally agreed that catheter use should be avoided wherever possible and only adopted for those for whom alternative strategies are unsuitable or unsatisfactory, after careful assessment of the patient and their particular problem [187].

This section examines the characteristics of urinary catheters, and provides a critical review of existing evidence to guide decision-making on choice of catheters, equipment and management strategies to minimise associated risks. Specific issues relating to short-term catheterisation are addressed, but the main focus of the section is on long-term management of bladder dysfunction, by intermittent catheterisation (least invasive) or indwelling catheterisation (most invasive). An overview of factors influencing choices of catheterisation strategy is provided in **Table XII-1**. Detailed discussion of key issues is provided under the following headings: user characteristics, catheter characteristics, associated risks / problems, catheter management.

The bulk of research evidence on catheter use relates to short-term catheterisation. In particular there are numerous trials which focus on catheter-associated urinary tract infection since this is well recognised as a major source of healthcare associated infection. The quality of data is very variable and many studies are limited by being underpowered and by other design issues, including poorly defined outcome criteria and highly selected study populations. Much less research has addressed intermittent or long-term indwelling catheter-related issues and guidance to healthcare practitioners remains largely based on expert opinion. Some of the difficulties in conducting research on use of continence products are discussed in Section III. Further discussion related specifically to catheters is provided within the following sections.

1. INTERMITTENT CATHETERISATION

Intermittent catheterisation (IC) is the act of passing a catheter into the bladder to drain urine via the urethra, or a catheterisable channel such as a Mitrofanoff diversion. The urine can be drained into a toilet, urinal, plastic bag, or other reservoir. The catheter is removed immediately after drainage. This technique avoids many of the problems associated with indwelling catheters. Intermittent catheterisation may be carried out using a sterile technique in some care settings, but clean intermittent catheterisation (CIC) or clean intermittent self-catheterisation CISC [188] is widely accepted as a safe technique for people who are self-caring in their own homes. Since some studies do not distinguish between CIC and CISC, the term CIC has been adopted to cover both throughout the following section. CIC provides much greater convenience than urethral catheterisation, without unacceptable

Table XII -1: Catheter choices. Catheters should only be considered where there is no satisfactory, non-invasive alternative to manage bladder drainage. ***(Grade of recommendation in brackets)***

Product category	User characteristics / priorities / contexts which:		Notes
	FAVOUR use	DISCOURAGE use	
Intermittent catheters (IC)	If more than 100ml retained in bladder (C) Concept of IC acceptable to user (or carer) User has sufficient dexterity and cognitive ability to manage regular drainage	In general (as with all catheters), where alternative, non-invasive management is satisfactory If user lacks motivation or unable to cope with regime	See Section 12.1 Greater independence for users No need for urine collection bags Reduced risk of catheter-associated complications Greater freedom for sexual activity.
Long-term indwelling catheters (LTC): general	Only for voiding problems which cannot be managed satisfactorily by other strategies (pads, other products or IC) (A) User or carer able to empty drainage bag regularly	In general (as with all catheters), where alternative, non-invasive management is satisfactory Avoidance of UTI is a priority (A) Cognitive impairment (danger of interfering with catheter) (C) High risk of recurrent catheter encrustation & blockage (B)	See Section 12-2 May be required: (i) to drain the bladder where there is urinary retention; (ii) to improve care of for those with severe incontinence who cannot manage otherwise, are terminally ill, or need secure urine drainage to heal skin lesions / wounds affected by the presence of urine
LTC: urethral insertion	Concept is acceptable	History of urethral trauma Haematuria of unknown origin High risk of catheter being expelled (bladder spasm)	
LTC: supra-pubic insertion	Concept is acceptable	Haematuria of unknown origin, Bladder tumour Small, contracted and fibrotic bladder User is obese	
Short-term indwelling catheter	Post-operative controlled drainage To monitor urine output To irrigate the bladder To instil medication To relieve retention of urine	In general (as with all catheters), where alternative, non-invasive management is satisfactory Avoidance of UTI is a priority (A)	

increases in infection rate, and has become a method of choice for management of bladder drainage for neurogenic and non-neurogenic bladder dysfunctions where urinary retention is a significant symptom and not easily remedied by other relatively simple means, eg TURP for prostatic obstruction. CIC can be taught to people of all ages, including the very elderly and children as young as four years old, with parental supervision [189] [190]. CIC can also be taught to carers, where this is an acceptable procedure to both patient and carer.

a) Quality of data

The majority of research evidence on intermittent catheterisation relates to catheter-associated urinary tract infection (CAUTI) and catheter materials and coatings. The most frequent complication of CIC is urinary tract infection (UTI) but it is unclear which catheter types, techniques or strategies, affect its incidence. There is wide variation in practice and important cost implications for using different catheters, techniques or strategies. Two relevant Cochrane reviews were identified; 'long-term bladder management by intermittent catheters in adults and children' [191]; and 'urinary catheter policies for long-term bladder drainage' [192]. The objective of the first review was to examine which intermittent catheter types, techniques or strategies, affect the incidence of UTI. Fourteen trials were included but sample sizes were small and attrition of participants was problematic. Definitions of outcome variables and follow-up periods differed, making it difficult to draw clinically useful conclusions. Several of the trials were more than 10 years old and were typically less rigorous in design and analysis. The authors concluded there is insufficient evidence to state that incidence of UTI is affected by use of sterile or clean technique, coated or uncoated catheters, single (sterile) or multiple use (clean) catheters, self-catheterisation or catheterisation by others, or by any other strategy. The objectives of the second review [193] were to determine if certain catheter policies are better than others in terms of effectiveness, complications, quality of life and economics. Comparisons included type of catheterisation (intermittent, indwelling urethral and indwelling supra-pubic) and antibiotic prophylaxis. Seven trials were included but all were small and confidence intervals were wide. There was limited evidence which indicated that prophylactic antibiotic therapy was associated with reduced episodes of bacteriuria (asymptomatic and symptomatic) in subjects using intermittent catheterisation. In both reviews, the trials which met the inclusion criteria were limited by small sample sizes and methodological weaknesses. A third review on 'catheter policies for management of long-term voiding problems in patients with neurogenic bladder' [194], which aimed to assess the effects of different types of urinary catheter (IC): in managing the neurogenic bladder, found there were no trials that met the inclusion criteria. Other research in this area is dominated by retrospective reviews of bladder management outcomes of patient cohorts. Long-term follow-up studies are almost exclusively of patient groups with neurogenic bladder disorders. Small scale, comparative studies of new products are common and are often industry-sponsored. Quality of life issues are vitally important for continence product users but studies are often limited by outcome measures predominantly based on user satisfaction, in the absence of clear criteria. Few studies have directly compared CIC with other methods of bladder drainage.

b) User characteristics:

CIC is a commonly recommended procedure for people with incomplete bladder emptying not satisfactorily managed by other methods. CIC can be appropriate for post-void residual urine volumes of 100ml or more in:

- Patients with neurological disorders that result in urinary retention problems, including failure to empty the bladder, incomplete emptying, detrusor sphincter dyssynergia.
- Patients with difficulty emptying the bladder after surgical procedures, if outflow obstruction occurs either in the short or long-term.
- Patients who accumulate a build up of residual urine caused by detrusor overactivity and inadequate bladder emptying.
- Acute urinary retention (most commonly in men).
- Management of urethral stricture.
- Emptying the bladder following continent urinary diversions such as a Mitrofanoff diversion.

CIC may be a practical option for patients who are:

- Sufficiently motivated to manage their bladder drainage by this technique.
- Sufficiently dexterous to perform the technique. An appropriate level of manual dexterity is essential but generally if people can write and feed themselves they have sufficient dexterity [195].
- Sufficiently cognitively aware to adhere to a regime and empty the bladder at appropriate time intervals to prevent bladder over-distension and preserve upper urinary tract function.
- Unable to perform the technique themselves but willing to accept the procedure from a caregiver.

Most men require some form of lubrication to aid catheterisation, which can be on the catheter surface or instilled into the urethra [196] (Level of Evidence 3). For those with preserved urethral sensation, a local anaesthetic gel may be needed. Many female patients also use a catheter lubricant / anaesthetic gel although some choose not to. In developing

countries, where resources are limited (or sometimes through patient choice), patients sometimes use plain water as lubricant [197] (Level of evidence 4). Some may benefit from adaptive equipment. An occupational therapist reported [198] on how a specially constructed penile trough (to hold the penis in a fixed position) allowed catheterisation with just one hand in a person with multiple brain injuries.

Regular bladder drainage is important to avoid potential damage to the upper urinary tract from urine reflux and raised intravesical pressure from build up of residual urine. Patients require individualised care plans to help identify appropriate catheterisation frequency, based on discussion of voiding dysfunction and impact on quality of life, frequency-volume charts, functional bladder capacity, and ultrasound bladder scans for residual urine. Some people need to catheterise several times per day, others less frequently. Catheterising frequently enough to avoid residual urine greater than 500ml is a general rule for adults but further guidance is also provided by urodynamic findings, detrusor pressures on filling, presence of reflux, and renal function. Disabilities such as blindness, lack of perineal sensation, tremor, mental disability and paraplegia do not necessarily preclude individuals from mastering the technique if they have sufficient manual dexterity [195]. Learning the technique may require more sessions for people with physical disability, such as MS, and cognitive impairment can contribute to less adherence over time [199]. Lack of motivation is the most common reason for failure, often linked to difficulty managing the technique or adhering to the required regime.

Children at school need a multi-professional assessment which may include a continence advisor, paediatric community nurse or school nurse, the child's consultant, the child and parents. With adequate training, suitable facilities and supportive teaching staff many children are able to carry out CIC themselves either on a toilet or from a wheelchair. CIC has been shown to be a viable therapeutic option for children with a large post-void residual urine volume in the absence of any neurological abnormality [200]. Intermittent catheterisation has also been shown to be an effective technique for elderly patients with post-void residuals more than 50% of the bladder capacity, resistant to other treatment [201]. In a group of 21 patients (mean age 76.5 years), 12 mastered the technique of CIC, with the remainder catheterised by their partners or nurses. Urinary continence was restored, urgency, frequency and nocturia decreased and UTI rate diminished, resulting in improved quality of life.

In a study in a 110-bed hospital, a bladder scanner was introduced to decrease unnecessary catheterizations using either a straight catheter (in-out) or an indwelling catheter [202]. Staff members were educated on the use of the new scanner in conjunction with an algorithm to guide decisions on treatment. Fourteen per cent (11) of the 79 scans resulted in catheterization, and there was an 80% decrease in catheterizations in 47 persons unable to void, based on clinical observation during a one month period. Most of those who required catheterization were surgical patients. There were three in-out catheterizations and eight indwelling catheters were inserted, more were female (73%), and over age 75 (p=0.035).

Advantages of intermittent over indwelling catheterisation include:

- Greater opportunity for individuals for self-care and independence.
- Reduced risk of common indwelling catheter-associated complications.
- Better protection of the upper urinary tract from reflux.
- Reduced need for equipment and appliances e.g. drainage bags.
- Greater freedom for expression of sexuality.
- Potential for improved continence between.

c) Catheter characteristics

Types and characteristics of catheters used in intermittent catheterisation vary considerably so evaluation and selection of products is complex [191]. Plain uncoated catheters, typically clear plastic polyvinyl chloride (PVC), are packed singly in sterile packaging. As per industry standards, all disposable catheters are intended for one time use, but PVC catheters are frequently cleaned and reused by individual users because of cost or concern about environmental issues. Recently, to address environmental concerns related to single use catheters, a new PVC-free catheter was created and evaluated by 173 persons in comparison to the standard PVC one [203]. Both catheters had a hydrophilic coating. No significant differences were found. Some health care professionals make a distinction between 'single-use' (i.e disposed of after insertion) and 'single patient use' (cleaned and re-used by the same patient for a limited period of time, such as one week). Where products are used in ways which differ from manufacturers' guidance, both patients and health care professionals should recognise their personal, professional / legal responsibilities. In some countries, including the US, there are very clear governmental directives that catheters identified as single-use devices should not be re-used in any setting. US patients should be provided with an adequate number of catheters to use a sterile catheter for each catheterisation, and patients and carers must be informed that catheters are identified for single use only. However, not everyone in the US using IC has the federal insurance program (Medicare), which began paying for single use catheters on April 1, 2008 at the rate of up to 200/month [204] [205]. In one US study of 34 IC users [206], many said they

did not have adequate insurance reimbursement for single use catheters, and 35% cleaned and reused catheters.

Most uncoated intermittent catheters are used with separate lubricant, although this is a matter of personal choice. Cleansing for re-use (where this occurs) varies from being washed with soap and water, boiled, soaked in disinfectants, or microwaved. Cleaned catheters are air dried and then stored in a convenient container (often plastic containers / Zip loc bags or paper bags). Metal catheters made from silver or stainless steel can be sterilized by heat or chemicals and may be used repeatedly for longer periods than other reusable materials.

Coated catheters are single use only (they are not currently suitable to be cleaned and reused) and are designed to improve catheter lubrication, ease of insertion and convenience. Coated catheters may reduce urethral trauma and CAUTI although good quality research evidence remains limited. The most common coatings are hydrophilic (which require the addition of water to the catheter to form a lubricious layer) or pre-lubricated (whereby the catheter is supplied pre-packed with a coating of water soluble gel). There are also several pre-lubricated products with an integrated collection bag (all-in-one) which gives flexibility for the user and are efficient for hospital use. Not all CIC users like this type of bag; thus trying several types of catheters for various activities, such as when home or when away, can help in decisions about what is best for the person [206].

Intermittent catheters range in size from 6-20 Ch, with most common sizes being 10-12 for females and 12-16 for males (**Figure XII -1**). Intermittent catheters are generally around 40cm long (male length) and are more rigid than indwelling catheters to aid insertion. A variety of aids to assist catheterisation are available (**Figure XII -2**).

Some women find a stiffer catheter easier to handle and some designs are slightly curved and made only in female length (around 18cm) to accommodate their requirements. A new compact catheter of 7cm was as effective in 23 of 24 women in removing residual urine as 20cm catheters [207]. Some manufacturers produce conveniently packaged 'catheter-sets' where the catheter is already attached to a urine containment pouch inside the pack and a non-touch, clean technique is facilitated by holding the catheter inside the bag and gradually advancing it from the bag during insertion. Catheter designs may include a protective tip to help reduce the transfer of bacteria from the distal region of the urethra further into the bladder. Patients should have the opportunity to try different catheters and choose which best suits their needs and lifestyle. Different catheters / packs may be appropriate at different times e.g. when added convenience for quick and efficient use and disposal is important, such as going to work or on holiday.

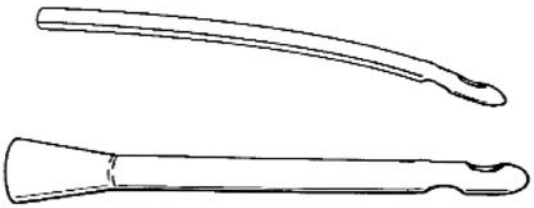

Figure XII-1: Examples of catheters for intermittent catheterisation: Scott (top) and Nelaton (bottom).

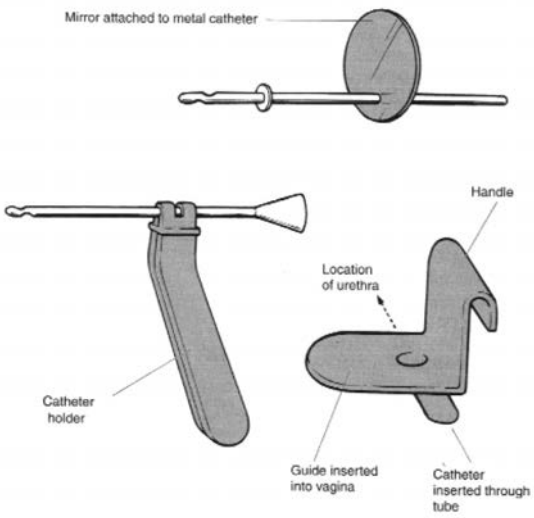

Figure XII-2: Examples of catheters for intermittent catheterisation: Scott (top) and Nelaton (bottom).

An effective intermittent catheter should have the following characteristics:

- Smooth for comfort, but sufficiently firm for easy insertion and maintenance of lumen patency.
- Minimal friction on insertion or removal.
- Smooth edges to catheter eyes to avoid tissue trauma on frequent catheterisation.
- Shaped for easy passage through urethral contours.
- Easy to hold and manipulate for those with limited dexterity.
- Easy to identify correct end for insertion and for drainage, for those with visual impairment.

Although there is an increasing range of intermittent catheter types on the market - including many pre-lubricated products with integrated collection bags - the quality of evidence for clinical benefit is poor. De Ridder et al [208] conducted a prospective, randomised, parallel, comparative trial of a hydrophilic coated catheter with an uncoated PVC catheter with

123 male spinal cord injured (SCI) patients. Only 57 completed the 12 month study but fewer patients with the coated catheter experienced one or more symptomatic UTIs (p=0.02). There was no difference in haematuria, leukocyturia and bacteriuria. However a recent Cochrane Review [191], concluded that overall current research evidence is weak, most studies are underpowered and conclusions are limited by serious design issues. A recent review indicated that hydrophilic catheters are beneficial for men with SCI, in relation to safety (preventing urethral damage and associated complications) and quality of life (comfort) [47].However research is limited in women, MS, and spina bifida. An earlier literature review [209] also indicated the wide variety of materials and techniques used for intermittent catheterisation. It concluded that there was no one best technique or material and that choice of both depend greatly on the patient's individual anatomic, social and economic status.

d) Associated risks / problems

Urinary tract infection is well-recognised as the most frequent complication of intermittent catheterisation [191]. The accumulation of urine in the bladder provides a reservoir for infection, but it has also been proposed that the increased intravesical pressure reduces the vascular supply to the bladder tissue rendering it more susceptible to bacterial invasion [210]. A post-void residual urine volume of 150ml has been demonstrated to be an independent risk factor for the development of UTI, in stroke patients [211] (Level of Evidence 2). In Wyndaele's review of complications of intermittent catheterisation (82 studies), prostatitis was identified as a risk in men but epididymitis and urethritis were relatively rare [209]. Trauma from catheterisation, measured by haematuria, was noted to occur regularly but lasting effects were more limited. The prevalence of urethral strictures and false passages increased with longer use of CIC but the review concluded that the most important preventative measures are good education of all involved in CIC, good patient compliance, use of an appropriate catheter material, good catheterisation technique and the avoidance of bladder over-filling. Similar findings were reported by Campbell [212] in a follow up of children with spina bifida who had used intermittent catheterisation with uncoated PVC catheters for at least five years. The incidence of urethritis, false passage, or epididymitis was very low whilst adherence to the protocol was excellent. However, Ku et al [213] found a higher incidence of epididymitis in their cohort review of 140 male, SCI patients followed over 16 years.

A study of medical and social complications of US data in 24,762 persons with SCI [214] who were evaluated every five years for 30 years, has been published (see section XII.1.g below for report on bladder management changes over time). Bladder management comparisons were done for indwelling (IC), CIC, condom, and spontaneous voiding. While there was some variation at different time points, medical complications were higher in persons with indwelling catheters, for pressure ulcers and days in the hospital, and kidney stones, though infrequent, were higher at times. Psychosocial outcomes also did not favour IC users, and each measure (satisfaction with life, perceived health status, and participation in society) was lower than the other groups, though not significantly so. The authors said that better understanding of psychosocial issues could be attained though prospective studies, as other factors than bladder management might affect quality of life.

1. Urinary tract infection

It is difficult to know the prevalence of UTI associated with intermittent catheterisation as reports vary widely and definitions of UTI are inconsistent, sometimes based on bacteriuria alone (asymptomatic) and sometimes on symptomatic UTI (with or without clearly defined criteria). In a study of 41 European centres serving children with spina bifida, although most centres had established protocols for diagnosis and treatment of UTI, no consensus was identified for common protocols [215]. Other variations found included methods of evaluation, catheterisation techniques, frequency of urinalysis / culture, administration or not of prophylactic antibiotics, and the patient group studied (including gender, functional ability, behavioural and personal hygiene factors).

In a prospective study of 128 SCI patients, where the incidence of UTI was calculated as the number of episodes per 100 person-days, the overall incidence of UTI was 0.68. The rate for males using CIC was 0.41, compared to 2.72 for those using an indwelling catheter [216]. Biering-Sorensen et al. [217] studied 77 SCI patients on CIC after five years and found that 81% had been treated for at least one UTI, 22% had two-three UTIs/year and 12% had four or more per year. The technique of intermittent catheterisation used does not seem to be a risk factor and despite different catheterisation techniques used, the number of episodes of clinically significant nosocomial urinary infections and the mean species turnover remains similar [218] (Level of Evidence 2).

In the Cochrane review cited above [191], the primary outcome measure was catheter-associated infection (definition of infection as used in the trial reports). Fourteen trials met the inclusion criteria but too little data could be entered into a metanalysis to produce meaningful data summaries. Based on the available data, the authors concluded that there appeared to be no clear difference between various methods of catheterisation (sterile catheterisation techniques, clean catheterisation with a single-use sterile catheter, or clean catheterisation with a clean reused catheter). Whilst the outcomes of this review raise questions over efficacy and cost-effectiveness of expensive coated catheters it is clear that further

robust research is needed. All sample sizes in the trials were small and only two included statistical power calculations, although they were unable to achieve their predicted sample sizes. Most studies suffered from high attrition rates and several reports were more than 10 years old. The challenges of obtaining sound data in this clinical area continue to hinder the accumulation of evidence to help guide healthcare practitioners. A common difficulty is in the establishment of robust outcome measures. UTI remains the most clinically important primary outcome variable but bacteriuria/ positive urine culture is not clinically relevant unless accompanied by symptoms. Symptoms themselves may present in vague and imprecise ways, especially in elderly and/or SCI patients where symptoms can be masked or unclear.

Since the Cochrane review two further studies have compared hydrophilic versus plastic IC catheters and examined the effect on UTI [219]. In a community study of patients with spinal cord injury (45 participants completed) Cardenas and Hoffman found no differences in the incidence of symptomatic UTI between the groups, although the number of antibiotic treated UTIs was significantly smaller in those using hydrophilic catheters. Regression analysis showed that women were more likely to have UTIs than men and it is noteworthy that there were twice the number of women in the control (plastic catheter) group compared to the hydrophilic group (N=11 versus N=5).

Cardenas and other co-workers also carried out a randomized trial of hydrophilic or plastic ICcatheters in SCI patients in hospital. This study demonstrated benefit from the hydrophilic catheter during initial early rehabilitation with a delay in the first symptomatic UTI [220]. Fifteen North American SCI centres took part, and 224 patients were randomized to the catheter type within 10 days of beginning IC, and were followed either in the hospital or rehabilitation then, when discharged to the community, for up to 3 months more, for a total of up to 6 months. This delay in first UTI resulted in a daily risk reduction of 33% and during the initial institutional time the UTI rate decreased by 21% ($p<0.05$) in the hydrophilic group. However, no differences were found between the two groups in the incidence of UTI over the whole study period.

A Cochrane review on urinary catheter policies for long-term bladder drainage [221] reported limited evidence that prophylactic antibiotic therapy was associated with reduced episodes of bacteriuria (asymptomatic and symptomatic) but all trials were small and confidence intervals were wide. The authors caution that possible benefits from prophylaxis must be balanced against possible adverse effects such as the development of antibiotic resistant bacteria.

In order to improve rigorous clinical evaluation of current and innovative products for CIC, more epidemiological data on user populations and characteristics of catheter use is needed. A recent Canadian national survey of intermittent catheterisation practices following SCI [222], reported on 912 responses to a 36-item self-report postal questionnaire. Fifty five per cent of respondents used intermittent catheterisation regularly, with users forming a significantly younger group than non-users ($p=0.001$). The majority of users (73%) used a clean technique. The remaining 27% reported using a sterile technique. Uncoated catheters were used most commonly; 74% only used uncoated catheters; 15% used hydrophilic coated catheters; and 11% reported using both types. These notable differences may be partially related to patient education, costs to patients and health insurance funding constraints. The majority of uncoated catheter users used their catheter only once (53%) but a further 30% used their catheter more than nine times. The mean frequency of self-reported CAUTIs in the past 12 months (symptomatic but not necessarily confirmed by laboratory evidence) was 2.6, with females experiences significantly more infections than males ($p=0.003$). Although the use of hydrophilic coated catheters was associated with a lower rate of CAUTI (2.46 versus 2.62 for those using uncoated catheters), this difference was not reported as statistically significant. However UTI rates are multi-factorial and are unlikely to be fully accounted for by the variables investigated. A significant relationship between number of catheterisations per day and CAUTI rates was identified, with those who catheterised only once a day having the highest rate of infections ($p=0.03$). This is consistent with previous suggestions that increasing the time that colonised urine is present in the bladder is associated with increased infection rates [208]. It is interesting to note that, while extra fluid intake was positively related to reduced rate of CAUTI ($p<0.001$), catheter re-use, catheter disinfection and antibiotic prophylaxis were not significantly associated with CAUTI rate. Clearly there are potential limitations in this study as with any which employs self-report methodology. These include self-selection of respondents, accuracy of recall and quality of information provided, but the large number of respondents and the degree of internal consistency reported by the researchers provide creditability to these results.

Several studies have sought to determine whether the antibacterial effects of cranberry extract will reduce or eliminate bacteriuria and pyuria in patients using intermittent catheterisation, particularly in SCI populations [223] [224]. In a randomised, double-blind, placebo-controlled study of 48 SCI patients living in the community and using intermittent catheterisation or external urine collection device, participants ingested 2g concentrated cranberry extract in capsule form or placebo daily for 6 months [224]. There were no differences between groups with respect to number of urine specimens with bacterial counts $>10^4$ cfu/ml, types and numbers of different bacterial species, numbers of urinary leukocytes, urinary pH, or episodes of symptomatic infection.

2. Tissue trauma, strictures and other complications

Long-term follow-up studies have examined other complications associated with intermittent catheterisation and found urethral trauma to be common [225] [226]. Urethral bleeding is frequent in new patients and has been noted to continue to occur in up to 30% on a long-term basis [226] [227], however risks of tissue trauma may be reduced with newer catheter products which are designed to reduce friction. Consequently the outcomes of older studies need to be considered with caution. The withdrawal frictional force was compared between two hydrophilic coated catheters and one uncoated catheter in a prospective, randomised, participant-blinded, crossover trial by Stensballe et al [228]. Forty participants completed the study and it was interesting to note that while one coated catheter (SpeediCath) exerted a lower mean withdrawal force than the other catheters, the second coated catheter (LoFric) exerted a significantly higher mean friction force than both the other catheters. Both hydrophilic coated catheters were associated with less microscopic haematuria than the uncoated catheter. Similarly, there was a lower incidence of microscopic haematuria reported in two of the coated catheter groups compared to uncoated catheters in trials included in the Cochrane review [191]; 0.31versus 0.65 [229]; 6/14 (43%) v 11/14 (78%) [230]. Trauma of the urethra, especially in men, can cause false passages. Treatment for false passages in SCI patients by six weeks indwelling catheter use and five days antibiotics, has been reported to be effective [231] (Level of Evidence 3). The false passages had disappeared on cystoscopy and CIC could be restarted.

It has been claimed that the long term risk of urethral stricture formation may be less when hydrophilic coated catheters are used [232]. The degree of urethral inflammation, measured by urethral cytology in two groups using CIC (one using ordinary PVC catheters with lubricant; the other using hydrophilic coated catheters), showed significantly less urethral inflammation in the hydrophilic coated catheter group. Although this data suggests some benefit in using hydrophilic coated catheters to minimise stricture formation in the long-term comparative studies are limited. One recent follow-up study of 31 females with spina bifida, using CIC for a median of 15 years, examined risk of urethral lesions. There were few problems reported (only on 20 occasions in a total of 459 patient-years), despite long-treatment periods and use of non-coated PVC catheters [233].

The relative importance and cost-effectiveness of hydrophilic catheter coatings has not been adequately addressed in large scale studies to date. Hedlund et al. [234] in their review of 28 CIC studies, called for a prospective, randomized, long-term, multi-centre study to address clinical benefit and cost effectiveness. Data on patient characteristics should include age; gender; diagnosis of bladder dysfunction; reason for CIC; physical and mental disability; manual dexterity; and previous treatments. Effect parameters should include number of catheterisations; urinary tract infection (symptomatic or asymptomatic); early and long-term urethral complications; patient satisfaction, preferences; and drop-out rates. Robust studies of this nature are still awaited.

3. Other complications

Formation of bladder stones has been found to be associated with long-term use of CIC in a number of studies [235] (Level of Evidence 2). Barroso et al. [236] reported an increased risk of developing bladder calculi in children performing CIC based on the records of 403 children. Stones were diagnosed in 28 patients. The incidence was slightly higher in those with a Mitrofanoff conduit but was not influenced by bladder augmentation (Level of Evidence 3). A retrospective study of 140 SCI patients, followed up from 1987 to 2003, identified 27.9% of patients diagnosed with epididymo-orchiditis. This problem was more common in patients using CIC compared to indwelling catheterisation (42.2% v 8.3%, P= 0.03). Multivariate analysis showed CIC to be an independent risk factor for epididymo-orchiditis, with SCI patients in this study subject to a 7-fold higher risk (OD 6.96; 95%CI, 1.26-38.53) [213]. While the risk of cancer in long-term indwelling catheter users is known, (see section 12.2.10 below) squamous cell cancer in persons with intermittent catheters has been reported also in at least eight cases. A number of factors may be involved including leukoplakia, bacteriuria, trauma from the catheter and squamous metaplasia, a premalignant change [237].

e) Catheter management

1. Education, support and quality of life (QoL)

Good education of all involved in CIC, good patient compliance, use of an appropriate catheter material, and good catheterisation technique have been identified as the most important measures to prevent adverse complications [209]. Factors affecting adherence to self-catheterisation procedures have been explored, addressing both initial mastery of technique and both short-term adherence and long-term adherence [238] [239]. Time taken to build confidence is variable and may range from days to years [239]. General determinants of adherence related to knowledge, complexity of the procedure, misconceptions, fears, shame, motivation, quality and continuity of professional care.

CIC may affect both sexuality and sexual activity [240] and sensitive support and teaching are needed. An emotionally negative response can occur, which requires individualized teaching in a relaxed, supportive environment [240]. Adequate information combined with thorough teaching and good

communication can help new CIC users gain initial acceptance and adherence to the procedure [239]. Some women are not able to locate the urinary meatus, and they may not be comfortable in learning and thus require additional coaching, encouragement, practice and support [241] [206] [240]. Other anatomical issues need to be considered as well, such as redundant prepuce in some males, false urethral passages, and bladder spasms [242]. In addition, lack of adequate bathroom accessibility, especially in public places, can be a major barrier to adherence [242] [206].

Integration of the CIC regime into everyday life was a recognised difficulty and for younger patients, in particular, availability of materials, physical impairments and resistance to 'sickness role' were factors which could also compromise adherence. Qualitative research studies using a grounded theory approach have identified similar factors influencing variations in quality of life (see also section XII.4). These include sex; lifestyle; frequency of duration of carrying out CIC; technical difficulties; type of catheter; comorbidities; and individual predispositions [241].

In the large scale Canadian survey above [222] 71% reported that CAUTIs had negatively impacted on their QoL score (a 10-point scale). Several significant variables associated with CAUTI and QoL were determined. Interestingly, time lost from social activities was more strongly associated with compromised QoL than actual number of infections or days lost from work. In another study in 41 persons with SCI, treatment success correlated positively with the Qualiveen QoL measure. Success criteria involved clinical symptoms of continence, lack of autonomic dysregulation (dysreflexia), and urodynamic testing for adequate bladder storage capacity (> 360 mL) and detrusor pressure (< 40cm water) [243].

Twenty two teenagers and young adults with myelomeningocele were interviewed about psychosocial factors related to CIC [244]. Deciding when to disclose CIC use was important in relation to peer support and friendships, and many wished they had done so at an earlier age, with the help of an adult. In fact everyone in a group needed to appreciate the need to avoid gossip. Those not in wheelchairs found it harder to convince others of their need to use CIC. In healthcare settings, many wanted to perform self-catheterisation instead of staff doing it. Information about sexual function was desired by many.

An Internet based qualitative study in the US aimed at discovering issues and problems in long-term CIC users [206] found key concerns related to use of bathrooms that were dirty and inaccessible and a lack of knowledge of options in supplies and/or insurance coverage. Other themes involved knowing the body, practising intermittent catheterization, hassles, and adjustment in making intermittent catheterization a part of life. Experienced CIC users explained how they made adjustments to include CIC in daily life by paying attention to their routines.

More education may be provided to catheter users through the Internet in the future. In a study using 18 articles written for persons with spinal cord injury (based on suggestions from patients and rehabilitation nurses), consumers were satisfied with the information and scored this approach as 8.02 on a 1-10 scale with 10 as being most satisfied [245]. Information was available in English and Spanish. Utilization during the 13 month study, scored as "hits" on the website, was far more frequent in the Spanish language materials (n=811, 70%) than "hits" for the English materials (n=351, 30%). Examples of article content in both languages included cranberry juice and UTIs, cleaning the drainage bag, types of urinary management and only in English, latex allergies and catheter use, autonomic dysreflexia, and sexuality.

2. Catheter cleaning for re-use

Where catheters are cleaned for re-use they may continue to be used many times, up to weeks or even months. However, health professionals and users need to recognise their personal responsibilities and liabilities in supporting this approach since manufacturers' guidance will normally relate to single use only (see also Section XII.1.c). Questions over how long the same catheter may be safely reused require further examination, and may be particularly important in developing countries, where access to new supplies may be limited [246]. Methods of cleaning or re-sterilising include soaking in a variety of antiseptic solutions or boiling water or microwave sterilisation. In a study which compared three home cleaning methods used by patients performing CIC, all of the following were found to be effective: 0.6% hydrogen peroxide; bleach in a 1:4 solution with tap water; and betadine in a 1:2 solution with tap water [247]. None of the cleaned catheters showed detectable bacterial growth for 48 hours after the cleaning procedure was performed (Level of evidence 4). Lavallee et al. [248] also compared the effectiveness of hydrogen peroxide, vinegar, dishwashing detergent, and tap water alone to clean catheters contaminated with Pseudomonas aeruginosa and Escherichia coli. They also examined the effect of immediate rinsing and drying before cleaning. Results indicated that rinsing and drying immediately after use was the most effective at reducing bacteria to near zero (Level of evidence 4). Microwave sterilization has been advocated by some, but has not been adequately evaluated. A study by Sherbondy, et al. [249] showed that even where standardized instructions (both verbal and written) were provided, microwave sterilization techniques by patients performing CIC varied considerably. Many patients surveyed did not follow the study instructions recommending sterilizing used catheters on a daily basis, cleaning with soap

Table XII-2 provides some guidance on patient education and troubleshooting for CIC.

Table XII-2: Intermittent catheterisation

Patient education & support:
• Discussion of individual bladder dysfunction and reasons for CIC. • Personal anatomy and identification of urethral orifice. • CIC technique – comfortable position, frequency, observation of patient's technique. • Hygiene. • Discussion of any psycho-sexual anxieties (body image, sexual function etc). • Single use versus reusable catheters (cleaning, storing, re-use, disposal). NB including awareness of personal / legal issues. • Difficulties and what to do. • Dietary advice and avoidance of constipation. • Obtaining supplies. • Follow-up visits and consultations.

Guidance for common problems:
• Catheter will not go in at first attempt – relax for a while and try again a bit later; lubricate catheter (eg dipping in water or gel); if necessary seek professional guidance. • Catheter inserted into vagina by mistake – withdraw, wash and re-insert. • Catheter will not come out – leave for a few minutes, relax and try to 'let go', cough gently and withdraw catheter. • UTI – report changes in urine (eg blood, sediment, smell). Know how to recognise signs of symptomatic infection and seek treatment and review of CIC technique.

and water and air drying before inserting into a microwave oven on a paper towel. Microwaving on a high setting for six minutes on a rotation table was recommended together with a heat sink – a cup of water in a microwave-safe container placed in the microwave to absorb extra heat. Catheter melting was reported by 63% and was significantly associated with the absence of a rotation table. If microwaving is to be accepted as an appropriate sterilization method then users must be provided with a standardised, evidence-based, protocol to follow. A recent study reported the development of titanium dioxide-coated catheters for CIC which were easily sterilized under certain light sources and were shown to be safe in experimental studies [250]. Preliminary clinical analysis with 18 volunteers was also promising.

f) Comparisons between intermittent and indwelling catheterisation

A systematic review of risk factors for UTI in adults with SCI reported evidence of fewer infections in patients using intermittent catheterisation compared to indwelling catheterisation [251]. Twenty two studies met the inclusion criteria for evaluation but the authors noted that many had important methodological deficiencies. Intermittent catheterisation has also been shown to be associated with fewer UTIs compared to indwelling catheterisation in elderly patients after surgical repair of hip fractures [252] and in a comparative study of patients at a hospital department of urology [253].

g) Catheter use over time in persons with SCI

Bladder management methods in 24,762 patients were tracked for over 30 years, using the US National Spinal Cord Injury Database, yielding the results summarsied in **Table XII-3** [168]. Surveys were completed every five years to evaluate catheter use at discharge from rehabilitation. In addition, continued use in the same individuals was evaluated 30 years later in follow up data with 12,984 to determine changes in use over time.

Table XII-3: From US data base of SCI, surveys of bladder management every five years for 30 years. (Cameron et al, 2010)[168). N=24,762.

Bladder management	Use (%) 1972	Use (%) 1991	Use (%) 2001	Continued use at 30 years (n= 12,984)
CIC	13	56	50	20
Indwelling catheter	33	17	23	71
Sheath	35	4.7	1.5	35

At discharge from rehabilitation, condom catheter use decreased gradually (35% in 1972 to 1.5% in 2001) while clean intermittent catheterization increased from 13% in 1972, peaked in 1991 at 56%, and fell slightly to 50% in 2001. Indwelling catheter use initially decreased during this time (33% in 1972 to 17% in 1991) but increased somewhat to 23% in 2001. In follow up data, the great majority of those originally using an indwelling catheter stayed with it, i.e., 71% after 30 years. However, most persons using CIC or condom drainage did not continue to use them, and only 20% and 35%, respectively, did so after 30 years. This indicates that despite CIC being the bladder drainage method of choice, individuals with SCI might use indwelling catheters if not able to manage CIC (Level of Evidence 3).

Patel et al. [254] examined the outcomes of different forms of urinary drainage for men with acute urinary retention. After a short period of indwelling urinary catheterisation patients were taught to use CIC (34 men). Patients who failed this were re-catheterised and taught to manage a valve or failing this a leg bag (16 men) and then discharged home. The CIC group had a higher rate of spontaneous voiding (56% v 25%) and a lower incidence of UTI (32% v 75%). At TURP 20% in the CIC group had a UTI compared to 69% in the indwelling catheter group. Patients using CIC preferred it and had fewer complications. The authors concluded that CIC was well accepted by those patients who were able to manage the technique, resulted in fewer UTIs and should be considered in patients presenting with acute retention.

In a recent 2-week prospective study of intermittent catheterisation versus indwelling urethral catheterisation in older female patients in a rehabilitation setting, 81 females >65 years with post-voiding residual volume persistently >300 ml were randomized to one of two groups [255]. Both groups demonstrated similar success in regaining bladder function and similar rates of bacteriuria. The authors concluded that intermittent catheterisation was justified in managing this patient group, particularly since indwelling catheters were deemed to hinder rehabilitation and adversely affected quality of life.

An RCT of 72 women post-urogyncological surgery (stress UI or pelvic organ prolapse) compared intermittent catheterization (CIC) with supra-pubic catheterization (SPC) [256]. The length of hospital stay was decreased significantly (Mann-Whitney p=0.003) with CIC (median 5 days, range 2-19) as compared with SPC (median 6 days, range 2-15). The days of catheterization also decreased significantly (Mann-Whitney p=0.01) with CIC (mean 4, SD 26, median 2) as compared with SPC (mean 5, SD 36, median 4), but the differences were viewed as limited clinically. Post-op UTIs were higher in the CIC group (13 versus nine in the SPC group), but not significantly (Fishers' exact p=0.44). Of note, the CIC group had the opportunity to void much sooner than the SPC group because the latter were on straight drainage for 48 hours post-operatively as hospital policy, and this may have had an impact on the results and clinical relevance.

In a prospective RCT of CIC versus supra-pubic catheterisation (SPC) for post-operative bladder care following hysterectomy in 40 women there was no significant difference in the length of bladder care between the two groups [257]. Bacteriuria was higher in the CIC group at days 3 and 5 (p=0.05 and 0.004, respectively) although it is unclear whether there was evidence of symptomatic infection. However, there was a higher incidence of symptoms / problems arising from the SPC site, of which 23% were shown to have a positive wound swab. The authors concluded that despite a higher rate of bacteriuria, the high incidence of site problems with SPC could be avoided by CIC. The technique of CIC was seen to be more acceptable to patients (p=0.009); allowing fewer disturbances at night (p=0.006); greater freedom to lead a normal life during the day (p=0.000); and less anxiety / embarrassment (p=0.005) compared to SPC. However, in a study of 43 persons with tetraplegia who were on artificial ventilation comparing IC and SPC, SPC users had significantly fewer urological complications and better quality of life, as measured by the ICIQ-SF (3 items), but not significantly better [258].

h) Summary

CIC is the preferred method of urinary drainage in patients with neurogenic bladder dysfunction and others with problems of bladder emptying who are

capable of performing the procedure and who find it acceptable. It can be taught to patients of all ages who have sufficient manual dexterity and motivation to manage the technique. Urinary tract infection is the most frequent complication and the most important preventative measures for all complications are good education of all involved in CIC management, good patient compliance and support, use of an appropriate catheter material and good catheterisation technique. Difficulties in carrying out the procedure such as physical and technical difficulties, embarrassment, time involved and lack of appropriate public facilities may deter users from adhering to the regime. Hydrophilic-coated catheters confer benefits in terms of comfort and minimised tissue trauma compared to non-coated catheters (Level of evidence 2/3) but evidence of benefit in relation to urinary tract infection is less clear.

The available data on intermittent catheterisation does not provide convincing evidence that any specific technique (sterile or clean), catheter type (coated or uncoated); method (single use or multiple use), person (self or other), or strategy is better than any other for all clinical settings. This reflects lack of reliable evidence rather than evidence of no difference. Currently clinicians will need to base decisions about which technique and type of catheter to use on clinical judgment, in conjunction with patients. Differential costs of catheters / techniques may also inform decision making.

In particular, CIC has been shown to have benefits over indwelling catheterisation in the following ways:

- Avoidance of common problems associated with LTC use such as catheter leakage and / or practical management of drainage systems
- Avoidance of complications linked to bacterial biofilm formation, including catheter encrustation and blockage. Strong evidence for reduced risk of CAUTI is less clear.
- Maintenance of some level of bladder capacity and muscle tone by allowing the bladder to fill periodically, compared to free drainage by indwelling catheter.
- Less urethral inflammation (measured by cytology) than urethral indwelling catheterisation (Level of evidence 2/3).
- Lower incidence of bladder calculi than indwelling catheterisation (Level of evidence 2/3).

2. INDWELLING CATHETERISATION

Indwelling catheters (**Figure XII-3**) may be used in the short-term to manage an acute need for controlled bladder drainage or as part of a long-term management strategy (**Table XII-1**).

Catheters may be inserted into the bladder urethrally (UC) or suprapubically (SPC) through an incision

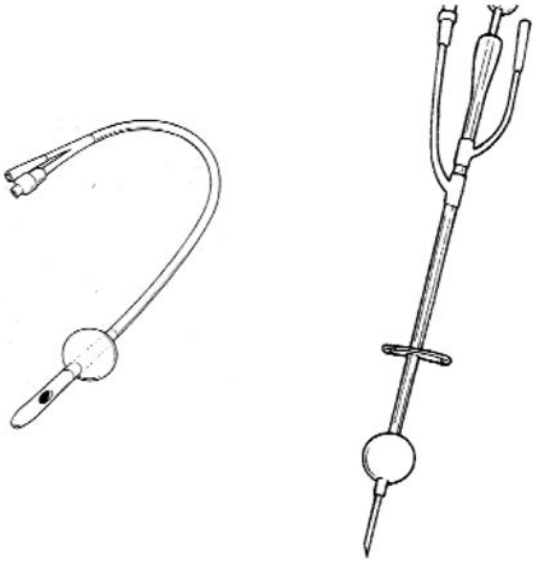

Figure XII-3: A Foley catheter (left) and a suprapubic catheter with a sharp trocar for introducing the catheter (right).

in the abdominal wall. The continued requirement for indwelling catheterization should be reviewed at regular intervals and the catheter removed promptly if no longer necessary, since catheter use is associated with a number of risks. The major complication associated with short-term, indwelling catheters used in acute care, is nosocomial (healthcare acquired) catheter-associated urinary tract infection (CAUTI), which can lead to life-threatening bacteraemia in vulnerable groups and may also contribute to reservoirs of antibiotic resistant microorganisms [187] [122] [259], Long-term catheters (LTC) are also associated with increased risk of CAUTI and a further range of problems including: recurrent blockage due to encrustation by mineral deposits; meatal tissue damage - often caused by excessive weight from heavy drainage bags; frequent bladder spasm with potential expulsion of the catheter; formation of bladder calculi; and potential for long-term neoplastic changes in the bladder (although further long-term studies are needed to establish this risk). Although for some patients an LTC catheter can provide satisfactory management of bladder problems and greater independence, others experience pain and discomfort with a catheter in situ and / or, are distressed by the impact of a catheter on their body image and sexuality. Intermittent catheterisation (See Section XII.1) is less invasive and is generally associated with fewer risks.

a) Quality of Data

Nine Cochrane reviews relating to short and long-term indwelling catheter use were identified. Five reviews on short-term (<14 days or other temporary

short-term use as defined by triallists) catheter issues included: types of urethral catheters for management of short-term voiding problems in hospitalised adults [260]; policies for bladder management[192]; the role of prophylactic antibiotics [221]; use of alpha blockers for acute retention prior to a trial without a catheter [261] and policies for removal of short-term indwelling catheters [262]. The objective of the first review [260] was to determine the effect of type of indwelling urethral catheter on the risk of UTI. Twenty-three trials - comparing different types of standard catheters or a standard catheter with an antiseptic catheter (silver alloy or impregnated with silver oxide), or an antibiotic impregnated catheter (either minocycline and rifampicin, or nitrofurazone) - met the criteria. The reviewers concluded that currently available evidence suggests that silver alloy catheters prevent asymptomatic bacteriuria in the short-term catheterised patient, although trials are generally of poor quality (Level of evidence 2/3). They also recommended that further economic evaluation is required to confirm that reduction of infection compensates for the increased cost of the silver alloy catheters. Catheters impregnated with antibiotics were also beneficial in reducing bacteriuria in hospitalised adults catheterised for less than a week but data were too few for those catheterised longer. However, it is important to note that although bacteriuria is a commonly used outcome measure in CAUTI studies there is much debate over the clinical utility of this measure. Many studies fail to distinguish between asymptomatic bacteriuria and symptomatic infection. This is discussed further in Section XII.2.h.3.

The second review [192] included 14 trials which reported on comparisons between SPC and UC for short term (up to 14 days). Higher relative risks scores were found for UC related to more bacteriuria (RR 2.60; 95% CI 2.12 to 3.18), more frequent re-catheterization (RR 4.12; 95% CI 2.94 to7.56) and increased discomfort (RR 2.98; 95% CI 2.31 to 3.85) (Level of Evidence 1). The third review [221] included six parallel group RCTs and reported weak evidence that antibiotic prophylaxis reduced the rate of symptomatic UTI in female surgical patients, compared to antibiotics given when clinically indicated. The review of policies for catheter removal [262] reported suggestive, but inconclusive, evidence of benefit from midnight removal of the catheter (larger volumes at first void) and shorter hospital stay after early rather than delayed removal.

In the fifth Cochrane review [261] use of alpha blockers prior to a trial without a catheter for acute retention was evaluated. This treatment is believed to relax smooth muscle in the prostate which would improve urine flow and decrease the need for recatheterisation. Five clinical trials were involved, in four trials ranging from 24-72 hours prior to catheter removal in most persons (up to eight days in one trial). In the other study, the drug was given for eight days. Results overall were mixed, with two trials favouring the treatment and two favouring placebo, and thus there was limited but positive evidence that this was helpful. There were some side effects, such as hypotension and headache, but this was similar in the placebo groups. Further research was suggested.

Of the four Cochrane reviews relating to long-term catheter use, a review of 400 articles for comparative methods of using catheters for neurogenic bladder management, updated in 2011 [194] failed to find any trial that met the inclusion criteria. A second review [263] to compare types of indwelling catheter for long-term use (defined as >30 days) found only three trials which met the inclusion criteria. One trial compared antiseptic impregnated catheters with standard catheters and two compared different types of standard catheter. The authors reported ‘an astonishing lack of evidence for this clinically highly relevant problem’. Since the included studies were very small and showed methodological weakness, the authors concluded that the available evidence was insufficient as a reliable basis for practice and catheter choice remains largely based on clinical experience. In the third Cochrane review on ‘urinary catheter policies for long-term bladder drainage’ [264], seven trials met the inclusion criteria. All were small, with wide confidence intervals. No appropriate trials addressed comparisons between: indwelling UC and SPC; UC and intermittent catheterisation; or SPC and intermittent catheterisation. Evidence pertaining to whether antibiotic prophylaxis is better than antibiotics given when clinically indicated, was insufficient as a basis for clinical practice.

A fourth new Cochrane review for long-term catheter care involved washout policies for the management of long-term catheters in adults [265] which examined five trials, four of which were poorly reported or designed. Two crossovers compared group differences not sequential treatments in individuals, and two parallel groups provided limited value. One trial with a strong methodology had a small sample size. No differences were found in three studies in which solutions were compared: saline, acidic, and antibiotic. Unfortunately, there was not enough evidence overall to conclude that washouts were of benefit. Larger size samples in full randomized trials are needed.

There was little research to judge the value of catheter clamping prior to removal, and one (non-Cochrane) systematic review [266] of postoperative clamping in three clinical trials in 224 surgical patients (mostly women) was inconclusive. In two studies, clamping in comparison with free drainage was not effective in reducing UTI (not defined) or retention post removal. Time to first void decreased in one study. Recatheterisation and length of stay were measured in one study each, and were not different between groups. More recently in a trial in Sweden, 113 persons >50 years with short term

catheters post hip fracture were randomized to clamping or free drainage [267]. The primary outcome was the time to normal voiding, with a median of 6 hours (Q14-Q38) in the group with clamping and four hours (Q13–Q37. 25) in the group with free drainage. This difference was not significant, nor were groups different related to recatheterization or length of hospital stay.

Overall long-term catheter care practices remain poorly supported by research evidence. This is at least partially due to difficulties in conducting trials in long-term catheterised populations for a variety of reasons, many of which have been discussed in earlier sections (See Sections XII, XII.1 and XII.1.d).

The impact of long-term catheters on users' quality of life (QoL) is a very important issue which has not been studied adequately. No Cochrane reviews have dealt with this topic directly, although several reviews have included issues with an impact on QoL such as catheter related complications and comfort. One RCT addressed education needs of catheter users. Other studies include a small number of prospective cohort studies, with the remainder being retrospective studies and case series reports, providing evidence at Level 3. Much relevant research uses qualitative research methodologies, aimed at understanding the nature of long-term catheter-related issues and patient concerns. Measures of QoL used commonly rely on a single question of quality of life or satisfaction on a 3- or 10-point scale. Validated QoL instruments, such as SF 36 are not only infrequently used, but are likely to lack sensitivity for the specific issues which concern catheter users. There is one device-specific measure for long-term catheter users [268], recently validated in two small samples for internal consistency reliability and content validity (expert review) [269]. Factor analysis yielded three subscales related to management, interpersonal, and psychosocial issues. Work in this area is continuing.

b) Prevalence of indwelling catheters use

1. Decreasing acute care use

Short-term catheterisation is common in acute care settings, with up to 25% of patients receiving a catheter during their hospital stay [270] [187]. Recently a change in the US, whereby CAUTI will not be reimbursed during hospital stays [271], has triggered a number of studies designed to reduce the use and duration of indwelling catheters in acute care, and subsequently the number of associated infections. A popular approach is a "bundle" in which several evidence-based strategies are grouped and implemented in a system-wide approach. Analysis of cause and effect are incorporated into the bundled activities, and checklists are often used to address the issues in methods (procedures), people, environment, and equipment [272].

In one study [273], in a community hospital's 22 bed intensive care unit (ICU), a bundled approach was used to decrease catheter use with a checklist, a decision algorithm and criteria based guidelines. A fishbone diagram helped the nurses to identify the (historical) reasons for extended catheter device days (duration of use) and to plan the intervention. The device days decreased significantly from 4.72 (SD 7.67) in 124 persons to 2.98 (SD 3.17) in 83 persons, p=0.38, t= -2.10, df 176, n=83). Similar results were found in an inner city ICU with 21 beds [274] with duration of catheter use decreasing from 312 days/month to 239 days/month. CAUTI events decreased as well, from 4.7/month in the 11 previous months, to zero during the six months' intervention. Also, a multidisciplinary team was successful in using a bundled approach and decreased catheter use by 56% and the duration of device days by 71% [275]. In a hospital in Brazil [276], the CAUTI rate went from 10 to 3.3/1000 catheter days after an intervention that bundled several activities in the previous year. Settings in rehabilitation [277] [278] and in an emergency department [279] have also been able to decrease catheter use and CAUTI by effective surveillance and an interdisciplinary approach.

Requiring documentation for the reason for catheter placement is critical to reducing unnecessary use. In one study with emergency room physicians [280] education and guidelines for placement contributed to an increase in appropriate indications for catheter use (72.6% to 82.2% post intervention), and unnecessary catheterizations decreased significantly from16.4% to 13% (p=0.018). Inappropriate catheter use (30%) in a hospital study in Italy with 461 patients [281] was linked with older age, not having had surgery, conscious state, comorbidities, the length of time the catheter had been used, and the hospital ward. In the only randomized (and patient blinded) trial related to interventions to decrease catheter use in acute care [282], automatic stop orders for inappropriate catheter indications were successful in decreasing catheter duration in 392 patients. For those randomized to stop orders, catheter duration was lower at 3.7 days, compared with 5.0 in usual care (mean difference -1.3; 95% CI= -2.1, -0.6). Likewise, inappropriate catheterizations were lower in the stop orders group at 2.2 versus 3.9 in usual care (mean difference -1.7; 95% CI= -2.2,-1.2). CAUTI and recatheterisation rates did not differ.

Simple approaches such as checklists and stop reminders have also been effective in decreasing catheter use. In one study testing a checklist [283] catheter duration decreased significantly in five acute care hospital units from 402 to 380 pre/post intervention (p=0.047), and CAUTI went down from 2.88 to 1.46/1000 catheter days (NS). Compliance with the checklist varied from 50-100% but provider surveys indicated most viewed the checklists as relevant, easy to use, and were satisfied with them. An educational intervention on issues related to infec-

tions and notification of the continued catheter presence [284] also successfully decreased catheter use and the CAUTI rate. A simple chart reminder sticker related to removing the catheter when not needed [285], resulted in a significant increase in appropriate indications and a decrease in CAUTI in a hospital setting.

In a study of an educational strategy to use reminders with or without structured education, Gokula and colleagues (2007) [286] reported a 14% reduction in the number of inappropriately catheterized elderly patients in emergency departments, following a staff education program and the use of an indications checklist attached to each catheter kit. The intervention also enhanced documentation about catheter use. In another study, the total duration of catheter use and number of days of inappropriate catheter use was significantly less for patients randomized to an intervention that required staff in three hospitals in Canada to remove the patient's catheter if six criteria for appropriate catheterization were not met [282]. Saint and colleagues (2005) [287] reported a similar outcome from a simple reminder to assist hospital staff to remember which patients had catheters. Using a pretest-posttest design, two of the four wards were assigned to the intervention group, and two served as controls. The researchers found that of 5,678 patients, the average duration of catheter use decreased by 7.6% in the intervention group and increased by 15.1% in the control group (p=0.007). Similarly, Voss (2009) [288] reported a reduction from 33% catheter use to 15.3% (p=0.0006) in acute care older patients after the implementation of a protocol designed to enhance clinicians awareness of the appropriate use of catheters and the parameters for catheter removal.

A systematic review of reminders and stop orders for catheter use in acute care settings [289] indicated a benefit in the rate of CAUTI, which was reduced by 52% (p=0.001), duration of use decreased by 37%, and 2.61 fewer catheter days' use in treatment versus control groups. Stop orders were more effective than reminders.

Empowering nurses to remove catheters when not indicated was also successful in a quality improvement project [290]. Daily prevalence of catheter use decreased from 24% to 17%. However, in an anonymous survey of 164 nurses [291] 54% said they were not comfortable removing a catheter without a physician's order, but 74% remind the physician daily of the presence of the catheter.

2. Prevalence of catheters and CAUTI

Despite the increase in research in preventing CAUTI, many hospitals do not have systems in place for prevention. Based on a large survey to 600 non-governmental hospitals and 119 VA hospitals in the US [292], only about 1/3 of the respondents stated that they use antimicrobial catheters or bladder scanners, and surveillance data were not tracked for catheter placement by 56%, nor duration of use by 74%. Catheter reminders were used by only 10%.

The prevalence of LTC use in home care or community care settings varies widely and can be more difficult to determine. A large scale survey of 4010 older people (>65 years) receiving home care in 11 European countries, found a mean prevalence of LTC use of 5.4%, ranging from 0% in the Netherlands to 23% in Italy [228]. In another large study of 1004 frail older women living in the community the reported LTC prevalence rate was 38.1% [229]. Duration of use can be for many years. In a US sample of 43 community dwelling long-term catheter users, who each provided data over a six months' period, mean use was 11.7 years (ranging in months from 1-589; median 8.8 years). Twenty persons had used it over 10 years [126].

There is evidence that older patients aged 65 years or more are often catheterised inappropriately [293] [294] [295]. Gokula et al. [294] surveyed a 10% random sample of patient charts from 2845 elderly patients who received an indwelling catheter during hospital admission in one year. Less than half the selected charts recorded an appropriate indication for catheterisation. An explicit reason for catheter insertion was documented in only 13% of charts and there was no written order for catheterisation in 33% of the charts. Only 18% had documented care plans for catheter removal. Expert opinion and experience suggests that even when there is an appropriate clinical reason for initial catheterisation, patients may remain catheterised unnecessarily if medical and nursing staff fail to review ongoing need (Level of Evidence 3). Problems of inappropriate catheter use may be compounded when patients are transferred from one clinical setting to another without adequate information on why the person was catheterised [296]. Wald et al [297] reported that 32% of patients catheterised during treatment for hip fracture in their study were discharged to nursing homes with the catheter still in place.

The prevalence of catheterized patients in nursing homes is generally higher than in people living at home and has been reported to be around 9% in the UK [298], but there may be considerable variation between homes [299]. In nursing homes in the US, it has been estimated that between 7-10% of the residents have an LTC [300], although figures vary from state to state. More recent data from analysis of a US National Nursing Home Survey [301] and a point prevalence study of nursing home-associated infections in the Department of Veterans Affairs nursing home care units [302] demonstrated similar prevalence. Tsan et al. [302] reported a prevalence of 10.7% for indwelling urethral catheters and 2.46% for suprapubic catheters amongst a nursing home population of 11,475 in 133 care home units.

There is some evidence of decreasing rates of urinary catheterisation in some places. A retrospective cohort study of the use of urine collection devices in skilled nursing facilities (SNFs) in five US states examined the characteristics of 57,302 patients who remained in an SNF for one year in 2003 [303]. The prevalence of indwelling catheterisation was 12.6% at admission and 4.5% at annual assessment ($p<0.001$). Paraplegia, quadriplegia, multiple sclerosis and comatose state were strongly associated with LTC use. Male residents were more likely to use a catheter at every assessment, as were obese patients; individuals with diabetes mellitus, renal failure, skin conditions, deep vein thrombosis, aphasia or end-stage disease; and those taking multiple medications.

A qualitative study of catheter use in 14 UK care homes (skilled nursing) [304] found that catheter use was higher in homes which were task-centred rather than patient-centred, and / or where patients were inappropriately given residential care when skilled nursing was actually needed. In contrast, the homes with lower rates of catheter use (6% or < versus 9% or >) were more proactive related to catheter removal (many of which had been "inherited from the hospital"), and they actively promoted toileting and mobility. Both groups had similar staffing and believed their approaches enhanced patient dignity.

Duration of catheter use in home settings varies widely, with a median of 3-4 years and some individuals using them over 20 years [305] [306]. Management regimes for continence problems in older people continue to demonstrate a predominance of containment strategies, using pads and catheters [307] and consequently unwarranted use of LTCs for incontinence continues in many places despite known catheter-associated risks.

In view of the considerable cost, and morbidity and mortality associated with the use of catheters, health services should consider adopting similar successful strategies, incorporate such information into their policies and ensure that education on catheters forms part of staff's continuing education.

c) User characteristics

Short-term catheterisation (usually defined as up to 14 days) is most commonly used:

- During surgical procedures and post-operative care.
- For accurate monitoring of urine output in acute illness.
- Instillation of medication directly into the bladder.
- For relief of acute or chronic urinary retention.

Long-term indwelling catheters - routinely changed and replaced, often over many months or years - may be required to aid those who have difficulty emptying their bladder due to obstruction or neurological disorders, where intermittent catheterisation is not a satisfactory option. LTCs may also be used to provide supportive care for those with severe incontinence who cannot manage otherwise, are terminally ill, or need treatment to heal skin lesions or surgical wounds affected by the presence of urine.

Long-term catheterisation is most commonly used to help manage:

- Bladder outlet obstruction (BOO), where patients are unsuitable for - or waiting for - surgical relief.
- Chronic retention, often as a result of neurological injury or disease (where intermittent catheterisation is not possible).
- Debilitated, paralysed or comatose patients (in presence of skin breakdown and infected pressure ulcers).

Intractable urinary incontinence where catheterisation enhances the patient's quality of life (as a last resort when alternative non-invasive approaches are unsatisfactory or unsuccessful).

d) Routes of catheter insertion

For some patients the insertion of an indwelling catheter suprapubically (SPC) into the bladder, through the abdominal wall, offers advantages over the urethral route (UC). SPC may be necessary following urethral or pelvic trauma but also offers advantages in acute and long-term care. In frail elderly men, and / or those prone to infection e.g. diabetes mellitus, SPC can be preferable to a urethral insertion to avoid urethritis, orchidoepidydimitis and prostatitis [107]. Strategies to support the SPC may be required (e.g anchoring to the abdominal wall with a BioDerm tube holder) to prevent traction and potential displacement of the catheter or balloon [308].

Advantages of SPC compared to UC are:

- Avoidance of risk of urethra trauma to men and women during catheter insertion and withdrawal.
- Avoidance of risk of urethral destruction / necrosis from pressure caused by the weight of poorly supported catheter bags, expulsion of the catheter (particularly in neurologically impaired women), or sitting on the catheter in wheelchair bound women.
- Ease of access to entry site in patients with reduced mobility, who are wheelchair bound, have restricted hip mobility, or experience urethral pain.
- Facilitation of post-surgical trial of voiding (by temporarily clamping the drainage tubing).
- Greater freedom for expression of sexuality, although this may be counteracted by perceptions of altered body image.
- Reduced risk of contamination where faecal incontinence is a problem.

SPC insertion is generally contra-indicated in patients with haematuria of unknown origin, bladder tumour, or small contracted or fibrotic bladders which may have resulted from long-term urethral catheterisation on free drainage. In obese or immobile patients the traditional SPC stoma site may become concealed by an apron of excess anterior abdominal wall fatty tissue which can lead to sub-optimal care by both patient and carer. SPC is an effective and well-tolerated method of bladder management for many SCI patients [309] [310] [311]. In Sheriff et al's study [309] the general level of satisfaction with SPC was very high with 70% of patients awarding a satisfaction score of 9/10 and 95% awarding 7/10 or more. It is of interest to note that in 18% of cases, an SPC was inserted following the request of the patient, having heard about this form of bladder management from others. A review of current literature on SPC in the neuropathic bladder, by Feifer & Corcos [311] identified some notable differences between early studies and more recent reports. Problems and complications of SPC identified in earlier studies of SCI patients were less common in the more recent investigations, in which patients were managed with anti-cholinergics, frequent catheter changes and volume maintenance procedures.

Recent studies demonstrated similar morbidity profiles to clean intermittent catheterisation. In one retrospective study from 2010 [312] comparing 85 persons with neurogenic bladder prior to SPC use, and after a mean of 65.3 (± 48.0) months with SPC, anti-cholinergic medicine and bladder clamping (with a valve) did not seem to be needed to preserve detrusor compliance nor renal function. Bladder capacity did decrease significantly, though, and renal function deteriorated in three persons, two of whom were on anticholinergics and none used clamping. Complications were reported by 62.6%, including recurrent blockage (19.2%), surgery for bladder stones (12.1%), and CAUTI (28%). 3.6% had septicaemia or were hospitalized for CAUTI. In another retrospective study of 179 men with SCI comparing indwelling urethral catheters (UC) and suprapubic catheters (SP) [313] complication rates were similar for UTIs, recurrent bladder/renal calculi and cancer. However, those with UC had higher urethral and scrotal complications and SP users suffered from leakage from the urethra and/or SP tube site. Individualizing care management was suggested.

Although SPC has gained wide acceptance for bladder drainage and many regard SPC insertion as a simple procedure, it is not without risks. The initial insertion of the SPC requires a minor surgical procedure which presents a potential risk of injury to adjacent structures to the bladder, especially the small and large intestines with resultant peritonitis [314] [309]. Other complications of initial SPC insertion include misplacement [315] [316] [317], displacement to the peritoneal cavity and sepsis, [318] and incisional hernia [319] [320]. There are a number of SPC techniques for insertion described in the literature and training models have been developed to facilitate teaching [321]. Some modern catheter insertion kits employ the initial introduction of a guide wire into the bladder, to facilitate accurate positioning of the catheter introducer. However, where patients are at high risk of bowel injury (eg previous abdominal surgery or small fibrotic bladders which do not expand well at cystoscopy), some authorities recommend introduction of the SPC by percutaneous technique using intraoperative ultrasonography combined with flexible cystoscopy [322] [323]. In low risk patients nurse specialists may undertake first insertion of an SPC, according to agreed policy and protocols [324]. Subsequent SPC changes can be competently managed by skilled nurses [325].

e) Catheter characteristics

An effective indwelling catheter should have the following design characteristics:

- Retained in the bladder effectively, yet easily removable without trauma to tissue.
- Soft 'tip' within the bladder to avoid pressure damage to the mucosa.
- Effective drainage while minimising risk of bladder mucosa being 'sucked' into drainage channel.
- Conforms to shape of urethra.

Despite some notable efforts to improve catheter design, the original Foley design has changed very little over the years and remains the most common. However traditional drainage systems may fail to drain the bladder to completion, due to potential outflow obstruction caused by air-locks within the curled, redundant drainage tubing segments. A novel, spiral-shaped, drainage tubing design has recently been reported which appears to optimize flow and minimize residual urine [119]. Adding more eyeholes has been suggested to reduce residual urine [326] and in a case report, leakage [327]. Further evidence of efficacy is awaited.

f) Catheter materials

An ideal catheter material requires the following properties:

- Soft for comfort.
- Causing minimal tissue reaction or friction.
- Sufficiently firm for easy insertion and maintenance of lumen patency in situ.
- Elastic recoil so that an inflated balloon can deflate to almost its original size.
- Resistant to colonisation by micro-organisms and to encrustation by mineral deposits.

Catheters are made of a variety of materials includ-

ing polyvinyl chloride (PVC) or other plastic, latex rubber with or without a coating, silicone or metal. Plastic catheters are relatively cheap to manufacture, have a thin wall and relatively large lumen, and are designed for short-term use (in situ up to 14 days). Latex catheters are restricted to short-term indwelling use (and commonly avoided where possible) because of potential discomfort due to high surface friction, vulnerability to rapid encrustation by mineral deposits from the urine and the implication of latex allergic reactions in the development of urethritis and urethral stricture [328] [329] [330] [331] [332] [333] or anaphylaxis [334].

Attempts to minimise friction during catheterisation and to reduce tissue reactions have led to the coating of latex catheters with tightly bonded materials designed to provide a smoother, less irritant surface which also minimizes absorption of water by the latex (and subsequent changes in internal and external catheter diameters). Polytetrafluoroethylene (PTFE or teflon) coated latex catheters are sometimes used for medium-term use (catheter can remain in situ up to 28 days) but the materials known to cause least friction and tissue reaction are silicone elastomer and hydrophilic polymer-coated catheters, or all-silicone catheters [335] (**Table XII-4**). These materials are therefore recommended for long-term use (i.e. expected to remain in situ for 14 days or more, and changed regularly for a new catheter as part of a long-term strategy of care). LTC materials are also less vulnerable to rapid colonisation by bacteria and encrusting by mineral deposits than short-term catheter materials. There is evidence that silver-alloy coated catheters can help to reduce risks of CAUTI in the short-term (where bacteriuria is used as the outcome measure) (See Section XII.3.a), but no currently available material or surface coating is completely immune to microbial colonisation.

Inflation of silicone catheters with water can sometimes lead to water loss from the balloon over time, [336] with an associated risk of the catheter falling out [337]. Consequently some manufacturers recommend filling the balloon with a 10% aqueous glycerine solution, or to fill the balloon with the full 10mL, knowing that 1/4 to 1/2 could be lost over time [336].

Most catheter materials are suitable for either UC or SPC, however not all UC catheters are also licensed for SPC. Suprapubic catheter removal is sometimes associated with trauma of tracts or stoma site where overgranulation has occurred, with bleeding and patient discomfort [338] [325]. This can be a particular problem with catheter materials such as all-silicone, which are prone to hysteresis, leading to balloon cuffing on deflation. This problem may also occur with hydrophilic coated catheters but is less common [339] [340]. Management of this and other catheter-related problems is considered below in Section XII.2.k.

The main finding of a recent Cochrane Review of types of indwelling urinary catheters for long-term bladder drainage in adults [263] was a remarkable lack of evidence for this clinically, highly relevant problem. Despite consideration of 11,000 abstracts and 74 full papers, only three trials met the inclusion criteria. Since these were very small and showed methodological weakness, the authors concluded that there was insufficient evidence to provide a reliable basis for clinical decision-making and catheter choice remains largely based on clinical experience.

g) Catheter size – catheter gauge, length and balloon size

Indwelling catheters are formed either by building up layers through dipping and coating on a shaped 'former' or by a process of extrusion of a single material. Catheter size is measured in Charrière (Ch) – also called French gauge (Fr) - which refers to the circumference of the catheter shaft in millimetres. Internal diameter varies depending on the manufacturing method, with the extrusion process resulting in a catheter with relatively thinner

Table XII-4: Catheter materials

Duration of catheterisation		Catheter material
Intermittent	Removed immediately after urine drainage.	Plastic: with or without hydrophilic polymer coating. Metal (silver, stainless steel).
Indwelling, short term use	Catheter expected to be *in situ* for < 14 days.	Latex or plastic PTFE-coated latex. Silver-alloy coated (catheter materials recommended for long-term use may also be selected).
Indwelling LTC	Catheter expected to be in situ for 14 days or more (recommended time between catheter changes depends on local catheter policy - may be up to 12 weeks).	Silicone elastomer-coated latex. Hydrophilic polymer-coated latex. All silicone

walls and a larger lumen for the same Charrière size. A size 12Ch catheter made by dipping and coating will have an external diameter of around 4mm and an internal diameter of around 2mm or less. Urinary flow rate is related to the internal diameter of the catheter but 12 -16 Ch catheters (usual sizes for adults) easily drain normal quantities of urine, including larger volumes produced by diuresis [341]. Although larger sizes may be needed following urological procedures where blood clots and other debris are a problem, large catheters are generally associated with increased bladder irritability and spasm [113], and with potential blockage of para-urethral glands and tissue damage, including urethral strictures. Therefore large catheter sizes should be avoided wherever possible. It is not known whether large catheters contribute to CAUTI, but the smallest size to maintain good drainage and prevent urethral and bladder neck trauma is recommended [342] further research may be needed to determine best practices [343]. Small balloon sizes are recommended for all patients (10ml for adults and 2.5-5ml for children) to minimise the risk of discomfort and bladder irritation. Larger balloons tend to sit higher in the bladder with potential for increased residual urine volumes to collect below the catheter eyes. Larger balloons are also associated with increased risk of meatal tissue damage caused by bladder spasm and possible expulsion of the catheter with a fully inflated balloon.

The most common sizes of SPC catheters for adults are also 12-16Ch. Some SPC kits provide a specific catheter in the kit and therefore dictate the sizes available; others allow the insertion of a range of Foley catheters. Since the catheter is inserted into the bladder via an artificial stoma it is possible that slightly larger sizes may be better tolerated than for UC although there is no research evidence to support this.

The standard male length catheter (41-45cm) is available to males and females but a shorter female length (25cm) can be more comfortable and discrete for some women. The female length catheter should not be used for males as inflation of the balloon within the urethra can result in severe trauma. In one case series report [344] six boys, aged < 1 month to 16 years suffered damage to the bulbar or prostatic urethra due to inflation within the urethra. Three required suprapubic catheters, and all healed without further complications. Insertion to the bifurcation of the catheter – that is, until only the inflation and drainage ports were visible - was advised to prevent this. Paediatric catheters are usually approximately 30cm long.

h) LTC–associated risks / problems: catheter-associated urinary tract infection (CAUTI)

The urinary tract is recognised as the commonest site for nosocomial infection in hospitals and nursing homes, accounting for between 21% and 45% of all healthcare-associated infections [345] [346] [65] [347] [302] [348]. National nosocomial infection surveillance systems monitor CAUTIs and provide guidance for benchmarking [349]. The presence of an indwelling catheter is a key risk factor in around 80% of nosocomial UTIs. The risk of bacteriuria increases by 5-8% per day of catheterisation [350] [351] [352] and virtually all LTC patients are likely to be bacteriuric within four weeks [342]. A majority of microorganisms derive from the patient's own colonic and perineal flora or from the hands of health-care personnel during catheter insertion or management [187]. Access is gained in two ways: (1) extraluminally during catheter insertion or via the periurethral space; (2) intraluminally following breaks in the closed system or contamination of urine in the drainage bag. The comparative importance of these routes is difficult to determine, but animal models have demonstrated rapid colonisation via the intraluminal route following a break in the closed system, compared to the extraluminal route (32-48 hours v 72-168 hours respectively) [353]. However, clinical studies have shown that colonisation will occur even when strict infection control practices are adhered to [354].

Indwelling catheters rapidly become colonised by micro-organisms which form a strongly adherent biofilm on catheter and drainage equipment surfaces. Biofilm formation begins by deposition of a conditioning layer of proteins, electrolytes and other organic molecules from the urine [355] which may then mask catheter surface properties designed to inhibit colonisation. Micro-organisms attached to catheter surfaces divide to form micro-colonies, ultimately developing a complex three-dimentional structure, including fluid filled channels through which the biofilm members receive nutrients, diffuse away wastes and send chemical signals to each other [356]. Catheter biofilms commonly comprise mixed communities of micro-organisms embedded in a matrix of host proteins and microbial exopolysaccharides [357], [358] (**Figures XII-4, XII-5 and XII-6**). Microorganisms growing as a biofilm are less susceptible to antimicrobial therapies than free-living organisms and are a major source of resistant, nosocomial pathogens [187] [359] [259]. Decreased susceptibility arises from multiple factors including; physical impairment of diffusion of antimicrobial agents, reduced bacterial growth rates; and local alterations of the micro-environment that may impair activity of the antimicrobial agent [356]. The close proximity of cells within a biofilm can facilitate plasmid exchange and the spread of antimicrobial resistance [355].

1. Antibiotic use

Hospitalized patients are likely to be on antibiotics for other causes than an indwelling catheter, which also might be present. In one study in an acute care setting, [360] catheterized patients on antibiotics

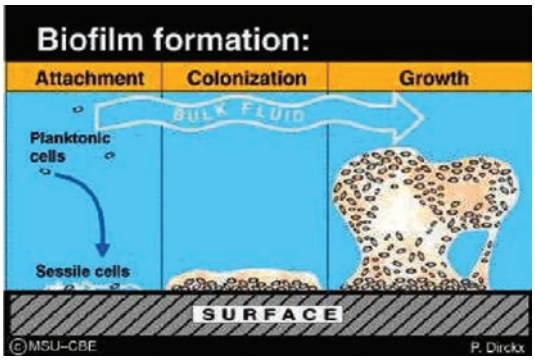

Figure XII-4: Biofilm - 'pillars, mushrooms and water channels' (Reproduced with the permission of Montana University Centre for Biofilm Engineering).

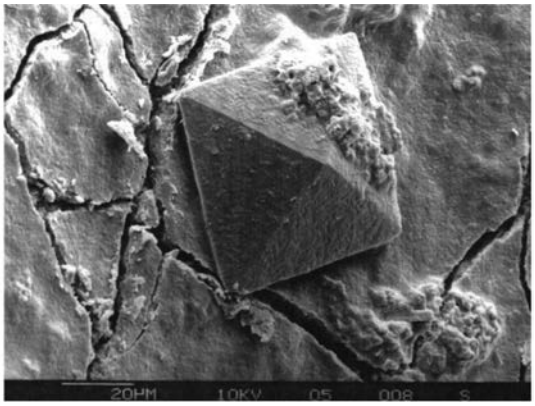

Figure XII-5: Scanning electron micrograph of biofilm.

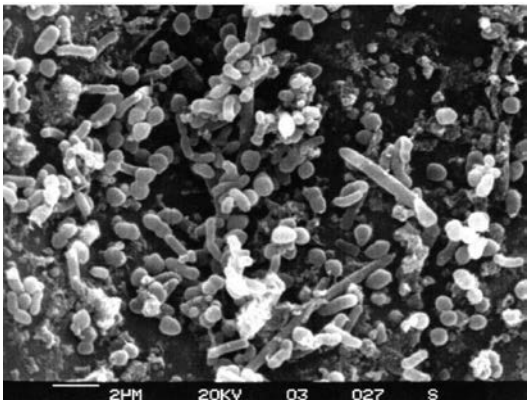

Figure XII-6: SEM of bacteria colonising catheter surface – Proteus mirabilis, Enterococcus faecalis, lactobacillus sp.

for a shorter period of time (< 5 days) were more likely to develop CAUTI than those taking antibiotics longer, and the former should be evaluated for this risk. In a prevalence study in France of antibiotics used to treat hospital acquired infections, [361] urinary tract infection had the highest association with antibiotics use, in particular with fluoroquinolone. The researchers' model predicted that decreasing CAUTI in hospitals with high rates (75th percentile or >) could reduce antibiotic use by 2.1% and 0.4% for fluoroquinolone.

2. Prevalence of CAUTI

The majority of research on the risks of CAUTI has been conducted in acute care settings where catheters usually remain in place for less than 14 days and many patients' health is already compromised by co-morbidities [362]. A series of reports from the International Nosocomial Infection Control Consortium (INICC) provided rates of CAUTI in intensive care unit (ICU), using the methodology of the US National Nosocomial Infections Surveillance system. The rates per 1000 catheter days were: Brazil 9.6 [363] and Peru 5.1 [364]. Overall, in 13 limited resource countries implementing INICC infection control guidelines for education and surveillance (Argentina, Brazil, Colombia, Costa Rica, Cuba, El Salvador,India, Macedonia, Mexico, Morocco, Philippines,Peru, and Turkey) the CAUTI rates dropped from 8.2 to 6.9 per 1000 catheter days [365]. A later report in ICUs in Cyrus, Greece gave a rate of 2.8/1000 catheter days [366]. From the U.S. National Healthcare Safety Network (NHSN) [367] from January 2006 through December 2008, the pooled mean CAUTI rate in ICUs ranged from 3.1 to 7.4 /1000 catheter days, depending on the type of specialty unit. Surveillance was suggested for a minimum of three months, based on a pilot study describing the protocol and surveillance tool used in six hospitals caring for elderly people in Scotland [368].

Less is known about the prevalence of CAUTI in long-term and home care settings or about the potential for reduction of CAUTI and improved cost benefits in the LTC population [352]. Encouragingly, in a recent U.S. study in North Carolina home health and hospice populations, [369] the CAUTI rates have decreased over 11 years of surveillance. The rate of catheter-associated UTI decreased in home health from 4.2/1000 catheter days in 1998 to 0 in 2008, and in hospice patients from 2.35/1000 catheter days in 1999 to 0 in 2008. Infection control specialists trained the persons collecting data, and presumably the rates reflect symptomatic CAUTI. However, in a hospital study of U.S. Veterans with spinal cord injury and disorder, [348] the rate was higher (8.9/1000 catheter days), reflecting greater risk. In a similar population of 100 inpatient and outpatient veterans with chronic catheters, candiduria was present in 17%, and all but one had an indwelling catheter. This was of concern due to the likelihood of reoccurrence of this microorganism [370].

In the multi-national survey of 4010 older people (>65 years) receiving home care in 11 European countries, the risk of a UTI was found to be 6.5 times greater for catheterised individuals than for non-catheterised [371]. Prevalence of a UTI amongst

1004 frail older women living in the community was 21% in catheterized women compared to 10% in non-catheterized subjects (p>0.001) [372]. Furthermore, catheterised subjects were more likely to die within a year (RR1.44; 95% CI 1.01-2.07). Tsan et al's point prevalence survey [302] of Nursing Home acquired infections found 13.2% of 11,475 residents had an indwelling urinary catheter. Of those, 13% of residents with a UC and 9.5% of those with a SPC had a UTI. In catheterised SCI populations the overall rate of urinary tract infection has been quoted as about 2.5 episodes per patient per year [373]. Although randomized trials are lacking there is some evidence of reduced rates of bacteriuria and CAUTI with SPC, condom catheters and intermittent catheterisation compared to UC [373] [374] [302].

Bacteraemia resulting from CAUTI invariably represents a serious complication which may occur in approximately 4% of catheterised patients with bacteriuria in acute care settings [375] [376] [377]. In their review, Saint et al. [375] statistically pooled results from several prospective studies on short-term indwelling catheterization (in which the definition of bacteriuria varied between studies, ranging from >103 cfu/ml to >105 cfu/ml) and estimated (Level of Evidence 2) that:

- 26% of patients (not receiving systemic antibiotics) with a short-term, standard non-coated indwelling catheter in situ for between two and 10 days will develop bacteriuria.
- 72% of patients developing bacteriuria will remain asymptomatic and not require treatment.
- 24% of those developing bacteriuria will develop a symptomatic UTI without bacteraemia.
- 4% with bacteriuria will develop bacteraemia.

This data is interesting since it provides supporting evidence that bacteriuria remains asymptomatic in a majority of catheterised patients. However, it can be difficult to generalize such data from acute care contexts to other practice settings. Unfortunately, few epidemiological studies or comparative catheter evaluations are conducted on long-term catheterised patients in community settings.

3. Outcome measures and criteria for CAUTI

Interpretation of the literature on CAUTI is often confused by the range of definitions and outcome measures used. In this chapter, the terms symptomatic infection and asymptomatic bacteriuria have been employed to distinguish as clearly as possible between symptomatic and asymptomatic conditions. However many studies make little or no distinction between these states, referring to both as infection. This can be particularly confusing when attempting to interpret results in terms of the magnitude of infection-related problems, clinical importance and implications for services and individuals.

Bacteriuria is commonly used as a surrogate outcome measure for the clinically more important outcomes of symptomatic UTI. Although symptomatic infection is far less common than asymptomatic bacteriuria, the frequency of catheter use produces considerable overall morbidity and mortality [378]for patients and high costs to healthcare services [377], often including unnecessary antibiotic drug therapy which may then become a major source of antibiotic resistant pathogens. Asymptomatic bacteriuria can lead on to symptomatic infection, but not necessarily. Questions about the significance of long-term asymptomatic bacteriuria in its own right (e.g. effects of chronic tissue inflammation) are currently unanswered.

In non-catheterised patients the criterion for 'significant' bacteriuria is commonly accepted to be $>10^5$ cfu/ml but since growth of micro-organisms in catheterised patients is rapid, many authorities consider $>10^2$ or 10^3 cfu/ml in a urine sample collected from the sampling port of the catheter, to be indicative [187] [342] [110]. Most definitions of symptomatic UTI [379] are based on those used for non-catheterised patients and include significant bacteriuria. For catheterised patients, these include presence of pyuria (>10wbc/mm3) plus one or more clinical signs and symptoms for which no other aetiology is apparent: fever, suprapubic or flank discomfort, bladder spasm haematuria, changes in mental state, or malaise / lethargy. Pyuria alone is not diagnostic of UTI. [110]. For SCI patients signs and symptoms may also include increasing spasticity and / or worsening autonomic dysreflexia (usually manifested by increase in blood pressure, headache, sweating above the SCI lesion, flushing below the SCI lesion) [380] or a "sense of unease" [110]. Elderly persons may have atypical or generalized symptoms [284]. In a study of the validity, accuracy and predictive value of UTI signs and symptoms in person with SCI using intermittent catheters, [381] cloudy urine had the highest accuracy (83.1%) and leukocytes in the urine was the most sensitive (82.8%). Fever was the most specific (99%) but least sensitive (6.9%) symptom. Moreover, patients might be better at identifying when they do not have UTI, as positive predictive value was 32.6% and negative predictive value was 82.8%.

However, commonly used criteria for symptomatic urinary infection have been questioned by Tambyah and Maki [362] in a prospective study of 1497 newly catheterised patients. No significant difference in reported symptoms of pain, urgency, dysuria and fever was found between patients with a catheter-associated infection and those without, nor was there statistical evidence that peripheral leukocytosis was predictive of infection (p=0.14) (Level of Evidence 2). The criterion for bacteriuria (catheter-associated infection) in this study was >= 10^3 colony forming units (cfu)/ml urine). This finding raises further questions over the selection of the most appropri-

ate outcome measures in studies of CAUTI. Indeed concerns have also been raised over current UTI criteria for non-catheterised populations, particularly for elderly groups, including nursing home residents. Consensus criteria (e.g. Loeb criteria 2001) have been found to be limited in terms of sensitivity, specificity and predictive value by Juthani-Mehta et al. [382] and these authors have called for clearer identification and evaluation of evidence-based clinical criteria associated with laboratory evidence of UTI. A further complication to difficulties in confirming 'best criteria' for UTI and CAUTI is the variation in the clinical and scientific definitions required for specific populations, for research purposes or to meet stipulations for reimbursement from governments and medical agencies. Asymptomatic bacteriuria might be treated inappropriately, as described in a study in which 32% were treated (53 of 164 episodes of bacteriuria) [383] further confounding the definitions of CAUTI that include treatment with antibiotics. It is important that efforts to resolve these issues are progressed as quickly as possible to provide greater clarity in the interpretation of existing research, the design of new studies and the application of clinically important findings.

4. Reducing the risk of CAUTI

Risk factors which are independently predictive of increased risk for CAUTI have been identified in a number of large prospective studies of short-term catheterised patients [187] (**Table XII-5**). There is evidence that females have a substantially higher risk than males (relative risk: RR 2.5-3.7), and 1.3-2.2, p=0.001 in an ICU setting [384]. But the greatest risk is associated with prolonged catheterisation > six days (RR 5.1-6.8). A recent retrospective cohort study of 35,904 undergoing major surgery reported that 86% of patients had a perioperative indwelling catheter [385]. Multivariate analysis showed that postoperative catheterisation for longer than two days was associated with increased risk of UTI.

Use of a preconnected drainage bag may be of value in preventing CAUTI in acute care settings. A prospective study in the UK of 205 patients in three medical wards over two periods, each of about six months' surveillance, [386] compared use of preconnected bags with the usual bags. The CAUTI rate was 41% lower in the group with the preconnected bags, with rates of 37.8/1000 catheter days for the usual bags, compared with 22.4/1000 catheter days in the intervention group (RR 0.59 (0.35–0.99) 0.04.

In Japan, a prospective observational study in five hospitals evaluated risks in persons with catheters 3> days, using a Cox proportional hazards model [387]. Risks were significantly associated with two practices in this study of 555 inpatients, not using a pre-connected closed system (RR 2.35, 95% CI 1.20–4.60, p=0.013) and the lack of daily cleaning of the perineum (RR 2.49, 95% CI 1.32–4.69, p=0.005).

Although there is some evidence to suggest there may be a reduced risk of CAUTI when SPC is employed compared to UC, the data is limited, studies are often small and most catheterisations are for post-operative care in acute care settings. One large scale point prevalence study of nursing home acquired infections in >11,000 residents [302] reported that 9.5% of residents with a SPC had a UTI compared to 13% of those with a UC. These data just fail to demonstrate a statistically significant difference between UC and SPC (one-sided, Fisher's exact test; p=0.066). A review of five published RCTs comparing SPC with urethral catheters

Table XII-5: Risk factors for catheter-associated infection based on prospective studies and use of multivariate statistical modelling (adapted from Maki & Tambyah 2001)[187].

Risk factor	Relative risk
Prolonged catheterisation >6 days	5.1-6.8
Female	2.5-3.7
Catheter insertion outside the operating room	2.0-5.3
Other active sites of infection	2.3-2.4
Diabetes	2.2-2.3
Malnutrition	2.4
Ureteral stent	2.5
Renal insufficiency (creatinine > 2.0mg/dL)	2.1-2.6
Using a catheter to measure urine output	2.0
Improper position of drainage tube (above bladder or sagging below drainage bag)	1.9

following colorectal surgery [388] reported that sample sizes were small, catheters were used short-term and there was no apparent difference in the duration of catheterisation between the two techniques. Significant UTI was defined in different papers as bacteriuria with either $>10^4$ or 10^5 organisms or cfu/ml. Frequency of UTI was less in the SPC group in three of the studies, with no significant difference in the other two. The SPC groups reported less pain and discomfort than the urethral groups and SPC was preferred by those patients who experienced both. The authors concluded that the results favoured SPC over urethral catheterisation as UTIs are reduced, particularly in females, and the ability to attempt normal voiding is facilitated, particularly in males (**Level of Evidence 2**).

Much of the recent research on reduction of risk of CAUTI has centered on the development of catheters with antimicrobial surfaces, such as silver. Silver ions are bactericidal [389], non-toxic to humans when applied topically, and have been used successfully in other areas of infection control such as burn wounds. Silver is also purported to have broad spectrum activity against Gram-positive, Gram-negative, aerobic and anaerobic organisms. Early silver-coatings incorporated silver oxide into the external surface of the catheter material only, but efficacy against CAUTI was limited [390]. Subsequently, silver-alloy coatings were developed to provide an integral coating on both internal and external surfaces and promote a slow release of silver ions. Other developments have been directed towards impregnation of catheter materials with antibiotic or antiseptic agents such as nitrofurazone [391] [392] [393] [394]; minocycline and rifampicin [395]; chlorhexidine, silver sulfadiazine, triclosan [396] and others. Although a large number of studies (both laboratory models and clinical studies) have attempted to examine the potential benefits of antimicrobial catheters, most have used bacteriuria - rather than symptomatic UTI - as a surrogate endpoint. Most reports were either prospective cross-over studies [397] or prospective surveillance of outcomes associated with introduction of new catheter types, in comparison with historical or baseline outcomes associated with previously used catheter types [398] [399] [400]. Almost all have examined short-term catheter use in acute care settings.

A recent Cochrane review [260], designed to determine the effect of type of indwelling urethral catheter on the risk of UTI, examined 23 trials, comparing different types of standard catheters or a standard catheter with an antiseptic catheter (silver alloy or impregnated with silver oxide); or an antibiotic impregnated catheter (either minocycline and rifampicin, or nitrofurazone). The reviewers commented that trials were generally of poor quality but concluded that current evidence suggests silver alloy catheters prevent asymptomatic bacteriuria in the short-term catheterised patient (Level of Evidence 1). They recommended that further economic evaluation is necessary to confirm the extent to which reduction of clinically important infection compensates for the increased cost of the silver alloy catheters. Catheters impregnated with antibiotics were also found to be beneficial in reducing bacteriuria in hospitalised adults catheterised for less than a week, but data were too few for patients catheterised longer.

An earlier systematic review of antimicrobial urinary catheters to prevent CAUTI in hospitalized patients [401] identified 12 randomised or quasi-randomised trials of silver-alloy coated (n=9) or nitrofurazone-coated catheters (n=3) compared to standard silicone or latex catheters. Pre-post study designs were excluded. No study addressed symptomatic UTI and therefore analysis was based on bacteriuria. Although all studies indicated some benefit in prevention or delay of onset of bacteriuria the effect size varied substantially between studies. Variations were related to catheter type, patient characteristics, control group bacteriuria rate and year of publication (i.e prevailing clinical conditions at the time of the study). Post enrolment exclusions, absence of intention to treat analysis, highly selected study samples and lack of data on clinically meaningful end-points, all limited the ability to draw definitive conclusions on efficacy. The authors concluded that, according to fair-quality evidence, antimicrobial catheters can prevent bacteriuria in hospitalized patients during short-term catheterisation (Level of Evidence 1), but trial results are highly context dependent. The relevance of results to other institutions or patient groups depends on the similarities between settings with respect to a range of variables, including: background bacteriuria rate, baseline catheter type, local catheter use and maintenance practices, patient groups and patterns of antimicrobial usage. The authors cautioned that older data may lack current relevance, particularly where background rates of bacteriuria have changed notably in the intervening period. Although there is evidence that antimicrobial-coated catheters prevent bacteriuria during short-term catheterisation, there is a lack of corresponding data to demonstrate clinical benefit [402]. Further well-designed and adequately powered randomised trials, with clinically relevant endpoints are needed to clarify comparative clinical utility and economic value.

In contrast to the majority of trials of silver-coated latex catheters Srinivasan et al [403] found no significant reduction in bacteriuria with silver-impregnated, silicone catheters despite similar performances in vitro. However, outcomes may have been affected by notable differences in the study groups in this prospective, cross-over study. The authors drew attention to the fact that not all silver products are the same and clinical trials of new products remain critically important. Any potential advantages of silver alloy catheters (or other antimicrobial catheters)

for LTC patients remain uncertain, although clinical experience suggests some benefits for individuals with frequent symptomatic infections. It is not known whether argyria (deposition of silver in the skin) may be a potential problem for long-term care patients or whether silver-resistant mutants may be selected by repeated exposure [404] [405].

A common concern over the use of antimicrobial impregnated catheters is that elution of sub-inhibitory levels of the antimicrobial agent into the urine may induce resistance in resident organisms with prolonged catheter use [406]. Antiseptic agents are generally considered more likely to confer resistance to surface colonization than antibiotics and not to select for infection with antimicrobial drug resistant bacteria. Alternative approaches to inhibiting biofilm development include development of catheter surfaces which reduce protein absorption [407]; inflation of the balloon with a biocide solution, such triclosan, which then diffuses throughout the catheter material and into the surrounding area [408] [409]; or efforts to disrupt matrix or glycocalyx components with agents such as heparin [410], and colonization with a competing benign organism. Bacterial interference with E. coli 83972 was attempted in 13 CIC users with SCI, [411] [110], and eight were successfully colonized in 19 three-day attempts. Monthly urine cultures (until colonization was lost in the urine) indicated a reduction in symptomatic UTI rate per year, 0.77 per patient year as compared with 2.27 per patient year prior to the study.

Relatively few studies have examined the cost benefits of different catheters. Those that have tend to rely heavily on assumptions that a certain proportion of patients with bacteriuria will develop the clinically important outcomes of symptomatic UTI or bacteraemia. The focus of economic studies generally falls on acute care settings and, as discussed earlier, it can be difficult to generalise results from one practice setting to another. Practitioners and/or institutions who are considering introducing a new product (e.g. catheter type) for a majority of their patients on the basis of claims of improved cost-effectiveness from clinical research studies, are advised to look carefully at the similarities and differences between their own local practice (and patient groups) compared to that described in the research. Economic studies are frequently required to make assumptions about certain data (e.g. increased length of hospital stay for CAUTI) which is then applied to an economic model. (?Cross ref to economics chapter). Such assumptions may or may not be applicable in local settings.

Numerous trials of oral antibiotics, antimicrobial bladder washes, drainage bag solutions and topical disinfectants all lead to the common conclusion that bacteriuria and UTI may be suppressed temporarily at best, but resistant organisms are highly likely to emerge [357]. The application of devices to secure catheters in place, to prevent a 'to and fro' pistoning effect that could favour invasion of catheter tracts by microorganisms, has been shown to reduce the incidence of catheter-related blood stream infection in central venous catheters. Only one prospective, randomised trial has examined a similar device for urinary catheters (StatLock) [380]. Although the study in 118 SCI patients failed to achieve statistically significant results the authors reported a clinically important reduction in the rate of symptomatic UTI of 45% and called for further larger scale trials. They also noted the polymicrobial nature of infections including the presence of a Candida species in more than 20% of infections.

5. Treating CAUTI: antibiotic use

Some studies have suggested that methenamine hippurate may have a beneficial effect in preventing bacteriuria in patients requiring short-term catheterisation during and post-surgery. However, a Cochrane review [393] designed to address this issue concluded there is not enough reliable evidence to conclusively support its use for urinary prophylaxis and identified a range of methodological limitations in existing studies. Caution is needed in translating research on reducing CAUTIs in short-term catheters to LTCs but treatment of asymptomatic bacteriuria is not recommended in either for either group. Urine cultures should be obtained before initiating treatment to permit selection of specific therapy for the infecting organism and the extensive use of broad spectrum therapy should be avoided [412].

Studies of LTC patients can be difficult given the relatively high proportion of disabled or elderly patients, many of whom are very frail. However, routine use of prophylactic antibiotics in LTC patients is not supported by research evidence and has been shown to favour the emergence of resistant organisms [110]. In a double-blind, cross-over study of 34 elderly nursing home patients with urethral catheters [413] subjects were randomised to receive antibiotic prophylaxis (200mg/day norfloxacin) or placebo for three months, followed by cross-over. Urine cultures were obtained once monthly. Episodes of UTI, catheter-related complications (obstruction, encrustation, leakage, suprapubic pain, inflammation of meatus, haematuria and side effects of treatment were monitored weekly. Symptomatic UTI was defined as bacteriuria $>10^5$ cfu/ml and (i) a temp>38.5^{o}C for two days in the absence of other clinical sources of infection or (ii) flank pain or unexplained mental disturbance or abdominal discomfort. Only 23 patients completed the study and although norfloxacin failed to reduce asymptomatic bacteriuria, there was a significant reduction in symptomatic UTIs (1 v 12, $p<0.02$) and a decrease in catheter-associated complications of obstruction and leakage ($p<0.05$). Of the 11 patients who did not complete the study, six died (of non-infectious causes), one died of septic shock and four were withdrawn. However, norfloxacin

treatment was also strongly associated with the acquisition of gram-positive norfloxacin resistant flora (RR 4.66, 95% CI 2.47-8.80), and there was a rapid recolonisation by norfloxacin-sensitive, gram-negative bacteria on cessation of treatment. Overall the study concluded that norfloxacin failed to prevent bacteriuria in long-term catheterised patients and favoured the emergence of quinalone-resistent organisms, although there were some clinically observable benefits in some patients.

Similarly there is little strong evidence of benefit in prophylactic antibiotics prior to re-catheterisationand it is not routinely recommended [110]. One RCT in which 70 residents in a long-term care home were allocated to a treatment group (1gm IV meropenem given 30 minutes before re-catheterisation) or control group (no antibiotics) showed no significant differences in urine cultures at 3, 7, 14 or 28 days [414].

When catheterised patients are prescribed a course of antibiotics for symptomatic infection a common question from healthcare practitioners is whether the catheter should be changed to a new one prior to starting antibiotics. There are concerns that this may allow time for a new biofilm to become established on the catheter within a few hours (and provide a source of re-infection) before the antibiotics have taken effect. In contrast, the 2009 International Clinical Practice Guidelines from the Infectious Diseases Society of America suggest a catheter change if the catheter had been in place for at least two weeks and was still needed. The rationale was that this would facilitate resolution of symptoms and decrease risk of bacteriuria and CAUTI [110]. There is little research to guide practice but in one RCT of 54 nursing home residents managed by long-term catheterisation, subjects were randomised to undergo catheter replacement, or no catheter replacement, before antibiotic intervention for clinical diagnosis of UTI [216]. Clinical outcomes (reduction in polymicrobial counts, time to achieve afebrile status and clinical status at 72 hours) were significantly better among subjects randomised to catheter change immediately before institution of antibiotics (Level of Evidence 2). Replacement of the catheter, in patients suspected of having a UTI, prior to collecting a urine sample for culture and sensitivity testing has also been shown to reduce the number of pathogens identified, the number of antimicrobials prescribed and laboratory costs [415]. There is evidence that certain bacterial strains may be particularly difficult to eradicate. In a prospective study of infection in catheterised nursing home patients a single genotype of P.mirabilis was shown to persist in the urinary tract despite many changes of catheter, periods of non-catheterisation and antibiotic therapy [416].

Cranberry juice has long been advocated as a treatment for urinary tract infection and there is some evidence of decreased symptomatic infections in some study populations, but not in catheterized persons [417]. However current evidence to date is limited to non-catheterised patients and caution needs to be applied in extrapolating results to catheterised patients.

i) LTC-associated risks and problems: recurrent catheter blockage

Recurrent catheter encrustation by mineral deposits, leading to catheter blockage occurs in up to 50% of LTC users, with resultant increased costs to services and patients [418] [419] [420] [421]. Heavy encrustation on external surfaces of the catheter tip and balloon can also cause painful tissue trauma on catheter removal. The major components of encrustation are calcium phosphates and magnesium ammonium phosphate (struvite) (**Figures XII-7 and XII-8**) which precipitate from the urine, most commonly under alkaline conditions.

The precipitation of different ionic species (ie Ca++, Mg++, and phosphates) is influenced by their ionic concentrations in the urine. In addition, the urinary pH at which different ions precipitate from the urine varies, not only for different ions, but also between individuals and at different times [422] [423]. These factors contribute, at least in part, to individual variability in terms of susceptibility to catheter encrustation and time to blockage. Catheterised patients can usually be classified into 'blockers' or 'non-blockers' [418] [424] where 'blockers' are those individuals who experience recurrent catheter blockage within a few days to a few weeks. Early recognition of recurrent 'blockers' facilitates proactive care through appropriate catheter change regimes [424]. Urine from recurrent blockers tends to have a very narrow 'safety margin' between 'voided' urinary pH and the pH at which crystallisation (or nucleation) occurs. This margin is much wider in non-blockers [425]. Precipitates occur most commonly under alkaline conditions caused by the presence of urea-splitting micro-organisms such as Proteus mirabilis, in the catheter biofilm [426] [424] [427] [425].

1. Reducing catheter encrustation – catheter materials

The majority of research on catheter encrustation comprises experimental, laboratory-based studies addressing current and / or potential catheter material surface properties in relation to bacterial adhesion and encrustation. Encrustation may sometimes take place in the absence of infection [428] and is influenced by catheter surface properties, including roughness and irregularity, hydrophobicity and wetability, charge, polymer chemistry and coatings. None of the currently available long-term catheter materials is resistant to biofilm formation and encrustation. In a series of laboratory studies of 18 types of catheter materials, using a model of the catheterised bladder, none resisted biofilm formation by a clinical strain of P.mirabilis [429] [430]. Relative times to catheter blockage were: silver-coated latex 17.7h; hydrogel-coated latex 34h; silicone-coated latex 38h;

Figure XII-7: Section of catheter showing encrustation and blockage.

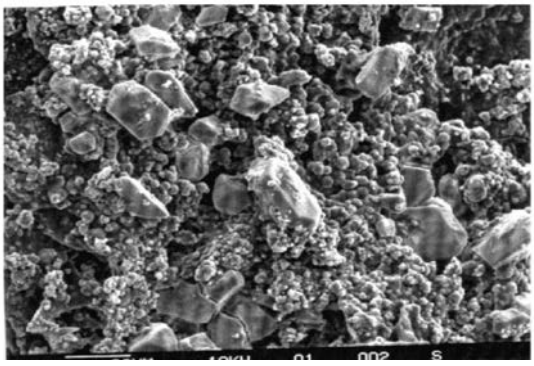

Figure XII-8: SEM of encrusting material - struvite and calcium phosphate.

all-silicone 47h. However, the authors note that the internal diameter of the coated latex catheters was much smaller than for the silicone catheters (1.5mm compared to 2.5mm).

This finding was confirmed [409] in tests with five types of catheters (pure silicone, silicone-coated latex, hydrogel-coated latex, hydrogel/silver-coated latex, and nitrofurazone silicone) colonized with P. mirabilis 108 cfu/mL and a urine pH of 8.5 All had heavy encrustation by 18 h. and were blocked within 40 h. There are implications for coated catheters, such as silver, because the bacteria can continue to grow even when attached to the crystalline biofilm, which shields them from the silver. To keep the pH from rising, antimicrobials need to get into the urine.

Targeting P. mirabilis infection for treatment as soon as it is introduced into the urinary tract may be beneficial in preventing recurrent encrustation and blockage [431]. While this organism, which is harboured in the intestines, may not cause problems in the urinary tract of a healthy person, it has many characteristics that negatively impact the bladder of a catheterized person who has an already inflammatory process taking place. These include: four adhesins that help make it stick to the bladder and catheter, a protective capsule, several secretions that promote extraction of host nutrients, quick migration capacity, and a powerful urease [431]. The ability of P.mirabilis to evade the host's immune response make it a very difficult organism to treat. For example, a structure in the membrane called LPS contributes to virulence and can cause hypotension, fever, DIC and shock. Another component (migration factor Cmf] improves swarming [432].

Although it is not possible to examine the effects of polymer surface properties on microbial adhesion and formation of catheter encrustation in detail here, recent studies have shown that strongly electron donating surfaces are less prone to adherence by P.mirabilis than more hydrophobic materials [433]. Some copolymer, polyurethane blends are associated with less microbial adherence and improved resistance to encrustation in an artificial bladder model [434]. The effect of iontophoresis produced by passing an electric current through silver electrodes attached to catheters has also been shown to inhibit bacterial growth [435]. Another potentially promising innovation is the use of the antiseptic agent triclosan in the catheter balloon [408] [436] [437]. In laboratory models of the catheterised bladder infected with P.mirabilis, silicone and latex-based catheters, with balloons inflated with triclosan, drained freely for seven days compared to 24h for controls inflated with water. Triclosan became impregnated throughout the silicone catheter material and strongly inhibited the formation of the crystalline biofilm. However, latex-based catheters required a higher concentration of triclosan (>1mg/ml) than silicone catheters to produce similar inhibitory effects on P. mirabilis. Diffusion through the latex balloon occurred but the latex-based catheter did not become impregnated with triclosan throughout. The potential benefits of triclosan in catheter balloons now needs to be tested in clinical trials but it is also important to note that not all microbial species responsible for CAUTIs are sensitive to this biocide and emergence of resistant strains is a common concern [437].

2. Reducing catheter encrustation – interventions

A number of studies have employed in vitro models of the catheterised bladder to examine the influence of urinary composition on bacteria growth and encrustation, and the ability of acidic irrigations to reduce encrustation build up. There is good evidence from laboratory studies that increased fluid consumption (leading to lower concentration of encrustation components) increases the time to catheter

blockage [438]. Increasing citrate concentration in fluid intake and urinary output (eg through drinking orange juice or other fruit juices such as lemon or lime) has also been shown to increase time to catheter blockage (see below). Cranberry juice has frequently been advocated to reduce UTIs, microbial adherence and biofilm development but an in vitro study by Morris and Stickler [439] drinking cranberry juice did not produce urine which was inhibitory to the development of P.mirabilis biofims and catheter blockage, although increased fluid intake was beneficial. Although some studies have claimed drinking cranberry juice can decrease urinary pH in healthy volunteers [440], this is unlikely to be accomplished in catheterised patients, in the presence of continued ammonia production by the action of urease-producing micro-organisms [441].

Urease inhibitors, including acetohydroxamic acid (1.0mg/ml) and fluorofamide (1.0microg/ml), have been shown to restrict the increase in urinary pH of P.mirabilis infected urine from 9.1 to 7.6, in a simple physical model of the catheterised bladder [430]. Significant reductions in precipitation of calcium and magnesium salts were also noted but the impact of possible side-effects remains unclear, and therefore clinical potential is uncertain. Clinical studies on the prevention or management of catheter encrustation are extremely limited and only two relevant studies addressing the use of urease-inhibitors were identified. One early clinical study [442] examined oral administration of a urease inhibitor (acetohydroxamic acid) to five patients who required frequent catheter changes (>1 every 2 weeks) due to encrustation and blockage. The dose was based on body weight (eg. 250mg three times daily for patients between 50-70kg). The degree of encrustation decreased significantly during therapy ($p<0.05$) and the authors reported minimal adverse side effects experienced by patients, but acknowledged the potential for more severe side effects to occur. A subsequent double-blind, RCT of acetohydroxamic acid in the palliative treatment of infection-induced urinary calculi, demonstrated lowered urinary pH in urine infected with P.mirabilis but the side effects were unacceptable to patients [443] (Level of Evidence 1).

An alternative approach to reducing catheter encrustation, aimed at increasing the 'safety margin' between urinary pH and the nucleation pH (pHn) (i.e. the pH at which crystals of calcium and magnesium are formed in the urine) warrants further clinical investigation. In laboratory studies using models of the catheterised bladder, the pHn of the urine was shown to increase when urine concentration was decreased and also by addition of citrate to the urine [438]. In models supplied with urine containing citrate at 1.5mg/ml or above, catheter drained freely for the seven day experimental period. Drinking 500ml pure orange juice per day can achieve concentrations of citrate of up to 1.2mg/ml urine [423] and further clinical evaluation of the effects of increasing a patient's fluid intake with citrate containing drinks is awaited. Viable cell counts of P.mirabilis in the model suggest that results were unlikely to be due to direct effects of citrate on the growth of metabolism of P.mirabilis in the catheter biofilm, but rather on the process of mineral crystallization.

Recent research provides more evidence. In a recent randomized six week crossover trial of citrated drinks in 24 persons with catheter blockage [444], it was demonstrated that the pHn could be significantly increased. The highest level of change was with lemon juice, with a "safety margin" of 0.84 (95% CI 0.63, 1.04), followed by fluid intake 0.57 (95% CI 0.37, 0.78), and potassium citrate 0.41 (95% CI 0.20, 0.61). Overall, the safety margin for the drinks was significant ($p<0.001$) when controlling for the three groups. Each participant, who had experienced at least three blockages within four weeks previously, received all three drinks. Baseline 24 hour urines were obtained after each week, allowing for a washout period between the one week drink consumption for each arm of the study. The lemon juice concentration was 60mL/1 litre of water, potassium citrate was 6 g/1 litre, and the fluid intake was also 1 litre additional. Participants were instructed to consume the drinks each day in addition to their usual fluid intake and they tracked their intake and output during the study. This study provides additional evidence that optimal and consistent levels of fluid intake could minimize catheter blockage or increase the interval between changes, in persons with persistent encrustation and blockage.

The reduction of encrustation and corresponding extension of 'catheter life' by regular instillation of an acidic catheter maintenance solution into the catheter has been advocated by some researchers, particularly where frequent catheter changes for recurrent blockage are difficult and / or unacceptable to patients. Solution G (Suby G) and Solution R (Table XII-5) have been shown to be effective in in vitro models of the catheterised bladder [445] [446] [447] and in vitro models of struvite stone chemolysis [448]. In response to concerns over potential damage to the bladder mucosa from acidic catheter maintenance solutions, Getliffe et al. [446] advocate the use of small volumes of solution so that less enters the bladder. Under controlled laboratory conditions smaller volumes of acidic solutions (Suby G) (50ml), retained in the catheter for 15 minutes, were shown to be as effective as the commonly available commercial standard of 100ml. Getliffe et al. also showed that two sequential washouts with 50ml were more effective than a single washout.

There is relatively little clinical evidence to draw on in this area and outcomes remain to be tested in well-controlled clinical trials. Most clinical studies are small-scale and descriptive although both Getliffe [424] and Kunin et al. [418] compared groups of 'blockers' and non-blockers' to identify

characteristics of recurrent 'blockers'. One small-scale, comparative trial of Suby G, Solution R and saline catheter 'washouts' in 14 older female patients [449] reported a higher incidence of red-cells in the retrieved washout fluid with Suby G compared to saline (mean incidence of 28% and 14%, respectively. However, increased shedding of uro-epithelial cells was present in the retrieved washout from all three solutions suggesting this was at least partially related to the physical process of administration. This issue was previously raised by Elliot et al. [450] who also demonstrated increased uroepithelial shedding following washouts with up to 60ml saline 0.9%; chlorhexidine 0.02% or noxythiolin 2.5%.

A more recent RCT with 73 community dwelling individuals, which aimed to compare weekly catheter flushes with saline or an acidic solution, with no flushes, reported the mean time until catheter removal was very similar between groups. Importantly, there was no evidence of detrimental effects, such as increased risk of symptomatic infection, from breaking the closed system in order to apply catheter flushes. Urinary pH did not change over the study time; at baseline the mean was 6.3 (SD 1.04), range 5-8.5. However the study was underpowered and subjects were only followed for a maximum of eight weeks, or until the catheter was changed three times, or a symptomatic UTI developed. There were considerable difficulties with recruitment of patients and target numbers fell short within each group (Level of Evidence 2) [358). A sample of 400 per group, 1200 in total, was estimated posthoc, as giving sufficient power for future research in this area [451]. Other clinical studies have focused on chemolysis of infection stones (principally composed of struvite). Stronger acidic solutions such as Solution R have been shown to dissolve fragments of struvite renal calculi following lithotripsy [452] but potential benefits may be outweighed by the greater risk of inflammatory tissue reactions when used as a catheter maintenance solution. Renacidin solution is approved for kidney stone disintegration in the US but although it may be effective for recurrent catheter blockers, there is no published research evidence of its use in this group.

Overall, methodological issues make it difficult to draw robust conclusions on the effectiveness of acidic solutions in managing catheter blockage. It is unlikely that any currently available strategies will completely prevent catheter encrustation and a more practical aim is to extend catheter life to a period which is acceptable to users and manageable by healthcare professionals. Early detection of impending blockage by determination of usual length of catheter-life [424] or by application of a sensor device designed to detect early stages of P. mirabilis biofilm formation [453] are likely to remain the main stays of management.

j) LTC-associated risks and problems: urethral trauma, bladder calculi and bladder cancer

1. Urethral trauma

Urethral trauma and discomfort can occur during catheterisation but may be minimised by using a sterile lubricant or anaesthetic gel [454], however clinical practice remains variable. More studies have considered the use of lubricants for male catheterisation but few have considered the procedure for women or for supra-pubic catheterisation [455]. A recent randomised, double-blind study with 62 alert, cooperative females requiring urethral catheterisation, demonstrated that the group receiving lignocaine gel had a significantly lower median procedural pain score compared to the group receiving a water-based lubricating gel [456]. It is not clear whether cleaning the urinary meatus prior to insertion is needed, based on two small trials (Level of Evidence II). In one study, 0.05% chlorhexidine gluconate or sterile water was tested in a home care sample (N=20), with four urine specimens cultured over two weeks. No difference was found, and no one developed a symptomatic CAUTI [457].In the other study of 60 women receiving outpatient gynaecological surgery,[458] povidone-iodine was compared with water. No significant differences in bacteriuria or symptomatic CAUTI were found in comparing urine samples just prior to insertion and 24 hours later.

2. Bladder calculi

Most long-term follow up studies of LTC use have addressed SCI populations. Indwelling catheters (UC and SPC) have been significantly associated with increased risk of bladder calculi formation in SCI patients, compared to intermittent catheterisation [460] [235]. In a retrospective cohort study of 457 patients, controlled for variable follow up times by regression analysis, both UC and SPC were significantly associated with increased risk of bladder calculi formation compared to intermittent catheterisation IC (hazard ratio 10.5; $p<0.0005$ and 12.8; $p<0.0005$) respectively [461]. This increased risk was independent of age, sex, level and degree of injury but calculi were no more likely to form with SPC than UC (hazard ratio 1.2, $p=0.6$). Another case series of SPC in 118 patients with neurogenic bladders [462] found common complications were bladder calculi (25%), (particularly associated with high urinary pH) and urethral leakage (10%). Bladder calculi-free rates at five and 10 years were 77% and 64% respectively, falling to 50% at 20 years.

Where SPC has been compared to CIC the main difference appears to be in a lower incidence of bladder calculi in the CIC group. A prospective comparison of long-term outcomes between 34 quadriplegic patients managed by SPC (mean period 8.6 years) and 27 paraplegic patients managed with CIC (mean period 9.9 years) reported no significant

difference between groups in respect of symptomatic UTI, renal stone, degree of bother and overall satisfaction [310] but there was a significantly increased incidence of bladder stones in the SPC group. However a recent review of current literature [311] (56 studies), concluded there were variations between older and more recent studies. More recent studies showed morbidity profiles to be similar for SPC and CIC, where patients were managed by anticholinergic medications, frequent catheter changes and volume maintenance procedures. A dedicated catheter clinic established to aid the management of patients having problems with LTC, reported the majority of patients were elderly with chronic disabilities. A significant proportion of those with catheter encrustation and blockage (45% of 147 patients) were shown to have formed bladder calculi [463].

3. Bladder cancer

A number of retrospective, cohort reports of SCI patients have linked bladder cancer with long-term indwelling catheterisation [464] [465] [466]. The reported incidence of squamous cell and transitional cell carcinoma associated with chronic indwelling catheterisation varies widely between studies but Groah et al. [466] in their follow-up of 3670 subjects, calculated that patients with SCI and an indwelling catheter were 25 times more likely to develop bladder cancer than the general population (Level of Evidence 3). For SCI patients without an indwelling catheter, the risk of bladder cancer was 15 times that of the general population. Since SCI patients are already at increased risk of developing bladder cancer compared to non-SCI groups, the influence of an indwelling catheter on bladder cancer requires further clarification, including the potential relationship between duration of catheterisation and cancer development. Bladder calculi have been identified as an independent risk factor for bladder cancer by some authors (464].

Most reports have grouped UC and SPC together as indwelling catheters but a small number of case study reports have drawn attention to long-term risks of carcinoma within the cystostomy tract with SPC, with or without further extension into the bladder [467] [468] [469]. However, in a retrospective analysis of screening biopsies for bladder malignancy in 36 patients with SPC for more than 12 years, Hamid et al. [470] found no tumours in the screened group although histological findings were frequently abnormal (Level of Evidence 2). These authors raise concerns over the interpretation of screening cystoscopy and biopsy in this population and note the importance of the distinguishing between histological changes and confirmed cancers when interpreting study results. Recently published guidance on management and prevention of catheter-associated urinary tract infection, based on an extensive survey of the literature, includes a recommendation that patients with urethral catheters in place for 10 years or more should be screened annually for bladder cancer [471] (Grade of Recommendation C).

k) Catheter management strategies

Although guidelines and protocols for catheter-care practices are abundant, relatively few practices are supported by research evidence and even fewer by evidence from randomized controlled trials. For example, in the 'Guidelines for prevention of healthcare associated infections in primary and community care' commissioned by the UK's National Institute for Clinical Excellence [472], of 29 recommendations relating to urinary catheterisation only six were Grade A (directly based on Level 1 evidence); with one each at Grades B and C. The remaining 21 were all grade D, being based on evidence from expert groups or clinical opinion.

1. Guidelines

In 2009, the U.S. Healthcare Infection Control Practices Advisory Committee issued through the Centers for Disease Control and Prevention (CDC) updated Guideline for Prevention of Catheter Associated Urinary Tract Infections [342]. This guideline, which updated the 1982 Guideline, expanded information about catheter related issues, including intermittent, condom, suprapubic, and chronically catheterised long-term users. The recommendations made by this committee for preventing catheter-associated urinary tract infections, based on systematic review of the best available evidence, address the following issues:

- who should receive an indwelling urinary catheter
- catheter insertion
- catheter maintenance
- quality improvement programs to achieve appropriate placement, care, and removal of catheters
- administrative infrastructure required
- surveillance strategies

This new guideline recommended selected practices at grade B based on level of evidence of 1 or 2. Therefore, many topics were judged as "no recommendation/unresolved issue" due to a lack of evidence.

2. Quality indicators and regulator initiatives

It is well established that guidelines alone do not change practice. Further efforts should be directed to disseminating evidence-based guidelines about catheter care through education and the use of quality indicators and regulatory initiatives.

Regulation that is accompanied by the use of evidence based quality indicators has a powerful influence on the quality of care. Quality indicators are defined as quantitative measures reflecting a professional

care standard which are used as guides to monitor and evaluate the quality of important patient care and support service activities. The ACOVE (Assessing Care of Vulnerable Elders) suite of quality indicators has been designed to measure the quality of care for vulnerable elders [473]. It incorporates one quality indicator to guide measurement of the quality of care related to catheter use.

"IF a VE has clinically significant urinary retention, and a long-term (> 1 month) urethral catheter is placed, THEN there should be documentation of justification for its use, BECAUSE treatment of certain underlying causes(s) of urinaryretention (e.g., treatment of constipation or bladder outlet obstruction) may carry less risk than long-term urinary catheterization" [473].

Another attempt to ensure the appropriate use of catheters is the use of assessment protocols. For example, regulation for long-term care settings in the USA mandates that all newly admitted Medicare/Medicaid funded residents receive an assessment using a standardized form called the Minimum Data Set (MDS). A further level of assessment is triggered when/if a resident is newly incontinent and the Resident Assessment Instrument Minimum Data Set is completed (RAI-MDS). This assessment information in turn, acts as a prompt for staff to design an individualized care plan based on direct contact with residents, appropriate staff, and through use of observation, interviews and record reviews. The MDS and RAI are now used in a number of other countries, including Canada and Iceland, and other countries have developed their own assessment instruments. Ideally, these assessment instruments should prompt staff to enquire about whether the residents' catheter is medically warranted, and to identify catheter related problems, and care plans should contain information about an individualized catheter care plan (including the frequency of catheter changes and ongoing maintenance). This assessment process is strengthened in the USA by its link to quality indicators. Specifically, long-term care facilities are required to use information from the residents' comprehensive assessment to provide assurances that:

- Catheters are used for only medically valid reasons;
- Catheters are removed as soon as clinically warranted;
- Efforts are applied to restore or improve bladder function as much as possible; and
- Efforts are made to prevent infection while the catheter is inserted (U.S Dept of Health and Human Services, 2004).

It remains to be seen if these measures will reduce catheter rates in long-term care, and how they will impact day-to-day catheter use and catheter care. However, similar regulatory approaches should be considered by government and health agencies in other countries.

3. Catheter change procedures and catheter comfort

Indwelling catheters can cause substantial patient discomfort but although anecdotal information on the discomfort experienced by many catheterised patients is readily available, there is a general lack of published evidence from research studies. Further investigation and guidance to practitioners is needed. Catheter-related pain or discomfort can occur as the catheter is passed, in situ and on removal. Local anaesthetic lubricant gels are commonly used to aid the insertion of indwelling catheters in males and protect the sensitive urothelium from trauma [474]. Similar use of anaesthetic gels is generally recommended for females although the procedure may be less consistent in some places and where only small amounts of lubricant are applied to the catheter tip this may be insufficient to coat the urethra adequately. There is little research evidence to underpin clinical practice in this area although the NICE guidelines on infection control [472] recommend: 'an appropriate lubricant from a single–use container should be used during catheterisation to minimise trauma and infection'. The choice of lubricating gel is usually left to practitioners but not all gels containing anaesthetic agents (eg lidocaine) are suitable for both urethral and suprapubic use. One prospective, randomized, double-blind, controlled trial of plain lubricant versus lidocaine gel prior to female catheterisation in an accident and emergency department found no significant differences in pain ratings, based on lubricant type or catheter size amongst 100 women recruited to the trial [475]. Anaesthetic gels may be contraindicated in patients with damaged or bleeding urethral membranes and should be used with caution in those with cardiac conditions, hepatic insufficiency and epilepsy [476]. Lubricants which contain chlorhexidine have been reported to trigger anaphylaxis in a small number of patients during catheter insertion and consequently a careful history is required to screen for sensitivities [477] [96].

In a study with 45 infants (2-24 months) who needed urethral catheterization, random assignment was made to either a topical lubricant (control), topical and intraurethral lubricants, or topical and intraurethral lidocaines [478].Infants with the lidocaine had less distress, but the lidocaine did not eliminate the distress totally.

Catheterization in males can be difficult at times, and different approaches can be used, including a Coude catheter, various guide wires or filiform catheters, and other techniques performed by urologists. Research in this area is needed to compare different practices and associated risks [479].

Catheters can be painful when in situ. In one study at a US Veterans Affairs Medical Centre, 42% of

catheterised patients reported it was uncomfortable, with 48% complaining it was painful, and 61% stated it restricted their activities of daily living [107]. In one small sample of 43 community dwelling persons with long-term catheters, pain was reported by 24 (54%) [126]. Causes of pain were bladder spasms, position of the catheter, or related to catheter changes. Three had pain all the time, but 21 of 24 persons had it intermittently. If bladder spasm is the cause of pain when a catheter is in situ a low dose of an anticholinergic medication can help [480]. Other helpful approaches include treating constipation if present, ensuring that the catheter is the smallest size to provide adequate drainage, and ensuring that the drainage bag is well supported to prevent dragging on the catheter. Attention to the catheter position is needed to prevent kinks or twists in tubing and ensurethat the catheter straps are not blocking urine flow [481]. Blockage in urine flow can cause bladder distension resulting in increases in hydrostatic pressure and bleeding points which open the way to bacteria, already present, to cause a symptomatic infection [210].

Bladder discomfort related to an indwelling catheter can exacerbate post-operative pain by mimicking overactive bladder syndrome that is resistant to conventional opioid therapy. Sub-lingual oxybutinin has been shown to be an effective treatment for pain after radical retropubic prostatectomy, with significant reduction in other pain relief requirements [482]. Cuffing of the catheter material on balloon deflation (see below) and / or encrustation of the catheter by mineral deposits may cause pain during catheter removal. Encrustation is discussed further in Section 12.2.9 and management of these problems is also discussed below.

4. Education of healthcare providers

Educational approaches should ensure that all healthcare practitioners have the necessary knowledge and skills to care for individuals with a catheter. Some research however, points to gaps in healthcare practitioners' knowledge about what catheter to select, and how to minimize and manage ongoing problems[483]. Mody and colleagues (2010) [484] assessed nursing home healthcare workers' knowledge and awareness of recommended catheter care practices, and found significant discrepancies between their knowledge and research-based recommendations. Respondents were drawn from seven community-based nursing homes in the USA and included nurses and nurse aides

Twin surveys were sent to healthcare providers in Minnesota to determine their level of knowledge about catheter use. The physicians (N=635) reflected awareness of the indications for catheter use, and about 1/3 said they remove them sooner. However, about 30% were unsure about how to prevent UTI [485]. Nurses (N=370) were aware of catheter indications, but some were likely to approve of catheter use in the ICU (for whatever reason) and of the value of silver coatings on catheters [485].Both studies had low response rates, of 9% and 4% physicians and nurses, respectively. Another survey to 333 persons, (70% RNs and 27% unlicensed assistants) indicated that there was a need for more education related to catheters [486]. Incorrect practices involved not securing the catheter (75%) and not knowing when to replace the catheter (74%). The response rate was 54%, and about half of those surveyed had less than two years work experience.

An audit of education given to nursing students in Greece indicated that there was a need to upgrade teaching methods [487]. Proficiency was impaired by a lack of attention to preparing the patient (including emotional and practical aspects), old textbooks, outworn traditions, little or no instruction on troubleshooting and a lack of sophisticated methods for teaching (e.g. DVDs showing the procedure).

An audit of adherence to standards of nursing care in one UK Trust related to catheter practices in patients' homes [488]. All nurses surveyed (N=25) indicated they would change the catheter every 12 weeks unless there was a reason to do this more often; no data were provided on the percentage with 12 week changes. Though a closed system was advocated by all nurses, washouts were performed by 75% and sampling ports for urine samples were used by 28%, and the rest used a clean drainage bag. A similar audit was conducted in a hospital setting [489]. Continuing catheter care was well documented at 98%, but 11% were missing details on insertion.

5. Catheter change frequency

Protocols on indwelling catheter change frequency vary widely from monthly to up to three months if the catheter is trouble-free. In the absence of clear supporting evidence this remains an area of controversy amongst clinicians with advocates of early change believing this to reduce the incidence of complications while others argue that frequent changes increase the risk of infection, trauma and long-term histological changes. However, very sparse evidence suggests that CAUTI might be less when the catheter is changed every 4-6 weeks, rather than only when it blocks, or with planned changes of every two weeks [490].

SPC changes can be competently managed by skilled nurses [325], often in the patient's own home, but the new catheter should be inserted as quickly as possible whilst the track is still easy to follow. A delay of only a few minutes can result in partial obliteration of the tract [491]. It is also possible to insert the new catheter too far through the bladder so it enters the urethra with resultant trauma when attempts to inflate the balloon are made. Careful observation of the length of catheter external to the abdomen and the angle of protrusion prior to catheter change can

help to ensure correct positioning of the new catheter [492]. Dressings around the stoma site are not normally required unless there is excessive discharge, causing staining and / or sticking to clothing.

While nurses do not usually order catheter insertions, and there may be times when delay in a clinically appropriate catheterisation is harmful to certain patients. A new protocol and algorithm was thus developed by nurses, physicians and other key stakeholders in an orthopaedic unit of a large urban hospital to facilitate catheter insertion in certain defined situations [493]. Indications, such as spinal column injury, and contraindications were depicted in a diagram to identify when to stop, consider the issues (e.g., neutropenia), and when to insert the catheter.

Urinary catheter 'deflation cuff' formation can be a problem in both SPC and UC, causing difficulty in removal and great discomfort to patients. Evidence suggests deflation cuff formation can be a particular problem for all-silicone SPCs. A retrospective study of 113 patients cared for by community nurses showed that 30% of nurses had experienced problems changing catheters in the previous 12 months [494]. In vitro studies have confirmed increased retention force and resistance to withdrawal caused by cuff formation and although cuffs can form with other catheter materials (eg hydrogel coated-latex) the retention force is less than with all-silicone material [339]. It has been suggested that slow deflation may enhance the probability of the silicone balloon returning to its pre-inflation shape [340]. Alternatively, reinsertion of 0.5-1ml water is sufficient to fill the catheter inflation lumen and eliminate the balloon cuff. Subsequent use of lubrication with gentle removal of the catheter has been well-tolerated by patients and produced virtually no trauma.

6. Personal hygiene and infection control

Meatal cleansing by simple washing with soap and water during routine bathing or showering is recommended (Level of Evidence 1) [495] [496]. No consistent reduction in bacteriuria has been demonstrated by any other meatal cleansing regimes, using povidone-iodine solution or cream, chlorhexidine, polymicrobial creams, 1% silver sulfadiazine or antiseptic lubricating gels, compared to routine bathing or showering [374] [122]. Effective handwashing by healthcare professionals, carers and patients, before and after handling catheters and drainage equipment is generally accepted to be the most important component of any infection control strategy. Healthcare professionals and formal carers should also wear gloves. Catheters and drainage equipment are commonly supported in position by tapes, Velcro and other securing devices (eg CathSecure, StatLock)

More securement devices are now on the market providing choices for long-term users, in particular. Consideration should be given to usual activity, clothing, size of the person (e.g. thighs) and the weight of the bag it would support. All, but especially those using adhesives, need to be comfortable, easy to use, and gentle to the skin [497].These securement devices are designed to control post-operative bleeding, maintain surgical anastomoses in the lower urinary tract, and prevent urethral erosion or trauma and accidental dislodgement from traction [498]. The importance of these in reducing risks of CAUTI and the mechanism involved are not well-established [380] (See also section XII.2.h).

7. Urine collection – catheter valves

Urine may drain continuously from the bladder into a drainage bag attached to the catheter (See Section XIII) or intermittently via a catheter valve. The valve is a small device connected to the catheter outlet in place of a bag. Closure and opening the valve allows bladder filling and intermittent drainage rather than continuous drainage into a bag. Valves are available in a variety of designs (**Figure XII-9**) ranging from simple inexpensive types used for up to a week, to more expensive, complex, forms which last longer and which may permit one handed action. However, valves are not available or licensed in all countries.

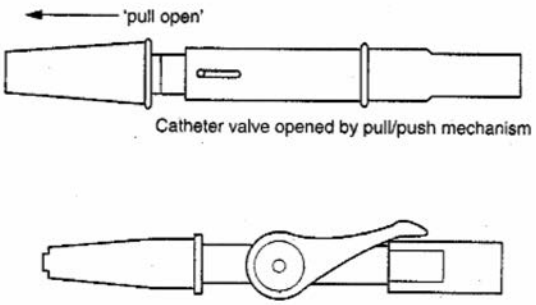

Figure XII-9: Example catheter valves.

Most valve designs can be attached to a drainage bag at night to allow free drainage while the patient sleeps. A valve can provide a discreet alternative to conventional urine drainage bags and may offer improved maintenance of bladder tone and capacity for appropriate patients. A spigot is not a suitable alternative to a valve since it must be removed from the catheter to allow drainage thereby breaking the 'closed system'. Patients must be able to manipulate the valve mechanism and empty the bladder regularly to avoid overfilling, with accompanying risks of back pressure on the upper urinary tract. Valves are generally inappropriate for patients with poor manual dexterity, poor bladder capacity, detrusor overactivity, ureteric reflux, renal impairment or cognitive impairment. There is relatively little research-based literature on catheter valves with much of the evidence supporting beneficial effects derived from the level of expert opinion. Concerns

over possible increased risk of infection associated with valves have not been realised although there is a paucity of research in this area. A lack of knowledge on valves may interfere with their use in appropriate situations; therefore, a full assessment is required to determine whether the person is a good candidate for a catheter valve using a systematic process, such as an algorithm [499].

The flushing mechanism resulting from bladder filling and emptying may be expected to contribute to reduction in problems of encrustation and blockage. One study was found that provides new evidence as to how a catheter valve might do this [500]. The laboratory study involved four experiments with a bladder model and artificial urine cultured with Proteus mirabilis. Manual valves were opened every two or four hours with continuous drainage at night, followed by experiments with automatic valves timed to open for five minutes every two to four hours around the clock for seven days. All experiments were compared with continuous drainage of urine. Analysis of variance showed that all models controlled by valves during the daytime (12 h) took significantly more time to block (62.6 versus 35.9 h, p=0.039) than 24 hour continuous drainage. Experiments were done with automatic valves which ran 24 hours day every two or four hours, and time to blockage extended to 119.8 h versus. 50.7 h, and 159.8 hversus. 44.7 h, respectively.

There is stronger evidence of benefits in terms of patient comfort and independence since this is a common finding in most studies. Five studies comparing a catheter valve with standard drainage (leg bag) were identified: three were cross-over designs, with 28, 16 and 18 subjects respectively [501] [502] [503] (Level of Evidence 3); two randomized their sample of 100 subjects to either catheter valve or standard drainage [504] [505] (Level of Evidence 2). None of the studies identified any significant difference in urinary tract infection and a majority found a high level of preference or acceptability of catheter valves (>72%). There were no differences in reported incidence of bladder spasms or discomfort; however, there was a higher incidence of nocturnal frequency and episodes of bypassing with valves. It was suggested that a combination of a valve during the day and free drainage at night through an open valve connected to a drainage bag could be an appropriate management strategy.

Several studies have evaluated a single valve design [506] [507] but only one has compared a broad range of valve designs [508]. Fader et al undertook a comparative evaluation of the seven catheter valves available on the UK market in 1996. Each valve type was tested for one week by between 19 and 36 subjects, followed by completion of a product evaluation questionnaire. Performance scores (and costs) varied widely between products but critical characteristics were: being easy to manipulate, leak-free, and inconspicuous. The authors concluded that prescribers need to be aware of the strengths and limitations of different valves for appropriate product selection (Level of Evidence 3). A more recent development concerns the design of a prototype, novel, automatic valve system for LTC patients [509] which may be helpful for patients who lack sufficient dexterity to manage a manual valve. In summary:

- Catheter valves provide a well-accepted system of bladder emptying for suitable patients who are able to manipulate the valve mechanism and empty the bladder regularly to avoid overfilling (Level of Evidence 2).
- There is no evidence of increased risk of urinary tract infection with valves compared to conventional drainage systems (Level of Evidence 2).
- Valves may promote maintenance of bladder tone and capacity (Level of evidence 4).

8. Maintaining effective catheter drainage

Use of urinary catheters is rarely completely trouble-free. Catheter drainage can be compromised by a variety of factors from simple causes such as kinked tubing or the position of the drainage bag, to bladder spasm, pressure of a constipated bowel on the adjacent urethra, suction of bladder mucosa into the catheter eye, or blockage by blood clots, mucous or encrustations formed by deposits of mineral salts. The algorithms in **Figures XII -10 to XII-12** combine current evidence-based knowledge and expert opinion to provide some guidance on troubleshooting common problems.

9. Recurrent catheter encrustation and blockage

Factors affecting persistent catheter encrustation leading to recurrent blockage have been discussed earlier in section XII.2.i. The day to day management of recurrent catheter encrustation and blockage is largely a nursing responsibility but there are few options available. Maintenance of dilute urine by a suitably high level of fluid intake has been shown to reduce encrustation in laboratory studies [438] and increased urinary citrate concentration produced by drinking orange juice or other fruit juices may also be beneficial [438]. However the amounts required may be relatively high and clinical studies are needed to assess benefits and possible detrimental side effects e.g on bowel behaviour. Use of a catheter valve in suitable patients may also help reduce build up of encrustation by facilitating periodic flushing but clinical evidence is currently unavailable. In a majority of patients a characteristic pattern of ‘catheter life’ can be identified with careful record-keeping of three or more catheter episodes [424] [418] [510]. This may allow pro-active strategies of care designed to change the catheter before likely blockage. However, very frequent catheter changes can be unsuccessful or

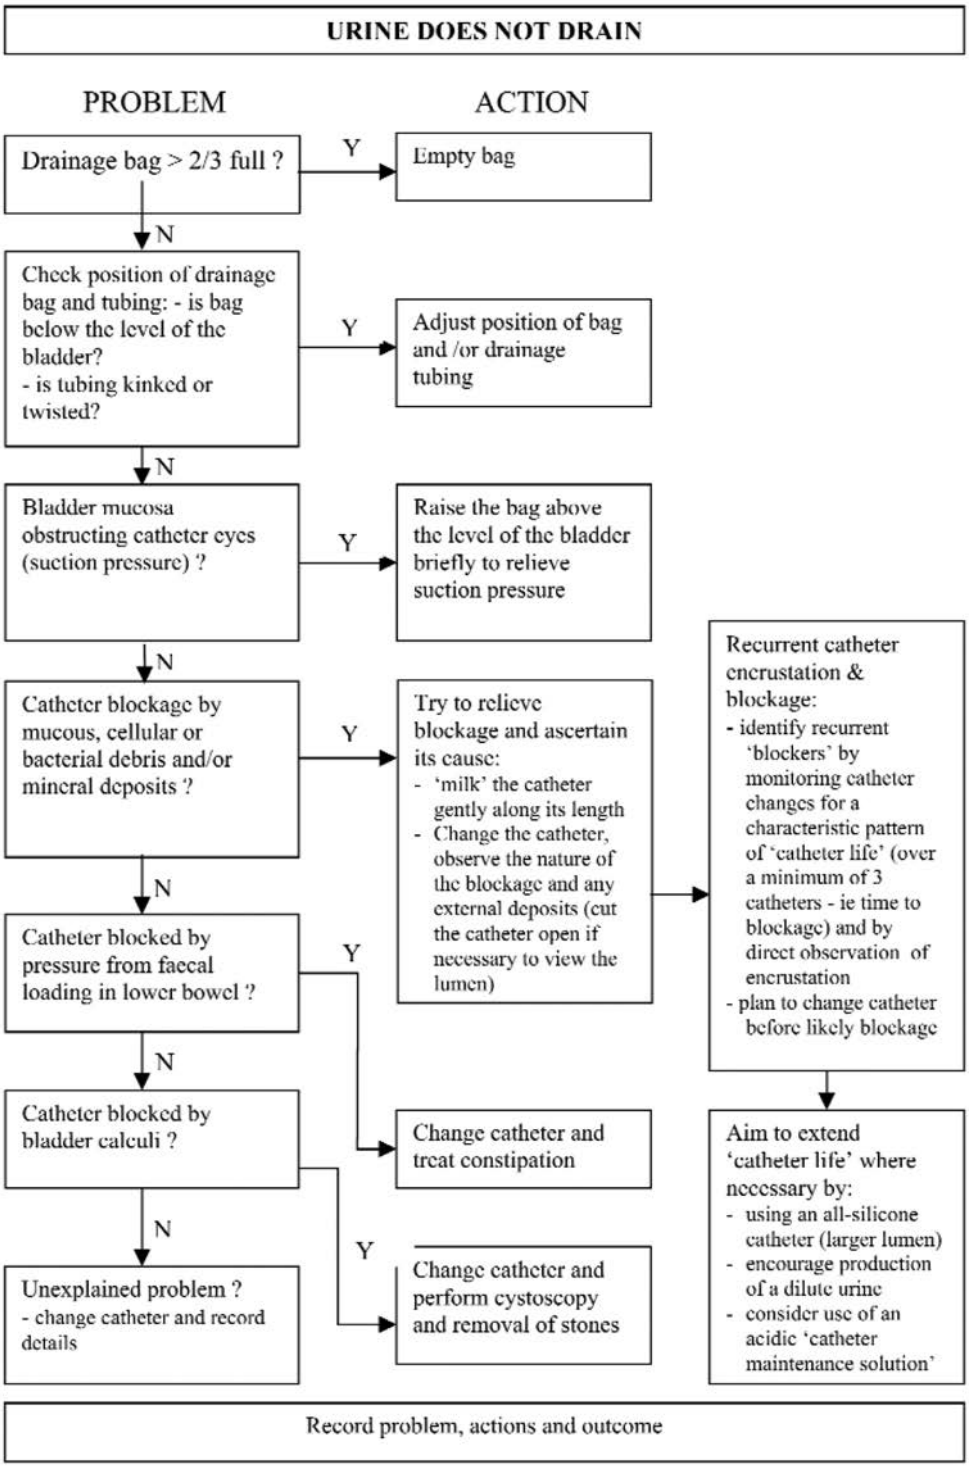

Figure XII-10: Troubleshooting long-term catheter problems: urine does not drain (N = No; Y = Yes). (Always have a spare catheter available)

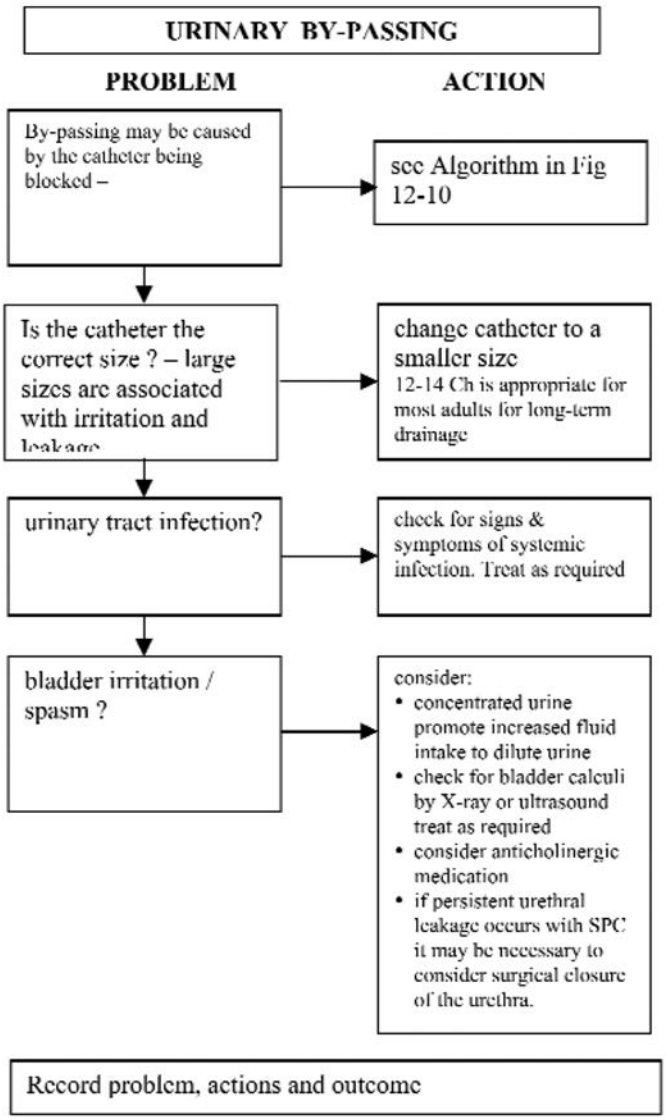

Figure XII-11: Troubleshooting long-term catheter problems: urinary by-passing.

unacceptable for some patients, as well as being costly in terms of health service resources [420]. In a study of planned catheter changes [511], based on observation of the intervals for three changes,urinary pH, and visual encrustation, unplanned changes decreased significantly from 46 the year prior (n=39) to 30 during the 12 months post intervention (n=21, p<0.01). The major impact on quality of life related to catheter problems decreased from 39% to 5%, though satisfaction with care management did not change much.

An alternative strategy is the regular prophylactic instillation or irrigation of the catheter with an acidic 'catheter maintenance' solution to dissolve mineral deposits. In older literature the term 'bladder washout' appears but as the aim is to wash the catheter, rather than the bladder, 'catheter maintenance solution' is a more appropriate term. A range of commercially available catheter-maintenance solutions is indicated in **Table 12-6**, although these are not necessarily available in all countries. Support for irrigations is strongly divided between those claiming benefit for specific patients who experience very frequent blockage and those who consider any break to the closed system to increase risks of infection. Research evidence is primarily derived from laboratory models of the catheterised bladder. The few clinical studies which have addressed this issue have been limited by methodological deficits and small sample size.

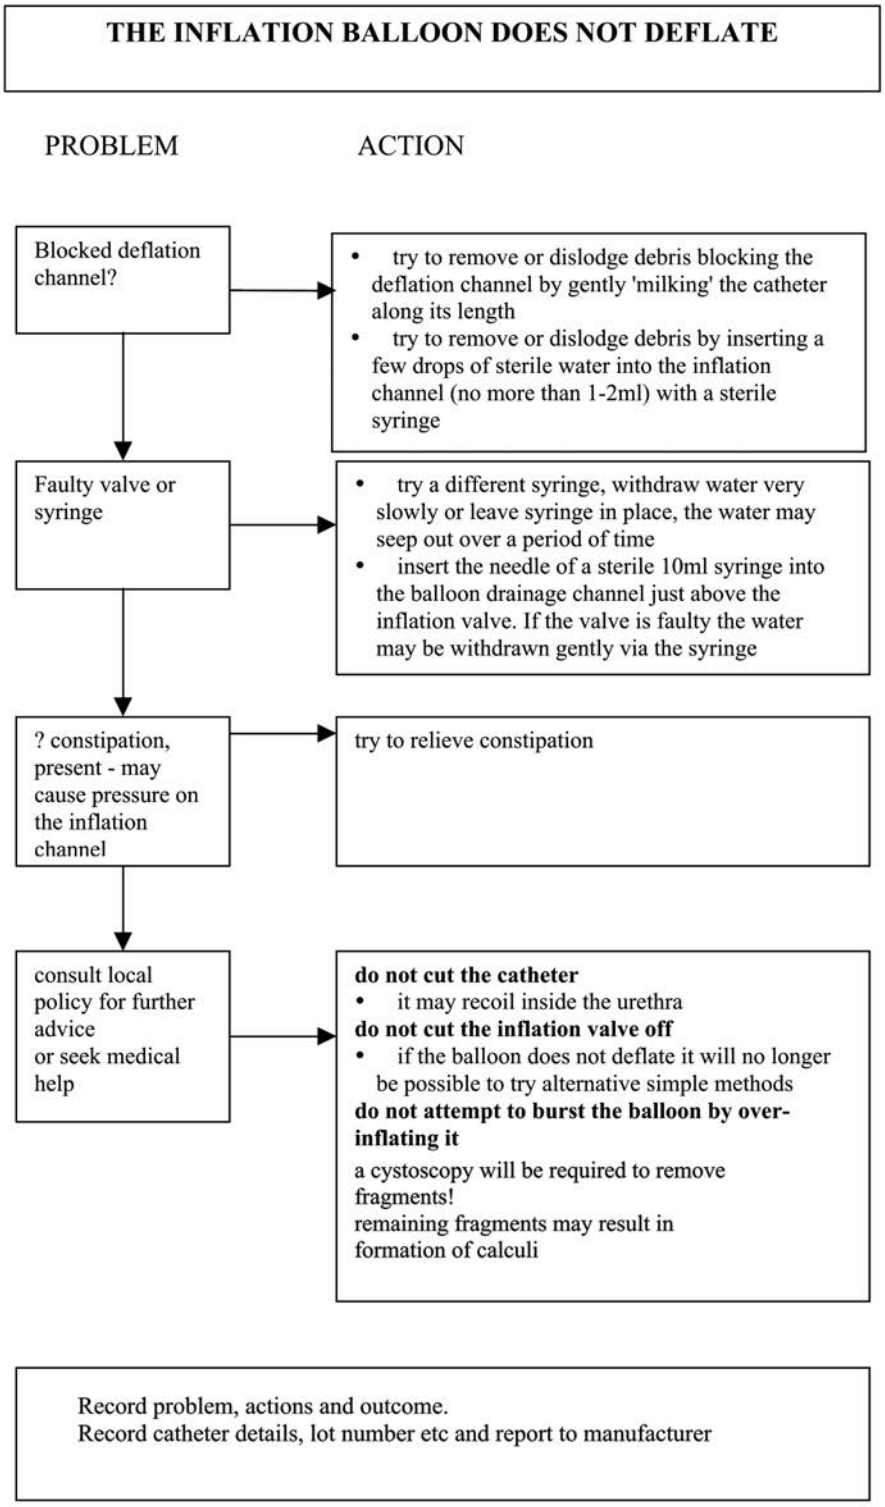

Figure XII-12: Troubleshooting long-term catheter problems: the inflation balloon does not deflate.

Table XII-6: Catheter maintenance solutions

Suby G or Solution G[1]	3.23% citric acid solution, pH 4, containing magnesium oxide to minimise tissue irritation, aimed at reducing encrustation. Used where routine catheter maintenance is required to reduce build up of encrustations.
Solution R[1]	6% citric acid solution, pH 2, containing magnesium carbonate, aimed at dissolving encrustations. A stronger acid than Suby G and therefore not recommended for frequent, regular use.
Renacidin[R2]	A citric acid solution, pH 3.5-4.2, containing glucono-delta-lactone to minimise tissue irritation and magnesium carbonate, aimed at reducing encrustation.
Mandelic acid 1%[1]	An acidic solution, pH 2, aimed at inhibiting the growth of urease-producers. A stronger acid which is not commonly used to reduce catheter encrustations
Saline 0.9%[1,3]	A neutral solution, pH 7, recommended for flushing of debris and small blood clots. Neutral pH solutions will not dissolve catheter encrustations.
Chlorhexidine 0.02%[1]	An antiseptic solution aimed at preventing or reducing bacterial growth, in particular E. coli and Klebsiella species (but will not prevent biofilm formation on long-term catheters)

[1] Available in the UK pre-packed in a sterile delivery devices designed for instillation into a urinary catheter.
[2] Renacidin[R] is approved in the USA for kidney stone disintegration only. Although it may be effective in certain situations for persistent catheter blockers, there are no supporting studies.

- **Saline is widely available**

I) Levels of evidence relating to catheter-associated risks and complications

- All currently available catheter materials are subject to bacterial biofilm formation (**Level of Evidence 1**).
- Silver alloy coated catheters are associated with a statistically significant reduction in incidence of asymptomatic bacteriuria in short-term catheterised, hospitalized adults (studies of varying quality included) (**Level of Evidence 1**). There is less robust data to show that silver-alloy catheters reduce symptomatic infection (**Level of evidence 4**). Silver oxide coated catheters are not associated with a statistically significant reduction in bacteriuria (**Level of Evidence 2**).
- Antimicrobial catheters can prevent bacteriuria in hospitalized patients during short-term catheterization (<14days) (**Level of Evidence 1**). Trial results are highly context dependent and the effectiveness of specific antimicrobial preparations may be limited to specific groups of microorganisms. Potential toxicity and / or antimicrobial resistance is unknown (**Level of Evidence 2**).
- There is little evidence to guide the precise timing of antibiotic cover (when required) for catheter change. One study has shown that clinical outcomes (i.e. reduction in polymicrobial counts in urine, time to achieve afebrile status and clinical status at 72 hours) are significantly better among subjects randomised to catheter change immediately before institution of antibiotics (**Level of Evidence 2**).
- A majority of health services have clear policies on the use of antibiotics, designed to limit unnecessary use. Current evidence does not support routine use of antibiotic cover during catheter changes unless the patient's condition renders them particularly at risk (**Level of evidence 4**).
- Meatal cleansing by simple washing with soap and water (i.e. not with antimicrobial agents) during routine bathing or showering is recommended (**Level of Evidence 1**).
- Recurrent urinary catheter blockage caused by encrustation occurs in 40-50% of all long-term catheterised patients (**Level of Evidence 2**). In the majority a characteristic pattern of 'catheter life' can be identified (**Level of Evidence 3**).
- Evidence from in vitro models of the catheterised bladder indicates that i) dilute urine; ii) high urine citrate content (> 1.5mg/mL) reduce risk of blockage (**Level of Evidence 2**).
- Evidence from in vitro models of the catheterised bladder indicates that acidic 'catheter maintenance'

solutions may have a role in dissolving encrustations in persistent blockers (**Level of Evidence 2**). There is insufficient evidence from RCTs to assign an in vivo level of evidence.

- Suprapubic catheterisation (SPC) is an appropriate alternative to urethral catheterization for many patients following appropriate risk assessment (**Level of Evidence 1**).
- There is some evidence for a reduction in catheter-associated infection in SPC use during short-term catheterisation (**Level of Evidence 2**), compared to urethral catheter insertion. However, there is no corresponding evidence for long-term catheterisation.
- Patient comfort, quality of life and satisfaction with SPC is generally good compared to urethral catheters (**Level of Evidence 1**).
- Catheter valves provide a well-accepted system of bladder emptying for suitable patients who are able to manipulate the valve mechanism and empty the bladder regularly to avoid overfilling (**Level of Evidence 2**).
- There is no evidence of increased risk of urinary tract infection with valves compared to conventional drainage systems (**Level of Evidence 2**).

m) Urinary catheters versus other care strategies

Very few studies have compared urinary catheterisation with other strategies to manage urinary incontinence, not least because of the difficulties in recruiting to and conducting robust trials. For male patients who do not have problems with retention of urine external urine collection systems are an option (See Sections VII, VIII and IX). One recent prospective, randomized, unblinded, controlled trial on men >40years in a US Veterans Affairs Medical Centre reported that the use of condom catheters was less likely to be associated with bacteriuria, symptomatic UTI or death than the use of indwelling catheters [101]. Patients reported that condom catheters were more comfortable (P=0.02) and less painful (P=0.02) than indwelling catheters.

A small number of studies have attempted to examine preferences for different urinary incontinence treatments in long-term care. In a descriptive, comparative study of preferences for treatments for frail older adults, residents in long-term care facilities were interviewed and groups likely to serve as proxy decision makers were surveyed (family members of residents and nursing staff) [512]. Forced choice comparisons of continence treatments were measured. Although there was wide variation within and between groups, most preferred non-invasive strategies (diapers and prompted voiding) to invasive strategies including indwelling catheterisation. Older adults stated they would choose a treatment based, in part, on feeling dry, being natural, not causing embarrassment, being easy, and not resulting in dependence. Similar results, showing urinary catheterisation as the least favoured choice, were found in a study of 117 medical inpatients aged 80 years or over, their physicians, nurses and family members [513].

3. CATHETER-RELATED QUALITY OF LIFE

Use of a LTC is often a last choice for bladder management when other options such as CIC, for males a sheath (condom) catheter, or other voiding treatments like Credé procedure, are either unsatisfactory or no longer practical. Catheter users must deal with a variety of problems that disrupt their daily activities and negatively affect QoL, such as CAUTI, blockage, leakage and catheter dislodgment. In addition, the visibility of a catheter or drainage bag can contribute to shame or stigma, and urine odour can be embarrassing. A catheter can also be a reminder of vulnerability associated with illness / mortality and a symbol of a loss in control of bodily function. Yet catheter users also acknowledge catheter-associated benefits of freedom from wetness, convenience, and utility in promoting urine drainage. While this section focuses on long-term catheter use, even short-term catheters can have a detrimental impact on QoL. For instance in a study of short term catheter use prior to surgery for acute urinary retention, leaking, blocking, urgency, and pain at the penis or during erection were all reported [514].

Studies of QoL issues commonly utilise qualitative research methodologies, such as phenomenology or grounded theory approaches (see also Section XII.1.e). In-depth interviews with catheter-users and carers provide important insights into aspects of 'living with a catheter' and contribute research based evidence to support development of effective care strategies. Measurement of QoL and the impact of factors which may affect it is complex. Most validated QoL instruments fall into one of two groups: i) generic measures designed to encompass domains including physical, mental and social wellbeing; ii) disease specific measures designed to measure change in QoL resulting from treatment. For those people whose urinary symptoms are managed by products or devices, including catheter users, it is particularly difficult to assess the impact of the product on QoL. This is partially because changes are more likely to be related to improved management of ongoing symptoms rather than actual change in symptoms, and partially because QoL is also dependent on the underlying disease process.

Much of the literature on LTC use involves people with neurogenic bladder, particularly those with spinal cord injury (SCI) or multiple sclerosis (MS). Thus, QoL in catheter users must be considered from a perspective of how the disease and the device affect the individual's life. For instance, in one postal survey of 230 people with SCI, the factors

which had most impact on QoL were social activities and accomplishments, including employment, attending school, and other activities. There was no association between QoL and different bladder drainage methods [515]. A particular problem for people with spinal cord injury or disease is autonomic dysreflexia (AD), an autonomic nervous system syndrome causing symptoms which include severe hypertension, headache and sweating. A blocked urinary catheter can be a common cause. AD can be a serious problem requiring emergency medical attention, but lack of knowledge and awareness of the risks by some health care providers can cause high levels of anxiety for SCI patients [516] [305] (Level of Evidence 3).

There is currently one instrument measuring quality of life in people with indwelling urinary catheters [269] though this measure was validated in two small samples. Further development and validation are ongoing in the US and in the UK (Level of Evidence 3).

The published literature addressing QoL in catheter-users is small, and is commonly limited to reports addressing levels of satisfaction with a device. Studies which include a broader perspective of QoL are discussed below under the following headings: changes in bladder management, embarrassment, sexuality, catheter-related pain, catheter adjustment, and self-management.

a) Changes in Bladder Management

Changes in bladder management are often made to promote QoL but there are trade offs that require weighing up the pros and cons of various methods. People sometimes switch from CIC to an indwelling catheter - despite the inherent problems with an indwelling catheter -because quality of life might be improved. In particular, women with cervical spinal cord injury (SCI) may need an indwelling catheter because of difficulties in transferring to the toilet, limited hand dexterity, or dependence on caregivers [517]. Moreover, many people have used different bladder drainage methods over time. In one study, of 30 long-term catheter users, 80% of the sample had used another form, and 33% had used two or three different types [518]. In another small study with a sample of 11, 100% had used another method, and 27% had used two or three other types [306]. Reasons for non-compliance with CIC in relation to QoL or satisfaction have been addressed in Section XII.1.e and in some studies comparing drainage methods (Level of Evidence 3).

Two studies provided additional evidence of how changes in bladder drainage methods are made to improve their quality of life. In a retrospective study assessing compliance with bladder management, 50 new spinal cord injury (SCI) patient records were reviewed after admission, discharge, and follow up from 1994-1997 [517]. Of 38 patients on IC at hospital discharge, 20 (52%) were back to UC at follow up. Six of 10 females on IC had resumed UC. Reasons for not continuing with IC were: the need to depend on caregivers, poor hand functioning, spasticity, incontinence (despite anticholinergic drugs), and for females with cervical injury, toileting inconvenience (Level of Evidence 3). In contrast, a retrospective chart review and follow up questionnaire was used with 236 SCI injured people (at least 10 years post injury) between 1956-1990 [519]. An 85% response rate was achieved in the sample, with 82% males who had tetraplegia (47%) or paraplegia (53%). Although 46% changed their bladder management method over time and 28% considered the method a problem, in 58% of those who had tetraplegia, the use of CIC went up from 11% at discharge to 36%. Suprapubic tapping decreased from 57% to 31% and Crede increased from 5% to 19%. CIC alone, or with other methods, was the most common method (Level of Evidence 2).

b) Embarrassment

Embarrassment and a sense of lack of bladder control are two major catheter-related issues that are ongoing problems for many people. In one study at a US Veterans Affairs Medical Centre, 30% of catheterised patients surveyed found the indwelling catheter embarrassing, and 61% stated it restricted their activities of daily living [107]. The catheter is placed in a position in the body normally considered 'private', yet health care providers frequently need access to the site to provide care. Also, the force of urine flow is something that catheter users must deal with on a daily basis. In a qualitative phenomenological study of 14 people with long-term catheters, people told stories of how getting wet in public was embarrassing and how the force of the urine was like water that had built up pressure [516]. They used the metaphor of "flowing water" to describe the force of urine flow, the weight of the drainage bag, and the sound of urine sloshing around in the bag.

Living with the catheter was described in one qualitative study [305] as a swing back and forth between stigma, when it contributed to embarrassment or shame, and acceptance when it was working right and did not cause problems. The catheter became a source of embarrassment during catheter changes, bag emptying, and when it leaked or spilled in public. Individuals used planning and great care when going out (e.g. mapping out the toilets) to prevent urine accidents. They were bothered also by their lack of bodily control, the monotonous care, and how it was a reminder of their condition and mortality (**Level of Evidence 3**).

Catheter related embarrassment is a common experience stemming from exposure to the opposite sex, the visibility of the urine bag, and unpredictability of urine accidents [520] [521] [305]. Breeches in privacy were identified in two qualitative studies of the lived experience of catheter use [522]

[523] [305] [524]. To care providers, catheters may seem commonplace, but male / female sensitivities may occur during catheter care, particularly catheter changes, including men who are embarrassed by a female care provider [520]. Embarrassment can be minimized by providing privacy during catheter changes and same sex care providers when possible [522] [305] [523]. Acknowledging the embarrassment that exists if the nurse is of the opposite sex paradoxically may diminish the vulnerability [305]. Humour is often used by care providers, catheter users, and caregivers, and a professional approach by the health care provider may help the catheter user accept the situation [522] [305] [523] (**Level of Evidence 3**).

A few studies have examined QoL issues related to practical aspects of living with the catheter, such as managing the drainage bag (See Section VIII). While most people who are self-caring cope with the management of their catheter drainage system, many find them restrictive and report a negative impact on QoL. In a small pilot study based on a postal questionnaire to LTC catheter users (n=59) [525] almost 25% of respondents stated that wearing a bag had a major negative affect on everyday living. Concealment of the bag was one of the most important concerns raised (89%). Keeping the urine drainage bag covered and its visibility minimized can help reduce embarrassment and the stigma related to using a catheter. The visibility of the bag can be considered demeaning and it exemplifies a loss of bladder control [305] [523]. Moreover, if a bag is unreliable, and springs a leak for instance, it contributes to vulnerability. Even using a catheter for a short time can be an assault to one's dignity. In a study in post-operative short-term catheter use, people complained about feeling "on display" and objectified [522] (**Level of Evidence 3**).

c) Sexuality

In a study of experiences of 25 men with prostate cancer, many of whom were treated with a urinary catheter, subjects reported the catheter contributed to feelings of shame, excess hospital visits for complications, and with other treatments for cancer, an end to sexual activity [526]. Men viewed healthcare professionals as having responsibility for medical decisions and they alone felt responsible for the catheter, micturition, and sexual life (**Level of Evidence 3**).

Issues related to sexuality were dominant in several other studies. Using a catheter compounded changes in sexual life caused by illness or injury [521] [524]. In one study, catheter users complained that care providers did not provide enough information about sexuality and how to adapt to a catheter [524]. Despite some care provider's reluctance to address these issues, sexual health should be a part of assessments [527], and information about sexual activity should be provided proactively, while recognizing that some catheter users will wish to engage in sexual intercourse and others will not (**Level of Evidence 3-4**).

In a study of 20 men in Nigeria with prostate-related obstruction, who used an indwelling catheter from 1-36 months, [528], negative changes in self-esteem and sexuality (manhood) were reported. However, family and friends were instrumental in providing support and encouragement, including financial help and transportation to the hospital. The underlying disease may also impact on sexuality. For instance, a urinary catheter complicates sexual activity in people with spinal cord injury (SCI). Moreover, men may have changes in sexual performance related to ejaculation, erectile function, and arousal [529]. For females with SCI, experimenting with positions, lubrication, and preventing spasticity may be helpful in sexual activity [529] (Level of Evidence 2). For people with SCI, sex-related autonomic dysreflexia (AD) occurs most often in people who suffer from AD during bladder or bowel care [530] (Level of Evidence 2). Autonomic dysreflexia is an autonomic nervous system syndrome that occurs in people with spinal cord injury or disease. Symptoms include severe hypertension and excruciating headache as well as sweating and goosebumps. It can be a serious problem—even life-threatening--requiring emergency medical attention, yet it is sometimes ignored or disregarded by health care providers [516]. A blocked catheter is also a frequent cause of AD. In a qualitative study [524], several people complained that care providers did not know much about AD and often dismissed their anxiety and concerns (**Level of Evidence 3**).

Promoting sexual health for persons with catheters [531] requires awareness of self (especially in relation to sexuality), training for health care providers, open communication, and advocacy for and validation of patients'experiences.

d) Catheter-related Pain

Pain related to catheter use is not always recognized although anecdotal information suggests that many people find a urethral catheter uncomfortable (see also Section XII.2 k.3 on catheter comfort and catheter change procedures). In Saint et al's study [107] 90% of catheterised patients surveyed reported they found the indwelling catheter uncomfortable or painful, and in a study of 43 community dwelling persons [126] 54% reported catheter-associated pain, and in a sample of 20 men who used a catheter for prostate obstruction, 35% had pain [528]. Sometimes women complained about the pain because of sitting on the catheter or sores in the vaginal area [516], however it is unclear whether sores or skin irritation are related to latex sensitivity, friction, or wetness or a combination. Bladder spasms, CAUTIs, blockage, and dislodgement can all contribute to catheter-associated pain, as well as insertion and removal procedures [532] [523] [516]

(**Level of Evidence 3**). Pain arising from AD in SCI patients can result from catheter blockage and has been discussed above.

e) Adjustment to a Catheter

Adjusting to living with a catheter may take a considerable time. In Roe's study [533] participants reported it had taken them up to a year. Similar lengths of time are commonly reported in anecdotal evidence. An educational booklet for catheter wearers has been shown to significantly improve knowledge and acceptance of the catheter [534]. Though the implications for this type of intervention are positive (Level of Evidence 1-2), the sample was small (n=45) and the study has not been replicated. The core category identified in a study using a grounded theory approach to examine older people's experiences of living with a LTC was 'all about acceptance'. Two further categories defined as 'at ease' and 'unease' reflected the extremes of their experience and these were mediated by 'interaction with others' [535]. The presence of a catheter can affect the individual's view of their own body and such shifts in body image can cause some people to exclude themselves socially. New catheter users (both urethral and suprapubic) may resist the "intrusion of the catheter" prior to acknowledging the need for it [536]. Qualitative studies have shown that although some people felt ill prepared for a catheter, and even viewed it as distasteful, most learned to accept the device over time [536] [523]. Catheter-users have described their changed perceptions of the body and of how they learned to pay attention to urine flow to prevent catheter related problems. Though most acknowledged feeling vulnerable because of disruptions caused by the catheter, they noted also that keeping urine flowing was critical to their wellbeing [537] (Level of Evidence 3).

Health care providers need to provide proactive support and education about the catheter and its care, particularly since some catheter users are uncomfortable in asking for help or support. Male / female sensitivities can interfere; for example, a woman might be disinclined to talk about her catheter with her son [536] [523] (Level of Evidence 3).

Guiding and supporting an individual's adjustment to living with a catheter involves promoting dignity, supporting the changed body image so that the catheter becomes a part of self (and almost not noticed), and learning self-management and self-care, and in planning for active life in the community. It is essential that catheter users know how to select suitable equipment. Simple advice such as not using a coloured catheter in the summer when white clothing would allow it to show can be very helpful. Knowing where toilets are and planning for outings (rehearsing) can prevent urine accidents [516] (Level of Evidence 3). Ambulatory females who use a belly bag need to face the toilet when emptying the bag. Since this position is associated with male toileting rather than female it can sometimes cause embarrassment. Some women may prefer to use a unisex toilet where possible.

While adjustment takes time, emotional distress with the catheter can swing back into the picture at any time if problems develop. Depending on whether the device is working well or not, people can move back and forth between acceptance and estrangement from the catheter [305] when the problem in the background emerges and brings the issue once again to the foreground [538] (Level of Evidence 3). Learning to live with a catheter involves recognizing that the benefits can outweigh the problems [524], watching for signs of problems, and adjusting to the interpersonal and sexual changes [536] (Level of Evidence 3).

f) Self-management

Self-monitoring, a component of self-management, involves awareness of what to notice and related measurements or observations [539]. Self-monitoring urine flow was found to be helpful in preventing or minimizing catheter-related problems in a pilot study with 11 community-based individuals over a six months' time [306]. In this study, a 3-day urinary diary of intake and output was combined with an educational program, individualized to the interests of participants. Most participants said they learned to pay attention to urine flow, through observing continuous drainage into the drainage bag, increased awareness of the urine colour, position of the catheter, and by monitoring the consistency of their fluid intake [306]. Health care providers can help catheter users to learn to manage their catheter themselves, (i.e. self-care) by identifying where they are in the process of learning self-care and by working with them [536] (Level of Evidence 3).

g) Summary

Most published studies of patients with indwelling catheters have focussed on short-term catheters (< 14 days) in hospitalised patients and relatively few have compared different modes of catheterisation (urethral, suprapubic, intermittent). The main subject of research on catheter use has been the risk of catheter-associated infection and the surrogate outcome measure of bacteriuria (asymptomatic) is commonly employed. However, there are important questions over the appropriateness of this as an outcome measure. Although there is clear evidence to support a small proportion of catheter care procedures (indicated below) the majority of procedures are based on clinical experience and expert opinion. Long-term studies are difficult to carry out for a variety of reasons (not least the frailty of many long-term catheterised patients) and there are relatively fewer studies based on community dwelling patients. RCTs may not be the most appropriate or pragmatic design for these groups. Although there are now a number of Cochrane reviews relating to

long-term catheter use it is clear that the quality of studies available frequently precludes drawing robust conclusions.

The published literature on SPC use is still relatively small, with much of it based on single centre cohort or case studies, or on short-term post-operative care following surgical procedures (not necessarily related to lower urinary tract symptoms). The majority of reports on SPC for long-term bladder drainage focus on the management of neurogenic bladder. Robust conclusions are often difficult to reach given the relatively short follow-up time frame of many studies and the lack of precise definitions of key outcome measures such as measurement of infection. Overall the risks associated with short and long-term use of indwelling catheters are common to both urethral and SPC insertions, including CAUTI, tissue trauma, catheter encrustation leading to blockage, formation of bladder calculi and histological changes.

Quality of life measures, including evaluation of psychometrics, need to be developed further and tested in this population, which may have different needs than others with incontinence. Studies of incontinent people that include catheter users should present data in ways that give the reader information about this sub-population. Sensitivity and a proactive stance from care providers could prevent or minimize some of the stigmatizing effects of the catheter, including those related to privacy needs, dignity, and sexuality. Further product development may help catheter users attain a higher quality of life. Additional research on the effects of self-management/self-care may provide direction for teaching that could contribute to a higher quality of life for catheter users.

4. OVERALL RECOMMENDATIONS RELATING TO CATHETERS

a) Intermittent catheters

- Clean intermittent catheterisation (CIC) is a treatment of choice for those with ongoing bladder emptying problems and residual urine > 100ml who are able to manage the technique (**Grade of Recommendation A**).
- CIC technique can be taught to all ages of people with appropriate motivation and manual dexterity (or to a carer where this is acceptable to both parties). Appropriate education and ongoing support is needed (**Grade of Recommendation C/D**).
- Frequency of catheterisation needs to be based on individual need, to prevent over-filling of bladder (**Grade of Recommendation C**).
- An external lubricant or lubricant-coated catheter is recommended to minimise urethral trauma (**Grade of Recommendation C**).
- CIC users may benefit from access to different catheters or catheter-packs for different purposes (eg ease of use may be particular important when at work or in public) (**Grade of Recommendation C**)

b) Indwelling catheters

- Indwelling catheters should only be used after alternative management strategies have been considered and rejected as unsatisfactory (**Grade of Recommendation A**).
- Duration of catheterisation should be minimal (**Grade of Recommendation A**).
- A closed drainage system should be maintained to reduce risk of catheter-associated infection (**Grade of Recommendation A**).
- Asymptomatic bacteriuria should NOT be treated with antibiotics (unless urological instrumentation is planned) (**Grade of Recommendation B**).
- Routine urine culture in an asymptomatic patient is not recommended (**Grade of Recommendation C**).
- Silver-alloy catheters should be considered for short-term catheterised patients to reduce the risk of catheter-associated infection (**Grade of Recommendation A)** but further economic evaluations are required to determine cost-benefit to institutions.
- Catheter materials designed for long-term use (all-silicone, silicone or hydrogel-coating) should be used where a catheter is expected to be used long-term (i.e. >14days) (**Grade of Recommendation B**).
- Meatal cleansing with plain soap and water (not with antimicrobial agents) is recommended (**Grade of Recommendation A**).
- Addition of disinfectants to drainage bags, bladder irrigation and antibiotic prophylaxis are NOT recommended as routine infection-control measure (**Grade of Recommendation A**).
- If an indwelling catheter is being considered, SPC should be considered alongside UC, following appropriate risk assessment (**Grade of Recommendation B**).
- UC and SPC insertion should be carried out only by appropriately trained and skilled practitioners using aseptic technique (**Grade of Recommendation C**).
- UC and SPC catheters and drainage bags should be adequately supported to prevent meatal or cystostomy damage from traction (**Grade of Recommendation C**).

- In patients with recurrent catheter encrustation and blockage, careful monitoring should be undertaken to identify a characteristic pattern of 'catheter life' and instigate pre-emptive catheter changes prior to likely blockage (**Grade of Recommendation C**).

c) Catheter valves

- A catheter valve can provide an effective means of catheter drainage following appropriate patient assessment (**Grade of Recommendation B**).
- A combination of a valve during the day and free drainage at night through an open valve connected to a drainage bag could be an appropriate management strategy (**Grade of Recommendation D).**

5. PRIORITIES FOR RESEARCH

a) General

- Despite much published research (primarily on short-term catheter use in acute care settings), catheter studies have been hampered by methodological weaknesses. There is a need for agreement on key criteria to permit robust comparisons between studies: (i) criteria for symptomatic UTI, (ii) significant bacteriuria in a catheterised patient and its clinical/research usefulness (iii) standardised time frames for following patients in studies of catheter-associated infection eg 48h, 5 days, 7 days, 14 days 21 days etc (iv) documentation of the use of antibiotics prior to and during a study eg preoperatively in surgery or commencement of antibiotics for other conditions during the study, (v) patient follow-up to include post catheter removal.
- A standardised definition of UTI should be adopted as the primary outcome variable. At present the most recent CDC/NHSN surveillance definition of health care-associated UTI is an example [379]. Although criteria for both symptomatic UTI and asymptomatic bacteriuria are defined by the CDC/NHSN, it should be recognised that definitions are applicable to non-catheterised populations and specific to acute care settings and additional definitions apply to catheterized patients [342].
- Moreover, definitions which distinguish between asymptomatic and symptomatic infection in catheterized patients can be prone to coding errors. Inappropriately treated asymptomatic bacteriuria confounds the errors [540] and contributes to a lack in knowledge of effective ways to treat symptomatic CAUTI [541].
- Better adherence to CONSORT guidelines [542] eg double blind randomization with appropriate power calculations, intention to treat analysis with inclusion of study drop-outs
- Need for clinical studies which are adequately powered to detect differences in clinically and economically important endpoints in preference to (or in addition to) more easily measured surrogate endpoints such as bacteriuria.
- Comparative studies of different patient groups eg. males and females, different age groups, patients at home and those in institutional care, including patients' comfort, satisfaction and quality of life measures.
- Further research on the development of biomaterials that resist microbial adherence and biofilm formation and /or prevent catheter-associated bacteriuria in both long-term and short-term catheter users.
- Further efforts aimed at reduction of short and LTC use, particularly acute care and nursing home populations. Targeted areas to include evaluation and management of skin problems, and alternative measures for people with diabetes mellitus, obesity and communication problems.

b) Intermittent catheters

There is lack of evidence demonstrating the effectiveness of any particular catheter type, technique or strategy. Variations in clinical practice and growth in the use of single-use catheters (particularly coated catheters) with associated increased costs mean that large, well-designed, parallel group RCTs are needed. RCTs are difficult to conduct in this area and must focus on the most important pragmatic questions, for both clinical and cost-effective reasons. Key issues are identified below.

- What evidence is there that coated (single-use) catheters are superior to uncoated (multi-use) catheters and in what ways (e.g infection, comfort, convenience)? Further studies are needed on the risks / benefits of single use catheterisation (new catheter used at each insertion) versus single patient use (patient cleans, stores and re-uses the same catheter for several days) for patients whose long-term bladder management is by CIC.
- To assist assessment of cost-effectiveness, it is recommended that patient acceptability / satisfaction with procedure and a measure of health state utility are measured for different situations (e.g. at home and when away from home) as a secondary outcome variable.

c) Indwelling catheters

- Epidemiological studies of CAUTI in LTC use in community care settings.
- Better prospective data on long-term sequalae of indwelling catheter use, eg ongoing symptoms, strictures, calculi, bladder cancer.

- Studies comparing catheterisation techniques eg CIC, suprapubic and urethral catheters, on CAUTI and other risks or potential benefits
- Studies to determine whether the frequency of regular re-catheterisation make a difference to CAUTI and other complications
- Studies to ascertain if there are detrimental effects on bladder tissue from persistent asymptomatic bacteriuria in long-term catheterised patients.
- Clinical evaluation of strategies to reduce recurrent catheter encrustation and blockage, including maintaining a dilute urine, increased level of urinary citrate, role of acidic 'catheter maintenance' solutions.
- Further development of catheter materials resistant to microbial biofilm formation, new approaches to disruption of the biofilm, or alternatives to catheterisation.

d) Catheter valves

- Clinical investigation of effect of catheter valves on incidence and frequency of catheter encrustation and blockage.
- Cost-effectiveness studies of disposable versus re-useable valves.
- Studies designed to demonstrate if catheter valves promote maintenance of bladder tone and capacity.
- Further examination of combination management strategies such as valve during the day and free drainage overnight.

e) Quality of life

- Identification of appropriate quality of life indicators/ criteria and measures for catheterised patients.
- Development of a quality of life measurement instrument including both subjective measures and objective measures, including factors such as: frequency of catheter blockage, catheter-associated infection, hospitalization, unplanned catheter changes, adequacy of equipment, knowledge about self care, interaction with caregivers in catheter management.
- Case study analyses to maximise evidence gained through clinical experience and expert opinion, particularly where opportunities for formal research are likely to be unrealistic.

XIII. PRODUCTS FOR PREVENTING OR CONTAINING FAECAL INCONTINENCE

The broader issues of conservative management of faecal incontinence are dealt with comprehensively in chapter 16 while this chapter deals with products for preventing or managing faecal incontinence. They fall into three main categories:

- Products that aim either to prevent or contain leaked stool.
- Products that seek to prevent or mask the offensive odour that occurs from leaked stool or flatus.
- Products for preventing or treating perianal skin damage associated with faecal incontinence (one of the primary complications of faecal incontinence and an important part of care).

Products dealing with skin health and odour are covered in Sections XIV and XV, respectively, while products for preventing or containing faecal incontinence are covered in this section (apart from absorbent pads, which are included in Section VI).

1. PRODUCTS TO PREVENT OR CONTAIN LEAKED STOOL

There is little knowledge about product management for people suffering with faecal incontinence. Peden-McAlpine et al. (2008) [543] show in their study the experiences of ten women with faecal incontinence. They show how a number of strategies, such as: bathroom rituals, eating habits or fiber supplements belong to the management strategies of the affected, so that they may actively participate in a normal public life. The use of aids is also a major strategy as Bliss et al. (2011) [544] also show. More than 1/3 of those questioned (189 participants) would no longer pursue their activities, when they had no aids at their disposal. Thereby, those who suffer seriously with faecal incontinence resort to absorbent aids, particularly to pantiliners from the range of feminine hygiene products. First and foremost of importance for the study participants was odour control, however, when asked about their satisfaction with various aspects of the product, they ranked odour control as the worst.

Products fall into three groups:

- Plugs to prevent leakage of faeces.
- Devices to channel faeces from the rectum into a storage container.
- Absorbent pads to contain leaked faeces (see Section 6).

An anal plug (**Figure XIII-1**) consists of a foam, cup-shaped plug that is collapsed and held by a film for insertion; the plug opens when the film comes in contact with the moist rectal mucosa [545] [546]. It is inserted like a suppository using a lubricant gel. It has a string for removal or it can be expelled by raising intra-abdominal pressure and pushing like during normal defaecation. The anal plug has been used mainly by community living people, both adults and children, who are independent in managing faecal incontinence and toileting. Another type

of experimental anal plug consists of a balloon at the end of a catheter connected to a notification device. The catheter is intended to be inserted into the rectum by the user and the inflated balloon acts as the anal plug; there are also vent holes on the distal tip of the catheter (**Figure XIII-2**). The disposable, double lumen, balloon-cuffed rubber catheter has an infra-red photo-interrupter sensor that is connected to a pager [547]. When faeces enter the rectum, a photosensor signal is sent to the pager which then notifies the person to inflate the balloon. Before a bowel movement, the balloon is deflated and the catheter is withdrawn. To prevent ischemic bowel damage, patients are advised to deflate the balloon for 10-15 min every 3-4 hours.

a: infrared photo-interrupter sensor and flatus vent holes incorporated into the catheter
b: 20 cc air cuff (similar to a regular bladder catheter)
c: flatus venting charcoal filter
d: cuff fill valve
e: monitor connector
f: monitor that resembles a "beeper" or pager

By contrast, devices for channelling faeces from the rectum to a storage container are used primarily by people who are acutely ill, critically ill, confined to bed, or in long-term care institutions and receive assistance in incontinence management and toileting by caregivers [548] [549] [550] [551] [552]. These devices do not prevent faecal incontinence and are used primarily for preventing or treating skin damage associated with faecal incontinence. They include rectal tubes, catheters, trumpets, and pouches.

Rectal tubes and catheters are inserted into the rectum and drain faeces through openings at their proximal end into a collection bag (**Figure XIII-3**). Sometimes a balloon slightly distal to the proximal tip is inflated with the aim of preventing leakage of faeces around the catheter and to retard inadvertent expulsion of the tube during defaecation [549]. This arrangement works best with liquid stool which is most likely to be able to flow without blocking the drainage lumen [553] [552]. Bowel management programs often include daily saline irrigations through the rectal catheter to maintain liquid consistency of stool and catheter patency. Differing amounts and frequency of irrigation have been reported (300 to 900 ml). Cutting the tip of the catheter off at an angle to facilitate drainage of stool of thicker consistency has been reported [554]. A rectal tube / catheter is contraindicated in patients who have intestinal mucosal disease, immunosuppression, gastrointestinal bleeding or bleeding tendencies, recent myocardial infarction or prostate surgery [555] [554]. Use of a rectal tube with or without inflating the balloon is controversial because of concerns of perforating the rectum, damaging the anal sphincter or rectal mucosa, stimulating intestinal secretion worsening diarrhoea and thus incontinence [553] [554] [556]. Critically ill patients, who often receive a rectal tube, may be at greater risk for intestinal ischemia and rectal damage because they experience shunting of blood from the gastrointestinal tract during shock or low perfusion states.

A rectal trumpet is a nasopharyngeal airway that is inserted into the rectum and connected to a collection bag at its distal end. The flange end of the trumpet is inserted into the rectum [557] (**Figure XIII-4**). A possible advantage of the rectal trumpet over a rectal tube is that it is shorter and has less contact with the rectal mucosa, so limiting the area of possible damage. Other limitations are similar to those for the rectal tube / catheter regarding risk of expulsion from forceful valsalva movements and dislodging during linen changes or from tugging on the collection bag [557]. Nasopharyngeal airways that can be used as a rectal trumpet are produced by several manufacturers.

An external anal pouch consists of a pliable wafer, which has an opening at its centre, an adhesive on the body side, and a collection bag on the other. The wafer adheres to the perianal skin (**Figure XIII-5**).

Figure XIII-3: Rectal catheters; Flexiseal Fecal Management System, Convatec (Nordic Capital Fund VII and Avista Capital Partners); Princeton, NJ (top); and Zassi Bowel Management System, Hollister, Inc. Libertyville, IL (bottom).

Figure XIII-4: A rectal trumpet.

The bag has a resealable port at its distal end through which faeces can be drained without the need to remove the wafer from the skin. The port can also be connected to a larger, gravity drainage bag. Some pouches have a small folded flap that allows flatus to escape so that it doesn't inflate and rupture the bag. The pouch avoids the risks of rectal or sphincter damage associated with the rectal tube or trumpet. If used without the additional drainage bag, it can collect leaked stool of any consistency without clogging. A limitation of the rectal pouch is difficulty in applying it on people who have a small space or severe oedema between the anus and vagina or scrotum. Other reported disadvantages include difficulties in maintaining the seal (especially when the perianal skin is already damaged); break of the seal when repositioning the patient; and skin tears by traumatic removal of the adhesive [557] [551].

An intra-anal stool bag is composed of a latex bag (20cm non-extended, to 26cm extended) that is inserted into the anus and an adhesive attachment (10 cm in diameter) applied perianally [558] (**Figure XIII-6**). There is a cut-out on the ventral urinary side of the adhesive wafer.

Aspects of patient assessment that are relevant to products to prevent or contain leaked stool include the following: a) physical characteristics (e.g. some anal plugs may be too large to fit smaller sized children), b) dexterity (e.g. some degree is needed to insert or remove an anal plug), c) mobility (e.g. rectal catheters are mainly used for patients who are in bed versus ambulatory), d) nature of incontinence (e.g. bowel catheters will require irrigation when stool consistency is not loose or liquid in order to remain patent; and e) personal priority and lifestyle (e.g., some persons will wear an anal plug on certain occasions such as when swimming, despite discomfort).

2. QUALITY OF DATA

Since the previous review there have been two observational studies in which the anal plug has been evaluated. One study was of adults [559] and

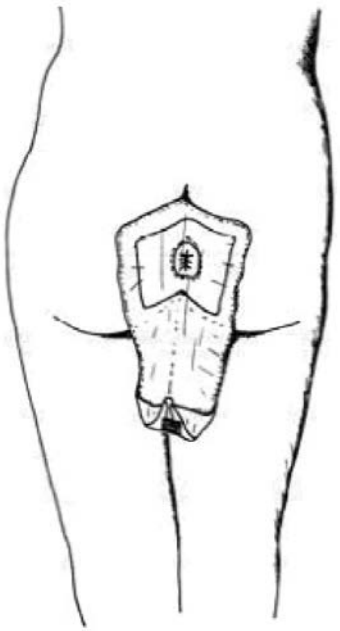

Figure XIII-5: An anal pouch.

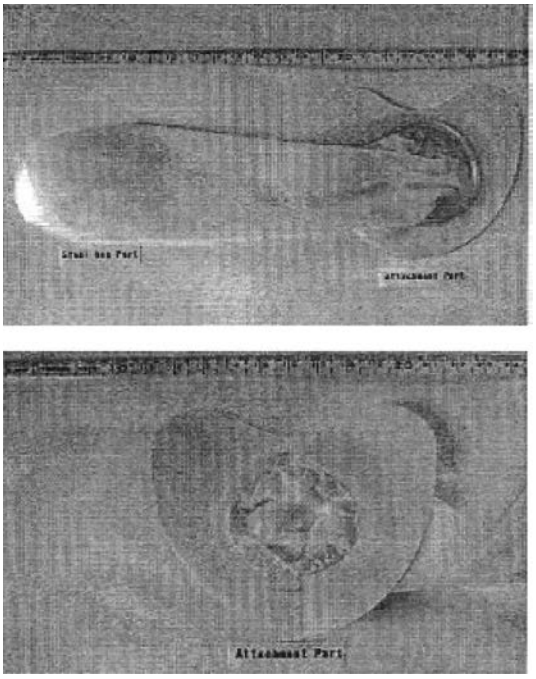

Figure XIII-6: Interanal stool bag (left) and Outer attachment wafer of Interanal stool bag (right). (Reproduced with the permission of Wiley- Blackwell Publishing)

the other of children [560] bringing the total number of published evaluations of anal plugs for controlling faecal incontinence to ten. There was one study of the anal catheter plug (Procon, AnaTech, El Paso, TX). Six reports included children of which two studied children exclusively [561] [562]. The study designs were one randomized clinical trial, four repeated measures (cross-over), one pre-post design, two prospective cohort studies, one cross-sectional survey, one case series, and one case report. One study did not specify the manufacturer of the anal plug studied [560], one study [561] compared plugs of two manufacturers (Coloplast, Denmark and Med.SSE-System, Germany) and all other studies of anal plugs evaluated products from the same manufacturer (Coloplast). There has also been one published evaluation of a rectal trumpet using a case series design [557] and one each of an external anal pouch and an intra-anal stool bag in which no comparison group or pre-post measures were included.

3. RESULTS

a) Anal Plugs

Most evaluations of anal plugs have involved relatively small cohorts of ambulatory subjects. The largest sample had 48 subjects and 26 of 31 persons in the intervention group who wore the anal plug completed the study [563]. The aetiologies of faecal incontinence varied across studies and included spina bifida, imperforate anus, spinal injury, post-surgical incontinence, sphincteric injury, and obstetric trauma. Faecal incontinence was measured by self-report using a daily stool diary in six studies [563] [562] [547] [545] [546] [564]. A questionnaire /survey was used in one descriptive [565] and one repeated measures study [561]. The main reported outcome measures were: the number of episodes of faecal incontinence per number of anal plugs used due to self removal or need for defecation [545]; the number of patients experiencing no faecal incontinence [564] [562] [561] [546] [560] or improved faecal incontinence [546] while using the plug; score on a 10-point visual analogue scale for control of faecal leakage, [559]; the number of patients able to retain 150 ml of viscous fluid while using the plug [564]; and the change in a faecal incontinence severity score [563] [547]. The percentage of participants lost to follow-up ranged from 10% [545] to 80% [564].

The effectiveness of the plug in preventing faecal incontinence in adults ranged from 83% [564] to 38% [562] (Level of Evidence 3). Bond et al [563] conducted a randomized clinical trial of the effectiveness of an anal plug that included 31 adults and children with spina bifida in the treatment group and 17 adults and children in a control group; 84% of the treatment group and 100% of the control group completed 12 months of follow-up. There was no statistical difference in the faecal incontinence severity score between the group wearing an anal plug and the one that did not; however, the study was determined to be underpowered to detect differences. Norton and Kamm [546] compared two anal plugs for two weeks each in random order in a cross-over design. Of the 20 adults (16 female) participating, 10 (50%) were continent, and 9 (45%) withdrew after trying the first plug. Three anal plugs were compared by 10 adults for one week each in a cross-over design in an earlier study by Mortensen and Humphreys [545]. Continence was achieved in 83% of anal plug uses overall. Faecal incontinence occurred in 18%, 19% and 15% of uses when Plug 1, 2 or 3 were worn, respectively. Only one subject withdrew from the study. In a pre-post comparison of an anal catheter plug, seven of 18 adults (39%) with various aetiologies of faecal incontinence and a Cleveland Clinic FI severity score >7 completed a 14-day wear period [547]. The mean (standard deviation (sd)) faecal incontinence score during wear of the anal plug (5.2 (3.0)) was less than half that before its use (12.7 (3.6)). Thirty middle-aged patients (aged 63 (52-70) years (mean (range)) with intractable FI of various aetiologies tested the anal plug for three weeks; the score for control of faecal leakage on a visual analogue scale (1= very poor to 10= extremely good) was 9 (median) after 1 and 3 weeks of using the plug [559]. Christiansen & Roed-Petersen [564] reported that 86% of persons were able to retain 150 ml of viscous fluid while an anal plug was inserted.

In the study of children only, 38 children (ages six to 15 years) after anorectal malformation repair compared two anal plugs (one made of polyurethane and one of polyvinyl alcohol) for three weeks each in random order in a cross-over design. Approximately two-thirds (61%) completed the study. Twelve children (32%) were completely continent using either plug and five (13%) reported "total failure." Two or fewer soiling accidents occurred in 74% using the polyurethane plug, and in 65% using the polyvinyl alcohol plug [561].

In a study of 20 children and adults with spina bifida, average age 12 years (range = 4-29 years), the weekly number of episodes of FI soiling decreased from 4 (0-28) to 0 (0-8) (median (range)) after using the anal plug [560].A survey of adults and children showed that a higher percentage of children tolerated using an anal plug over a longer period of time [565]. Five of eight (63%) adult survey respondents who had faecal incontinence of various aetiologies stopped using an anal plug immediately while three used it periodically for 12 to 20 months. Two of seven child respondents stopped anal plug use immediately while five (71%) used it weekly for an average of 2.5 years.

The most common reported problems associated with wearing an anal plug included discomfort and failure to retain the plug. Despite efficacy, approximately two-thirds of the subjects in two studies [564] [546] said they would not continue to wear the plug due to discomfort. Discomfort occurred in 10% to 12% of the times that one of the three anal plugs were worn in another study [545]. In more recent studies, 23% and 33% of subjects reported discomfort [563] [560]and 23-25% withdrewfrom studies because of pain [562] or discomfort[560]. More men than women withdrew from one study because of discomfort [559]. Adults who experience discomfort do not seem to adapt over time [559]. After three weeks of wear, adults reported a score on a ten-point visual analogue scale for comfort while inserting the anal plug was 7 (5-9) and while removing it was 8 (7-10) (median (range)). There was no association between comfort of the plug and anorectal sensitivity during anal-rectal physiology tests in adults [546]. Children seem to experience less discomfort than adults while wearing the anal plug. [561] [559]. Approximately 20% of children reported that insertion of the polyvinyl alcohol plug was painful while 17% found removal of the polyurethane plug to be painful; one child experienced bleeding on removal of this second plug. Rectal bleeding also occurred in adults but infrequently [545].

Failure to retain the anal plug was reported by 13% of subjects in two studies [563] [562] and was noted by one child in the paediatric study as a reason for withdrawal [561]. The size of any plug tested was too large for six children in one study [561]. Twenty-seven of 30 adult subjects preferred a small size anal plug [559]. Other tolerance problems were fairly uncommon. In one study, adults rated all three anal plugs that were evaluated as relatively easy to insert. Two plugs were difficult to remove in only 5% and 6% of uses, respectively, while the third was difficult to remove in 23% of uses [545]. Other reported problems were feeling a need to defecate [546], inconvenience or difficulty in managing [546] [547], and local irritation [565].

b) Rectal Trumpet

One case series study evaluated the use of a rectal trumpet in 22 acutely or critically ill patients with faecal incontinence and perineal skin damage [557]. For 90% of the subjects, the skin damage had been caused by wearing a rectal pouch immediately prior to the study. Subjects used the trumpet for periods varying between 36 hours and 16 days (mean 6.5 days; sd 4.4 days). The reasons for any discontinuation of use were reported. Outcome was determined using a daily questionnaire completed by patients' nurses and the health of the perianal skin was noted by subjective assessment. No standardised definitions or criteria for restoration of skin integrity or healing of skin damage were reported. Two subjects were lost to follow up. Faeces were successfully diverted to and contained by the collection bag in all patients. Recovery from skin damage was reported in 7 (39%) patients and partial healing of skin in the remaining 11 (61%). Discomfort on insertion was noted for 41% of subjects (Level of Evidence 3).

c) Rectal Catheter Systems

Closed rectal catheter and collection bag systems specifically designed for extended use and diversion of faeces are commercially available, primarily for acutely-ill or bed-ridden patients (Flexi-Seal™ and Flexi-Seal™ Signal™ Faecal Management System, Convatec A Bristol Myers Squibb Company; Princeton, NJ; Actiflo Indwellling Bowel Catheter (formerly Zassi® Bowel Management System); Hollister, Inc., Libertyville, IL; Dignicare® and Dignishield™ Stool Management Systems, Bard Medical). The catheters of these systems typically contain a retention cuff that collapses to assist with insertion (US FDA approved for up to 29 days) and a port for irrigation. In one system (Acti-flo) there is also a collapsible zone below the cuff that resides in the anus to allow normal anal sphincter function during use and a second port for sampling intestinal fluid. A third catheter has an inner balloon that can be inflated to serve as an anal plug to promote retention of an enema, for instance (Kim, US Patent 5 569 216, apparently not currently commercially available).

Six studies evaluated use of a rectal catheter system. Three studies used one type of catheter while the other three studies used three different types of systems. One study was of children [566]. The designs included a prospective single cohort in four studies [548] [567] [549] [566], a pre-post descriptive design[568], and a retrospective case-matched

pre-post design [569]. The largest sample size was 106 in the retrospective chart review whereas sample sizes in the prospective studies were relatively small, ranging from 20 to 42 subjects. In the studies of adults, subjects were burn patients in two studies [567] [569] and acutely or critically-ill patients in three studies [548] [568] [549]. In three studies, irrigation of the catheter with saline, a combination of lactulose and saline irrigation or use of an enema was used to keep the stool liquid and the rectal catheter patent [567] [569] [549].

In only two studies was the effectiveness of the rectal catheter system in reducing faecal incontinence reported (Level of Evidence 3). In the one paediatric study, 31 children (11 females) participated. Eight families refused to stop using the rectal catheter to complete an incontinence diary without use of a catheter. Two children had balloon extrusions and three were noncompliant resulting in their study withdrawal. The mean number of daily faecal incontinence episodes as reported on a daily diary decreased from 3 to 1.5 in males and from 1.6 to 1.1 in females ($p<0.05$ for both) [566]. Three children experienced no improvement of faecal incontinence. In the one adult study, 39 of 42 subjects (62% female) with diarrhoea in intensive care units in seven hospitals completed the study. There was up to 29 days of follow-up. Varying degrees and types of leakage around the rectal catheter were reported in 71% of 198 assessments; 35% of these leakages extended to pads on the bed or beyond [548]. Seven (17%) of subjects had difficulty retaining the rectal catheter. Section 6.11 discusses use of a small gauze dressing for absorbing small amounts of stool leakage and a moisture barrier as skin protective strategies that might also help prevent damage from stool leakage around a rectal catheter. Skin damage from the tape holding the catheter in place and rectal bleeding are other reported but uncommon complications [567] [548].

The effect of a rectal catheter on various outcomes associated with stool leakage has also been studied. Two studies reported costs savings in terms of reducing laundering of soiled bed linens. One study reported that the number of bed linen changes in burn patients with diarrhoea decreased eight-fold and dressing changes in hospitalized or burn patients decreased in half after a bowel system was introduced [567]. A multi-site study of 146 bedridden patients in the U.S. showed that one catheter (Hollister, Inc) reduced the rate of bed linen changes (1.2 changes per day) more than another (1.7 per day) (Convatec). Estimates of cost savings based on staff time and laundry costs was almost $14 USD per patient per day [570].

Other outcome measures of rectal catheter use included urinary tract infections, incidence of skin / soft tissue damage or infections, prevalence of pressure ulcers, and number of linen changes (Level of Evidence 3/4). In a retrospective review of medical records, approximately twice as many burn patients had skin / soft tissue or urinary tract infections before a bowel catheter system was introduced than after ($p<0.01$) [569]. A prospective study of acutely and critically-ill patients showed that 41% who had normal skin in the perineum or buttocks at baseline maintained normal skin during use of the bowel catheter, 44% with some degree of skin damage improved, and 8% had worsened skin condition [548]. The percentage of intensive care unit patients with a stage II or greater pressure ulcer was observed to be less at nine months after use of a bowel catheter was introduced. The total number of patients observed was not reported. The length of time during which the prevalence of pressure ulcers was determined prior to catheter use was also not reported [568].

The condition of the rectal mucosa was observed endoscopically in 40 patients total across three studies; the evaluations were not blinded or independent and did not use a rating scale [548] [567] [549]. All endoscopic observations were reported as being normal after rectal catheter use. Few complications associated with use of the rectal catheter system were reported in one study. Leakage around the rectal catheter seemed to be the most frequent problem. Catheter expulsion occurred in a small number of patients and skin damage from trying to secure the tube occurred only in one patient. Altered rectal sphincter function occurred using one of the catheters [549]. As the catheters are used more widely in clinical practice, there are more case reports of complications including rectal or lower gastrointestinal bleeding and need for blood replacement, mucosal pressure necrosis, fistula, and autonomic dysreflexia [571] [572] [573] MAUDE http://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfmaude/search.cfm. (Level of Evidence 3).

d) Anal Pouch

One case series study evaluated the use of an external anal pouch (Technoline, Concordia, Moderna, Italy) in 120 nursing home or hospitalized patients (65 men, 55 women, ages 45-96 years) [574]. The nursing home residents (n = 92) were bedridden and had faecal and urinary incontinence or were treated for constipation for rectal enemas that drained into the pouch. Ten had a pressure ulcer. They used the pouch for four weeks or more. Acute care patients (n = 28, of which 10 were in the intensive care unit) had diarrhoea and were temporarily bedridden. Forty-five patients who had surgery of the perineal area received a pouch to collect post-surgical drainage for up to three days. In the nursing home residents free of pressure ulcers, no new ulcers developed. In those with a pressure ulcer, healing occurred in five residents, ulcer diameter was reduced by 50% in three residents, and there was less than 50% reduction in two residents. Of the nursing home and acute

care participants, 77% found the pouch comfortable and 75% thought it was better than a sanitary napkin. Seventy-seven percent of the nurses thought the anal pouch was easy to apply and 78% thought is easy to remove. Reported complications included moderate pain on removal in 18 (15%) patients in the nursing home or acute care (Level of Evidence 3).

An internal anal stool bag (Terumo Corp., Tokyo, Japan) was applied to five bedridden patients (3 female, 2 male) aged 68-90 years [558]. Persons were administered a biscodyl suppository prior to insertion of the stool bag into the anus to control excretion of faeces. The bag was successful in collecting stool 50% of the time (Level of Evidence 3). The bag was removed after each stool was collected.

Bliss and Savik (2008) [88] carried out a study, to examine the use of a surgical dressing to absorb a small leak of feces. These anorectal dressings can be placed between the buttocks. Of 28 people who had faecal incontinence, 27 had used the dressing and 23 of them wanted to continue to use it. 79% reported no skin complications, and 80% of the participants rated their confidence in its effectiveness as very good to good. Use of the dressing lessened anxiety about faecal soiling in 81% and was thought to improve quality of life in 76%. The authors stated that new types of absorbent products will become available.

4. SUMMARY

- An anal plug can successfully prevent faecal incontinence but it is associated with high levels of discomfort, more so in adults than children (Level of Evidence 3).
- A rectal catheter system diverts faeces to a collection bag and promotes healing of damaged perineal skin but requires liquid stool consistency to remain patent. Some catheter systems enable irrigation of the rectum to maintain liquid stool consistency.
- Non-blinded and non-independent endoscopic observations suggest the rectal catheter does not cause rectal mucosal damage during the recommended length of use (≤ 29 d in the US). As rectal catheter usage increases in clinical practice, case reports of complications have become evident; among the common ones reported are perianal skin damage, rectal bleeding, and mucosal pressure necrosis. (Level of Evidence 3).
- A rectal trumpet can successfully channel faeces to a collection bag and there is some evidence that it can thereby enable damaged perianal skin to recover but it has been associated with discomfort and its safety has not been determined (Level of Evidence 3).
- An external anal pouch and an internal anal bag can be used to collect stool (Level of Evidence 3) but the adhesive wafers used to adhere them can cause skin damage upon removal. The internal anal bag has been primarily used when a bowel movement is induced using a suppository.

5. RECOMMENDATIONS

- Anal plugs may be tried but many patients are likely to use them on a limited basis or reject them due to discomfort (Grade of Recommendation C).
- The use of a rectal trumpet (i.e. a nasopharyngel tube inserted into the rectum) in patients with loose / liquid stool consistency offers an alternative to the rectal pouch when pouch adherence is a problem and may preserve perianal skin integrity or facilitate healing (Grade of Recommendation C). The safety of the rectal trumpet has not been determined, but it suggests a lower risk due to its shorter length than a standard, longer rectal tube (Grade of Recommendation C).
- Use of a standard rectal tube with and without an inflatable balloon for faecal diversion is indicated primarily for non-ambulatory patients with liquid stools (Grade of Recommendation C).
- Use of an anal pouch attached to a drainage catheter to divert liquid stool is recommended, but there is a risk of skin damage. For this reason it is not recommended in cases where skin is already damaged or the need for faecal diversion is less acute (e.g. where stool is more formed) (Grade of Recommendation C).

6. PRIORITIES FOR RESEARCH

- Development of an anal plug that is more comfortable and tolerable.
- More rigorous evaluation of anal plugs using larger subject cohorts and more objective outcome measures over longer periods of use.
- More rigorous evaluation of rectal tubes / catheters and trumpets using larger subject cohorts and more objective outcome measures (e.g. for assessing health of the rectal mucosa) over longer periods of use.
- Development and evaluation of an external anal pouch that is easy to apply and remove, adheres to skin better and, perhaps, even promotes healing of damaged skin to which it would be applied. Further evaluation of an internal stool bag with similar adherent properties (as recommended for the external anal pouch) is needed.

XIV. SKIN HEALTH AND CONTINENCE PRODUCTS

1. BACKGROUND

The skin of an incontinent individual will be regularly exposed to contact with urine and / or fae-

ces and damage to the skin is the main physical health consequence of urinary and faecal incontinence. The majority of current knowledge about the effects of urine and faeces on skin has been obtained from studies with pads or pad materials on animals, healthy infants, and on body areas such as the forearm or back of adults. Where clinical trials have been conducted, they have usually been on infants and rarely on adults using pads. Skin irritation within the pad occlusion area is usually termed diaper dermatitis in infants. In adults the term perineal dermatitis (PD) has commonly been used, but more recently it has been proposed that incontinence-associated dermatitis (IAD) is a better term because affected skin areas are not confined to the perineum [575] [576]. A consensus panel in 2005 defined IAD as 'erythema and oedema of the surface of the skin, sometimes accompanied by bullae with serous exudate, erosion, or secondary cutaneous infection [577] and this term and definition has been widely used since then [578] [575] [579]. More recently IAD has been classed as a sub-category of 'moisture-associated skin damage' (MASD) which includes intertriginous dermatitis and peristomal and periwound moisture-associated dermatitis [579] [580].

Literature reviews and consensus papers

There has been considerable interest in IAD over the last few years, particularly with regard to its definition and aetiology and there have been three review/consensus papers on the subject [578] [575] [579] and one focusing on the prevention and treatment of IAD [581].

a) The role of urine and faeces in skin irritation

Prolonged exposure to water alone has been shown to cause hydration dermatitis [582] [583] and prolonged occlusion of the skin (as within a continence product) has been demonstrated to reduce skin barrier function [584] and significantly raise microbial counts and pH [585] [586]. Repeated wetting and drying makes the skin more vulnerable to substances that are usually innocuous, e.g., bile salts [587] [588]. A product that simply maintains wet and occluded skin (even without the additional constituents of urine and faeces) is therefore likely to cause skin irritation and increase skin permeability to other irritants.

Using a hairless mouse model Buckingham and Berg [589] examined the role of faeces in the aetiology of diaper dermatitis. They identified proteases and lipases as the major irritants and noted that these faecal enzymes not only irritated the skin directly but also increased the susceptibility of the skin to other irritants such as bile salts. The irritant effect of faeces was virtually eliminated by heating, which destroys enzymes, and was restored by the replacement of specific enzymes [e.g. lipase and protease). Skin damage appeared dependent on the concentration and length of exposure to enzymes in faeces [590].

A similar mouse model was used by the same researchers to examine the role of urine in the aetiology of diaper dermatitis [588]. They found that the irritant potential of urine by itself was minimal over short periods (48 hours) but after continuous exposure (10 days), skin damage became apparent. The researchers also measured skin permeability and found that continuous exposure to urine greatly increased skin permeability (more than 15 fold) compared to occluded skin or skin exposed only to water.

However, the combination of urine and faeces caused significantly higher levels of irritation than urine or faeces alone. The authors concluded that the presence of faecal urease results in the break down of urinary urea causing an increase in pH, which increases the activities of faecal proteases and lipases leading to skin irritation. The role of microorganisms - which comprise approximately 50% of the solid component of faeces - in skin damage is unresolved. Microorganisms on the skin of infants with and without diaper dermatitis were similar [591]. Zimmerer [592] sampled the microflora of the skin after pre-loading with pre-wetted patches containing urine and found that the microbial counts were significantly higher for wet patches relative to the dry patch controls. It was nearly impossible to establish infection with the opportunistic organism, Candida albicans, on normal skin without complete occlusion of the site [593]. Therefore, it is thought that bacterial or fungal infection is secondary to alterations in the skin barrier that allow penetration of the microorganisms [594].

Zimmerer et al. [592] examined the role of skin wetness in the development of diaper dermatitis by using the volar forearms of adult volunteers. They aimed to determine the effects of wet and dry diaper materials on skin health with respect to friction, abrasion damage, permeability and microbial growth. Pre-wetted patches of baby diapers were placed on the volar forearms of adults for two hours and then the skin was subjected to friction and abrasion. The coefficient of friction for the 'wet' skin was significantly higher than for 'dry' skin although increased fluid loading of wet patches did not further increase skin friction. Similarly, skin hydrated with a wet patch showed a significant increase in skin abrasion damage relative to a dry patch. Again, variations in the fluid loading of the patch did not produce significant changes in abrasion damage.

Although the volar forearm is most commonly used for skin experimentation, it has not been shown to be a valid model for the skin exposed to an incontinence pad, i.e. buttocks and groins. Schnetz and colleagues [595] demonstrated that trans-epidermal water loss (TEWL) measurements (used to measure both skin barrier function and excess water in the skin) from the volar forearm did not correlate with those taken from the face, although the left and

right side of the face showed good correlation. The researchers concluded that TEWL measurements for the study of facial cosmetics should be taken from the face rather than the forearm. Similarly, studies using the volar forearm may not be valid for the buttocks and groin. Skin in the perianal area was shown to be more sensitive to faecal irritation than that on the inner arm [596].

Recently Fader and colleagues (2010, 2011) [597] [598] reviewed the literature on measurement of TEWL for assessment of overhydrated skin and found that there was a lack of standardization in all components of the method including the analysis and interpretation of findings [597] and they describe the development and testing of a more valid and robust method and compare measurements made on younger and older women and on volar forearm and hip skin. The authors conclude that age did not significantly affect measurements but those made on the hip were consistently higher and more variable than those made on the forearm. It is recommended that the forearm is used for future work.

Berg [588] analysed the aetiological factors contributing to infant diaper dermatitis and developed a model (**Figure XIV-1**) to show its development and resolution. However, the applicability of this model to adults with incontinence has not been tested, and other factors such as low mobility and prolonged pressure - which are common in frail, older adults - are not accounted for in this model. In addition, this model assumes the presence of urinary and faecal incontinence, which is much less common in adult populations than urinary incontinence alone.

b) Prevalence of incontinence-associated dermatitis / perineal dermatitis

Incontinence-associated dermatitis (IAD) has been defined most recently as "an inflammation of the skin occurring with or without erosian or secondary cutaneous infection". Perineal dermatitis (PD) is an inflammation of the skin characterized by redness, tissue breakdown or denudement, vesiculation, oozing, crusting, soreness, itching, and in its more severe form, pain and fungal patches [599] [600] [575] within the pad area. In the largest study of assessment records of more than 59,000 residents in 510 nursing homes located in 31 US states, Bliss et al. [601] reported a prevalence of perineal dermatitis of nearly 6%. In studies with smaller sample sizes and other populations, perineal dermatitis (**Table** XIV-1) has been shown to affect about a quarter to a half of patients.

Recently there has been further clinical evidence supporting the role of faeces in the development of IAD. Bliss et al (2011) [544] studied the development of IAD in 45 criticially ill adults in three critical care units. Most (76%) were male and all were free of IAD at the start of the study. IAD developed in 36% of patients and the median time to onset was 4 days (range 1-6). Severe IAD (denudement) occurred in 9% of the observed time. Frequent incontinence of loose or liquid stools and diminished cognitive awareness were significant independent risk factors for development of IAD sooner.

Shigeta and colleagues (2011) [610] studied the skin of 100 older Japanese patients in a nursing

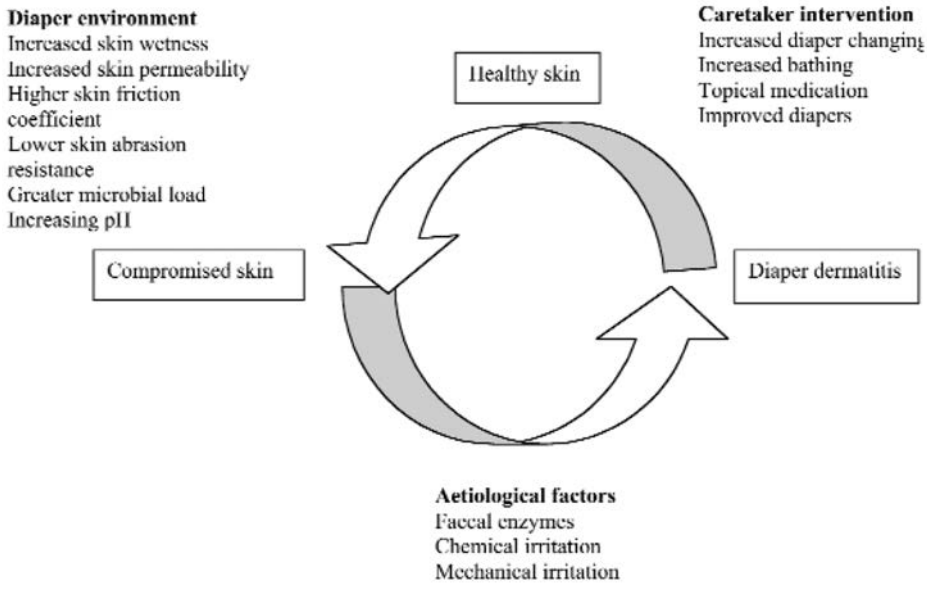

Figure XIV-1: Berg's model of diaper dermatitis (1987).

Table XIV-1: Studies reporting the prevalence of incontinence-associated dermatitis

Authors	Sample	Prevalence of dermatitis (%)
Lyder et al., 1992 [602]	15 older people: hospital psychogeriatric wards	33
Keller et al., 1990 [603]	95 older people: long stay	53
Brown, 1994 [22]	166 adults (acute medical wards)	35
Bale et al., 2004 [604]	79 nursing home residents	25
Zehrer et al., 2005 [605]	398 nursing home residents on a skin damage prevention regimen	4
Bliss, Savik et al., 2006 [601]	59,558 nursing home residents	5.7
Bliss, Zehrer et al., 2006 [601]	1,918 nursing home residents on a skin damage prevention program	3.5
Ehman et al., 2006 [606]	45 adult intensive care unit patients	36
Junkin et al., 2008 [607]	698 paediatric and adult hospitalized patients	20
Shigeta et al., 2008[608]	100 older Japanese patients in a nursing home	36
Beeckman et al., 2011[609]	141 long-term care patients	22.5

home who had faecal and/or urinary incontinence and wore absorbent products. Multivariate logistic regression analysis showed that the presence of diarrhea was an independent risk factor.

Bliss et al. [611] prospectively investigated the development of IAD using assessment data of 1,850 elders who were free of IAD at admission to a nursing home. The preliminary report showed that at three months after admission, faecal incontinence alone and double incontinence were significant predictors of IAD, but urinary incontinence alone was not a significant risk. The prevalence of IAD appears to be influenced not only by the type of patient (nursing home versus hospitalized) but also by the type of incontinence and whether or not a skin damage prevention program is followed.

Measurement of IAD

There is no widely available valid or reliable tool for the assessment of PD / IAD although four instruments have been published [614] [615] [601] [617]. One of these tools, the Perineal Assessment Tool, despite its name, is an instrument primarily for assessing the risk of IAD (versus assessing skin health) and it has been described and used by its developer as such [616]. The most recently published tool [617] has been subject to internal validation and determines degree of redness, amount of skin loss and presence of rash on 13 body locations; a revised version for dark-toned skin is also being tested. Most researchers have reported ratings of colour changes (degree of erythema) based on visual inspection, which may be confounded by the presence of reactive hyperaemia on areas subject to pressure (particularly the buttocks, hips and sacrum). In some studies (mainly those finding higher proportions of IAD) trained staff or researchers have been utilised to carry out skin inspections at pre-specified times and in others (mainly those finding lower proportions of IAD) the usual care staff have been asked to report skin problems or written records have been used; this may explain the wide range of prevalence reported.

Few studies report the severity of PD. In a prospective surveillance study of 981 nursing home residents with incontinence of urine and/or stool over six weeks, the most common anatomical locations of PD were the buttocks (73% of those with PD) and perianal area (70%) followed by the genitalia, scrotum and groin (36%) and thighs (24%) with the smallest percentage near the sacrum (9%). Approximately one-third of residents had PD in more than one location. Mild PD was by far the most common (69% of residents); severe PD affected only 8% of residents [616].

c) Pressure ulcers and incontinence

The role of urinary and faecal incontinence in the development of pressure ulcers is uncertain. Studies aiming to identify risk factors for the development of pressure ulcers have generally found that the presence of both urinary and faecal incontinence was a risk [617] [618] [619] [620], but some studies have only found faecal rather than urinary incontinence to be a risk factor [621] [622]. Pressure ulcer risk assessment scales all have a sub-scale of incontinence or moisture-level, and the main mechanism for the development of pressure ulcers has been thought to be the increased friction and increased vulnerability to abrasion of wet skin.

Some researchers have used pressure ulcer classification systems, such as those published by the National Pressure Ulcer Advisory Panel (NPUAP) or the European Pressure Ulcer Advisory Panel (EPUAP), to measure skin health. The validity and reliability of most of these tools have not been established. Doughty et al [623] and Bethell [624] described numerous other limitations of pressure ulcer staging systems and despite recent revisions of the NPAUP and EPUAP staging systems, many of the shortcomings still apply. The reliability of the EPUAP staging score (which is a modified version of the NPUAP score) has been tested recently in three studies using photographs of pressure ulcers. These photographs included 'moisture lesions' (defined as lesions resulting from prolonged exposure of the skin to excessive fluid because of urinary or faecal incontinence, profuse sweating or wound exudate). A high degree of reliability for classification of moisture lesions was found amongst 44 pressure ulcer experts (Kappa =0.80) [625]. However, inter-rater reliability was found to be much worse (Kappa = 0.37) when photographs were viewed by 473 non-expert nurses [626] and subsequently in

a European study of 1,452 non-expert nurses from five European countries (Kappa = 0.36). The authors concluded that better descriptors needed to be incorporated into the EPUAP system and more education was needed.

An education tool aimed at improving skills in pressure ulcer classification (the PUCLAS education tool) was developed by a workgroup of the EPUAP and was tested by Beeckman and colleagues [627] in a randomised controlled trial. 1217 nurses from Belgium, the Netherlands, UK and Portugal participated. At baseline 45% of skin photographs were classified correctly and results were significantly improved in the intervention group who received the PUCLAS education tool (63% classified correctly) compared to the control group (53% classified correctly). Furthermore the proportion of correct assessments for IAD was 71% in the intervention group and 36% in the control group. The authors conclude that the PUCLAS tool improved pressure ulcer classification.

However there is still debate regarding the validity of separately classifying IAD from pressure ulcers particularly when skin damage occurs over bony prominences. To investigate the validity of classifying moisture lesions, Houwing et al. [628] examined the histology of 14 biopsy samples of damaged patient skin. Skin damage was classified using the EPUAP system: 12 were moisture lesions, one was a grade 4 pressure ulcer (extensive tissue destruction / necrosis) and one was a combination of a moisture lesion and a grade 1 pressure lesion (non-blanchable erythema). Both pressure ulcers had a histological pattern suggesting ischemic pathology; the histology of the moisture lesions, however, was either of an ischemic or irritation pattern. Because of the overlap in histology patterns of some of the moisture lesions and the pressure ulcers, the authors concluded that there is no justification for classifying moisture lesions separately from pressure ulcer lesions.` This finding requires further study as there are several limitations of their study. First, the true aetiology of the skin damage and the veracity of the EPUAP classification were not determined; some moisture lesions seem to be partially over a bony prominence so that a mix of pressure and moisture damage cannot be ruled out, which might explain the mixed histology patterns. Secondly, the moisture lesions and the pressure ulcer were both described as having blanchable erythema.

Identification of moisture lesions as distinct from pressure ulcers is sought as a way to solve the tension between inadequate prevention / treatment of a pressure ulcer and inappropriate use of costly prevention relieving devices / measures. It is also of importance in determining care quality. Pressure ulcers are deemed as quality indicators in many countries and are considered to be preventable. Facilities may not be allowed to charge for the care and treatment of patients who develop pressure ulcers and may also be fined. The 'correct' classification of IAD and pressure ulcers therefore has financial and reputational implications.

Fader et al. [629], examined the effects of absorbent continence pads on mattress interface pressures using an articulated model or "phantom" as the subject and found that the presence of a pad significantly and substantially (around 20%) increased the peak pressures recorded between the buttocks and the pad / mattress. Peak pressures were frequently found at the locations of pad creases and it was considered that pad folding and compression may contribute to raised interface pressures. It is therefore possible that continence product use contributes to the formation of pressure ulcers by raising interface pressures.

Black et al. (2011) [579] have categorized IAD as distinct from pressure ulcers as shown in **Table XIV.2**

2. CLINICAL STUDIES OF THE IMPACT OF PRODUCTS AND PRODUCT MATERIALS ON SKIN HEALTH

In the 1980s, product manufacturers introduced diapers with super-absorbent polymers (SAP), which were designed to reduce skin wetness, buffer pH and reduce urine / faecal contact in order to help prevent diaper dermatitis. This led to clinical and laboratory studies to evaluate the efficacy of diapers with different materials, in particular, super-absorbent polymers (SAP) compared to those without, and compared to conventional washable diapers.

a) Quality of data

There are three types of studies testing the effects of different products or product materials on skin health: (i) clinical trials of normal infants wearing diapers; (ii) laboratory wet patch testing of adult forearms with diaper or continence pad patches; and (iii) clinical trials of adult absorbent pads containing different materials. The infant diaper studies were randomised controlled trials with large samples and blind measurement of outcomes. It should be noted that these studies were carried out by industry-employed staff. The infant and laboratory studies used a probe comprising two hygrosensors and thermistors (an evaporimeter) placed on the 'wet' skin to measure trans-epidermal water loss (TEWL), an indicator of skin hydration level. However, there is uncertainty about the optimum procedures for measuring TEWL, and different procedures and outcomes were used in the studies, making it difficult to compare results. Probably the most important threat to the validity of these studies is the selection of products or materials used in the study. None of the studies adequately described the products used - in particular, regarding their total absorbency. Thus it is possible that an alternative explanation for the fairly consistent findings that disposable pads with

Table XIV-2: Differentiation of IAD Versus Stage I and II Pressure Ulcers

Factors	IAD	Stage I Pressure Ulcers	Stage II Pressure Ulcers
History of condition	Exposure to urine or stool	Exposure to pressure, shear and/or microclimate from immobility or inactivity	Exposure to pressure, shear and/or microclimate from immobility or inactivity
Location of affected skin	Skin folds in areas where urine or stool can accumulate	Skin usually over bony prominences or exposed to other external pressure (eg, medical device)	Skin usually over bony prominences or exposed to other external pressure (eg, medical device)
Colour of wound bed	Shiny, red, glistening, no slough in wound bed	Nonblanchable erythema of intact skin	Shiny pink or red open wound, no slough in wound bed
Colour of periwound tissue	Red, irritated, edematous	Normal for race/ethnicity, edema may be palpable	Normal for race/ethnicity, edema may be palpable
Characteristics of involved area	Blotchy, not uniform in appearance	Tend to be single areas of erythema	Tend to be single ulcers with distinct ulcer wound margin
Pain	Burning, itching and tingling	Sharp pain, usually no itching; pain may intensify when patient is initially moved off of injured areas	Sharp pain, usually no itching; pain may intensify when patient is initially moved off of injured areas
Odour	Urine, faecal odour	None	None unless infected and then may have odour of infecting organism
Other	Candidiasis common (seen as satellite lesions)	Redness tends to resolve with offloading or repositioning of device	Ulcer bed is shallow and heals through epithelialization

SAP perform better on skin outcome measures may be that those with SAP simply had greater absorbency than those without.

b) Results

1. Clinical studies of infant diapers

Campbell and colleagues [630] conducted four clinical studies involving 1,614 infants randomly assigned to either disposable diapers with SAP, disposable diapers without SAP or washable cloth diapers. Disposable diapers with SAP were associated with significantly reduced skin wetness as measured by TEWL, lower pH and lower ratings of diaper dermatitis when compared to the two other diaper products (Level of Evidence 2).

Lane et al., [631] randomised disposable diapers without SAP and disposable diapers with SAP to 149 newborn infants and assessed their skin condition seven times over a 14 week period. Skin rash ratings were significantly lower for infants wearing diapers with SAP at only one time period (14 weeks) (Level of Evidence 2).

Davis and colleagues [632] assessed 150 infants over 15 weeks in a cross-over study involving four different disposable diaper types, two with different levels of SAP and two with different levels of fluff pulp only. Both diapers containing SAP were associated with significantly less skin wetness and significantly lower pH. Clinical skin ratings showed significantly lower ratings for the SAP-containing pads compared to the lower weight fluff pulp pad, but not compared to the higher weight fluff pad (Level of Evidence 2).

2. Laboratory studies of diaper patches

Wilson and Dallas [633] used the adult normal volar forearm skin model to compare patches taken from 16 different infant diapers. They found that disposable diapers containing SAP left the skin significantly drier than washable diapers and disposable diapers without SAP ($p<0.01$). Disposable diapers without SAP did not differ significantly from reusable diapers and there were no significant differences between products within any of the three groupings (Level of Evidence 2).

However, in a subsequent study involving 20 disposable and washable adult incontinence pads incorporating a similar range of materials to the baby diaper study Dallas and Wilson [634] found significant differences between products within each of the three product groupings but not between groupings (Level of Evidence 2). Grove et al. [635] used a similar approach to compare three infant diapers and found a significant difference in skin wetness between two that contained similar quantities of SAP ($p<0.001$). The one in which the SAP was in a layer near the water-proof backing kept the skin dryer than that in which it was near the coverstock. The third diaper – which had a microporous (breathable) backing kept the skin significantly dryer than each of the other two ($p<0.001$) (Level of Evidence 2).

3. Clinical studies of adult absorbent products

There has been one clinical study of adult incontinent patients comparing underpads with and without SAP, diapers with and without SAP and washable cloth underpads and which used skin condition as the primary outcome variable [22]. This study included 166 incontinent patients (urine, faeces or both) from three acute care facilities who were divided into the five groups. It is unclear whether randomisation to group occurred by patient or by facility. One facility used the washable cloth underpads only for their patients. Other patients tested either diapers or underpads and crossed-over from without SAP to with SAP products after six weeks. Skin measurements were made for colour, integrity and symptoms using rating scales. Both blind and non-blind measurements were made.

Findings were rather complex and difficult to interpret and no corrections for multiple comparisons

appear to have been made. Overall there were no differences in skin measurements between the diaper and underpad groups but - for some measurement sub-groups - differences were found with mean colour scores being significantly higher (worse) in the without-SAP diaper group and the washable cloth underpad group. Blinded 'worst' skin colour scores were highest for without-SAP diapers and washable cloth underpads and lowest for with-SAP products. Overall the findings supported the favourable effects of SAP on skin health but, as with the infant diaper studies, total absorbency of the products was not reported (Level of Evidence 2).

Hu et al. [66] randomised an unnamed range of disposable insert pads with mesh pants to 34 nursing home residents who were matched (based on incontinence severity) with 34 residents who received the usual reusable cloth diaper product. Skin condition was rated at baseline and after the five week intervention period by a blinded nurse researcher. Skin condition was reported to be significantly better in the disposable pad group (Level of Evidence 2).

More recently Beguin and colleagues (2010) [636] tested a modified diaper design (incorporating a top layer of specialised cellulose – beneath the top sheet – to maintain skin pH, and air-permeable side panels to minimise skin occlusion) in a small study of 12 patients using a pre-post test design. Skin pH was significantly lower when patients used the modified diaper and 8 out of 12 patients had resolution of pre-existing skin lesions. A larger more robust trial would be needed to establish any important clinical benefit.

3. CLINICAL STUDIES OF SKIN-CARE PRODUCTS AND NURSING PRACTICES TO MAINTAIN OR IMPROVE SKIN HEALTH

The skin of incontinent people requires frequent cleansing to remove urine and / or faeces. Soap and water is in common use [637] but it is known that repeated exposure to anionic surfactants (common in soaps) results in skin irritation [638] [639]. In addition, the action of washing is also considered likely to contribute to mechanical damage of the stratum corneum.

Cleansing of skin soiled with urine and / or faeces should occur immediately if possible or promptly after episodes of incontinence [640] [641] [642] [643] [644] [579] [575]. In addition, an individualized schedule for cleansing the perineum according to patients' needs or preferences [645] [646] [575] [579] or at routine intervals, such as daily or at bath time [647] [576] [640] [642] [648] has been recommended (Level of Evidence 3).

The practice of cleansing or wiping the perineum front to back is recommended as standard practice in the literature - particularly for women [649] [650] [651] [652] [653]; this recommendation is based on the physiological rationale of lowering presumed risk of contaminating the urethra with faecal bacteria and subsequent urinary tract infection [653]. One retrospective study of pregnant women found a significantly higher association of urinary tract infections in women who self-reported they wiped back to front (25.8%) than among those who wiped front to back (18.5%) [654] (Level of Evidence 2).

To minimize friction damage of the skin during the perineal cleansing process, gentle cleansing and patting dry the skin [655] [656] rather than rubbing or using a soft cloth is recommended by clinical experts [616] [657] [576] [643] [644] [658] [659] [659] (Level of evidence 4).

However there is some evidence that drying the skin by patting may be less effective than gentle towel drying or drying with a hair dryer [660]. Damp skin is more vulnerable to friction damage and special care may therefore be needed to ensure that the skin is dry. For already damage skin, there are clinical anecdotes of using a small hand-held hair-dryer set on a low and cool setting rather than drying with a cloth. Further research into cleaning and drying techniques and products is encouraged.

Alternative cleansers are available which have been formulated with the intention of overcoming some of the limitations of soap and water. Although overhydration of skin is detrimental, an excessively dry stratum corneum develops cracks and fissures and can be as ineffective a barrier as an over hydrated one [583]. Soap has a high pH (9.5-11) [661] and under laboratory conditions skin that has been exposed to high pH solutions has been found to have increased stratum corneum swelling and other signs of skin damage. However, there is a lack of controlled clinical trials comparing standard (high pH) soap with pH neutral soap or cleansers.

Many modern cleansers are designed to be used without water [i.e. 'no-rinse') and are designed to provide a less aggressive skin environment than soap (e.g. lower pH) but this may compromise their effectiveness in cleaning the skin of urine and faeces. This question has been addressed by Ronner et al, (2010) [662] who compared soap and water and a no-rinse cleanser in terms of their ability to remove escherichia coli and staphylococcus aureus. This laboratory study employed volunteer volar forearms and found low level and comparable levels of residual bacteria on the skin.

The use of topical products aiming to prevent or treat skin irritation is common but there is a lack of standardisation in definitions and descriptions of products, which makes comparisons difficult. Products such as 'moisturisers' or 'barriers' may be applied to the skin after cleansing, and some cleansers also incorporate moisturisers. The aim of moisturisers (also known as emollients) is to hydrate the skin by reducing trans-epidermal water loss through occlusion (e.g. petrolatum), by drawing

water into the stratum corneum by the addition of a humectant (a hygroscopic substance, e.g. glycerol) or by adding water in the applied water-miscible product. These modes of action are often combined in the same product, but there are exceptions - such as petrolatum - which only work by occlusion [663]. Some products are designed specifically to prevent penetration of water into the stratum corneum ('barrier' products) such as liquid skin sealants containing polymers, and may allow trans-epidermal water loss whilst preventing external water penetration. Simple occlusive products such as petrolatum may also act as barrier products to water but also occlude trans-epidermal water loss.

The application of skin barriers is recommended on areas that would come in contact with leaked urine and / or faeces. In general these areas include the buttocks and perianal area, groin, and inner thighs. Community-living persons report leaking small amounts of faeces that remain between the buttocks. Clinically, nursing staff have observed seepage of faeces around a rectal catheter in hospitalized patients. In both groups, perianal skin protection is important, and skin barriers are recommended (Level of evidence 4).

Topical creams are commonly used to prevent and treat dermatitis but controlled experiments to assess efficacy on human and animal skin have produced equivocal results. Ghadially et al. [663] showed that barrier recovery (measured by TEWL) on experimentally irritated skin was accelerated by the application of petrolatum and De Paepe K et al. [664] showed similar results using a different moisturising cream. Hannuksela and Kinnunen [665] showed that treatment with moisturisers prevented the development of irritation in an experiment involving frequent skin washing with liquid detergent. However, Gabard [666] was unable to demonstrate significant acceleration of barrier recovery to chronically irritated skin following application of different moisturisers using a chronic irritation model and also found that some creams enhanced irritation.

The efficacy of barrier products in preventing water penetration of the skin has been tested in laboratory settings. Vinson and Proch [667] applied wet patches with a water-soluble marker to skin coated with three different barrier products and measured dye extracted from the skin by absorbance spectrophotometry. One multiple barrier product performed significantly better than a petrolatum-based and an allantoin-based protectant. Waring and Hoggarth [668] used a Chromameter to measure skin colour change after staining skin with a water-soluble dye, covering it with a barrier product and washing the skin. Petrolatum products were found to be more effective barriers than dimethicone-based products. In a later study, Hoggarth et al. [669] investigated the barrier function and skin hydration properties of six skin protectants when applied to the volar forearms of 18 healthy volunteers. The researchers found that each had different performance properties with the water-in-oil products containing petrolatum performing better than the oil-in-water products containing dimethicone for protection against irritation or maceration. However the dimethicone products had higher hydration properties compared to the petrolatum products. Overall the water-in-oil petrolatum-based product was the only product to be efficacious for all performance variables. A limitation of some petrolatum-based moisture barriers compared to a non-alcohol barrier film for individuals wearing absorbent pads or briefs is that the petrolatum-based products have been shown to transfer from the skin onto the absorbent product and reduce fluid update by 54% to 90%. [605]. However this has not been tested in clinical trials and the effects of different topical products on the leakage performance of absorbent pads is unknown.

Other practices that may affect skin health include frequency of pad changing. Increasing pad changing may reduce skin wetness by application of a dry pad and may therefore benefit skin health. Increased pad changing is commonly recommended to prevent or treat dermatitis particularly in infants [670] Level of Evidence 4.

a) Quality of data

Several studies of skin cleansing and / or moisturising / barrier products to prevent perineal dermatitis have been limited by being uncontrolled [614] [671] [604] [672] and of small size and lacking adequate power calculations [673] [674] [602], or not including any clinical outcome measures [673]. Measurement of dermatitis may also have been compromised by reactive hyperaemia on skin areas subject to pressure. Only four randomised controlled trials of a skin cleansing regimes to prevent perineal dermatitis could be found, and two RCTs of products to treat dermatitis. Two trials focused on the costs of barrier products use. In addition there was one randomised crossover trial of pad changing frequency.

b) Results

1. Skin cleansing / moisturising products to prevent dermatitis

Byers et al. [673] compared four different cleansing / moisturising regimes including soap and water using a multiple cross-over design. Despite having a very small sample size (n = 12 elderly women) they found statistically significant differences in TEWL, pH and erythema between some of the regimes, and soap and water was found to be the least effective product for skin health. No clinical outcomes were measured and differences in outcomes were small (Level of Evidence 2).

Beeckman et al, 2011 [609] randomised 141 nursing home residents to receive standard cleansing with pH neutral soap and water with the use of a

3-in-1 perineal care washcloth impregnated with a 3% dimethicone skin protectant over a period of 120 days. Skin health was measured using the IAD skin condition assessment tool. Although no differences in the severity of IAD were found there were substantial differences in prevalence of IAD (experimental: 8.1% versus control: 27.1%, F = 3.1, p=0.003) (Level of Evidence 2).

Cleansing products

Cooper and Gray [657] randomised 93 long-term elderly subjects to skin cleansing with soap and water or with a foam cleanser over a 14 day period and blindly assessed perineal skin photographs at zero, seven and 14 days. The skin of 37% of subjects using soap and water remained 'healthy' compared to 66% of subjects using the foam cleanser. However, statistical analysis was not carried out (Level of Evidence 3).

Lewis-Byers et al. [658] randomised 32 nursing home residents with incontinence to a soap and water or no-rinse cleanser regime over a period of three weeks. No significant differences in skin condition were found but no power calculations were included (Level of Evidence 3).

Taken together, the evidence from these trials indicate that specialised cleansers may be better than soap and water for skin health, although there is still a need for further robust clinical trials. Reported staff opinion tends to favour specialised cleansers rather than soap and water and there may also be cost savings [614] [673] [674] [658] although the reliability and validity of the health economic analyses carried out to date has been questioned by Beeckman (2009) [581].

Costs of barrier products to prevent dermatitis

Zehrer et al. [605] compared the cost and efficacy of three incontinence skin barrier products in 250 nursing home residents from four facilities. A polymer-based barrier film was used either once daily or three times weekly, and one of two petrolatum ointments was used after each episode of incontinence. Residents were monitored for skin damage for six months. There were no significant differences in effectiveness among the various barrier film and ointment protocols of care. Time and motion measures were used to determine the costs of the products and associated nursing labour. Daily cost of barrier product ranged from $0.17 for the barrier film applied three times per week to $0.76 for a petrolatum ointment applied after each incontinent episode. When nursing staff labour to apply the barrier products was included in the cost analysis, costs increased from $0.26 per day for the less frequently applied barrier film to $1.40 per day for the more frequently applied petrolatum ointments (Level of Evidence 3).

Bliss et al. [616] randomly selected 16 nursing homes to compare the cost and effectiveness of four skin damage prevention regimens. In three of the four skin prevention regimens, a moisture barrier ointment or cream of different compositions (43% petrolatum; 98% petrolatum; and 12% zinc oxide + 1% dimethicone) was applied after each episode of incontinence, while in the fourth, a polymer-based alcohol-free barrier film was applied three times per week. All regimens used a pH-balanced, moisturizing cleanser of the same manufacturer as the barrier. Time and motion measures were documented for the amount of skin care products used, the number, type, and time of caregivers performing IAD prevention care, and the number and type of supplies used. Compared to the three regimens in which a barrier was applied after each episode of incontinence, the use of a regimen in which a barrier film was applied three times weekly had significantly lower costs for the barrier product, labour associated with barrier application, and total cost which included products, labour, and supplies. There were also savings in total product (cleanser and barrier) and total labour costs. The total cost was lowest for the regimen using the barrier film compared to the other regimens in which a barrier needed to be applied after each episode of incontinence. The total cost savings ranged from $ 0.40 to $0.85 per episode of incontinence (Level of Evidence 2).

Although both these studies demonstrated cost savings when using barrier-film products such savings are dependent on relatively infrequent application of the barrier-film product. This may be achieved by assigning product application to care staff on particular shifts but uncontrolled use of such products may be expensive.

2. Skin products to treat dermatitis

In a double blind controlled trial of 64 subjects, Anthony et al. [675] compared the efficacy of cream formulated to treat dermatitis (Sudocrem) with zinc cream BP. Thirty subjects showed inflammatory lesions of the buttocks and a significantly greater proportion of subjects allocated to Sudocrem showed reduction in skin redness at both seven days and 14 days. No differences were found in the prevention of inflammatory lesions between the two groups. Skin measurements were made over the ischial tuberosities but the effect of reactive hyperaemia was not accounted for. There was no control group receiving no skin treatment and therefore it was not possible to establish the efficacy of using cream as treatment per se (Level of Evidence 2).

Baatenburg de Jong & Admiraal [676] determined the cost of treating moderate to severe IAD in 39 nursing home patients in the Netherlands randomly assigned to treatment with a non-stinging barrier film or zinc oxide oil. The barrier film was applied every 48 - 72 hours for less severe skin damage and 24 - 48 hours for more severe damage. Zinc oxide oil was applied twice per day and after each episode of incontinence. Both barriers reduced IAD but the no-sting barrier film was significantly associated

with reduced severity of skin redness and skin loss, although skin assessments were not blinded. The cost per day of the nursing staff labour in the regimen using the barrier film was €68.58 (sd = € 23.61) compared to €88.20 (sd = €22.88) in the regimen using the zinc oxide oil The total cost (including barrier, labor and supplies) per day of the regimen using the barrier film (€76.13, sd = €25.48) was also less than for the regimen using the zinc oxide oil (€102.96, sd = €23.25) (Level of Evidence 2).

3. Pad changing frequency

Fader et al. [629] investigated the effect of different frequency of night-time pad changing on 81 incontinent nursing / residential home subjects from 20 homes. Following a two week baseline period, subjects were randomised by home to pad changing at 22.00 and 06.00 for four weeks followed by 22.00, 02.00 and 06.00 for four weeks, or vice versa. Blinded skin measurements of instrumental erythema (using an erythema meter), visual rating, trans-epidermal water loss and pH were made at baseline and during the last two weeks of each regime with instrumental erythema measurements used as the primary outcome variable. Trans-epidermal water loss measurements were significantly higher when pads were changed less frequently (22.00 and 06.00) indicating that skin was wetter. No other significant differences were found. However, five subjects developed stage II pressure ulcers in the less frequent pad changing regime compared to none in the frequent pad changing regime. Although more frequent pad changing did not demonstrate less dermatitis / erythema, the pressure ulcer findings - though non-significant - make it unwise to conclude that less frequent pad changing does not damage skin health (Level of Evidence 2).

4. SUMMARY

- Incontinence-associated dermatitis is a common problem amongst absorbent product users (**Level of Evidence 2**).
- Skin wetness overhydrates skin and potentiates the effects of other irritants (**Level of Evidence 2**).
- Faecal incontinence is more irritating than urinary incontinence, but the combined effects of urine and faeces are particularly damaging to skin (**Level of Evidence 2**).
- Absorbent pads containing super absorbent polymers are associated with reduced skin wetness (**Level of Evidence 3**).
- Wet skin is more vulnerable to friction and abrasion injury (**Level of Evidence 2**).
- Pressure ulcers are associated with urinary and faecal incontinence (**Level of Evidence 2**).
- Bodyworn absorbent products may raise interface pressures measured under the buttocks (**Level of Evidence 3**).
- There are indications that skin cleansers may be more cost-effective than soap and water (**Level of Evidence 3**) and may be better for skin health (**Level of Evidence 2**).
- Barrier skin products may impede water penetration into the stratum corneum (**Level of Evidence 3**).
- A regular and structured skin care regimen using topical preparations such as moisturisers or barrier creams is associated with a low incidence of perineal dermatitis (**Level of evidence 4**).
- More frequent pad changing has not been shown to prevent dermatitis, but less frequent pad changes may be associated with pressure ulcers (**Level of Evidence 3**).

5. RECOMMENDATIONS

- Absorbent pads with SAP should be selected in preference to those without (**Grade of Recommendation B**).
- Absorbent pads should be changed regularly to minimise skin wetness (**Grade of Recommendation C**).
- Patients with faecal or double incontinence should be changed as soon as possible after incontinence has occurred to prevent the development of dermatitis from protease and lipase activity (**Grade of Recommendation B**).
- Patients should be washed gently at times of pad change with either soap and water or cleansers. Cleanser may be less time-consuming than soap and water (**Grade of Recommendation C**).
- Skin barrier products should be applied to areas that potentially come in contact with leaked urine and / or faeces (**Grade of Recommendation D**)
- Barrier products may be applied to skin within the pad area to reduce water penetration of the skin (**Grade of Recommendation C**).
- Buttock and sacral areas should be protected using topical skin barrier products, containment products or diversion devices in patients vulnerable to IAD or pressure ulcers (**Grade of Recommendation C**).

6. PRIORITIES FOR RESEARCH

- Controlled randomized trials that investigate the effectiveness of skin care products or skin care regimes to prevent or treat perineal skin damage due to urinary and faecal incontinence are recommended. Trials which

aim to test the comparative effects of different cleansing regimes, different barrier products and use of barrier products compared to careful cleansing are needed in particular. Such studies should determine appropriate sample sizes using power analyses. Analyses need to be powered to distinguish effects on participants with faecal or double incontinence. Objective measures from instruments, standardized clinical assessments, and patient symptom ratings should be included.

- Laboratory-based studies on healthy volunteers are recommended to help select products and establish potential efficacy of products before undertaking RCTs.
- Further work is needed to examine the relationship between IAD and pressure ulcers, in particular the potential and/or methods to discriminate between them, including use of biomarkers and technology.
- Studies to identify markers or ways of discriminating between pressure ulcers and IAD are required. Trials to test the comparative effectiveness of different skin cleansing regimes are needed as are trials to determine whether skin barrier products deliver benefits over careful cleansing alone and, if they do, which work best.

XV. ODOUR CONTROL PRODUCTS

Fear of smelling is a major concern that preoccupies many people suffering from incontinence and it is an issue that has been raised in several qualitative studies that have explored the subjective opinion of the patient eg [677] [678] [5]. Accordingly, there is a demand for products which will mask odour or, preferably, prevent it.

1. PRODUCTS FOR URINARY INCONTINENCE

Fresh, infection-free urine smells only slightly but bacterial action on urea over time yields pungent smelling ammonia.

A variety of anti-microbial solutions are available for washing such products as hand-held urinals or for treating urine spillage onto soft furnishings such as carpets. They aim to prevent smell by destroying the bacteria responsible for break down of urea. There are no robust published studies that have sought to evaluate such products. Another approach is to mask the smell of stale urine using a strong but (hopefully) pleasant smelling liquid. There are no robust published studies on such products either but anecdotal evidence suggests that, in time, the masking smell comes to be associated with the incontinence that it is intended to disguise. Several companies supply products (washable bedpads, carpets, chairs, clothing and bed linen) made with fabrics that have been treated with anti-microbial agents intended to reduce the smell of any urine on or in them. However, again, there have been no robust published studies to investigate efficacy.

One of the 12 disposable bodyworn pads for lightly incontinent women evaluated by Clarke-O'Neill et al. [18] was treated with a lavender scent but it was not found to perform significantly better than the other products in terms of preventing smell. However, the scent was appreciated by 18% of the 50 test subjects, who commented favourably on it.

2. PRODUCTS FOR FAECAL INCONTINENCE

Odour associated with faecal incontinence may occur from involuntarily leaked stool or flatus. In a study with subjects eating a self-selected diet, Moore et al. [679] identified the volatile chemicals primarily responsible for faecal odours as the methyl sulphides: methanethiol, dimethyl disulphide, and dimethyl trisulphide. Hydrogen sulphide was thought to make a smaller contribution. In a subsequent study with persons consuming a bolus of pinto beans and lactulose (a non-absorbable carbohydrate) Suarez et al. [680] attributed the odour of flatus to the sulphur compounds, hydrogen sulphide, methanethiol, and dimethyl sulphide. The intensity of the odour in flatus was related to the concentration of the sulphur-containing compounds: the ability of the human nose to recognise malodorous odour appears to be related to the amount of gas expelled [680]. Different states of health and gastrointestinal function, diet composition, relative concentrations of sulphide gases and, possibly, short chain fatty acids or ammonia are expected to contribute to the odour of faeces and flatus [679] and [680].

There are several commercially available devices that are designed to absorb the odour of flatus. One such product originally called the "Toot Trapper" and renamed the "Flatulence Filter" (UltraTech products, Inc., Houston, TX, USA) is a cushion or pad (which can be placed directly against the anus) that is lined with activated charcoal. Both the cushion and pad are encased in either a washable or a disposable cover. There are similar products by other manufacturers (e.g., Flat-D by Flat-D Innovations, Inc., Iowa, USA and GasMedic and GasBGon by Dairiair and manufactured by ECVC, Greenville, NC, USA). Pads comprising fabric covered activated charcoal that can be worn next to the anus or attached to a brief (GasMedic underair pad by Dairiair and Flat-D, Flat-D Innovations, Inc., Cedar Rapids, IA). There is also underwear (briefs) entirely made of covered activated carbon cloth (Underease protective underwear (UltraTech Products, Inc., Houston, TX). Ohge at el. [681] compared the effectiveness of

11 devices containing activated carbon in six normal adults (50% female) under controlled conditions in absorbing odoriferous rectal gases. Five types of seat cushions, four types of pads, and two types of briefs (one that held a pad next to the anus and one made of activated carbon fiber fabric) were tested. A mixture gas comprising 100 ml of nitrogen with traces of hydrogen sulphide (40 ppm), methylmercaptan (40 ppm) and hydrogen (5,000 ppm) was instilled into the rectum of the subjects via a rectal tube. Since hydrogen does not react with charcoal, the amount of unabsorbed sulphide was determined from the ratio of sulphide to hydrogen collected from the pantaloons relative to the ratio in the instilled gas. The subjects wore mylar pantaloons that were sealed at the thighs and waist with elastic bandages to reduce convection to the air.

The subjects' clothing, apart from any device, absorbed approximately 22% of sulphide gas. The cushions absorbed an amount comparable to usual clothing, 20%. The various pads and the brief with an attached pad held near the anus absorbed 55-77% of the rectal gas. The underwear made of charcoal fabric was the most effective and removed nearly all (95-99%) of the sulphide gas. The charcoal fabric briefs are reusable and the charcoal is allegedly regenerable with heat. There are no reports of any odour absorbing devices being evaluated in persons with faecal incontinence. In vitro studies showed that each device had the capability of absorbing the rectal gases and that their performance efficiency depended on contact between the charcoal element and gas. Briefs entirely made of activated charcoal fabric appear to provide the greatest surface area for contact with malodorous rectal gas. The absorption of odorous gas by clothing suggests that washing outer clothing as well as underwear is important to reduce odour.

Some products aim to reduce the amount of malodorous flatus that is produced. Administration of the probiotic, Lactobacillus plantarum, (5 x 10^7 cfu/ml) in a randomized trial of 60 patients with IBS significantly reduced flatulence (by half in 44% of patients). Only 18% of the placebo group reported reductions of flatulence [682]. Although administration of charcoal, yucca and zinc acetate reduced the percentage of episodes of malodorous gas [683], there are inconsistent findings about reductions in flatulence from ingesting activated charcoal in humans [165] [684]. Two clinical trials involving small sample sizes (19 and eight persons, respectively) showed that the over-the-counter product, Beano, which contains α-galactosidase, reduced flatus frequency in normal persons following the ingestion of beans [685] [686]. A significant reduction in cumulative breath hydrogen excretion over an 8-hour period after α-galactosidase versus placebo suggests α-galactosidase reduces flatus production [686]. Although Ganiats et al., 1994 [685] reported a significant decrease in flatus using 240 galactosidic units (GalU), Di Stefano reported that effects of 1200 GalU but not 300 GalU were significantly different from placebo. One GalU is the amount of galactosidase that releases 1 μmol of galactose from its substrate in one minute [686]. Differences in the test diet or lack of adequate statistical power may explain these differences since neither study reported a power analysis. Although a reduction in the amount of intestinal gas produced may decrease the volume of odour, it may not decrease its potency or perceived odour.

A few products are available that aim to prevent, absorb, or control odour associated with involuntarily leaked stool or flatus associated with faecal incontinence. These include cushions and pads that absorb odour as well as probiotics and enzymes, which aim to reduce production of malodorous gas.

3. RECOMMENDATIONS

- Briefs made of activated charcoal fabric are recommended over pads or cushions containing activated charcoal for absorbing odoriferous rectal gas (**Grade of Recommendation C**).
- Since some pads absorb up to 75% of gas, there may be value in offering patients who have smaller amounts of gas the opportunity to compare pads and briefs for themselves. (**Grade of Recommendation D**).
- For those persons experiencing stool leakage due to flatus, over-the-counter α-galactosidase containing products, which reduce flatus frequency, can be tried in an attempt to reduce FI frequency (**Grade of Recommendation B**).
- Washing of outer as well as under clothing after flatus is recommended to reduce odour due to absorption of gas by clothing (**Grade of recommendation of C**).

4. PRIORITIES FOR RESEARCH

- Investigation of whether probiotics or changes in dietary intake can modulate or reduce the odour of flatulence or leaked faeces.
- Development of an absorbent product that can reduce the odour of leaked faeces while protecting the skin.
- Investigation of the efficacy of anti-microbial agents in textile products (soft furnishings and bedding) for reducing odour associated with urinary and faecal incontinence.

I. LITERATURE SEARCH

A systematic review of the literature using online databases Scopus, Medline/Pubmed, Embase, Biosis, Cinahl, Pychinfo, Psychlit, ERIC, Cochrane Library, Web of Knowledge, and CNKI (China National Knowledge Infrastructure) was conducted. The focuses of the searches were from 2008 to March 1, 2012, although literature from the preceding 15 years was also searched to ensure thorough coverage. The following search terms were used in various combination: awareness, consumer, education, urinary incontinence, faecal incontinence, incontinence, continence, continence awareness, continence promotion, health education, public education, population-based prevention, health promotion, help-seeking, care seeking, continence nurse, continence advisor, public awareness, prevention, primary prevention, pelvic organ prolapse, interstitial cystitis, bladder pain syndrome, painful bladder syndrome, allied health care professionals, self-care practices, outcome measures. There was significant overlap between the searches made on different databases, as would be expected. Non-English language guideline references were noted, but excluded from the review unless they contained an English-language abstract providing sufficient information.

II. INTRODUCTION

Continence promotion, education and primary prevention involves informing and educating the public and health care professionals that urinary and fecal incontinence can often be prevented, can be treated successfully in most cases, and can always be managed. Other bladder disorders, with links to incontinence, such as bladder pain syndrome/interstitial cystitis and pelvic organ prolapse, can also be treated and managed successfully and are often included in continence awareness programs. The Fourth International Consultation on Incontinence (ICI) Continence Promotion, Education & Primary Prevention Committee stressed the importance of all health care professionals promoting primary prevention of incontinence [1]. It was acknowledged that this would require raising the level of community awareness, providing public education as well as addressing health care professionals' education. While some advances have been made, these strategies remain a priority.

Taboos surrounding disorders of the bladder and bowel are gradually lifting in most cultures [2]. Two decades ago it was almost impossible to discuss urinary incontinence in the media. Today, in many countries, government funded initiatives and practice guidelines have been developed in the area of urinary and faecal incontinence [1,3,4]. Around the world, expert panels have suggested that urinary and fecal incontinence be combined through a multidisciplinary approach to further research priorities. Thus, there have been advances in promoting awareness of both of these conditions. Popular magazines, local and national papers, radio, and television, regularly cover topics of men and women relating to urinary incontinence in most developed countries. Many countries have run national or local public awareness campaigns, often spearheaded by a national continence organization. Many also have confidential "help lines," which can be accessed anonymously. The internet provides a convenient source of health information for a growing number of consumers. Some experts believe that persons with incontinence might get valuable advice and comfort by using interactive services such as internet "chat rooms." However, in many developing countries, accessible public information and campaigns relating to continence are limited or non-existent. Though information may be available in principle on the internet, access to the internet may itself be limited.

This chapter updates previous ICI chapters on four areas: continence awareness and promotion, service delivery, professional education, and primary prevention along with the recommendations in each area. The majority of information available relates primarily to urinary incontinence (UI) and faecal incontinence (FI) and less to bladder pain syndrome/interstitial cystitis (BPS/IC) and pelvic organ prolapse (POP). The first section reviews continence awareness by discussing health promotion and help-seeking (care-

seeking) behaviors (HSB) for these conditions. It is evident that progress has been made in the promotion of continence on a worldwide basis, but not much has changed in HSB for these disorders. There is a lack of evidence on translating awareness into behavioral change and on what triggers HSB. Information is provided on continence promotion programs and advocacy through worldwide organizations. Although there is a great deal of published information on building public and health care professional awareness of incontinence, there is minimal information on the effectiveness of changing public and professional attitudes and knowledge about it. The second section discusses service delivery and models of continence care. The third topic reviewed is the education of professionals in these areas (UI, FI, BPS/IC and POP) including the development and use of medical guidelines and care pathways. Finally, since these conditions are prevalent but often ignored by sufferers and professionals, the fourth and final topic addressed is population-based primary prevention research. There is a need for further research to substantiate the benefits of primary preventative strategies, including long term follow-up. The committee found more information about initiatives in all of these areas but very little evidence-based research to support the effectiveness of the initiatives or care.

III. CONTINENCE PROMOTION AND AWARENESS

1. BACKGROUND

Health promotion was defined by the Ottawa Charter for Health Promotion in 1986 as "the process of enabling people to increase control over and to improve their health."[5] Hence, health promotion is an important factor in primary, secondary and tertiary prevention efforts directed at individuals, communities and populations with, or at risk of developing, incontinence.

Efforts to promote continence awareness may be enhanced by adopting evidence based theories and methods from the field of health promotion. Health promotion frameworks can be used to plan and evaluate the effectiveness of strategies and programs used to promote continence. When planning health promotion interventions, consideration needs to be given to the demographic features of target groups including age, gender, culture, language and socioeconomic background [6].

2. RAISING AWARENESS AND UNDERSTANDING

The main reason to educate consumers – individuals with, or at risk of, incontinence and their family members or informal caregivers – is to increase awareness of incontinence and the benefits of prevention and management, with goals of eliminating stigma, promoting help-seeking, and reducing suffering [7,8,9]. While in some countries there is strong governmental support, much of the health promotion effort related to continence issues is undertaken by the many professional bodies, non-governmental continence organizations, and advocacy groups listed in Appendix I. Health education activities can involve educational, health-care, and community service providers, and may include a range of components including materials that are accessible, comprehensible, trustworthy, and culturally sensitive, formal and informal health advice systems such as including a hotline, online support and health care professional learning systems [10].

Consumer education is a critical component of effective continence promotion. This includes both general information about UI[11] and methods to identify potentially modifiable risk factors for UI [12]. Patients with UI have a wide variety of ideas and attitudes about why they leak urine [13]. Knowledge about specific aspects of UI is often limited, indicating an area for improved consumer education.

Consumer knowledge about FI is also generally limited. A recent study found that many patients had a significant emotional component to their experience of FI and that knowledge about the terms used to describe the condition was often limited [14]. A United States (USA) Public Broadcast (PBS) Second Opinion medical television program was develop to educate consumers about FI and attempts to dispel the stigma of this condition (www.iptv.org/video/detail.cfm/12719/sopt_20101018_fecal_incontinence_apt).

The Internet is frequently searched for health information, and coverage of relevant health topics is growing. This method of acquiring health information is widely accessible, anonymous and informal, with estimates indicating that around 20% of USA adults use the internet for this purpose [15]. Since one-quarter of adults do not go online, the percentage of health information seekers is 59% among the total U.S. adult population (http://pewinternet.org/Reports/2011/HealthTopics/Summary-of-Findings/Looking-for-health-information.aspx). Thus, accessing information about incontinence has become much easier in the age of digital technology, especially for internet users with a higher literacy level [10]. A 2011 Google search for "urinary incontinence" and "faecal incontinence" yielded about 4.8 million and 311,000 websites respectively; "interstitial cystitis" - 2.2 million sites, "bladder pain syndrome" – 105,000 sites and "pelvic organ prolapse" – 382,000 sites. These figures are all two to three times greater than a similar search in 2008. Many of the sites were related to non-government organizations such as the International Continence Society (ICS), the National Association For Continence (NAFC), the Simon Foundation, the Interstitial Cystitis Association (ICA), and the International Foundation for Functional Gastrointestinal Disorders (IFFGD).

In light of the reluctance of those affected by stigmatized illnesses such as incontinence to seek treatment or to ask health care professionals for information, the Internet may prove to be a useful tool for consumer education and public health outreach [16,17]. In a national survey of internet users in the USA, Berger et al[18] found a trend among people with a stigmatized illness such as UI to be more likely to report that internet use increased their communication with a health care provider and utilization of health care. The quality of these materials can vary widely and providers should help interested patients to navigate resources that provide accurate information. A recent study showed that most websites that provide UI information are not certified by any accrediting body [19]. There were also differences observed between sites run by professional organizations, educational and government agencies, and companies either for profit or non-profit.

Among those who do not use the Internet, 60% are aware of publicly available Internet access points within their community [20]. However, people with low levels of education and low socioeconomic status are less likely to use the Internet [21]. Research has questioned the quality of continence information on the internet and suggested that validation is needed [22]. Healthcare professionals can assist patients in finding reliable information sources by providing details of reputable web sites [23].

The Internet has changed the way many people access health information, and has much to offer as a means of health education and raising awareness. But Internet access is far from universal, especially in developing nations and among older and poorer sections of society in developed nations. Thus, it is important that more traditional awareness-raising and education methods are still used, such as information posters, leaflets and booklets distributed through health outlets such as clinics and pharmacies, and articles in the popular media. In both developing nations and in countries with limited health systems and dispersed populations, more innovative techniques have been successfully used for health education, such as dissemination of information through community nursing infrastructures and lay health workers.

Social network sites may be the future source of information for consumers. Sajadi and Goldman[24] used the word “incontinence” to search for information on Facebook, Twitter, and YouTube, to evaluate its usefulness. Their conclusion was that social networks have insufficient useful incontinence content, especially from healthcare professionals and incontinence organisations. However, they recommended that medical professionals and societies target these avenues to reach and educate consumers.

3. HELP-SEEKING (CARE-SEEKING) BEHAVIOR

Estimating the prevalence of continence problems is difficult due to different definitions of incontinence, different populations and different data collection strategies,[25] and this lack of clarity regarding baseline prevalence of incontinence undermines efforts to determine the proportion of those affected that seek help. Despite the considerable impact of both UI and FI on quality of life (QoL), it is clear that many people never seek help for their incontinence, although the precise level of under-reporting is difficult to determine [26,27]. Perhaps of more concern is a recent comparison of HSBs in two surveys conducted sixteen years apart (1991 and 2007) which revealed that there had been virtually no increase in the proportion of women seeking help for lower urinary tract symptoms (LUTS) [28].

Qualitative research has described a process that takes place and influences the decision to seek treatment (or not), whereby consumers affected by incontinence, or other chronic, non-life-threatening conditions, weigh the perceived costs and benefits of treatment (in terms of discomfort and inconvenience as well as financially) against the effect of the condition on QoL [29].

Instead of seeking care, individuals with UI and FI alter their lifestyle and develop elaborate “self-care” practices (e.g., stopping exercising, use of protective products, dietary and fluid changes) to conceal and/or mange symptoms and improve QoL [30,31,32,33]. Data from focus groups of women showed self-reliance and the development of personalized strategies to alleviate symptoms [34]. Some patients have been known to make major changes in their lives (e.g., quitting their jobs). Surveys have also revealed extensive use of coping mechanisms for overactive bladder (OAB) symptoms of urgency and frequency (e.g., toilet mapping) [35].

Several studies have estimated levels of help-seeking for specific consumer groups. An integrative literature review of HSB for UI symptoms among non-institutionalized women of all ages indicated that less than 38% of women sought help for their UI symptoms [36]. Age, type, and severity of UI, and embarrassment have been found to be significantly related to seeking care [37,38,39].

Kinchen and colleagues [26] noted that women with UI waited more than a year before seeking help from a health care provider or professional [26]. This delay is in line with a European survey that reported that consumers wait from 2 to 11 or more years before seeking treatment [40]. Huang et al[41] reported that fewer than 50% of women in the USA with clinically significant UI reported seeking treatment. This was despite the fact that all women in this study had health insurance to cover such services and had continuous access to a primary care provider. Only 12% of women with UI attending obstetric and gynaecology clinics in Turkey had sought help for their incontinence [42]. Shaw and colleagues[43] surveyed adult women attending primary care practices in United Kingdom (UK) and of those who noted UI symptoms (n=3273), only 15.8% of women with

stress UI, 32.3% of those with urge UI, and 33.7% with mixed UI had sought help for urinary symptoms during the preceding 12 months. Rizk[44] found that of women affected by UI in the United Arab Emirates (UAE), only 30.9% had sought medical advice.

Surveys of individuals with FI also indicate a lack of HSB. In 2010, the IFFGD conducted an online survey to help explain what it is like to live with and manage FI from the point of view of those who experience the condition (http://www.aboutincontinence.org/pdfs/319-IFFGD%20Incontinence%20Survey%20(9-11).pdf). A total of 142 individuals completed the survey, responders were recruited primarily from the IFFGD websites. Ninety-seven (68%) of the survey responders indicated they had never been diagnosed by a physician, giving reasons such as "too embarrassed to bring it up" and "feel I can manage the condition on my own." Of the 32% who had mentioned their FI problems to a physician, the physician implied there is not much to be done about it or it is a normal part of aging.

a) Barriers to seeking care

Understanding the barriers and reasons why people do or do not seek treatment for incontinence is hampered by the ethnic homogeneity of the existing data, which has been derived mostly from white populations, and there is a lack of comparisons with ethnic and minority populations. The strategies for promoting HSB need to be culturally appropriate to the populations of interest [45,46,47]. Rates of HSB for UI amongst minority groups may relate to a number of factors such as access to care, socioeconomic factors and access to or comprehension of health education campaigns or materials [48,49,50].

Help-seeking behaviour is dependent upon awareness and understanding [51] and lack of knowledge has been a significant barrier to people seeking help for continence issues. Furthermore, HSB for UI, FI, BPS and POP may be different depending on the person's culture, ethnicity, gender and socioeconomic groups.

Questionnaires have been developed and validated which can be used to assess consumer knowledge about UI and POP [52]. In 2008, a study (n = 126) found that white women had greater knowledge of UI than non-white women while both groups of women had higher levels of knowledge of UI compared to POP [53]. Using this instrument, research has shown that there appear to be important differences in health literacy about these conditions in different racial and ethnic groups.

Another study found that Korean American women living in America tend to rely on information and social support from family and friends rather than seeking professional advice for UI [54]. The women in this study sought help less frequently, had less knowledge and more negative attitudes towards UI than other community members. It was suggested that these factors influenced help-seeking in this group of women [55].

In certain parts of the world, cultural factors can affect the experience of incontinence and HSB and the gender of the health care provider may be a barrier. Knowledge of continence issues in UAE women was researched by Rizk and Hassan [56]. It was found that UAE women perceive continence problems to be neurological or "senile" disorders rather than related to childbirth or menopause. Quantitative data was derived from a community-based descriptive cross-sectional study conducted in Sri Lanka from 2006 to 2007 with 1,718 married women, aged 15-49, of whom 9.8% reported problems of stress UI [57]. Although incontinence affected outdoor activities, sexual life, and sense of wellbeing, women did not consider it a health problem, rarely discussed it with others, and rarely sought treatment. Barriers to help-seeking included fear of vaginal examination, shame and embarrassment, and belief that stress UI was a natural consequence of aging and childbirth. Within all cultures, embarrassment or shyness may prevent some women from seeking care for UI [58,59,60,61]. These have been shown to impact help-seeking in Middle Eastern women, where both UI and FI are underreported. In the UAE, cultural attitudes and inadequate public knowledge, and male health care providers have been identified as barriers to seeking health care for women, despite the effect on QoL. Rizk[44] found that women affected by UI in the UAE, were troubled by their inability to pray (90%) and to have sexual intercourse (33.3%). Saleh[62] found similar results when surveying women in Qatar who reported that UI interfered with their ability to pray (64%) because of lack of cleanliness and need to void, and 47% reported that UI interfered with marital relationships. El-Azab and colleagues[63] found that encouragement from husbands, severe UI and the desire to be able to pray were associated with an increased likelihood of HSB [63].

Rizk and colleagues (2001) investigated the prevalence and HSB of UAE women with FI (n = 400, mean age 37.9) and also found that many did not seek medical advice because they were too embarrassed to consult their physician and preferred to discuss the difficulty with friends (64.7 %), assumed that FI would resolve spontaneously (47.1 %), felt it was normal (31.3 %), or they chose self-treatment as a result of low expectations of medical care (23.5 %). As with UI, women with FI were bothered by the inability to pray (92.2 %) and to have sexual intercourse (43.1 %).

These studies reinforce the need for different strategies to be targeted to cultural and minority groups with low levels of HSB for UI and FI. In addition, public education efforts related to UI should not just focus on older adults [64]. An earlier study of high-school and college age athletes in the USA found that more than 25% of the young women surveyed

experienced UI during strenuous physical activity, but 90% had never reported their symptoms to anyone [65]. A recent study of nulliparous female athletes also found that young women have low levels of HSB for UI [66]. This study found that UI issues occurred particularly during training and to a lesser extent, during competition in women of varying competitive levels ranging from high school to elite level athletes. The prevalence rates of UI in nulliparous women in recent studies have varied from 28% to 52% and are influenced by the type of athletic activity. A 2011 study found a lower prevalence rate of UI in women playing volleyball compared to higher rates occurring in women performing track and field, soccer and gymnastics [66].

Barriers to seeking help for continence issues that have been frequently identified in the literature include embarrassment, social stigma and the mistaken belief that incontinence is inevitable, untreatable, and/or a normal part of aging [67]. The authors of a Swedish study suspected that lack of knowledge, worries about different procedures and negative expectations may be important factors in reducing the desire to seek treatment among even those most severely affected [68]. Embarrassment and fear of humiliation have been identified as the major factor influencing reluctance to seek help among women with long-term UI [69]. Among women affected by UI in the UAE, reasons for not seeking help included embarrassment (38.2%), choice of self-treatment because of low expectations from medical care (38.2%) and assuming that UI is normal (23.3%) [44]. Among women with gynaecological cancers who experience concomitant LUTS, the failure to seek help for the latter symptoms has been attributed to a perception that the LUTS were not serious enough symptoms to warrant attention and lack of awareness of treatment options [70].

Advice given by physicians can affect a patient's ability to change health behaviours [71]. Opportunities to promote continence can present themselves during other health screening activities (e.g., yearly physical examination) [72]. While health care professionals may enable people to seek help, those who have a lack of interest in incontinence can negatively affect HSB in consumers [73,74].

Other initiatives to promote HSB can include providing written information [75]. Continence health promotion information provided in a brochure [76] and in a computer based program,[77] have been found to improve HSB. However, language, level of education and cultural factors may also be barriers to seeking help [78]. Consideration should be given to health literacy in target populations and this will affect the ability to read and understand health information in written formats. Poor health literacy results in lower rates of health seeking behavior [79].

The Boston Area Community Health (BACH)[80] population-based random epidemiological survey of urologic symptoms (n=5503) indicated that the stigma of UI also includes other LUTS. They reported that OAB symptoms of urgency and frequency were linked to social interruption, loss of socially-expected control of the body, not understanding the nature of the bladder problem, and the need to mix private behavior and public space. The stigma of OAB and UI was correlated to whether the problem was perceptible (i.e., odor, or observation of trips to the bathroom or soiled clothes) or concealed. Men reported feeling stigmatized for being seen making frequent trips to the bathroom and feared being viewed as impotent. Women feared being stigmatized based on having an unclean body and a compromised social identity. Like others, Hispanic individuals wanted to keep urinary symptoms a secret from others.

Surprisingly, the perception that incontinence is not important or serious enough to warrant treatment has even been found to affect HSBs in women with recurrent UI following surgery for UI and POP [81]. Women with POP have also reported that fear and embarrassment are barriers to seeking help. Symptoms such as nocturia have been linked with serious consequences such as falls and associated morbidity in older adults. Bladder and bowel incontinence is a deviation from social norms, which in most cultures there are defined complex and sensitive rules and behaviours for bladder and bowel emptying [82,83]. If incontinence occurs in adulthood, it can cause a decrease in self-esteem and feelings of not being "normal."[84] These perceptions, which can affect help-seeking, are shared by the public as well as by many health care providers [85].

b) Gender-specific disparity

The impact of UI may also differ depending on gender but little is known about gender differences in HSB. Teunissen and colleagues [86] interviewed independently living patients (56 men, 314 women) 60 years and older with uncomplicated UI. Men reported higher impact scores than women, despite the fact that incontinence was less severe in men. The most important effect of incontinence reported in men was ''being out of control," while most women considered ''feeling compelled to take several precautions'' to be the most important consequence of UI. Researchers in Egypt interviewed 353 patients attending clinics at hospitals in Alexandria, Egypt [87]. They found differences in men and women as women suffered from at least one negative impact on their social lives compared to men. The impact of symptoms on QoL appeared to be the main trigger for seeking help for UI in both men and women. Women had fewer hospital admissions and hospital days and less use of diagnostic procedures and surgery.

There is very limited data on ways to improve men's awareness of bladder and bowel health [88]. Gender specific health disparity may exist as men tend to be less proactive in HSB for UI. There is a need

for gender specific strategies to address this [89]. Men with LUTS have been found to seek help less frequently than women [90]. Consumer surveys conducted over a 5-year period by the USA continence advocacy group, the NAFC, indicated that only 26% of respondents (18% of men and 33% of women) reporting bladder control symptoms had discussed them with a doctor [91]. However, a study into the prevalence of UI in men in the USA found that while a low proportion of men with continence issues sought help, those who did, consulted their doctor within 12 months of the onset of symptoms, a shorter period than the length of time taken by women to seek help [92]. Men are more likely to seek help for LUTS if they have had advice from others or received information in the media, rather than seeking help as a result of their symptoms [93].

In certain parts of the world, the gender of the health care provider may be a barrier. Doshani et al[94] explored views and experiences of South Asian Indian women with UI and found that feelings of embarrassment were present, especially with male health care providers.

c) Symptom impact and bother

The level of perceived bother (physical, emotional and/or economic) associated with incontinence also affects HSBs. A number of studies have found that those affected by incontinence are not necessarily so bothered by it as to want to seek professional help. In Japan, it has been found that 55% of elderly incontinent people do not consider incontinence a bother [95]. Of women with UI attending obstetric and gynaecology clinics in Turkey, 53% were found not to be bothered by their incontinence [42]. In a population-based study in Sweden (a supplement to a comprehensive survey of public health and general living conditions), a postal questionnaire comprised of 12 questions on UI received a response rate of 64.5% from 15,360 randomly selected residents (aged 18–79 years) [68]. The prevalence of UI was 19% (when defined as “any leakage”) and most considered their problems to be minor. Only 18% of those with UI desired treatment. Of the 17% who had reported severe problems that interfered with daily life, 42% did not want treatment. A recent study by Visser and colleagues[39] showed that older adult women, who did not consult a general practitioner (GP) about incontinence symptoms, were more often younger and had lower levels of distress due to their urogynaecological symptoms, but the main reason for not seeking help was they did not consider their symptoms to be severe enough [39]. An internet survey in the USA, the UK and Sweden, noted that in men and women who reported LUTS less than a third of respondents reported seeking treatment [96]. Rates of bother were greatest for those who reported multiple storage, voiding and post-micturition LUTS (men 83%, women 89%) and correlates of treatment seeking across genders included bother due to weak stream, incomplete emptying, perceived daytime frequency, nocturia and urgency.

With chronic problems like UI, FI, POP and BPS/IC, it is important to understand what triggers the consumer to consult a health care provider [83]. Yet factors that lead those affected to seek help for continence issues remain less well researched than those that prevent help seeking. Women with stress UI are more likely to seek help when there is severe leakage that is having a significant impact on their QoL [97]. The importance of the effect of UI on QoL is supported by Brazilian research [98]. An American study suggests that worsening severity of UI, along with increasing age and not being obese, were associated with an increased likelihood of help seeking [99]. Older people may be keen to seek help if they are concerned that a health issue, such as incontinence, impacts on their ability to remain independent and living in the community [100].

In conclusion, the most commonly reported reasons for not seeking help for incontinence are lack of knowledge and awareness, embarrassment, a perception that incontinence is not sufficiently important to warrant treatment or is “normal” either at certain stages of life or in association with childbirth or certain illnesses, and low expectations of the effectiveness of treatments offered. The more serious the impact of incontinence is on QoL, the greater the likelihood of seeking help, but this will be balanced against the perceived disadvantages of treatment in terms of cost, discomfort or inconvenience.

4. CONTINENCE PROMOTION PROGRAMS

Continence promotion programs vary across countries and cultures, but share the same aim of increasing awareness and understanding of incontinence. Efforts to raise awareness of continence issues need to consider the following:

Target population - Continence promotion programs need to consider age, gender and culture of target populations. It is necessary to consult with target groups when planning programs in order to meet the needs of these groups and to enhance HSB [101].

Target issues - A continence promotion program needs to address risk factors and management options in different target groups. Community-based interactive continence promotion workshops conducted in a recent cohort study in Canada were shown to be well-received by participants and the interventions changed knowledge, attitudes, skills, and appeared to increase rates of HSBs [102]. A similar study showed that improved understanding about UI and POP was associated with improved QoL scores among women who attended a nurse-led educational workshop [103].

Promotional material – Newman [104] reported on a mail survey of 1,500 women, noting that most of the 422 respondents wanted more information regarding UI, and while they may not be equipped to fully

understand the problem, they expect doctors, nurses, medical professionals, retail outlets, medical supply companies, and mail order houses to provide the information, including information through consumer advertising.

Communication and expectations – Health care professionals may launch campaigns or seminars to increase practice revenues. Commercial companies often fund public campaigns in order to sell their products, whereas continence organizations may be driven by missionary zeal or organizational growth. Regardless of motivation, care should be taken to avoid raising public expectations beyond what the services or products can deliver [105].

a) Creating public awareness

In the area of UI, building awareness among the general public has usually been attempted via the media. The USA National Institutes of Health, in partnership with the American Urogynecological Society, American Urological Association, American Foundation for Urologic Disease, NAFC, Society of Urologic Nurses and Associates and the Simon Foundation for Continence, launched a national awareness campaign in 1997. The Let's Talk About Bladder Control for Women awareness campaign (http://kidney.niddk.nih.gov/kudiseases/pubs/bcw_ez/index.htm) offered easy-to-read booklets explaining the symptoms, types and causes of poor bladder control, as well as treatment options. The materials were designed to encourage and enhance communication between and among women and their health care providers. Free consumer and health care provider kits were available through a toll-free phone number. In 2007, the USA National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), National Institutes of Health (NIH) State of the Science Conference Statement on Prevention and Fecal and Urinary Incontinence in Adults paved the way for the 2011 national campaign, Let's Talk about Bowel Control (www.bowelcontrol.nih.gov). In 2001, the NAFC in the USA produced and disseminated continence awareness public service announcements (PSAs) to 380 television media markets, including Hispanic outlets. In the UK, the Bladder and Bowel Foundation (BBF), supported by the pharmaceutical industry, has conducted a lengthy campaign to raise awareness of OAB and to encourage HSBs (www.bladderandbowelfoundation.org/?p=1550). The campaign has featured advertisement of a toll-free information line on television, in the print media and on public transport. The BBF also provides informational leaflets on a variety of continence-related topics and a website containing a great deal of information as well as a directory through which visitors can locate their nearest continence professionals and clinics. Another UK organization, Education and Resources for Improving Childhood Continence (ERIC), offers courses for school nurses on how to deal with school children with UI, as well as children with medical issues (http://www.telegraph.co.uk/education/primaryeducation/5956231/Pupils-start-school-still-in-nappies.html). In Australia, the government has provided a high level of support to continence promotion activities via the National Continence Program [106,107,108]. These are just a few examples of campaigns conducted by organizations to bring awareness to lower urinary tract conditions.

Media campaigns should use multiple channels to ensure the broadest coverage [109]. Channels can include print media, television and radio, while the Internet, phones, and other mobile devices are also effective outreach channels [110]. Specialised age and health publications offer potentially valuable channels for dissemination of continence advice. At a more local level, a useful channel for dissemination can be the use of posters and brochures placed in medical offices, hospitals, seniors' centres, pharmacies and churches and direct presentations to the public, such as at senior citizen's centres [111] or retirement communities [112]. In many cultures, an effective strategy for reaching the public is through an informed journalist. Journalists often use a "media hook," an interesting story that will take priority over other news on the television, radio or newspaper. In addition, having a spokesperson affected by incontinence or finding a celebrity who is willing to speak for the cause can help [82]. These individuals can act as "influence leaders."

The Japan Continence Action Society held a "Toll Free Telephone Clinic" and callers were asked how they heard about the line. The responses in 2006 were: 30% from television, 16% from the web, 11% from a newspaper, 9% from a book, 6% from a friend, 5% from a brochure, 3% from a magazine and 20% other and/or unknown. A UK campaign [113] found that newspapers were by far the most common source of information, followed by radio. However, with the growth of the Internet and social media, print campaigns may no longer be the most effective avenue for awareness.

Roe [114] suggested that local initiatives on the availability of services and how to access them, as well as health education information on UI, may be particularly effective in raising public awareness and should supplement national campaigns. Awareness raising materials include pamphlets, self-care instructions, visual aids, pictographs, posters, banners, decals and advertisements in newspapers, magazines, newsletters, CD and films. Muller [115] believed that the change related to increased public awareness and HSB for continence care is likely to fuel the demand for innovation in technology and products. The Simon Foundation for Continence developed an innovative community education initiative, The Bladder Health Mobile. The goal of this initiative was to provide education, increase public awareness, and promote early diagnosis and proper treatment of UI and other bladder control problems [116]. However, it was never launched due to a lack of funding.

Health literacy related to UI is an important issue,

and is a potential target for additional consumer education. Raising awareness of health problems and providing information on terms used to describe symptoms assists in promoting HSB [117]. The words "continence" or "incontinence," "interstitial cystitis," or "painful bladder syndrome," or bladder pain syndrome and "pelvic organ prolapse" are poorly understood [118] and simpler terms may achieve greater public recognition in many languages and cultures. The use of "overactive bladder" in advertising has increased reporting of the condition to primary care professionals in the USA. Palmer and Newman [74] reported on a USA health promotion project conducted in 2000 to determine the needs of senior citizens concerning bladder control issues. Focus groups of older adults attending health seminars in urban, community and church settings were conducted. The primary objective of the project was to determine the understanding of older adults in the areas of general health and their beliefs surrounding the problem of UI. The 82 participants were predominantly African-American women representing all socio-economic levels. Seniors expressed confusion when asked if "overactive bladder, bladder control issues and UI" were the same condition. An evaluation of Australia's National Continence Management Strategy in 2006 noted that recognition of the barriers to help-seeking and identification of the most appropriate terminology and key messages would strengthen awareness raising strategies [106,119].

In the UK, campaigns and consumer literature often avoid clinical terms in favor of lay terms that focus on the need to go to the toilet often, worrying that one may not make it to the toilet on time or have "leaking" of urine or feces. In the area of bowel disorders such as FI, it is felt that people find it difficult to find the right words to discuss their symptoms [85]. The IFFGD in the USA has found that people will often report having diarrhea to their physician. If the physician or nurse does not question the patient any further regarding the ability to control gas, liquid or solid stool, the incontinence may not be discovered.

Lack of understanding about terminology and physiology may lead to difficulties with communication between patients and providers. A survey of 138 women attending continence clinics in the UK, Australia, and Italy found that over 20% of women were unsure of the meaning of basic continence terminology commonly used by health care providers [120]. Terms tested in this study included "daytime frequency, nocturia, urgency, urge UI, stress UI, and hesitancy." Two recent studies highlight the confusion and lack of knowledge about LUTS. Smith and colleagues [121] study of focus groups with women who experienced OAB, showed that there were high levels of misunderstanding about symptoms and physiology, and miscommunication between patients and providers. The finding was more pronounced among the older women in this study. Senejian and colleagues[118] corroborated this finding and recommended that public health campaigns about UI and other pelvic floor disorders need to use terminology targeted to the basic understanding of consumers.

Some researchers have targeted health literacy of patients undergoing urodynamic testing [122]. Theoretically, this may help to improve understanding of the procedure and reduce patient anxiety. This particular study did not reveal significant differences in overall satisfaction between the group that received this additional information and those who did not. A similar study revealed that after reading this type of material, most women (78.1%) felt they understood the indications for urodynamic testing [123]. However, fewer felt they understood what the procedures would involve (68.2%) or that they had enough information about the tests (64.9%). Many patients still expressed anxiety or embarrassment about the procedure. Additional research will be needed to determine how best to deliver this type of information to improve patient experiences.

b) Program evaluation

Evaluating the effectiveness of health promotion programs is notoriously difficult. Evaluation methods should be established prior to developing the continence promotion program. Evaluation should include quantitative measurements and qualitative measures. Open-ended questions may be more sensitive than "direct satisfaction" questions [124]. Health promotion evaluation methods include process evaluation, impact evaluation and outcome evaluation.

Research-based evidence for the effectiveness of programs aimed at raising awareness of continence issues or at improving help-seeking behaviors is rare [125]. A number of studies have considered the effectiveness of leaflets or brochures in raising awareness of UI and of treatment options and while generally supportive of such information, the evidence is contradictory in some areas and far from conclusive. In a good quality study of 1,175 participants, Wagg et al [126] reported that a self-help standard treatment leaflet is as effective as structured help from a continence nurse in reducing bothersome urinary symptoms in women. A small Australian study considered an information leaflet to have influenced the HSBs of people with UI who had received it, but these were people who were identified in a primary care setting and had already reported a UI problem [127]. A similar study found that individuals given a continence education package, which included a Continence Educational Brochure, helped to improve the health-seeking behaviours of participants who were bothered by UI symptoms [128]. Within 3 months following the education, of the 111 participants who were bothered by UI symptoms, 49 participants (44.1%) indicated that they had discussed the issue of bladder or bowel problems with a health care professional, but this could have been either directly because of the information contained in the brochure or because of

information contained in the leaflet. But there is research that indicates that education alone may not improve a person's understanding or experience with specific medical care. A study that investigated the effectiveness of detailed educational materials, about the urodynamic tests given to women undergoing these investigations, did not significantly improve their experience [129]. A Swedish population-based study found that the distribution of a brochure on UI to the general public was well received and can be an efficient method to spread knowledge and encourage self-management [130].

In France, the effect of direct health education was evaluated in a randomized study in sheltered accommodation for the elderly [131]. Twenty centers were randomized to either a single one-hour health information meeting or control group. During a 30-minute talk, a nurse encouraged people to visit a physician if they had urinary problems. A questionnaire three months later found that the experimental group was much more likely to have had treatment if they were incontinent (41% vs. 13% controls). Similarly, knowledge and symptoms were found to have significantly improved three months after a 2.5 hour nurse-led workshop for women with UI and POP [132].

A health promotion project called 'Dry Expectations' was developed and implemented in six ethnically diverse, predominantly minority, and inner city senior centres in the USA in 1996 [111]. The program was designed to address an older population. The project consisted of three phases: orientation and training of key staff members/peer educators at the centres (train-the-trainer model); educating seniors through four one-hour weekly sessions involving visual aids and completion of bladder records and quizzes; and follow up sessions with senior staff/peer educators to reinforce the previous training. The program was very well received by the participants and approximately 80% felt they had more control over their bladder by the end of the last session.

The interventions that are most effective in reaching the public and triggering the desired behaviour seem to vary between countries and cultures. Television and newspapers work best in Singapore, with a "cured" patient bearing testimony to former suffering and its alleviation having the most impact. In the USA, television advertising targeting OAB, funded primarily by pharmaceutical companies, has yielded a significant response. Nationwide television reaches more people than the circulation of any single newspaper or the distribution of a booklet through physician offices. In March 2008, Japanese National Television broadcast a program about UI during "golden time" (2000 to 2045 hours). The audience rating was 15.6%, the highest in a year (usual rating 12%), and more than 500 calls were received in one night, requesting repeat broadcast and more details about treatment. However, the Internet is rapidly becoming the most effective and quickest way to reach the largest number of people. But there are cultural differences in the how online health information is used, as well as the types of sites users prefer to surf [110].

5. RECOMMENDATIONS FOR CONTINENCE PROMOTION AND AWARENESS (GRADE D)

Based on the literature reviewed in this section, the following recommendations can be made:

- Continence awareness should be part of mainstream and on-going health education and advocacy programs with emphasis on eliminating stigma, raising awareness of effective treatments, promoting HSB and improving QoL.
- Continence awareness programs should include education, health-care, and community service providers.
- Research is needed to provide higher levels of evidence on the effectiveness of continence promotion programs to include:
  - o Identification and understanding of barriers to HSBs
  - o Translation of promotion research into improved clinical practice and identification of methods by which this occurs.
  - o Effectiveness and impact of consumer education initiatives.

IV. CONTINENCE ADVOCACY

1. BACKGROUND

Advocacy is defined as the act or process of defending or maintaining a cause or proposal. Advocacy, as it pertains to incontinence, involves assisting individuals in finding necessary health care and treatment. Organisations consisting of professional and public members promote continence advocacy as a core mission.

There is little doubt that incontinence is a common problem that often goes unreported, with those affected anxious to conceal the problem and reluctant to discuss it. Misconceptions fuel this reluctance, such as the widespread belief that incontinence is normal in some circumstances, especially in women following childbirth or in both sexes after a certain age. Incontinence is associated with a very strong stigma that sets it apart from most other health problems and will inevitably influence behaviours. Whereas many formerly stigmatized health issues such as cancer and women's health are more openly discussed today than previously, incontinence remains for the most part shrouded in silence [133,134]. Yet the effect of incontinence on self-image, emotional well-being and QoL cannot be underestimated. Lowered self-esteem, shame, embarrassment, despair and depression are often reported; incontinence can

affect the ability to form or maintain personal relationships, leading to isolation [135,136,137,138].

In such circumstances, there is a need among the general public for better awareness and understanding of bladder and bowel problems, and of the services and treatments that are available. There is also a need for both practical and emotional support to those affected and for advocacy on their behalf in pursuit of development in treatments and services. In response to these needs, continence advocacy organizations have emerged in many countries.

2. CONTINENCE ADVOCACY WORLDWIDE

A central goal of most continence advocacy organizations is the raising of public awareness and understanding of the types of incontinence, the risk factors for incontinence and treatments, services and management products available. These organizations provide a valuable voice for an often unheard consumer population in political and health-care governance, development and planning processes. In recent years, consumers and clinicians have been involved in identifying and prioritizing important areas of research relating to incontinence in order to inform research development and funding decisions [139,140]. In addition, through advocacy organisations, the consumers of health care have become more closely involved and influential in the activities of clinical professional organisations.

Another major role that has been adopted by many continence organizations is the direct provision of information support to those affected by incontinence and to caregivers. The types of information provided include background information about symptoms, risk factors and conditions, treatments and management strategies, and availability of, and access to, health and social services. Such information is provided through a variety of sources, including regularly produced magazines, internet-based information resources, telephone support lines (often staffed by qualified nursing or counseling staff), and printed media such as leaflets and booklets on a wide variety of topics. Other innovative strategies have included outreach work through travelling information roadshows and events [116]. Organisations also provide emotional supports to people with incontinence by putting them in touch with others similarly affected either through direct contact at meetings or through internet discussion forums.

For the Fifth International Consultation on Incontinence, forty-seven continence organisations in twenty-eight countries were identified, with an additional two international consumer-based organisations (Appendix 1). Continence organisations vary in scale and in nature, from small consumer or clinician groups that focus on quite specific bladder symptoms or conditions, to large and well-funded national organisations that address bladder problems generally. Often the founding and development of such organisations has resulted from the dedication of a small group of sufferers consumers, clinicians or both, who have worked tirelessly to promote awareness and understanding of incontinence among the public or colleagues and to provide better services and supports to those affected. They represent a wide diversity of models, including consumer-led, company-sponsored, consumer-only, professionals-only, and organisations which have deliberately set about trying to bring together all relevant stakeholders in a relatively democratic model. In every part of the world, these organisations play a dynamic role in building both public and professional awareness of this underserved and underreported condition.

a) Funding

The degree of funding available inevitably affects the level of work that organizations can undertake. Whereas in some countries, such as Australia, relatively strong governmental support has been provided for the work of continence support organisations, in other countries such as the USA and UK, financial support has come for the most part through charitable donations from individuals and foundations, or through the support of the pharmaceutical industry and continence products manufacturers. Most continence organisations are poorly capitalized, being either under- or unfunded (i.e., run by volunteers) and are held together initially by either a dedicated consumer advocate or an energized healthcare professional. In most cases, this professional is an urologist or nurse whose patient population includes persons with UI. In developing countries, where the need for improved awareness, support and services is often greatest, the availability of funding for continence advocacy work is particularly challenging.

Lack of funding limits the work of continence organisations, and searching for funding can present a considerable burden in terms of time and skills for an organisation's paid or voluntary staff. The very source of funding can present additional challenges: in most parts of the world, organisations are at least partially, if not totally, dependent upon funding from pharmaceutical and product manufacturers. In order to avoid a perceived or real conflict of interest, organisations are well advised to have clear and robust policies dictating the nature of their relationships with commercial entities, to declare their arrangements fully and, if possible, to ensure that they are not dependent for funding upon only one company.

b) Collaboration

Within countries, some previously separate consumer-led organisations have merged with clinician-led organisations in order to make best use of funding available and to prevent duplication of efforts [133]. In other countries there may be good reasons why this is not possible, while in some circumstances there is merit in the independence of groups focusing on specific areas within the continence field. However, both within countries and internationally, there is much to be gained from the networking and cooperation of organisations.

Duplication of effort in the production of materials and other activities can often be avoided, and although it may not be practical to develop global and uniform strategies for continence promotion and public awareness, much can be learned from the positive and negative experiences of other organisations in other countries. For instance, in 1998, the Asia Pacific Continence Advisory Board member countries including Thailand, Korea, China, Hong Kong, Taiwan, Malaysia, Indonesia, India, Philippines, Singapore and Pakistan joined to develop continence promotion programmes that collaborated with health care professionals and the general public. Their mission was to develop strategies to increase awareness and reduce the social burden of UI in the Asia Pacific Rim.

In addition, the cooperation and coordination of continence organisations on an international level can result in more effective engagement with influential international clinical and research organisations. Professionals (e.g., urologists, urogynaecologists, gynaecologists, geriatricians, primary care practitioners, physiotherapists, nurses) and professional organisations have been instrumental in promoting awareness of continence in all care settings. The International Continence Society (ICS) established the Continence Promotion Committee (CPC) to promote education, services and public awareness about incontinence throughout the world, and to facilitate communication, exchange of information and partnerships between continence organisations, health care professionals, governments, and industry. The CPC's multinational and multidisciplinary representation, which includes representatives of continence organisations from around the world, aims to identify broad issues through an international forum that can facilitate translation at the local and national level. Each year at the ICS's annual meeting, the CPC holds workshops around various themes that have a broad national focus, such as prevention, GP education and promotional strategies. Its relevance, as is the case with each of the national organisations, is to recognize the interface between continence management and continence awareness and promotion. The CPC is also promoting continence awareness through the hosting of public forums in conjunction with the ICS annual meeting and sponsorship of the yearly World Continence Week.

The level of evidence on the impact of national organisations increasing continence awareness is Level 3.

3. RECOMMENDATION FOR CONTINENCE ADVOCACY (LEVEL OF EVIDENCE-3, GRADE D)

Based on the literature reviewed in this section, the following recommendations can be made:

- Research is needed on the activities or effectiveness of organisations that target consumers or the general public.

V. SERVICE DELIVERY, MODELS AND ACCESSING CARE

1. BACKGROUND

There has never been a comprehensive examination of an optimal service or model for delivery of continence care. It is not known whether academic, specialist-led centres will achieve better and more cost-effective results than primary care clinics, domiciliary services or any other model. However, most experts believe that female UI is initially most effectively diagnosed and managed by primary care providers compared to specialist services. A large cross-sectional community mail survey of women with UI in France, Germany, Spain, and the UK found that many women actually prefer to be treated for UI by primary care providers, despite easy access to specialized services [141]. Appropriately trained continence nurses and physical therapists can provide high quality UI care for women; women are satisfied with care provided by continence nurses [142,143,144]. In 2000, the UK Department of Health issued guidance on continence services that outlined a good practice model to achieve more responsive, equitable, effective continence services [145].

In the USA, the primary sources of care for the majority of Medicare patients (primarily an elderly population) are family physicians and primary care physicians [146]. Less than 1 person in 1000 is admitted to an academic, medical centre hospital [147]. Thus, in the USA, elderly persons with UI and FI will probably be seen by primary care physicians for initial assessment. This is unlikely to address the needs of developing countries (such as the Asia Pacific area or in Africa) where dissemination of expertise to rural communities and isolated community health care workers is more logical. Continence services are being implemented in several countries using shared teaching and educational resources through co-operative arrangements of the respective Continence Foundations. Thus, the general practitioner (GP) or family physician plays an important role in the first line treatment of UI that may be treated successfully with conservative treatments in the majority of patients [148,149].

In fact, UI is often a complex and multi-faceted problem, particularly in frail or dependent individuals, and it may require input from a wide variety of disciplines to tackle it effectively. Drennan and colleagues[150] interviewed thirty-two caregivers about their strategies for managing a person with UI and dementia. They recommended that professionals, especially those in primary care, could be more proactive in questioning patients about incontinence and toileting habits to identify counter-productive and harmful strategies. Symptoms typically associated with incontinence may also be indicative of other conditions, as evidenced by the urgency and frequency symptoms of BPS [151,152]. The ICI Committee 19 addresses Bladder Pain Syndrome. While it may not be practical for all specialties to work in close prox-

imity, there is a need to consider carefully specialist roles, responsibility, and which protocols will guide appropriate referrals and ensure good collaboration. It is important that there are neither gaps nor overlaps in the service.

Although some might see multidisciplinary relationships as the ideal, the reality is not always smooth. In some situations, rivalries and competition between disciplines and medical specialties is evident. This may be because of competition for patients and revenue, or because of disputes over the demarcation of the scope of different disciplines (such as the boundary between urology and gynaecology, or between nursing and physiotherapy).

Implementation of integrated service mandates can be challenging due to infrastructure limitations and other barriers. For example, despite national recommendations for multidisciplinary integrated continence services in the UK, audits indicate that this requirement is not yet being met [153,154,155].

2. NEED FOR SERVICES

There are no studies directly comparing the effectiveness of specific delivery systems for continence care. In certain cases, enthusiasts have conducted research, and results may not generalize to the wider setting. Others have combined the expertise of multidisciplinary teams to maximize service delivery. The level of evidence on service delivery models is 4.

A Japanese survey of over 1,000 caregivers of elderly incontinent people in the community found that more than 80% of caregivers are female and over half were more than 60 years old [95]. The caregivers felt that incontinence caused problems with the home getting dirty (10%), extra laundry (9%), need to wake at night (7%), and not being able to leave their homes because of incontinence (9%). When asked what kind of government service they wanted, caregivers replied “health training” (10%), “knowledge about incontinence” (10%), and “supply of a portable toilet” (3%). Only 6% wanted the government to send them professional caregivers and only 4% desired referral to a specialist physician.

Knowledge and attitudes about UI and care certainly may influence consumer choices. Some studies suggest that as QoL worsens, care-seeking increases [156]. In some cultures, particularly those where living with extended family is more common, UI may be viewed as a family issue rather than a disorder affecting just one family member [157]. Family support is often seen as an important component when dealing with UI [158].

Buckley and Lapitan[159] conducted an online survey of 1,040 community-dwelling adults in the UK to examine attitudes and behaviours related to care-seeking for UI, FI, and nocturnal enuresis [159]. Overall, 75% said they would turn to their GP for help. However, a surprising 23% said they did not know where to turn for help. This confirms that there are still major needs for continence promotion and consumer education at the community level.

This can create a dilemma and raises many questions. Should health care professionals attempt to persuade or educate people who do not see UI as a problem that it is an abnormal condition? Should a patient who is “not bothered” by symptoms be treated because the partner or caregiver requests the physician’s assistance? This is concerning as Rodriquez, et al.[160] found that physicians underestimated the degree to which patients were bothered by their symptoms 25% to 37% of the time. Is lack of bother genuine or simply a defense against having to tackle an unpleasant problem? Does early intervention prevent later deterioration in symptoms? Does delay in treatment mean that success rates are lowered? There is scant evidence on any of these issues or on the most acceptable way of providing help.

Using narrative analysis of structured patient interviews, Bradway and Strumpf[161] found that women with UI who sought professional care were more likely to “tell a story,” describe UI as having a negative impact on their sense of self, were older, Caucasian, were in ‘good or excellent’ self-reported health, and had suffered from UI longer compared to those who did not seek care [161]. They also confirmed that many women found that UI impairs their sexual health and intimacy.

In contrast, some studies have shown that compared to general health care, many women prefer to take a more active role in their care for UI. In a survey of 265 Norwegian women with UI, O’Donnell and Hunskaar found that 60% of women wanted to be actively involved in their UI care decisions compared to only 38% for their general health care needs [162]. However, this may also be influenced by the context of care and the education level of the patient [163] .The findings are not universal, and may be more associated with a desire for adequate clinical information rather than a desire to make active treatment decisions [164].

It is the impression of all members of this committee that due to the high percentage of people not seeking help for UI (for all the above mentioned reasons), health care professionals must develop the concept of a “reaching-out” service and to actively provide service for incontinence care. This means promoting awareness, openly discussing and actively detecting UI, while providing simple and efficient therapy. While not all patients with voiding disorders (e.g., bothersome lower urinary tract symptoms including urgency, frequency, nocturia, poor stream and hesitancy) have incontinence, many of these patients will also benefit from a service that will provide assessment, education and relevant treatment prior to the potential onset of incontinence.

3. MODELS OF CARE

Continence care was defined by the Canadian Continence Foundation as “all measures directed

toward the prevention, improvement and or management of UI" (http://www.canadiancontinence.ca/pdf/en_dec2000vol_1.pdf). Models of care for the frail elderly with UI are covered by Committee 11: Incontinence in the Frail Elderly. A report on continence care services worldwide noted that services were scattered, inconsistent and considerable discrepancies exist in their funding. It was concluded that there is a need for accessible (and affordable) continence care and multidisciplinary teamwork [165]. Models of service delivery for FI, BPS/IC and POP have not been defined.

The provision of continence care and services in each country will depend on the organisation and infrastructure of its health services. It is difficult to make specific recommendations that will apply in such a variety of contexts. In addition, UI is so widespread and affects men and women of all ages who receive medical care from a variety of health care providers (e.g., PCP, family physician, geriatrician, gynaecologist, nurse practitioners). This means that there will seldom be one point of entry to continence care. There has been little systematic assessment of continence services aimed at identifying an optimal service. It is not known whether academic, specialist-led centres will achieve better and more cost-effective results than primary care clinics, domiciliary services or any other model. There are no studies directly comparing the effectiveness of specific delivery systems for continence care. A range of service delivery models is described below. The level of evidence on service delivery models is Level 4.

a) Single specialist

This is a service led by a consultant or specialist physician (urologist, gynaecologist or urogyaecologist), often focused around the "urodynamic unit" providing medical or surgical treatment. This is the most common model in developed countries; the best of them have a nurse continence advisor or continence nurse specialist as an integrated part of the service.

b) Nurse specialist or advisor

In some health systems, both UI and FI have traditionally been seen solely as a nursing problem, with little interest or input from other members of a multidisciplinary medical team. Except for a few isolated areas, the main intervention has been trying to help individuals and caregivers cope with symptoms, rather than attempting to treat the underlying cause of the UI. For example, in the UK, it is common for an elderly person presenting with UI to be referred directly to the district nurse "for assessment for pads and pants," with no physical examination or further investigation considered.

There are many examples of nurse-directed models of incontinence care described in the literature. Farrell and colleagues [166] studied a modification of UI care that involved step-wise care delivery, including a continence advisor and nurses, which were found to be as effective as the traditional medical model. In countries such as Australia, New Zealand and the UK, a national network of Continence Nurse Advisors (CNAs) or Continence Nurses liaise, integrate services, and guide individuals through the referral route most appropriate to meet their needs. The efficacy of Continence Nurse Practitioners (CNPs) in the UK was reported by Matharu and associates [167] who studied four hundred and fifty (450) women over 40 years of age who underwent urodynamic studies in the UK after seeing a trained CNP. In patients diagnosed with bladder overactivity, the CNP had prescribed drug therapy to 79% of patients and pelvic floor muscle training (PFMT) to 64.8%. In those with urodynamic stress UI, 88% had appropriately been prescribed PFMT. Nursing assessment has the potential to assign patients the correct conservative treatment thereby shortening waiting times for urodynamics and specialist assessment.

There is more evidence that treatment of incontinent community-dwelling individuals by a "continence nurse" is beneficial in terms of clinical outcomes [168]. Jeffrey and colleagues[144] assessed the clinical effectiveness and patient satisfaction with nurse-led, telephone follow-up of women with lower urinary tract symptoms. Participants were offered telephone follow-up with a nurse instead of a conventional outpatient appointment. Suitability for this option was decided by the doctor who saw the woman at her last visit. In total, 116 women received "telephone consultations" and the mean overall satisfaction score was 77 (maximum score was 100). Only 16 patients (17%) did not prefer telephone follow-up to a clinic visit. The authors concluded that nurse-led telephone follow-up is associated with high satisfaction and has the advantages of consistent follow-up by the same clinician, convenience to the patient and cost-savings [144]. Shaw, Williams, and Assassa[169] conducted a postal survey of people in the UK receiving services for UI by CNPs. Participants expressed satisfaction with nurse-led services because of the interpersonal, technical, communication and information-giving skills of the nurses.

The nurse continence advisor (NCA) may be independent, but is usually associated with community/area health centres, where they may have variable professional support from GPs and family physicians. Continence nurses often work in both hospital and community settings, and the service is focused on primary care. This is particularly true for district nurses. Key roles include patient assessment and implementation of conservative management strategies where appropriate and facilitation of patient access to incontinence product subsidies or schemes.

The Department of Health in the UK has commissioned an evaluation of different models of nursing services, with and without specialist NCAs. It was found that where there is a continence nurse incontinent people are more likely to receive a tar-

geted referral to specialists such as an urologist, are more likely to have had investigations such as urodynamic testing and are more likely to receive appropriate treatment and care for their UI. These patients were also more likely to report satisfaction with the service. In contrast, there are still concerns that general nurses continue to "contain the problem" instead of promoting continence, despite acknowledging its importance [170].

Unfortunately, there is often still an emphasis on containment and simple management of UI rather than on active therapy. Part of this may be due to cost, which has been shown to be lower for containment compared to active continence evaluation, promotion, and treatment [171]. Even in this case, provision of care may be substandard. An audit of the continence services in the UK revealed that rationing of pads and absorbent products was widespread, with most patients limited to four pads per day [172]. In addition, 59% of the continence services surveyed provided pads for children under the age of four, which is outside of the published national guidelines. This indicates a need for improved implementation of continence services with regard to use of pads and products.

In a series of studies performed in Leicestershire UK, the short and long-term outcomes of a new CNP-led service for urinary symptoms (three and six months after implementing the program) were examined and evaluated [173,174,175]. Williams, et al.[175] reported on a randomized, controlled study (RCT) of 3,746 community-dwelling individuals greater than 40 years of age (61% women) who had incontinence, frequency, urgency, and nocturia all impacting QoL. The experimental group was comprised of 2,958 patients. The standard care was the control group (n=788) who accessed GP services and existing continence services in the area. The experimental group received an 8-week primary intervention package by the CNP (21 generalist nurses who trained as CNPs). The CNPs delivered evidence-based behavioral interventions using predetermined care pathways in four visits over an 8-week period. Interventions included advice on diet, fluids, bladder training, pelvic floor muscle awareness and healthy eating. Individuals whose symptoms persisted after primary intervention were offered urodynamic testing. The CNP led service had a 10% higher cure rate than standard care with statistically and clinically significant reductions in urgency, frequency, nocturia and UI. In addition, QoL improvements were greater in users of the CNP-led service and higher levels of patient satisfaction were achieved. This is the first study to show the effectiveness of nursing services on urinary storage symptoms (rather than simply incontinence) and associated QoL. The authors noted that the public health value of a 10% reduction in symptoms is substantial when applied to such a common problem.

An additional number of studies support the efficacy of specialist NCA in the delivery of community continence care [148,176,177,178]. In the USA, urology nurses have been trained as "teachers" to successfully implement behaviour modification programs to groups [179]. Nurses may also play an important role in the evaluation and management of POP, a condition which is often associated with concomitant UI [180].

Regional continence nurses have also been successfully incorporated into primary care practices, however they need to be given both the authority and opportunity for interactions. A survey of 22 district continence nurses found that having regularly scheduled appointments with patients who were actively involved in their assessment and management led to the best nurse provider satisfaction and sense of professionalism [181].

In the USA, there has also been an increase in nurses who specialize in dealing with patients with pelvic floor disorders including UI, FI, POP and BPS/IC/PBS, although there are no academic or clinical proficiency requirements in order to be considered a CNP or "continence nurse specialist." Those nurses who do specialize in continence care have obtained their knowledge and skills through self-motivated activities [182]. Masters prepared or educated "advanced practice registered nurses" (APRNs) have become increasingly interested in, and knowledgeable about, the assessment, diagnosis, and treatment of people suffering with UI. These nurses are developing a nursing subspecialty in the care of individuals with UI and related pelvic floor dysfunction, providing comprehensive assessment and treatment (drug and conservative therapy), and acting as educators and researchers [183].

A 2000 study in the USA demonstrated significantly improved outcomes for three clinical problems, UI, depression, and pressure ulcers, when advanced practice gerontological nurses worked with nursing home (NH) staff to implement scientifically-based protocols [184]. In addition to working with NHs to provide resident evaluation as physician extenders, this research indicates that this service model using an APRN can be an effective link between current research-based knowledge about clinical problems and NH staff. This study also showed that consistent educational efforts with staff and NH residents demonstrated that interventions could improve or stabilize the level of UI in this population.

c) Multidisciplinary resource and referral centre

Multidisciplinary clinics, as service models, have been shown to provide comprehensive continence care. In multidisciplinary clinics, such as a "Pelvic Floor Clinic," the gynaecologist, urologist, colorectal surgeon, and continence nurse work together [185]. Some pelvic floor clinic staffing models also include physical therapists (PTs) and registered dieticians.

An Australian study took all community referrals of those who had been incontinent for at least two months and had at least one episode in the preceding two weeks to a continence clinic [186]. Patients were randomized to conservative treatment or control, with a crossover design. Patients were asked subjective questions about embarrassment, odor, depression, family relationships, isolation, and laundry, on a 4-point scale ranging from no effect to major effect upon life. The questionnaire was completed at the start, and at 2, 4, 8, and 12 months. Seventy-eight patients entered the study and 87% improved with treatment (versus 41% controls). Fifty-two percent were moderately or severely embarrassed at the start of the study period, but at 4 months, only 17% were. Depression decreased from 49% to 22% and isolation from 28% to 12%. Odor and the use of extra laundry also decreased. All benefits were maintained at 12 months. Controls did not improve on these items until crossed over to active treatment, despite feeling better. The authors conclude that conservative treatment in a multidisciplinary community clinic improves continence and well-being.

The Continence Foundation of Australia (CFA), funded by the Australian Government, employs CNAs to answer the National Continence Helpline and to provide advice to consumers and health professionals, including referral advice [187]. Evaluation of this service indicated availability and uptake of information, as well as increased traffic to the Bladder and Bowel website and the National Public Toilet Map. There had also been a general increase in the number of consumers seeking help for their incontinence.

An expansion of this service provision is exemplified by the National Centre for Continence in Israel, which aims to provide an integrated service [188]. The Center's professional team not only treats incontinent patients, but also educates GPs and nurses who come from pre-selected peripheral/outlying clinics. They also provide ongoing support and advice as well as a pathway for tertiary referral. A local team (GP and nurse) is also selected to be in charge of promotion, detection and treatment of incontinence at the clinic. They later become "in charge" of incontinence in their region. This model allows national distribution of continence services with support from the resource centre and provides interdisciplinary exchange, as well as maximum co-operation between Medical Centres and community health services. The national centre is funded by government and industry to provide a "Hotline" for the public, to promote education programmes in nursing and medical schools, hospitals and NHs, and to develop guidelines for diagnosis and management of incontinence by primary healthcare staff.

Multidisciplinary services should initially focus on a step-wise approach to evaluation and management. This need not be limited to tertiary level centers, but can be incorporated into care in local communities when providers with expertise are available [189].

The multidisciplinary model has also been used for delivery of community-based services. One model used a combination of clinic and home visits, multidisciplinary care delivery to targeted client groups, and use of multidisciplinary tools and provider education [190]. Overall, a generalist approach was found to be most effective in this study, although this may depend on the community context and other factors. The model shown in **Figure 1** combines an academic center and community services. Although it was proven feasible, there were significant challenges due to funding and infrastructure [191]. This program in Canada is ongoing, and additional research will be needed to assess overall outcomes.

d) Primary care

Although primary care practitioners can certainly do a large portion of general continence care, the literature notes barriers to care provision and poor adherence to evidence-based recommendations [192,155]. This precludes efficient delivery of continence care and prevents appropriate first-line treatment. Cohen and colleagues [193] found that, among primary care providers, only 25% initiated a discussion of incontinence with their patients. In their cohort, older patients were less likely to be asked about incontinence compared with younger patients. Findings from a USA survey indicate that the majority of primary care practitioners were unlikely to ask about UI [194]. Forty percent recommended pad use for treatment, and only 17% were aware of clinical practice guidelines. The identical situation exists in other countries such as in Europe and Canada [195,196]. Although most primary care practitioners recognize that UI is common, only a minority have an organized plan for its evaluation and management, and report feeling very comfortable dealing with UI. Ten years ago, attempts by the U.S. Agency for Health Care Policy and Research, now known as the Agency for Healthcare Research and Quality (AHRQ), to use physician group interventions to raise awareness through UI guidelines failed to improve screening and management rates in the primary care setting [197]. There have been other innovative methods used to increase UI screening. Yazdany[198] prospectively randomized patient charts (n=88) to receive a chart-alert sticker ("Do you leak urine?") that reminded resident physicians to ask about UI in their general gynaecology clinics. Overall, the rate that resident physicians inquired about incontinence increased with the alert-sticker from 4% to 34%. This method may be more easily implemented in electronic health records.

Many countries have sought to shift the provision of primary care from doctors to nurses in order to reduce the demand for doctors and improve healthcare efficiency. A Cochrane review found that quality of care is similar for nurses and doctors, since nurses tend to provide more health advice and achieve higher levels of patient satisfaction compared to doctors [142]. A RCT in the Netherlands compared usual care for UI in GP clinics to those that included

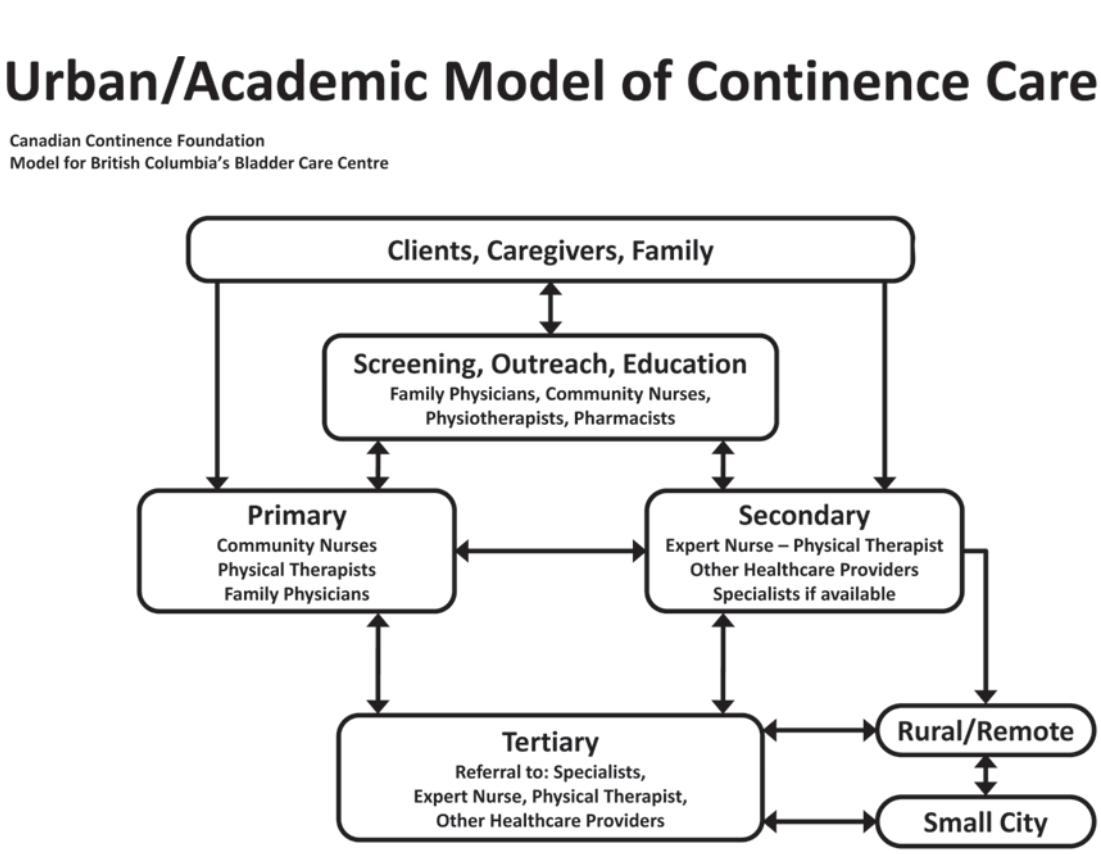

Figure 1. Urban/ Academic Model of Continence Care

a nurse specialist [199,200]. Short-term outcomes revealed better continence rates in those patients seen in clinics that involved care by the nurse practitioners. However, the results were not sustained at the one-year follow-up, and both groups had equivalent continence outcomes. A focus group analysis with the nurse practitioners revealed that they felt competent to provide the needed services and appreciated by the patients [201]. In addition, they felt they added value to the practice, particularly since many of the GPs were seen as lacking interest in UI. Overall, the results do suggest a benefit from this type of multidisciplinary care delivery. Future research will be needed to determine if long-term outcomes can be maintained and if the model may have other unmeasured benefits, such as better cost-effectiveness.

Therefore, primary care practitioners may not be the most appropriate professional to mange UI, and this committee's recommendations include a care delivery model (**see Figure 2**) based on a chronic care approach that has been used successfully in other chronic conditions (e.g., diabetes, CHF, asthma) [202].

There are many factors that can persuade health care planners about the importance of adequate investment in community continence services. The prevalence and the number of incontinent people is likely to increase with an aging and increasingly dependent population and many frail, disabled or elderly people are incontinent for reasons extraneous to the urinary system (such as poor mobility, an inappropriate physical environment or lack of an individualised care regime). It is often best to provide an initial assessment for such individuals in their usual surroundings and to reserve hospital or clinic (specialist or academic) referral for those who do not respond to simple measures such as treatment of constipation, modifying a diuretic medication, or provision of accessible toilet facilities. A number of guidelines have suggested an algorithmic, stepwise approach to UI assessment and treatment, and many conservative treatments have a good success rate in primary care [203,204,205,206].

e) Other service models

In a structured literature review, Chin and colleagues found that primary care clinics for continence led by nurses and allied health professionals were common across the world [207]. Although there were a number of differences that were culture specific, there were also a number of key factors that predicted high quality care across all cultures. These included identification and recruitment of appropriate patients, improving access to care, enhancing engagement with primary care providers, using small teams with adequate training, developing structured referral lines,

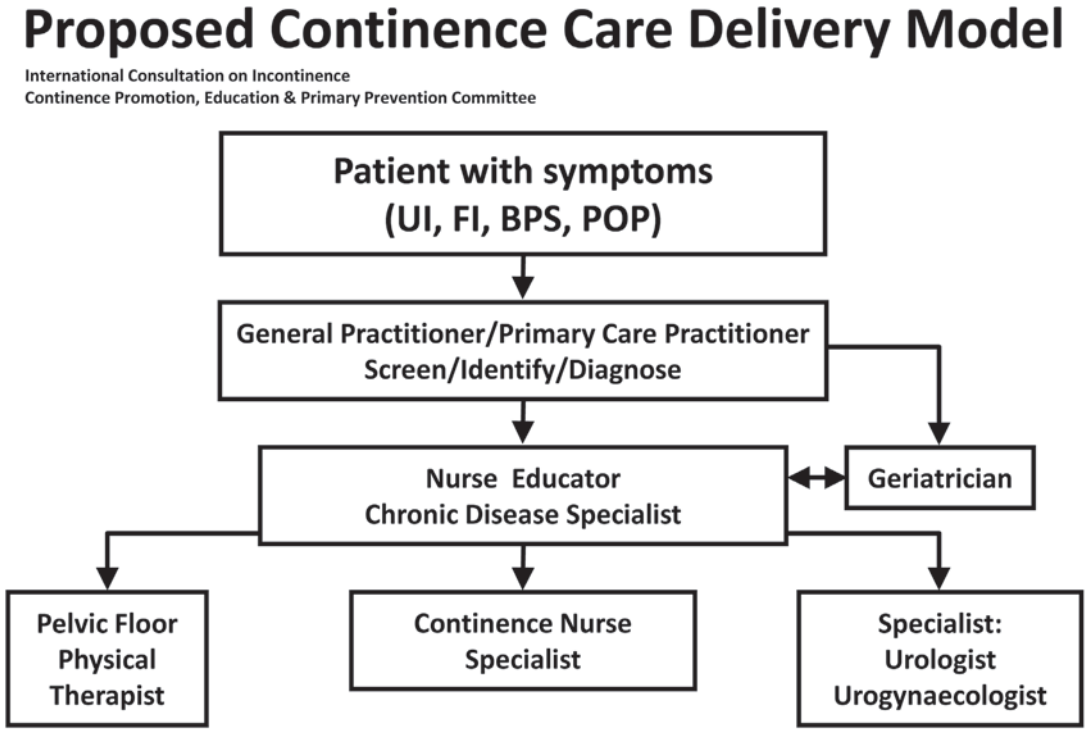

Figure 2. Proposed Continence Care Delivery Model

and working to employ evidence-based practices including guidelines and treatment protocols.

Group intervention models for delivering first-line treatment for UI is feasible [208,112,209] and may be an equally effective and potentially cost-saving approach to this form of therapy [210]. Even simple group education about UI in general, may improve self-care among postmenopausal women with the condition [11]. Another study has shown that non-medical lay instructors can be taught how to instruct patients in proper pelvic floor muscle exercises [211]. This train-the-trainer model may be useful to help disseminate behavioural therapy on a more widespread basis.

Education of other professionals who interact with UI patients, but do not themselves provide direct health care, may also be quite useful. For example, improved education about UI and other lower urinary tract disorders among teachers may help improve not only their own continence health, but that of their students as well [212].

Many consumers seek information from the Internet, although the quality of materials can be highly variable. Some websites include an interactive component, including e-mail of other communication methods that allow users to interact with a health educator or other professional [213]. Computerized education methods have been developed to disseminate consumer education materials about UI [214]. Usability was considered good and these methods may help disseminate continence promotion materials.

1. Acute or sub acute care to community

Patients with UI who receive care in acute care hospitals have been shown to lack appropriate care because of the lack of knowledge amongst acute care nurses about assessment or management of UI [215]. Nursing education must change to improve this situation. The value of tackling this is shown in a retrospective review of 6,773 episodes of care in 54 medical facilities [216]. The discharge destination was altered by the presence or absence of UI – 57% versus 82% respectively being discharged home, and 29% versus 12% being discharged to a NH or other health care venue. In addition, the time in rehabilitation was 185.6 days for those with UI compared with 156.8 days without UI, and geriatric costs in evaluation and management were higher in the UI group. The level of functional independence and motor function also impacted outcome.

Continence promotion, education and treatment may occur in a variety of clinical settings, particularly in relation to other associated clinical conditions. For example, UI occurs commonly after acute stroke. Rehabilitation nurses who work with post-stroke patients could play an important role in continence care, however research shows this may not happen

regularly. A recent multinational qualitative study examined a focus group of rehabilitation nurses in the UK, Sweden and China [217]. They found that only a superficial assessment of continence was routinely performed by most nurses in this setting. The authors noted a focus on containment and social continence although process models of practice were seen in all countries. Other studies have corroborated these findings and reveal the emphasis in the rehabilitation setting is containment rather than continence promotion or active therapy [218]. The results highlight a need for systematic assessment and development of patient-centered care plans.

Heart failure is another common clinical condition, particularly among older adults, that is frequently associated with UI. A recent study of 182 heart failure patients with at least monthly UI revealed that 83% had not asked for help with their incontinence symptoms and 64% were interested in learning more [219]. Many patients, particularly those with concomitant diabetes, were contemplating changing their behaviours and seeking care.

Clinical care around the time of pregnancy and delivery is another potential time for patient education and interventions aimed at preventing or treating UI [220]. Studies have shown that women are generally very receptive to this type of clinical education in the post-partum interval [221]. Additionally, women who were instructed in pelvic floor muscle exercise by a PT during the immediate post-partum period were more likely to continue the exercises at one year after delivery compared to controls [222]. However, in many cases, this opportunity is missed due to lack of training on the part of care providers. A study of nurse midwives in Australia found that the majority do not assess for UI in the peripartum period [223]. In addition, the survey respondents indicated a lack of guidelines for nurse midwives.

2. Elder services (long term care or nursing homes)

There is growth worldwide in the use of APRN "continence" specialists practicing in home care and LTC settings, providing expert consultation in UI and related disorders [183,182]. Many have developed innovative approaches to management of UI in NHs. Bucci [224] developed the CHAMMP (Continence, History, Assessment, Medications, Mobility, Plan) tool to educate NH staff in the USA on a comprehensive continence assessment and to assist in implementation of individualized plans of care. The CHAMMP program improved one facility's Quality Measure Indicator Report. ICI Committee 11 discusses services for frail elders.

Many older adults rely on home care services for a variety of health care needs, including UI. The methods used to implement and deliver services can differ a great deal depending on the care model used in a particular region. Implementation of guidelines is felt to be an important part of this process [225]. This allows care providers to try to put evidence into direct practice. A recent study examined 19 home care agencies in the Netherlands to determine if the quality of care systems influenced outcomes [168]. Most models included designation of the continence nurse and documenting UI-related actions on the patient care record. However, no differences in clinical outcomes were observed in this study of 155 home care teams. The authors concluded that additional research examining specific implemented practices would be required in the future.

Even within the long-term care setting, the focus is too often on containment and use of pads or absorbent products compared to active continence promotion or treatment. A recent Cochrane review supported this finding, and noted that none of the studies reviewed focused on attempts to maintain continence in facility residents [226].

One new innovative model has described the development of individualized continence profiles for use with NH residents [227]. This may help NH staff identify residents who may benefit from various forms of assessment and interventions. Another model has worked to involve NH residents more actively in their fluid intake and continence care. After a 12-week intervention, overall hydration status improved and time spent in wet diapers decreased significantly in a cohort of 153 NH residents who participated in the intervention [228]. Education of staff was felt to be important to the observed success in this study. Within the context of 'person-centered care,' there is a growing need to develop and encourage bladder rehabilitation and prevention with a proactive focus, particularly for older adults [229]. This may help to expand the focus beyond containment only in this population.

Another study found that the best performing long-term care facilities in terms of UI care generally utilized a multidisciplinary process improvement team [230]. In addition, more were likely to use a clinical practice guideline in evaluation and management compared to the poorer performing facilities.

Data have shown that a nurse's level of knowledge and attitudes about UI may influence care within the NH environment [231]. Overall perceptions about physical functioning in older adults may also impact this issue in hospitalized patients [232]. Physical functioning is a complex entity and nurses in this focus group study identified system-level approaches that could be used to prevent additional functional decline in their patients.

Education specifically targeted at family caregivers may also be important in the promotion of continence for community dwelling older adults. A recent report by Jackson and colleagues [233] used focus groups of family caregivers and health care professionals to identify the types of materials and methods of delivery preferred by participants [233]. Most wanted printed materials such as summary brochures or fact sheets with answers to frequently asked questions.

Electronic materials were not as readily desired in this study.

Distance learning techniques have been successfully used to teach and implement programs and strategies for management of UI in NH [234]. This training method might help to improve dissemination of information, particularly in rural and otherwise underserved communities in more remote locations.

3. Models in developing nations

Continence services are a relative luxury, to which countries with a low per capita income are unlikely to devote scarce resources, especially while other population health issues have precedence.

The potential demand for UI services in developing nations far outstrips the resources that are available. The provision of services will depend on dedicated healthcare professionals with support by government or industry, and by a local continence organisation to educate a new generation of service providers who will carry the services to remote communities. Increased use of advanced communication technologies can help to disseminate continence promotion materials among nurses and other health professionals worldwide [235].

In some instances, consideration will have to be given to cultural and social mores and taboos. For example, Ethiopia's Health Minister has stressed the need to develop rural health services to reduce the incidence of fistula and to have first time mothers examined by Traditional Birth Attendants (TBAs). The ICI Committee 18, Vesico vaginal fistula in the developing world, addresses service for this specific condition. It is planned that TBAs will be trained to identify high-risk women and thereby divert expenditure from high cost physicians and urban health services to training community health workers and to health education. Attitudes on female circumcision, contraception and women's health, matters that are often decided by their husbands, obviously have much wider implications than just continence care.

4. RECOMMENDATIONS FOR SERVICE DELIVERY, MODELS AND ACCESSING CARE

Making recommendations for interdisciplinary and multidisciplinary models for continence advocacy and service delivery remains a rather elusive goal. Although there have been more publications since the last ICI, there has been little evidence of substance generated. Implementation is quite difficult, funding is often limited, and there are few studies on outcomes. Based on the literature reviewed in this section, the following recommendations can be made:

- There is a need to move beyond the theory and work on research about the practice of continence care delivery and education. We recommend a care delivery model based on a chronic disease approach. (Grade D)
- There needs to be an increased emphasis on non-physician models of care (nursing, nurse practitioner, continence advisor, physiotherapy, physician assistants, etc.). (Grade C)
- Despite the proliferation of guidelines, there is increasing evidence that practicing clinicians are not following them. Implementation models should be developed on how to translate guidelines into practice. (Grade C)
- There still appears to be a shortage of physician specialists in continence care (urology, gynaecology, etc.) which needs addressed. (Grade D)

VI. PROFESSIONAL EDUCATION

1. BACKGROUND

With the continued advances in health care, increasing public pressure to provide high quality evidence-based care, limited time for health professionals to update their knowledge and the recognised ineffectiveness of passive 'lecture style' education provision, the need for new models to change health care providers behaviour is essential. Nowhere is this more relevant than in the provision of care for those with UI and FI, where educational provision has been inconsistent at best.

Professional education is a key component in the provision and care of individuals with UI and FI. In their state-of-the-science statement on the prevention of faecal and UI, Landefeld et al[8] identified that education of health care providers alone is insufficient to improve detection and treatment of UI and FI. However, they recognise that in order to appropriately detect and evaluate incontinence professional education is required along with outreach and practice-based resources. To date, the education and training of those involved in the provision of continence care has been poor.

There is limited literature on the educational preparation and ongoing training of those health care professionals engaged in continence promotion, care, and referral and even less on the evaluation of education programmes in terms of educational or practice outcomes. It has long been recognised that professional education with reference to UI and FI remains only a small part of the basic training of physicians, nurses, or allied health professionals and on-going training is largely 'ad-hoc' with huge variation in the types, content and quality of such training. An early survey in the UK found minimal attention given to incontinence in both medical and nurse training, and a key recommendation for improving continence care was an increase in the quality and quantity of professional education [236]. This has clearly not occurred. While educational initiatives have been undertaken, they remain fragmented and inconsistent internationally. Most notable is the absence of evidence demonstrating an impact of professional or public education on the burden of suffering posed by OAB and UI. The

ICS has established an Education Committee to promote, organise and co-ordinate all educational advances undertaken under the auspices of the ICS. Details are available on the ICS website (www.icsoffice.org).

There is a paucity of published work on professional education on UI or FI. Similarly there are few studies addressing the effectiveness of education in improving the knowledge of learners, or on whether improved knowledge impacts patient outcomes. Information has been building since the publication of the ICI chapter in 2009,[1] but the level of evidence on the effectiveness of professional education remains at Level 4. This section will examine the available evidence on the effectiveness of professional education on incontinence for different groups of health care professionals.

2. MEDICAL EDUCATION

a) Generalists (family physicians/general practitioners/primary care physicians)

Physicians (general, primary care, and family physicians) have been viewed as having a gate-keeping role in continence provision since they are often the most likely first point of contact when consumers seek formal help for their incontinence. Most physicians have received little education or formal training about incontinence, fail to screen for it, and view the likelihood of successful treatment as low, so most avoid the topic with patients. At the same time, there are no data confirming the benefits of screening as a method to reduce the burden of suffering from UI. A postal survey noted that only 18% of respondents said providers asked them to complete a questionnaire about bladder control during routine office visits, and a majority (69%) felt it would be very helpful in prompting discussion if their physician or health care professional provided a form for them to check off symptoms of incontinence [104].

Traditionally, UI and FI have formed only a very small part of the undergraduate medical curriculum. Education on UI has usually been fragmented across different organ systems, with training scattered between gynaecology, urology, and geriatric medicine. Bladder and pelvic floor anatomy is poorly covered in preclinical training and relevant physiology is rarely mentioned. A survey of urology residency directors, medical student educators in urology, and urology applicants identified UI as one of the eight most commonly cited topics to be included in a core urology curriculum [237]. Minimal training is provided on paediatric continence issues.

Recent studies have shown that there has been an overall decline in the amount of time devoted to urologic education in most medical school curricula [238]. Surveys have shown that general levels of knowledge about common conditions such as hemaeturia and OAB are low. In addition, respondents indicated a low likelihood of seeking urologic consultation for many conditions. A similar study found that exposure to issues of pelvic floor dysfunction in women was extremely limited in medical education, with more than 80% of medical students receiving no formal training in this area during the first two years of training [239]. This represents a critical shortfall in training, particularly since many patients with genitourinary problems will initially present to a primary care provider for evaluation and management.

A survey of program directors for internal medicine residency training programs in the USA was conducted to determine whether they felt their residents should master thirteen core competencies identified to be central to the health care of women (including UI) [240]. Although almost all felt this was an important goal, there was a large discrepancy in whether they actually achieved this level of learning. This indicates there is still a wide educational gap among primary care physicians who are often the first portal into the organized health care community for patients with UI.

There is very little available literature on knowledge among family doctors on FI. A study has recently been undertaken to explore GP awareness of surgical treatment options for FI [241]. A postal questionnaire was mailed to 1,100 GPs in the Yorkshire region in the UK, and a response rate of 48.5% was achieved. The questionnaire assessed basic knowledge of FI and treatment options. Overall knowledge was poor, with the majority unaware of available investigations, treatments and specialist centres. The authors recommend better communication between specialist centres and GPs, as well as CME programme implementation.

There is growing evidence to suggest that traditional ‘lecture style’ medical education is ineffective in changing physician behaviour and, ultimately, patient outcomes [242]. More innovative teaching methods are clearly required. Levine and colleagues [243] used a train-the-trainer model to evaluate the management of a number of common geriatric conditions including incontinence. This model involved training, by an expert faculty, a team of non-expert peer educators. These peer educators used a toolkit to conduct small group learning sessions, which were evaluated immediately after and 6 months after the education sessions. The model used principles of knowledge translation and active teaching using tool kits based on guidelines to train geriatricians. Results showed statistically significant improvements in self-reported knowledge, attitudes and office-based practices. The study concluded that modest changes in practice in relation to geriatric conditions were achieved using this peer-led approach. While such evaluations are promising, these models are difficult to sustain and costly. Perhaps most importantly they point to the need to use innovative teaching methods to ensure that educational efforts actually make a difference.

Web-based training and the use of standardized patient case studies has become very popular in medical education and has been successfully incorporated into residency training programs. In one recent project, training about UI was included with a number of other geriatric syndromes [244]. In fact, those internal medical residents who received the information via web-based methods had better overall test results than those who completed paper-based training.

Some models of physician education have incorporated training on UI into modules on quality care. For example, the Assessing Care of Vulnerable Elders (ACOVE) project in the USA includes UI as one of the target conditions. A recent study looked at implementation of this information into community-based physician education within practice groups [245]. These authors found that dissemination of this information was well received by primary care physicians, and some intended to make changes in their practice related to this new knowledge. Similar studies have also found that primary care physicians specifically educated about UI assessment and interventions were more likely to recommend care for UI to their patients [246,247]. Large-scale dissemination of information using these types of training models might ultimately help improve access to care.

b) Specialist physicians

There is little new published evidence on medical specialist training in the form of effective training interventions. Specialist training in incontinence is not always adequate. Both UI and FI still may be perceived as exclusive to "super-specialists," potentially alienating colleagues.

Even among subspecialists, training may not be ideal. A survey of 163 urodynamic services in the UK found that half the respondents felt their training in urodynamics was inadequate [248]. Marsh and colleagues[249] surveyed 100 gynaecologists and urologists in the UK and found widespread inconsistent and inappropriate diagnosis of PBS/IC [249].

Increased use of advanced surgical technology has led to greater need for procedure specific training. Examples include use of laparoscopic and robotic techniques for treatment of POP. Some of these procedures have a steep learning curve and require additional training for surgeons [250]. Structured training and curricula have been developed for a variety of surgical procedures used to treat UI and POP [251]. Inclusion of this training in residency will lead to increased numbers of physicians who are qualified to offer this type of care to patients suffering from UI. A variety of models have been developed to help teach some basic skills such as cystoscopy or methods for grading the degree of POP. One option includes the use of cadaver labs [252]. Others have used inanimate objects to replicate the female pelvis and teach basic anatomic concepts [253,254]. Script concordance models have been developed to assess clinical reasoning skills related to care for UI in older adults [255]. This may allow better measurement of clinical practice behaviours for this condition.

Ongoing education and utilisation of evidence-based training with incorporation of guidelines has been suggested as a way to maintain high quality standards of treatment, particularly for surgical care of UI [256].

In the USA, there has recently been a push to develop sub-certification for specialists who care for women with UI and associated pelvic floor disorders [257]. This has involved cooperation between the certifying boards in both urology and obstetrics and gynaecology. The field of 'female pelvic medicine and reconstructive surgery' has recently been approved by the relevant certifying boards. This means there will soon be a separate board examination in this field. Continued emphasis on quality education for specialist physicians is needed worldwide [258]. A study of gynaecologists in Germany found that most considered their specific post-graduate training in urologic issues and urogynaecology to have been inadequate. The vast majority of general gynaecologists in this study referred their patients with voiding or incontinence issues to subspecialists in urology or urogynaecology.

3. NURSING PROFESSIONALS

Nurses have a significant role to play in the area of incontinence since they are the largest single group of health care professionals around the world and are often the first to become aware that the patient is experiencing incontinence. Cheater and colleagues[25] found that in the UK, an average community nurse case load will comprise approximately one-third of patients with UI. There have been a number of recent studies that explore the use of new innovative methods of education provision for nurses. Rogalski[259] reports a persisting lack of educational emphasis on common symptoms like UI and recommends a curriculum model based on existing guidelines and best available evidence, which could address this shortfall and would increase the quality of continence service provision.

a) Generalist nurses

There are significant gaps in knowledge and clinical practice adoption related to both UI and FI, although nurses worldwide have played a major role in developing new information and testing interventions [260]. Although nurses can provide effective interventions in the area of UI, there is limited research on effective interventions for FI.

Innovative methods of improving knowledge among nurses have undergone recent evaluation. An important study undertaken by Cheater and colleagues [261] adds to the debate by examining the value of audit and feedback, and educational outreach, which in the past has often focused on doctors' behaviours rather than nurses'. In this study, the researchers

undertook a cluster-randomized trial to evaluate 194 nurses in 157 family practices with 1,078 patients with a diagnosis of UI. They found that when compared to educational materials alone, there were no improvements in care for either educational outreach or audit and feedback (all groups did improve, but differences between groups were not significant). McConnell et al[73] described how advanced practice nurses learned evidence-based approaches to managing complex cases, including incontinence, in NH residents. Advanced practice nursing skills include evidence-based assessment and diagnosis for implementing management. The authors suggest that such practices can enhance both student and facility outcomes, although no systematic evaluation was undertaken.

Ostaszkiewski[262] describes a nursing leadership model to enhance continence care in older adults. Evaluation of the program suggests improved management and assessment of incontinence for individuals sustained after a two-year period. Leadership programs have proved effective in a number of areas in nursing provision. Within these more recent studies, the use of innovative methods of knowledge transfer and education are beginning to be adopted, and such methods used in other areas of professional education may be well suited to UI and FI.

Education related to UI may often be linked to training about other concomitant disorders or conditions. For example, training on prevention and treatment of pressure ulcers or dermatitis may include significant components related to UI [263,264,265]. Training about improved mobility in the geriatric population has also shown this educational link [266]. This can help to disseminate information about continence care and promotion to a wider audience of nurses who have direct patient contact.

Although APRNs may have good levels of knowledge and positive attitudes about treating UI in women, many have difficulty applying this directly to practice in the clinical setting [267]. These authors suggest that there needs to be increased exposure to these topics in clinical experiences during training for graduate nurses.

Programs have focused on nurse education for continence care in specific settings, such as the NH [268]. Competency-based UI education with use of case examples has been used successfully in the training of generalist nurses [269]. Experiential activities have also been used with good results [270].

b) Specialist nurses

Educational courses on incontinence are available for nurses in the UK, USA, Europe and Australia, and are beginning to appear in Asia, notably Hong Kong and Singapore. These courses vary from two to four weeks of face to face didactic courses to distance learning courses lasting 12 months that lead to a post-basic nursing certificate and, in some cases, post-graduate degrees.

In the UK, education programs are documented at the Association for Continence advice website (http://www.aca.uk.com/education_modules.php) and comprise information on 1 day courses, as well as diploma courses, degree modules and masters level study. Such databases of courses offer an excellent overview for students and providers. Likewise, the CFA (http://www.continence.org.au/pages/continence-courses.html) is an excellent resource for nurses to access information and be linked to educational organisations that provide a variety of programs which focus on or incorporate both UI and FI in the curriculum. Many can be continued through to post-graduate tertiary education. A number of these programs can be undertaken externally and therefore are popular with nurses in rural and remote areas, as well as students of nursing who practice in other countries. Clinical support is arranged to complement the theoretical components.

Williams, Assassa, Smith, Shaw[271] conducted a small study in the UK that showed improvements in both knowledge and attitudes of nurses who undertook a specially designed, full-time, 3 month program that included a continence module.

Internationally, there is inconsistency in the provision of specialist education to prepare nurses to practice as experts in the field of incontinence. Innovative web-based learning programs incorporating modern information and communication technology (e-learning) may offer one way of providing standardized programs of study to practitioners.

Beitz and Snarponis[272] describe their innovative on-line learning program which includes continence nursing. They feel that such teaching strategies are acceptable to nurses. As with physicians, it is unlikely that improving nursing knowledge alone will translate into improved clinical practice or into the ultimate goal of improved patient outcomes.

Jha, Moran, Blackwell, and Greenham[273] conducted a small study of women attending gynaecology outpatient departments with incontinence problems. Thirty-five percent (7/20) patients did not need to see a doctor, as they were symptom free following treatment recommendations by continence nurses using an integrated care pathway. The authors felt this process facilitated earlier diagnosis and improved access to specialist services and discharge from secondary care.

The level of knowledge about UI within the general nursing community appears to be less than ideal in both the USA[274,275,276] and Sweden [277]. Many non-specialist nurses (referred to as general nurses) desire, and have a need for, more education about what they can do to better manage incontinent patients. Moreover, the QoL of the incontinent NH resident is often more dependent upon the skill, education, and attitudes of the nursing aide than of the qualified nursing staff.

Improved education of school-based nurses regarding normal bowel and bladder habits of children may help to improve pediatric continence and promote healthy elimination patterns [278]. Although 61% of school nurses surveyed reported they had never received training on the topic, many (43%) had been asked to provide information to their teacher colleagues.

In the USA, although there are a growing number of nurses who are developing expertise caring for incontinent patients, there are no academic or clinical proficiency requirements to be considered a "continence nurse practitioner or specialist."[279] In 1993, the Wound, Ostomy, and Continence Nurses Society developed the first certification program for continence care nurses in the USA. This nursing organization recently published a position statement on the role of continence nurses [280]. The Society of Urologic Nurses and Associates certifies different educational levels of nurses in the area of urology and in urodynamic testing. The norm is that most "continence" nurses in the USA obtain their knowledge and skill through self-motivated activities.

Recently, there has been some debate about the need to provide special education and credentialing to non-baccalaureate nurses regarding UI and associated conditions [281]. However, to date, most of the focus on UI education has been at the baccalaureate and advanced degree levels.

Other discussions have focused on whether specialty training in wound, ostomy and continence nursing should be at the doctoral level. In the USA, the new Doctor of Nursing Practice (DNP) degree may help to fill this training gap [282].

A study of 231 vulnerable elders with complex disease and enrolled in a 'Special Needs Plan' in the USA were shown to benefit from a nurse care management program with nurse practitioners in addition to physician care, as opposed to those who received care from a physician alone [247]. The model has continued to develop and requires further evaluation. A smaller study[168] in the Netherlands demonstrated that there were short-term benefits following referral to a continence nurse, however these benefits were not sustained long-term. Both studies demonstrate the need to further evaluate the effectiveness and sustained benefits of specialist continence nurses. A Cochrane Review[142] that explored the substitution of doctors with nurses showed similar patient health outcomes, at least in the short-term, over the range of care investigated.

Albers-Heitner and colleagues[283] evaluated the cost-effectiveness of involving UI nurse specialists in primary care compared to care-as-usual by GPs [283]. From 2005 until 2008, an economic evaluation was performed alongside a pragmatic multicenter RCT comparing patients with UI receiving care by nurse specialists with patients receiving care-as-usual by GPs in the Netherlands. One hundred eighty-six adult patients with stress, urgency, or mixed UI were randomly allocated to the intervention and 198 to care-as-usual; they were followed for 1 year. Main outcome measures were 'QALYsocietal' (Quality Adjusted Life Years based on societal preferences for health outcomes), the EuroQol-5D, 'QALYpatient' (based on patient preferences for health outcomes) (EuroQol VAS), and 'Incontinence Severity weighted Life Year' (ISLY) based on patient-reported severity and impact of UI (ICIQ-UI SF). Health care resource use, patient and family costs, and productivity costs were assessed. Compared to care-as-usual, nurse specialist involvement yielded slightly more favorable cost-effectiveness results. Based on these results, the authors recommended adopting the nurse specialist intervention in primary care.

c) Nursing assistants

There is also a need to address the training of nursing assistants (NAs) and aides, particularly in the long-term care setting. In the USA and many other countries, one concern is the high turnover rate among first-line caregivers in institutional and homecare settings, making it difficult to maintain desired training levels. Nursing assistants are often the people providing 'hands-on' incontinence care, and yet they often have the least training. Certainly, in terms of published evidence, there are few reports of efforts to train NAs. A cross-sectional study via postal survey to gather self-reported data from nurses and NAs in NHs was conducted in Taiwan [284]. Results indicated UI-related knowledge scale and practice behaviors differed significantly in both groups. The authors recommended that enhancing staff competence in incontinence care was needed in both levels of nursing to improve NH residents with UI. Educational efforts, particularly in the NH setting, must involve not only professional nurses, but NAs and other staff, as well. A study of nurses' knowledge about UI in NHs that used a standardized examination about UI and associated care demonstrated that professional nurses answered about two-thirds of questions correctly, but that baseline knowledge among NAs and aides was much lower [285].

4. PHYSIOTHERAPY AND OTHER ALLIED HEALTH PROFESSIONALS

Physiotherapists or physical therapists (PTs) have long played a part in continence care and the management of UI. In some countries, patient self-referral to specialised PTs has become commonplace. Physiotherapist's involvement in UI appears to be either on the basis of individual interest or through association with women's hospitals or obstetric departments, rather than as part of a general physiotherapy practice [286]. As such, they tend to be highly motivated and enthusiastic.

Generalist PTs have been encouraged to be more aware of the risk factors for incontinence in males and females, to identify patients with risk factors for incontinence and to assist them

in seeking further advice or treatment. The "Red Flags" Project conducted in 2005 was a collaborative effort of the Australian Government's National Continence Management Strategy and the Australian Physiotherapy Association's Continence and Women's Health Group to enhance HSB in people with incontinence visiting generalist PTs.

Throughout the world national physical therapy organizations have established continence physiotherapy sub-groups [287]. The International Organisation of Physical Therapists in Women's Health represents over 20 member countries with PTs practicing continence and women's health physiotherapy and offers professional development programs. A number of specialist continence PTs also treat men and children. Universities in many countries offer short courses or post-graduate continence education programs to PTs that may range from post-graduate degree courses to Masters and PhD programs [288].

The Scope of Practice for continence PTs may include PFMT, bladder training, management of sexual dysfunction, anorectal dysfunction and treatment of pelvic pain syndromes, FI and male continence issues.

Pharmacists have a variety of roles to play in continence care. In Australia, they have been avid consumers of continence education programs. In 2004, the Pharmacy Guild launched an educational and promotional program for their members with appropriate outcome evaluation measures. The public sees pharmacists as important and approachable sources of health information, especially information on medicines that may cause or exacerbate UI and FI. Many retail pharmacies display health promotion literature on a range of subjects, including UI. Pharmacists may also advise the consumer on appropriate continence products. Educational seminars for pharmacists are generally well received. There are a growing number of CME programs for pharmacists on the Internet, either through new products or through sites such as www.worldwidelearn.com.

Regulatory issues are often linked not only to quality of care, but also to reimbursement for clinical care and services. Reimbursement policies for services frequently determine which professionals are able to provide continence care. In the Netherlands, for example, the government pays for up to 14 visits to a PT for incontinence therapy. In the USA, patient's visits to a PT are typically restricted by the need for referral and cost.

5. IMPACT OF CLINICAL GUIDELINES

In the past several years, there has been an explosion in the rate of development and publication of clinical guidelines for UI and associated conditions. Since the last ICI, at least 20 different guidelines or consensus recommendations have been published regarding UI and associated conditions. Many of these have been developed by professional organizations focused on urologic, gynaecologic, geriatric, or related fields. Some have been created and disseminated on behalf of national governing bodies. Several older guidelines have recently been updated using evidence-based methodology.

Most of the guidelines target physician practice, although some do include recommendations specific to PTs, nurses, or other health care professionals. Different guidelines focus on specific clinical areas, and some are gender specific. Some only examine issues related to either the assessment or the treatment of UI. Some of the treatment-centered guidelines are specific for either surgical therapy or conservative therapy. Others look at clinical conditions in specific patient populations including those with underlying neurological disorders, women with POP, or patients who have previously undergone surgical treatment for UI. There can be some confusion, particularly when guidelines present conflicting or even contradictory recommendations about specific issues of evaluation or management. **Table 1** summarizes many of the recently published guidelines.

Guidelines have also been developed for different care settings. In the USA, the Centers for Medicare and Medicaid Services (CMS) issued F-Tag 315 in 2005. This guideline provides recommendations for bladder management in the long-term care setting. Nursing journals have published recommendations on ways to enhance implementation and compliance with the U.S. government regulatory guidelines [289].

Some guidelines have focused on education rather than on care delivery. The International Urogynaecological Association (IUGA) issued a set of guidelines specific for training in the area of female pelvic medicine and reconstructive pelvic surgery [290]. Other professional organizations have issued similar information under the headings of 'consensus statements,' 'recommendations,' and 'curricula.'

Many of the published guidelines focus on younger, healthy, community dwelling adults. Guidelines for evaluation and treatment of UI and FI in children and the elderly population or those with significant comorbidity need to be developed. These will need to take into account issues such as cognitive impairment, which can influence continence status in older adults [291]. Fung,[292] in a study in a large academic Veterans Affairs medical centre in the USA, used guidelines to develop condition-specific computerized templates to serve as guides for clinicians to ask questions and perform elements of a physical exam for two specific medical conditions:

Table I. List of Published Guidelines

Citation	Year	Topic	Professional Organization	Country	Language
Rao, 2004	2004	Diagnosis and management of fecal incontinence.	American College of Gastroenterology Practice Parameters Committee	USA	English

UI and falls. This study demonstrated that a set of templates can be developed within an existing electronic heath record system that can be used to prompt a clinician to obtain elements of a history and to perform physical examination.

In 2006, a national UK guideline was produced on UI in women [293]. Within the document, the area of surgeons' competence is discussed; however, there is no mention of other care providers' education and training (including GPs, nurses, physiotherapists, etc.). In order for services to be delivered effectively, primacy needs to be given to practitioners education and training in such documents.

a) Audits and assessments of guidelines

A number of recently published studies have examined the degree to which clinicians actually follow published guidelines. Many of these have focused on primary care providers.

A postal survey of Dutch general practitioners found that most adhered to guidelines when making the diagnosis of UI [199]. However, implementation of other measures and treatments were less robust. At least 25% reported difficulty adhering to the guideline due to lack of time, staff, diagnostic tools, competency in care delivery, and perceived low motivation on the part of patients. Others have questioned the utility of this specific guideline when viewed from the perspective of urologists [294]. They proposed future research to determine if recommendations for referral to specialists are adequate and if they will be implemented in a manner that will benefit patients. Another study with Dutch general practitioners identified therapeutic nihilism among the physicians and low motivation on the part of patients as major barriers to guideline implementation [86]. Other barriers included lack of time, difficulty explaining therapeutic options, limitations in patient mobility, and increased patient comorbidities.

A survey of primary care clinicians in the UK revealed that 56.8% agreed or strongly agreed that the NICE guideline on UI in women reflected their current practice [295]. However, more than half of clinicians indicated that they had not changed their practice to be fully compliant with the guideline. In another study, general practitioners in the UK identified knowledge limitations, time constraints, and access to resources on UI as important barriers to better implementation of the guidelines [296].

Adherence to guideline recommendations may also be less than optimal among specialist providers. Ismail[297] examined records of women undergoing sling surgery for treatment of stress UI at an academic medical center in the UK [297]. Only 45.3% of the patients had documentation in the medical record that they had previously tried conservative therapies. Documentation of underlying risk factors was highly variable. A similar study among urologists in Spain showed that compliance with guideline recommendations was less than ideal [298].

Rovner et al [299] examined published literature to determine the degree of adherence to the 1997 American Urological Association guidelines for the surgical treatment of stress UI in women [299]. They found that none of the 90 articles examined actually met all of the guideline criteria, although most complied with at least half of the recommendations. This directly influences the quality of literature available for evidence-based reviews and development of future guidelines.

Some components of guidelines may be particularly difficult to implement. For example, the NICE guideline recommendation that women undergoing PFMT should have a pelvic examination with assessment of muscle contractions may be challenging to perform in a busy clinical practice [300].

Studies have also examined the degree of awareness and adherence to guidelines among specific patient populations. Ismail reported on the results of a survey of 223 women in the UK who had recently delivered their first child [297]. According to the NICE guideline, these women should have been taught pelvic floor muscle exercises in the antenatal period. Although 95% reported awareness of the importance of the exercises, many did not have accurate information and only a small minority actually practiced them.

Guideline recommendations are not without controversy. In a retrospective database analysis of 6,276 women, Agur et al[301] noted that of women felt to have pure stress UI based on history alone, at least 25% were found to have other forms of voiding dysfunction based on urodynamics [301]. They concluded that the recommendation in the NICE guideline to avoid urodynamic testing in women with pure stress UI symptoms might be unwise and could miss other important findings, which could influence care.

Recent audits in the UK have shown that the mandate to develop and implement integrated continence care services has not been met [153,302,155].

There is even more limited data on whether adherence to guidelines actually leads to substantive changes in measurable continence outcomes [302]. In cases where organized services were available, overall quality outcomes were better compared to areas where these services were not offered [303].

A recent audit of the NICE guideline in the UK revealed that patient age may be associated with differential implementation of guideline recommenda-

tions for UI evaluation and treatment [304]. In this study, data from 7,846 women treated at either acute hospitals or primary care trusts in the UK, revealed that elderly women were significantly less likely to receive guideline compliant care compared to younger women. Actual levels of adherence by the care providers varied widely depending on the specific recommendation being evaluated. Levels of guideline adherence also appeared to differ between specialists providing care in acute hospital settings compared to general practitioners in the primary care trusts. In response to this finding, a recent editorial analysis asked rhetorically if lack of adherence to published guidelines for UI may actually represent a form of ageism on behalf of clinical providers and patients [305].

DuBeau et al[306] assessed the knowledge and attitudes of NH staff (including directors of nursing and nursing home surveyors) following revised USA government guidelines on continence care (Tag F315 - http://www.cms.hhs.gov/transmittals/downloads/R8SOM.pdf) [306]. They used a questionnaire in a convenience sample of 558 staff attending workshops. The authors report striking deficiencies in knowledge amongst staff and identified managerial structures as barriers to guideline implementation. They suggest such barriers need to be overcome in order to improve the quality of continence care.

Realistically the likelihood of obtaining adequate independent funding for effective professional education on UI and FI is unlikely in the current economic climate.

6. RECOMMENDATIONS FOR PROFESSIONAL EDUCATION (GRADE D)

Based on the literature reviewed in this section, the following recommendations can be made:

- There remains a need for rigorously evaluated continence education programmes which adhere to defined minimum standards for continence specialists and generalists, utilizing web-based and distance learning techniques alongside audit and feedback, train-the trainer models and leadership models, as well as traditional methods.
- Models of education content delivery (professional and patient education) are changing with technology with increased emphasis on Internet, web modules, etc. There needs to be ongoing quality control that includes maintenance of accuracy, methods of delivery, etc.
- There is a need for research on the most effective means to educate professional groups on continence issues. Specifically, there is need for research on:

o The effectiveness of innovative teaching methods in improving knowledge and practice.

o Translation of research into improved clinical practice and identification of methods by which this occurs.

o Mechanisms for increasing professional motivation to acquire education and improve performance.

VII. PRIMARY PREVENTION

1. BACKGROUND

Urinary incontinence is a highly prevalent and chronic condition that can often be prevented by addressing modifiable risk factors through primary prevention [307]. Although the evidence base for FI, PBS/IC, and POP is more limited than that for UI, the conditions share many similarities with respect to risk and treatment, suggesting that similar benefits may derive from population-based strategies [1].

Primary prevention refers to efforts directed to an individual, community or population level, to promote protective health behaviours in order to reduce the risk of these conditions. Since the Fourth ICI, there continues to be an increasing body of evidence linking incontinence with other conditions. These links provide opportunities to benefit from cooperative efforts with other health promotion initiatives. Primary prevention of UI using behavioral modification programs, including lifestyle changes (e.g., weight loss, diet modification) has been investigated in at-risk populations, including older women, childbearing and obese women, and women with diabetes. Obesity and diabetes have now been recognized as independent risk factors for UI [307]. ICI Committee 12: Adult Conservative Management reviews the evidence base for prevention of UI and POP in those persons with associated known risk factors and includes the levels of evidence for the respective interventions. Reference has also been made to prevention in other chapters, including ICI Committee 11: Incontinence in the Frail Elderly. Consequently, the focus of this section will be on the principles of population-based prevention, its application in other health conditions, and suggestions for translation into preventative programs for incontinence.

2. POPULATION-BASED PREVENTION

Recent research has predicted that due to population increases and a rise in the number of older adults, there will be a worldwide increase in the prevalence of UI by 20% by 2018 [308]. This has led to repeated calls to boost efforts to provide better continence education, promotion and prevention strategies throughout the world [235].

Prevention strategies should include education about lifestyle factors and behaviours that increase the probability of incontinence, the normal functioning of the urogenital and gastrointestinal tracts, expected age-related and developmental changes, healthy bladder and bowel habits,

and how to find the appropriate treatment providers [309]. A meta-analysis of physical activity programs found that behavioural interventions (such as goal setting, exercise prescription and self-monitoring) were more effective in increasing levels of physical activity than cognitive interventions (described as health education and the provision of information) [310]. Interventions for UI and FI (e.g., lifestyle changes, bladder and bowel training, PFMT) may also be better suited to behavioural rather than cognitive interventions. In addition, programs developed to raise awareness of continence issues should consider targeting a range of groups, including people of different cultures, ages and genders [106]. Consideration should also be given to targeting specific groups, including those who are socio-economically disadvantaged, as they may be hard to reach through population-based programs [311].

In 2011, the CFA launched a population-based campaign titled “Pelvic Floor First” to address concerns regarding the negative impact of some forms of physical activity on pelvic floor health. The campaign sought to raise awareness of pelvic floor related bladder and bowel health issues and to educate people at risk of UI and FI. Fitness instructors taught ways to minimise strain on the pelvic floor muscle when exercising. The campaign consisted of a dedicated web page (http://www.pelvicfloorfirst.org.au), on-line and printed education materials, screening tools for men and women, referral information and accredited on-line training for fitness professionals. Health consumers could also obtain information materials from the web page as well as links for further support from continence health professionals and the Australian National Continence Helpline.

Community based continence education workshops have been found to increase knowledge of continence issues and continence related QoL in women. In a study of 51 women who attended a 2.5 hour workshop, there was an increase in continence knowledge that was sustained for three months after the workshop [103]. The authors conclude that learning self-management strategies are important to improve pelvic floor health and that education in a public forum may be beneficial for these patients.

In 2011, a panel of experts released a consensus statement, A Healthy Bladder [312]. This follows from consensus work conducted that has examined the evidence base for preventative strategies for incontinence,[313,314] reiterating the ongoing need for primary prevention efforts to be addressed not only by healthcare professionals, but also by policymakers and funding bodies.

Consideration should be given to the setting in which the health promotion program is to be delivered, such as schools, work places, community groups and health care institutions [315]. It is acknowledged that while some nations are successfully implementing primary prevention strategies, others have yet to effectively implement secondary prevention measures, such as assessment and management of continence conditions [316]. In Australia, the UK and the U.S.A, continence organisations have received additional support from national governmental departments and agencies resulting in greater resources being applied to preventative and continence promotion programs. Evaluation and research are essential components of population-based prevention programs[317] and it is necessary to include funding for these as part of the program.

The WHO has stressed the importance of intersectoral collaboration involving governments, local communities and the private sector in efforts to tackle the effects of obesity and lack of physical activity upon chronic health conditions (http://www.who.int/dietphysicalactivity/en/). This type of collaboration may assist in spreading the cost of preventative programs for incontinence. A proposed diabetes population based prevention program found that governments are often reluctant to commit to high expenditure programs when the results may not be apparent until a considerable time later [318]. If a preventative program was developed for a combination of chronic health conditions, such as diabetes and incontinence, there may be economies of scale that would make funding such a program more attractive to governments, particularly when there is evidence that bladder changes and UI can be reversed if diabetes is prevented.

There have been a number of population-based prevention programs throughout the world that have been developed to reduce the incidence of obesity and chronic health problems by promoting physical activity and daily consumption of fruits and vegetables. An evaluation of a program in Australia to increase fruit and vegetable consumption in children found that increased parental knowledge as a result of the program was the strongest predictor of fruit and vegetable intake [319]. Evaluation of data from these programs is likely to benefit researchers and practitioners planning continence prevention programs for adults as well as children. The evidence for population-based prevention strategies remains at Level 4, Grade C.

3. PREVENTION OF UI IN OLDER ADULTS

Older adults are a heterogeneous group, and therefore preventive strategies for older adults need to take into consideration the well aged as well as the frail aged. It is important to involve older people and upcoming generations in health promotion research and health promotion intervention programs targeted at older people [320]. Promoting self-efficacy, such that the individual has a belief that they have the capacity and skills to im-

prove their own health, has been used in research on prevention of older, well-educated women with UI [321]. Self-efficacy improves the ability to cope with symptoms and is linked to motivation, knowledge of the benefits of making changes, and adherence to behavior change [322,323]. Self-efficacy over UI may be enhanced if women are taught self-monitoring techniques, such as adjusting fluid and caffeine intake, resolving constipation, PFMT, and monitoring voiding intervals. Self-efficacy measures, such as the Geriatric Self-Efficacy Index for Urinary Incontinence can be used to determine adherence to behavioural programs developed for the prevention and management of UI [6].

Community continence education of older adults has been advocated in several studies. A descriptive cross-sectional study conducted in China found that community-dwelling older persons often expressed negativity toward UI [158]. They considered UI as shameful, their own fault, and not preventable. Despite these feelings, they indicated that UI was not a sufficiently serious problem to justify treatment. In addition, nearly half of the nurses surveyed reported ignoring the initial onset of UI. Findings from this study indicated a great need for UI education for community-dwelling older persons and community nurses [158]. A similar conclusion, that advocated the need for education, was drawn from a cross-sectional descriptive study of 182 community-dwelling Korean American women [324].

Workshops can be an effective tool for population-based prevention education in older women. Tannenbaum [102] carried out a quasi-experimental prospective cohort study to evaluate the effectiveness of an interactive continence workshop. Ninety incontinent women, ages 55 to 87, were involved in this study. The interventions significantly increased knowledge and attitudes about the condition (94%). Sizeable proportions of participants either initiated self-treatment strategies, such as pelvic floor muscle exercises, scheduled toileting or dietary change (43%), or sought consultation with a health care provider (42%). The authors concluded that interactive continence workshops can promote self-management and consultation seeking among older women with incontinence. Incontinence-related knowledge, attitudes, self-perceived skills and intentions for seeking care improved after attending the workshops [102]. A behavioural modification program delivered to a group of women over 55 years of age reported the preventive effects of increasing pelvic floor muscle strength and increasing time between voids upon continence status, suggesting that preventive strategies are effective in older women [309,325].

Correlations have been found between poor general health and severe UI and/or FI in frail older people [326]. There are a number of strategies (e.g., mobility training, progressive strength training, balance and walking exercises), combined with behavioral interventions (e.g., pelvic floor muscle exercises) that may be successful in improving UI in this population. A systematic review of 3 RCTs and 4 quasi-experimental studies aimed to identify conservative interventions for reducing UI in non-institutionalized frail older adults [327]. With 683 participants involved (75% female), the studies concluded that multi-component behavioral interventions, including pelvic floor muscle exercises and bladder training, can improve UI frequency. However, there is need for more RCTs to demonstrate the efficacy of multidimensional treatments to guide clinical practice in the prevention and management of UI in frail older adults. (LOE 2)

4. PREVENTION OF FAECAL INCONTINENCE

While it appears that people are seeking help more readily for UI, the problem of FI remains under–reported,[241] especially in older people,[328] and few physicians ask patients about it in those persons at-risk [329]. A variety of risk factors associated with FI is reported by Committee 16: FI: Conservative Treatment. Analysis of studies on FI is hampered by a lack of standardised terminology with regards to stool consistency, gas leakage and frequency of incontinent episodes [314,330,331]. In order to be all inclusive, search terms for FI were expanded to include additional terms,(stool consistency, gas leakage, frequency of incontinent episodes,flatus,copracrasia). However, there were fewer matched papers about this area. Only an RCT in China revealed that PFMT is effective on the prevention of copracrasia by sphincter preservation operation on mid-lower rectal cancer. One hundred and fifty-one participants who received the surgery were randomized to two groups. Intervention group (n=75) received PFMT for six months but the control group (n=76) did not. The results from 1, 3, and 6 month follow-ups showed that PFMT contributed a positive effect against the development of FI [332]. (LOE 2) While acknowledging that prevention of FI is important, it is recognized that more research is needed to determine the effectiveness of population-based interventions that focus on the risk factors of FI.

5. RECOMMENDATIONS FOR PRIMARY PREVENTION (GRADE C)

Based on the literature reviewed in this section, the following recommendations can be made.

- Primary prevention studies should not be limited to individual interventions, but also test the impact of population-based public health strategies.
- More high quality, randomised controlled trials are needed to strengthen the effectiveness of population-based primary prevention intervention.

I. INTRODUCTION

Since writing the first chapter about the economics of incontinence in the initial report of the ICI in 1999, our knowledge about this subject, along with the number of treatment options, has increased substantially. The global economic crisis that began in 2008 has led to contracting budgets, both for individuals and governments, and a heightened interest in maximizing value. Economic tools are useful for understanding the value equation. Often economists are called on to enumerate the costs and benefits, and payers are increasingly using these tools to determine what treatments should be provided in order to maximize their population's health.

The first ICI report focused on stress, urge and mixed incontinence. The last report also included pelvic organ prolapse and faecal incontinence. We have developed, in part due to the ICI, better data for understanding how to manage these conditions. For example, stress incontinence can be readily cured by a variety of conservative and surgical options, but the benefit may decay over time. Similarly, pharmaceutical companies have developed new anticholinergic treatments for the overactive bladder, but these may require prolonged administration with longstanding drug costs. Such pharmacotherapy needs to be accompanied by bladder training, which also requires patient compliance to achieve success. The immediate benefit of Botox injections is well documented, as is the fall off in efficacy over time.

The good news is that this new information is making its way into the economic analyses. The bad news is that economic analyses are becoming more complex and harder to evaluate. Because of their unique aetiologies, it is more accurate to talk about the subtype of incontinence, making the blanket term of "the economics of incontinence" less applicable. This chapter takes account of these considerations, and is arranged according to incontinence subtype.

In the last five to ten years, the "aging" of the post WWII baby boomers is changing the consumption of health care resources. The median lifespan of a woman in OECD countries is now 83 years, and rising, with similar enhanced lifespan in men. Thus patients are living longer and are at greater risk for developing a range of conditions, including urinary and faecal incontinence, as well as prolapse. In order to compete for precious healthcare resources, in this contracted global economy, continence clinicians must construct robust health economic analyses of any new treatments if we hope to see these new treatments implemented for the benefit of our patients. In this chapter we present a summary of the appropriate methods, then present a critical analysis of recent publications.

II. BACKGROUND

1. PERSPECTIVE

When a patient with urinary or faecal incontinence (and to some extent prolapse) walks into a doctor's office in any country, they will have already incurred some personal costs in managing the condition at home, such as pads or laundry expenses. He or she will then have a basic consultation, tests will probably be ordered, a range of outpatient conservative (including pharmacological) treatments may be initiated, or a surgical procedure that may be recommended. These are treatment costs. At some stage, particularly in the elderly, the patient may suffer a urinary tract infection that may be associated with the incontinence/ cystocoele, or may slip and fall in their urine on the way to the toilet. These are the costs associated with treating the consequences of incontinence [1, 2].

The way in which these various costs can be measured varies a great deal from country to country. Although all countries regulate health care to some degree, they do so in very different ways e.g., the regulatory environment within which health care is provided can differ greatly from country to country, the need for private insurance and the coverage they provide is usually very country specific. Different countries also limit the building of hospitals in various ways, and control health care costs such as drug prices to a different extent [3]. Health care systems, whether a nation, province, or organization, can limit the treatments for which they will pay, or set limits on the prices. This has implications for estimating costs.

More importantly, this places an important duty upon researchers to describe explicitly where, when and how the costs were calculated. Researchers in one country need to be able to extract as much economic information as possible from the research carried out on a particular condition in other countries, to save "re-inventing the wheel" whenever possible.

Patients often observe very different "costs" for health care goods and services. In health care, we often think of cost as the amount to produce the good, whereas a charge represents the stated amount on a bill, which often includes profit for the manufacturer. Therefore, different accounting systems can yield very different cost estimates. For example, most of the hospital accounting systems in the U.S. focus on billing and payments. The charges listed on the bill usually overstate costs, on average by a factor of three, and are rarely paid in full by the payer. For example, in a study of the costs of surgery for female fecal incontinence in the US,[4] hospital "charges" were defined as the amount on the hospital bill, but the hospital "costs" were defined as the amount that the hospital actually received in payment. Only after understanding this definition can one make sense of the fact that hospital "charges" for FI surgery rose from $48 million to $57 million over 3 years, but the hospital "costs" increased only slightly from $23 to $24.5 million over the same 3 years [4].

In the U.S., many researchers prefer to use payments as the estimate for cost. Researchers have developed imperfect methods for adjusting charges with a hospital-specific ratio of costs to charges to better estimate costs [5]. Charges, however, are not always available. Integrated health care systems, including Canada and the U.K, do not routinely generate bills. For these systems, researchers have developed methods for generating pseudo-bills and cost estimates [6-8].

Many cost determination methods are used. Most analyses include a combination of "gross costing" and "micro costing" [9]. These terms are similar to the phrases "top-down" and "bottom-up". Accounting and billing systems use activity based micro-costing methods, whereby detailed estimates of time and products (inputs) are combined with unit costs to estimate total costs. Micro-costing (or "bottom-up") is challenging to perform because a single inpatient stay or outpatient procedure might have hundreds or thousands of inputs. For example, Morris et al[10] performed over 3621 observations to determine expenditure on urinary faecal or mixed incontinence in a one month study of 29 patients in a sub-acute care facility. Even when there is just a single input, such as a tablet, the cost can vary by location or the time of purchase if prices fluctuate.

At the other end of the spectrum, gross cost methods ("top-down") identify a limited number of important characteristics such as the Health Care Resource Group (HRGs) in the U.K., Diagnosis Related Groups (DRGs) in the U.S or Australia, and length of stay. However, DRG costing lack precision and can be problematic because this method does not track the actual treatment activities, but are based on an average treatment. For example, in Australia the DRG for Tension Free Vaginal Tape and Colposuspension is the same. In the section of this chapter on Sacral Nerve Stimulation (SNS) for faecal incontinence, the costs for temporary stimulation and permanent implantation vary considerably between Spain[11], Italy[12] and the UK[13] as shown in **Table1**.

Table 1. Comparison of the costs of temporary and permanent SNS between Spain, Italy and the UK.

	Spain (€)	Italy (€)	UK (£)
Temporary SNS	1,484	6,400	510
Permanent SNS	10,700	6,400	8,480

Accounting systems are limited in that they always report the health care payer's costs or charges. If researchers want to estimate societal costs, which are often of most interest,[9, 14] one must include both provider-incurred costs and patient-incurred costs. This distinction is important for urinary incontinence, since most providers do not pay for routine care (e.g., pads and protection). These costs are usually incurred by individuals, and in the year 2000 the routine care costs in the U.S. were $1347 per person for urinary incontinence and $1554 for people with OAB [15].

Thus the conclusion drawn by a researcher may be heavily dependant upon their perspective. For example, a study from the USA analysed Medicare claims for the treatment of urinary incontinence among women aged 65 or older for 3 years (1992, 1995, 1998) including outpatient, inpatient and emergency department visits [16]. Such Medicare claims nearly doubled over the time frame, from $128 million to $234 million, largely due to increased numbers of women treated by office visits and ambulatory (day only) surgery for items such as collagen injections. When the per capita changes were analysed, and inflation was considered, costs had actually declined by 15%. However, the editorial comment following this article points out that Medicare claims have a payer's perspective, do not quantitate pad usage, and cannot record pharmacotherapy for urge incontinence. Since we know that overactive bladder is more common as age increases, such pharmacotherapy is likely to be increasingly important in the over 65 age group, so that the conclusion of a 15% drop in per capita Medicare expenditure is not likely to be valid representation of costs in general. The editors pointed out that the article was mainly representative of patients with stress incontinence as a result. Such methodological issues are important.

In the example described above, the "perspective" that the researchers used was that of Medicare claims. In other words, Medicare was the "payer", not

the patient. This highlights the fact that costs can be evaluated from several different perspectives. The four most commonly used perspectives are (1) overall society costs, which includes all aspects of care and treatment (which this committee recommends), (2) the payer, such as Medicare, (3) the provider, such as a hospital or managed care plan and (4) the patient.

In general, health economists prefer that a societal perspective (include all costs) is used [9, 14]. This facilitates comparison of the cost of illness across different countries. The problem is that different countries use different frameworks for reimbursing some or all of the costs of various conditions, so that international comparisons remain controversial.

2. COUNTRY SPECIFIC ECONOMIC ISSUES

From the perspective of a patient, large costs are often incurred when paying for routine care products, treatments, and long-term care. These patient costs vary by country. For example, in Sweden and Spain, the government (tax based) health insurance covers routine care products. In the UK, age-dependant patient subsidies are available for pads. In Germany and Spain, pad costs are reimbursed if prescribed by a doctor [17]. In Australia, low-income patients can apply for a subsidy to reimburse most of their routine care products, but more wealthy patients must pay all costs. In the USA, such products are rarely covered and can be very expensive [17].

The degree of government subsidy to the patient varies greatly by country. In the UK, most patients use the National Health Service (NHS) so that all office visits, tests, outpatient visits and surgical treatments are free to the patient. Pharmacotherapy does attract a small out of pocket payment for each drug. In Italy and Sweden pads are reimbursed, but not in Germany. Pads are not routinely subsidized, only at the discretion of the local Care Trust. In Australia, about 70% of patients only have government insurance, similar to the UK NHS, but 30% of patients also have private insurance so that inpatient treatments attract a rebate from their health fund. In the USA, adults over age 65 and those with a disability are covered by the Medicare program. This provides coverage for inpatient, outpatient and pharmacotherapy, although patients are generally responsible for sizable co-payments and nursing home care is capped. Those not covered by Medicare often have private insurance or Medicaid (a health insurance program for people with low incomes); nonetheless about 48 million Americans lack any insurance.

In the Netherlands, all legal residents are obliged to purchase a basic health policy (the purchase of a complementary policy covering extra health services remains voluntary). The choice of health insurer and type of health plan is free. The government establishes what is in the basic package and under what conditions people are entitled to care.

In regards to long term care benefits for those in residential care, considerable variation occurs. In the USA, Medicare and Medicaid benefits are time limited for re-imbursements to nursing homes and other assisted living facilities. Usually, after several months, benefits stop and payment must come from private insurance or the patient's pocket. In Australia, low income patients who have no private superannuation (pension fund) can receive the "old age pension" which covers fully funded long term care, albeit in lower-calibre facilities than would be chosen by those who could afford better (similar to the Netherlands system). In Japan, generous long term benefits are provided to long term institutional residents, so that out of pocket payments are reduced.

3. COSTS AND TIME

Costs change over time and researchers need to account for temporal changes in their analysis. The easiest way is to present the costs in a specific year (e.g., 2012). Costs borne in past years should be inflated. In many countries, the governments track and publish inflation indices. In the US, inflation is represented in the Consumer Price Index (e.g., www.stats.bls.gov). In the UK, the Health Service Cost Index or the Retail Price Index, published by the NHS Executive, Leeds, UK, can be used to adjust the costs of health care services (www.statistics.uk.gov).

Caution is needed because general inflation relates to the cost of a consistent set of goods over time, e.g., the goods must be of the same quality over time, and thus the costs observed five years ago can be observed today. If so, then the inflation index is informative. However, medical goods change rapidly as does their quality. For example re-usable laparoscopic equipment has been replaced by disposable equipment that is usually more expensive, and the newer drugs for OAB are generally more expensive. This makes it difficult to determine whether any change in price is due to inflation or due to (real or perceived) improvements in quality. Thus, just inflating costs from many years ago can be misleading. Consequently, many researchers recommend against using price indexes that are developed specifically for medicine because these indexes do not take quality into account. Researchers must also be cognizant of the fact that the published success rates for various treatments change over time. For example, in Adang et al.[18] dynamic graciloplasty is portrayed as having a stable success rate over time in the treatment of faecal incontinence (see **Figure 1**). In fact, we now know that dynamic graciloplasty has a very poor success rate over 10 years, so that the estimated data shown below in **figure 1** from 1998, is no longer accurate.

In addition, many continence treatments have costs that extend into the future. Drug treatments require that patients take drugs in the future. People have time preferences for money and future costs should be discounted to represent the present value. Controversy exists about the appropriate discount rate[19-21] but most international studies use a discount rate of 3% per annum. See Adang et al. [18] for example.

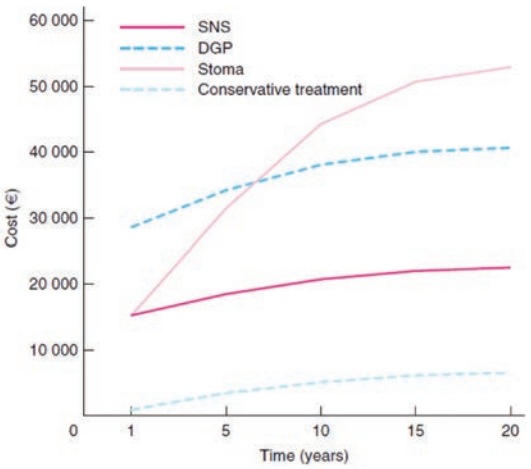

Figure 1. Estimated long-term costs per patient for each treatment: sacral nerve stimulation (SNS), dynamic graciloplasty (DGP), stoma and conservative treatment after 1, 5, 10, 15 and 20 years. Costs are in € and discounted to present values at a 5 per cent rate [18], from analysis by Hetzer et al, 2006 [22].

In summary, defining and measuring costs in health care can be imprecise. Often there is variation across regions and time. This variation needs to be taken into account in the economic analysis and the easiest way is to conduct sensitivity analysis to investigate how different cost estimates can influence the results. By this we mean re-running the analysis with different input parameters. As we describe in the next section, explicitly describing these contextual issues is crucial for interpreting results.

III. TYPES OF ECONOMIC ANALYSIS

1. OVERVIEW

A typology of economic analysis for health and medicine has emerged over the past few decades. This section reviews these studies.

a) Cost of illness (COI)

As already described, COI studies summate the costs related to a condition for a given population. The costs are annualized for a given year (i.e., 2012). A COI is a descriptive analysis. However, COI studies provide little information to decision makers about how to allocate scarce resources for treating conditions, because there is no attempt to measure the "value" of the relevant treatments.

b) Cost minimization analysis (CMA)

CMA compares the costs of alternative health care strategies, assuming that the benefits of the alternatives are equivalent. When the two treatments are truly equivalent in their risks, outcome, and an individual's preference for them, then a cost minimization analysis is sufficient; the cheapest intervention is to be preferred.

c) Cost consequence analysis (CCA)

CCA is a variation on cost-minimization analysis, which involves assessing whether a new treatment results in a greater decrease in health care utilization than another treatment. Thus costs of the intervention are compared to health care utilization, such as the cost per hospitalization averted. There is a naturally appealing rationale for conducting this analysis. Unfortunately, when examined in detail, this rationale boils down to an analysis of whether the new treatment saves money in comparison to the alternative treatment. Accordingly, a cost-utility or cost-benefit analysis provides many advantages over a cost consequence analysis.

d) Cost-effectiveness analysis (CEA)

CEA refers to the broad class of calculations where the effectiveness measure is a general health outcome. CEAs with narrowly focused health outcomes (e.g., incontinence episodes) have well-known limitations. Most notably, the use of narrowly focused health outcomes will miss other important effects. For this reason, there has been widespread agreement on the use of quality adjusted life years (QALYs) as the preferred health outcome in cost-effectiveness analysis. In the US, CEA has become synonymous with cost-utility analysis.

e) Cost-utility analysis (CUA)

CUA refers to a CEA when QALYs are used as the outcome measure. Gold et al.[9] and Drummond et al.[14] have published texts that discuss standard techniques for conducting a CUA. In health and medicine, the CUA is considered to be the gold standard. Utilities capture all potential benefits of an intervention and allow comparisons with other health conditions, making cost-utility analysis a powerful research tool.

Compared to other medical fields, we have insufficient data on utilities in incontinence or on the effect of treatment or change in incontinence severity upon cost utility measures, to date.

Data in a CEA and CUA are represented by an incremental cost-effectiveness ratio (ICER). The ICER represents the average cost of the intervention group minus the average cost of the control group. This amount is then divided by the average utility of the intervention group minus the average utility of the control group (see Section IVb).

f) Cost benefit analysis (CBA)

Involves measuring the benefits in dollars. When everything is measured in dollars, optimal choice can be easily found by addition and subtraction. However, it is difficult to measure benefits in dollars, and many researchers and policymakers are averse to placing a dollar value on life. CBA is rarely used in health.

g) Summary

COI and cost-minimization analyses are simple, yet limited economic tools. Most new treatments offer ad-

ditional benefits at an additional cost. The CBA, CUA and CEA were designed to determine how much money it costs to obtain another unit of effectiveness. Although the CUA is the preferred method, there are many challenges with calculating a QALY. We will discuss these issues in more depth because different methods for calculating QALYs can have a very profound effect on the interpretation of the CEA/CUA.

2. DETAILS OF DECISION ANALYSIS

Decision analysis is a tool that can be used to summarize effectiveness data, costs data, or combine both cost and effectiveness data in a CUA. The value of decision analysis is highlighted by a multi-site clinical trial by Albo and colleagues[23] that compared Burch colposuspension to fascial sling for stress incontinence. They concluded that the fascial sling yielded a higher rate of successful treatment, measured as a composite outcome, but also resulted in greater morbidity. Even in well-designed multi-site clinical trials, the results may be ambiguous. Decision analysis may be used to overcome this ambiguity. Decision analysis is a quantitative probabilistic tool for resolving problems when there is uncertainty with regards to treatment options.

There are two primary decision analytic methods (see below); each has its strengths and weaknesses. The starting point with any decision analysis is a clinical question, such as how to treat women with stress urinary incontinence or how to treat patients with faecal incontinence (see **Fig 2** below from Dudding et al., 2008 [13]). The question should fully and fairly address the clinical questions. One might develop add on questions, such as how to treat women who had surgical failure or sacral nerve implants that become infected or in which leads migrate, but it is often best to address these more specific questions as part of the broader decision analysis.

A benefit of decision analysis is that researchers can combine data from multiple clinical trials and marry that data to observational information (e.g., long-term follow-up data). Decision analytic tools are flexible and can be used to identify the treatment that maximizes quality of life. One can also use the same model to address issues of cost-effectiveness. Hence, one of the first tasks in the decision analysis is to identify the primary outcome. Outcomes such as quality adjusted life years (QALYs), that can reflect treatment and disease, are recommended. By using QALYs, one can overcome conflicting data—for example, the finding that vaginal slings have higher success rates but also greater morbidity. As is discussed elsewhere in this chapter, QALYs value all aspects of quality of life and include mortality. Next, the researcher must

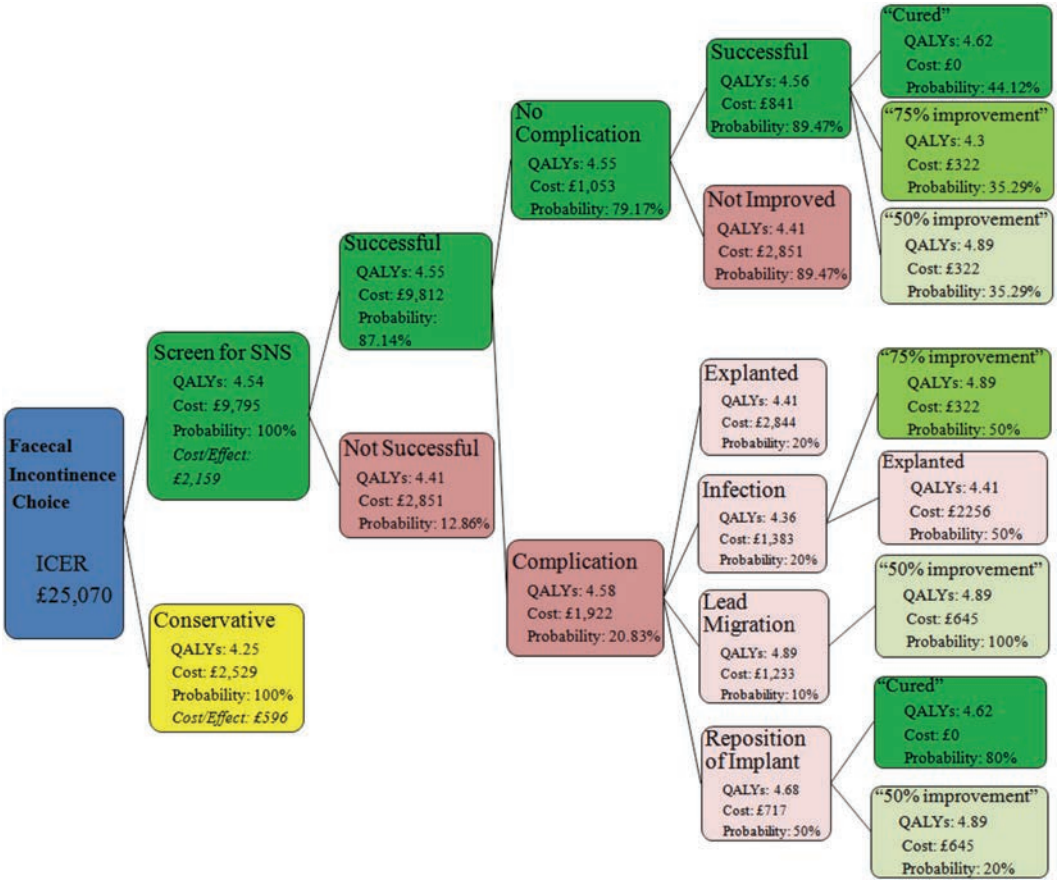

Figure 2. Decision tree for SNS treatment of faecal incontinence modified from Dudding et al (2008) with permission [13]

determine whether the model will include cost information or not. Some decision analytical models focus only on outcomes, while others add cost data to address resource allocation questions.

By combining data from multiple sources, decision analysis can be used to model lifetime costs and benefits. Researchers are often asked to identify the treatment(s) that maximizes lifetime benefits or lifetime cost-effectiveness. Randomized trials, while the gold standard for assessing causation, are time limited, often following participants for less than five years. Decision analysis can extend such data to consider future events, such as surgical failure rates, nursing home admission or life expectancy. Decision analysis can also be used to understand whether the analysis differs by perspective. Payers, providers and patients all have different perspectives, and decision analysis makes it relatively easy to consider each of these perspectives and whether they differ from a society perspective.

a) Steps in a decision analysis

Decision analysis can be boiled down into five steps. The first step involves identifying the structure of the problem and this requires the listing of all decision alternatives, all clinical outcomes, and a sequence of events. After completing step one, step two involves assigning probabilities to all chance events (e.g., death). Step three involves quantifying the benefits (e.g., QALYs) for all outcomes. The fourth step involves the mathematical calculation of expected utility for each strategy (or this can be taken from published data). Step four will often identify the preferred strategy. The final step involves conducting sensitivity analysis to check that the model is robust across a range of clinically meaningful possibilities.

Every decision model involves some assumptions. Frequently, assumptions are needed to incorporate clinical trial data in the model. For example, a common assumption is that the effect shown in a clinical trial is generalizable to the broader population—treating women with TVT will result in effects like those seen in Lier and colleague's paper[24] (discussed later in the chapter). Some assumptions may seem trivial, but it is best to delineate each assumption along the way. Published decision analysis should include a table of assumptions along with other data inputs; frequently this is the first table in the decision analysis.

The clinical question and the structure of the problem (step 1) should provide guidance on the decision model. Frequently decision trees are used because they are simple and address the question at hand. Decision trees are so named because they look like a tree with a trunk, branches and leaves. For example see **Figure 3**, taken from a study of Botox therapy versus clam augmentation cystoplasty by Padmanabhan et al[25], to be discussed later in this chapter.While decision trees are easy to describe and conduct, it is hard to include changes over time in the analysis. Diseases often change over time and people may transition into and out of different health states over time. One strength of Markov models is their ability to include these time-related transitions. We will discuss decision trees first and then Markov models in more detail afterwards.

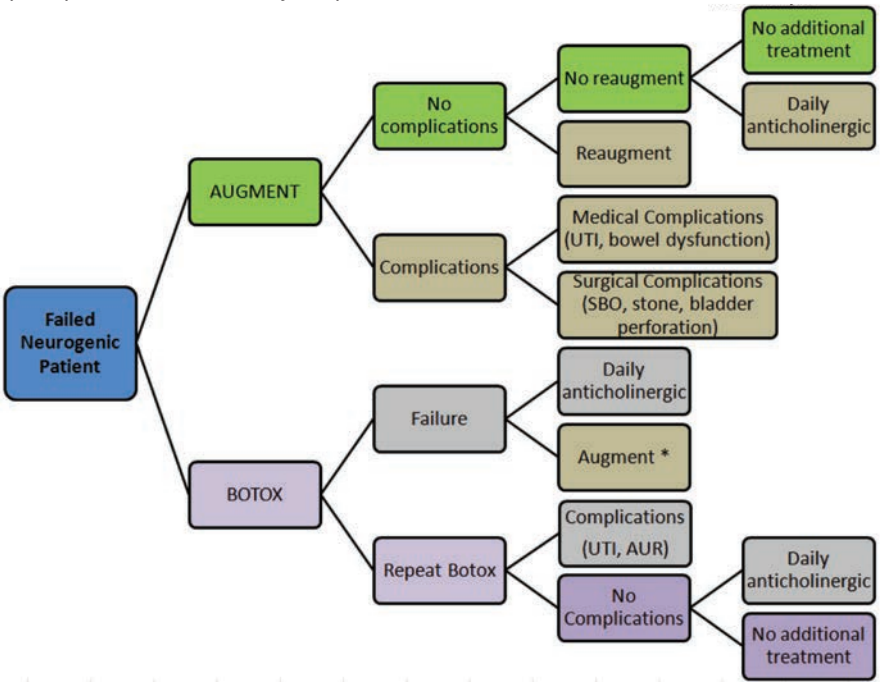

Figure 3. Decision tree for Botox treatment of severely refractory neuropathic DO patients, modified from Padmanabhan et al (2011) [25].
**** indicates the treatment algorithm continues along the augment pathway***

b) Decision Tree

In a decision tree, there is a distinction between a decision node and a chance node. A decision node is a point where a choice is made by the decision maker (typically a physician or patient). For example, for a woman with stress incontinence, the choice to operate (yes or no) would be represented with a decision node. A choice must have at least two options and more than two choices are permitted. However, each choice must be mutually exclusive. A patient cannot choose both operation and no operation. A chance node is a point where chance determines fate. For example, the decision maker chooses to operate or not operate, and hopefully the treatment is successful, but treatment success or failure is a chance node. Not only must chance nodes be mutually exclusive, but they must also be collectively exhaustive (one of the chances must happen and the sum of probabilities for all of the chances must add to 100%).

In addition to chance and decision nodes, there are terminal nodes. These nodes are the final outcome for the pathway taken. Sometimes understanding the nodes makes more sense when looking at the pictorial representation. **Figure 4** shows a hypothetical decision tree for treating a patient with stress incontinence. In this hypothetical situation, we structure the model to have two options: surgery or drugs. It is overly simplistic in that we do not differentiate between drugs.

The main choice is surgery versus medical management. Surgery carries some risks—a small probability of operative death, for example, in the case of clam cystoplasty for refractory detrusor overactivity. The decision nodes are represented by squares while chance nodes are represented by circles. The terminal nodes are cure, no cure, operative death or non-adherence, which is the same as no cure. This is a hypothetical decision model, and most decision models are much more complex. Clearly this model could be expanded to include behavioral treatment and each decision node could be expanded to consider all relevant alternatives (autologous sling, Burch colposuspension, tension-free vaginal tape, trans-obturator tape).

For the next step in the decision model, one must include probabilities at each chance node. We must identify the probability that the disease is cured after operation. Researchers should review the published literature to find this probability and ideally some information about the distribution around this probability (e.g., probability= 58% with a 95% CI 51-68%).

After including probabilities, one must place values next to the terminal nodes. These values must be a single outcome and QALYs are preferred, although life years (unadjusted for quality) are used for some diseases. With outcomes and probabilities, one can then "run" the decision tree. Because there is one decision node with two options, we will be computing expected values for the two options. Running the model involves starting at each endnode and working left or backwards. The expected value for the surgical survival node is 3.8 QALYS. (**Figure 5**)

The expected value for the surgical operative death node is 0. When we combined a 10% chance of operative death (0 QALYS) and a 90% chance of survival (3.8 QALYS), we find the expected value of surgery is 3.42 (**Figure 6**). If we do the calculation for the lower branch, we get the expected value for drug therapy is 3.76 QALYs. Because 3.76 >3.42, we would recommend surgery over drugs IF the sensitivity analysis shows this result to be robust. The decision tree in the example focuses on QALYs for UI treatment and it ignores cost differences, but it could be easily modified to include cost information.

c) Markov Model

The decision tree, as shown above, assumes the chance of events is stable over time. Our knowledge about urinary incontinence suggests otherwise. A person, for example, could get surgery for stress incontinence, but over time we need to include the potential for surgical failure. Markov models are good

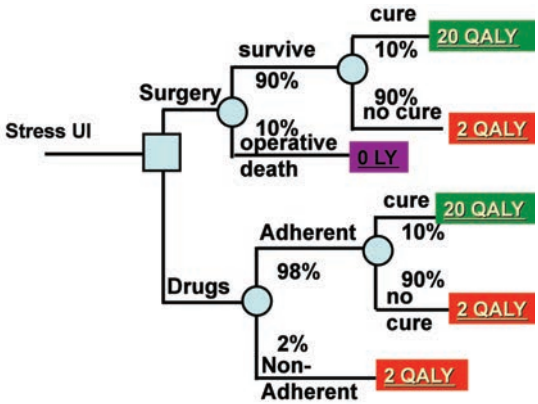

Figure 4. A hypothetical decision tree for treatment of patients with stress incontinence. Squares = decision nodes, Circles = Chance nodes and terminal nodes.

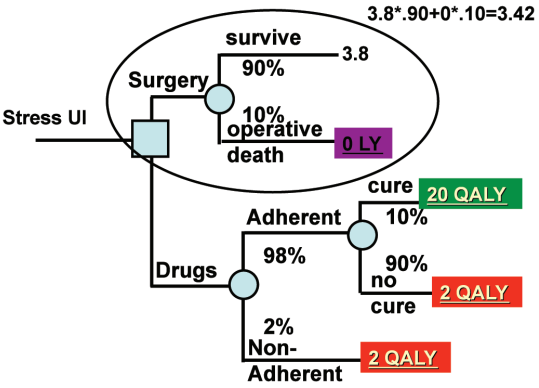

Figure 6. Computation of expected QALY values after surgery for stress incontinence.

for incorporating changes in health states over time. At their core, Markov models are mathematical techniques, derived from matrix algebra, that describe the transitions a cohort of patients make among a number of mutually exclusive health states over time. The model works by cycling to make new calculations for each period of time.

The pictorial depiction of a Markov model is typically shown as a decision state. **Figure 7** shows a very basic four-state Markov model. At each period in time, a person has to be in one and only one of the states. But with each change in time (cycle), the person can move to another state, shown with arrows, depending on the possible states and a probability. If the person dies, they are shown to enter the death state. The person cannot leave this state.

Some aspects of the Markov model construction are similar to a decision tree. Setting up the model is quite similar. One must identify the health states and the transition probabilities. What is quite different is that one must determine the cycle length—the rate at which you allow people to change states. The cycle length should be a clinically meaningful period of time and this choice is also frequently affected by the availability of data. There may be publications showing annual failure rates for surgery and so one could choose an annual cycle. For a Markov model, one needs to know the value for each state. Again, QALYs is the preferred metric. When the model runs, the program keeps track of the amount of time each person spends in each state. Transitions to other states are handled by transition probabilities (i.e. the likelihood of cure or failure). Decisions, such as the decision to change from one treatment to another, can affect transition probability. Models can use cohort simulations where a large hypothetical cohort of patients is run through the model. This does not provide information on the distribution of expected values. Monte Carlo simulations run each patient through the model a large number of times (e.g.,10^4). In doing so, this provides a distribution and variance information on patients.

With Markov models, sensitivity analyses remain a crucial step to test the robustness of the model. Recent advances in sensitivity analyses and in the graphical presentation of data general require the use of specific software. Although some people program Markov models into a spreadsheet, such as Excel, both Tree Age and Decision Maker software, are well known for their ability to streamline decision analysis and provide many advanced features that would be very difficult in Excel.

3. STATISTICAL ANALYSIS

In the last ICI chapter, we discussed alternative statistical techniques, but did not discuss bootstrapping, which has become quite common in cost utility analysis, especially in analyses alongside clinical trials. Bootstrapping is a method of resampling that enables researchers to estimate parameters based on the observed sampling distribution. It is particularly useful when estimating the confident intervals for the incremental cost-effectiveness ratio (ICER). The ICER involves dividing the mean difference in costs by the mean difference in utilities. Statistical software can easily determine whether two samples have different costs or different utilities (e.g., t-test). But software cannot easily calculate the confidence interval around the ratio of these two differences. Bootstrapping involves randomly drawing cases from the sample and replacing the case back in the sample. Resampling is done until the original sample size is met. The same process is then done again and again, typically 4000 times. Thus, by resampling, the analyst can calculate the ICER 4000 times, thereby providing a distribution around the ICER.

4. BUDGET IMPACT ANALYSIS

Providers and payers often have priorities that are not directly addressed by a cost-effectiveness analysis from a societal perspective. Budget impact analysis (BIA) was developed to inform a decision maker on how alternative technology will affect their budget. A BIA will often focus on the decision maker's costs and over a short time frame (e.g., 1-3 years). Other parameters in the model, such as patient characteristics or input costs, can also be tailored specifically for the

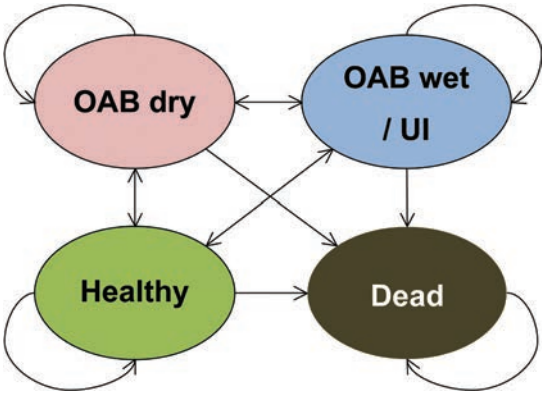

Figure 7. A basic four-state Markov Model

decision maker. Making decision based solely on a BIA can lead to suboptimal societal results. Hence, scientists advocate that a BIA be done in conjunction with a CEA so that decision makers are informed about the broader social implications of their decision. The International Society for Pharmacoeconomics and Outcomes Research (www.ispor.org) has created guidelines for conducting a BIA and these can be found on their website.

IV. PRACTICAL ASPECTS OF ECONOMIC ANALYSIS IN THE CONTINENCE FIELD

1. HEALTH OUTCOME MEASURES SUITABLE FOR USE IN ECONOMIC ANALYSES

There are a number of health outcomes that are used in economic evaluations of incontinence. These include disease-specific outcomes, health status and health value (e.g., QALY). Each is discussed in turn.

a) Incontinence specific outcomes

Cost-Effectiveness in Health and Medicine[9] recommends using QALYs as the effectiveness measure in the CEA. However, the panel also notes that analysts can use a clinical outcome measure. For incontinence, clinical outcome measures include 24-hour pad test, a voiding diary, or urodynamics. These outcomes are attractive for clinicians because they often use these measures in clinical practice.

Clinical outcomes can be very valuable in identifying when a treatment is efficacious. However, using clinical outcomes in a CEA yields results that are limited in scope. A treatment might have improved a person's quality of life, but had little effect on the clinical outcome measure. In this case, the results would be biased. In addition, a CEA with a clinical outcome measure might not be comparable to another CEA with a different clinical outcome measure. A clear advantage of cost utility analysis is that QALYs can be generalized beyond incontinence. For this reason, QALYs and CUAs are the gold standard.

b) Health Status and Quality of Life Measures

There are a number of frequently used and highly regarded general health status measures, such as the SF-36, the Sickness Impact Profile and the Nottingham Health Profile, which describe a person's current health state. Instruments that assess how a person perceives or feels about their health state are called quality of life (QOL) measures.

Chapter 5 in this book reviews generic and disease – specific quality of life measures, which are useful for understanding the effects of a treatment. However, because they cannot be used to create QALYs they are of limited value in economic analysis. An example of an exception is the SF-36 for which Brazier et al. [26] have created a utility scoring system known as the SF-6D.

c) Health value

Although there are several ways of measuring the value of a health state, the most common are willingness to pay (WTP) [27] and the quality-adjusted life year (QALY). We focus on QALYs as they represent the current standard for measuring health value in cost utility analysis.

QALYs denote the relationship between the value of a given health state and the length of time a person lives in that health state. The value of a given health state is measured in 'utilities', where 'utilities' represent preferences for a given health state.

To understand utilities, consider the following: most people would prefer to be healthy over a given time rather than suffer constant urinary or fecal incontinence. Utility measurement refers to valuing these preferences on a perfect health-death scale with endpoints of 1.00 and 0.00, where 1.00 is perfect quality of life (best imaginable) and 0.00 is death equivalent quality of life. For example, the measured utility for urinary incontinence may be 0.60. If treatment improves this to 0.70, then the value of the treatment is 0.70 – 0.60 = 0.10. If this utility gain is maintained over time, say for 10 years, then the gain is 0.10 x 10 = 1.00 QALY. Because utilities are measured on an absolute scale (perfect health to death), they can be used across different health states and therefore can be used to compare the effect of interventions in different health fields, or different interventions within the same field. For example, the QALYs gained from treatment for incontinence could be compared with those gained from treatment for depression. Where treatment costs (including costs to the patient) are known, the treatment providing the lowest incremental cost-per-QALY gained is preferred as this ensures society gains the greatest benefit from the health care dollar.

Direct and indirect methods have been used to elicit utilities [28]. The most common direct elicitation methods for valuation include time trade off (TTO), standard gamble (SG), and the visual analog scale (VAS). For description of these methods, see our previous chapter in this ICI series [29].

1. Instruments measuring utilities suitable for QALY calculation

Multi-attribute utility (MAU) instruments can be used instead of the direct elicitation methods. Simply, a MAU-instrument decomposes HRQoL into health domains (e.g., mobility and emotions). Respondents provide estimates for each attribute, which are then 'valued' and summarized into a utility. The three most commonly used MAU instruments are Quality of Well Being Scale (QWB), Health Utilities Index (HUI) and EQ5D (as reviewed by Hawthorne & Richardson[30]).

Quality of Well-Being Scale (QWB)

The QWB has three dimensions (Mobility, Physical Activity, and Social Activity), with 3–5 levels each,

and 27 illness symptoms [31]. The QWB requires trained interview administration (15–35 minutes), although a shorter version is available; a self-report version is under development. The upper boundary is 1.00, lower boundary is 0.00

Health Utilities Index (HUI)

The HUI uses 12 items that measure 8 domains (Vision, Hearing, Speech, Ambulation, Dexterity, Emotion, Cognition and Pain). The upper boundary is 1.00, lower boundary is –0.36.

EQ5D

The EQ5D was developed by the Euroqol team from 7 European countries [32, 33]. It has 5 items measuring Mobility, Self-care, Usual Activities, Pain/Discomfort and Anxiety/Depression. The upper boundary is 1.00, lower boundary is –0.59. This has become a very popular instrument in clinical trials because it has been widely used in many languages and it is very brief.

A recent study [34] tested the effect of stress urinary incontinence on quality of life, as measured with the EQ5D. Investigators in the Stress Urinary Incontinence Treatment (SUIT) study, a 12-month, prospective, observational, multicenter study multicountry in four European countries, described the association of SUI symptoms with the EQ5D among 3762 women seeking treatment for symptoms of SUI. Participants had a mean age of 58 years, mean body mass index of 27.7 kg/m2, and had at least one comorbidity in addition to UI. The health state index scores were significantly and independently influenced by the presence of comorbidities affecting quality of life, total number of stress and urge incontinence episodes. In summary, the number of incontinence episodes and type of UI had a significant impact on the EQ-5D index score.

SF-6D

Whenever SF-36 raw scores are available, SF6D utilities can be computed [26]. The SF-6D measures physical functioning, bodily pain, mental health, physical role, emotional role, social functioning, and vitality. The endpoints for the SF-6D are 1.00, and 0.30 for the worst possible health.

The 15D

The 15D was created in Finland. It has 15 items, measuring Mobility, Vision, Hearing, Breathing, Sleeping, Eating, Speech, Elimination, Usual Activities, Mental Function, Discomfort & Symptoms, Depression, Distress, Vitality and Sexual Function [32]. The upper boundary is 1.00, lower boundary is +0.11.

The 15D is a generic, comprehensive, standardized, self-administered measure of HRQOL that can be used both as a profile and single index score measure [35]. The single index score (15D score) on a 0-1 scale and representing the overall HRQOL, is calculated based on population-based preference or utility weights. The 15D scores are shown to be highly reliable, sensitive and responsive to change, and valid for deriving quality-adjusted life years (QALYs) gained for resource allocation purposes. The 15D score is sensitive to urinary incontinence in a cross-sectional study [36, 37] and is sensitive to change in incontinence severity following intervention [24, 38]. A recent population-based survey of over 3700 Finnish adults found that increased severity of urgency and urgency urinary incontinence is associated with statistically significant decreases in the total 15D score and on all 15D dimensions ($p<0.001$ for all) [36].

The Assessment of Quality of Life (AQoL)

The Assesment of Quality of Life (AQoL) includes five dimensions: Illness (not used in utility computation), Independent Living, Social Relationships, Physical Senses and Psychological Well-being [39]. The upper boundary is 1.00, lower boundary is –0.04.

The Rosser Index has two dimensions measuring disability and distress, and measured 29 health states. Values (magnitude estimation) were from a convenience sample of 70 respondents [40]. A revised version in the early 1990s included discomfort as an additional dimension [40]. Administration requires a trained interviewer. The upper boundary is 1.00, and the lower boundary –1.49, which means that health states worse than death are permitted.

Note that many people with incontinence are not cognitively able to complete a MAU or go through a standard utility elicitation process. Some of the MAUs, such as the HUI3, have been validated for use with proxies. Although not always possible, if proxies are expected then proxies should be gathered for all cases, even those patients who complete the utility measure themselves, so that the method is applied in a standard, consistent fashion.

2. "DO IT YOURSELF" - HOW TO CONDUCT A COST UTILITY ANALYSIS: THE COMMITTEE'S RECOMMENDATIONS

The cost utility analysis (CUA) now represents the gold standard for medical decision making. Therefore, the remainder of this section highlights ten key issues that must be addressed in a CUA. These ten principles, summarized below, comprise an appropriate minimum standard for performing and reporting cost utility analyses. The principles were identified from guidelines established by the Panel on Cost-Effectiveness in Health and Medicine convened by the United States Public Health Service [9]. Each principle should be explicitly addressed in every study.

a) The ***Research Question*** must be clearly stated. All CUAs must compare at least two different treatments or interventions. One of these should include the current standard practices. For example when comparing surgeries for stress incontinence, one of the comparators should be a longstanding method, avoid comparing two new methods side by side.

b) The ***Time Frame*** over which costs and benefits are measured should be long enough to capture the economic impact of an intervention and future health outcomes. Pharmacology studies of 12 weeks duration give very little real economic information, and surgical complications/ failures seldom emerge in less than 1-2 years.

c) Perspective: The choice of perspective should be clear. Total society perspective (all payers) is the gold standard. Other perspectives, such as the payer or patient perspective, may be useful but must be stated clearly.

d) Probabilities are needed for each "chance" event, such as chance of cure or chance of an adverse event. The best sources of probabilities come from meta-analyses of randomized clinical trials, or if not available use data from individual clinical trials.

e) Costs: Units of expense and unit costs should be described in detail. Information on the source (e.g., charges, payments) and year of the cost data should be presented. If the costs were inflated and/or converted from another currency, then this must be described.

f) Outcome Measure: Measures of effectiveness depend on the type and objectives of analysis. Quality adjusted life years are the gold standard, as described previously in this chapter.

g) Analytic Model: Each intervention being assessed must be described and possible courses of events identified, including the expected course of disease, treatments, complications, and outcomes. This may be performed using a spreadsheet/ clinical trial path, or Decision Tree, or Markov Model.

h) Discounting: Since the value of both costs and benefits may decrease over time, discounting is used to calculate the present value of money and health states that will occur in the future. Future costs and utilities should be discounted to present value; 3 % per year is a recommended starting point.

i) Incremental Analysis: The purpose of a CUA is to describe the relative value of one health care strategy compared to another. An incremental cost-effectiveness ratio (ICER) is the incremental cost divided by the incremental effectiveness of intervention a compared to intervention b, and is calculated as follows.

$$ICER = \frac{\text{Average Cost intervention A} - \text{Average Cost intervention B}}{\text{Average Utility intervention A} - \text{Average Utility intervention B}}$$

Averages should be used rather than other measures of central tendency, such as medians, because it is important to include the effect of outliers. The leverage of the outliers should be tested in a sensitivity analysis.

j) Sensitivity Analysis: A sensitivity analysis should allow the reader to understand whether the conclusion of the analysis would hold true if either the Costs or the Probabilities (of cure or complications) were to vary substantially. For example if one treatment costs €5,000 and has a cure rate of 90%, and the second treatment costs €2,000 with a cure rate of 80%, then the ICER will assess whether the resultant benefit in QALY/ Quality of Life makes the first treatment worthwhile.

Having reached this conclusion, the researcher should then vary the costs and the cure rates in the model, to see how much variation in real life would be allowed yet still maintain a valid conclusion.

Documenting these boundaries helps define the conditions under which a treatment is preferred. Researchers are developing innovative methods for conducting sensitivity analyses. Probabilistic models that use simulations are becoming more common, although they can be computationally complex. Some journals require probabilistic sensitivity analyses.

V. SUMMARY OF RECENT ECONOMIC ANALYSES

Two trends stand out while reviewing the recent literature. First, many studies are choosing relatively short time frames. This makes it difficult to project the long-term economic consequences. Second, a number of studies are claiming that one treatment is dominant with very small differences in parameter estimates. This raises questions about whether one treatment is non-inferior.

1. SURGERY FOR STRESS INCONTINENCE

Previous reports from this ICI committee[41] on the cost-effectiveness of surgical treatment for stress incontinence can be summarized as:

- minimally invasive surgery (TVT, injectable therapy) are likely to be cost-effective compared to more invasive surgeries like the Burch colposuspension
- studies are limited by poor longer-term data on the effectiveness of less invasive procedures, lack of primary and/or generalizable data on costs, clinical outcomes and utilities and not using a accepted and generalizable outcome (cost per QALY or cost per "cure")
- there is a need for longer-term follow-up data from methodologically rigorous randomized trials to provide a better data to estimate the relative benefits and cost implications

Since the last ICI meeting in 2008, few cost-effectiveness analyses of surgical interventions for stress incontinence which systematically compare costs and outcomes within an RCT framework have been published.

In late 2008, the U.S Urinary Incontinence Treatment Network group estimated costs for incontinence management, health-related quality of life, and willingness to pay for incontinence improvement in women electing to have surgery for stress urinary incontinence [42]. This cross-sectional study included 655 incontinent women enrolled in the Stress Incontinence Surgical Treatment Efficacy Trial (SISTER), a randomized surgical trial. Baseline out-of-pocket costs for incontinence management were calculated by multiplying self-report of resources used (supplies, laundry, dry cleaning) by national resource costs (in 2006 USD). Post-treatment costs were given in a later report.

Health-related quality of life was estimated with the Health Utilities Index (HUI) Mark 3. Participants estimated willingness to pay for 100% improvement in incontinence. Potential predictors of these outcomes were examined by using multivariable linear regression. Mean age was 52 ± 10 years, and mean number of weekly incontinence episodes was 22 ± 21. Mean (SD) and median (interquartile range) estimated personal costs for incontinence management among all women were $14 ± $24 and $8 (interquartile range $3, $18) per week, and 617 (94%) women reported any cost. Costs increased significantly with incontinence frequency. Mixed leak cost more than pure stress incontinence.

The mean and median Health Utilities Index Mark 3 scores were 0.73 ± 0.25 and 0.84 (interquartile range 0.63, 0.92). Women were willing to pay a mean of $118 ± $132 per month for complete resolution of incontinence, and willingness to pay increased significantly with greater expected incontinence improvement, household income, and incontinent episode frequency. Urinary incontinence is associated with high costs, with women reporting expenses of nearly $750 per year out of pocket for incontinence management. Women were also willing to pay a lot - nearly $1,400 per year - for incontinence cure, reflecting the high degree of bother of the condition. Incontinence was also associated with a significant decrement in quality of life.

Subak et al (2010)[43] then studied 491 women who completed 24 months of the Stress Incontinence Surgical Treatment Efficacy Trial (SISTER) who underwent Burch colposuspension or sling surgery. Self-reported out-of-pocket incontinence management costs were measured at 24 months post-operatively. Women quantified the resources used for management of UI including number of supplies for UI and additional laundry and dry cleaning needed each week. Total costs for management of UI were estimated by multiplying these resources by national resource costs (2006 USD). The analysis combined both treatment groups to examine the effects of change in UI over 24 months on cost. Univariate and bivariate changes in cost were analyzed using Wilcoxon signed rank test. Potential baseline predictors of change in cost were examined using multivariate mixed models adjusting for age, ethnicity, baseline BMI, annual income, ≥3 UTIs, POP-Q stage, fecal incontinence, diabetes, prior non-surgical UI treatment, menopause, smoking, treatment group, and accounting for site clusters.

The mean (±SD) age of participants with complete resource use data at baseline and 24 months was 53 ± 10 years. The mean weekly UI frequency was 23 + 21 episodes at baseline, which decreased by 86% at 24 months (P<0.001). Mean weekly cost was $14.88 ± $25 (median $8.42) at baseline which decreased to $4.10 ± $14 (median $0.09) at 24 months (P<0.001). The proportion of women reporting any cost decreased from 95% at baseline to 50% at 24 months (P<.0001). There was a similar reduction in weekly cost for both treatment groups (-$10.83 for Burch vs. -$10.73 for sling; P=0.49). In multivariable analyses, cost decreased by $0.96 ± $0.23 per week for each decrease of 7 UI episodes per week (P<0.001) and was strongly associated with greater improvement in UDI and IIQ scores and decreased 24-hour pad weight (P<0.001 for all). In summary, incontinence management costs decreased by 73% ($580 per woman per year) and were strongly and independently associated with decreasing UI frequency 24 months following Burch or sling.

Lier and colleagues [24] performed a within trial cost-utility analysis in a randomized trial of transobturator tape (TOT) compared with tension-free vaginal tape (TVT) in the surgical treatment of stress urinary incontinence (SUI) among 194 women in Canada. Cure was assessed by objective pad tests. They assessed costs in 2007 Canadian dollars from the public-payer perspective, i.e. 807$ Can for surgical kits, plus day only surgical costs and 12 months of care costs. The 15D utility instrument was used to measure QALYs. At 1 year post-surgery, 81% of TOT patients were dry on 24 hour pad test, versus 77% of TVT patients; 15% of the TOT had groin pain (versus 6% of TVT) but whether this contributed to medical costs over 12 months was not clear. The TOT group had a non-significant average saving of $1133 (95% CI -2793; 442), or 17%, with no difference in average QALYs between groups (95% CI -0.02; 0.01). TOT was cost-saving in over 80% of sensitivity analyses, suggesting that TOT would be cost-effective compared with TVT in the treatment of SUI. However, longer-term assessment of clinical and economic outcomes are needed to confirm the finding and observe for effectiveness, surgical complications, and re-treatment.

Jacklin et al [44] published a decision tree/Markov model in 2010 which proposed to consider the cost

utility of second line treatment for women with stress incontinence who had failed PFMT. The Markov model was controversial, because patients were expected to have either duloxetine or a TVT and then be followed up for 2 years, there was no opportunity for patients not responding to duloxetine to progress to a TVT. However patients failing the initial TVT were able to have a repeat TVT. The purpose of the article was to employ recently published long term followup data for duloxetine (as initial studies only reported to 12 months, with 68% of women estimated to continue therapy, but recent studies showed much poorer continuation rates, i.e. 9% and 8% at 12 months and 2 years). No actual QALY data for the TVT patients were cited from the literature, and QALY date for duloxetine patients was cited from a small study [45].

Unsubstantiated assumptions were made about the QALY loss associated with adverse events from duloxetine therapy. An 8 week course of duloxetine cost £30 (which would be very low cost for this medication in most countries), a TVT cost £2,044. They concluded that TVT is a cost effective second line therapy, but duloxetine, although cheaper, is not cost effective because of high discontinuation rates and lower efficacy. One of the authors was part funded by NICE, a second author had previously been funded by the manufacturers of duloxetine.

Patel et al. [46] compared the operating/bedstay billing costs in 45 patients from South Carolina having surgery for stress incontinence with or without prolapse, who had either commercial mesh kits, or segments of prolene mesh that were sewn in by the surgeon, with or without biomaterials during 2007-2008. Operative billing sheets including operative time, hospital "cost", bedstay time, and the insurance billings were reviewed. Surgeon payment was not included. The definition of cost is unclear and may represent hospital charge rather than cost. In both pure stress incontinence or coexistent prolapse, the surgeon-made prolene mesh operations were less expensive than the surgical kits, not surprisingly. No efficacy data or QALY data were included.

In our last report, Wu et al. [47] had very recently performed a methodologically excellent cost-effectiveness analysis of Burch colposuspension compared with TVT for stress incontinence, using a Markov model to compare costs (2005 USD) and QALy's (measured by the Health Utilities Index) over 10 years from a health care system perspective. In this well done study using state-of-the-art methods, Burch colposuspension was not cost-effective compared with TVT. However, if the tension-free vaginal tape failure rate was to increase over time, Burch may become cost-effective, reinforcing the need for long-term follow-up in surgical trials and cohorts.

In our last chapter, we reported a study regarding open vs. laparoscopic colposuspension by Dumville et al [48], which the Committee pointed out was a good example of the importance of evaluating costs over a long time frame to allow cost effectiveness to emerge. In the initial economic analysis of the two procedures at 6 months, healthcare costs were higher for the laparoscopic arm than for the open Burch arm (£1805 vs. £1433; differential mean cost £372; 95% CI 274, 471) due to increased theater costs. QALYs were slightly higher in the laparoscopic arm relative to the open arm (0.005; 95% CI -0.012, 0.023). The ICER was £74,400 at 6 months. At 24 months, higher mean QALY's persisted in the laparoscopic arm and modeling showed the ICER was reduced to £9300. While laparoscopic colposuspension was not cost effective compared with open colposuspension during the first 6 months following surgery, it may be cost effective over 24 months.

In the last report, we discussed the multicentre RCT of Manca et al (2003)[49] who assessed the cost effectiveness of TVT with open colposuspension for primary stress incontinence at 6 months, in 344 women from 24 centres in the UK and Ireland. The EQ-5D was used to measure QALYs. The TVT had lower mean costs and higher mean QALYs at 6 months, which persisted over 95% of sensitivity analyses. The 2 year and 5 year follow-up of this study has since been published but no further economic analysis appears to have been reported.

2. SURGERY FOR URGE INCONTINENCE

a) Studies regarding Botulinum Toxin A Injections (Botox A)

Three studies comparing Botox A with other treatments have been published since our last report. Wu et al (2009) from the USA performed a Markov model analysis of Botox A versus anticholinergic medication [50]. The model was conducted over a two year time frame, and assumed that 33% of patients would comply with anticholinergic therapy over this time. The Botox treatment cycles were more expensive (US$ 4,400) than the anticholinergic medication (US$ 2,560), but the Botox was more effective (QALY gain 1.63 versus 1.50), yielding an ICER of $14,377.

Wefer et al (2009) from Germany evaluated Botox A injections in 214 patients with neuropathic detrusor overactivity [51]. 300 IU of Botox were injected in each patient (which is common practice in neuropathic DO, but varies from some clinical practice in Idiopathic DO which 200IU are often given). The injections were given as inpatients. Pad costs per day were reduced from €2.11 per day to €1.05, and medications for urinary tract infection fell by half (from €162 per annum to €80 per annum). Unfortunately no QALY measurements were performed.

Robinson et al. (2010)[52] undertook a Markov model study comparing Botox with percutaneous tibial nerve stimulation (PTNS), over a 2 year time frame in refractory idiopathic detrusor overactivity. Repeat botox injections were assumed to occur every 8 months; 20% of patients were assumed to perform clean intermittent self-catheterization for 4 months.

QALY data was assumed from the literature. PTNS was cheaper than Botox (£1,700 versus £4,067) and had a lower ICER (£50,133 versus £111,953) but neither would satisfy UK NICE guidelines for cost-effectiveness (i.e. not less than £30,000 per QALY).

Padmanabham et al (2011) from USA performed a decision tree analysis of Botox injections versus Clam Cystoplasty[25] (which is an arguable model, since Sacral Nerve Stimulation has largely overtaken clam cystoplasty in the western world). Nevertheless, this was a group of severely refractory neuropathic DO patients, who were performing clean intermittent self catheterization (CISC) but still had upper tract dilatation and recurrent urinary tract infection (UTI). Their decision tree is shown in **Figure 3** (earlier in this chapter). Botox 300 IU was injected every 6 months for 5 years, the cost of each injection was US$ 2,800, equaling 28,000 over 5 years. The Clam Cystoplasty cost US $33,000. In their model, it was assumed that 10% of patients would fail Botox, of whom 85% would go on to have a Clam Cystoplasty (this model is controversial in the modern day climate).

No QALY data were provided, but the authors concluded that if the durability of Botox benefits exceeded 5.1 months, then the cost effectiveness of Botox dominated, so long as the complication rate of the Clam Cystoplasty was less than 14%. The first proviso appears quite reasonable, but the complication rate of Clam cystoplasty is known to be higher than 14%, and the 1% mortality is not mentioned (which would have adversely affected any QALY data taken from a real life study).

b) Sacral nerve stimulation

Sacral Nerve Stimulation (SNS) is a minimally invasive FDA approved second line treatment for refractory overactive bladder (OAB) dry and wet. Currently five papers describe different aspects of cost analysis and cost-effectiveness of SNS, some with comparison to other treatment strategies for OAB [53-57].

Aboseif et al[53] in the U.S.A. retrospectively reviewed the costs related to SNS for a period extending from one year pre- to one year post-implantation. In a heterogeneous group of patients, also including patients with urinary retention and chronic pelvic pain, a one year SNS treatment reduced 92% of outpatient doctor visits and diagnostic and therapeutic procedure costs, along with a 30% reduction in drug costs [53]. This however did not include the costs of the neuromodulation implant itself, nor the surgical implantation costs. QALYs were not ascertained.

A cost analysis evaluation was also conducted in a large multicenter cohort study in France,[56] which included 190 OAB wet patients and neuropathic DO, as well as another 85 patients with OAB wet plus faecal incontinence (double incontinence). Treatment costs included insertion of preliminary tined leads under GA as an outpatient then permanent implant as an inpatient, with Botox injections given as an inpatient. Health-related travel costs were also included in the analysis, which extended from the pre-test evaluation, over the temporary stimulation procedure until two years after the implant procedure.

The median overall cost per OAB wet patient for the first two years was €16,403, which was on average €8,525 more per patient compared to patients on alternative treatments, which comprised conservative measures (medication and diapers/pads), botulinum toxin injection, enterocystoplasty or urinary diversion. Importantly, devices and hospital stays accounted for 40% and 52% of the total cost respectively. Although the authors provided a limited cost-effectiveness analysis over the two year period, the interpretation of the results are difficult because of the heterogeneity of the study population, surgical procedures and the lack of clear descriptions of the cost-effectiveness parameters. Their data, however, suggest that SNS for OAB wet is not cost-effective over the two years period. This is in agreement with the data from Siddiqui et al[57] (see below), and not surprising since the initial costs are very high due to the device costs. Interestingly, their data suggest that SNS may be cost-effective even in the short term for patients with double incontinence [56]. This deserves attention in future research.

Siddiqui et al [57] performed a cost-effectiveness analysis of SNS vs intravesical Botulinum Toxin A in patients with idiopathic “OAB wet” in the US. A two year period was chosen for evaluation because no long-term data were available for Botulinum Toxin A. The base case scenario included a staged implant procedure for SNS using the tined lead, and office injections of 200 units Botulinum Toxin A. For the SNS strategy, no data were provided on the procedure (local vs general anesthesia; outpatient vs inpatient clinic). The relevant base case estimates are provided in **table 2**. Based upon their Markov decision model, the base case SNS treatment was more expensive ($15,743 vs $4,392) but also more effective (1.73 vs 1.63 QALYs) than Botulinum Toxin A. During the two year period, SNS was not cost-effective with an ICER of $116,427 [57]. As stated above, the relevance of a cost-effectiveness analysis over a two years period with a costly implant device is questionable.

Two cost-effectiveness studies have considered the longer term, comparing SNS and Botulinum Toxin A in the Netherlands[55] and Spain [54]. The parameter estimates are provided in **Table 2**. In the Netherlands, Leong et al. (2011)[58] showed that SNS becomes cost-effective from the fourth year post-implant on, given an ICER threshold of 40,000€/QALY [55]. These data are based upon two procedures under general anesthesia (1) a staged SNS procedure involving a tined lead test phase in the operating theatre on an outpatient basis, followed by an inpatient stay for device implant; (2) inpatient stay for Botulinum Toxin A injection in the operating theatre.

Table 2. Comparison of studies conducted in the USA, Netherlands and Spain regarding SNS and Botox therapy

		Siddiqui et al (2009)		Leong et al (2011)		Arlandis et al (2011)	
Base Parameter Estimates (years)		2		5 (with 10 year analysis)		10	
Country of Origin		USA		Netherlands		Spain	
Sacral Nerve Stimulation	**Success rates (%)**	Tined lead placement (TLP) (all success go to implant)	75	TLP	75	TLP	80
						1 year	90
				1 year	90	5 year	75
						10 year	75
	Implant longevity	2 year	90	Yearly drop-out	4.3	Not stated

	Threshold cost effectiveness	50-000 to 10000 $/QALY		<40000 €/QALY		Not stated	
	QALYS	Not stated		Success (continence)		0.95	Success 0.793
				Failure (leaking)		0.73	Failure 0.573
	Failure treatment SNS-Botox (%)	Not stated		Opt for other treatment:		75	Opt for other treatment 77-79
				No further treatment		25	Cystoplasty 5
							Conservative treatment 16

These data are in agreement with the Spanish study by Arlandis et al.,[54] which showed SNS to be cost-effective from five years post-implant on, given an ICER threshold of 30,000€/QALY. These results are based on (1) a staged SNS procedure involving a tined lead test phase; (2) 100 units Botulinum Toxin A. No further data were provided on the procedure (inpatient vs outpatient; local vs general anesthesia). In both studies,[54, 55] several estimates or assumptions had to be made due to the lack of long-term data beyond 1 year for Botulinum Toxin A injections and 5 year for SNS therapy, such as therapy transition rates after failure and drop out rates. To what extent these data are reliable and valid is currently unknown.

Furthermore, both studies quote a one year success rate for SNS of 90%, based upon Van Voskuilen et al,[59] that describes the effect of SNS in 39 patients with OAB over 15.5 months follow up. However, in that study 10 patients were lost to follow and were excluded from the analysis. Therefore the 90% success rate

may be an overestimation, and the worst scenario, considering the ten lost to follow up patients as failures would give a 61% success rate. How this would influence the cost-effectiveness evaluation is unknown. A similar consideration applies for the 5 years success rate of 70% based upon Van Kerrebroeck et al[60] which considers patients lost to follow up as last observation carried forwards.

Sensitivity analyses for several parameters estimated by expert opinion have been performed. In the Netherlands, SNS over a 5 years period remained cost-effective (ICER < 40,000€/QALY) when the estimated dropout rate of 4.3% for both treatments was changed to 2% or 6%, and when utility value for incontinence was changed from 0.73 to 0.80. SNS was no longer cost-effective over 5 years in the following cases:

a. when Botulinum Toxin injections were done under local anesthesia (which is common practice in several countries),

b. when the Peripheral Nerve Evaluation test for SNS screening is used (because of the lower success rate of 55% compared to 75% for Tined Lead screening),

c. when bilateral testing is done

d. when the new and smaller stimulator (Interstim II) is used [55].

Because there is no standard protocol of Botulin Toxin A injection, a different protocol using 200 units every 14 months was evaluated in the Arlandis study, which proved cost-effective on the ICER < € 30000/QALY threshold [54].

3. OUTPATIENT CONSERVATIVE THERAPIES

An important study regarding the baseline "cost of illness" for women with stress or urge leak was detailed in our last chapter (Subak et al.[61]).

A more recent study of the "Cost of Illness"[62] included 528 women with UI weekly or more enrolled in the Reproductive Risks for Incontinence Study at Kaiser population-based study. Similar to the prior studies, routine care costs were calculated with the use of national resource costs ($2005). Potential predictors of these outcomes were examined by multivariable linear regression. Among women with weekly UI, 69% reported incontinence-related costs. Median weekly cost was $1.83 (25%-75% interquartile range [IQR], $0.50, $5.23) and women spent a mean of >$250 per year out-of-pocket for UI routine care. Costs increased with incontinence severity (P < .001) and body mass index (P < .001) were 2.2-fold higher for African American versus white women (P < .0001) and 42% higher for women with mixed versus stress incontinence (P < .05).

Since costs for incontinence management increase with leakage severity, data are needed to explore whether effective treatment will be associated with decreased incontinence costs.

Recently, Subak et al.[63] performed a planned secondary analysis among overweight and obese women, who were enrolled in a clinical trial of a weight loss intervention. The purpose was to estimate the effect of a decrease in incontinence frequency on incontinence management costs [63]. The study included 338 obese and overweight women with at least 10 weekly urinary incontinence episodes at baseline. They enrolled in a randomized clinical trial to determine the effect of an 18-month weight loss and maintenance intervention compared to a structured education program, upon the frequency of incontinence.

Quantities of resources used for incontinence management, including pads, protection, additional laundry and dry cleaning were reported by participants. They estimated direct costs for urinary incontinence management ("cost") by multiplying resources used by national resource costs (in 2006 U.S. dollars). For the total cohort (combined randomization groups), mean (±SD) age was 53 ± 10 years and baseline weight was 97 +17 kg. Mean weekly urinary incontinence frequency was 24+18 at baseline, which decreased by 37% at 6 months and 60% at 18 months follow-up (both P<0.001).

At baseline, adjusted mean cost was $7.76 ± $14 per week. Costs increased significantly with greater incontinence frequency. Mean cost decreased by average of 54% at 6 months and 81% at 18 months (both P < 0.001). In multivariable analyses, cost independently decreased by 23% for each decrease of 7 urinary incontinence episodes per week, 21% for each 5 kg of weight lost, and was strongly associated with greater improvement in UDI and IIQ scores at 18 months (P < 0.001 for all). In this cohort of obese and overweight women enrolled in the clinical trial, management cost for urinary incontinence decreased by over 80% at 18 months ($327 per woman per year) and was strongly and independently associated with decreasing incontinence frequency. This suggests that effective incontinence treatment will be associated with decreasing costs of incontinence management

Although not primary data, Imamura et al (2010) published a comprehensive review of the cost effectiveness of non-surgical treatments for women with stress incontinence [64]. In this report, a group of senior clinicians and other experts obtained funding from the Medical Research Council of the UK to evaluate 88 studies of conservative treatment involving 37 distinct treatment regimes, in a total of 9,721 participants. QALY data were taken from a study by Haywood et al[65] which employed the EQ-5D [64]. In brief, the authors found that a treatment strategy of Pelvic Floor Muscle Training (more than 4 visits) along with lifestyle advice, followed by a TVT where necessary, was the least costly strategy, at £1644 per person, and was the most effective, with a cost utility of 16.20 QALY per annum. This strategy had a 70% likelihood of being the most cost effective across a wide range of sensitivity analyses.

A smaller review of cost effectiveness evaluations for pelvic floor exercise interventions, which included data from 3 older studies (from 1996, 2003, 2006) has also recently appeared [66].

In the last Chapter, we reported an abstract from Ho et al. [67] in Australia who performed a "bottom up" study of the short and long-term treatment costs of conservative and surgical management of childbirth-related stress and mixed urinary incontinence (UI). This report has now been published in full [68]. Costs of treatment episodes during conservative and surgical management were calculated for a cohort of 150 women and related to cure. At 6-13 years follow up, personal and treatment expenditure was measured using a postal questionnaire. During active treatment, patients with stress UI treated conservatively incurred a median cost of AU$658 per capita (IQR 476 – 1191 AU$) compared to a median cost of $6,870 per capita for surgical treatment (IQR 6,320 – 7,508 AU$). Similar cost difference was seen for the two treatment options in mixed incontinence. Of regular clinic attendees, 39% of conservatively treated and 78% of surgically treated patients were cured.

At 6-13 years follow up(82 women with a known address), 43 (52%) responded to the survey, of whom 46% remained cured. The median treatment cost for the total group of postnatal incontinence (irrespective of continence status) was AU$885.80 per capita per annum (IQR 338- 2,589 AU$). The costs per cure are shown in **Table 3**, in Australian dollars.

4. PHARMACOTHERAPY OF URINARY INCONTINENCE

a) Economics of pharmaceutical therapies

Although pharmaceutical companies must show that a new drug is safe and efficacious prior to approval and marketing, the requirement for economic studies (ie whether the new drug is cost-effective compared to standard treatment), varies from country to country.

The U.S. Food and Drug Administration does not require any economic data in its review of a new drug. Instead it leaves economic questions to the purchasers (e.g., insurance companies, government purchasers or individuals), similar to the Netherlands. In the UK, however, the National Institute for Health and Clinical Excellence (NICE) requires economic review. They have denied approvals for new drugs that have an incremental cost effectiveness ratio greater than £30,000 per QALY. In Australia, manufacturers must prove cost-effectiveness in order to achieve listing on the Pharmaceutical Benefit Scheme (whereby patients pay a subsidized cost for the drug). However, only therapeutic efficacy and safety must be shown in order for it to be available in Australia as a non-subsidized "private" prescription.

In response to the regulatory requirements, drug developers routinely conduct economic evaluations. In the UK, such efforts are done as part of the NICE review. In the US, developers present economic data to purchasers for post approval marketing. Many purchasers (as in Australia) have formularies, or lists of medications that they are willing to pay for, and the economic evaluation is frequently part of the request to place the new drug on the formulary.

In the next sections, we review the recent literature on the economics of drugs for incontinence and overactive bladder.

1. Pharmacotherapy for stress incontinence

Mihaylova et al. (2010) assessed the cost-effectiveness of duloxetine compared with conservative therapy in women with SUI [69]. Cost and outcome data from a 12-month, prospective, observational, multicenter, multicountry study were used (the Stress Urinary Incontinence Treatment (SUIT) study). Costs were assessed in 2007 £ from the healthcare plus patient perspective; outcomes were measured in quality adjusted life years using the EQ-5D. Duloxetine alone and with conservative treatment (not explicitly defined but varied by physician practice) were associated with incremental quality-adjusted life-years (QALYs) of about 0.03 over a year compared with conservative treatment alone or with no treatment. Conservative treatment alone did not show an effect on QALYs. Duloxetine either dominated (lower

Table 3. Costs per cure, modified from Ho et al. (2012) [68]

	Costs of pure stress incontinence (A$)	**Costs of mixed incontinence (A$)**	**Treatment duration (days)**
Conservative treatment	Median = 658 (IQR = 476-1191) n = 84	Median = 772 (IQR = 531-985) n = 43	Median = 156 (IQR = 69-367)
Surgical treatment	Median = 6,870 (IQR = 6320-7508) n = 12	Median = 6,894 (IQR = 6733-7206) n = 11	Median = 902 (IQR = 408-1552)
Conservative treatment cost per patient cured	4,073	2,415	
Surgical treatment cost per patient cured	9,415	8,587	

cost and greater change in QALY) or had an incremental cost-effectiveness ratio (ICER) below £900 per QALY gained, compared with no treatment and with conservative treatment alone. Duloxetine plus conservative therapy had an ICER below £5500 (compared with no treatment or conservative treatment alone). Duloxetine compared with duloxetine plus conservative therapy showed similar outcomes but an additional cost for the combined intervention. While limited by the observational design, the study suggests that initiating duloxetine therapy in SUI is a cost-effective treatment alternative.

(NOTE: Duloxetine failed the US approval for stress urinary incontinence due to concerns over liver toxicity and suicidal events. It is approved for SUI in Europe, where it is recommended as an add-on medication in stress urinary incontinence instead of surgery.)

In a similar vein, we reported in our last chapter that Brunenberg[70] conducted a Markov model to assess the cost-effectiveness of duloxetine alone and duloxetine after inadequate response to pelvic floor muscle training [PFMT] compared with PFMT or no treatment for women 50 years of age or older, which narrowly focused upon pharmacotherapy and PFMT for stress incontinence, with no consideration of surgery.

Das Gupta and colleagues[45] also developed a model to assess the cost-effectiveness of duloxetine for moderate to severe SUI, but they assumed that drug treatment was fully effective. Thus duloxetine studies published to date have methodological limitations.

2. Pharmacotherapy for Urge Incontinence

There are five commonly used medical treatments for overactive bladder: Oxybutynin (ditropan) as a tablet or as Oxytrol patches; tolterodine (Detrol), darifenacin (Enablex), trospium (Sanctura), solifenacin (Vesicare), and a sixth recent introduction, Fesoteridine (not yet widely used).

Many economic evaluations are funded by drug developers and compare the investigational drug to placebo or to an older compound that has known problems with side effects (e.g., immediate release oxybutynin). In the Fourth ICI report [41] we reported one study by Ko et al. [71] who conducted an independently funded economic evaluation of five antimuscarinic drugs (in eight formats) for overactive bladder (see **Figure 8**). They concluded that solifenacin had the lowest costs and highest effectiveness, compared to immediate-release (IR) oxybutynin, extended-release (ER) oxybutynin, transdermal oxybutynin, IR tolterodine, (ER) tolterodine, trospium, and darifenacin. However, their study did not meet minimum standards for cost-effectiveness analysis [9, 14]. It also focused on the payer's perspective (rather than a societal perspective), had a short time frame

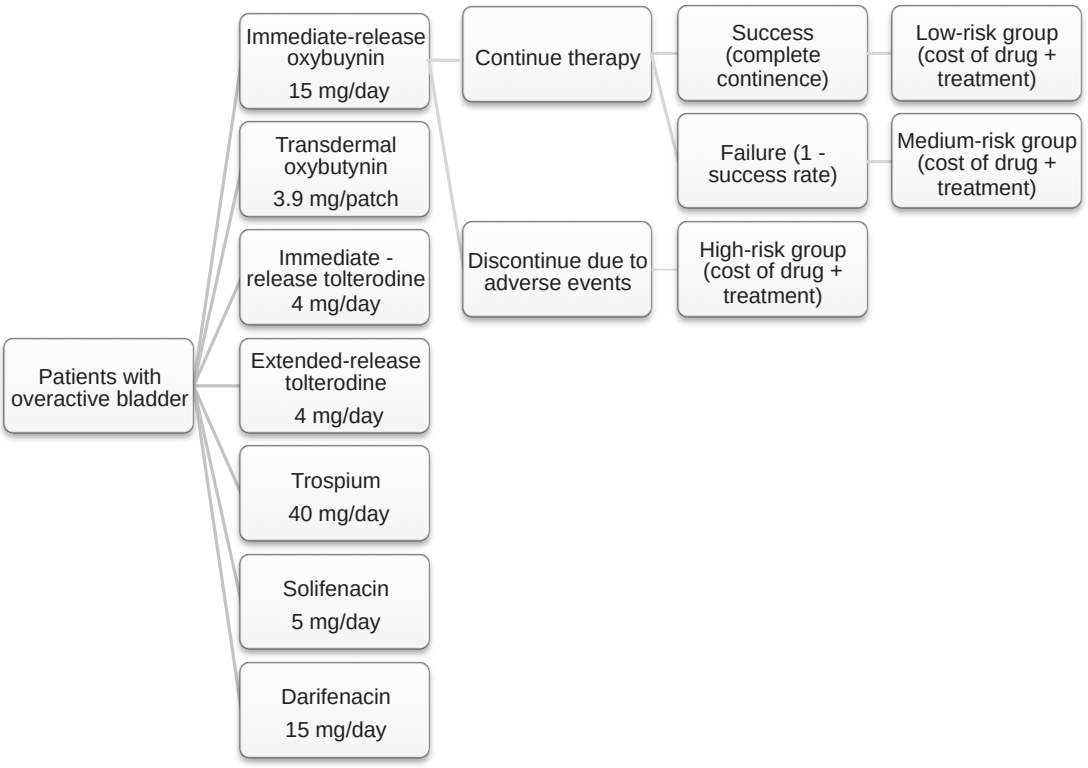

Figure 8. Decision-analysis model used to compare cost-effectiveness of antimuscarinic agents for the treatment of overactive bladder. Modified from Ko et al. (2006)[72].

of 3 months, and used complete continence as the main effectiveness measure (rather than QALYs). Given these limitations, we recommended that these results must be interpreted cautiously and that additional studies using standard methods were needed.

3. Solifenacin Studies

Milsom et al[72] performed a cost effectiveness analysis of Solifenacin flexible dosing (5-10 mg) versus tolterodine 4 mg Sustained release in 4 Nordic Countries. The efficacy data was based upon the STAR RCT (Chapple et al, 2005[73]) and 2 other RCTs of solifenacin versus tolteridine and placebo. QALYs were not included in the original trials, but the EQ5D was estimated from original HRQOL data collected in 1997. The cost differences between solifenacin and tolteridine ranged from €6 to €127. The authors concluded that Flexible dose Solifenacin was more cost effective than Tolteridine 4 mg. This study was supported by Astellas.

Herschorn et al[74] undertook a Markov model based upon the VECTOR study, which compared Solifenacin 5 mg/ day versus Oxybutynin 15 mg / day in Canada. The withdrawal rate due to side effects of oxybutynin (19%) was much greater than that for solifenacin (3%). No QALY data was included in the original VECTOR study. Their 8 week efficacy data was projected over 1 year, which is an arguable model. Solifenacin yielded a cost saving of Can $ 1,830 per annum, giving an ICER of Can $14,000. This study was also funded by Astellas.

Cardozo et al[76] performed a decision tree analysis of solifenacin, versus fesoteridine, oxybutynin ER, propiverine, tolteridine ER and IR in the UK. In this one year model, success was individually defined for frequency, urgency and urge incontinence. The model was problematic (**Fig 9**), in that it assumed if the patient had no success on a drug that was only available in one dose, then the patient was given no further treatment. The original study did not include QALY data, which were calculated from willingness to pay data published by Kobelt in 1998 [77]. The calculation of QALYs from willingness to pay is not a standard methodology and created confusion among the Economics Committee members. Because oxybutynin was so much cheaper than the other drugs (20% of total costs, versus 60-70% of total costs for the other therapies), oxybutynin was dominant for 2 of the 3 outcomes.

In 2005, Getsios and colleagues[78] published a review of the economic studies for overactive bladder, highlighting many of the limitations including a lack of comparisons of drugs to behavioral training.

4. Darifenacin hydrobromide (Enablex)

Darifenacin was approved by the FDA in 2004, based on Phase II and III controlled clinical trials with over 8,800 patients. Short term efficacy (12 week) as well as longer term effects (24 and 52 week) were evaluated [79]. Abrams and colleagues [80] found that darifenacin was associated with significant improvements in quality of life as measured by the King's Health Questionnaire at 12 weeks relative to placebo. Chancellor et al. [79] found that darifenacin and darifenacin combined with a behavioral modification plan both resulted in improvements in symptoms and quality of life, as measured by the Overactive Bladder Questionnaire (OAB-q), but there were no differences between the two groups. Unfortunately, neither the Abrams nor the Chancellor study measured utilities. Besides the Ko [71] article discussed above, there is little data on the cost-effectiveness of darifenacin.

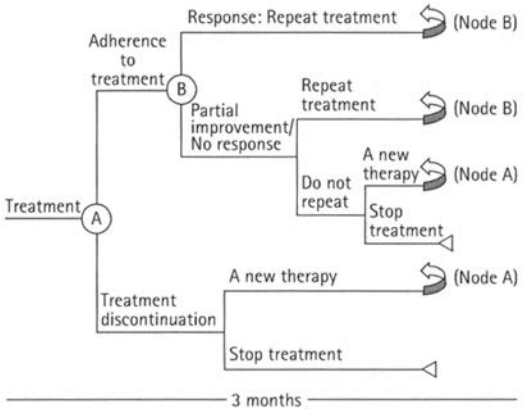

Figure 9. Solifenacin vs fesoteridine, oxybutyin ER, propiverine, tolteridine ER and IR in UK. Reproduced from Cardozo et al. (2010)[77] with permission.

5. Tolterodine (Detrol)

In late 2008, Burgio et al (The UTIN group) conducted a clinical trial of 10 weeks of open-label, extended-release tolterodine alone (n = 153) or combined with behavioral training (n = 154), followed by discontinuation of therapy and follow-up at 8 months [81]. Among 237 participants completing the trial, the rate of successful discontinuation of therapy at 8 months was the same in the combination therapy and drug therapy alone groups (41% in both groups; difference, 0 percentage points [95% CI, -12 to 12 percentage points]). A higher proportion of participants who received combination therapy than drug therapy alone achieved a 70% or greater reduction in incontinence at 10 weeks (69% vs. 58%; difference, 11 percentage points [CI, -0.3 to 22.1 percentage points]). Women in the combination therapy group reported better outcomes over time on the UDI and the OAB-Q (both P <0.001) for patient satisfaction and perceived improvement but not health-related quality of life. They concluded that the addition of behavioral training to drug therapy may reduce incontinence frequency during active treatment but did not improve the ability to discontinue drug therapy and maintain improvement in urinary incontinence. Economic evaluations are ongoing.

Two studies evaluating the cost-effectiveness of tolterodine versus percutaneous tibial nerve stimulation (PTNS) have recently been published. In 2009, Robinson et al[82] undertook a cost minimization study of PTNS versus tolterodine ER 4mg, involving 1-2 year follow-up, from the perspective of the NHS. In the model, the two treatments were assumed to have equivalent efficacy (based on unpublished data), and adverse effects were considered to be cost neutral. The patients having tolterodine were followed for 2 years, the duration of follow-up for PTNS was not clearly stated. Tolterodine appeared to be the cheaper treatment but alteration of the variables in the model had a large effect.

In 2010, Chen et al[83] performed a very similar evaluation of PTNS versus tolterodine, cost-utility values were obtained from the literature [84], yielding an ICER of $70, 754 per QALY, thus PTNS was not cost effective in the treatment of OAB over a 1-year period.

6. Trospium Chloride (Sanctura)

Besides the Ko[71] article discussed above, there is little published data on the cost-effectiveness of trospium chloride.

5. COST IMPLICATIONS OF INCONTINENCE IN NURSING HOME SETTING

Two key aspects of cost of care for nursing homes are (1) cost of nursing home admissions attributable to urinary incontinence, and (2) the treatment cost of urinary incontinence. In the last 4 years, no new studies were found regarding this aspect of the economics of incontinence, therefore our previous findings are briefly summarized.

Additional nursing home admissions cost is often a major component in the total cost of urinary incontinence. In a 2001 study [16] the cost estimate was $2.4 billion in 1995 dollars. In a 2004 study [15], the cost estimate was $4.0 billion in 2000 dollars. In a 2006 study,[85] the attributable fraction (AF) statistics from published data was shown to be $6.0 billion in 2004 dollars. The Attributable Fraction (AF) statistics are obtained by using incontinence prevalence rates for those admitted to nursing homes, as compared to those who were not admitted to nursing homes. It shows that reimbursement for treatment of UI in the community might help or delay institutionalization and offset some costs of staying in nursing homes. The AF method has been used in the economic cost of mental illness, smoking, and cancer diseases. The new estimated magnitude shows that reimbursement for treatment of UI in the community might help or delay institutionalization and offset some costs of staying in nursing homes.

Holroyd-Leduc et al. [86] conducted a population-based prospective cohort study (from 1993-1995) in over 6,500 elderly (>age70) patients. After adjusting for confounders, UI was not an independent predictor for death, nursing home admission, or functional decline. Within nursing homes, labor costs are a major component of caring for incontinent patients. These costs are studied via time/motion observation, correlated with severity and type of incontinence. In 49 long-term care facilities in North Carolina, USA, it was found that the incremental labor costs (per shift) were $3.31 for patients with occasional UI and $5.61 for patients with frequent UI [87], in keeping with Morris et al[10].

Bliss et al. [88] addressed the cost/effectiveness of incontinence-related treatment of skin condition in 16 US nursing homes. Four regiments of different moisture barriers were applied. Time and motion measurements included skin products and time spent. Using acrylate barrier film spray achieved cost savings of between $854 to $1,862 per resident, with better skin protection than the use of an ointment or cream.

6. LONGITUDINAL BURDEN OF DISEASE STUDIES

For the first time in the last ICI report, we found a number of studies that measure the cost of incontinence over the long-term time frame. As pointed out by Birnbaumn et al.[89], the study of “the lifetime cost of illness” is a recent area of research. These authors combined case-control methods (to calculate annual medical costs of stress incontinence, etc) with knowledge of the incidence of the conditions, assuming “steady state conditions” of the costs, to project the lifetime costs of each disorder.

As regard the impact of incontinence upon employed women, Fultz et al. [90] sent a postal questionnaire to 2326 employed women, 37% had leaked urine in the past month. The impact of incontinence upon ability to concentrate, performance of physical activities, self confidence, and ability to complete tasks without interruption increased with the severity of the leak and affected nearly 75% of all those with severe leak status. Similarly, Wu et al. [91] focused upon the work loss burden of women with OAB. The number of days absent was 15% higher among 3077 OAB employees compared to 6154 controls. OAB subjects had 4.4 more days off work than non-OAB subjects, yielding an annual excess cost of $1220 per OAB employee.

In the last chapter, Reeves et al. [92] employed a theoretical model based upon a large “EPIC” prevalence study of OAB [93] to derive the future cost burden for OAB in five European countries. They calculated an annual per capita expense of €269-706 per annum.

A more detailed analysis of OAB costs in Germany [94] that included psychiatric costs of OAB-related depression, and nursing care, indicated an annual per capita expense of €609-1170 per annum in that country.

Since the last report, this same group of authors obtained updated data for the treatment costs of “OAB wet” and “OAB dry” [95]. They also provided new data about the non-treatment costs of OAB, such as lost productivity, depression, sleep disturbance, falls

and fractures, skin infections and UTIs. The manuscript lists 23 website links that were used to access unit costs for each of the six developed countries (Canada, Germany, Italy, Spain, Sweden and UK). A summary of the costs in each country is shown in **Table 4** [95], with summary data in **Table 5** [95]. Overall, the annual treatment costs of OAB in six countries is shown to be ≈ €3.9 billion, with additional costs for nursing home stays (€4.7 billion per year) and loss productivity due to work absenteeism (€1.1 billion per year). The estimated total cost therefore for the ≈25 million patients with OAB in these countries is €9.7 billion.

Cisternas et al [96] undertook an analysis of the economic burden of overactive bladder syndrome in Medicare beneficiaries in the USA[96]. They obtained data for all Medicare claims for patients over age 65 during 2003-2004, compared with non-OAB subjects. Multiple regression analysis was used to estimate costs attributable to OAB after adjusting for demographic characteristics and comorbidities. They used a narrow definition of OAB (detrusor overactivity, urge incontinence, frequency with polyuria) and also a broader definition of OAB (that included incontinence without sensory awareness, nocturnal enuresis, continuous leakage, etc).

Costs were based on the amount of money reimbursed to providers by Medicare (which generally yields 80% of "allowed amounts") that includes inpatient stays, skilled nursing facilities, outpatient visits and procedures such as cystoscopy. **Figure 10** shows the prevalence of the two definitions of OAB compared to other chronic conditions. The prevalence of OAB in this over 65 group was 9-14% for the two definitions.

The mean annual expenditure attributable to OAB ranged from US$825 – 1184 per subject, which comprised 9-12% of all their medical expenditure.

Table 4. Estimated costs per patient with OAB per annum, reproduced from Irwin, 2009 [95] with permission

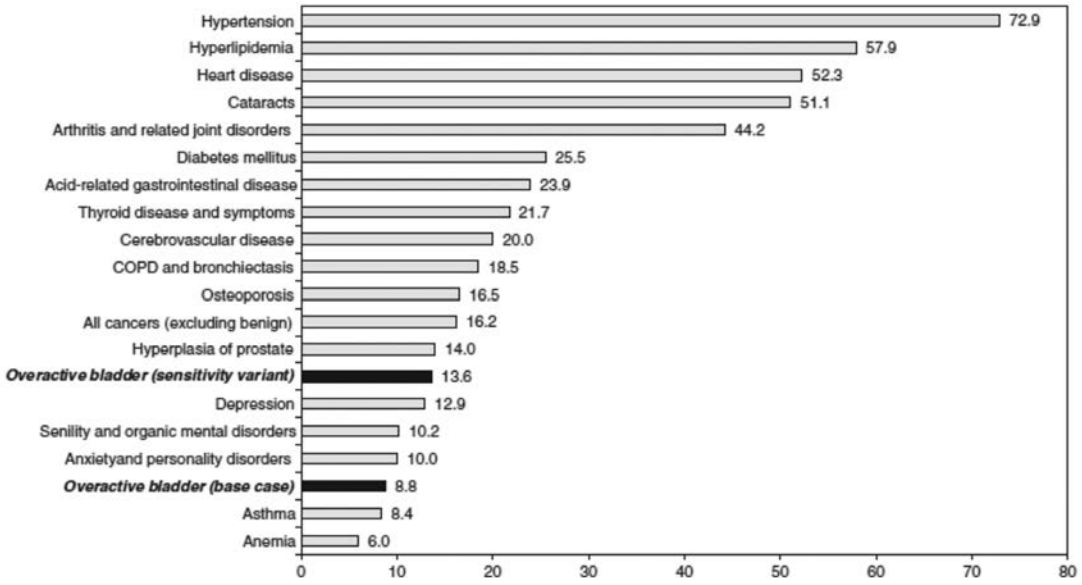

Figure 10. Treated prevalence (%) of OAB compared to other common chronic conditions (each subject may have more than one diagnosis), Medicare enrollees 2003-2004, reproduced with permission from Cisternas et al. (2009)[96].

The total cost of OAB expenditure was 1.8- 3.9 Billion US $ per year. These authors also considered the consequences of incontinence. For example, The OAB cohort had a higher occurrence of events such as falls/ fractures (46% OAB versus 34% non-OAB; RR = 1.4) urinary tract infections (42% OAB versus 17% non-OAB, RR = 2.4), and depression (21% OAB versus 12% non-OAB, RR = 1,8) all p< 0.001. The authors pointed out that this is the first study to evaluate the treatment costs of OAB in over-65 year individuals using "real-world" Medicare claims data.

In the last 4 years, the Committee found 3 publications reporting a new trend towards conducting Internet studies of the Burden of Disease associated with OAB. Because of difficulties in achieving telephone surveys, researchers have moved towards internet surveys, however the Committee feels that such method can be subject to considerable bias.

For example, Kannan et al[97] reported an internet survey in 2009 that was actually conducted in 2006, in which 62,833 American subjects who were members of an industry-based feedback panel were questioned as to whether they had LUTS or OAB. The survey compared 13,954 men and women with LUTS/OAB (comprising 24% of the survey population) with age matched subjects having similar comorbidities. They found that subjects with LUTS/OAB had approximately US $ 1,000 more health care costs per annum. They concluded that the projected costs of LUTS/OAB were US$ 51 Billion per annum more than age/comorbidity matched controls. However, in Discussion, the authors admitted that the study was quite biased towards subjects who were connected to the internet, yet not fully employed, i.e. having sufficient time to enroll in the Industry Feedback Panel.

A similar internet study was reported by Onukwugha et al [98], derived from the Epi LUTS study, which yielded a projected LUTS/OAB cost of 24.9 billion US$. Neither of these projected costs agrees with other cost estimates from non-internet based studies.

Finally Ganz et al [99] performed an overall estimate of the costs of OAB, which used a panel of expert urologists in Boston USA, via a Delphi technique to obtain consensus on the model. The authors accumulated all known costs for OAB, including patients in nursing homes. They projected costs based upon known projected prevalence figures, with respect to the ageing of "baby boomers" (**Figure 11**) showing a projected marked increase in OAB costs as this cohort "swells" the numbers of elderly in the community.

7. PROLAPSE TREATMENTS, COST IMPLICATIONS

Despite the high prevalence of pelvic organ prolapse and frequency of surgery for prolapse, there are minimal data on costs or cost-effectiveness of medical care for this condition

In the previous chapter, we reported an important cost of illness study from 2001, regarding the annual treatment cost of surgery for pelvic organ prolapse in the U.S. [100]. Treatment costs of pelvic organ prolapse surgery were US$1,012 million (1997 US$; 95% CI 775-1,251 million). Hospitalization accounted for a majority of the total cost (71%) with the remainder being physician services (29%). Twenty-one percent of pelvic organ prolapse operations included urinary incontinence procedures (US$218 million). The annual treatment costs of operations for pelvic organ prolapse are substantial and similar to other surgical interventions for women (breast cancer, gynecologic cancer, urinary incontinence).

In 2009, Subramanian et al. [101] estimated the rate, type and costs of surgical interventions for pelvic organ prolapse (POP) in Germany, France, and England. They identified hospital admissions for pelvic floor surgery in 2005 from national hospital activity databases in each country: the German Hospital Episode, the French Medical Care Program Information System, and the National Health Service England Hospital Episode Statistics. Costs to the payer were estimated using the Diagnosis-Related Group reimbursement rates for each country. In 2005, the number (rate) of admissions for POP surgery was 36,854 (0.87 per 1000 women) in Germany, 36,679 (1.14 per 1000 women) in France, and 28,959 (1.13 per 1000 women) in England. Admissions for POP surgery constituted 10.4%, 16.7% and 16.9% of all admissions for female genital tract therapeutic interventions in Germany, France and England, respectively. At least 20% of hysterectomies were performed for the primary indication of POP. 57.4%, 45.0%, and 40.1% of all admissions for POP surgery included a hysterectomy. The costs to payers were €144,236,557, €83,067,825, and €81,030,907 in Germany, France, and England, respectively. These data effectively document the substantial burden and costs associated with POP surgery in the three countries studied using generalizable data and appropriate methods.

A multicentre international randomized controlled trial of pelvic floor physiotherapy for mild to moderate prolapse (the POPPY study) was published as an abstract in 2011[102]. A total of 447 women were randomized to either 5 physiotherapy visits over 16 weeks, or were given written instructions about lifestyle advice re constipation, obesity etc. Although the POPSS quality of life test [103] was employed, and showed significant benefit for physiotherapy treatment, the authors had not been able to find a QALY test that was responsive to change for prolapse treatment in the literature. The net cost of active physiotherapy treatment was £127 per patient, yielding an average decrease in POP-SS of 1.52 points. This would approximately equate to a 10% improvement in quality of life for one year, yielding a cost per QALY of £16,000.

In 2011, Hullfish and colleagues from the UK [104] developed a Markov model to compare the relative cost effectiveness of treatments for post-hysterectomy pelvic organ prolapse (POP), including expectant management, use of a pessary, and surgery. They used probabilities from published studies and expert consensus and generalizable national costs from national charge data from the 2007 Healthcare Costs and Utilization Project Nationwide Inpatient Sample adjusted for all payor cost to charge ratio. They could not identify published HRQOL or utility scores for POP conditions, so estimated these based on a range of 1.0 for repaired POP without complications to 0.0 for major complication or re-operation. Over a 1 year timeframe, initial pessary use was the least expensive and had the lowest QALY. Vaginal reconstructive surgery had the highest QALY. Unfortunately, the results were not presented as incremental analyses so they are difficult to interpret. Sensitivity analysis demonstrated that these baseline results depended on several key estimates in the model: probabilities of POP complications, surgery following pessary use, and late complications following surgery, utility of pessary use, and the cost of robotic assisted surgery.

In 2011, Murray et al. [105] investigated the cost of traditional anterior colporrhaphy (AC), hand-cut mesh, and mesh kit anterior vaginal prolapse (AVP) repair using a decision analysis model. The model included mean operating room (OR) times, mesh extrusion rates, and recurrence rates obtained from a meta-analysis and Medicare reimbursement for surgeon fees and office visits, and hospital costs of supplies, OR time, and room and board. Non-kit mesh repair was $3,380, AC $3,461, and mesh kit $4,678. One-way sensitivity analyses demonstrated recurrence rate of AC would need to be 28% to be cost equivalent to non-kit mesh repair and the non-kit mesh cost must be < $480 (basecase $400) to remain less expensive than AC. Mesh kit repair did not reach cost equivalence, even with an OR time of 0 minutes. Two-way sensitivity analysis comparing mesh extrusion and AC recurrence demonstrated AC is less costly if recurrence is <20% or extrusion >25%.

As per our previous report, a Cochrane review of surgeries for the management of pelvic organ prolapse emphasized the importance of CEA and CUA [106]. They observed that abdominal sacrocolpopexy is associated with a lower rate of recurrent vault prolapse and dyspareunia than the vaginal sacrospinous colpopexy yet these benefits must be balanced against a longer operating time, longer time to return to activities of daily living and increased cost of the abdominal approach. Similarly, the use of mesh or graft

inlays at the time of prolapse repair may reduce the risk of recurrence and the addition of a continence procedure to a prolapse repair operation may reduce the incidence of postoperative urinary incontinence. Yet, these benefits needs to be balanced against possible differences in costs and adverse effects, which have not been assessed and, like surgical treatment for stress incontinence, are inherently appropriate for CEA since there may be differences between procedures in costs, clinical outcome and health-related quality of life.

Maher et al. [2004] performed a randomized trial of abdominal sacral colpopexy vs. vaginal sacrospinous colpopexy to treat vaginal vault prolapse among 95 women [107]. Secondary outcomes included the impact on cost (measured as Australian bed and operating theater costs) and general- and incontinence-specific quality of life. Two years after the operation, the subjective and objective success rates were similar between groups. The abdominal approach was associated with a longer operating time, a slower return to activities of daily living, and a greater cost than the sacrospinous colpopexy (P<.01). Both surgeries significantly improved the patient›s quality of life (P<.05). These data suggest that formal cost-utility analysis would be beneficial to further compare these two common procedures for pelvic organ prolapse. Additional data with generalizable costs and utility measures and long-term efficacy outcomes are needed.

In the chapter of this text regarding surgery for pelvic organ prolapse (Chapter 15), the authors give further references that provide surgical cost data for a variety of procedures, such as laparoscopic sacrocolpopexy, robotic sacrocolpopexy, versus abdominosacrocolpopexy, and laparoscopic sacrocolpopexy versus total vaginal mesh procedures. Readers are referred to that chapter for details, however no Utility measures were provided in these reports.

8. FECAL INCONTINENCE

a) Cost of illness

In the previous chapter, several cost of illness studies regarding faecal incontinence were reported. However these studies mainly employed previously collected databases[108, 109], or focused upon inpatients [10], subjects with constipation as the main complaint [108], women with faecal incontinence after obstetric injury [110]. Few conducted face-to-face direct enquiry of the personal costs of leakage of faeces[10]. Most did not employ a validated measure of severity [10, 108-110]. Deutekom et al[111] from the Netherlands did measure treatment and non-treatment costs along with the Vaizey continence score, no QALYs were measured and the relationship between cost and severity was not explored.

In 2011, Parkin et al[112] conducted personal interviews with a consecutive sample of 54 ambulatory home dwelling men (5) and women (49) patients who presented with faecal incontinence to a tertiary outpatient Unit, to collect cost data prior to the onset of treatment in relation to baseline severity as measured by St Marks score[113], maximum score 24 points.

Costs were determined by administering a 3 page questionnaire, modelled on the DBICI questionnaire for urinary incontinence[114]. Interviews were conducted face to face, taking approximately 15 minutes each. The information included basic personal hygiene costs (pads, laundry, wipes, cleansers), medication costs (loperamide, creams & stool bulking agents etc) and diagnostic costs (including medical attendance, anorectal physiology, colonoscopy). Following each interview, the personal hygiene items used by patients were costed from known tables compiled by visiting local pharmacies and suppliers. Costs were recorded in AU$.

The median age was 69.5 (IQR 61.5-74) and the major personal expense was for pads and personal hygiene items (median 70.89 per annum, IQR 0.63-310.68). Medicare costs included medical consultation and rebates for physiology testing and endoscopy (median $576.92 IQR). There was no relationship between these overall costs and incontinence severity. The Spearman rank correlation showed no significant relation between total personal costs and severity (r=0.21). When the costs just for pads and creams alone was evaluated, a relationship became apparent (r= 0.34, p=0.05, **Figure 12**).

b) Prevention

The cost effectiveness of two sphincter preserving treatments for anal fistula (anal fistula plug versus endoanal advancement flap) in the treatment of cryptoglandular fistulae to prevent faecal incontinence was studied by Adamina et al in 2010 [115]. The primary end-points were absence of drainage and fistula openings on physical examination at 6 months and absence of abscess formation at any time during follow-up.

This was a microcosting analysis of treatment costs, adjusted for inflation. Non-medical costs and lost productivity costs were not assessed, sensitivity analyses were performed. The study was flawed in that the success rates of healing in advancement flap group were lower than the majority of published studies on this technique. Cost-effectiveness was based on healing and complication rates, with no direct measurement of faecal incontinence. Use of the anal fistula plug saved $1,588 US per healed fistula.

Tan et al (2008) studied the cost effectiveness of primary sphincteroplasty versus delayed sphincteroplasty for anal sphincter injury, in the prevention of faecal incontinence [116]. They constructed a decision tree analysis over 10 years. QALYs were derived from SF36, but no direct QALY tests were measured. The primary sphincteroplasty was associated with a gain of 5.72 QALYs for a cost of £2,750,

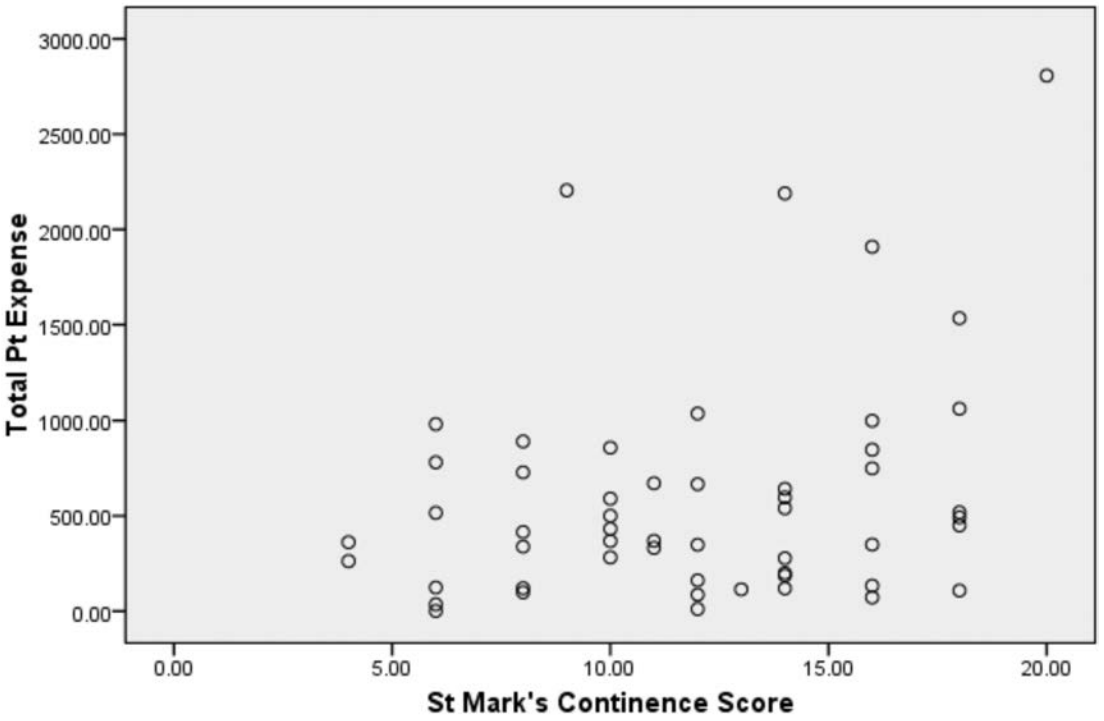

Figure 12. Total personal costs vs incontinence severity St Mark's score

the delayed sphincteroplasty yielded a QALY gain of 3.73 for a cost of £2,667, thus the primary sphincteroplasty was judged to be cost effective.

c) Treatment costs

Reflecting the increased use of sacral nerve stimulation (SNS) as a first-line surgical treatment for patients with faecal incontinence, recent cost-effectiveness analyses have primarily focused on this therapy. Brosa et al (2008) performed a cost effectiveness study of Sacral Neuromodulation for the treatment of faecal incontinence[11]. In their decision tree, they employed two decision pathways, firstly, for patients with an intact anal sphincter (IAS) and secondly for patients with a structurally deficient anal sphincter (SDAS) who had previously undergone a sphincteroplasty. Two of the authors worked for the Medtronics company (international makers of sacral neuromodulation equipment), and "4 authors received an unrestricted grant from Medtronics".

Because recent NICE guidelines recommend Sacral Nerve Stimulation (SNS) as first line therapy in patients with an intact sphincter, and as second line therapy in those with a deficient sphincter[117], their aim was to evaluate the previous scenario (no option to perform SNS) with a new decision tree that included SNS. QALYs were obtained from Deutekom et al [118], [ie for patients with faecal incontinence QALY = 0.68, for patients with no faecal incontinence QALY = 0.87]. Costs were obtained from Spanish Health Costs Database[119]. Temporary SNS evaluation cost €1,484, whilst permanent SNS cost €10,700. Other treatments in the model were more expensive, such as Dynamic graciloplasty €12,000 and Artificial Anal Sphincter €12,000 (taken from Spanish DRG figures).

The timeline for the model was 5 years, with 3% discount rate per annum. Prevalence figures and Medtronics sales forecast were used to estimate numbers of patients likely to receive SNS over the next 5 years, to perform Budget Impact Analysis. Monte Carlo simulation analysis was performed for a cohort of 1,000 patients (i.e. Bootstrapping, see Methods of this chapter) to test sensitivity.

The results of their decision tree analysis showed that patients obtained an additional symptom free year of 0.31 and 0.34 per patient per 5 years in the two pathways respectively. In patients with an intact sphincter, SNS had a cost of €16,181 per QALY gained; for those with a deficient sphincter, SNS cost €22,195 per QALY gained. Budget Impact Analysis on the basis of 75-100 expected patients per annum would yield a budget impact of 0.1% in patients with faecal incontinence.

The authors commented that dynamic graciloplasty in 123 patients yielded complications in 74% of patients with a total of 189 complications [120]. Artificial anal sphincter was performed in 112 patients with 51 patients required a total of 73 further reoperations with 41 (36.6%) subjects requiring device removal [121]. No corresponding figures for reoperation rates were given for those undergoing SNS.

The relationship between the Markov model developed in the above paper by Brosa et al [11], and a patient cohort study published by a similar group of authors [122] also from Spain in the same year, is unclear. In the paper from Munoz-Duyos et al.,[122] patient level cost data is given for 57 temporary evaluations under local anaesthetic in 47 patients, giving a success rate of 61% (which is lower than many other publications). Permanent SNS devices were implanted in 29 patients, who were followed for a median of 3 years.

The study was reported on an intention to treat basis over a five-year time horizon. Only treatment costs were evaluated. The actual Markov model was not provided. Costs were not discounted. No sensitivity analysis was performed. It is unclear how the QALY were determined, as no QALY tests were administered, and data arising from calculating QALYs from SF36 were quoted as being derived from the paper by Brosa et al [11]. Thus it appears that this report from Munoz-Duyos [2008] was in some aspects a duplicate of the earlier Brosa paper [11, 122].

Despite this paper being entitled a "cost effectiveness study" there was little individual cost data given, for example, the temporary evaluation cost was €397, and the SNS permanent device cost was €10,178. Mainly, group totals of costs were given, for example, operating room costs of €26,000 for all the temporary evaluations, and €17,000 for all SNS implantations in the study group. Thus the majority of costs were associated with implantation of the permanent SNS device (due to upfront device costs).

In patients with an anatomically intact anal sphincter, SNS versus maximum conservative treatment had an ICER of €16 181 per QALY gained, well within the €30 000 per QALY threshold accepted in Spain.

In 2010, Indinnimeo et al. [12] from Italy, published a cost effectiveness study of SNS based on the decision tree model of Brosa (who was a co-author of this paper also)[11]. The decision tree parameters appeared to be identical, based on the same NICE guidelines, but cost data from the Italian NHS reimbursement list were substituted. For example, the cost of temporary evaluation of SNS was €6,400, the cost of permanent implantation of SNS was €6,400, the cost of dynamic graciloplasty was €8,760 and the cost of artificial anal sphincter was €4,620 (as shown in **Table 1**, earlier in this chapter).

Clinical data were obtained from published studies and from "expert" panel consensus. Note should be made that one of the authors worked for Medtronic Italia and that some data on SNS were taken from a review in which the majority of patients were implanted using an open surgical rather than percutaneous technique. Treatment success was defined as "the cessation of the patient to seek further treatment due to a satisfactory reduction of incontinent episodes with the therapy". Measurement of success was based on outcome at 6-month follow-up and it was assumed that loss in efficacy over time for each treatment was equal. The committee felt that this may have biased the results, as generally (for example) the efficacy of sphincter repair declines with time (80% ‹success› at 1 year, 50% at 5 years, 20% at ten-years [123]). In contrast, loss of efficacy with SNS is more likely to occur in the first year (in the absence of device failure).

There were several difficulties regarding the design of the decision tree. Firstly, the study assumed that all patients with a structurally deficient anal sphincter should undergo sphincter repair. Structural deficiency was defined as damage up to 120 degrees in radial extent affecting partial or full length of the internal or external anal sphincter, or both.

No reference was given to sphincter function in assessing the role of sphincteroplasty.

The Committee felt that in real life, those with partial length defects or isolated internal anal sphincter defects would not be considered for sphincteroplasty; only patients with full length defects with adequate residual muscle bulk and function would generally be considered for sphincter repair.

Generally, the indications for sphincter repair or dynamic graciloplasty are end-stage faecal incontinence in the presence of a substantial muscular defect and / or neural defect of the anal sphincter. However, the Decision Tree analysis assumed that all patients (even those with intact anal sphincters) would undergo one of these operations, which seems to make the model flawed in the case of patients with an intact anal sphincter.

Secondly, the model also assumed that of those undergoing a neo-sphincter procedure, 95% would undergo dynamic graciloplasty and only 5% artificial anal sphincter. The Committee felt that artificial anal sphincter is more readily performed in current clinical practice, with the recent understanding of poor long-term outcome of dynamic graciloplasty. Only 65 DG were performed in 21 European Centres in 2011 (Personal correspondance Medtronic Inc.). Finally, the model indicates that colostomy achieved 100% continence. In practice patients may still be incontinent of mucous which can cause considerable morbidity and impact upon quality of life.

The cost utility analysis revealed an ICER (€ per QALY gained) of €28,285 in those with sphincter defects, and €38,662 in those with intact sphincters. These results were within €40,000 acceptability threshold of the Italian NHS. Their Budget Impact Analysis appeared to give a low estimate of the total number of patients being treated with SNS (that is 86 to 115 patients per year over five year period in a population of 48 million people).

Mitchell et al [2011] performed economic analysis of the use of local anaesthetic (LA) versus general anaesthetic (GA) for insertion of temporary test electrodes (single electrode helical wires were used rather than tined quadripolar leads) [124]. Because LA was used, determining the optimal site for electrode placement was based upon sensory perception of the stimulus effect, rather than motor response. However, one third of patients undergoing SNS are known to have poor sensory localization and are unable to define the exact location of the stimulus making electrode placement difficult [125].

This was a retrospective cohort study of 111 consecutive age and sex matched patients, 42% of patients had LA which cost £613, and 58% had GA which cost £743, yielding a saving of £130 for the LA cases.

All were planned as day case procedures, but 89% of LA patients went home that day versus 62% of GA cases. A greater proportion of patients had success in the GA group (77% versus 64%). The small sample size resulted in a modest effect and a large standard error with non-significant effects. Reduced cost with the LA procedure was not correlated with effectiveness, so it is difficult to make conclusions about the outcome of study.

In late 2009, Dudding et al [13] performed a cohort analysis of 70 consecutive patients treated with SNS at a single UK institution over a ten-year period [1996-2006] with subsequent followup for approximately 2 years, which was then projected over a 7 year time horizon. Unlike the previous publications, these authors collected data prospectively at the patient level for baseline cost information and evaluated actual success, failure and complications, which comprised the Decision Tree analysis (as previously shown in **Fig**. **2**, Decision Analysis).

All of the patients had failed standard conservative therapy, and these costs were assessed at baseline, for comparison with subsequent intervention with SNS. A societal perspective was taken and sensitivity analysis was performed.

Treatment and non-treatment costs were assessed. The treatment costs were taken from UK national tariff and health resource group codes. Face to face data on routine care costs was not collected but careful calculations of typical costs of pad usage, loperamide consumption, outpatient visits etc were undertaken.

The non-treatment costs were derived from publications regarding time off work [110, 126, 127] and loss of work productivity[111, 128], from non-British sources, yielding a figure of £912 per patient per annum (which may not have been applicable to the UK population studied).

QALY data were calculated from conversion of elements of the Short-form 36 questionnaire, which is a standard methodology [26], although it must be noted that the SF-36 was not designed for economic evaluations. Inconsistencies can occur with this conversion which makes it possible for a patient with a better health state to record a lower QALY value than a patient with a worse health state [129].

Because the study included a self-selected group of patients who had failed to benefit from conservative treatments, it may not be representative of all patients who undergo conservative management for faecal incontinence (many of whom do achieve success from conservative treatment).

All procedures were performed under general anaesthesia, but the costing for short stay procedures was such that this had little economic effect. The cost for temporary evaluation was £510, the cost of permanent SNS implant was £8,480. **Figure 2** shows the clinical pathway with resultant success rates and complication rates of this patient cohort (earlier in this chapter). Complications occurred in nearly 20% of patients (several were mild but required some form of medical intervention); these were carefully costed in the manuscript at the patient level. The basic conservative regime cost £596 per QALY gained, and SNS cost £2159 per QALY gained. Sensitivity analysis was performed to assess robustness of the model and rates were discounted by 3.5%. Including all treatment and non-treatment costs the ICER for SNS was £25,070 per QALY gained. This equates to £1038 more per year to treat patients with SNS for a median reduction in 286 incontinent episodes (£3.63 per episode reduced). Lost productivity make up a large proportion of the total cost of faecal incontinence and this was reflected in this study. When lost productivity was included, the ICER was reduced to £12,959 per QALY gained for SNS versus conservative therapy.

In conclusion the ICER of £25,070 per QALY gained was within the £30,000 per QALY threshold recommended by the UK National Institute of Clinical Excellence as an effective use of UK NHS funding (**Figure 2**).

In 2009, Dudding and Nugent[130] published an abstract which compared the costs of using a permanent quadripolar tined lead electrode for temporary testing as part of a staged implant versus the single electrode helical wire as part of a two-stage procedure. This was a decision tree analysis based upon published literature, which took into account success, failure and complication rates. On an intention to treat basis of 100 patients, a saving of £27.78 per patient can be made by adopting a staged implant strategy. They concluded that a permanent quadripolar electrode should be used for temporary SNS.

VI. SUMMARY AND FUTURE RESEARCH PRIORITIES

In the four years since the last ICI consensus conference, some high quality economic analyses of surgery for stress incontinence treatments have been published. The Committee notes that evidence regarding cost utility of outpatient therapies for stress incontinence remains limited, aside from the recent economic study of obesity treatment for this condition. However the economic analysis of therapy for overactive bladder syndrome requires greater effort, to encompass longer time frames and wider use of QALYs that can yield cost utility analysis (CUA). The Committee was disappointed to find that most of the recent economic studies of anticholinergic therapy did not include collection of raw QALY data.

In the last 4 years, the implementation of Sacral Nerve Stimulation for refractory detrusor overactivity has been the subject of several economic analyses, which are indeed important. However the Committee reiterates the need to collect primary data for QALY outcomes in future studies of this technique.

In the field of prolapse, it is not yet known whether any currently available QALYs are sensitive to treatment benefit, so that CUA may still not be feasible in this area. The recent POPPY study is to be commended for including patient-level cost data and quality of life information about conservative treatment.

As regards faecal incontinence, research into Cost of Illness remains rather preliminary, so that broader more long term studies are still needed. It is encouraging to see economic analyses of Sacral Nerve Stimulation in this field as well, however more data about Cost Utility in Faecal Incontinence is urgently needed.

As regards methodology, researchers need to consider carefully how they construct the model parameters for Decision Tree Analysis and Markov Models, so that "real life" assumptions are made. The gold standard remains Cost Utility Analysis in parallel with Randomized Controlled Trials, and we urge all clinicians to consider cost and QALYs as important outcome measures.

VII. APPENDIX – SEARCH STRATEGIES

We performed a comprehensive computerized medical literature search (PubMed) for the years 2007-2012 to identify all economic, health-related quality of life and cost-effectiveness analyses published on urinary incontinence, fecal incontinence or pelvic organ prolapse. Our initial search strategy was very broad and meant to be very sensitive but not specific. We performed a search for the following Medical Subject Headings (MeSH) and keywords: cost-effectiveness analysis, health care costs, quality-adjusted life years, costs and cost analysis, sickness impact profile, or utilities and urinary incontinence, overactive bladder, fecal incontinence, anal incontinence, uterine prolapse or pelvic organ prolapse. The initial searches were reviewed to identify articles appropriate for more detailed evaluation. Inclusion criteria were: urinary or fecal incontinence or prolapse as primary disease, data on costs available. Studies were excluded when they were a review or case-report.

CONTENTS

I. INTRODUCTION

1. LEVELS OF EVIDENCE
2. PRIMARY GUIDING ETHICAL PRINCIPLES
3. INFORMED CONSENT IS AN ETHICAL CORNERSTONE OF HUMAN SUBJECT RESEARCH.
4. SPECIFIC INFORMED CONSENT IS REQUIRED FOR RESEARCH PARTICIPATION.
5. THE INVESTIGATOR HAS AN ETHICAL RESPONSIBILITY TO TAKE RESPONSIBILITY FOR ALL ASPECTS OF THE RESEARCH.
6. ENSURING PARTICIPANT SAFETY IS PARAMOUNT.
7. HIGH QUALITY DATA MANAGEMENT IS KEY TO PROVIDING VALID AND ETHICAL RESEARCH RESULTS. (41).
8. USEFUL WEBSITES:
9. FINANCIAL CONFLICTS OF INTEREST

II. DEFINING THE RESEARCH QUESTIONS

III. EXPERIMENTAL STUDIES

1. RANDOMIZED CONTROLLED TRIALS
2. NON-RANDOMIZED CONTROLLED CLINICAL TRIAL(S)
3. PRAGMATIC AND EXPLANATORY TRIALS
4. DRUG TRIALS ARE CATEGORIZED ACCORDING TO THE FOLLOWING DEFINITIONS (30, 50).
5. BIAS, BLINDING AND EFFECTS ON VALIDITY

IV. ELIGIBILITY CRITERIA

V. SAMPLING STRATEGIES

VI. DATA COLLECTION

VII. OUTCOME MEASURES

1. PRIMARY OUTCOMES
2. SECONDARY OUTCOME
3. TYPES OF OUTCOME MEASURES

VIII. SATISTICAL CONCERNS

1. SAMPLE SIZE CONSIDERATIONS

I. INTRODUCTION

This chapter provides general recommendations for good research practice, including principles of clinical trial design and statistical methodology. In addition, we present specific recommendations applicable to trials for certain types of treatments and certain subgroups of patients.

1. LEVELS OF EVIDENCE

Most contributions to this consultation used the Oxford Centre for Evidence-based Medicine Levels of Evidence and Grades of Recommendation (http://www.cebm.net/levels_of_evidence.asp). However, as these are not an appropriate metric for recommendations in this chapter, the Research Committee used the following categories.

- High: Supported by strong evidence (multiple strong publications)
- Medium: Supported by moderate evidence (limited/moderate level publications)
- Low: Expert/Panel opinion

The report endorses consistent use of the methodology and approved terminology that will not only facilitate incontinence research by producing high quality studies but also facilitate communication about research. Recognized published guidelines produced by the International Continence Society (ICS) [1-15] and Society for Female Urology and Urodynamics (SUFU) [16-18] are useful examples of standardized terminology that advances communication in research.

Research is defined as "systematic investigation designed to develop or contribute to generalizable knowledge" [19] and participants accept risks to advance scientific knowledge and to benefit others [20]. The aim of clinical research in functional urology and urogynaecology is to evaluate treatments intended to prevent and/or significantly reduce symptoms of lower urinary tract dysfunction. The research methodology presented herein is intended to facilitate production of high-impact, high-quality research which will provide evidence needed to inform clinical practice, stimulate other investigators, generate new research ideas, and lead to a better understanding of physiology and pathophysiology of the human health and disease.

Although it is beyond the scope of this section to review the rules of conducting human subject research in depth and extensive coverage is available elsewhere [21-25], all investigators should understand the difference between "research" and "clinical practice". At a minimum, criteria for an ethical research study should meet the following criteria:

- the study should well planned, scientifically sound with clearly defined aims;
- clinical research should be prospectively registered whenever possible;
- the study should be feasible with a realistic chance for completion;
- there should be a reasonable assumption that new knowledge will be provided at the end of the study; and
- there should be an expectation that the results will be published to advance scientific knowledge [21, 26].

Human subject research protocols must be approved by an Institutional Review Boards (IRB), although IRB approval should be regarded only as a minimal ethical standard for research. Ultimately it is responsibility of the investigator to ensure the research is ethically acceptable.

2. PRIMARY GUIDING ETHICAL PRINCIPLES

There are 3 primary guiding ethical principles for human research outlined by the 1979 Belmont Report on "Ethical Principles and Guidelines for the Protection of Human Subjects of Research" [27]. These principles are essential for ethical clinical research and are briefly reviewed in the following section.

a) Respect for Persons recognizes the voluntary nature of research participation and includes informed consent without undue influence.

b) Beneficence requires investigators to maximize

benefits and reduce risks to the subject. The primary concern of the investigator should be the safety of the research participant and careful consideration of the risk/benefit ratio; this includes an ongoing responsibility to monitor research and medical literature as the research proceeds. The investigator needs to critically consider within the expert medical community if there is clinical equipoise for the proposed interventions in their trial. Is one treatment no better than another? Are the research risks reasonable in relation to anticipated benefits? It is the responsibility of the investigator to ensure risks are minimized and potential benefits enhanced as well as that the knowledge gained outweighs the risaks [26]. Of note, invalid research cannot be ethical no matter how favorable the risk–benefit ratio for study participants.

c) Justice requires that the benefits and risks be distributed fairly (i.e. not only using people without access to health care, prisoners, or those impaired). Justice is of particular concern in Phase I testing of pharmacuetical agents and in early investigation of surgical devices/implants. Payment offered for participation in such drug trials may be extremely attractive to poor and disenfranchised subjects. Early device studies may target countries with lax regulatory environment even if there is little intent to market the device there in the long term.

3. INFORMED CONSENT IS AN ETHICAL CORNERSTONE OF HUMAN SUBJECT RESEARCH.

Peer review of protocols by a multidisciplinary team may include members of the scientific community, clinicians, pharmacists, the public/patient groups, the legal profession and individuals who can provide an ethical perspective. Each member of this team reviews the protocol from their particular type of expertise and in doing so aids in safeguarding patient health and well-being.

4. SPECIFIC INFORMED CONSENT IS REQUIRED FOR RESEARCH PARTICIPATION.

The length and depth of detail in consent forms vary widely between institutions. In the extreme, they involve exhaustive pages of information, which explain every alternative treatment with its pros and cons in detail. A general list of requirements for a consent form includes: name of the investigators and contact numbers, a detailed description of the new treatment and its known side effects, rationale for why the new therapy may be preferred to standard therapy. A summary table of the results of previous studies using the drug can be helpful when available. A statement that the patient may decline to be in the study with no subsequent consequence to their ongoing medical care is generally provided and whether or not remuneration is expected. Additionally, there should be a statement about payment for medical care required during the course of the study if there is an adverse event associated with the intervention. An understanding that the patient will be randomly assigned to treatment should be included when relevant, written using terms that are meaningful to potential participants [28-29].

5. THE INVESTIGATOR HAS AN ETHICAL RESPONSIBILITY TO TAKE RESPONSIBILITY FOR ALL ASPECTS OF THE RESEARCH.

This will insure that the work is done rigorously and to maintain the integrity of the research [30]. International Committee of Medical Journal Editors (ICMJE) now requires that information about trial design be placed into an accepted clinical trials registry prior to participant enrollment [31]. For more information, see more extensive information available elsewhere [30, 32-35]. A list of registries acceptable to the ICMJE can be found on their website. One objective of trial registration is to reduce publication bias given that trials with positive findings are more likely to be published than those with negative findigs. An important feature of one registry, clinicaltrials.gov, is a results database [36].

Consider this pragmatic, simple test to use when resolving an ethical research dilemma: “Imagine what you are preparing to do will be reported the next day on the front page of your local newspaper. If you are comfortable having colleagues, friends, and family know what you did, chances are you acted responsibly”.

6. ENSURING PARTICIPANT SAFETY IS PARAMOUNT.

An independent data safety monitor (DSM) or data safety monitoring board (DSMB) is important to evaluate the study on an ongoing basis to determine early evidence of significant harm or benefit [37-38]. Depending on the size, complexity, and risks of a trial, the DSMB is comprised of experts needed to monitor interim data to ensure the safety of the participants. The DSMB should be established prior to initiation of the trial. In addition to reviewing results of the study for safety monitoring they may evaluate interim analyses to ensure that a treatment is not producing unacceptable levels of side effects and/or efficacy [29, 37]. A priori stopping rules or boundaries are established to assess if the study should continue or be terminated due to futility (that is, no conclusion will be drawn due to low enrollment, few outcome events, or high drop out rates etc.), reaching an endpoint, or identifying increased risks. Guidelines for stopping the study should be agreed upon, prior to the start of the trial [30]. Interim analyses (in particular those based on efficacy) will have implications for the study power. Specialist statistical advice and support will be essential to address these issues [39, 40]. Investigators must not be aware of the results of interim analyses, however, since this may cause bias by influencing how vigorously any given patient is recruited into or followed up in the study, and most importantly, runs the risk of a type

II error (ie mistakenly concluding benefit when there is none). Nevertheless, emergency procedures for unblinding a patient's allocation are required in case of a severe side effect or concomitant serious illness where knowledge of treatment assignment is essential for patient management and safety.

7. HIGH QUALITY DATA MANAGEMENT IS KEY TO PROVIDING VALID AND ETHICAL RESEARCH RESULTS [41].

In addition, ethical conduct of research includes timely and complete reporting. Clear guidelines for authorship have been established by medical journals [42]. Beginning with the research contract, authorship rules should be established according to accepted guidelines. In general, authorship credit should be based on 1) substantial contributions to conception and design, or acquisition of data, or analysis and interpretation of data; 2) drafting the article or revising it critically for important intellectual content; and 3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

9. FINANCIAL CONFLICTS OF INTEREST

Many investigators are involved in testing new drugs or devices developed by industry and have the potential to significantly supplement to personal income. It is acceptable for investigators to receive contracted financial support to perform this research and a principled partnership between industry and investigators is essential if we are to preserve medical progress [43]. Financial conflict of interest policies have been developed due to ethical concerns about potential biases that may influence trial design, conduct, over interpretation of positive results or not publishing negative results [30, 44]. It is important that investigators do not receive money directly (personal income) from industry sponsors but rather through a research contract through an appropriate entity with research oversight capabilities. Disclosure of these relationships helps maintain scientific integrity and preserve public trust in the scientific process. This is a rapidly evolving area and investigators are encouraged to clearly understand and disclose such relationships.

An investigator's institution may have additional definitions and reporting requirements for financial conflict of interest disclosures. There are many potential relationships between physicians and industry; it is preferable that the nature of the relationship and its financial magnitude if any, be fully defined rather than categorized (i.e. "consultant") so that the reader can appropriately assess the disclosure.

II. DEFINING THE RESEARCH QUESTIONS

The investigator(s) should take a deliberate approach to formulate the specific research question, based on a careful review of related clinical research and relevant studies that are well designed and clinically relevant. The research reviews provided by the Cochrane Incontinence Group (http://healthsci.otago.ac.nz/dsm/wch/obstetrics/cure) provide an excellent starting point for most major incontinence topics. Based on a thorough literature review, the investigator clearly describes the primary research question(s), summarizes the background information, and formulates the rationale, objectives and hypotheses for the study. The investigator(s) should formulate the simplest study design which will provide the highest quality of evidence to test the given hypothesis in a cost and time-efficient manner. Whenever possible, basic or translational research should occur as part of the clinical research study in order to advance discovering of underlying mechanisms or pathophysiology. This balance between breadth and depth greatly increases the yield of the research effort [45].

III. EXPERIMENTAL STUDIES

1. RANDOMIZED CONTROLLED TRIALS

Experimental studies have the potential to provide a higher level of evidence than observational studies. The randomized double-blind clinical trial (RCT) is considered the gold standard study design. Properly planned and executed, the RCT is the optimal approach to limiting allocation bias [46]. The study participants are assigned to a treatment group by a random (chance) mechanism that ensures adequate concealment so that neither the study participant nor the investigator can influence treatment group assignment in order to reduce allocation bias. Subject assignment must be concealed during enrollment (for example, by separating allocation from the process of recruiting subjects, and by using remote randomization such as by telephone or web-based procedures), and wherever possible treatment allocation must be concealed during the trial (for example, using blinding with or without placebo). In order to minimize bias, the randomization process must be concealed from those recruiting subjects to the trial [48- 49). This can be achieved most effectively by the use of central telephone randomization.

In drug studies, a pharmacy can maintain identical treatment drug and placebo already randomly allocated into individual subject portions. These are distributed consecutively as subjects are enrolled in the study. In some studies, blinding of subjects and health care providers may not be possible, for example in trials of some surgical procedures or health care delivery methods. In almost all cases, however, the personnel collecting outcome data should be unaware (blinded) to the subjects' treatment allocation. RCTs require ethical equipoise and are usually expensive to conduct optimally.

The purpose of randomization is to produce groups that are, on average, comparable. A per-protocol analysis retains this property only in the unlikely situation when non-compliance is unrelated both to the patient's underlying state of health and the treatment received [50]. The intention-to-treat approach in pragmatic trials retains the full benefits of randomization and has the advantage that the comparison will more closely reflect the relative effectiveness of the treatments when applied in real clinical practice, where non-compliance is a common occurrence [51].

a) Simple randomization can use computer-generated random numbers, either prepared specifically for the trial or using existing tables of random numbers where the digits of 0-9 appear with equal likelihood in each entry. Treatments are assigned to odd or even numbers. As the total number of subjects in the trial increases, the balance of numbers and characteristics of subjects between the groups improves. In small trials, however, balance is not assured by simple randomization. Appreciable imbalances in subjects per group may be particularly important in a multicenter study where imbalances in assignment can occur within individual institutions.

b) Block randomization is one method used to prevent imbalances in subject numbers assigned to each group, particularly when the number of subjects in the trial is small. With block randomization, the total sample size is divided into blocks of a given size. Within each block, the group is assigned so that there are equal numbers allocated to each group. To prevent investigators from learning the block size and being able to guess order of assignment, the block size can be varied, usually at random from a small number of alternatives. In any case, blocking prevents serious imbalances in characteristics across groups when used in conjunction with stratification as described below.

c) Stratified randomization

Most disease states have factors known to influence the outcome of treatment, for example symptom severity or gender. A form of randomization that accounts for such factors is called stratified randomization [46-47]. Stratified randomization ensures equal distribution of subjects with a particular characteristic in each group when blocking is employed within strata. Stratification is usually restricted to a small number of factors, in particular those most likely to influence outcome. Despite its complexity, stratified randomization is usually helpful in a multicenter trial, so that both the numbers of subjects in each group and the important factors influencing the outcome can be balanced within each site. An alternative method exists to cater for more factors at once, known as minimization, where the characteristics of individuals already randomized alter in a systematic manner the chances of a given subject being allocated to the different trial groups, so as to maximize the resulting balance of these factors [46-47, 52].

Although the classical RCT involves the study of parallel groups, other options are possible and may overcome some of the limitations of the classical approach [53]:

d) Parallel Group Trials

This design generally includes one group of subjects assigned active treatment and a second (parallel) group a placebo or another treatment not believed to be an active treatment. The key feature of this design is that both groups (treatment and comparison group) are assembled and followed at the same time. In clinical trials of drugs the dose of the drug tested may be either a single dose or multiple doses to determine clinical benefit and/or minimize side-effects. More complex study designs can in some circumstances be worth considering – for example, factorial trials where two or more interventions can be investigated simultaneously [54-55], and cluster randomized trials whereby groups of participants (defined by some common feature, e.g. members of the same health maintenance organization, clinic, etc.) rather than individuals are randomly allocated to the trial arms [56]. This strategy might be employed when studying an intervention requiring policy changes in an institution, with a hospital, clinic, or health care system being the unit of randomization.

e) Crossover Trials

Subjects receive both the treatment being studied and the placebo/alternative treatment, with random order of treatment assignment. The benefit of crossover studies is that they eliminate the effect of variation between groups of participants seen in parallel trials, that is each subject serves as his/her own control. Crossover studies are particularly well suited for small studies, where the course of the disease under study is believed to be stable, and where the primary objective is to measure a short-term change in the outcome (e.g. urinary symptoms) in response to treatment. The duration of treatment required before the anticipated effect may be observed is critical in determining whether the crossover study design is appropriate – too long a period time before an effect becomes evident, and the disease state may vary before the study

participant has completed all arms of the trial; too short, and it may not be possible to detect the effect during the period of data collection. Carryover of treatment effects from one treatment period (or observation period if a placebo follows treatment) to another, make this a challenging study design to implement in many cases. To avoid a carryover effect, a washout period should be included, in which participants receive either placebo or no treatment. A run-in period in which signs and symptoms of the illnesses studied are monitored may be necessary before treatment begins to ensure that only those whose disease state is stable are entered into the study. Given all thesefeatures and limitations, this design is unlikely to be widely applicable in studies of interventions for incontinence.

There are two types of clinical trial designs that show the similarity of medical treatments: non-inferiority trials and equivalence trials.

f) Non-inferiority trials

the primary objective of a non-inferiority trial is to demonstrate that the new treatment is not unacceptably worse than that of the standard treatment. This design may be appropriate when one treatment is less costly , may offer advantages related to improved quality of life, or has fewer side-effects, and the current belief is that both treatments have a a similar effect on the disease or condition of interest . A key feature of this type of trial design is the ability to rule out a non-inferiority margin; that is, a minimum threshold for an unacceptable loss of efficacy [57-59]. As an example, if prior independent studies found similar effects of pelvic floor exercises and a drug in the treatment of stress incontinence, one might set up a study to demonstrate that no important difference in clinical effect was present between the two treatments by direct comparison. Currently there is considerable uncertainty about the design of non-inferiority trials as it relates to U.S. and European drug regulatory bodies [60-62]such that there have been recommendations to consider alternative designs [57]. Non-inferiority trials have been infrequently used in studies of urinary incontinence. A recent example is the Value of Urodynamic Evaluation (ValUE) trial, a non-inferiority randomized trial of preoperative urodynamic investigation in women undergoing stress urinary incontinence surgery [63].

g) Equivalence trials

The goal of an equivalence trial is to show that the experimental treatment is not more inferior and not more superior to a standard treatment by a given amount [64-66]. The clinically important difference between the standard treatment group and the new therapy is established prior to start of the study (Fleming TR 2000), and it is shown, by formal statistical testing, that the difference between the control and study treatments are not large in either direction (more beneficial or less beneficial). A recent trial of midurethral sling surgery illustrates this type of study design [67].

h) Superiority trials

The most common study design for clinical trials of urinary incontinence and for many other diseases/ conditions is the superiority trial where the goal is, in its most simple form, to show one treatment is better than another (or no treatment, placebo). The general approach is to establish a priori a clinically meaningful effect that you wish to detect. Once conducted, determining superiority requires that the findings permit the investigator to reject the null hypothesis that the two distributions of the treatment effect are equal, in favor of the new treatment being better than the control [58].

2. NON-RANDOMIZED CONTROLLED CLINICAL TRIAL(S)

This category includes trials in which treatment allocation is known to the investigator prior to obtaining informed research consent (for example, day of clinic appointment). This approach often results in baseline characteristics of the treatment groups being significantly different, decreasing the ability to interpretate trial results. Because of this major shortcoming, this type of study should be used rarely, if at all.

3. PRAGMATIC AND EXPLANATORY TRIALS

There is an important distinction between pragmatic and explanatory trials [68- 69], and correspondingly, between intention-to-treat and per-protocol approaches to data analysis [50, 70]. This distinction has a number of facets. In pragmatic trials the interventions are designed to be as close as possible to treatment options in clinical practice (including multiple patient management choices) and entry criteria are usually relatively liberal in comparison with explanatory trials. In addition, pragmatic trials may involve a wide variety of outcome domains, including patient-completed questionnaires, and an economic evaluation of outcomes. As a result of intention-to-treat data analysis, pragmatic trials will tend to yield lower estimates of treatment differences than explanatory trials. It may be of interest to gauge the effect of treatment given full compliance; therefore, full data analysis ideally incorporates both intention-to-treat and per-protocol approaches [50]. The primary analysis, though, should follow the intention-to-treat principle.

Data from pragmatic trials are analyzed by intention-to-treat, according to the group to which subjects were randomized, regardless of the extent of compliance with the intended treatment. In explanatory trials, data are analyzed accounting for compliance. This per-protocol approach may exclude serious non-compliers, analyze data according to treatment actually received, or allow for degree of compliance in a statistical model.

At first sight, the explanatory approach appears more attractive. However, there are considerable limitations to the explanatory approach, particularly when the intention is to draw inferences from the trial to wider clinical practice (generalizability).

4. DRUG TRIALS ARE CATEGORIZED ACCORDING TO THE FOLLOWING DEFINITIONS [30, 50].

a) Phase I studies

The first studies of a drug in humans, often open label and uncontrolled, concentrating on safety and frequently but not exclusively carried out in healthy volunteers. Pharmacokinetic and tolerance information is obtained from Phase I trials.

b) Phase II studies

The first attempts to investigate treatment efficacy, often the first use of the drug in subjects and focusing on short-term outcomes. A common objective of Phase II studies is dose finding in terms of efficacy. Two sub-types may usefully be distinguished: Phase IIA studies where single treatments are considered in relation to a minimum response prior to further investigation; Phase IIB where direct comparisons are made between interventions, albeit on a small scale and not necessarily involving randomization [71].

c) Phase III studies

Large-scale, authoritative randomized studies performed once the most likely effective and tolerated treatment regimens have been established. The objective is often to establish that the intervention is suitable for registration/approval with the appropriate regulatory authority. Trials are conducted after submission of a new drug application (NDA), but before the product's approval for market launch. Phase IIIB trials (between submission for approval and receipt of marketing authorization) may supplement or complete earlier trials, or seek different kinds of information (for example, quality of life or marketing). Phase III trials are also used to investigate the effectiveness and cost-effectiveness of various interventions – that is, non-drug including organizational issues – and not necessarily with reference to regulatory authorities. All Phase III trials should be subject to a formal sample size calculation – for instance to obtain sufficiently precise estimates of the comparisons between treatments or to have a reasonable chance (power) of detecting a difference if one exists (see section II C 7 below).

d) Phase IV studies

These investigations are usually carried out after registration/approval, to investigate the drug's safety and efficacy in different populations. Such post-marketing surveillance studies are typically larger and simpler than regulatory studies; they may lack a control group and are often conducted using surveys.

5. BIAS, BLINDING AND EFFECTS ON VALIDITY

Bias can be introduced at many stages of a study including patient selection, randomization, assessment of outcomes, and statistical analysis and interpretation. Bias occurs because of previously conceived ideas held by those involved, which consciously or unconsciously affect their actions and observations. In addition to observer bias, an amount of observer error is inherent in outcome measures that require clinical interpretation.

a) Blinding

In order to minimize bias, research design should strive for the highest practical level of blinding. Blinding is the process by which key elements of knowledge are withheld that can otherwise lead to bias. Blinding should not be confused with concealment of allocation, referring to withholding knowledge of assignment in advance, which is a prerequisite for the validity of any trial [48, 72]. While blinding is important, its effect is lower than that of concealment of allocation [73]. In most drug studies placebo pills allow blinding of all relevant participants.

b) Unblinded trials

They are conducted in an open manner where both subjects and study investigators are aware of which treatment has been assigned. While certain types of therapy may require investigation in this manner (e.g., some surgical trials), there remains considerable opportunity for bias. Both subjects and investigators may have preconceived ideas regarding the benefits of a particular treatment that can influence the reporting of symptoms and/or their outcome.

c) Single blind trial

Commonly, in a single blind trial, 'single blinding' may refer to blinding the outcome assessor (but not the subject); this is common in trials in which blinding the subject is not possible (such as pelvic muscle exercise trials). It is important to specify who is blinded to which aspects of study execution, rather than using only the vague term "blinded".Hence, in these studies the only possible blinded person is the assessor. It may be advantageous for the clinical staff to be aware of the assignment to allow them to monitor the health and safety of individuals, since the potential effects of the treatment (side effects) will often be known in advance. Single blinding ameliorates biased reporting of symptoms and/or side effects by subjects. However, clinical staff can influence data collection and change other aspects of subjects' care when they know which study treatment subjects are receiving.

d) Double blind trials

In double blind trials, both parties who could influence outcome are unaware of group assignment. Often this is just the subjects and the clinical team responsible for their care. Selection of an appropriate external comparison group is challenging and factors unknown or not measured by the investigators may adversely influence the findings.

IV. ELIGIBILITY CRITERIA

Eligibility criteria impact every aspect of a study's progress, from recruitment to analysis to acceptance of the study's results by the community. Yet, in the planning phase of a study, this vital aspect is often given short shrift. Eligibility criteria will differ, depending on the main goal of a study. For a Phase I trial, designed to understand safety of an intervention, eligibility criteria should be very narrow, and should focus on minimizing risk and maximizing ability to demonstrate proof of concept. A Phase II trial, designed to test the efficacy of a treatment in a fairly ideal population, will have broader eligibility criteria, but will exclude individuals in whom it is highly unlikely a treatment will be helpful, or highly likely that a treatment might be harmful. If a treatment shows promise at this point, eligibility criteria for a Phase III trial are as broad as possible, to test the effectiveness of the treatment in as real world of a setting as possible, thus maximizing generalizability. Conclusions can only be as broad as the eligibility criteria allow. Thus, a drug found to be effective in a study that included only healthy middle-aged people can be recommended for that group, but not for older people, children, people with medical conditions, or other groups excluded by the eligibility criteria.

While some **exclusion criteria** are necessary to reduce risk to potential participants, it is important to include individuals in whom the treatment would likely be used once widespread. For example, in testing a new drug for urgency incontinence, that is excreted by the kidneys, it is important to exclude people with high serum creatinine levels, but equally important to include older individuals with multiple co-morbidities in specific studies, as these are also likely to benefit from a drug for urgency incontinence once released.

Particularly in longer-term studies of pelvic floor disorders, some exclusion criteria are needed to maximize potential for follow-up. Such studies often exclude people likely to move or die during the study period, people with conditions that impair adherence (such as drug or alcohol dependence, severe mental illness or homelessness) or factors that make follow-up more difficult (such as lack of a telephone). For ethical reasons, it is important to either exclude people with significant cognitive impairment (such that informed consent is impossible) or to plan a consent process with a legally authorized representative in mind. However, all exclusions impact the generalizability of the conclusions and so such trade-offs must be carefully thought through.

Additionally, inclusion criteria related to the condition of study must be considered in concert with the consideration of the primary outcome measure. If an inclusion measure defines "disease", it is essential that the outcome measure does not include this same measure or cut-point as "success". For example, if a surgical trial comparing two treatments for pelvic organ prolapse defines prolapse as >/= stage II (and excludes from enrollment only women with </= Stage I prolapse) and the primary outcome measure defines successful treatment as prolapse at or above the hymen, then women enrolled with maximal prolapse at points 0 or -1 may be considered successfully treated when in fact, their condition has subjectively not changed. It is also important to note that a given condition, such as stress urinary incontinence, will be present or absent depending on which outcome measure is used to define it. Avoid using one outcome measure to exclude women from a study and then a different outcome measure defining the same condition as the primary outcome measure.

V. SAMPLING STRATEGIES

Every study must address its sampling strategy, that is, the selection of participants. In principle, sampling should involve random selection. In practice, however, this ideal is rarely met outside of large-scale epidemiological studies. For example, RCTs are drawn from a subset of the population, often limited to those with access to academic medical centers plus the willingness and ability to participate. Where this is the case, it is crucial to provide descriptive information about the study sample, so that its representativeness can be judged. Guidelines for reporting of RCTs include requirements to state the study population, give details of inclusion and exclusion criteria, and present clearly the numbers of eligible subjects who were not randomized and the reasons [32, 48- 49].

A study may require a sample that is representative of the community overall or one representative of patient groups suffering the condition/ disease. In principle, this is achieved by taking a simple random sample from a known population. In practice, a list of all eligible individuals is obtained and then a sample is drawn by a method in which each member of the population has an equal probability of selection ('epsem'). Even in ideal circumstances, however, some sophistication on this basic method is usually desirable or necessary. For example, in stratified sampling, subjects are arranged into subgroups and the sampling is performed within each subgroup separately. This ensures that the sample is representative of the population in terms of these subgroup character-

istics. In multi-stage random sampling, the population is first divided into primary sampling units (such as hospital, health center, or surgeon), and a sample of primary units is selected. The secondary sampling units, usually individual subjects, are selected within the primary sampling units. A special case of multi-stage random sampling is cluster sampling where all individuals within each primary unit are included. Standard procedures for sampling should be followed [56, 74].

It is important to note that, while the technicalities of random selection of subjects for a study are closely related to the random allocation of subjects in an RCT (and indeed there are similar issues in trials relating to stratification and clustering)[56], there is an important distinction in the objectives of the two procedures. First, the (ideally random) selection from the population of eligible subjects concerns the external validity or generalizability of the study findings (RCT or otherwise). Independent of this, the random allocation of subjects in an RCT is concerned with the internal validity or comparability of the trial groups. It is usually obvious whether the study can be performed at a single institution, or whether a multicenter study will be required. Single institution studies have the benefit of being less complicated from a logistical perspective. While multicenter trials are more complex to manage and are usually more expensive, they provide larger numbers of participants in a shorter period of time, and increase the generalizability of research findings.

VI. DATA COLLECTION

Although the number of questions in a single study should be limited, it is still relevant to record as many as observations as is possible without jeopardizing recruitment or retention with onerous demands. Strong consideration should be given to collection of the following data groups [16],[75].

a) Baseline data:

b) Observations:

1. Patient's observation/Subjective measures
2. Clinician's observation/Objective measures

c) Tests

1. Quantification of symptoms—bladder diary, and
2. Pad tests for incontinence outcomes
3. Urodynamics

d) Follow-up

e) Quality of life measures

f) Socioeconomics

It is useful to consider collection of the following variables:

- Age
- Race/ethnicity
- Gender
- Body mass index (height and weight)
- For women – obstetric history, including parity and menopausal status
- Smoking status
- Co-morbidities such as cardiovascular, respiratory and neurologic conditions and diabetes
- Medication use
- Past surgical history
- Level of education
- Mental and physical status
- Prior treatment for pelvic floor disorders, including behavioural, pharmacological and/or surgical interventions
- Sexual function

VII. OUTCOME MEASURES

Specific discussions of the most appropriate outcome measures for particular studies of incontinence and pelvic organ prolapse are discussed elsewhere in this consultation. The purpose here is to define the general concepts of primary and secondary outcomes, which are relevant to both sample size determination and data analysis. The distinction between these two sets of outcomes depends on the context of the trial, and should be decided at the planning stage of the study. Primary and secondary outcomes should not be confused with the distinction between primary and secondary analyses of trial data.

1. PRIMARY OUTCOMES

Primary outcomes are those viewed by the researchers to be of central interest. Sample size calculations are based on anticipated changes in the primary outcomes. The final study population may or may not be sufficient to allow robust comparisons of secondary outcomes. Trial results that are based on the primary outcomes can lead to reseponsible alterations in standards of patient care.

The number of primary outcomes in a particular trial will depend on the nature of the interventions and the number of independent domains. The number of primary outcomes is usually limited to three. Sample size calculation is based on the primary outcomes. The number and nature of outcome domains in a particular study will vary depending on the study's perspective. Careful selection of outcome measures

that are valid and clinically relevant is intrinsic to the success of research; usually no single measure can fully express the outcome of an intervention.

2. SECONDARY OUTCOME

Secondary outcomes can be relatively large in number. They are not the focus of the main study objectives and are rarely used directly in sample size estimation. Secondary outcomes are exploratory, i.e., as hypothesis-generating exercises for which independent confirmation is essential or used to monitor: e.g. safety, side-effects, costs or patient acceptance.

3. TYPES OF OUTCOME MEASURES

Traditionally, a patient's success after a particular treatment was reported by the physician, using subjective information that differed from physician to physician. Given the mismatch between physicians' and patients' perceptions of treatment effectiveness, this type of physician reported outcome measure has been largely replaced with patient-reported outcomes (PROs). The Food and Drug Administration defines a PRO as any report of the status of a patient's condition that comes from the patient, without interpretation of the response by the clinician or anyone else.

(http://www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/UCM193282.pdf)

There is emerging consensus that PROs are most appropriate when describing success or failure of therapies. However, physician-reported outcomes can yield valuable information about mechanistic effects of therapies and are also vital in developing predictive data for future use. As an example, a patient's report of a bulge is a reasonable outcome measure for a study of surgical treatment for POP. However, if, over time, women with stage II POP after treatment who were initially asymptomatic became symptomatic, it would be pertinent to include prolapse stage, as an anatomic outcome measure, in the definition of success.

Other types of physician reported outcome measures (often called "objective outcomes"), used frequently in pelvic floor disorder research, include results obtained from urodynamic testing (e.g., presence or absence of detrusor overactivity incontinence), radiologic imaging (e.g., various angles measured during pelvic ultrasonography), physical examination (e.g., the POP-Q system for assessing pelvic organ prolapse), laboratory values, biomarkers, etc. , as well as tests collected by the patient but interpreted by the physician (such as pad tests and bladder diaries).

The primary types of PROs include [76].

- **Disease/condition specific**: measure patients' perceptions of a specific condition. These cannot be administered to people without the condition under study.
- **Population specific:** specific to a certain population (for example, women or men or elderly) with or without a given condition.
- **Dimension specific:** assess one aspect of health status. The primary dimensions studied include:
  - Physical function (e.g., activities of daily living)
  - Symptoms (e.g., urinary incontinence)
  - Psychological well-being (e.g., depression)
  - Social well-being (e.g., sexual function)
  - Cognitive function (e.g., mental status evaluation)
  - Role activities (e.g., household or work activities)
  - Personal constructs (e.g., body image)
- **Generic measures:** measure broad aspects of health which can be used to compare across populations (The SF- 36 is a commonly used measure). These are often less responsive to clinically significant changes in health than condition-specific instruments
- **Utility measures:** (e.g., EuroQol) incorporate preferences or values attached to individual health states. This type of instrument produces evidence for the overall value of health states to society and can be used in cost-utility analysis.
- **Summary items:** participants summarize an overall picture of their status in one item (for example, the transitional item queried in the SF 36: "Compared to one year ago, how would you rate your health in general now: excellent, very good, good, fair, poor?"
- **International Classification** of Functioning, Disability and Health (ICF), WHO 2001
- **Unified and standard language** and framework for discription of health and health-related states
- **Body, Individual, Society**
  - Body functions and structures
  - Activities and participation
- **Body functions:** physiological and psycological functions of body systems
- **Body structures:** anatomical parts
- **Impairments:** problems in body function or structure such as significant deviation or loss

- **Activity:** execution of a task or action by an individual
- **Participation:** involvement in a life situation

While not yet in wide use, web-based resources for administering computerized adaptive tests are being developed. One example is the Patient Reported Outcomes Measurement Information System (PROMIS) system (www.nihpromis.org). Using this type of testing, researchers can lower participant burden substantially. For example, in a measure of physical function, someone who endorses inability to dress themselves would not be asked the next series of questions in a typical validated physical function questionnaire about walking or exercising; someone who endorses ability to run marathons would not be asked questions about less strenuous activities. Nascent work has begun on the use of the PROMIS system in pelvic floor disorders [77].

Investigators should strive to use validated outcomes measures whenever possible. A fully validated outcome measure is demonstrated to 1) be reproducible when administered to the same person twice, 2) yield results that align with other gold standard measures (content validity), 3) change with successful treatment (be responsive to change), and 4) measure what it is intended to measure (face validity). (A full discussion of psychometric properties needed to validate a questionnaire can be found elsewhere in this consultation.) Much progress has been made in this area over the last decade, and therefore, when planning a study, the default position should always be choosing a validated outcome tool as a primary outcome measure. However, it is important to note that just because a questionnaire is "valid" does not mean it can be used in any population in any language. Researchers must take care to use instruments in the populations for which they were intended.

Adverse event recording and analysis is an important aspect of outcome measures, especially when the benefits may be offset by harms. Adverse event assessment should be systematiclly included in every interventional study. The Clavien-Dindo system for structured reporting and analysis of surgical complications has been used in several studies comparing pelvic floor interventions[78]. In this system, complications are classified into one of four categories based on the type of therapy needed to correct the complication.

The timing of outcome assessment should reflect the study question. Studies reporting efficacy of incontinence treatment should follow subjects for a minimum of one year. Although early follow-up can provide important insights about adverse events, a great deal more emphasis needs to be placed on long term effectiveness. The follow-up time for a trial should be at a fixed time (for logistical reasons, this is in practice often a short time window) relative to randomization rather than when treatment was actually received, since again this is the only way of ensuring a valid comparison. The planned timing of follow-up at a fixed time relative to randomization should, however, allow for any likely delays in receiving treatment, e.g., due to surgical waiting lists.

VIII. SATISTICAL CONCERNS

1. SAMPLE SIZE CONSIDERATIONS

There is no single answer for sample size determination; often the calculation proceeds around a 'circle of specifications' (involving, say, power, targeted difference in effect size and population available for study). Furthermore, the ideal of the target being the minimum for clinical significance cannot always be met; rather, the aim in practice is to produce a convincing argument (among the researchers themselves, and also to funding bodies and regulatory agencies) that the sample size has an adequate chance of detecting differences that are (a) feasible, and (b) worthwhile detecting in clinical terms. A common failing is selecting a target difference that is too large, often derived from differences that have been observed or published previously rather than based on considered clinical judgment. Preliminary investigations into the levels of treatment effects that patients themselves consider worthwhile should be carried out much more commonly than is the case at present.

Sample size should be calculated in the planning stage of all studies. There are many formal equations to assist in this process, details of which will not be given here [70-71, 79-80]. Rather, the emphasis for this discussion is on the concepts involved and the information required for the calculations to proceed.

2. SAMPLE SIZE CALCULATION

One approach to sample size calculation is based on the required precision of an estimate, which is relevant to both descriptive and analytical investigations. The basic issue is one of precision (measured by the standard error, SE) or margin of error (which depends on the SE but is more specifically defined as half the width of the 95% confidence interval [CI] around the estimate). The higher the level of precision specified in advance (i.e., the smaller the SE and the narrower the CI), the larger the sample size will need to be. However, the margin of error depends on the nature of the primary outcome variable, i.e., whether it is a continuous variable (such as maximum urinary flow rate) or a binary variable (such as the presence or absence of self-reported urgency incontinence). For a continuous variable, the variability (standard deviation) of the measure must be estimated for relevant subjects; this may

be derived from some combination of clinical experience, the literature, or a pilot study. The larger the variability, the larger the sample size required. For a binary variable, its prevalence must be estimated in the population to be studied, since the SE for such variables depends on their prevalence.

A second approach, based on power, is the most commonly used and requires that the study have adequate probability (power) of detecting a given (target) magnitude of effect. It requires similar prior information, including estimates of the variability for continuous measures and the magnitude of proportions for binary variables. In addition, it requires specification of three other quantities: the significance level, the power, and the target difference. Significance is a statistical term that tells how certain one can be that a difference or relationship exists. It does not necessarily imply that the result is clinically relevant, just that the result is likely to be accurate. The significance level, termed alpha, is conventionally, though not necessarily, set at 5%. Power is defined as the probability that the study will detect (as statistically significant at the alpha level specified) a given target difference between the groups, if such a difference exists. Power is commonly specified in the range of 80% to 90%, which implies a risk of not detecting the target difference of between 20% and 10%, respectively. For a trial involving anything other than minor risks and expenditure, a power closer to 90% than 80% would seem preferable [32], which leads to a larger sample size (as does a stricter alpha level of, say, 1%). This is most pertinent when a lack of statistical significance is obtained in a small trial, particularly when the sample size was not planned using a power calculation [47]. This is the basis for the adage that "the absence of evidence is not evidence of absence"[25]. A planned unequal allocation to the trial groups also requires an inflation of the sample size [47], as does interim analyses. By multiplying the number of significance tests performed, studies with interim analyses generally require stricter significance levels at each analytical point [50, 70].

3. THE TARGET DIFFERENCE

This is the last, and arguably the most important, quantity that must be specified for the power-based approach to sample size calculation. The target difference is defined as the minimum difference between treatment groups considered to be clinically significant. Clinical significance is an entirely different concept from statistical significance. Investigators must estimate the clinical significance as the magnitude of difference (in means or proportions) that would lead to a change in clinical management for the target group of patients. For example, a study might propose that a 20% difference in incontinence episode frequency is a clinically meaningful response. Ideally, such an assumption would be based on surveys of patient behavior but in practice the decision is often based on clinical judgement. In any case, the smaller the clinically significant target difference, the larger the required sample size. Statistical significance means that the observed difference, whatever its magnitude, cannot reasonably be considered as being due to chance. Statistical significance (denoted by the p-value) represents the strength of evidence against the null hypothesis [81]. The degree of clinical significance can be inferred only with the additional information of a confidence interval for the comparison between groups. A very large trial may achieve a high level of statistical significance with a very small effect size and therefore be of little clinical significance. A trial designed in such a way poses ethical challenges because many extra subjects are exposed to risk without meaningful benefit.

With each approach, appropriate adjustment for attrition (loss to follow-up) should be performed. This is commonly achieved by simply increasing the planned sample size in proportion to the anticipated attrition (i.e. to predict the reduced effective sample size that will be available for the analysis).

IX. ANALYSIS

The analytic plan should be consistent with study aims and the a priori analytic plan should be included at the time of the protocol entry into a clinical trials registration system. Currently, high tier journals will often request the statistical analysis plan and protocol at the time of the review of the report. This section will not contain any technical details of statistical methods, which are available in standard texts [47, 82-83], but rather will summarize concepts of data analysis.

It is established practice that the **primary analyses** (for both primary and secondary outcomes) of an RCT should be on an intention-to-treat basis [48, 72]. **Secondary analyses** incorporating non-compliance and/or which treatment was actually received may be justified in addition to the primary analyses. In practically all situations, hypothesis tests should be two-sided (i.e., allowing for the possibility that the difference could have been in either direction, that is benefit or harm), rather than one-sided. One-sided tests are only appropriate if a difference in one direction is not just unlikely, but would not be of interest, such a demonstrating only superiority of a new drug.

Regardless of the type and complexity of statistical techniques used in analysis, the general underlying principles behind hypothesis testing and estimation apply. In particular, the statistical significance of a hypothesis test should be interpreted critically. The actual p-value should be considered, rather than just whether or not it is below an arbitrary threshold such as 5% [48]; indeed, the p-value is better considered a measure of the strength of evidence against the null hypothesis, on a continuum or 'shades-of-grey

[83-84]. The direction and magnitude of the trial comparison should be presented with an appropriate confidence interval to indicate the possible clinical significance and precision of the comparison [48, 85].

Appreciable **loss to follow-up** in a trial (which is not the same as adherence with intended treatment, lack of efficacy, or the observation of adverse events) may present serious problems both in terms of generalizability of the findings to the wider population and, in the case of differential loss to follow-up across treatment groups, to the validity of the comparisons. Indeed, strictly speaking any missing outcome data means that not all of those allocated to the various randomization groups can be included in the analysis [86], and this might lead to the conclusion that the term 'intention-to-treat' should only be used if follow-up is complete. Under current guidelines, **intention-to-treat** relates more to the broad strategy adopted by the researchers for data analysis [39, 87]. Results should always be accompanied by a full and clear statement of how deviations from intended treatment and missing outcome measures have been handled in the analysis. The discussion should include how missing outcome data may have affected the conclusions [86]. Sensitivity analyses can be used to test the exclusion of, or assumptions about, missing values; practical examples of such analyses are becoming more common [88]. Another design strategy, modified intent to treat (MITT), is common in drug trials. It requires the participant to take at least a single dose of the study medication in order to be included in the analysis.

It is essential that a statistical analysis plan be developed for the trial prior to implementation. The CONSORT statement provides an outline of the various stages of data analysis for RCTs [32, 72]. Here we present the underlying concepts of data analysis at a particular follow-up time relative to randomization, and considers initially the simplest case of a clinical trial with two treatment groups. Multiple treatment groups will be covered briefly, but repeated measurements of outcomes and interim analyses involve considerably more complex methods of planning and analysis, for which expert help is essential [71, 89].

- **Stage of data analysis**

The first stage of data analysis is to address the representativeness of randomized subjects compared to the target population of eligible patients. The number of eligible patients who were and were not randomized should be provided, along with reasons for excluding potential study participants. This aspect of the findings of the trial will only prove useful if all eligible patients are considered: in practice there is a tendency for researchers to avoid approaching certain potentially eligible patients (selective pre-screening), for any of a wide variety of reasons, and this behavior may introduce bias in which subjects from the target population are included in the study. The presentation of this information is facilitated by use of the CONSORT flow diagram [48, 72]. Use of the CONSORT guidelines is associated with improved quality of reporting of trials generally [32]. Descriptive statistics should also be given of important characteristics of health care professionals approached for involvement in recruiting subjects to the trial, both for those taking part and those declining.

The second stage of data analysis is to compare the two groups at randomization (baseline) including demographic, prognostic, and outcome variables. A common error at this point is to rely on statistical testing for these comparisons [47, 50, 70]. If the randomization procedure has been performed correctly, then any statistically significant differences in baseline characteristics are likely due to chance. Statistical testing of this kind is not a test of the comparability of trial groups; rather, it is a test of the allocation procedure [47, 50, 70]. It may be seriously misleading, particularly if lack of a statistically significant difference for a given characteristic is taken to imply comparability. Baseline comparability is best assessed by simply obtaining descriptive statistics for the groups and making a judgment as to whether any observed differences are likely to be influential or not. If differences are likely to be influential, they should be considered in the analyses. Notable exceptions to this are baseline measures of the outcome variables, which should be considered in the analysis regardless of the situation at baseline, since removing variance in the outcome measure that is purely attributable to differences between individuals at baseline has potentially marked benefits in terms of precision and power [50]. Investigators should consider stratifying the randomization on any strongly prognostic variable (for reasons of efficiency rather than bias). Since there are practical limitations as to how many variables a trial can stratify for, a technique known as minimization may also be considered [46, 74]. Any variables stratified or minimized at randomization should be allowed for in the analysis [50]. In incontinence research, variables such as prior failure of therapy in drug and surgical studies or the degree of anatomic support in surgical or injectable trials or degree/amount of incontinence might be considered important enough to stratify, or to include in the analysis if unequally distributed.

The next stage of data analysis is to perform the primary (comparative) analyses for the outcome variables. First, though, it is essential to derive and report actual numeric data – even if simply in the form of descriptive statistics – rather than just reporting for instance a percentage change, even if the latter are relevant and provided as well. Graphs can be misleading, especially when subsections of the scales are magnified, and should be used to supplement or clarify the numerical data,

not to replace it. Primary outcomes should initially be analyzed by intention-to-treat comparisons of the groups as randomized, both using hypothesis tests for statistical significance and CIs for comparisons between the groups to assess clinical and statistical significance, usually adjusting for baseline measurements of the outcome variable. With a small number of primary outcomes, multiple testing is not a concern. However, when a large number of statistical tests are performed for secondary outcomes, corrections to the observed p-values should at least be considered.

The most commonly used procedure for multiple testing of many outcomes is the **Bonferroni correction** [47, 50, 82]. The Bonferroni correction is fairly conservative in reducing the risk of a statistically significant effect occurring purely by chance, at the cost of reduced power for individual outcomes. This is particularly pertinent when, as is usually the case, the outcomes are positively associated with one another. While there are alternative procedures that improve this deficiency, none of them are entirely satisfactory [50]. It is emphasized that whatever strategy is adopted to deal with multiple testing, the major errors are to rely solely on p-values rather than present confidence interals "CI"s as well, to over-simplify the presentation of p-values to just non-significant"NS" or "p<0.05" rather than to quote the actual p-values, and above all to report selectively the results of significance tests.

Another example of a **"multiplicity"** is where there are more than two treatment groups, e.g., when different doses of a drug are being investigated or when more than one 'active' procedure is being compared with placebo [50]. Similar issues to multiple testing of different outcomes are involved here, but there are a greater variety of commonly used procedures available to deal with the central concern of finding a difference purely by chance. Standard methods for dealing with this multiple comparisons problem include the procedures attributed to Tukey, Newman-Keuls and Dunnett [90].

Secondary analyses of trial data include per-protocol analyses with adjustments using regression methods for pertinent process measures such as degree of adherence with the allocated treatments. Secondary analyses also include **planned subgroup analyses,** such as the investigation of different intervention effects across age, ethnic, or disease severity groups. Subgroups should be analyzed by using appropriate interaction terms in regression models [48, 70]. Using interaction terms rather than performing repeated, separate, subgroup-specific analyses considerably reduces the risk of false positive findings [91-92]. Subgroup analyses should be carried out sparingly, specified in advance (preferably with a clinical rationale), and above all should not be reported selectively [48, 92-93]. This last point relates not just to subgroup analyses but to all stages of reporting randomized trials. Pre-specification of the primary outcomes in the study protocol and analysis plan, along with clear statements about all the outcomes considered is essential to avoid selective reporting. The large volumes of data accumulated in major multicenter RCTs almost guarantee that something "significant" can be identified by "data-mining". If not identified by the investigators as an a priori item of interest such findings should be viewed with great skepticism.

X. REPORTING RESEARCH RESULTS

Over that past decade, progress has been made in reporting research results. However, faster progress would occur if investigators would follow the reporting recommendations. As part of the "Enhancing the QUAlity and Transparency Of health Research" **(EQUATOR)** Network project, a website was developed at www.equator-network.org. On the website, the Consolidated Standards of Reporting Trials **(CONSORT)** statement provides guidelines for reporting the design, detailed methods, and results of RCTs. For studies of diagnostic tests the Standards for Reporting of Diagnostic Accuracy **(STARD)** [94] statement fills the same role and information is also included on the EQUATOR website. Guidelines for reporting meta-analyses are described by the Quality of Reporting of Meta-analyses (QUORUM-37) and Epidemiologic research reporting guidelines are contained in STROBE, Strengthen the Reporting of Observational Studies in Epidemiology [38, 72].

The CONSORT statement is specifically designed to provide standards for reporting RCTs [48, 72]. It includes a checklist of items that should be included by authors preparing manuscripts. Adherence to these guidelines and the use of flow diagrams in particular is associated with improved quality in reporting of RCTs [95]. Errors in presentation of statistical information are extensively covered in many textbooks [47, 82]. This section will emphasize the most important points on reporting of RCTs, to ensure an objective and comprehensive presentation of the trial itself, and also to facilitate any subsequent synthesis of research evidence including formal meta-analyses of RCTs. Meta-analyses are themselves the subject of separate reporting guidelines: the QUORUM statement [96]. However, such guidelines are not a panacea [97]; deficiencies in reporting are still common [72]. [98]

The CONSORT statement for reporting **parallel group randomized trials** have recently been updated Statements have also been issued for pragmatic trials [99-102] and noninferiority and equivalence trials. The CONSORT statement includes a checklist of items and a comprehensive set of characteristics of a clinical trial to assist investigators to write reports of their findings, journal editors and

reviewers in the review of manuscript submitted for publication and permit consumers of the literature to critically appraise articles. Clear statements about the objectives of the trial, intended study population, and planned comparisons. Subgroup or covariate analyses should be clearly specified and justified. The method of randomization should be stated, as should the unit of randomization; in most cases, this will be the individual participant but occasionally an aggregate group of subjects will be allocated jointly in a cluster randomized design [56]. Cluster randomized designs are also now the subject of separate reporting guidelines [103], and involve particular complications in terms of data analysis [104]. For all trials, specifications for the sample size calculation (primary outcomes, target differences, etc.) should be stated and justified. In addition, the precision actually obtained in a study must be presented. This requires confidence intervals as well as the observed p-values, at least for primary outcomes but preferably for all outcomes. The principal confidence intervals should be for comparisons between the groups, rather than for differences in the outcomes within the trial groups [47, 50]. Results should include a trial flow diagram, with numbers and reasons for the exclusion of eligible subjects, the number randomized, and subsequent losses to follow-up [32]. Protocol deviations should be described and explained [70]. Harms of the trial should be described for each treatment group. Finally, the discussion should include a brief summary of the trial's findings, possible explanations for the results, interpretation of the findings in light of the literature, limitations of the trial including internal and external validity, and the clinical and research implications of the study[48].

Recommendations on Study Conduct and Statistical Methods

- The role of quality RCTs as providing the strongest level of evidence in incontinence research should be fully acknowledged by researchers, journal reviewers, and editors. **HIGH**
- Careful attention to the planning and design of all research, especially RCTs, is of the utmost importance. **HIGH**
- Appropriate expertise in biostatistics and clinical trial design should be employed at the design phase of a RCT and thereafter on an ongoing basis. **HIGH**
- The design, conduct, analysis and presentation of RCTs must be fully in accordance with the CONSORT Statement. **HIGH**
- The design, conduct, analysis and presentation of observational studies should follow STROBE guidelines. **HIGH**
- The design, conduct, analysis and presentation of meta-analyses should follow QUORUM guidelines. **HIGH**
- Reporting studies of diagnostic tests, including urodynamics, should follow the STARD state¬ment guidelines. **HIGH**

XI. SPECIAL CONCERNS FOR SPECIFIC STUDIES

1. BEHAVIORAL AND PHYSIOTHERAPY TRIALS

a) Terminology

The lack of consistent terminology severely hampers our ability to build a body of literature about conservative interventions. The terms "behavioral therapy", "lifestyle intervention", "conservative treatment", "non-surgical treatment", "physiotherapy", "biofeedback", and pelvic floor muscle exercise" are often used interchangebly and incorrectly to describe both the same, and different interventions. While such therapies are discussed elsewhere in this consultation, we here advance this committee's opinion about appropriate terminology:

b) Behavioral interventions

According to Oxford Advanced American Dictionary the term behavioral is «the way someone behaves, especially towards other people», and behavioral science is the study of human behavior. We recommend that behavioral science be limited to studies that evaluate how people do or do not behave as desired.

c) Lifestyle interventions

Lifestyle interventions for UI are discussed elsewhere in this consultation and have traditionally included change in diet, intake of caffeine and carbonated soft drinks, fluid restriction, weight loss, smoking cessation and advice of increasing general physical activity level. Behavioral science can be used to understand how and why people change life-style to, for example, adhere to exercise and weight loss programs, but it should not be used as term to replace specific therapies such as physiotherapy or pelvic floor muscle training.

d) Physiotherapy

Physiotherapy refers to assessment, prevention and treatment given by an authorized physiotherapist (ICS physiotherapy committee www.icsoffice.org). It involves "using knowledge and skills unique to physiotherapists" and, "is the service only provided by, or under the direction and supervision of a physiotherapist" (WCPT 1999). This implies that the term physiotherapy should only be used in trials where the professional providing the intervention is a physiotherapist. We recommend describing the actual intervention instead of using the term physiotherapy: eg pelvic floor muscle training

with or without biofeedback, electrical stimulation, pelvic floor muscle training with vaginal cones or resistance device etc. This accurately describes the intervention and is neutral towards profession. Publications should report the actual profession of the interventionist (e.g., physiotherapist, general practitioner, urogynecologist, urologist, midwife, nurse, fitness instructor), rather than using the vague term, "therapist".

e) Biofeedback

Biofeedback encompasses "a group of experimental procedures where an external sensor is used to give an indication on bodily processes, usually in the purpose of changing the measured quality" [105]. Biofeedback equipment was developed within the area of psychology, mainly for measurement of sweating, heart rate and blood pressure under different forms of stress. Today, a variety of biofeedback apparatuses are commonly used in clinical practice to assist with PFMT, and the biofeedback can be either visual, auditory or both. In many textbooks the term "biofeedback" has been used to classify a method as different from PFMT. However, biofeedback is not a treatment on its own. It is an adjunct to training. For example, it may measure the response from a single PFM contraction or provide visual feedback during attempts to relax the muscles. Hence, a more precise terminology is PFM training or relaxation with or without biofeedback.

In addition to traditional biofeedback apparatuses, other instruments can offer valuable feedback. Vaginal and anal surface EMG, urethral, vaginal or anal squeeze pressure measurements, ultrasound and MRI can all be used to make the patients more aware of muscle function, and to enhance and motivate patients' effort during training [106].

f) Conservative interventions/treatments

Conservative interventions include all of the above, and this term includes everything except medication and surgery. As several studies have found that more than 30% of women with pelvic floor dysfunction are not able to perform a correct PFM contraction at the first consultation [107-110] it is mandatory to report how ability to perform a correct contraction was assessed before commencing an exercise trial. Also in electrical stimulation research one should report in which way response to the stimulation was assessed.

Although there is level A, grade 1 evidence for some of the conservative interventions such as PFMT for SUI, a variety of new conservative methods to treat the condition are frequently suggested in clinical practice and in the literature. These new methods are often presented as being effective, but are usually a hypothesis based on theories, data from small experimental laboratory studies/ small clinical series, or associations found in large epidemiological studies. If the clinicians like the approach, it soon enters clinical practice and textbooks without any further critical testing [113]. A model for how new therapies ideally should enter clinical practice has been proposed [114]. In this model the new idea should go through at least the 4 first stages before they enter practice:

Clinical observation and laboratory studies

- Clinical exploration
- Pilot studies
- Randomized controlled trials
- Refinement, eg dose-response issues
- Active dissemination of the method if it has proven to be effective

It is important that the patients participating in the 3 first stages before the RCT are given full information that they are participating in an experimental treatment, and that the clinician does not know if this new approach is effective. The patients also need to be informed if there are other proven effective treatments available.

g) Reporting of trial characteristics

In addition to reporting the specific type of intervention (eg.PFMT with biofeedback compared to PFMT alone or electrical stimulation) and the profession adminstering the intervention, the intervention needs to be described in such detail that other investigators can reproduce the intervention. This includes:

- Ability to perform a correct PFM contraction.
- Frequency: number of home training sessions and supervised training sessions (eg every day, 3 times/week)
- Number of repetitions and sets (eg. 12 sets x 3 times/ day)
- Duration: length of each training session (eg. 20 minutes), and duration of the total training period (eg, 3 months, 6 months)
- Intensity: In exercise science, this is usually reported as % of one repetition maximum for strength training. In pelvic floor muscle training it is often described as attempts to reach maximum contractions or utilizing submaximal contractions. Another description of intensity is the holding time in seconds, eg: 6-8 sec
- Adherence: the degree to which participants follow the prescribed protocol, usually reported as a percentage of the total possible.

Educational material provided, such as DVDs, brochures and booklets should be described.

Assessment: All devices used for assessments (eg manometers, dynamometers, ultrasound and EMG) must be described in detail, and their re-

sponsiveness (ability to detect small changes), reliability and validity should be reported [111].

h) Adherence vs effectiveness

It is important to note that adherence is not the same as the effectiveness of a program, as it is possible to have high adherence, but still little effect of training. Hence, when reporting the effect of conservative interventions it is ideal to measure also the exposure variable that the treatment is expected to change (eg muscle strength, ability to relax etc). This variable should not be confused with the primary or secondary outcomes of the intervention (eg leakage measured with pad testing, number of leakage episodes or QoL).

In many areas of conservative interventions there are high quality RCTs, systematic reviews and meta-analysis showing statistically significant and clinically relevant differences between the intervention and the untreated control group or other interventions. Of conservative therapies, PFMT for SUI/MUI has the strongest evidence to support its use; further, the more intensive the program (more supervision, higher dosage of training) the better the effect. Therefore, when comparing new methods and innovations with established PFMT, it is important to compare the new intervention with the current best evidence, meaning the effective arm of the reported RCTs. Unfortunately it is common to compare new methods with an ineffective training protocol, thereby overestimating the effect of the new method and claiming that it is equal to or better than "the old method". When comparing different methods the dosage also needs to be the same in both treatment arms, eg when comparing PFMT with and without biofeedback, the number of supervised sessions, length of the sessions, frequency of home treatment and duration of the intervention must be the same.

i) Adverse events and cost

There are few adverse effects or complications reported after conservative interventions, but they do exist, eg in electrostimulation [112], and adverse effects or lack of adverse effect, and inconvenience to the patients should be reported. Although seldom harmful, conservative treatments are time consuming and can be costly for participants and paying parties because of the need for close follow up during the interventions. Cost effectiveness studies are crucial to fully understand where conservative therapies fit in the treatment armamentarium.

j) Outcome measures

The need for use of responsive, reliable and valid outcome measures in research is covered elsewhere in this chapter. The RCTs published in conservative treatment have applied a huge variety of outcome measures, making systematic reviews and meta-analysis difficult or impossible to conduct. Therefore, in future research it is important to use established and recommended outcome measures. In addition to description and use of responsive, reliable and valid primary and secondary outcome measures, future studies should include description and assessment of adherence to the intervention protocol, measurement of the independent variable (the intervention; eg strength training, relaxation training) and measurement of the possible underlining mechanisms of how the treatment works. It is usually not possible to blind the participants or those providing the intervention, but the assessors of outcome should always be blinded to group allocation.

k) Specific and non-specific effects

There have been some concerns that the effect of conservative treatments can be attributed to non-specific effects such as the extra attention of the therapist. The role of the therapist is to educate, motivate and empower the patient to be able to perform the actual program, secure high adherence, and minimize drop-outs. In patient reported outcomes and reports on quality of life it may be difficult to separate the effect of the attention and the actual effect. However, the effect of the attention is less likely to affect outcomes such as muscle strength, urodynamic assessments, pad testing and morphological changes measured by ultrasound and MRI. To minimize bias, all assessments should be conducted by investigators blinded to treatment allocation; the logistics of this should be addressed during the planning phase of the study. In a high quality RCT, Dumoulin et al address the problem of attention in physiotherapy research [115]. Women with persistent UI, three months after childbirth were randomized to either two different training regimens or a control group receiving relaxation massage for the back and limbs for the same amount of time as the supervised training groups. 70% were cured on pad testing in both treatment groups while there was no effect on urine loss in the relaxation massage group. Participants in the massage control group had improvement in disease specific quality of life.

l) Power calculations and number of participants

Some of the RCTs on conservative treatments are flawed by small sample sizes, this being especially evident in electrostimulation studies and may account for negative effects caused by type II errors. It is important that future studies use results of previous published studies to make appropriate power calculations that incorporate estimates of drop-outs and loss to follow-up to decide the optimal number of participants needed. Recruiting large numbers of participants may come at the expense of the rigor of the intervention [116]. Weak interventions (eg non-optimal training dosages or

suboptimal electrostimulation parameters) are unlikely to be effective and do not yield the true effect of an intervention. In meta-analyses, adding RCTs with large sample sizes but weak and ineffective interventions, can dilute the effect of smaller RCTs with higher methodological and interventional quality [116].

m) Long term studies

To date there are no quality criteria for how to report long term follow-up studies or how to conduct meta-analyses of long term studies. Challenges in long term follow-up studies include cross over to the more effective treatment after cessation of the original RCT, co-interventions during the follow-up period, recurrent events (eg new pregnancy), competing events (other diseases leading to incontinence) and loss to follow up. For conservative interventions it is expected that any training effect will diminish over time if no maintenance training is conducted or the pre- or co-contraction of the pelvic floor muscles has not reached an automatic level during the original trial. In order to control for as many of the above mentioned factors as possible, it is recommended that the long term follow up study should be planned together with the original RCT. Loss to follow-up and adherence to the protocol during the follow-up period must be reported [106, 111-117].

Recommendations for conservative treatment trials:

- Use correct terminology to describe the intervention. HIGH
- Report details of ability to perform correct contraction, dose-response issues and adherence. HIGH
- Use recommended outcome measures with high responsiveness, reliability and validity. HIGH
- Compare new methods with the best available intervention. HIGH
- Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions. HIGH
- For long-term follow-up studies report crossover, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up

2. EXPERIMENTAL DEVICES AND MATERIALS

Surgical research presents unique challenges to efforts at optimizing patient care. It is important to create a pathway for real advances while simultaneously protecting patient safety. When new procedures are substantially different from prior operations there should be a broad based preliminary exploration leading to a comparative trial if warranted. At the same time, many minor modifications of surgical procedures are inappropriate for randomized trials and if required, surgical progress would be slowed [118].

a) Randomisation

It has been argued that the first patient in whom a procedure is performed should be randomized [119-120]. Alternatively, it has been suggested that case series for new procedures are allowed until the procedure finds its intended use and to avoid doing studies while those performing the procedures are on the “learning curve”. Typically, new surgical procedures for incontinence have been reported as case series [121-122]. Not only do surgical case series provide the lowest level of evidence for treatment effects, case series may be “harmful”. An accumulation of “positive” case series may present a premature certainty about benefits of a procedure and make it even more difficult to perform randomized trials [123-124]. Influential members of the surgical community may endorse a new procedure and if the procedure is considered better it may be difficult to get surgeons and patients to randomize or a trial may appear to be unethical with a “proven” procedure [119, 123, 125].

b) Adoption by clinicians

Therefore, devices often are widely adopted by clinicians based on anecdotal data, marketing, or small case series. This raises a unique problem for trials in this area: 1) Surgeon buy-in can be difficult to obtain as some surgeons (“early adopters”) may perceive that the newest therapy is best and thus be unwilling to randomize patients to receive the traditional therapy, 2) Other surgeons (“late adopters”) may perceive that the data available do not support use of the newest therapy and thus be unwilling to randomize patients, 3) Patients may be unwilling to be randomized to traditional therapy because they are influenced by marketing forces propelling the newest devices to the forefront, and 4) Device companies frequently modify their materials or technique recommendations; therefore, by the end of the 3-5 years it typically takes to complete the earliest outcome assessment for a surgical randomized trial, the device tested is no longer the same as the device used in the trial. Thus, the results may be discounted as being no longer applicable.

c) Recruitment procedures

An important area of concern in surgical and device studies is patient recruitment procedures. Both in this regard and for all components of a study, we strongly support reporting according to the CONSORT guideline for randomized trials and the STROBE guidelines for observational studies. Subjects should be enrolled in a manner that minimizes selection bias. The protocol should detail the procedure by which consecutive patients meeting

the inclusion criteria are selected. All situations in which a patient meets the inclusion/exclusion criteria but is not offered enrollment by the investigator should be documented. The number of patients who decline enrollment should be stated, along with the reasons. It is vital that clinician researchers do not "cherry pick" from their patients, that is, that they do not limit recruitment to those patients considered to have the greatest chance of cure or lowest chance of risk. The study population should be as generalizable as possible. There should be a complete accounting of all participants in the study including the reasons for subject withdrawal.

Participants must be well informed about what is known and not known about devices or procedures being tested. They should not be led to assume that because a device is on the market, it is "safe and effective", as gaining knowledge about this is the purpose of the trial.

3. SURGICAL STUDIES

Cross-sectional studies of surgical procedures by type can provide estimates of prevalence, variation by age, race, and region as well as morbidity and mortality [126-127]. This type of information raises important health policy questions regarding physician practices, patient preferences for incontinence treatment, and differential access to and the utilization of care.

Case series are the most common study design found in the surgical literature, especially for new "innovative" surgical procedures. This is true despite the fact that case series cannot account for selection bias on the part of both the patient and surgeon, non-reporting bias of failures or loss to follow-up, lack of long-term follow-up, and provide the lowest level of evidence for treatment effects. Observational studies can provide important information about effectiveness and complications of surgical procedures, and also are very helpful in designing and selecting potential randomized clinical trials.

The randomized controlled trial is the accepted "gold standard" for research of treatment effects. In all surgical specialties, there has been growing concern regarding the limited number of randomized controlled trials for surgical procedures, poor methodological standards in those that have been performed, and a perception that surgeons are reluctant to rigorously test new surgical interventions [119, 123, 128-129]. A number of reasons for the paucity of surgical trials have been suggested including the lack of a regulatory board similar to the Food & Drug Administration responsible for the development of new medications [130].

The body of literature of surgical randomized trials in pelvic floor disorders is small, though increasing. However, many RCTs have serious limitations including a sample size too small to detect differences between groups, lack of blinding of the participants and/or individuals assessing the outcomes, short follow-up, inclusion of limited number of surgeons only, poor description of the technique, and lack of standardized outcome measures. Multi-center treatment networks are useful to overcome some of these limitations.

Differential drop out after randomization (or for cohort studies, after the intervention) can introduce bias. In a large and methodologically sound randomized controlled trial comparing the tension-free vaginal tape (TVT) and colposuspension, a large number of women withdrew from the colposuspension arm after randomization [131-132]. The loss of participants after randomization introduced bias in favor of the TVT because the drop outs had less severe incontinence resulting in the colposuspension group having more severe incontinence. It has been suggested that participants were only willing to continue if they were randomized to the "new and better" TVT procedure [132- 133]. Accounting for subjects "lost to follow-up" must also be detailed as per the CONSORT and STROBE recommendations. In the UK TVT RCT, drop out after surgery was similar for both procedures. In contrast, in two large study comparing two incontinence procedures performed by the Urinary Incontinence Treatment Network, randomization was done in the operating room after the patient was anesthetized and therefore no participant was lost to randomization [134],[67].

For studies of specific surgical procedures, the technique should be described in such detail that it could easily be reproduced in another study. **Standardization of the procedure** may vary depending on the research question [135]. Surgical trials using a small number of highly skilled surgeons are analogous to medical trials where only compliant patients are randomized, reflecting efficacy of the procedure in an ideal setting. It may be more generalizable to a mixture of skill level among surgeons in the community, and so reflect effectiveness of the procedure in usual practice [124].

Masking of participants as to their assigned intervention and those assessing the outcome is particularly important for surgical trials for incontinence because there may be enthusiasm by the patient or surgeon for a new procedure, many outcomes are based on the patient's own assessments such as symptom and quality of life scores, and the intervention is primarily for improvement of symptoms [118].

For new surgical procedures, important issues of adequate informed consent and conflicts associated with incentives for developing, starting and using new procedures have been raised. **Informed consent for a new procedure must include**:

- acknowledgement that the procedure is new and has not been shown to be more effective than a traditional approach
- discussion of potential complications, especially any integrally related to the procedure or device
- disclosure that information on complications are limited, and
- disclosure that the long-term benefits are unclear [122].

Incentives for adopting new procedures prior to sufficient evidence can arise from self-interest by attracting patients to one's practice, industry marketing, and patient desire for "cutting edge" techniques. Industry sponsorship or a surgeon's financial interest must be disclosed.

Organizations and treatment networks have been established to address many issues related to surgical interventions. Examples include the UK National Institute of Clinical Excellence (NICE www.nice.org.uk), the Australian Safety and Efficacy Register of New Interventional Procedures-Surgical (ASERNIP-S www.surgeons.org/asernip-s), and the US treatment networks: Urinary Incontinence Treatment Network (UITN http://www. niddk.nih.gov/patient/uitn/uitn.htm) for the NIDDK and the Pelvic Floor Disorders Network (PFDN). The NICE and ASERNIP-S provide systematic reviews of new operations, assessment of effectiveness, and recommendations that the technique has sufficient data for widespread use, or that the techniques appear unsafe, or that further audit/research are required before its widespread usage. The UITN and PFDN were established to provide the infrastructure for multicenter large randomized controlled trials for incontinence and prolapse.

Recommendations for Surgical and DeviceTrials:

- The safety and serious side effects of new operations must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicenter cohort studies when RCTs are not practical. **HIGH**
- Safety and serious side effects of incontinence devices must be completely defined with adequate follow-up, especially for use of implantable devices and biologic materials, so that risks can be weighed against efficacy.**HIGH**
- Valid informed research consent is required in all trials of surgical interventions, which is separate from the consent to surgery. **HIGH**
- We recommend ongoing research into the usefulness of pre- and post-operative predictive testing (such as urodynamics, ultrasound, MRI, etc) in surgical trials. **HIGH**
- Reports of successful treatment should be limited to subjects with a minimum (not mean) of one year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated. **HIGH**
- Randomization for surgical trials should occur at the time of surgery to minimize dropouts and switch of procedure **HIGH**
- Long-term follow-up of RCT cohorts in an observational cohort is recommended. **HIGH**

4. PHARMACOTHERAPY TRIALS

Although many RCTs have been published in recent years on pharmacotherapy for urinary incontinence a great deal more remains to be learned. The trials have almost all been limited to 8-12 weeks of treatment giving very little information about long term safety and efficacy of drug therapy. Inclusion criteria are often stringent, such that the study population of healthy middle-aged people bears little resemblance to the patients for whom providers wish to prescribe medication. There is less than adequate information about special patient groups—men, children, neurogenic patients, and especially the frail elderly. Because incontinence creates such an impact on the older population, good studies to define the utility and safety of drug therapy are greatly needed in this group.

An issue of special relevance in trials of pharmaceutical agents (although germane to other treatment modalities) is the controversy regarding placebos in clinical trials. Regardless of whether a drug is effective or not, simply giving a drug to a patient may produce a beneficial response. To assess if a drug has an effect over and above the placebo response, it is usually tested against an inactive substance (placebo). In incontinence studies, the placebo effect may be quite large, anywhere from 30-50% in recent published studies. To account for this, investigators and regulators have generally demanded a placebo arm in most clinical trials of medication. While this may be acceptable to participants for short trials, it is neither ethical nor feasible to withhold treatment for longer periods of time. Further, clinicians and patients generally want to know how a new drug compares with established treatment.

Masking, while desired in all types of trials, is especially important in pharmacological trials. Further, it is feasible to do in such trials (as opposed to surgical or conservative interventions, in which masking may not always be possible) and thus should be prioritized. However, the identical appearance of two pills does not guarantee that participants will be unaware of group assignment. Side effects

common with anti-cholinergic therapy, such as dry mouth, may unmask participants. Studies should assess the degree to which masking was successfully maintained.

Recommendations for Pharmacotherapy Trials

- As effective drug therapy is available for most forms of incontinence, active drug comparator arms are recommended for most trials. **HIGH**
- Very little is known about the safety, efficacy and tolerability of drug therapy beyond 12 week trials. A concerted effort is needed to create this type of information base. Long-term follow-up of RCT cohorts in an observational cohort is recommended **HIGH**

XII. COST ANALYSIS

Economic and health policy outcomes are gaining increasing importance, as policy makers deliberate the values of different therapies. The financial burden on the health care system, the patient and patient's family of various treatment options makes cost an important outcome to measure. We recommend that cost analyses be planned with clinical studies whenever possible. Costs may be influenced by economic and political factors that are subject to change at any time; however, when basic units of work, time, and resources are carefully defined, models of costs remain useful even if market forces change in an unforeseen manner.

In health and medicine, economic analyses are descriptive and/or comparative. Descriptive data include the socioeconomic cost caused by the disease and its current treatment, whereas comparative data provide an economic evaluation of different treatment strategies and interventions where costs are compared to health outcomes.

There are several relevant types of cost analysis, some of which require a high level of expertise to conduct:

- **Cost of illness analysis** (COI) typically quantifies the burden of medical expenses (direct costs) and the resulting value of lost productivity (indirect costs) attributable to a specific condition such as an illness or injury [136], [132].
- **Cost effectiveness analysis** (CEA) measures the costs and consequences of two or more diagnostic or treatment pathways related to a single common effect or health outcome. It then summarizes the results in ratios that demonstrate the cost of achieving a unit of health effect for different types of patients and for variations of the intervention [137], [133].
- **Cost utility analysis** (CUA) is a form of cost effectiveness analysis in which particular attention is paid to the quality of health outcome related to treatment. In CUA, health effects are expressed in terms of quality-adjusted life years (QALYs) [138], [107]. A QALY is a measure of health outcome that assigns to a given period of time a weighting that corresponds to the health-related quality of life during that period, and then aggregates these weights across time periods. The QALY is important because it considers both quantity and quality of life.
- **Cost benefit analysis** estimates the net social benefit of an intervention by comparing the benefit of the intervention with the cost, with all benefits and costs measured in dollars [24], [134]. Health outcomes are converted into monetary values using "willingness to pay" (the value an individual would pay for reduction in illness severity) or "risk of death" or "human capital" methods (an individual's value to society based on productivity or future wages) [139- 140], [135-136].

Recommendations on Cost Analysis in Incontinence:

- Cost analysis should be incorporated into clinical studies whenever possible [137]. **HIGH**

XIII. RECOMMENDATIONS FOR SPECIFIC PATIENT GROUPS

1. MEN WITH LUTS

When considering men with LUTS, one must consider some unique factors which may influence urinary tract symptoms independently of any intervention, and so confound any data. These are the presence of the prostate gland which can cause bladder outlet obstruction (BOO), and the rarity of sphincter incompetence except in men who have undergone surgery for benign or malignant prostatic disease. For short term outcomes after intervention studies, these factors are unlikely to be relevant, but longer term follow up, and large observational or epidemiological studies may need to take these factors and changes over time into account when analyzing data. The prostate gland may complicate research outcomes as a result of outflow obstruction (either at baseline, or development of a new problem during follow up studies). Also, for patients with prostate cancer (either at the time of enrolment, or during follow up of longer studies), it is likely that both the disease, and the treatment given (surgery or radiotherapy) may alter urinary tract function and symptoms independently of any intervention in the study and thus confound the outcomes. , Overall, about 2/3 of men with LUTS have urethral obstruction and over 50 % have detrusor overactivity, al-

though a much smaller number have urinary incontinence due to detrusor overactivity [141].

If prostate size is considered to be a variable that could affect outcomes, measurement of prostate volume should be made before and after treatment. The method used to measure volume and its reliability and validity should be provided if available or their absence indicated. Any associations between outcomes and change in prostate size should be tested for using appropriate methods and reported. Consideration should be given to stratifying participants by prostate volume when there is suspicion that response to therapy may be size dependent.

Insofar as about 2/3 of men with LUTS have bladder outlet obstruction (BOO), any research protocol in men should consider inclusion of a method to screen for it. At the least, maximum free urinary flow rates and measurement of post-void residual urine should be recorded before and after treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. Synchronous pressure-flow studies are generally desirable and should be included whenever feasible. Several pressure-flow nomograms have been proposed to diagnose obstruction in men. The ICS nomogram is recommended and it is important to specify which if any nomogram is being used [142]

Recommendations for Research in Men:

- Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a potentially important variable, or to change during the intervention and follow up. **HIGH**
- Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. **HIGH**
- Participants should be stratified by prostate size at randomization when size is considered to be a potentially important determinant of treatment outcome. **LOW**

2. WOMEN WITH LUTS

a) Hormonal effects

Our knowledge of hormonal influences on the lower tract remains limited. Recent RCTs and prospective cohort studies have demonstrated that hormone replacement therapy (HRT) does not improve or may worsen incontinence [143-145). It therefore seems appropriate that information about menstrual and hormonal status should be an integral part of the baseline history. New studies designed to examine the influence of hormones on incontinence (if considered ethical by an appropriate review board) should include details of hormonal status (premenopausal, postmenopausal without HRT, post-menopausal with HRT), the route and type of HRT (oestrogen only, combined sequential, combined continuous), and whether or not oophorectomy has been performed.

b) Obstetric History

The influence of vaginal childbirth on the structure and function of the female pelvis is the focus of much recent and ongoing research but the complex interactions remain incompletely understood. While it is clear that childbirth, and particularly vaginal childbirth increases the risk of incontinence and pelvic organ prolapse, the potential effect of further childbirth on previous or current treatments of incontinence (especially surgery) has yet to be determined.

Potentially confounding variables include: number and route of deliveries (vaginal/Cesarean), use of forceps or vacuum, infant birthweight and head circumference, duration of second stage of labor, use of episiotomy and any vaginal or perineal trauma, and epidural anaesthesia. The importance of these variables will depend upon the specific study design; for randomised studies the allocation process should balance these between groups, but consideration should be given to stratifying or minimizing the randomization against one or more of these important factors, depending on the exact intervention. For epidemiological or observational research each of these factors should be collected and included in univariate and multivariate analyses.

c) Pelvic Organ Prolapse

The effect of pelvic organ prolapse on lower urinary tract function remains poorly understood. Pelvic organ prolapse may potentially affect lower urinary tract function by obstruction of the urethral outflow, and thereby mask sphincter weakness (so called “occult” stress incontinence). Emerging evidence suggests that prolapse may contribute to the symptoms of OAB and correction of the prolapse may modulate these symptoms. Thus, it is important to include assessment of pelvic organ prolapse in incontinence research on women. A validated assessment method for prolapse should be used to identify the stage of proplase; the Pelvic Organ Prolapse Quantification System (POP-Q) [9] is recommended. Research protocols should be developed, either excluding women with prolapse severity beyond a specified stage, or the analysis plan should include stratification for stage of prolapse in randomization, and adjustment for prolapse stage in any analysis. For larger studies where regression analyses are planned, stage of prolapse should be considered a mandatory factor for inclusion. Prolapse should be graded at the same time as the outcome assessment for incontinence and LUTS is performed.

Recommendations for research in women:

- Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. **HIGH**
- High quality, symptom and bother scores (e.g.,ICIQ-FLUTS, KHQ, PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes **HIGH**
- Standardized assessment of pelvic organ prolapse (by POPQ) should be performed before treatment and at the time of other outcome assessments in all research where prolapse and continence outcomes are being assessed. **HIGH**
- Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests. **HIGH**
- Assessment of the impact of treatment on sexual function should be performed with other outcome assessment when appropriate. **MEDIUM**

3. FRAIL OLDER AND DISABLED PEOPLE

There are a number of unique and pertinent research issues for this population.

In the frail elderly, important variables include:

- **Demographic information:** Advancing age, white race, and women [145-148) are associated with an increase risk of incontinence and each of these variables should be adjusted for in most analyses.
- **Medical Conditions:** Medical conditions related and unrelated to the lower urinary tract have been shown to increase the risk of incontinence in older women and are especially important to assess in the frail older population [147, 149-151]. Prior hysterectomy has also been suggested as a potential risk factor for incontinence in older women [152-153].
- **Medication Inventory:** Certain medications may exacerbate incontinence and therefore a complete medication inventory is essential [151, 153-155].
- **Physical function:** Mobility is often impaired in the frail elderly and impacts urinary control [156], therefore mobility should be assessed using validated instruments such as the Bartel Orcats or ADL scales [156-157]. Data on walking aids or wheelchairs, gait speed, and manual dexterity may also be collected.
- **Cognitive function:** Cognitive function impairment and/or dementia increase the risk of incontinence [158]. The Mini-Mental Status Scale Examination [130] assesses global cognitive function, and the Confusion Assessment Method (CAM) [159] is a standardized assessment for delirium. A battery of neuropsychological tests to measure subtle impairments in cognitive function include the Buschke Selective Reminding Test (verbal learning and memory) [160], the Digit Symbol (incidental memory, visual scanning and motor speed) [161], and the Trails A (attention and visual) [162].

Outcome measures should be selected for applicability to the frail elderly. Commonly used self-reported measures of frequency of urinary symptoms, severity, or level of bother may not be possible in the cognitively impaired frail elderly patient. Similarly, voiding diaries that have been shown to be valid and reliable in assessing urinary frequency, nocturia, and incontinence episodes by type [138, 162-164] may not be feasible or reliable. Motivated and trained staff, caregivers, or family members may be able to adequately collect diary data; however, this has not been validated.

In nursing home or inpatient settings, **wet checks by staff** at set intervals have been used in a number of studies. There are limitations to the measurement including visually determining what is “wet” because of new absorbent materials and staff reports not always being reliable or valid, due to underreporting [165-166]. To overcome the limitation of defining wetness and underreporting, 24-hour **pad weighing tests** [167-168] may be used. Pad weighing tests and wet checks are feasible and can provide important outcome data if staff is well trained and checks are often [14]. New outcome measures specific to the frail older population such as increased socialization or decreased caregiver burden need to be developed.

4. CHILDREN

The conduct of clinical research in children is generally more difficult than in adults. Four overriding issues separate pediatric research from the general recommendations. First, physiology varies widely within the group referred to as “children”, differs from adults, and changes with time. Because children are growing, any treatment, especially pharmacological and surgical therapy, may affect them profoundly in the long term. This is particularly true of the immature brain, nervous system and other incompletely developed systems. Second, compliance with therapy is more complicated as children may depend on caregivers to administer treatment in many studies. Third, reporting of symptoms and outcomes may be difficult. Symptoms reported by a caregiver may not be interpreted in the same way as the child. Finally, the issue of informed consent is complex with children.

Urinary incontinence in children falls into four main categories: neurogenic (myelomeningocele and other less common neurogenic etiologies), **monosymptomatic nocturnal enuresis, detrusor overactivity,** and **dysfunctional voiding without neurologic disease.** This issue of age groups is most crucial in children with myelomeningocele. These children are often on medication beginning at a very young age and continuing for many years; the long-term safety of medications in children must be established in all age groups. Therapy for other causes of incontinence in children tends to start at a later age, by which time size is the main difference between children. We recommend that clinical studies have long-term (five years or more), open label extension arms to monitor safety, particularly focusing on normal growth and development and the effects on treatment of liver and central nervous system function.

Assessment of compliance with therapy is always difficult, and even more so with children. Compliance with voiding diaries, a significant issue in the adult population, may be even more problematic with children. The social and family interactions between the child and parent or carer can influence the accuracy of data collection and treatment compliance, both positively and negatively.

Outcome measures are not as well developed in children as in adults. Validated, age-specific symptom and disease-specific quality of life instruments must be developed for the pediatric population. Early efforts in this area have been reported for dysfunctional voiding [169] and daytime incontinence [170]; much more work remains to be done. Invasive urodynamics can be used when deemed appropriate (specifically in the neurogenic population); however, the test-retest reproducibility of urodynamic investigations in children is still under investigation.

Recommendations for Research in Children:

- Long-term follow-up is of critical importance in the pediatric population in order to ascertain the effect of a treatment on normal growth and development. **HIGH**
- Research is needed to develop standardized outcome measures including validated, age-specific symptom and disease-specific quality of life outcome measures. **MEDIUM**

5. NEUROGENIC POPULATIONS

a) Classification

Classification of NLUTD has three primary aims—to aid in discriminating or identifying an unknown underlying neurological disease process, to characterize the nature of the dysfunction so as to develop a treatment plan, and to assess the risk of secondary effects (e.g. on the upper tract) which may influence the necessity and aggressiveness of treatment. The latter two are clearly relevant to research in neurogenic incontinence and must be reflected in study design and patient description.

It is difficult to find a classification system of NLUTD as a base for research that is satisfactory for each of the three aims. The published systems have been reviewed in detail [171]. Both the disease process and the site of the neurologic lesion(s) are relevant in the study of NLUTD, yet even this information is inadequate to predict the functional characteristics for an individual patient. There is no one method that meets the broad needs of classification in this group. Typical or classic cases are often well described but it is especially difficult to describe mixed and incomplete lesions. Thus, classification systems necessarily oversimplify or become extremely cumbersome. Finally, it must be acknowledged that the complexity of neurologic diseases and variations in individual behavior almost always call for a customized approach to therapy, further complicating research in the neurogenic patient. All of these factors complicate study design as it becomes difficult to create workable inclusion and exclusion criteria that apply to other than a narrow segment of the neurogenic population. Ideally a broad population of potentially relevant participants would be enrolled in research studies with full characterization of both the neurologic condition and the nature of the lower urinary tract dysfunction so as to allow for subgroup analysis.

b) History and evaluation:

Study planning is best undertaken with the cooperation of urologist, neurologist, and other clinicians, who have a specific interest and special training in the neurogenic patient. Baseline data collected by history in subjects with neurogenic lower urinary tract disorders should include:

- bladder volumes by diary or examination (maximum voided or catheterized volume, post voiding residual urine, total capacity);
- mechanism of bladder evacuation: normal (volitional), spontaneous involuntarily (“reflex”), Credé, sterile intermittent catheter (SIC), clean intermittent catheter (CIC), intermittent catheter by second person, or suprapubic or urethral catheter;
- use of external appliances (e.g., diaper or pad use, condom catheter, urethral catheter, suprapubic tube);
- the typical time span of continence (continence interval) following last bladder evacuation and maximal continent bladder volume.
- bowel function, sexual function, and specific neurologic deficits
- the evolution of the condition of (changes in)

the upper tract should be included in the outcomes evaluation of treatment for NLUTD.

Where possible these factors should be controlled for in analyses, and stratified for in randomization for interventional studies, or patients with certain factors should be excluded. The details will depend on the research question to be asked.

c) Urodynamics:

Baseline urodynamics are recommended for research studies of neurogenic incontinence, because the symptomatic response is usually of lesser relevance, compared to objective response in NLUTD, especcially where NDO or reduced compliance is involved in the dysfunction. Neurogenic disorders commonly cause complex and generalized lower tract dysfunction, often with combined bladder and urethral sphincter abnormalities.

Recommendations for Research in Populations Affected by Neurogenic Lower Urinary Tract Dysfunction:

- Detailed urodynamic studies are recommended for classification of neurogenic lower urinary tract disorders in research studies because the nature of the lower tract dysfunction cannot be accurately predicted from clinical data. Videourodynamic studies are preferred but are not mandatory. **LOW**
- An area of high priority for research is the development of a classification system to define neurogenic lower urinary tract disorders. Relevant features could include the underlying diagnosis, the symptoms, more precise documentation of the neuromuscular lesion by clinical neurophysiologic testing, and the nature of the urodynamic abnormality. **LOW**

6. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY FAECAL INCONTINENCE

- High quality, validated, symptom and bother scores (e.g., ICIQ-BS, Wexner score, FQIL, Manchester Questionnaire, FISI) should be employed when assessing outcomes **HIGH**
- Due to the high concordance of faecal and urinary incontinence, and the potential for urinary incontinence therapy to affect bowel function, data on faecal incontinence should be collected at the outset and during trials of urinary incontinence whenever practical. **HIGH**

7. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS)

- Broader entry criteria should be used to reflect the full spectrum of the BPS/IC patient population. **MEDIUM**
- The primary endpoint of BPS/IC trials should be patient driven and the Global Response Assessment is recommended. A wide spectrum of secondary endpoints will be useful in defining the effect of treatments. **MEDIUM**

8. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

- A validated standardized assessment of prolapse (eg POP-Q) should be used for baseline and outcome assessments. **HIGH**
- Complete reporting of outcomes including a validated assessment of anatomy, functional status, and complications is essential. **HIGH**
- Complications/adverse events (especially for mesh) must be explicitly and completely
- Long term outcomes (> 2 years) of intervention studies are needed **HIGH**

XIV. CONCLUSIONS

The 2012 Consultation examined and classified available data in order to determine the level of evidence that supports our care of incontinent patients. This committee's contribution was to provide guidance to facilitate high quality research for the next Consultation. All quality research, be it prospective or retrospective, clinical or preclinical, begins with a clear research question and benefits from detailed planning—establishing a clear and relevant hypothesis, developing a trial of appropriate magnitude to accept or reject the hypothesis, and defining methods of adequate sensitivity and specificity to produce credible data.

and the Members of the Committees

INTRODUCTION

The 5th International Consultation on Incontinence met from February 23rd – 25th 2012 in Paris and was organised by the International Consultation on Urological Diseases and the EAU, in order to develop consensus statements for the diagnosis, evaluation and treatment of urinary incontinence, faecal incontinence, pelvic organ prolapse and bladder pain syndrome.

The consensus statements are evidence based following a thorough review of the available literature and the global subjective opinion of recognised experts serving on focused committees. The individual committee reports were developed and peer reviewed by open presentation and comment. The Scientific Committee, consisting of the Chairmen of all the committees then refined the final consensus statements.These consensus statements published in 2013 will be periodically re-evaluated in the light of clinical experience, technological progress and research.

6. RECOMMENDATIONS FOR EPIDEMIOLOGY
7. RECOMMENDATIONS FOR CLINICAL RESEARCH

Annex 1 : Bladder Charts and Diaries

Annex 2 : International Consultation on Incontinence Modular Questionnaire (ICIQ) - ICIQ UI SF (short-form)

1. Definitions

The consultation agreed to use the current International Continence Society definitions (ICS) for lower urinary tract dysfunction (LUTD) including incontinence, except where stated. These definitions appeared in the journal Neurourology and Urodynamics (2002; 21:167- 178 and 2006; 25: 293) or can be viewed on the ICS website: www.icsoffice.org

The following ICS definitions are relevant:

1. Lower Urinary Tract Symptoms (LUTS)

LUTS are divided into ***storage*** symptoms and ***voiding*** symptoms.

Urinary incontinence is a storage symptom and defined as the complaint of any involuntary loss of urine. This definition is suitable for epidemiological studies, but when the prevalence of bothersome incontinence is sought, the previous ICS definition of an "Involuntary loss of urine that is a social or hygienic problem ", can be useful.

Urinary incontinence may be further defined according to the patient's symptoms

- ***Urgency Urinary Incontinence*** is the complaint of involuntary leakage accompanied by or immediately preceded by urgency.
- ***Stress Urinary Incontinence*** is the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing.
- ***Mixed Urinary Incontinence*** is the complaint of involuntary leakage associated with urgency and also with effort, exertion, sneezing and coughing.
- ***Nocturnal Enuresis*** is any involuntary loss of urine occurring during sleep.
- ***Post-micturition dribble*** and ***continuous urinary leakage*** denotes other symptomatic forms of incontinence.

Overactive bladder is characterised by the storage symptoms of urgency with or without urgency incontinence, usually with frequency and nocturia.

2. Urodynamic Diagnosis

- ***Overactive Detrusor Function***, is characterised by involuntary detrusor contractions during the filling phase, which may be spontaneous or provoked.

The overactive detrusor is ***divided*** into:

  - ***Idiopathic Detrusor Overactivity***, defined as overactivity when there is no clear cause
  - ***Neurogenic Detrusor Overactivity*** is defined as overactivity due to a relevant neurological condition.

- ***Urodynamic stress incontinence*** is noted during filling cystometry, and is defined as the involuntary leakage of urine during increased abdominal pressure, in the absence of a detrusor contraction.

3. Bladder Pain Syndrome *

- ***Bladder pain syndrome*** is defined as an unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptom(s) of more than 6 weeks duration, in the absence of infection or other identifiable causes.

4. Pelvic Organ Prolapse

- ***Uro-genital prolapse*** is defined as the symptomatic descent of one or more of : the anterior vaginal wall, the posterior vaginal wall, and the apex of the vagina (cervix/uterus) or vault (cuff) after hysterectomy. Uro-genital prolapse is measured using the POP-Q system.
- ***Rectal prolapse*** is defined as circumferential full thickness rectal protrusion beyond the anal margin.

5. Anal Incontinence *

- ***Anal incontinence***, defined as "any involuntary loss of faecal material and/or flatus" and may be divided into:
  - ***Faecal incontinence***, any involuntary loss of faecal material
  - ***Flatus incontinence***, any involuntary loss of gas (flatus)

** To date, these definitions are not included in the current ICS terminology*

2. Evaluation

The following phrases are used to classify diagnostic tests and studies:

- ***A highly recommended*** test is a test that should be done on every patient.
- ***A recommended test*** is a test of proven value in the evaluation of most patients and its use is strongly encouraged during initial evaluation.
- ***An optional test is a test*** of proven value in the evaluation of selected patients; its use is left to the clinical judgement of the physician
- ***A not recommended test*** is a test of no proven value.

This section primarily discusses the ***Evaluation of Urinary Incontinence*** with or without ***Pelvic Organ Prolapse*** (POP) and ***Anal Incontinence.***

The recommendations are intended to apply to children and adults, including healthy persons over the age of 65.

These conditions are highly prevalent but often not reported by patients. Therefore, the Consultation strongly recommends case finding, particularly in high risk groups.

I. HIGHLY RECOMMENDED TESTS DURING INITIAL EVALUATION

The ***main recommendations*** for this consultation have been abstracted from the extensive work of the 23 committees of the 5th International Consultation on Incontinence (ICI, 2012).

Each committee has written a report that reviews and evaluates the published scientific work in each field of interest in order to give ***Evidence Based*** recommendations. Each report ends with detailed recommendations and suggestions for a programme of research.

The main recommendations should be read in conjunction with the management algorithms for children, men, women, the frail older person, neurogenic patients, bladder pain, pelvic organ prolapse, and anal incontinence

The ***initial evaluation*** should be undertaken, by a clinician, in every patient presenting with symptoms/signs suggestive of these conditions.

1. History and General Assessment

Management of a disease such as incontinence requires caregivers to ***assess*** the sufferer in a holistic manner. Many factors may influence a particular individual's symptoms, some may cause incontinence, and may influence the choice and the success of treatment. ***The following components of the medical history are particularly emphasized:***

a) Review of Systems:

- Presence, severity, duration and bother of any urinary, bowel or prolapse symptoms. Identifying symptoms in the related organ systems is critical to effective treatment planning. It is useful to use validated questionnaires to assess symptoms.
- Effect of any symptoms on sexual function: validated questionnaires including impact on quality of life are a useful part of a full assessment.
- Presence and severity of symptoms suggesting neurological disease

b) Past Medical History:

- ***Previous conservative, medical and surgical treatment,*** in particular, as they affect the genitourinary tract and lower bowel. The effectiveness and side effects of treatments should be noted.
- ***Coexisting diseases*** may have a profound effect on incontinence and prolapse sufferers, for example asthma patients with stress incontinence will suffer greatly during attacks. Diseases may also precipitate incontinence, particularly in frail older persons.
- ***Patient medication:*** it is always important to review every patient's medication and to make an assessment as to whether current treatment may be contributing to the patient's condition.
- ***Obstetric and menstrual history.***
- ***Physical impairment:*** individuals who have compromised mobility, dexterity, or visual acuity may need to be managed differently

c) Social History:

- ***Environmental issues:*** these may include the social, cultural and physical environment.

- ***Lifestyle***: including exercise, smoking and the amount and type of food/fluid intake.

d) Other Treatment Planning Issues:

- ***Desire for treatment*** and the extent of treatment that is acceptable
- ***Patient goals*** and expectations of treatment
- ***Patient support*** systems (including caregivers).
- ***Cognitive function***: all individuals need to be assessed for their ability to fully describe their symptoms, symptom bother and quality of life impact, and their preferences and goals for care. They must be able to understand proposed management plans and to discuss, where appropriate, alternative treatment options. In some groups of patients formal testing is essential e.g. cognitive function testing for individuals for whom the clinician has concerns regarding memory deficits and/or inattention/confusion, and depression screening for individuals for whom the clinician has concerns about abnormal affect. Proxy respondents, such as family and caregivers, may be used to discuss history, goals of care, and treatment for individuals with dementia, but only if the individual is incapable of accurate reporting or weighing treatment decisions.

2. Physical Examination

The ***more complicated*** the history and the more extensive and/or invasive the proposed therapy, the ***more complete*** the examination needs to be. Depending on the patient's symptoms and their severity, there are a number of components in the examination of patients with incontinence and/or pelvic organ prolapse.

Physical examination should be performed regardless of whether the patient is a child, a woman, a man, someone with neurological disease or a frail elderly person.

a) General status:

- Mental status
- Obesity (BMI)
- Physical dexterity and mobility

b) Abdominal/flank examination: for masses, bladder distention, relevant surgical scars

c) Pelvic examination:

- Examination of the perineum and external genitalia including tissue quality and sensation.
- Vaginal (half-speculum) examination for pelvic organ prolapse (POP)
- Bimanual pelvic and anorectal examination for pelvic mass, pelvic floor muscle function, etc
- Stress test for urinary incontinence.

d) Neurological testing (see chapter on assessment)

3. Urinalysis

In patients with urinary symptoms a ***urinary tract infection*** is a readily detected, and easily treatable cause of LUTS, and urine testing is highly recommended. Testing may range from dipstick testing, to urine microscopy and culture when indicated.

Conclusion

For simple treatments, particularly non-invasive and inexpensive therapies, management may start without the need for the further investigations listed below.

II. RECOMMENDED FURTHER ASSESSMENT PRIOR TO, OR DURING, SPECIALIST ASSESSMENT

The tests below are recommended when the **appropriate indication(s) is present**. Some recommended tests become highly recommended in specific situations.

This section should also be read in conjunction with the relevant committee reports.

1. Further Symptom and Health-Related QoL Assessment

In patients with ***urinary symptoms*** the use of a ***simple frequency volume chart*** or ***bladder diary*** (examples in Annex 1) is highly recommended to document the frequency of micturition, the volumes of urine voided, incontinence episodes and the use of incontinence pads.

The use of the ***highest quality questionnaires*** (Grade A, where available) is recommended for the assessment of the patient's perspective of symptoms of incontinence and their impact on quality of life.

The ICIQ is highly recommended (Grade A) for the basic evaluation of the patient's perspective of urinary incontinence, with other Grade A questionnaires recommended for more detailed assessment. ***Further development is required in the areas*** of pelvic organ prolapse, bladder pain syndrome, and for specific patient groups, as only Grade B questionnaires are currently available (see Annex 1).

2. Renal Function Assessment

Standard ***biochemical tests for renal function*** are recommended in patients with urinary incontinence and a possibility of ***renal impairment.***

3. Uroflowmetry

Uroflowmetry with the measurement of post void residual urine is recommended as a screening test for symptoms suggestive of urinary voiding dysfunction or physical signs of POP or bladder distension.

4. Estimation of Post Void Residual Urine (PVR)

In patients with ***suspected voiding dysfunction***, PVR should be part of the initial assessment if the result is likely to influence management, for example, in neurological patients.

5. Imaging

Although ***routine imaging is not recommended,*** imaging of the lower urinary tract and pelvis is ***highly recommended*** in those with ***urinary symptoms*** whose initial evaluation indicates a possible co-existing lower tract or pelvic pathology. Initial imaging may be by ultrasound, or plain X ray.

Imaging of the upper urinary tract is highly recommended in specific situations. These include:

- Haematuria,
- Neurogenic urinary incontinence e.g. myelodysplasia, spinal cord trauma,
- Incontinence associated with significant post-void residual,
- Co-existing loin/kidney pain,
- Severe pelvic organ prolapse, not being treated
- Suspected extra-urethral urinary incontinence,
- Children with incontinence and UTIs, where indicated
- Urodynamic studies which show evidence of poor bladder compliance.

In anorectal conditions, anal US or MRI prior to anal sphincter surgery is highly recommended, when obvious anatomic defects are not evident. Defaecating proctography or dynamic MRI is recommended in suspected rectal prolapse which cannot be adequately confirmed by physical examination.

6. Endoscopy

Although ***routine*** cysto-urethroscopy is not recommended, LUT endoscopy is ***highly recommended:***

- When initial testing suggests other pathologies, e.g. haematuria
- When pain or discomfort feature in the patient's LUTS, these may suggest an intravesical lesion
- When appropriate in the evaluation of vesicovaginal fistula and extra-urethral urinary incontinence (in childbirth fistulae, endoscopy is often unnecessary).

In anorectal conditions, proctoscopy or flexible sigmoidoscopy should routinely be performed in the evaluation of patients with faecal incontinence. Colonoscopy, air contrast barium enema or CT colography is highly recommended in the presence of unexplained change in bowel habit, rectal bleeding or other alarm symptoms or signs (see Basic Assessment chapter).

7. Urodynamic Testing

a) Urodynamic evaluation is recommended

- When the results may ***change management***, such as prior to most invasive treatments for UI and POP,
- After ***treatment failure***, if more information is needed in order to plan further therapy,
- As part of both initial and long-term ***surveillance*** programmes in some types of neurogenic lower urinary tract dysfunction,
- In "***complicated incontinence***" (for details please see relevant subcommittee reports).

b) The aims of Urodynamic Evaluation are

- To reproduce the patient's symptoms and correlate these with urodynamic findings
- To assess bladder sensation
- To detect detrusor overactivity
- To assess urethral competence during filling
- To determine detrusor function during voiding
- To assess outlet function during voiding
- To assess residual urine

8. Small bowel follow-through, CT entography or capsule endoscopy.

These tests are recommended in the presence of unexplained diarrhoea or when Crohn's disease is suspected.

III. OPTIONAL DIAGNOSTIC TESTS

1. Additional Urodynamic Testing

Video-urodynamics may be useful in the management of UI in children, in patients who fail surgery and in some neurogenic patients, to obtain additional anatomical information. Both US and X-ray imaging can be used.

If a more ***detailed estimate of urethral function*** is required, then the following optional tests may give useful information:

- Urethral pressure profilometry
- Abdominal leak point pressures
- Video-urodynamics
- Electromyography

If initial urodynamics have failed to demonstrate the cause for the patient's incontinence then the following tests are optional:

- repeated routine urodynamics
- ambulatory urodynamics

2. Pad Testing

Pad testing is an optional test for the routine evaluation of urinary incontinence and, if carried out, a 24 hr test is suggested.

3. Neurophysiological Testing and Imaging

The ***information*** gained by clinical examination and urodynamic testing may be ***enhanced*** by ***neuro-physiological testing*** of striated muscle and nervous pathways.

Appropriately trained personnel should perform these tests. The following neuro-physiological tests can be considered in patients with peripheral lesions prior to treatment for lower urinary tract or anorectal dysfunction.

- Concentric needle EMG
- Sacral reflex responses to electrical stimulation of penile or clitoral nerves.

Pudendal nerve latency testing is ***not recommended.***

Further imaging of the central nervous system, including spine, by myelography, CT and MRI may prove useful if simple imaging, for example by spinal X-rays in patients with suspected neurological disease, proves normal.

4. Further Imaging

Cysto-urethrography, US, CT and ***MRI*** may have an indication :

- Suspected pelvic floor dysfunction
- Failed surgery, such as recurrent posterior vaginal wall prolapse or failed sling surgery
- Suspected fixed urethra

5. Cysto-urethroscopy

This is an ***optional test*** in patients with complicated or recurrent UI (e.g. after failed SUI surgery)

6. Anorectal physiology testing

Anorectal manometry is useful to assess resting and squeeze anal pressures.

3. Management Consensus statements

The consensus statements are derived from the ***detailed work in the committee reports*** on the management of incontinence in children, men, women, the frail elderly and neurological patients, as well as those with obstetric fistula, pelvic organ prolapse, bladder pain syndrome, and faecal incontinence. The management of incontinence is presented in ***algorithm form*** with accompanying ***notes.***

The Consultation recognises that no algorithm can be applied to every patient and each patient's management must be individualised.

There are algorithms for

I. Urinary Incontinence in Children
II. Urinary Incontinence in Men
III. Urinary Incontinence in Women
IV. Fistulae
V. Pelvic Organ Prolapse
VI. Urinary Incontinence in Neurological Patients
VII. Bladder Pain Syndrome
VIII. Faecal Incontinence in Non-Neurological Patients
IX. Faecal Incontinence in Neurological Patients
X. Urinary and Faecal Incontinence in Frail Older Men and Women

These algorithms are divided into two for groups I to III, VII and X. The two parts, initial ***management*** and ***specialised management*** require a little further explanation.

Although the management algorithms are designed to be used for patients whose predominant problem is incontinence, there are many other patients in whom the algorithms may be useful such as those patients with urgency and frequency, so-called "***OAB dry***"

➦ The algorithms for *initial management*

are intended for use by all ***clinicians*** including health care assistants, nurses, physiotherapists, generalist doctors and family doctors as well as by specialists such as urologists, geriatricians and gynaecologists. The consultation has attempted to phrase the recommendations in the basic algorithms in such a way that they may be readily used by clinicians in all countries of the world, both in the developing and the developed world.

➦ The *specialised* algorithms

are intended for use by ***specialists***. The specialised algorithms, as well as the initial management algorithms are ***based on evidence where possible,*** and on the ***expert opinion*** of the 400 healthcare professionals who took part in the Consultation. In this consultation, committees ascribed levels of evidence to the published work on the subject and devised grades of recommendation to inform patient management.

It should be noted that these algorithms, dated ***December 2012***, represent the Consultation ***consensus at that time***. Our knowledge, developing from both a research base and because of evolving expert opinion, will inevitably ***change with time.*** The Consultation does not wish those using the algorithms to believe they are "carved in tablets of stone": there will be changes both in the relatively short term and the long term.

◆ Essential components of basic assessment

Each algorithm contains a core of recommendations in addition to a number of essential components of basic assessment listed in sections I to III.

- General assessment
- Symptom assessment
- Assessment of quality of life impact
- Assessment of the desire for treatment
- Physical examination
- Urinalysis

◆ Joint decision making

The patient's desires and goals for treatment : Treatment is a matter for discussion and joint decision making between the patient and his or

her health care advisors. This process of consultation includes the specific need to assess whether or not the sufferer of incontinence wishes to receive treatment and, if so, what treatments he or she would favour. Implicit in this statement is the assumption that the health care provider will give an ***appropriate explanation of the patient's problem*** and the ***alternative lines of management,*** and the indications and the ***risks of treatment.*** The assumption that patients almost always wish to have treatment is flawed, and the need to consult the patient is paramount.

In each algorithm, treatments are listed in ***order of simplicity,*** the least invasive being listed first. This order does not imply a scale of efficacy or cost, two factors which need to be considered in choosing the sequence of therapy. The order is likewise not meant to imply a suggested sequence of therapy, which should be determined jointly by the treating health care provider and the patient, considering all the relevant factors listed above.

In the ***initial management algorithms***, treatment is ***empirically based,*** whilst the ***specialised management*** algorithms usually rely on precise diagnosis from urodynamics and other testing.

The assumption is made that patients will be reassessed at an appropriate time to evaluate their progress.

◆ Use of Continence Products

The possible role of c***ontinence products*** should be considered at each stage of patient assessment and treatment, and if treatment is not (fully) successful, subsequent management.

- ***Firstly***, intermittent catheterisation or indwelling catheter drainage often have a role to play in addressing urinary retention.
- ***Secondly,*** assisted toileting using such devices as commodes, bedpans, and handheld urinals may help to achieve ***dependent continence****** where access, mobility and/or urgency problems undermine a patient's ability to maintain ***independent continence****, be it urinary and / or faecal.
- ***Finally,*** containment products (to achieve ***contained incontinence****) for urine and / or faeces find an essential role in enhancing the quality of life of those who:
- Elect not to pursue treatment options
- Are awaiting treatment
- Are waiting for treatment to take effect
- Are unable to be (fully) cured

Further guidance and care algorithms on which products might be suitable for a given patient are given in Committee 20.

** Useful terms suggested by Fonda & Abrams. (Cure sometimes, help always – a "continence paradigm" for all ages and conditions. Fonda D and Abrams P, Neurology & Urodynamics 25: 290-292, 2006).*

I. URINARY INCONTINENCE IN CHILDREN

A. INITIAL MANAGEMENT

Children present specific management problems for a variety of reasons: assessment requires help from their parents and caregivers; consent to treatment may be problematic; and cooperation in both assessment and treatment may be difficult.

1. Initial *assessment should involve a detailed investigation of voiding and bowel habits using bladder/bowel diaries and structured and validated questionnaires*.

The child's social environment and general and behavioural development should also be formally assessed and recorded. Physical examination should be done to detect a palpable bladder, faecal loading and exclude anatomic and neurogenical causes. Urine analysis and culture is sufficient to exclude the presence of infection. If possible, the child should be observed voiding.

➦ ***Referrals for specialist treatment are recommended for children who have complicated incontinence associated with:***

- Recurrent and febrile urinary infection
- Voiding symptoms or evidence of poor bladder emptying
- Urinary tract anomalies
- Previous pelvic surgery
- Neuropathy or neuropathic origin
- Bowel dysfunction not responsive to treatment
- Comorbid behavioural (e.g. ADHD and ODD) and emotional disorders.

➦ ***Initial treatment is recommended for the remaining patients who have:***

- Nocturnal enuresis without other symptoms (mono-symptomatic enuresis).
- Daytime symptoms of frequency, urgency, voiding postponement, straining, interrupted voiding, urgency incontinence with or without night-time wetting.

2. Treatment

➦ Initial treatment for ***mono-symptomatic nocturnal*** enuresis should include:

- parental and child counselling and motivation
- review of bladder diary with attention to night-time polyuria
- a choice between either bed wetting alarm (Grade A) and anti-diuretic hormone analogues of desmopressin (Grade A). It may be a parental and child choice if advantages and disadvantages are well explained.

➦ ***Daytime incontinence*** should be managed holistically including:

- counselling, timed voiding, behaviour modification and bowel management when necessary (Grade B);
- antimuscarinics may be used if there are symptoms that suggest bladder overactivity (Grade A)

Initial Management of Urinary Incontinence in Children

HISTORY/ SYMPTOM ASSESSMENT

Nocturnal enuresis (monosymptomatic)

Daytime ± Nighttime wetting ± Urgency / frequency

"Complicated" Incontinence associated with:

- Urinary tract anomaly
- Neuropathy
- Pelvic surgery
- Voiding (emptying) symptoms
- Recurrent urinary infection
- Bowel dysfunction not responsive to treatment
- Comorbid behavioral and emotional disorders

CLINICAL ASSESSMENT

General assessment (see relevant chapter)
- Physical examination: abdominal, perineal, ext. genitalia, back/spine, neurological
- Assess bowel function -> if constipated, treat and reassess
- Urinalysis ± Urine culture -> if infected, treat and reassess
- Assess post-void residual urine by abdominal examination (optional : by ultrasound)

PRESUMED DIAGNOSIS

MONOSYMPTOMATIC NOCTURNAL ENURESIS

URGENCY INCONTINENCE

RECURRENT INFECTION

DYSFUNCTIONAL VOIDING

Any other abnormality detected e.g. Post void residual

TREATMENT *

- Explanation/education
- Enuresis Diary
- Alarm
- Desmopressin

Failure

- Explanation/education
- Fluid/voiding regime
- Bladder training
- Antimuscarinics
- Alarm (bed wetting)

Failure

SPECIALISED MANAGEMENT

* At any stage of the patient's care pathway, management may need to include continence products

I. URINARY INCONTINENCE IN CHILDREN

B. SPECIALISED MANAGEMENT

➦ ***Two groups of children*** with ***"complicated" incontinence*** should have specialist management from the outset (Fig. 2).

- Children whose incontinence is due to, or associated with, ***urinary tract anomalies*** and **neuropathy.**
- ***Children*** without urinary tract anomalies, but with ***recurrent febrile infection*** and, proven or suspected, ***lower urinary tract dysfunction***.

➦ Children who ***fail the basic treatment***, but who have neither neurogenic nor anatomical problems, should also receive specialist management.

Children with comorbid behavioural and emotional disorders require referral to mental health services, as compliance and treatment outcomes are lower.

Assessment and treatment should follow evidence-based practice parameters and guidelines

1. Assessment

➦ As part of further assessment, the measurement of ***urine flow*** (in children old enough), together with the pelvic ***ultrasound estimate of residual urine*** and appearance of the bladder wall and rectum are highly recommended. An evaluation of the ***upper urinary tracts with ultrasound is also highly recommended.***

Those who do not improve ***with treatment*** and have neither neurogenic nor anatomical problems ***should be reassessed*** using micturition charts, symptom scores, urinalysis, uroflowmetry and residual urine determination.

If there are recurrent and febrile infections, upper tract imaging and possibly a VCUG should be considered. However, endoscopy is rarely indicated.

➦ ***Urodynamics should be considered:***

- If the type and severity of lower tract dysfunction ***cannot be explained by clinical findings.***
- If ***invasive treatment*** is under consideration, for example, stress incontinence surgery if there is sphincteric incompetence, or bladder augmentation if there is detrusor overactivity.
- ***If upper tract dilatation exists*** and is thought to be due to bladder dysfunction.

Invasive urodynamic studies are generally not recommended if the child has normal upper tract imaging and is to be treated by noninvasive means.

➦ ***Spinal Imaging*** (US/X-ray/MRI) may be needed if a bony abnormality or neurological condition is suspected.

2. Treatment

The treatment of incontinence associated with ***urinary tract anomalies*** is complex and cannot easily be dealt with in an algorithm. In many children ***more than one pathophysiology*** demands treatment. If there are ***complex congenital abnormalities present***, the treatment is mostly surgical and it should be individualised according to the type and severity of the problem (please see Children's Committee Report).

Care should be given by specialist children's nurses and therapists.

➦ ***Initial treatment should be non-surgical.***

- ***For stress urinary incontinence*** (SUI): pelvic floor muscle training (Grade C).
- ***For suspected bladder overactivity*** (OAB): fluid/voiding regimes and antimuscarinics (Grade A).
- ***For voiding dysfunction:*** timed voiding, voiding re-education, pelvic floor muscle relaxation (+/- biofeedback), intermittent catheterisation (when PVR >30% of bladder capacity) (Grade B/C).
- ***For bowel dysfunction:*** high fibre diet and laxatives as appropriate.

The child's progress should be assessed and, if quality of life is still significantly impaired, or if the upper urinary tracts are at risk, ***surgical treatment*** is likely to be necessary.

➦ ***If surgical treatment is required,*** then urodynamic studies are recommended to confirm the diagnosis.

- ***For SUI***, sling surgery, bulking agent injection and AUS may be considered.
- ***For DO/poor compliance,*** botulinum toxin (for DO, and off-label) and bladder augmentation may be performed.
- ***If the child cannot do IC*** then a Mitrofanoff channel may be needed.

Specialised Management of Urinary Incontinence in Children

EXPERT HISTORY & PHYSICAL EXAMINATION

Incontinence without suspicion of urinary tract anomaly

Incontinence with suspicion of urinary tract anomaly

CLINICAL ASSESSMENT

- Urinalysis: if UTI, treat and reassess as appropriate
- Treat bowel dysfunction and reassess
- Renal / bladder ultrasound
- Assess post void residual
- Flow rates ± electromyography
- Behavioural Evaluation

if abnormal -->

Consider:
- Micturating cystogram
- Renal scintigram
- Urodynamics
- Cystourethroscopy
- Spinal imaging

DIAGNOSIS

- STRESS URINARY INCONTINENCE
- DETRUSOR OVERACTIVITY / POOR COMPLIANCE
- VOIDING DYSFUNCTION
- ANATOMICAL CAUSES OF URINARY INCONTINENCE

TREATMENT *

- Pelvic floor muscle training
  - Failure
  - AUS
  - Sling
  - Bulking agent injection
- Fluid/ voiding regime
- Antimuscarinics
- Bowel management.
  - Failure
  - Botulinum toxin
  - Bladder augmentation
- Timed voiding
- Pelvic floor relaxation ± biofeedback.
- Pharmacotherapy
  - Antimuscarinics
  - α-blockers
- Intermittent cath.
- Bowel management
- Antibiotic if infection
  - Failure
  - Mitrofanoff if IC fails
- Correct anomaly (see : surgical treatment in children)

* At any stage of the patient's care pathway, management may need to include continence products

II. URINARY INCONTINENCE IN MEN

A. INITIAL MANAGEMENT

1. Initial Assessement should identify :

➦ ***Complicated" incontinence group***

Those with pain or with haematuria, recurrent infections, suspected or proven poor bladder emptying (for example due to bladder outlet obstruction), or incontinence following pelvic irradiation or radical surgery, are recommended for ***specialised management.***

Poor bladder emptying may be suspected from symptoms, physical examination or if imaging has been performed by X-ray or ultrasound after voiding.

➦ ***Four other main groups*** of men should be identified by initial assessment as being suitable fo***r initial management.***

- Those with ***post-micturition dribble*** alone,
- Those with **overactive bladder** (OAB) symptoms: urgency with or without urgency incontinence, together with frequency and nocturia
- Those with ***stress incontinence*** (most often post-prostatectomy),
- Those with ***mixed*** urgency and stress incontinence (most often post-prostatectomy)

2. Management

➦ For men with ***post-micturition dribble,*** this requires no assessment and can usually be treated by teaching the man how to do a strong pelvic floor muscle contraction after voiding, or manual compression of the bulbous urethra directly after micturition. (Grade B)

➦ For men with ***stress, urgency*** *or* ***mixed*** urgency / stress incontinence, initial treatment should include appropriate lilfestyle advice, pelvic floor muscle training, scheduled voiding regimes, behavioural therapies and medication. In particular:

- Lifestyle interventions (Grade D)
- Supervised pelvic floor muscle training for men with post radical prostatectomy SUI (Grade B)
- Scheduled voiding regimes for OAB (Grade C)
- Antimuscarinic drugs for OAB symptoms with or without urgency incontinence (Grade B) if the patient has no evidence of significant post-void residual urine
- α-adrenergic antagonists (a-blockers), can be added if it is thought that there may also be bladder outlet obstruction. (Grade C)

➦ ***Should initial treatment be unsuccessful*** after a reasonable period of time (for example, 8-12 weeks), ***specialist advice*** is highly recommended.

Clinicians are likely to wish to treat the ***most bothersome symptom*** first in men with symptoms of ***mixed*** incontinence.

Initial Management of Urinary Incontinence in Men

HISTORY

- Post-micturition dribble
- Incontinence on exertion (usually post-prostatectomy)
- Incontinence with mixed symptoms
- Urgency / frequency, with or without urgency incontinence
- "Complicated" incontinence
  - Recurrent or "total" incontinence
  - Incontinence associated with:
    - Pain
    - Haematuria
    - Recurrent infection
    - Prostate irradiation
    - Radical pelvic surgery

CLINICAL ASSESSMENT

- General assessment (see relevant chapter)
- Urinary symptom assessment and symptom score (including frequency-volume chart and questionnaire)
- Assess quality of life and desire for treatment
- Physical examination: abdominal, rectal, sacral, neurological
- Urinalysis ± urine culture -> if infected, treat and reassess
- Assessment of pelvic floor muscle function
- Assess post-void residual urine

Any other abnormality detected e.g. significant post void residual

PRESUMED DIAGNOSIS

- STRESS INCONTINENCE presumed due to sphincteric incompetence
- MIXED INCONTINENCE Treat most bothersome symptom first
- URGENCY INCONTINENCE presumed due to detrusor overactivity

MANAGEMENT *

- Urethral milking
- Pelvic floor muscle contraction

DISCUSS TREATMENT OPTIONS WITH THE PATIENT

- Lifestyle interventions
- Pelvic floor muscle training ± biofeedback
- Scheduled voiding (bladder training)
- Incontinence products
- Antimuscarinics (OAB ± urgency incontinence) and α-adrenergic antagonists (if suspected bladder outlet obstruction)

Failure

SPECIALISED MANAGEMENT

* At any stage of the patient's care pathway, management may need to include continence products

II. URINARY INCONTINENCE IN MEN

B. SPECIALISED MANAGEMENT

The specialist may first **reinstitute initial management** if it is felt that previous therapy had been inadequate.

1. Assessment

➦ Patients with "***complicated" incontinence*** referred directly to specialised management, are likely to require ***additional testing,*** such as cytology, cystourethoscopy and urinary tract imaging.

If these tests prove normal then those individuals can be treated for incontinence by the initial or specialised management options as appropriate.

If symptoms suggestive of detrusor overactivity, or of sphincter incompetence ***persist,*** then ***urodynamic*** studies are advisable in order to arrive at a precise diagnosis, prior to invasive treatment.

2. Treatment

When basic management has failed

and if the patient's incontinence markedly disrupts his quality of life then ***invasive therapies*** should be considered.

➦ ***For sphincter incompetence*** the recommended option is the artificial urinary sphincter (Grade B). Other options, such as a male sling, may be considered (Grade C).

➦ ***For idiopathic detrusor overactivity***, (with intractable overactive bladder symptoms) the recommended therapies are: Botulinum toxin A (Grade B), neuromodulation (Grade C), and bladder augmentation (Grade C).*

**Note: At the time of writing, botulinum toxin for idiopathic DO is being used "off-label".*

➦ When incontinence has been shown to be associated with ***poor bladder emptying*** and ***detrusor underactivity,*** it is recommended that effective means are used to ensure bladder emptying, for example, intermittent catheterisation (Grade B/C).

➦ ***If incontinence is associated with bladder outlet obstruction***, then consideration should be given to surgical treatment to relieve obstruction (Grade B). α-blockers and/or 5α- reductase inhibitors would be an optional treatment (Grade C). There is increased evidence for the safety of antimuscarinics for overactive bladder symptoms in men, chiefly in combination with an □-blocker (Grade B).

Specialised Management of Urinary Incontinence in Men

HISTORY/ SYMPTOM ASSESSMENT

CLINICAL ASSESSMENT

DIAGNOSIS

TREATMENT *

Post-prostatectomy incontinence

Incontinence with urgency / frequency

"Complicated" Incontinence :
- Recurrent incontinence
- Incontinence associated with:
  - Prostate or pelvic irradiation
  - Radical pelvic surgery

- Consider urodynamics and imaging of the urinary tract
- Urethrocystoscopy (if indicated)

STRESS INCONTINENCE due to sphincteric incompetence

MIXED INCONTINENCE Treat major component first

URGENCY INCONTINENCE due to detrusor overactivity (during filling)

Consider:
- Urethrocystoscopy
- Further imaging
- Urodynamics

with coexisting bladder outlet obstruction

with coexisting underactive detrusor (during voiding)

Lower urinary tract anomaly/ pathology

If initial therapy fails:
- Artificial urinary sphincter
- Male sling (see chapter 13)

- α-blockers, 5ARI
- Correct anatomic bladder outlet obstruction
- Antimuscarinics

If initial therapy fails:
- Botulinum toxin A
- Neuromodulation

- Intermittent catheterisation
- Antimuscarinics

- Correct anomaly
- Treat pathology

* At any stage of the patient's care pathway, management may need to include continence products

III. URINARY INCONTINENCE IN WOMEN

A. INITIAL MANAGEMENT

1. Initial assessment should identify :

➦ ***"Complicated" incontinence group.***

Those with pain or haematuria, recurrent infections, suspected or proven voiding problems, significant pelvic organ prolapse or who have persistent incontinence or recurrent incontinence after pelvic irradiation, radical pelvic surgery, previous incontinence surgery, or who have a suspected fistula, should be refered to a specialist.

➦ **Three other main groups** of patients should be identified by initial assessment.

- Women with ***stress incontinence*** on physical activity
- Women with ***urgency, frequency*** with or without urgency incontinence
- Those women with ***mixed*** urgency and stress incontinence

Abdominal, pelvic and perineal examinations should be a routine part of physical examination. Women should be asked to perform a "stress test" (cough and strain to detect leakage likely to be due to sphincter incompetence). Any pelvic organ prolapse or urogenital atrophy should be assessed. Vaginal or rectal examination allows the assessment of voluntary pelvic floor muscle function, an important step prior to the teaching of pelvic floor muscle training.

2. Treatment

➦ For women with ***stress, urgency or mixed*** urinary incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, PFMT), scheduled voiding regimes, behavioural therapies and medication. In particular:

- ***Advice*** on caffeine reduction (Grade B) and weight reduction (Grade A)
- ***Supervised pelvic floor muscle training*** (Grade A), ***supervised vaginal cones training*** for women with stress incontinence (Grade B)
- ***Supervised bladder training*** (Grade A) for OAB.
- ***If oestrogen deficiency*** and/or ***UTI*** is found, the patient should be treated at initial assessment and then reassessed after a suitable interval using vaginal oestrogens. (Grade B).
- ***Antimuscarinics*** for OAB symptoms with or without urgency incontinence (Grade A); duloxetine* may be considered for stress urinary incontinence (Grade B)

PFMT should be based on sound muscle training principles such as specificity, overload progression, correct contraction confirmed prior to training, and use of the Knack for 12 weeks before reassessment and possible specialist referral.

Clinicians are likely to wish to treat the ***most bothersome symptom first*** in women with symptoms of mixed incontinence. (Grade C).

➦ Some women with significant ***pelvic organ prolapse*** can be treated by vaginal devices that treat both incontinence and prolapse (incontinence rings and dishes).

** Duloxetine is not approved for use in United States. It is approved for use in Europe for severe stress incontinence (see committee report on pharmacological management for information regarding efficacy, adverse events, and 'black box' warning by the Food and Drug Administration of the United States).*

Initial Management of Urinary Incontinence in Women

HISTORY

Incontinence on physical activity

Incontinence with mixed symptoms

Incontinence / frequency with urgency

Complicated incontinence

- Recurrent incontinence
- Incontinence associated with:
  - Pain
  - Haematuria
  - Recurrent infection
  - Significant voiding symptoms
  - Pelvic irradiation
  - Radical pelvic surgery
  - Suspected fistula

CLINICAL ASSESSMENT

- General assessment (see relevant chapter)
- Urinary symptom assessment (including frequency-volume chart and questionnaire)
- Assess quality of life and desire for treatment
- Physical examination: abdominal, pelvic and perineal
- Cough test to demonstrate stress incontinence if appropriate
- Urinalysis ± urine culture -> if infected, treat and reassess *If appropriate*
- Assess oestrogen status and treat as appropriate
- Assess pelvic floor muscle function
- Assess post-void residual urine

PRESUMED DIAGNOSIS

STRESS INCONTINENCE presumed due to sphincteric incompetence

MIXED INCONTINENCE Treat most bothersome symptom first

OAB -with or without URGENCY INCONTINENCE presumed due to detrusor overactivity

- If other abnormality found e.g.
- Significant post void residual
- Significant pelvic organ prolapse
- Pelvic mass

TREATMENT *

- Life style interventions.
- Pelvic floor muscle training for SUI, MUI, or OAB
- Bladder retraining for OAB
- Antimuscarinics (OAB ± urgency incontinence) or Duloxetine** (SUI)

- Other adjuncts, such as electrical stimulation
- Vaginal devices

Failure

SPECIALISED MANAGEMENT

** Subject to local regulatory approval (see black box warning).

* At any stage of the patient's care pathway, management may need to include continence products

III. URINARY INCONTINENCE IN WOMEN

B. SPECIALISED MANAGEMENT

1. Assessement

Women who have "***complicated" incontinence*** (see initial algorithm) may need to have additional tests such as cytology, cystourethroscopy or urinary tract imaging. If these tests are normal then they should be treated for incontinence by the initial or specialised management options as appropriate.

➦ Those women who have ***failed initial management*** and whose quality of life is impaired are likely to request further treatment. If initial management has been given an adequate trial then ***interventional therapy may be desirable.*** Prior to intervention ***urodynamic testing*** is highly recommended, when the results may change management. It is used to diagnose the type of incontinence and therefore inform the management plan. Within the urodynamic investigation urethral function testing by urethral pressure profile or leak point pressure is optional.

➦ Systematic assessment for ***pelvic organ prolapse*** is highly recommended and it is suggested that the POP-Q method should be used in research studies. Women with co-existing pelvic organ prolapse should have their prolapse treated as appropriate

2. Treatment

➦ ***If urodynamic stress incontinence is confirmed*** then the treatment options that are recommended for patients with ***some degree of bladder-neck and urethral mobility*** include the full range of non-surgical treatments, as well as retropubic suspension procedures, (Grade A) and bladder neck/sub-urethral sling operations:(Grade A). The ***correction of symptomatic*** pelvic organ prolapse may be desirable at the same time.

For patients with ***limited bladder neck mobility,*** bladder neck sling procedures, (Grade A) injectable bulking agents (Grade B) and the artificial urinary sphincter (Grade B) can be considered.

➦ **Refractory *urgency incontinence*** (overactive bladder) secondary to idiopathic detrusor overactivity may be treated by botulinum toxin A (Grade C)*, neuromodulation (Grade A) or bladder augmentation (Grade C).

➦ Those patients with ***voiding dysfunction*** leading to significant post-void residual urine (for example, >30% of total bladder capacity) may have bladder outlet obstruction or detrusor underactivity. Prolapse is a common cause of voiding dysfunction.

** At the time of writing, botulinum toxin is being used "off-label" and with caution.*

Specialised Management of Urinary Incontinence in Women

HISTORY/ SYMPTOM ASSESSMENT

- Incontinence on physical activity
- Incontinence with mixed symptoms
- Incontinence with urgency / frequency

"Complicated" incontinence:
- Recurrent incontinence
- Incontinence associated with:
  - Pain
  - Haematuria
  - Recurrent infection
  - Voiding symptoms
  - Pelvic irradiation
  - Radical pelvic surgery
  - Suspected fistula

CLINICAL ASSESSMENT

- Assess for pelvic organ mobility / prolapse
- Consider imaging of the UT/ pelvic floor
- Urodynamics (see notes)

DIAGNOSIS

- URODYNAMIC STRESS INCONTINENCE (USI)
- MIXED INCONTINENCE USI/DOI
  Treat. most bother-some symptom first
- DETRUSOR OVERACTIVITY INCONTINENCE (DOI)
- INCONTINENCE associated with poor bladder emptying
  - *Bladder outlet obstruction*
  - *Underactive detrusor*

Consider:
- Urethrocystoscopy
- Further imaging
- Urodynamics

Lower urinary tract anomaly / pathology

TREATMENT *

If initial therapy fails :
- Stress incontinence surgery
  - bulking agents
  - tapes and slings
  - colposuspension

If initial therapy fails :
- Botulinum toxin
- Neuromodulation
- Bladder augmentation

- Correct anatomic bladder outlet obstruction (e.g. genito-urinary prolapse)
- Intermittent catheterization

- Correct anomaly
- Treat pathology

* At any stage of the patient's care pathway, management may need to include continence products

IV. FISTULAE

GENERAL INTRODUCTION

In the developing world fistulae are often a consequence of poor peri-natal care. The epidemiology, aetiology, diagnosis, treatment and prevention have been described in detail during the recent International Consultation on Obstetric Fistula.

In contrast to the field of obstetrical fistulae where the numbers of patients are high, the prevalence of non-obstetrical fistulae seems to be much lower. The published series have small patient numbers, are usually retrospective and have a low level of evidence. The published obstetrical series show impressive numbers and demonstrate the level of skill that many of the fistula surgeons have obtained while working in difficult and isolated situations.

Both committees are convinced that obstetric fistula surgeons in the developing world and reconstructive pelvic surgeons in the developed countries can learn a lot from each other.

PART I: OBSTETRIC FISTULA

INTRODUCTION

Epidemiological studies on obstetric fistulae are inadequate.

The incidence of fistulae is expressed per 1,000 deliveries and would appear to be between 0.1% rising to 1.5 per 1,000 pregnancies in rural areas.

The major risk factors appear to be age at first marriage, short stature, pregnancy with a male child rather than a female child, failure to attend ante-natal care, low socio-economic status, low social class, lack of employment and illiteracy.

The consequences of obstetric fistulae include divorce (16-92%), social isolation, worsening poverty, malnutrition, sexual dysfunction and mental illness (including anxiety/depression), insomnia, general ill health and thoughts of worthlessness and suicide.

ASSESSMENT

Early detection of fistulae could improve by examining all women after their delivery or Caesarian section who suffered prolonged labour and who are at risk of developing an obstetric fistula.

Associated pathologies should be actively searched for and should be taken into account in the treatment plan: all components of the 'obstructed labour injury complex' should be examined.

Classification of fistulae is recommended. Although many classification systems exist, the committee recommends the use of the Waaldijk classification, since it is supported by the largest amount of data. It involves precise measurements of the distances between the external urinary meatus and the distal edge of the fistulae, together with the widest diameter of the fistulae. Fistulae are classified into types 1, 2 and 3. Type 3 fistulae are those fistulae other than vesico-vaginal fistulae (VVF) and include recto-vaginal fistulae (VVF) and uretero-vaginal fistulae. **(Grade C)**

The formal classification of the fistulae should be done under anaesthesia when the patient is on the operation table, just before surgery.

MANAGEMENT OF NEW AND ESTABLISHED VVFs

Management of VVF depends on whether the fistulae is diagnosed within two or three months of its occurrence or whether the woman presents late with an established fistula. (Algorithm 1)

Early fistulae (less than 75 days after obstructed labour). There is evidence that early catheter care will result in the cure of a significant minority of VVFs. **(Grade C)**

Established fistulae (>75 days after obstructed labour) and those that fail catheter treatment should be treated surgically by a fistula surgeon. **(Grade C)**

TREATMENT

If catheter drainage fails, then fistula repair will be necessary. There are certain principles behind fistula repair:

- Necrotic tissue must be removed prior to fistula repair.
- Fistula repair must only be undertaken by a properly trained surgeon.
- Adequate post-operative care is essential.
- Proper follow-up should be arranged.

A vaginal approach under spinal anaesthesia is preferred.

A tension-free single layer closure of the bladder wall and closure of the vaginal wall in a separate layer are advocated. A Martius flap in primary obstetric fistula repair is not recommended.

In principle most fistulae can be dealt with by vaginal approach, but an abdominal approach can be useful in some cases (e.g. concomitant reconstructive procedures). Advanced training and surgical skills are prerequisites for treating this type of fistula.

When reporting on outcome after fistula repair, authors should make a clear distinction between fistula closure rates and post-operative stress incontinence rates and the time at which the follow-up was organized.

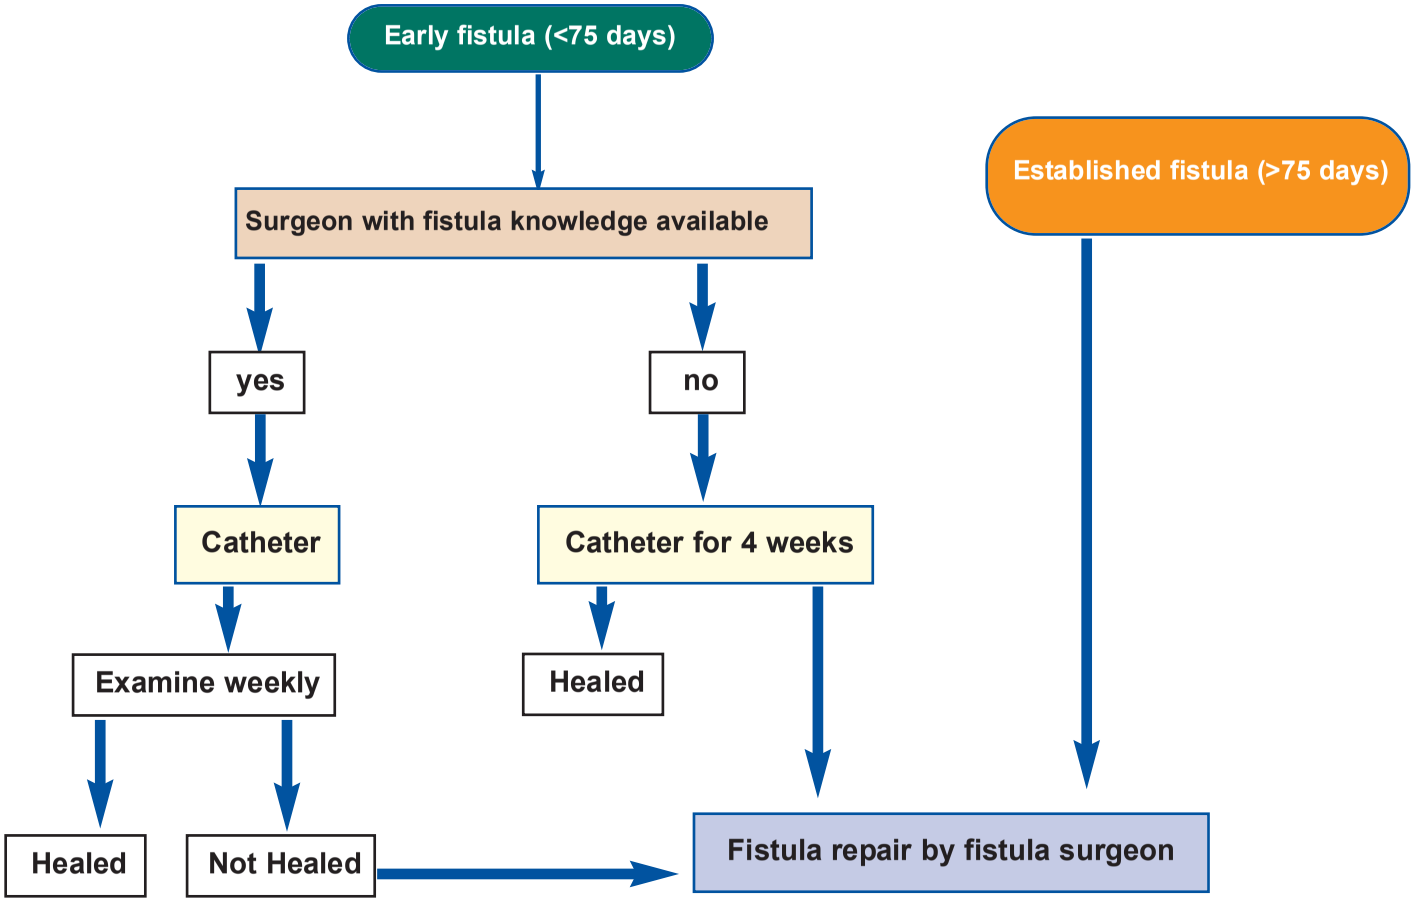
Prevention of post-operative stress incontinence must be added to the surgical procedure if the urethral closing mechanism is involved. This can be done by a good repair of the pubocervical fascia and refixation or by adding a sling procedure.

MANAGEMENT OF THE COMPLICATIONS OF VVF

The complications of vesico-vaginal fistulae are many but include:

- Persistence or recurrence of urinary incontinence
- Persistence of lower urinary tract symptoms or occurrence of new lower urinary tract symptoms, including overactive bladder
- Urinary tract infections
- Upper urinary tract symptoms, including loin pain
- Dyspareunia and sexual dysfunction
- Infertility
- Neurological symptoms
- Psychological problems and mental illness

MANAGEMENT OF OBSTETRIC VESICOVAGINAL FISTULAE *



* At any stage of the patient's care pathway, management may need to include continence products

PART II: NON-OBSTETRIC FISTULAE

INTRODUCTION

Iatrogenic urogenital fistulae are known complications of pelvic surgery and oncological treatments such as radiotherapy, chemotherapy or a combination of both. In the oncological context, fistulae may also occur as a result of primary or recurrent malignancy. The development of fistula following radiotherapy for primary treatment should trigger a search for evidence of tumour recurrence (Grade D)

- Urogenital fistulae are more frequent in women who have undergone hysterectomy.
- The risk of injury to the bowel or urinary tract and of subsequent fistula formation is higher in women with malignant disease undergoing radical surgery than in women with benign disease undergoing simple surgical procedures
- Several modifications to conventional radical hysterectomy have been described, although they have not consistently been shown to mitigate the risk of urinary fistula postoperatively.
- Data on exenterative surgery are inconsistent, although the risk of fistula formation may be higher following exenteration for recurrent disease as compared to that following radical hysterectomy for the primary treatment of malignancy.
- The rate of visceral injury and fistula formation is inconsistently reported following laparoscopically assisted radical hysterectomy, but may be somewhat higher than following open surgery.
- Local ablative treatments applied in gynaecological oncology, whilst apparently relatively low risk as single treatments, may carry considerable risk for fistula formation when repeated.
- The rate of fistula formation following radiotherapy for gynaecological cancer appears to be of the same order as that following surgical treatment.
- The risk of fistula formation following radiotherapy for locally recurrent malignancy is higher than following its use in primary disease.
- The use of neoadjuvant or adjuvant therapies is likely to be associated with a greater risk of fistula development than the primary treatment alone.
- The most common non-obstetric causes of fistulae involving the gastro-intestinal tract are diverticular disease, Crohn's disease, malignancy and radiotherapy.

ASSESSMENT OF FISTULAE

- Leakage of stool, urine, or possibly both is the hallmark sign of a fistulae.The leakage is usually painless, may be intermittent if it is position dependent, or may be constant. Unfortunately, intraoperative diagnosis of a GU or GI injury is made in only about half of the cases that result in fistulae.
- CT and cystoscopy appear more consistent in the confirmation and location of possible intestino-vesical fistulae, than other investigations (Grade C)
- Level 3 evidence indicates that the routine use of cystoscopy with dye testing at gynaecological surgery has high sensitivity, specificity and negative predictive value in the detection of ureteric injury, although false positive tests do occur. The clinical and cost-effectiveness of routine cystoscopy remains to be established. (Grade C)
- Ureteric injury or fistulae may be suspected in patients following pelvic surgery if a fluid leak or pelvi-calyceal dilatation occurs postoperatively. (Grade D)
- Uretero-arterial fistula may be suspected in patients presenting with haematuria with a history of relevant pelvic surgery and indwelling ureteric stent. (Grade D)
- Elevated levels of creatinine in drainage fluid following pelvic surgery are suggestive of a urinary tract injury. (Grade D)

MANAGEMENT OF VESICOVAGINAL FISTULAE

The literature relating to surgical fistulae is extensive, but of limited quality.

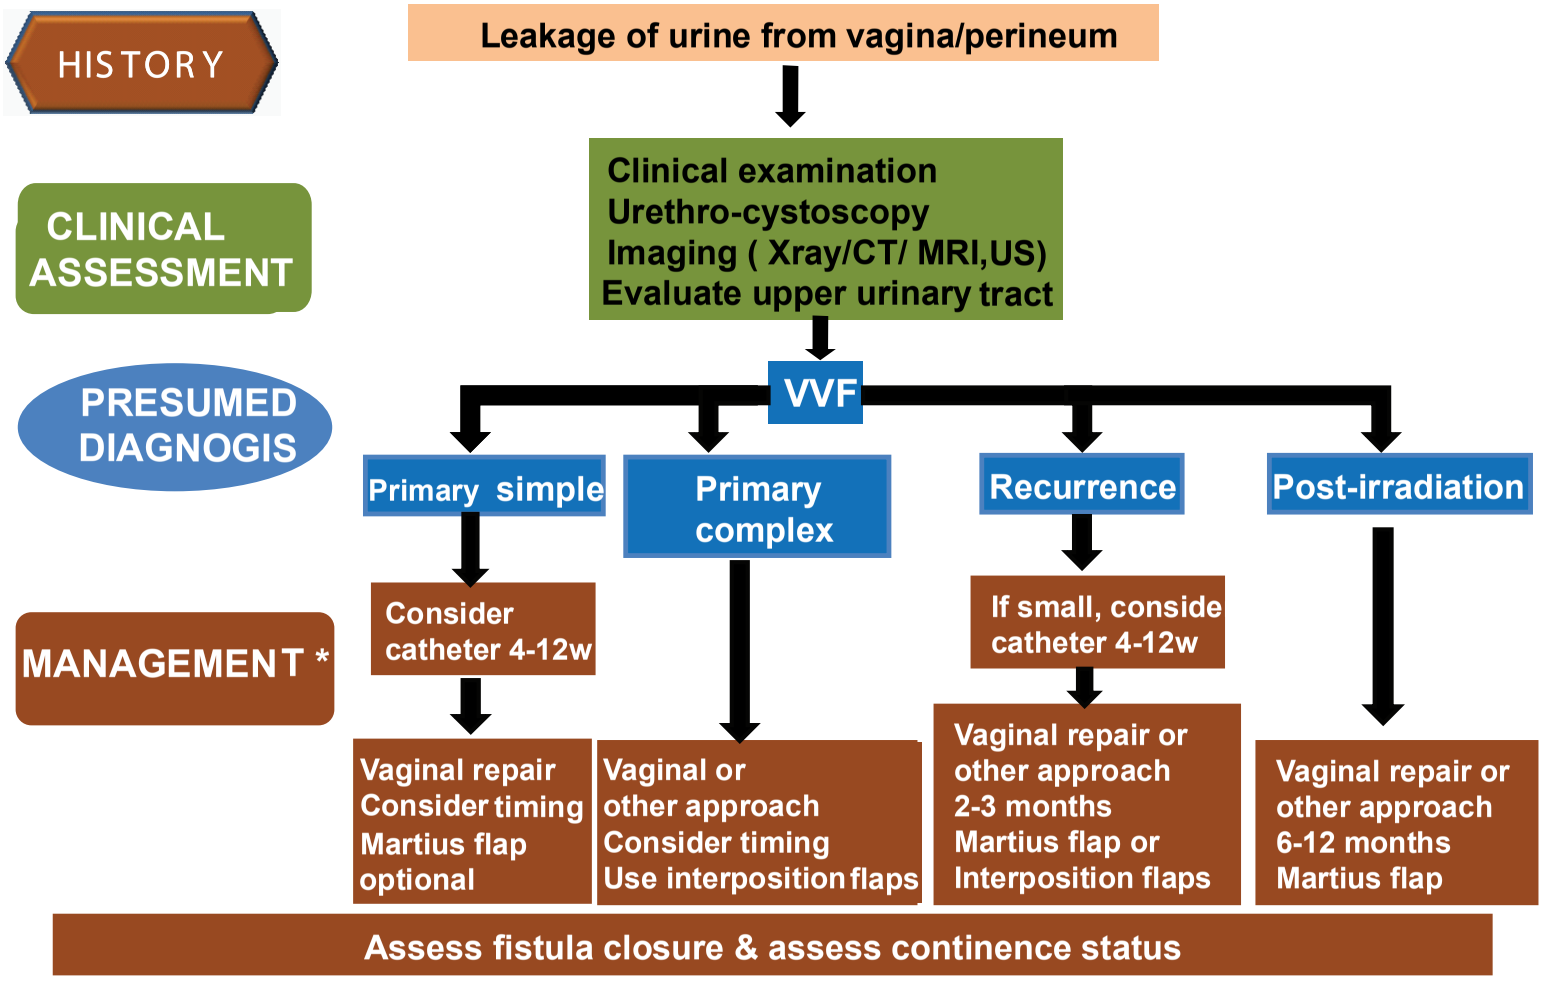
- Spontaneous closure of surgical fistulae does occur, although it is not possible to establish the rate with any certainty; if a vesicovaginal fistulae is diagnosed within six weeks of surgery, indwelling catheterisation can be considered for a period of up to 9 weeks (*i.e.* up to 12 weeks after the causative event). (Grade C)

- Attention should be given as appropriate to skin care, nutrition, rehabilitation, counselling and support prior to and following fistulae repair. (Grade D)
- Perioperative antibiotic prophylaxis should follow local policies. (Grade D)
- There is no benefit from mechanical or laxative bowel preparation prior to colonic surgery; it is reasonable that this recommendation be extrapolated to apply to fistulae surgery. (Grade B)
- There is no proven benefit to delayed repair of vesicovaginal fistulae; the timing of repair should be tailored to the individual patient and surgeon requirements, but can be undertaken as soon as any oedema, inflammation, tissue necrosis, infection are resolved. (Grade B)
- There are no high quality data to indicate greater cure rates for any one technique as compared to others ; level 3 evidence indicates similar success rates for vaginal and abdominal, and for transvesical and transperitoneal approaches. (Grade C)
- Surgeons involved in fistulae surgery should have appropriate training, skills, and experience to select an appropriate procedure for each patient. (Grade D)
- The majority of vesico-vaginal and all urethro-vaginal fistulae can be repaired vaginally, regardless of aetiology. (Grade C)
- Where concurrent ureteric re-implantation or augmentation cystoplasty are required, the abdominal approach is necessary.(Grade D)
- A variety of interpositional grafts can be used in either abdominal or vaginal procedures, although there is little evidence to support their use in any specific setting. (Grade C)
- Conventional and robotically-assisted laparoscopic approaches have both been shown to be feasible in selected cases; the indications for, or optimal patient for these techniques is not yet clear. (Grade C)
- A period of continuous bladder drainage is crucial to successful fistulae repair; there are no high level data to support any particular type, route, or duration of catheterisation; current practice suggests: 10-14 days for simple and/or post-surgical fistulae; 14-21 days for complex and/or post-radiation fistulae. (Grade D)

RADIATION FISTULAE

- Whilst diversion is used more widely in radiation-associated fistulae of all types as compared to non-radiated fistulae, there is low level evidence that repair procedures can achieve successful fistulae closure and continence in appropriately selected cases. (Grade C)
- Where urinary and/or faecal diversions are required, attempts should be made to avoid using irradiated tissues wherever possible, and to minimise the potential for anastomotic complications. (Grade C)
- There is low level evidence to support the use of interposition grafts when repair of radiation-associated fistulae is undertaken.(Grade C)
- In patients with intractable urinary incontinence from radiation-associated fistulae, where life expectancy is very short, ureteric occlusion might be considered; there is insufficient evidence to recommend any particular technique. (Grade D)

MANAGEMENT OF IATROGENIC VESICOVAGINAL FISTULAE



* At any stage of the patient's care pathway, management may need to include continence products

MANAGEMENT OF FISTULAE INVOLVING BOWEL

- There is limited evidence to support a non-surgical or conservative surgical approach in colo-vesical fistulae where there are minimal symptoms or evidence of limited bowel involvement. (Grade C)
- There is only limited low level evidence to support a non-surgical approach in colo-vesical fistulae associated with diverticular disease; nevertheless, in the frail elderly, or in patients who have limited symptoms of urinary infection or urinary diarrhoea it is reasonable to consider a trial of conservative management. (Grade D)
- A one-stage approach to surgery for intestino-vesical fistulae is appropriate in many cases, but should be limited to those patients whose nutritional state is good, and where there is no evidence of additional intra-abdominal pathology (*e.g.* severe inflammation, radiation injury, advanced malignancy, intestinal obstruction) or major co-morbidity. (Grade B)
- A laparoscopic approach to one-stage management has been shown to be feasible, although there is no high level evidence to allow comparison of outcomes with open surgery. (Grade D)

MANAGEMENT OF URETERIC FISTULAE

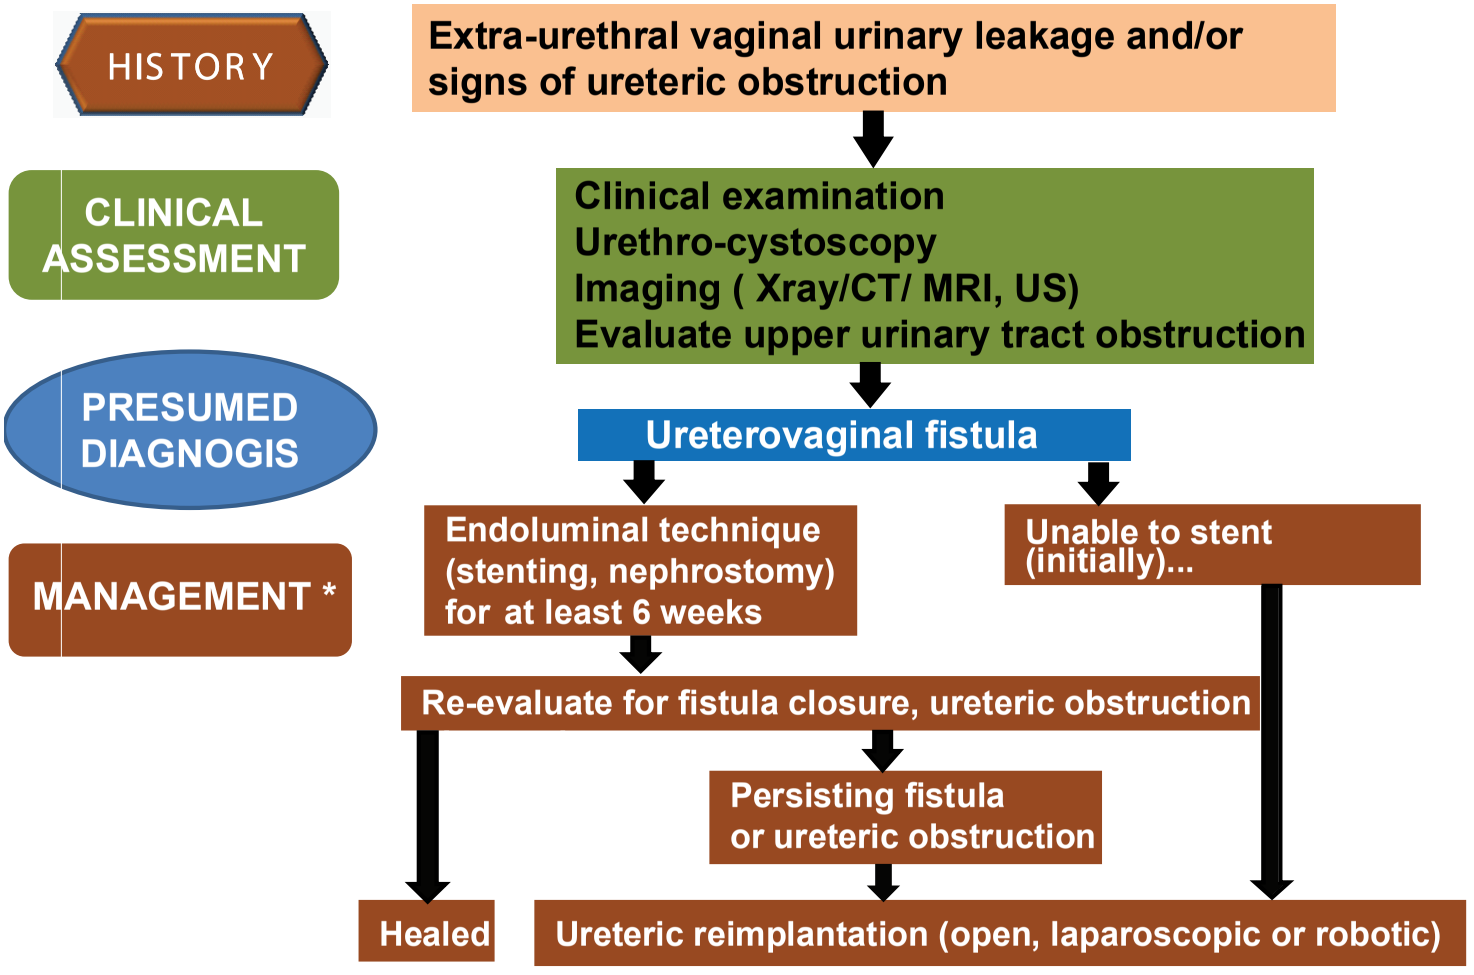
- Surgeons undertaking complex pelvic surgery should be competent at identifying, preserving and repairing the ureter. (Grade D)
- Ureteric stents are not required as prophylaxis against injury during routine gynaecological surgery, while their role in more extensive surgery remains to be established. (Grade B)
- Most upper urinary tract fistulae should be initially managed by conservative or endoluminal techniques where such expertise and facilities exist. (Grade B)
- Persistent ureterovaginal fistulae should be repaired by an abdominal approach using open, laparoscopic or robotic techniques according to availability and competence. (Grade D)
- For patients with ureteric fistulae associated with advanced pelvic cancer and poor performance status, palliation by nephrostomy tube diversion and endoluminal distal ureteric occlusion is an option. (Grade C)

MANAGEMENT OF URETHRO-VAGINAL FISTULAE

Recommendations

- Urethrovaginal fistulae are preferably treated by a vaginal approach. (Grade C)
- A variety of autologous tissue interposition techniques have been described, but their value remains uncertain. (Grade C)
- Urethrovaginal fistulae repair may be complicated by stress incontinence, urethral stricture and urethral shortening necessitating long-term follow-up. (Grade C)

MANAGEMENT OF IATROGENIC URETERIC FISTULAE



* At any stage of the patient's care pathway, management may need to include continence products

V. PELVIC ORGAN PROLAPSE

I. INTRODUCTION

Pelvic organ prolapse includes ***urogenital*** and ***rectal*** prolapse. Treatment for pelvic organ prolapse should be reserved for ***symptomatic women***, except in rare, selected, cases.

1. ASSESSMENT

Symptom enquiry may reveal a variety of symptoms. Symptom severity ***may not correlate*** with the severity of the anatomical changes.

Physical examination should:

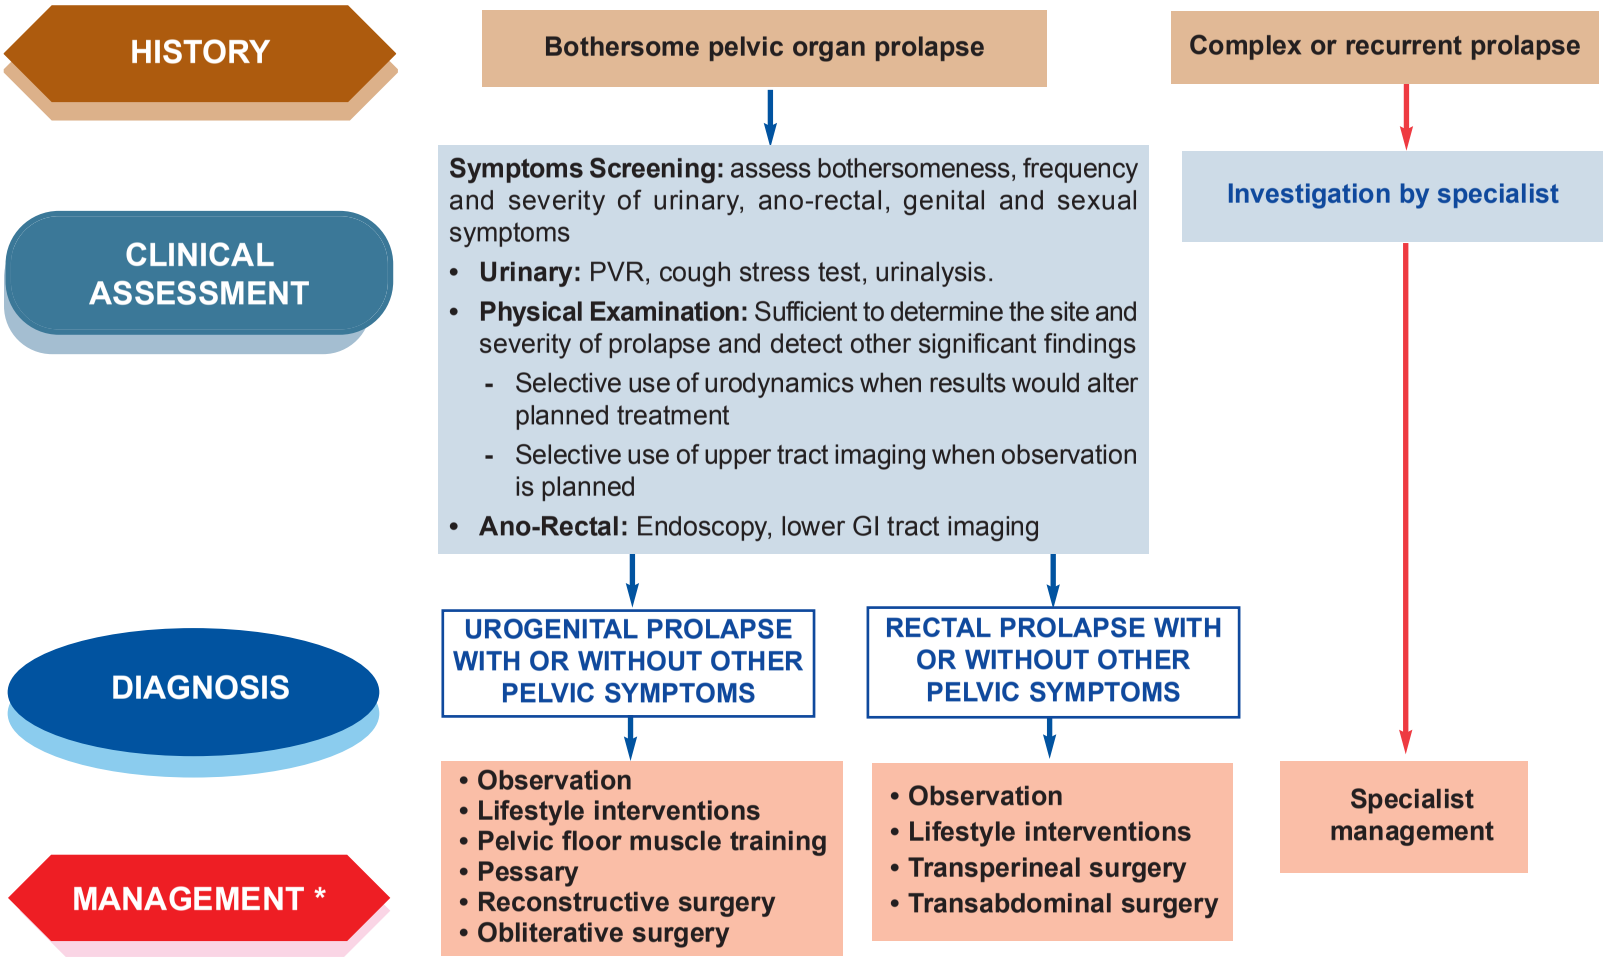
- define the severity of maximum anatomical support defect,
- assess pelvic floor muscle function and
- determine if epithelial/mucosal ulceration is present.

Post void residual should be measured; nearly all elevated post void residuals resolve with treatment of urogenital prolapse. ***Imaging of the upper tract*** is indicated when treatment of vaginal prolapse beyond the hymen is observation only (i.e. no pessary or surgery).

2. MANAGEMENT

- ***Observation*** is appropriate when medically safe and preferred by the patient (Grade C).
- ***Pelvic floor muscle training may:***
  - reduce the symptoms of urogenital prolapse (Grade A), although topographic change is not expected
  - prevent or slow deterioration of anterior urogenital prolapse (Grade B)
- ***Pessaries,*** when successfully fitted, may improve protrusion symptoms (Grade B). Regular follow up is mandatory. ***Support pessaries*** that concurrently treat stress incontinence should be considered when appropriate.
- ***Local oestrogens*** may benefit hypoestrogenic women for the prevention and/or treatment of vaginal epithelial ulceration (Grade C).
- ***Reconstructive surgery*** should aim to optimise anatomy and function (see full text for grades of recommendation for specific surgical techniques). Pre and postoperative pelvic floor muscle training may promote quality of life and fewer symptoms after surgery for urogenital prolapse (Grade C).
- ***Obliterative surgery*** is reserved for selected women who agree to permanent vaginal closure (Grade B).

Management of Pelvic Organ Prolapse
(including urogenital prolapse and rectal prolapse)



* At any stage of the patient's care pathway, management may need to include continence products

VI. URINARY INCONTINENCE IN NEUROLOGICAL PATIENTS

A. Initial Management

I. STRONG GENERAL RECOMMENDATIONS

- Patients with known neurological disease often need evaluation to exclude bladder dysfunction, not only if symptoms occur, but as a standard assessment as ***neurogenic bladder*** has a high prevalence in this disease (for prevalence figures see chapter)
- ***A possible neurological*** cause of " idiopathic " incontinence should always be considered. Diagnostic steps to evaluate this include basic assessments, such as history and physical examination, urodynamics and specialised tests.
- ***Incontinence in neurological*** patients does ***not necessarily relate*** to the neurologic pathology. ***Other diseases*** such as prostate pathology, pelvic organ prolapse, might have an influence. These have to be ruled out.
- ***Extensive diagnostic evaluation*** is often useful and necessary to tailor an individual treatment based on complete neurofunctional data. This ***may not be needed in every patient*** e.g. patients with suprapontine lesions or in patients where treatment will consist merely of bladder drainage due to bad medical condition or limited life expectancy.
- There is often a need to manage ***bladder*** and ***bowel*** together

II. INITIAL ASSESSMENT

- The management of neurological urinary incontinence depends on an ***understanding of the likely mechanisms*** *producing incontinence.* This can in turn depend on the ***site and extent of the nervous system abnormality.***
- Therefore neurogenic incontinence patients can be divided into those having:
  - ***peripheral lesions*** (as after major pelvic surgery) including those with lesions of the cauda equina (eg.lumbar disc prolapse);
  - ***sacral spinal cord lesions involving the sacral micturition centre***
  - ***suprasacral spinal cord lesions*** (suprasacral infrapontine spinal cord lesions);
  - ***central lesions of the brain or brain stem*** (stroke, Parkinson's disease).
- ***History*** and ***physical examination*** are important in helping ***distinguish*** these groups.

III. INITIAL TREATMENT

➦ Patients with ***peripheral nerve lesions*** (e.g. denervation after pelvic surgery) and patients with ***spinal*** cord lesions (e.g. traumatic spinal cord lesions) should get ***specialised management*** (A)

➦ Initial treatment for patients with incontinence due to ***suprapontine pathology***, like stroke; need to be assessed for degree of mobility and ability to cooperate. Initial recommended treatments are behavioural therapy (C) and anti-muscarinic drugs for presumed detrusor overactivity (A). Continence products (B) or catheters (C) may be necessary for non-cooperative or less mobile patients.

Initial Management of Neurogenic Urinary Incontinence

HISTORY, level of lesion

- **Peripheral nerve lesion (e.g. radical pelvic surgery). Sacral cord/cauda equina lesion (e.g. lumbar disc prolapse)**
- **Suprasacral infrapontine and pontine lesions e.g. trauma, multiple system atrophy.**
- **Suprapontine cerebral lesion (e.g. Parkinson's disease, stroke, multiple sclerosis**

CLINICAL ASSESSMENT

- Further history
- General assessment including of home circumstances
- Urinary diary and symptom score
- Assessment of functional ability, quality of life and desire for treatment
- Physical examination: assessment of sensation in lumbosacral dermatomes, anal tone and voluntary contraction of anal sphincter, bulbocavernosus and anal reflexes, gait, mobility, contractures, hand fuction.
- Urine analysis + culture (if infected: treat as necessary)
- Urinary tract imaging, serum creatinine : if abnormal to specialised management
- Post void residual (PVR) assessment by abdominal examination or optional by ultrasound

This assessment will give basic information, but does not yield precise neurourological diagnosis

PRESUMED DIAGNOSIS

Stress urinary incontinence due to sphincter incompetence with negligible PVR

Urinary incontinence due to detrusor overactivity

- **Urinary incontinence associated with poor bladder emptying (significant PVR)**
- **With negligible PVR**

MANAGEMENT *

- Behavioural modification
- External appliances

Failure

- Intermittent catheterisation ** with or without
- Antimuscarinics

Failure

Depending on cooperation and mobility :
- Behavioural modification,
- Antimuscarinics,
- Continence products,
- Indwelling catheter

Failure

Specialised management preferable for more " tailored " treatment

* At any stage of the patient's care pathway, management may need to include continence products

** Some patients omit IC through personal choice or inability to self catheterise

VI. URINARY INCONTINENCE IN NEUROLOGICAL PATIENTS

B. Specialised Management

I. ASSESSMENT

- Most patients with neurogenic urinary incontinence require specialised assessment : ***urodynamic studies should be used*** with videourodynamics if available when surgical interventions are planned or when the “bladder may be unsafe”.
- ***Upper tract imaging*** is needed in some patients and more detailed renal function studies will be desirable if the upper tract is considered in danger: high bladder pressure, upper urinary tract dilatation, recurrent or chronic upper tract infection, (major) stones, (major) reflux.
- In patients with ***peripheral lesions*** clinical ***neurophysiological testing*** may be helpful for better definition of the lesion

II. TREATMENT

Also for specialised management conservative treatment is the mainstay (A). Management of neurogenic urinary incontinence has several therapeutic options. The algorithm details the recommended options for different types of neurological dysfunction of the lower urinary tract. The dysfunction does not necessarily correspond to one type/level of neurological lesion but ***must depend*** mostly on ***urodynamic findings***. One should always ascertain that the management is ***urodynamically safe*** (low pressure, complete emptying)

It is recommended to look at ***urinary*** and ***bowel*** function ***together*** if both systems are affected, as symptoms and treatment of one system can influence the other and vice versa (A).

As therapeutic approaches can differ in various neurological diseases, the most prevalent diseases are discussed separately in the chapter

III. TREATMENT MODALITIES (often in combination)

➦ Conservative

- Intermittent catheterisation (A)
- Behavioural treatment(C)
- Timed voiding (C)
- Continence products (B)
- Antimuscarinics(A)
- Alpha 1 adrenergic blockers (C)
- Intravesical electrical stimulation (C)
- Bladder expression (B)
- Triggered voiding (C)
- Indwelling catheter (C)

➦ Surgical treatment

- Artificial sphincter (A)
- Bladder neck Sling (B)
- Sub-urethral tapes (D)
- Bulking agents (D)
- Bladder neck closure (D)
- Stents intraurethral (B)
- TUI sphincter (B)
- Botulinum toxin for : sphincter(C) detrusor (A)
- Sacral deafferentation (B)
- Sacral anterior root stimulator (B)
- Enterocystoplasty (B)
- Autoaugmentation (D)

Specialised Management of Neurogenic Urinary Incontinence

LEVEL AND EXTENT OF LESION, HISTORY AND CLINICAL ASSESSMENT

- Peripheral nerve lesion (e.g. radical pelvic surgery) conus cauda equina lesion (e.g. lumbar disc prolapse)
- Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)
- Suprapontine cerebral lesion (e.g. Parkinson's disease, stroke, multiple sclerosis)

SPECIALISED ASSESSMENT

- Urodynamic testing (usually videourodynamics.
- Urinary tract imaging

DIAGNOSIS

- Stress UI due to sphincteric incompetence
- Incontinence associated with poor bladder emptying due to detrusor underactivity / sphincter overactivity
- UI due to detrusor overactivity
  - With DSD
  - No DSD

CONSERVATIVE TREATMENT

- Timed voiding Ext. appliances
- IC
- α-1 blockers
- Straining
- IC + AM
- IDC + AM
- Bot tox to detrusor + IC
- Behavioural
- IC + AM
- Triggered voiding
- Indwelling cath. + AM
- Continence products + AM
- Botulinum toxin to detrusor

AM = antimuscarinics
SDAF = sacral deafferentation
SARS = sacral anterior -roots stim

SURGICAL TREATMENT *

- Artificial sphincter
- Bladder neck sling
- Antologous sling
- Bulking agents
- Bladder neck closure
- (Synthetic midurethral tapes)**
- Stents intraurethral
- TUI sphincter
- Botulinum toxin to sphincter *
- SDAF + IC
- SDAF + SARS
- Enterocystoplasty
- [Autoaugmentation]

IC = intermittent catheterization
PVR = postvoid residual
TUI = transurethral incision
DSD = Detrusor sphincter dyssynergia
IDC = indueting catheter

** if urethral hypermobility is the cause of SUI; the long-term risks of tapes in the neurogenic population are undefined

* Intravesical botulinum injections undertaken according to national licensing. Sphincteric botulinum injections are not currently licensed.

Stoma/diversion may be an option in selected cases

* At any stage of the patient's care pathway, management may need to include continence products

VII. BLADDER PAIN SYNDROME

I. DEFINITION

Bladder Pain Syndrome in the absence of a universally agreed definition, the European Society for the Study of Interstitial Cystitis (ESSIC) definition is given along with the definition of the American Urological Association

- **ESSIC :** *Chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent urge to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.*
- **American Urological Association Guideline Definition:** *An unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than 6 weeks duration, in the absence of infection or other identifiable causes.*

II. BLADDER PAIN SYNDROME (BPS)

1. NOMENCLATURE

The scientific committee of the International Consultation voted to use the term ***"bladder pain syndrome"*** for the disorder that has been commonly referred to as interstitial cystitis (IC). The term painful bladder syndrome was dropped from the lexicon. The term IC implies an inflammation within the wall of the urinary bladder, involving gaps or spaces in the bladder tissue. This does not accurately describe the majority of patients with this syndrome. Painful Bladder Syndrome, as defined by the International Continence Society, is too restrictive for the clinical syndrome.

Properly defined, the term Bladder Pain Syndrome appears to fit in well with the taxonomy of the International Association for the Study of Pain (IASP) (see below), and focuses on the actual symptom complex rather than what appears to be long-held misconception of the underlying pathology.

Bladder Pain Syndrome

Bladder pain syndrome is the occurrence of persistent or recurrent pain perceived in the urinary bladder region, accompanied by at least one other symptom, such as pain worsening with bladder filling and day-time and/or night-time urinary frequency. There is no proven infection or other obvious local pathology. Bladder pain syndrome is often associated with negative cognitive, behavioural, sexual, or emotional consequences as well as with symptoms suggestive of lower urinary tract and sexual dysfunction.

2. HISTORY / INITIAL ASSESSMENT

Males or females whose symptoms meet the requirements of the definition of bladder pain syndrome should be evaluated. The presence of commonly associated disorders including irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia in the presence of the cardinal symptoms of bladder pain syndrome also suggests the diagnosis. Abnormal gynecological findings in women and well-characterized confusable diseases that may explain the symptoms must be ruled out.

➦ The initial assessment consists of a frequency/volume chart, focused physical examination, urinalysis, and urine culture. Urine cytology, cystoscopy, and urodynamic evaluation are recommended if clinically indicated and/or the diagnosis is in doubt. Patients with urinary infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and microscopic or gross haematuria are evaluated with appropriate imaging and endoscopic procedures, and only if findings are unable to explain the symptoms, are they diagnosed with BPS. **Grade of recommendation: C**

3. INITIAL TREATMENT

- patient education,
- dietary manipulation,
- non-prescription analgesics,
- stress reduction,
- pelvic floor muscle relaxation techniques comprise the initial treatment of BPS. In the patient with findings suggesting pelvic floor dysfunction, pelvic floor muscle physical therapy with myofascial trigger point release and intravaginal Thiele massage is often an effective therapeutic intervention.

The treatment of pain needs to be addressed directly, and in some instances referral to an anaesthesia/pain ***centre can be an appropriate early step in conjunction with ongoing treatment of the syndrome***.

Treatment should be focused on the most bothersome or distressing symptoms(s).

➦ ***When conservative therapy fails or symptoms are severe*** and conservative management is unlikely to succeed,

- oral medication, or
- intravesical treatment can be prescribed.

It is recommended to initiate a ***single form*** of therapy and observe results, adding other modalities or substituting other modalities as indicated by degree of response or lack of response to treatment. **Grade of recommendation: C**

4. SECONDARY ASSESSMENT

➦ **If initial oral or intravesical therapy fails**, *or before beginning such therapy based on clinician judgment,* it is reasonable to consider ***further evaluation*** which can include urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anaesthesia.

Findings of ***detrusor overactivity*** suggest a trial of antimuscarinic therapy.

The presence of a ***Hunner's lesion*** suggests therapy with transurethral resection, fulguration of the lesion, or direct steroid injection into the lesion. ***Distention*** itself can have therapeutic benefit in 30-50% of patients, though benefits rarely persist for longer than a few months. **Grade of recommendation: C**

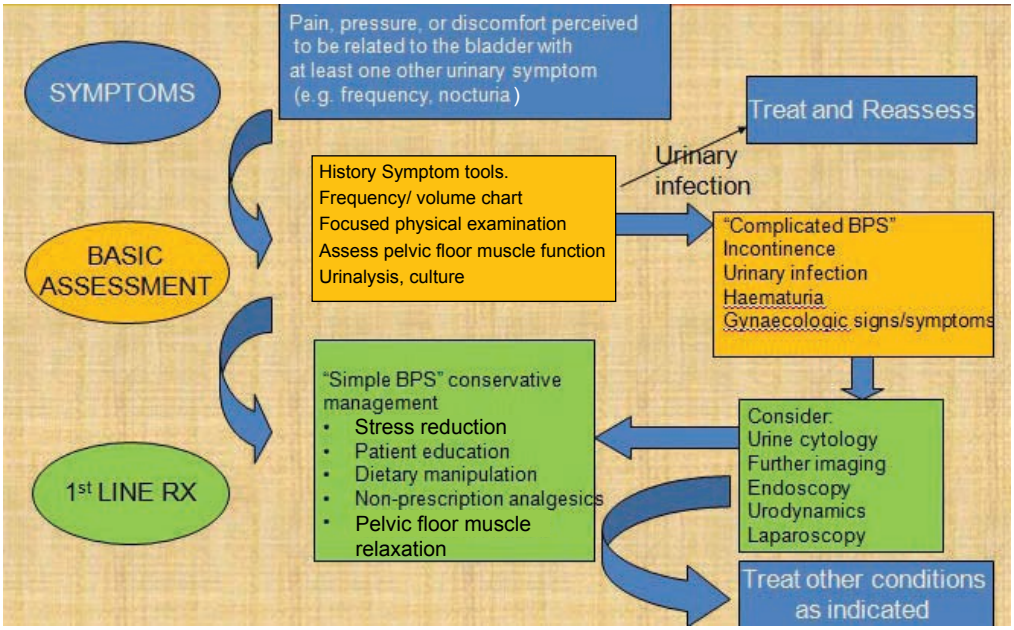
5. REFRACTORY BPS

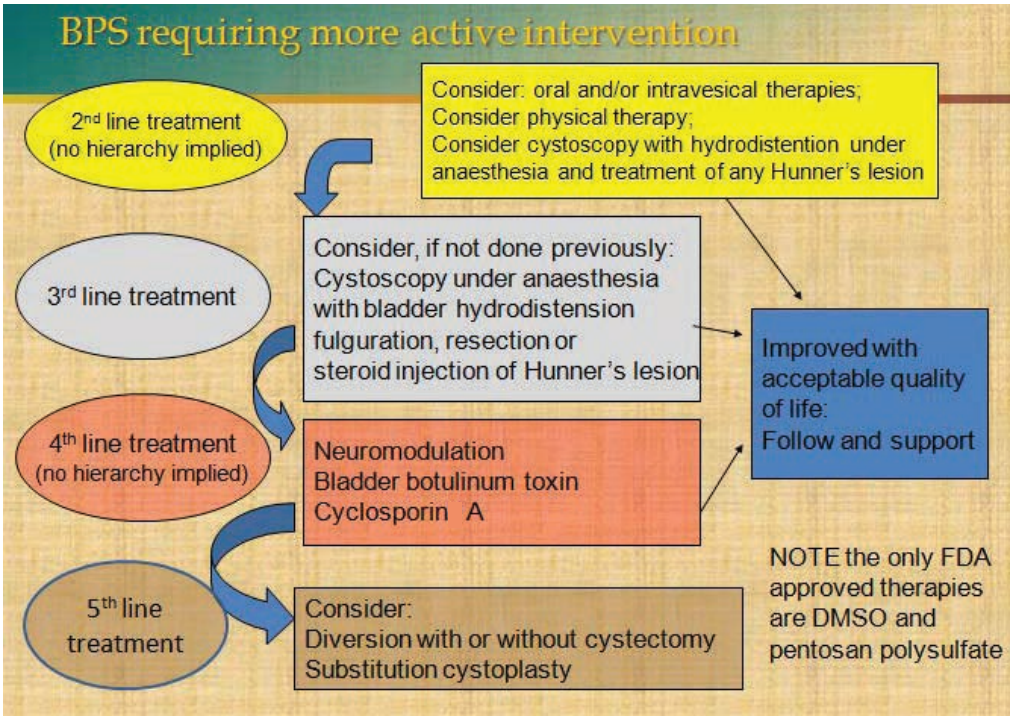
➦ Those patients with ***persistent, unacceptable symptoms*** despite oral and/or intravesical therapy are candidates for ***more aggressive modalities.*** Many of these are best administered within the context of a ***clinical trial if possible.*** These may include neuromodulation, intradetrusor botulinum toxin, oral cyclosporine A, or clinical trials of newly described pharmacologic management techniques. At this point, most patients will benefit from the expertise of an anaesthesia pain clinic.

➦ ***The last step in treatment*** is usually some type of ***surgical intervention*** aimed at increasing the functional capacity of the bladder or diverting the urinary stream.

- ***Urinary diversion*** with or without cystectomy has been used as a last resort with good results in selected patients.
- ***Augmentation*** or ***substitution cystoplasty*** seems less effective and more prone to recurrence of chronic pain in small reported series. **Grade of recommendation: C**

Bladder Pain Syndrome





- Pain management is a primary consideration at every step of algorithm
- Patient enrollment in appropriate research trial is reasonable option at any point
- Evidence supporting neuromodulation, cyclosporin A, and botulinum toxin for BPS indication is limited. These interventions are appropriate only for practitioners with experience treating BPS and willing to provide long-term care post-intervention

VIII. FAECAL INCONTINENCE IN NON-NEUROLOGICAL PATIENTS

INITIAL MANAGEMENT

I. INITIAL CLINICAL ASSESSMENT

Patients with faecal incontinence present with a variety of symptom complexes. As many people are reluctant to admit to having faecal incontinence, it is important to proactively enquire about it, especially in known high risk groups (such as older community-living individuals, post partum women who might have had an obstetric injury, and patients with loose stools).

- ***History*** will include bowel symptoms including loose stools, severity and types of incontinence, systemic disorders, neurological disorders, and anorectal surgeries (e.g., haemorrhoidectomy), obstetrical history for women, medications, diet, chronic straining, cognitive status, and effects of symptoms on quality of life.
- ***Types of incontinence:*** *urgency faecal incontinence,* often a symptom of external anal sphincter dysfunction; *flatus incontinence* (leakage of rectal gas) may indicate rectal sensory impairment and/or internal anal sphincter dysfunction; and *soiling after defaecation*, typically related to a defect in the internal sphincter or poor closure of external sphincter due to rectal prolapse or stage III/IV haemorrhoids.
- ***Physical examination*** will include anal inspection, abdominal palpitation, a brief neurological examination, digital rectal examination and usually proctosigmoidoscopy or colonoscopy.
- ***Further diagnostic testing*** needs to be considered if the patient has symptoms such as an unexplained change in bowel habit, weight loss, anaemia, rectal bleeding, severe or nocturnal diarrhoea, or an abdominal or pelvic mass and bowel pathology when organic conditions such as cancer, inflammatory bowel disease (IBD), a recto-vaginal fistula, full thickness rectal prolapse, or cloacal deformity are suspected. ***Condition specific management*** is indicated for these patients.

Reversible factors (such as inadequate access to toilets and side effects of medications resulting in loose stools) should be assessed and addressed at the outset.

II. INITIAL INTERVENTIONS

➦ Initial management can often be performed in primary care. After environmental factors and local or systemic pathology have been excluded, ***initial interventions include:***

- Discussion of **options** and **goals** of management with the patient
- Provision of patient or caregiver **information** and **education** (Grade A)
- Adjustment of **diet** and fluid advice, **fibre** intake (Grade A)
- Establishing a **regular bowel habit** (Grade C) or **urgency training** if relevant (Grade C)
- **Anti-diarrhoeal** medication can help if stools are loose (Grade B)
- **Rectal Irrigation** to achieve complete rectal evacuation of faeces (Grade B)
- Use of **continence products** including various types and sizes of absorbent pads, briefs, etc., to contain leaked faeces and prevent skin damage

III. SECONDARY INTERVENTIONS

- If initial interventions fail to improve symptoms after 8-12 weeks, consideration should be given to referral to an **incontinence specialist** (e.g., gastroenterologist, continence nurse, advisor physiotherapist, or colorectal surgeon) for other interventions or further assessment.
- **Pelvic floor muscle training (PFMT) – c**ontraction of pelvic floor muscles multiple times per day to improve strength of contraction and increase awareness of anorectal muscle function. (Grade C)
- **Biofeedback therapy** – behavioural treatment designed to enhance the strength of sphincter contraction and improve rectal sensation using specialised equipment. Biofeedback therapy can be combined with PFMT to improve strength. (Grade B)

IV. SECONDARY ASSESSMENT

- A variety of anorectal investigations, including manometry, anal ultrasound, and possibly MRI, defaecagraphy, and neuro-physiological testing can help to define structural or functional abnormalities of anorectal function and guide management if initial and/or secondary interventions are ineffective

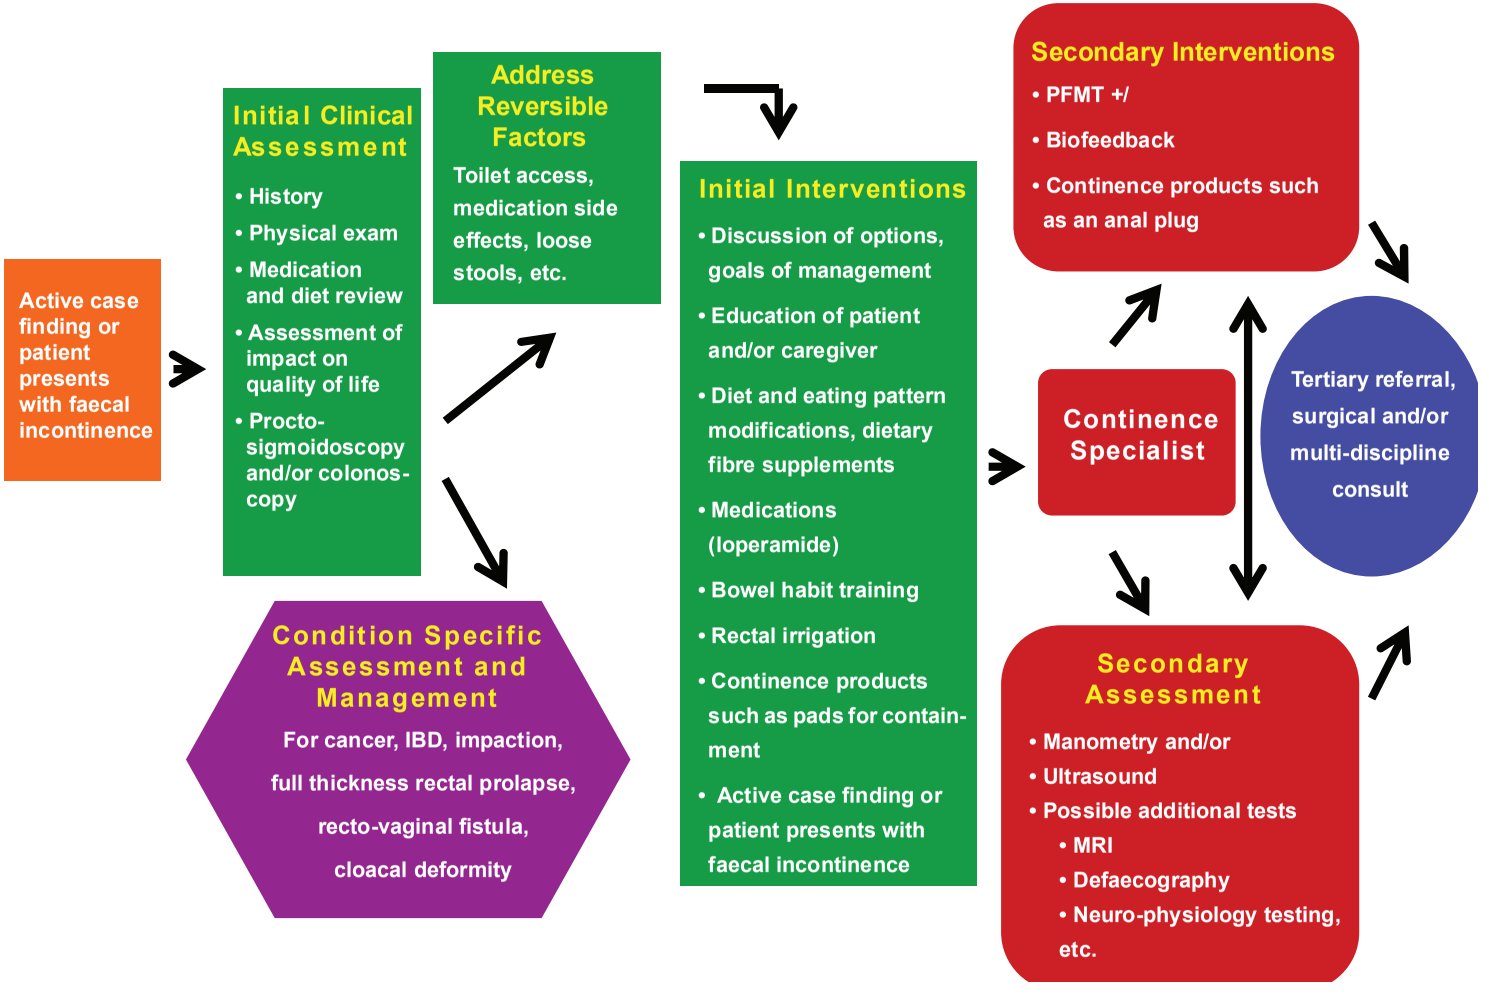
V. TERTIARY REFERRAL, SURGICAL OR MULTI-DISCIPLINARY CONSULTATION

- **Faecal** incontinence that fails to respond to initial and secondary management requires specialised consultation by a gastroenterologist, colorectal surgeon, urogynecologist, and/or a multi-disciplinary team.

RESEARCH RECOMMENDATIONS

- Data should be collected on faecal incontinence whenever practical as part of research on urinary incontinence.
- Development of techniques for diagnosing FI and its severity using new and available technologies
- Well designed and adequately powered studies are needed to evaluate all treatment modalities currently available including
    - Effectiveness of lifestyle modifications including weight loss, exercise, modifying diet and eating pattern and supplementing dietary fibre as primary and adjuvant management strategies
    - Comparative effectiveness trial comparing instrumented biofeedback training to neuromodulation for the treatment of FI
    - Effectiveness of tibial nerve stimulation
- Studies are needed to develop interventions for supporting coping and self-management of faecal incontinence, odour, and urgency and increasing care seeking

Initial Management of Faecal Incontinence



VIII. FAECAL INCONTINENCE

Surgery for Faecal Incontinence

I. INITIAL ASSESSMENT AND MANAGEMENT

The reader is referred to the relevant sections on "Dynamic Testing" and "Conservative Treatment for Faecal Incontinence." In general, patients referred for surgical management of faecal incontinence must either have failed conservative therapy or not be candidates for conservative therapy due to severe anatomic or neurological dysfunction.

Prior to surgical management of faecal incontinence, the integrity of the anal sphincter complex should be assessed. This assessment is best performed with endoanal ultrasound, though pelvic MRI may also be useful. Ancillary tests include anal manometry, electromyography, and defaecography.

- Patients with rectal prolapse, rectovaginal fistulae, and cloacae often have associated faecal incontinence. Initial therapy should be directed at correction of the anatomic abnormality (in the case of rectovaginal fistula or cloaca, this surgical repair may include overlapping sphincteroplasty.) If the patient has persisting faecal incontinence, she should undergo repeat assessment, including especially endoanal ultrasound.

II. SPECIALISED MANAGEMENT

The surgical approach to the incontinent patient is influenced by the presence and magnitude of an anatomic sphincter defect. If no defect is present, or if the sphincter defect is minimal, options include SNS and injection therapy.

- For patients with moderate sphincter defects, sphincteroplasty, SNS or injection therapy can each be considered. For patients with large sphincter defects (>120 degrees), sphincteroplasty is likely the best option, though a PNE trial for SNS can be considered.
- Patients with sphincter defects of greater than 180° or major perineal tissue loss require individualised treatment. In some cases, initial reconstruction can be performed. Should incontinence persist, alternatives include stimulated muscle transposition, artificial anal sphincter implantation, or sacral nerve stimulation.

III. SALVAGE MANAGEMENT

For patients who remain incontinent following sphincteroplasty, repeat endoanal ultrasound should be undertaken to reassess the status of the repair. If no defect is present, or if the sphincter defect is minimal (<30 degrees), options include SNS and injection therapy. If there is a large persisting sphincter defect, repeat sphincteroplasty can be considered.

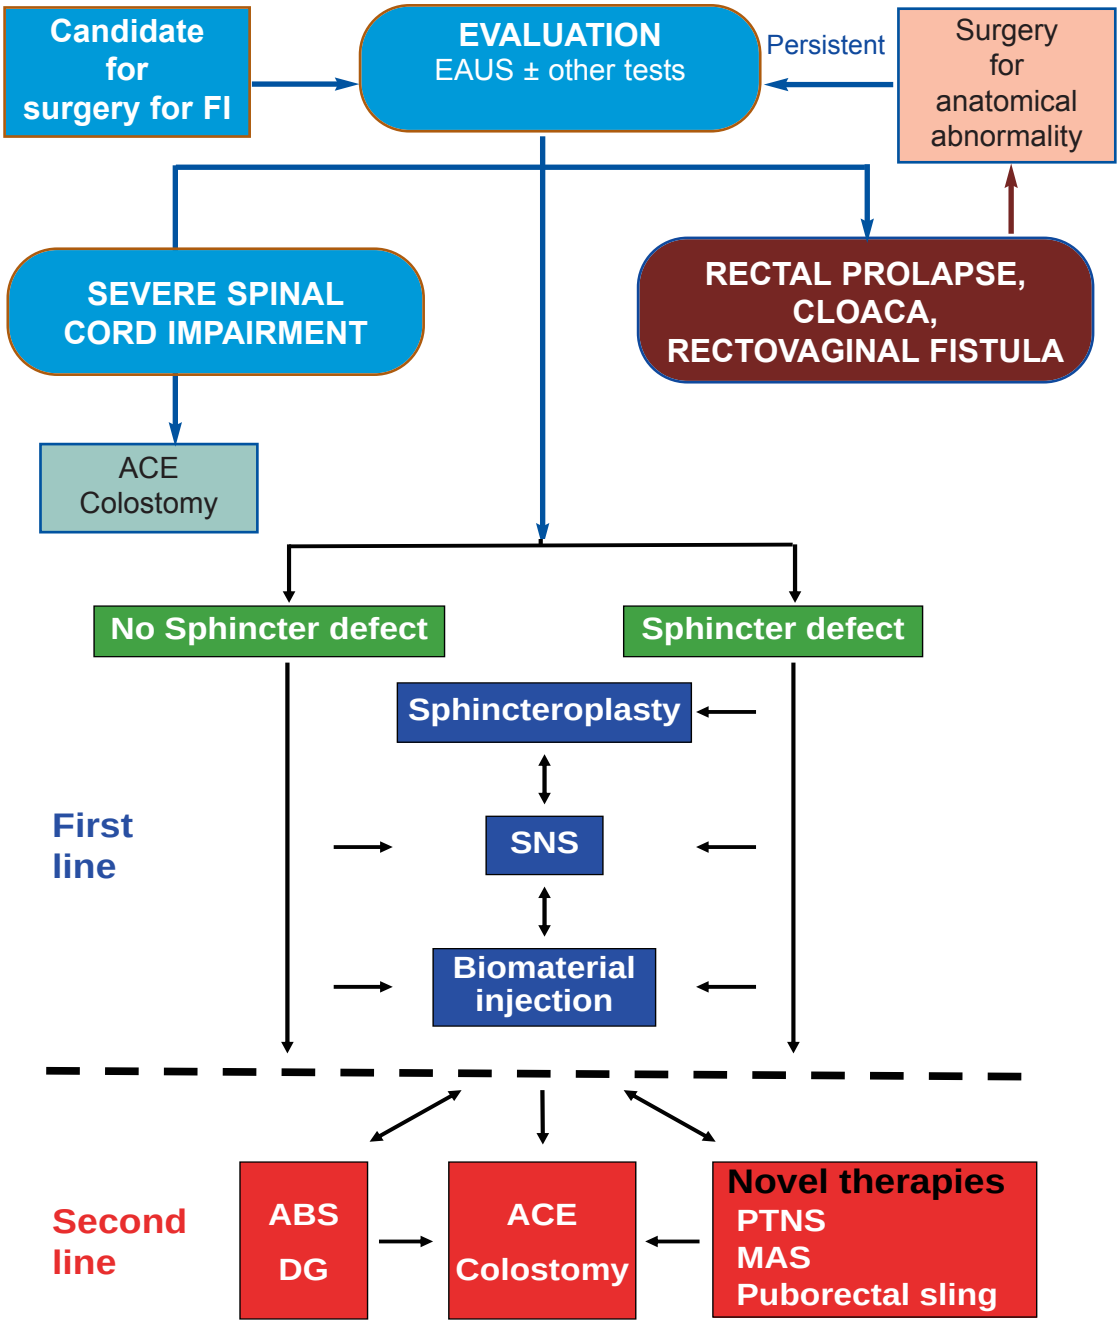
Patients who have failed sacral nerve stimulation can be considered for injection therapy or sphincteroplasty if a sphincter defect is present. Other alternatives include stimulated graciloplasty and implantation of an artificial anal sphincter.

Patients who fail surgical therapy for faecal incontinence, or who do not wish to undergo extensive pelvic reconstruction, should consider placement of an end sigmoid colostomy. While this procedure does not restore continence, it does restore substantial bowel control and appears to improve social function and quality of life. Novel therapies can also be considered under protocol: PTNS, the magnetic anal sphincter and sling procedures.

IV. SPECIAL SITUATIONS

Individuals with severe spinal cord dysfunction (due, e.g., to injury or congenital abnormality) should be considered for an Antegrade Continence Enema (ACE) procedure or colostomy.

Surgical Management of Faecal Incontinence *



EAUS: endoanal ultrasonography, ACE: antegrade continence enema,
SNS: sacral nerve stimulation, ABS: artificial bowel sphincter,
DG: dynamic graciloplasty, PTNS: posterior tibial nerve stimulation,
MAS : magnetic anal sphincter

* At any stage of the patient's care pathway, management may need to include continence products

IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

A. INITIAL MANAGEMENT

➦ Patients with ***known neurological disease*** may present with symptoms related to neurologic bowel dysfunction – difficulty in defaecation, constipation and faecal incontinence which disturb their activities of daily living and quality of life. Many have permanent impairments and functional limitations and disabilities, which are due to neurological deficits and complications

I. INITIAL ASSESSMENT

➦ ***History taking***: this includes

- Neurological diagnosis and functional level
- Previous and present lower gastrointestinal (LGIT) function and disorders
- Severity of neurogenic bowel dysfunction
- Current bowel care and management including diet, fluid intake, medications affecting bowel functions
- Co-morbidity / complication e.g., urinary incontinence, autonomic dysreflexia, pressure ulcers, sexual dysfunction
- Patient's satisfaction, needs, restrictions and quality of life
- Environmental factors and barriers and facilitators to independent bowel management.

➦ ***Physical examination***:

- Cognitive functions; motor, sensory and sacral reflexes – voluntary anal sphincter contraction, deep perianal sensation, anal tone, anal and bulbocavernosus reflexes
- Spasticity of the lower limbs
- Abdominal palpation for faecal loading and rectal examination

➦ ***Functional assessment***:

- hand and arm use, fine hand use, mobility – maintaining body position, transfer and walking ability.

➦ ***Environmental factors assessment***:

- toilet accessibility; devices for bowel care and mobility; caregivers' support and attitude;

II. BASIC INVESTIGATIONS:

Stool exam, plain abdomen XRay

III. INITIAL TREATMENTS

- ***Patient education and goals-setting*** - complete defaecation on a regular basis and faecal continence based on right time, right place, right trigger and right consistency
- ***Adequate fibre diet and fluid intake***; appropriate trigger according to preservation of sacral (anorectal) reflex – digital rectal stimulation; suppository and enema; if no anorectal reflex, manual evacuation; abdominal massage can also be helpful
- ***Prescribe medications*** – stool softener, laxative, prokinetic agents, anti-diarrhoea drugs as neccessary
- Assistive techniques may be necessary for
  - defaecation – irrigation
  - for incontinence – anal plug

The diagram does not apply to management in acute neurological patients that need regular bowel emptying.

Initial Management of Neurogenic Faecal Incontinence

HISTORY, level of lesion

- Sacral cord/cauda equina lesion (e.g. lumbar disc prolapse). Peripheral nerve lesion (e.g. radical pelvic surgery)
- Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)
- Suprapontine lesions (e.g. Parkinson)

CLINICAL ASSESSMENT

- History taking including diagnosis, pre-morbid bowel function and sensation and their disorders, current bowel and bladder programme, co-morbid diseases/disorders, QOL and needs
- Physical & neurological examination including cognitive function, voluntary anal contraction, sensation, sacral reflexes, digital rectal examination, abdominal palpation for faecal impaction
- Functional assessment including hand and arm use, fine hand use, balance, transfer and walking
- Environmental factors assessment including toilet accessibility, assistive device, caregivers' support and attitude
- Basic investigation: stool exam, plain film abdomen in selected patients (diarrhoea, impaction not felt on rectal examination)

This assessment will give basic information but does not permit a precise diagnosis of neurogenic bowel dysfunction

PRESUMED DIAGNOSIS

- Incontinence due to sphincter incompetence
- Incontinence due to lack of cognitive function, sensory awareness disorders, unable to control by voluntary anal contraction
- " False incontinence " due to faecal impaction

TREATMENT *

- Manual evacuation
  Assistive device – anal plug
  mini-enema, transanal/transrectal irrigation
- Digital rectal stimulation
  Chemical stimulant: suppository, mini-enema, stool softener, laxative; given by patient/caregiver
- Faecal disimpaction incl. enemas and transanal/transrectal irrigation

Necessary in all

Patient education, adequate fibre diet and fluid intake; regular bowel care, preferably ± 3 times a week

Specialised management preferable for more " tailored " treatment

* At any stage of the patient's care pathway, management may need to include continence products

IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

B. SPECIALISED MANAGEMENT

I. ASSESSMENT

- ***Some patients*** with neurogenic faecal incontinence will need ***specialised assessment,*** especially if initial management is unsuccesful to look for comorbidity and certainly before performing invasive treatment
- ***Do not assume*** that all symptoms are ***due to neuropathy,*** e.g. women with neurological pathology might have had childbirth injury to the sphincter
- **Special investigations**: manometry, endoanal ultrasound, (dynamic) MRI, (needle) EMG. These specific bowel functional tests and electro-diagnostic tests must be considered ***optional*** as their value in neurological pathology is not sufficiently demonstrated so far.

II. TREATMENTS

➦ ***Also for specialised management, conservative treatment for neurological faecal incontinence is the mainstay***

➦ ***Management of neurological*** incontinence does not include very extensive treatment modalities and many conservative interventions are still empirical.

- Transanal irrigation (C)
- Electrical stimulation sphincter, (C)
- Percutaneous neuromodulation : further research is required

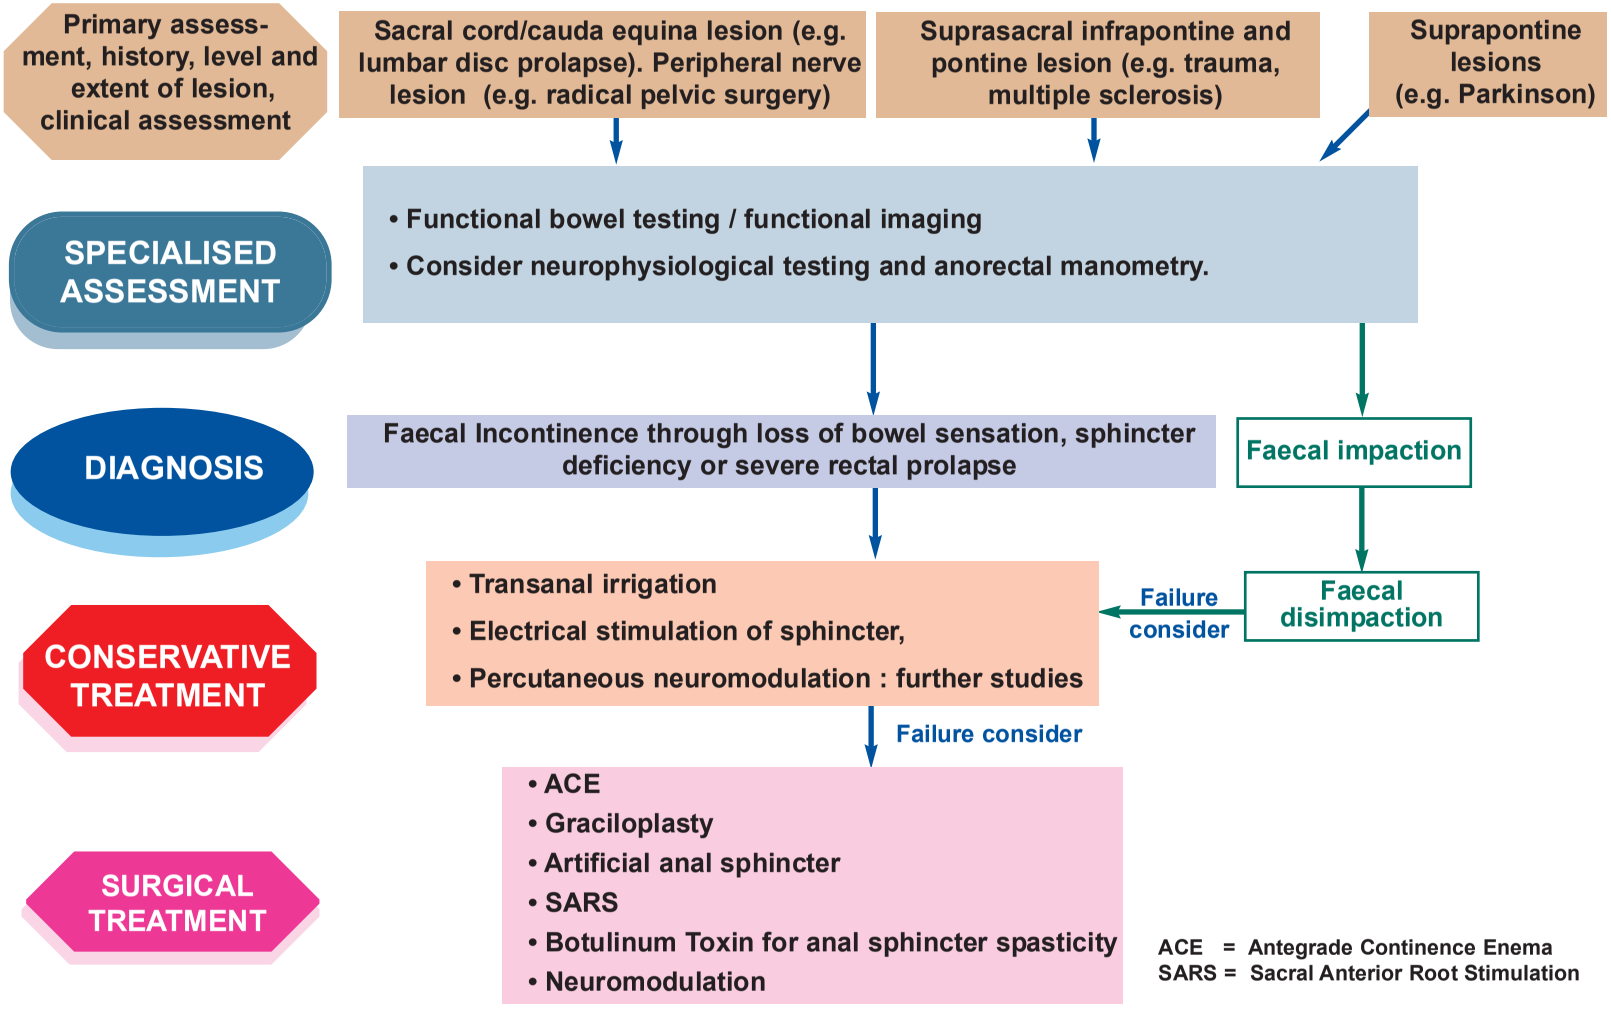
➦ Surgical management of neurogenic faecal incontinence has different options which need a very strict patient selection

- Antegrade Continence Enema ACE (C)
- Graciloplasty (C)
- Artificial sphincter (C)
- Sacral Anterior Root Stimulation SARS (C)
- Botulinum Toxin (C)
- Neuromodulation (C)

➦ It is recommended to look at urinary and bowel function together if both systems are affected, as symptoms and treatment of one system can influence the other and vice versa (A).

➦ As therapeutic approach can differ in different neurological diseases, the most prevalent diseases are discussed separately in the chapter.

Specialised Management of Neurogenic Faecal Incontinence *



Stoma/diversion may be an option in selected cases

* At any stage of the patient's care pathway, management may need to include continence products

X. URINARY AND FAECAL INCONTINENCE IN FRAIL OLDER MEN AND WOMEN

There is no reason to suspect why interventions which have proven efficacy in the community dwelling elderly should not also be effective in frail older people. Clinicians should, however, take due regard of the practicality, potential benefits and dangers of employing any single intervention in this population. Frail older people do require a different approach addressing the potential role of co-morbid disease, current medications (prescribed, over the counter and/or naturopathic), and functional and cognitive impairment in urinary and faecal incontinence. The extent of the investigation and management should take into account the degree of bother to the older person and/or caregiver, the goals for care, the degree that the older person is able to undertake any intervention and the overall prognosis and life expectancy. Effective management to meet the goals of care should be possible for most frail older people.

I. HISTORY AND SYMPTOM ASSESSMENT

- Active case finding for urinary and faecal incontinence should be done in all frail older people (Grade A). History should include comorbid conditions and medications that could cause or worsen incontinence. Physical examination should include a rectal examination for faecal loading or impaction (Grade C), functional assessment (mobility, transfers, manual dexterity, dressing and undressing ability, ability to toilet) (Grade A), a screening test for depression (Grade B), and cognitive assessment (to assist in planning and management, (Grade C)). The mnemonic DIPPERS (see urinary and faecal incontinence algorithms) covers some of these comorbid conditions. Note that urogenital atrophy does not, in itself, cause urinary incontinence and should not be treated for this purpose (Grade B). The patient and / or caregiver should be asked about the degree of bother of urinary incontinence and/or faecal incontinence(Grade B); goals for urinary and faecal incontinence care (dryness, decrease in specific symptoms, quality of life, reduction of comorbidity, lesser care burden) (Grade B); and likely cooperation with management (Grade C).
- Evaluation for bowel “alarm” symptoms (rectal bleeding, positive blood screening from stool studies, obstructive symptoms, recent onset of constipation, weight loss, and a change in stool calibre) will need more extensive evaluation (Grade A)
- Urinalysis is recommended for all patients, primarily to screen for haematuria (Grade C). Treatment of otherwise asymptomatic bacteriuria/pyuria is not beneficial (Grade C), and it may cause harm by increasing the risk of antibiotic resistance and severe adverse effects. e.g., *Clostridium difficile colitis* (Grade C).
- Stool studies may not be needed in all patients with faecal incontinence. Patients with diarrhoea, especially those with more acute onset diarrhoea, may need to be tested for infectious causes of their diarrhoea. Other stool studies could involve testing for malabsorption syndromes.
- The utility of the Clinical Stress test in this population is uncertain (Grade D).
- Wet checks can assess urinary incontinence frequency in long-term care residents (Grade C):

  A post voiding residual volume (PVR) test is impractical in many care settings and there is no consensus for the definition of what constitutes a “high” PVR in any population. A PVR measurement is **not** recommended in the routine initial assessment of frail older people with urinary incontinence.
- However, there is compelling clinical experiential evidence for PVR testing in selected frail older people with: diabetes mellitus (especially long standing); prior urinary retention or high PVR; recurrent UTIs; medications that impair bladder emptying (e.g., opiates); severe constipation; persistent or worsening urgency urinary incontinence despite antimuscarinic treatment; or prior urodynamics showing detrusor underactivity and/or bladder outlet obstruction (Grade C). Treatment of contributing comorbidity may reduce PVR. Trial with catheter may be considered for PVR > 200-500 ml if the PVR is felt to contribute to UI or urinary frequency (Grade C).
- **Nocturia** Assessment of frail elders with bothersome nocturia should identify potential underlying causes including nocturnal polyuria (by bladder diary/frequency-volume chart or wet checks; oedema on examination) (Grade C),primary sleep problems (e.g., sleep apnoea); and low voided volumes (e.g., from high PVR).
- Stool impaction/ loading. If suspected on digital rectal examination, an abdominal x-ray may be necessary to further evaluate the degree and location of impaction /loading in frail older adults.

II. CLINICAL DIAGNOSIS

The most common types of Urinary Incontinence in frail older people are urgency, stress, and mixed urinary incontinence. Frail older people with urgency urinary incontinence also may have detrusor underactivity and high PVR (without outlet obstruction). There is no evidence that antimuscarnincs are less effective or cause retention in this situation (Grade D).

The most common types of faecal incontinence in frail older people are related to urgency and passive leakage. Passive leakage can refer to leakage, seepage and staining following bowel movements that are not associated with faecal urgency and may also occur with faecal impaction. Because constipation and impaction often contribute to faecal incontinence in older adults, these are considered separately in the algorithm.

III. INITIAL MANAGEMENT

- Initial treatment should be individualised and influenced by goals of care, treatment preferences and estimated remaining life expectancy, as well as the most likely clinical diagnosis (Grade C). In some frail older persons the only possible outcome may be containment; management with continence products, especially for people with minimal mobility (require assistance of $\geq$ 2 people to transfer), advanced dementia (unable to state their name), and /or nocturnal urinary and faecal incontinence.
- Conservative and behavioural therapy for UI includes lifestyle changes (Grade C), bladder training for more fit alert persons (Grade B), and prompted voiding for frailer, more impaired older people (Grade A).
- For the select cognitively intact older person with UI or FI, pelvic floor muscle therapy can be considered, but there are few studies (Grade C). Antimuscarinics may be added to conservative therapy of urgency UI (Grade A-C, depending on agent).
- For the select cognitively intact older with FI, biofeedback may be considered, but few studies exist among frail older adults.
- Alpha-blockers may be cautiously considered in frail men with suspected prostatic outlet obstruction (Grade C). All drugs should be started at the lowest dose and titrated with regular review until either care goals are met or adverse effects are intolerable.
- DDAVP (vasopressin) has a high risk of severe hyponatraemia in frail older persons and should not be used outside specialist centres (Grade A).
- Improving stool consistency can be done with dietary fibre and supplementary fibre in older adults (Grade C). In older adults with diarrhoea, loperamide may be considered at low doses to improve stool consistency. However, close monitoring for constipation and impaction is needed.

IV. ONGOING MANAGEMENT AND REASSESSMENT

Optimal urinary and faecal incontinence management is usually possible with the above approaches. If initial management fails to achieve the desired goals the next steps are reassessment and treatment of contributing comorbidity and/or functional impairment.

V. SPECIALISED MANAGEMENT

If frail older people have either other significant factors (e.g., pain, haematuria, bowel “alarm” symptoms), UI or FI symptoms that cannot be classified as urgency, stress, or mixed or overflow or other complicated comorbidity which the primary clinician cannot address (e.g. dementia, functional impairment), then specialist referral should be considered. Referral may also be appropriate when there is been insufficient response to initial management. The type of specialist will depend on local resources and the reason for referral: surgical specialists (urologists, gynecologists, colorectal surgeons), gastroenterologists, geriatricians or physical therapist (functional and cognitive impairment); or continence nurse specialists (homebound patients). Referral decisions should consider goals of care, patient/caregiver desire for invasive therapy and estimated remaining life expectancy.

Age *per se* is not a contraindication to UI or FI surgery (Grade C), but before surgery is considered, all patients should have:

- evaluation and treatment for any comorbidity, medications, and cognitive or functional impairments contributing to UI that could compromise surgical outcome (e.g., dementia that precludes patient ability to use artificial sphincter) (Grade C)
- adequate trial of conservative therapy, including pharmacological therapies where relevant (Grade C)
- discussion (including the caregiver) to ensure that the anticipated surgical outcome is consistent with goals of care in the context of the patient’s remaining life expectancy (Grade C)
- urodynamic testing or anorectal manometry, because clinical diagnosis may be inaccurate (Grade B)
- preoperative assessment and perioperative care to establish risk for and to minimize common geriatric post-operative complications such as delirium and infection (Grade A), dehydration and falls (Grade C).

Management of Urinary Incontinence in Frail Older Men & Women

HISTORY/SYMPTOM ASSESSMENT

CLINICAL ASSESSMENT

- **D**elirium
- **I**nfection
- **P**harmaceuticals
- **P**sychological
- **E**xcess urine output
- **R**educed mobility
- **S**tool impaction

(and their factors)

Avoid overtreatment of asymptomatic bacteriura

CLINICAL DIAGNOSIS

* These diagnoses may overlap in various combinations, e.g., Mixed UI, DHIC (see text)

INITIAL MANAGEMENT *

(if Mixed UI, initially treat most bothersome symptoms)

ONGOING REASSESSMENT and MANAGEMENT

Active Case Finding in all Frail Elderly people

- **Assess, treat and reassess potentially treatable conditions, including relevant comorbidities and ADLs (see text)**
- **Assess QoI, desire for Rx, goals for Rx, patient & caregiver preferences**
- **Targeted physical examination (cognition, mobility, neurological and digital rectal examination)**
- **Urinalysis**
- **Consider bladder diary or wet checks, especially if nocturia is present. PVR in specific patients (see text)**

UI associated with:

- Pain
- Haematuria
- Recurrent symptomatic UTI
- Pelvic mass
- Pelvic irradiation
- Pelvic / LUT surgery
- Prolapse beyond introitus (women)
- Suspected fistula

URGENCY UI*

- **Lifestyle interventions**
- **Behavioural therapies**
- **Consider trial of antimuscarinic drugs**

SIGNIFICANT PVR*

- **Treat constipation**
- **Review medications**
- **Consider trial of alpha-blocker (men)**
- **Catheter drainage if PVR 200-500 ml, then reassess (see text)**

STRESS UI*

- **Lifestyle interventions**
- **Behavioural therapies (See text)**

*** Other**

If insufficient improvement, reassess for and treat contributing comorbidity ± functional impairment

If continued insufficient improvement, or severe associated symptoms are present, consider specialist referral as appropriate per patient preferences and comorbidity (see tex)

* At any stage of the patient's care pathway, management may need to include continence products

Management of Faecal Incontinence in Frail Older Men & Women

HISTORY/SYMPTOM ASSESSMENT

Active Case Finding in all Frail Elderly people

FI associated with:
- Pain
- Rectal bleeding
- Change in stool calibre
- Weight loss
- Chronic diarrhoea
- Faecal impaction
- Inflammatory bowel disease
- Pelvic irradiation
- Malabsorption syndromes
- Prolapse beyond introitus (women)
- Suspected fistula

CLINICAL ASSESSMENT

Rx reversible causes:
- Delirium
- Infection
- Pharmaceuticals
- Psychological
- Excess stool output (diarrhoea)
- Reduced mobility
- Stool impaction (and their factors)

- Assess, treat and reassess potentially treatable conditions, including relevant comorbidities and ADLs (see text)
- Assess QoI, desire for Rx, goals for Rx, pt & caregiver preferences
- Targeted physical examination (cognition, mobility, neurological and digital rectal examination)
- Urinalysis
- Consider bowel diary and clean checks, especially if nocturia is present. PVR is specific patients (see text)

CLINICAL DIAGNOSIS

** These diagnoses may overlap in various combinations, e.g., Urgency-related,passive/seepage, and impaction (see text)

Urgency FI**

Constipation/ Faecal Impaction*

Passive FI*

*** Other**

INITIAL MANAGEMENT *

- Lifestyle interventions
- Behavioural therapies
- Biofeedback
- Improve stool consistency

- Treat constipation (osmotic laxatives) If impacted, Glycerine or Bisacodyl suppositories. Phospate enemas if severe.
- Review medications that may contribute to constipation
- Consider biofeedback if dyssynergic defaecation is suspected

- Lifestyle interventions
- Behavioural therapies
- Biofeedback
- Improve stool consistency

ONGOING REASSESSMENT and MANAGEMENT

If insufficient improvement, reassess for and treatment of contributing comorbidity ± functional impairment

If continued insufficient improvement, or severe associated symptoms are present, consider specialist referral as appropriate per patient preferences and comorbidity (see tex)

* At any stage of the patient's care pathway, management may need to include continence products

4. Recommendations for Further Research in Epidemiology

1. Longitudinal study designs are needed to: (i) estimate the incidence and remission rates of urinary incontinence (UI) anal incontinence (AI) and pelvic organ prolapse (POP) and to (ii) describe the natural course of these conditions and (iii) to investigate risk factors and possible protective factors. In addition similar studies regarding other lower urinary tract symptoms (LUTS) should be initiated.
2. Although there is today more information regarding prevalence, incidence, and other epidemiological data in developing countries further information is still needed. It is recommended that fundamental research regarding prevalence, incidence and other epidemiological data in developing countries should be encouraged, and tailored to the cultural, economic and social environment of the population under study.
3. Some potential risk and protective factors deserve more attention. For example, the role of pregnancy and childbirth in the development of UI, AI and POP must be studied in a fashion that links population-based methods to clinical assessment of pregnancy, delivery and birth trauma and follows women over many years. Such a design is necessary because the effect of pregnancy and childbirth may become clear only years later when the woman is older and because the woman will not then be able to report the exact nature of the tear, episiotomy, etc.
4. There should be more emphasis on the associations between UI, AI and POP and specific diseases like stroke, diabetes, and psychiatric diseases.
5. The variation of disease occurrence in groups of different racial origin yet similar environmental exposures, lend support to the presumed genetic influence on the causation of UI, AI and POP. This again provides circumstantial evidence for a genetic contribution to pelvic floor muscle disorders since most of these studies have been unable to control for heritability in relation to the complex interaction of environmental factors.

   The aetiology of UI, AI and POP is widely recognised to be multifactorial, yet the complex interaction between genetic predisposition and environmental influences is poorly understood. Genetic components require further investigation. Twin studies provide a possible means of studying the relative importance of genetic predisposition and environmental factors. By comparing monozygotic female twins with identical genotype, and dizogytic female twins who on average share 50 percent of their segregating genes, the relative proportions of phenotypic variance resulting from genetic and environmental factors can be estimated. A genetic influence is suggested if monzygotic twins are more concordant for the disease than dizygotic twins whereas evidence for environmental effects comes from monozygotic twins who are discordant for the disease.

5. Recommendations for Further Basic Science Research

1. Integrate data from reductionist experiments to inform the formulation of better systems-based approaches in the investigation of the pathology of the lower urinary tract (LUT), the genital tract (GT) and the gastro-intestinal tract (GIT).
2. Encourage greater emphasis on basic research to characterise tissues receiving relatively little attention: ie the lower gastrointestinal tract; the bladder neck and urethra.
3 Generate improved experimental approaches to investigate the pathophysiology of the LUT and GIT by:
   - developing fully-characterised animal models
   - using human tissue from well-characterised patient groups.
   - developing emerging areas such as: tissue engineering; protein structure modelling
   - increasing collaborations between biological, physical and mathematical sciences.
4. Use genome-wide bioinformatic surveys to generate testable hypotheses regarding the physiological and pathophysiological functions of the LUT and GIT
5. Develop centres of excellence in LUT and GIT research
   - integrate expertise from university departments, academic medical units and industry
   - encourage translational approaches to research.
   - develop inter-institutional research-training programmes to allow new researchers the opportunity to better interact and exchange ideas

6. Bring about a greater emphasis on the importance of research to medical trainees through:

- establishing research training as a core component of medical training
- increased access to support funds, especially scholarships and personal awards
- organisation of focused multidisciplinary research meetings, either stand-alone or as dedicated sessions during international conferences
- greater interaction between medical centres and Higher Education Institutions (HEIs)
- allow researchers-in-training better access to international meetings through reduced registration charges and travel grants.
- Lobby research-funding organisations about the medical and social importance of LUT and GIT disorders.

7. Increase emphasis on research into lower urinary tract and gastro-intestinal tract in HEIs through:

- greater representation on grant-funding agencies
- encouragement of submission to high impact-factor journals and recognition of research published in specialty journals
- more integrated teaching and training opportunities

6. Recommendations

Continence Promotion, Education and Primary Prevention

Continence promotion, service delivery, education, and primary prevention involves informing and educating the public and health care professionals that urinary and faecal incontinence are not inevitable, but are treatable or at least manageable. In addition, other bladder disorders such as bladder pain syndrome and pelvic organ prolapse can be treated successfully. Progress continues to be made in the promotion of continence awareness through advocacy programmes and public access to information on a worldwide basis. Professional education of these conditions has increased. However, screening and help-seeking behaviour have not noticeably improved. Published studies focus on developing better models of existing service provision and education, rather than testing new strategies to increase screening. There have been advances in primary prevention of urinary incontinence.

CONTINENCE AWARENESS AND PROMOTION

- Continence awareness should be part of mainstream and on-going health education and advocacy programmes with emphasis on eliminating stigma, raising awareness of effective treatments, promoting help-seeking behaviour and improving QoL.
- Continence awareness programmes should include education, health-care, and community service providers.
- Research is needed to provide higher level of evidence on the effectiveness of continence promotion programmes to include:
  - º Identification and understanding of barriers to help-seeking behaviours
  - º Translation of promotion research into improved clinical practice and identification of methods by which this occurs.
  - º Effectiveness and impact of consumer education initiatives.

CONTINENCE ADVOCACY AND MODELS OF SERVICE DELIVERY

- There is a need to move beyond the theory and work on research about the practice of continence care delivery and education. We recommend a care delivery model based on a chronic disease approach.
- There needs to be an increased emphasis on non-physician models of care (nursing, nurse practitioner, continence advisor, physiotherapy, physician assistants, etc.).
- Despite the proliferation of guidelines, there is increasing evidence that they are not being followed by practicing clinicians. Implementation models should be developed on how to translate guidelines into practice.
- There still appears to be a shortage of physician specialists in continence care (urology, gynaecology, etc.) and this needs to be addressed. (**Grade D)**
- Research is needed on the activities or effectiveness of organisations that target consumers or the general public.

PROFESSIONAL EDUCATION

- There remains a need for rigorously evaluated continence education programmes which adhere to defined minimum standards for continence specialists and generalists, utilising web-based and distance learning techniques alongside audit and feedback, train-the trainer models and leadership models as well as traditional methods.
- Models of education content delivery (professional and patient education) are changing with technology with increased emphasis on internet, web modules, etc. There needs to be ongoing quality control that includes maintenance of accuracy, methods of delivery, etc.
- There is a need for research on the most effective means to educate professional groups on continence issues to include:
  - The effectiveness of innovative teaching methods in improving knowledge and practice.
  - Translation of research into improved clinical practice and identification of methods by which this happens.
  - Mechanisms for increasing professional motivation to acquire education and improve performance.

PRIMARY PREVENTION:

- Primary prevention studies should not be limited to individual interventions, but also test the impact of population-based public health strategies **(Grade C)**
- More high quality randomised controlled trials are needed to strengthen the effectiveness of population-based primary prevention intervention.

7. Recommendations for Clinical Research Methodology

PART I: RECOMMENDATIONS ON STUDY CONDUCT AND STATISTICAL METHODS

The role of quality RCTs as providing the strongest level of evidence in incontinence research should be fully acknowledged by researchers, journal reviewers, and editors. HIGH

Careful attention to the planning and design of all research, especially RCTs, is of the utmost importance. HIGH

Appropriate expertise in biostatistics and clinical trial design should be employed at the design phase of a RCT and thereafter on an ongoing basis. HIGH

The design, conduct, analysis and presentation of RCTs must be fully in accordance with the CONSORT Statement. HIGH

The design, conduct, analysis and presentation of observational studies should follow STROBE guidelines. HIGH

The design, conduct, analysis and presentation of meta-analyses should follow QUORUM guidelines. HIGH

Reporting studies of diagnostic tests, including urodynamics, should follow the STARD statement guidelines. HIGH

PART II: RECOMMENDATIONS ON RESEARCH CONDUCT

RECOMMENDATIONS FOR CONSERVATIVE TREATMENT TRIALS

Use correct terminology to describe the intervention. HIGH

Report details of ability to perform correct contraction, dose-response issues and adherence. HIGH

Use recommended outcome measures with high responsiveness, reliability and validity. HIGH

Compare new methods with the best available intervention. HIGH

Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions. HIGH

For long-term follow-up studies report cross-over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up.

RECOMMENDATIONS FOR SURGICAL AND DEVICE TRIALS

- The safety and serious side effects of new operations must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicenter cohort studies when RCTs are not practical. HIGH
- Safety and serious side effects of incontinence devices must be completely defined with adequate follow-up, especially for use of implantable devices and biologic materials, so that risks can be weighed against efficacy.HIGH
- Valid informed research consent is required in all trials of surgical interventions, which is separate from the consent to surgery. HIGH
- We recommend ongoing research into the usefulness of pre- and post-operative predictive testing (such as urodynamics, ultrasound, MRI, etc) in surgical trials. HIGH
- Reports of successful treatment should be limited to subjects with a minimum (not mean) of one year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated. HIGH
- Randomisation for surgical trials should occur at the time of surgery to minimize drop-outs and switch of procedure HIGH
- Long-term follow-up of RCT cohorts in an observational cohort is recommended HIGH

RECOMMENDATIONS ON COST ANALYSIS IN INCONTINENCE

- Cost analysis should be incorporated into clinical studies whenever possible (137). HIGH

Part III: RECOMMENDATIONS FOR SPECIFIC PATIENT GROUPS

IIIa: MEN WITH LUTS

- Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a variable, or to change during the intervention and follow up. HIGH
- Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. HIGH
- Participants should be stratified by prostate size at randomization when size is considered to be a potentially important determinant of treatment outcome. LOW

IIIb: WOMEN WITH LUTS

- Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. HIGH
- High quality, symptom and bother scores (e.g.,ICIQ-FLUTS, ICIQ-SM, KHQ, PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes. HIGH
- Standardized assessment of pelvic organ prolapse should be performed before treatment and at the time of other outcome assessments in all research where prolapse and continence outcomes are being assessed. HIGH
- Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests. HIGH
- Assessment of the impact of treatment on sexual function should be performed with other outcome assessment when appropriate. MEDIUM

IIIc: CHILDREN

- Long-term follow-up is of critical importance in the paediatric population in order to ascertain the effect of a treatment on normal growth and development. HIGH
- Research is needed to develop standardised outcome measures including validated, age-specific symptom and disease-specific quality of life outcome measures. MEDIUM

IIId: NEUROGENIC POPULATIONS

- Detailed urodynamic studies are recommended for classification of neurogenic lower urinary tract

disorders in research studies because the nature of the lower tract dysfunction cannot be accurately predicted from clinical data. Videourodynamic studies are preferred but are not mandatory. LOW

- An area of high priority for research is the development of a classification system to define neurogenic disorders. Relevant features could include the underlying diagnosis, the symptoms, more precise documentation of the neuromuscular lesion by clinical neurophysiologic testing, and the nature of the urodynamic abnormality. LOW

IIIf: POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS)

- Broader entry criteria should be used to reflect the full spectrum of the BPS/IC patient population. MEDIUM
- The primary endpoint of BPS/IC trials should be patient driven and the Global Response Assessment is recommended. A wide spectrum of secondary endpoints will be useful in defining the effect of treatments. MEDIUM

IIIg: POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

- A validated standardised assessment of prolapse (eg POP-Q) should be used for baseline and outcome assessments. HIGH
- Complete reporting of outcomes including a validated assessment of anatomy, functional status, and complications is essential. HIGH
- Complications/adverse events (especially for mesh) must be explicitly and completely reported in any research. HIGH
- Long term outcomes (> 2 years) of intervention studies are needed. HIGH

IV. RECOMMENDATIONS FOR ETHICS IN RESEARCH

Continuity in clinical direction from design through authorship is mandatory. Investigators should be involved in the planning stage and a publications committee should be named at the beginning of the clinical trial. The Uniform Requirements for Manuscripts Submitted to Biomedical Journals, from the International Committee of Medical Journal Editors should be followed. Authorship requires:

- Substantial contributions to conception and design or acquisition of data or analysis and interpretation of data,
  - Drafting the article or revising it critically for important intellectual content,
  - Final approval of the version to be published
- Authors should provide a description of what each contributed and editors should publish that information.
- Authors should have access to all raw data from clinical trials, not simply selected tables

Clinical trial results should be published regardless of outcome. The sponsor should have the right to review manuscripts for a limited period of time prior to publication but the manuscript is the intellectual property of its authors, not the sponsor.

- All authors should be able to accept responsibility for the published work and all potential conflicts of interest should be fully disclosed

International Consultation on Incontinence Modular Questionnaire (ICIQ)

The scientific committee which met at the end of the 1st ICI in 1998 supported the idea that a universally applicable questionnaire should be developed, that could be widely applied both in clinical practice and research.

The hope was expressed that such a questionnaire would be used in different settings and studies and would allow cross-comparisons, for example, between a drug and an operation used for the same condition, in the same way that the IPSS (International Prostate Symptoms Score) has been used.

An ICIQ Advisory Board was formed to steer the development of the ICIQ, and met for the first time in 1999. The project's early progress was discussed with the Board and a decision made to extend the concept further and to develop the ICIQ Modular Questionnaire to include assessment of urinary, bowel and vaginal symptoms. The first module to be developed was the ICIQ Short Form Questionnaire for urinary incontinence: the ICIQ-UI Short Form. The ICIQ-UI Short Form has now been fully validated and published [2].

Given the intention to produce an internationally applicable questionnaire, requests were made for translations of the ICIQ-UI Short Form at an early stage, for which the Advisory Board developed a protocol for the production of translations of its modules. The ICIQ-UI Short Form has been translated into 30 languages to date. Two further, newly developed and fully validated, modules have been finalised since the third consultation and are now being incorporated into clinical practice and research, and translated accordingly for international use. The ICIQ-VS[7] provides evaluation of vaginal symptoms and the ICIQ-B [3] can be used to assess bowel symptoms including incontinence. Both questionnaires also provide assessment of the impact of these symptoms on quality of life (**Table 1**).

Where high quality questionnaires already existed within the published literature, permission was sought to include these within the ICIQ in order to recommend them for use. Eleven high quality modules have been adopted into the ICIQ which are direct (unchanged) derivations of published questionnaires (Table 1).

www.ICIQ.net provides details of the validation status of the modules under development for urinary symptoms, bowel symptoms and vaginal symptoms and provides information regarding the content of existing modules. Information regarding production of translations and the ICIQ development protocol is also available for those interested in potential collaborations to continue development of the project.

ICIQ-UI on Urinary Incontinence Questionnaire (short form)

Initial number **CONFIDENTIAL** DAY MONTH YEAR
Today's date

Many people leak urine some of the time. We are trying to find out how many people leak urine, and how much this bothers them. We would be grateful if you could answer the following questions, thinking about how you have been, on average, over the PAST FOUR WEEKS.

1 Please write in your date of birth: DAY MONTH YEAR

2 Are you *(tick one)*: Female ☐ Male ☐

3 How often do you leak urine? *(Tick one box)*

never ☐	0
about once a week or less often ☐	1
two or three times a week ☐	2
about once a day ☐	3
several times a day ☐	4
all the time ☐	5

4 We would like to know how much urine you think leaks.
How much urine do you usually leak (whether you wear protection or not)?
(Tick one box)

none ☐	0
a small amount ☐	2
a moderate amount ☐	4
a large amount ☐	6

5 Overall, how much does leaking urine interfere with your everyday life?
Please ring a number between 0 (not at all) and 10 (a great deal)

0 1 2 3 4 5 6 7 8 9 **10**
not at all — a great deal

ICIQ score: sum scores 3+4+5 ☐☐

6 When does urine leak? *(Please tick all that apply to you)*

never – urine does not leak ☐
leaks before you can get to the toilet ☐
leaks when you cough or sneeze ☐
leaks when you are asleep ☐
leaks when you are physically active/exercising ☐
leaks when you have finished urinating and are dressed ☐
leaks for no obvious reason ☐
leaks all the time ☐

Thank you very much for answering these questions.

Table 1. Fully validated ICIQ modules and derivation

MODULES AVAILABLE FOR USE	
ICIQ – MLUTS (IC*Smale* Short Form [4])	Urinary symptoms (male)
ICIQ – FLUTS (BFLUTS Short Form [5])	Urinary symptoms (male)
ICIQ-VS [2]	Vaginal symptoms
ICIQ-B [3]	Bowel symptoms
ICIQ - UI Short Form [1]	Urinary incontinence short form
ICIQ – N (IC*Smale* [6]/ BFLUTS [7])	Nocturia
ICIQ – OAB (ICSmale [6]/ BFLUTS [7])	Overactive bladder
ICIQ – MLUTS Long Form (IC*Smale* [6])	Urinary symptoms long form (male)
ICIQ – FLUTS Long Form (BFLUTS [7])	Urinary symptoms long form (female)
ICIQ – LUTSqol (KHQ [8])	Urinary symptoms quality of life
ICIQ – Nqol (N-QOL [9])	Nocturia quality of life
ICIQ – OABqol (OABq [10])	Overactive bladder quality of life
ICIQ – MLUTSsex (IC*Smale* [6])	Sexual matters related to urinary symptoms (male)
ICIQ – FLU7])	(female)

Annex 1 : Bladder Charts and Diaries

The ICS defines three types of Bladder Charts and Diaries which can be used to collect data:

Micturition Time Chart

• times of voiding and

• incontinence episodes

Frequency Volume Chart

• times of voiding with voided volumes measured,

• incontinence episodes and number of changes of incontinence pads or clothing.

Bladder Diaries

• the information above, but also

• assessments of urgency,

• degree of leakage (slight, moderate or large) and descriptions of factors leading to symptoms such as stress leakage, eg. running to catch a bus

It is important to assess the individual's fluid intake, remembering that fluid intake includes fluids drunk plus the water content of foods eaten. It is often necessary to explain to a patient with LUTS that it may be important to change the timing of a meal and the type of food eaten, particularly in the evenings, in order to avoid troublesome nocturia.

The micturition time and frequency volumes charts can be collected on a single sheet of paper (Fig. 1). In each chart/diary, the time the individual got out of bed in the morning and the time they went to bed at night should be clearly indicated.

Each chart/diary must be accompanied by clear instructions for the individual who will complete the chart/diary: the language used must be simple as in the suggestions given for patient instructions. There are a variety of designs of charts and diaries and examples of a detailed bladder diary are given. The number of days will vary from a single day up to one week.

INSTRUCTIONS FOR COMPLETING THE MICTURITION TIME CHART

This chart helps you and us to understand why you get trouble with your bladder. The diary is a very important part of the tests we do, so that we can try to improve your symptoms. On the chart you need to record:

1. When you get out of bed in the morning, show this on the diary by writing 'GOT OUT OF BED'.
2. The time, eg. 7.30am, when you pass your urine. Do this every time you pass urine throughout the day and also at night if you have to get up to pass urine.
3. If you leak urine, show this by writing a 'W' (wet) on the diary at the time you leaked
4. When you go to bed at the end of the day show it on the diary - write 'WENT TO BED'.

INSTRUCTIONS FOR USING THE FREQUENCY VOLUME CHART

This chart helps you and us to understand why you get trouble with your bladder. The diary is a very important part of the tests we do, so that we can try to improve your symptoms. On the chart you need to record:

1. When you get out of bed in the morning, show this on the chart by writing 'Got out of bed'.
2. The time, eg. 7.30am when you pass your urine. Do this every time you pass urine throughout the day and also at night if you have to get up to pass urine.
3. Each time you pass urine, collect the urine in a measuring jug and record the amount (in mls or fluid ozs) next to the time you passed the urine, eg. 1.30pm - 320 mls.
4. If you leak urine, show this by writing 'W' (wet) on the diary at the time.
5. If you have a leak, please add 'P' if you have to change a pad and 'C' if you have to change your underclothes or even outer clothes. So, if you leak and need to change a pad, please write 'WP' at the time you leaked.
6. At the end of each day please write in the column on the right the number of pads you have used, or the number of times you have changed clothes.

When you go to bed at the end of the day show it on the diary - write 'Went to Bed'

INSTRUCTIONS FOR USING THE BLADDER DIARY

This diary helps you and us to understand why you get trouble with your bladder. The diary is a very important part of the tests we do, so that we can try to improve your symptoms. On the chart you need to record:

1. When you get out of bed in the morning, show this on the diary by writing 'GOT OUT OF BED'.
2. During the day please enter at the correct time the drinks you have during the day, eg. 8.00am - two cups of coffee (total 400 ml).
3. The time you pass your urine, eg. 7.30am. Do this every time you pass urine throughout the day and night.
4. Each time you pass urine, collect the urine in a measuring jug and record the amount (in mls or fluid ozs) next to the time you passed the urine, eg. 1.30pm/320ml.
5. Each time you pass your urine, please write down how urgent was the need to pass urine:

'O' means it was not urgent.
+ means I had to go within 10 minutes.
++ means I had to stop what I was doing and go to the toilet.

6. If you leak urine, show this by writing an 'W' on the diary at the time you leaked.
7. If you have a leak, please add 'P' if you have to change a pad and 'C' if you have to change your underclothes or even outer clothes. So if you leak and need to change a pad, please write 'WP' at the time you leaked.
8. If you have a leakage please write in the column called 'Comments' whether you leaked a small amount or a large amount and what you were doing when you leaked, eg. 'leaked small amount when I sneezed three times'.
9. Each time you change a pad or change clothes, please write in the 'Comments' column.
10. When you go to bed at the end of the day show it on the diary - write 'Went to Bed'.

Frequency - Volume chart - Standard Version - 7 days

Cell Biology

I. INTRODUCTION 111
II. INTERSTITIAL CELLS: THEIR ROLES IN MUSCLE AND SUBUROTHELIAL LAYERS 111
1. IMMUNOHISTOCHEMICAL MARKERS USED TO CHARACTERIZE BLADDER INTERSTITIAL CELLS 112
2. STRUCTURAL IMMUNOHISTOCHEMICAL MARKERS USED TO IDENTIFY INTERSTITIAL CELLS 113
a) Suburothelial interstitial cells 113
b) Surface muscle interstitial cells 114
c) Intramuscular interstitial cells 114
d) Muscle coat interstitial cells 115
3. FUNCTIONAL CHARACTERISTICS OF INTERSTITIAL CELLS 115
a) Suburothelial interstitial cells 115
b) Interstitial cells in the detrusor layer 115
III. THE UROTHELIUM – STRUCTURE AND FUNCTION 117
1. RELEASE OF TRANSMITTERS 118
a) Stimuli for release 118
b) Transmitter chemicals, ATP 118
c) Transmitter chemicals, acetylcholine 119
2. UROTHELIAL ION TRANSPORT AND PERMEABILITY 119
a) Urothelial ion transport 119
b) Urinary tract infections 120
3. FUNCTIONAL INTERACTIONS WITH THE DETRUSOR LAYER 120
a) Urothelium-derived relaxing factors 120
b) Contractile activity of the mucosa 120
c) Interaction between mucosa and detrusor 121
IV. DETRUSOR SMOOTH MUSCLE CONTRACTILE ACTIVATION 122
1. SMOOTH MUSCLE CELLS 122
2. CONTRACTILE PROTEIN ISOFORMS AND THE CONTRACTILE MACHINERY 123
a) Myosin 123
b) Actin isoforms 124
c) Actin-associated proteins in the thin filaments 124
3. CONTRACTILE ACTIVATION OF SMOOTH MUSCLE 124
a) Receptor-mediated activation of detrusor smooth muscle 124
b) Molecular mechanisms for activation of the contractile machinery 125
c) Role of the Ca2+-sensitization pathway in the regulation of the myosin-mediated pathway for smooth muscle contraction 125
d) The role of thin filament-mediated regulation of contraction 126
e) Smooth muscle relaxation 126
f) Alterations to contractile and regulatory proteins in lower urinary tract dysfunction 127
4. SPONTANEOUS ACTIVITY 127
a) The origin of spontaneous activity 127
b) The myogenic hypothesis 128
c) The neurogenic hypothesis 129
5. ELECTRICAL ACTIVITY AND ION CHANNELS 129
V. THE OUTFLOW TRACT 129
1. TRIGONE 129
a) Developmental origins of the trigone and insertion of the vesicoureteral junctions 130
b) Superficial and deep trigone 131
2. THE URETHRA AND SPHINCTER MECHANISMS 131
a) Bladder-urethral coordination 131
b) The internal sphincter 132
c) External urethral sphincter (EUS) 134
d) Consequences of EUS dysfunction and treatments 134
3. PROSTATE 134
a) Prostatic lobes and their cellular components 134
b) Prostatic innervation and its role in seminal fluid secretion and emission 135
c) Benign prostatic hyperplasia (BPH), prostatitis and therapeutic approaches 136
VI. NOVEL MOLECULAR TARGETS FOR OAB AND DETRUSOR OVERACTIVITY 137
1. INTRODUCTION 138
2. SEVEN TRANSMEMBRANE SPANNING RECEPTORS (7-TM, METABOTROPIC RECEPTORS) 138
a) Acetylcholine (ACh)-muscarinic receptors 138
b) Adrenergic β-receptors 139
c) Cannabinoids, GPR18, GPR55, GPR119 139
d) GABAB 140

e) Glutamate metabotropic receptors 140
f) Prostanoid receptors 140
g) Tachykinins 141
3. LIGAND-GATED ION-CHANNELS 143
4. ION-CHANNELS 143
a) Acid-sensing (proton-gated) ion channels (ASICs) 144
b) Epithelial sodium channels (ENaC) 145
c) K+ channels 145
d) Transient receptor potential (TRP) cation channels 146
VII. BIOMARKERS FOR OAB AND DO 150
1. INTRODUCTION 150
2. URODYNAMIC FINDINGS 151
3. URINARY BIOMARKERS 152
a) Cytokines and chemokines 152
b) Prostaglandins in OAB 152
c) Urine ATP and nitric oxide (NO) 152
d) Urinary nerve growth factor (NGF) in OAB 152
4. SERUM BIOMARKERS 153
a) C-reactive protein (CRP) 153
5. BLADDER WALL IMAGING BIOMARKERS 153
a) Ultrasonography 153
b) Near-infrared spectroscopy (NIRS) and DO 154
6. CONCLUSION 154
VIII. THE LOWER GASTROINTESTINAL TRACT (ANUS AND RECTUM) AS RELEVANT TO FAECAL INCONTINENCE 155
1. INTRODUCTION 155
2. BASIC PHYSIOLOGY OF THE RECTUM AND ANUS 155
a) The internal anal sphincter (IAS) 155
3. INNERVATION OF THE RECTUM AND ANUS 156
a) Parasympathetic innervation 156
b) Sympathetic innervation 156
c) Non-adrenergic, non-cholinergic (NANC) innervation 157
d) Sensory innervation 157
4. SMOOTH MUSCLE AND INTERSTITIAL CELLS 157
a) Smooth muscle 157
b) Interstitial cells 158

Urodynamic Testing

I. INTRODUCTION 431
A. URODYNAMICS 431
I. WHAT IS URODYNAMICS? 431
II. WHAT SHOULD BE THE ROLE OF URODYNAMIC STUDIES IN CLINICAL PRACTICE? 432
III. THE TESTS OF CONVENTIONAL URODYNAMICS 433
1. UROFLOWMETRY 433
2. FILLING CYTOMETRY 433
3. PRESSURE-FLOW STUDIES (VOIDING CYSTOMETRY) 433
4. URETHRAL PRESSURE PROFILOMETRY 434

5. ABDOMINAL LEAK POINT PRESSURE 434
IV. TECHNOLOGICAL INNOVATIONS IN URODYNAMICS 434
1. AIR-CHANGED CATHETERS FOR PRESSURE MEASUREMENT 434
2. OBJECTIVE ASSESSMENT OF BLADDER SENSATION 434
3. NON-INVASIVE PRESSURE (& FLOW) MEASUREMENTS 435
4. URETHRAL RETRO-RESISTANCE PRESSURE 436
5. URETHRAL PRESSURE REFLECTOMETRY 437
6. ULTRASOUND IMAGING 437
B. URODYNAMICS: NORMAL VALUES, RELIABILITY AND DIAGNOSTIC PERFORMANCE 437
I. REPRODUCIBILITY OF FILLING CYSTOMETRY AND AMBULATORY URODYNAMICS 437
1. INTER-OBSERVER, TEST-RETEST AND PRACTICE VARIATION 437
2. SHORT-TERM (WITHIN-SESSION) REPRODUCIBILITY 438
3. INTERMEDIATE-TERM REPRODUCIBILITY 439
4. LONG-TERM REPRODUCIBILITY 439
5. REPRODUCIBILITY OF AMBULATORY URODYNAMICS 440
II. CYSTOMETRY: NORMAL VALUES 440
1. NORMAL VALUES: FILLING CYSTOMETRY AND AMBULATORY URODYNAMICS 440
2. COMPLIANCE 441
3. NORMAL SENSATIONS AND BLADDER CAPACITY 441
4. DETRUSOR (OVER-) ACTIVITY IN NORMAL SUBJECTS 442
5. INFLUENCE OF CATHETER ON VOIDING 442
III. REPRODUCIBILITY, RELIABILITY AND NORMAL VALUES OF URETHRAL PRESSURE MEASUREMENTS 443
1. NORMATIVE AND COMPARATIVE DATA FOR MAXIMUM URETHRAL CLOSURE PRESSURE 443
2. RELIABILITY OF URETHRAL PRESSURE VARIABLES 443
3. AGING 443
4. OTHER PARAMETERS AFFECTING THE MEASUREMENT OF URETHRAL CLOSURE PRESSURE 443
IV. LEAK POINT PRESSURE 444
1. INTRODUCTION 444
2. RELIABILITY OF LEAK POINT PRESSURE MEASUREMENTS 444
a) Diagnosis 444
b) Treatment 445
c) Within-patient variability 445
V. DIAGNOSTIC PERFORMANCE OF FILLING CYSTOMETRY AND AMBULATORY MONITORING 446
1. SENSITIVITY AND SPECIFICITY OF FILLING CYSTROMETRY IN OVERACTIVE BLADDER SYNDROME 446
a) Detrusor overactivity incontinence 446
b) Detrusor overactivity alone 447
c) Overactive bladder syndrome and detrusor overactivity 447
d) Distinguishing or defining characteristics of detrusor overactivity 450
e) Provocative manoeuvres 451
2. AMBULATORY URODYNAMICS: SENSITIVITY AND SPECIFICITY 452
3. THE ADJUNCT USE OF IMAGING AND ELECTROMYOGRAPHY 453
VI. THERAPEUTIC PERFORMANCE OF FILLING CYTOMETRY AND AMBULATORY MONITORING 453
1. PREDICTION OF TREATMENT RESPONSE 453
a) Filling cystometry 453
b) Ambulatory monitoring 453
C. CLINICAL APPLICATIONS OF URODYNAMIC STUDIES 454
I. PATIENT EVALUATION: WOMEN 454
1. INTRODUCTION 454
2. STRESS URINARY INCONTINENCE 455
a) Urethral pressures and severity of stress urinary incontinence 455
b) Aspects of urodynamic studies relevant to therapy for stress urinary incontinence 456
c) Prediction of failure of surgery 457
d) Voiding difficulties after surgery 457
e) Postoperative urgency 458
f) The role of urodynamic studies in predicting occult stress urinary incontinence in women due to be treated for pelvic organ prolapse 459
3. URGENCY URINARY CONTINENCE 459
a) Pathophysiology and severity of urgency urinary incontinence 459
b) Prediction of treatment response 460
4. RECOMMENDATIONS FOR URODYNAMIC STUDIES IN WOMEN WITH URINARY INCONTINENCE 460
II. PATIENT EVALUATION: MEN 461
1. INTRODUCTION 461
2. URODYNAMIC TESTING OF DETRUSOR OVERACTIVITY AND OVERACTIVE BLADDER IN MEN 461
3. LOWER URINARY TRACT SYMPTOMS RELATED TO MALE LOWER URINARY TRACT DYSFUNCTION: DETRUSOR OVERACTIVITY AND BLADDER OUTLET OBSTRUCTION 462
4. POST-PROSTATECTOMY INCONTINENCE 463
a) General 463
b) Transurethral resection of the prostate and Open Prostatectomy for benign disease 464
c) Radical Prostatectomy and Radiotherapy 464
d) Artificial urinary sphincter and male sling 466
5. NEUROLOGICAL LESIONS RELATED TO MALE INCONTINENCE 467
a) Nocturnal enuresis 467
b) Stroke 468
c) Parkinson's disease 468
d) Diabetes Mellitus (DM) 469
e) Recommendations for urodynamic investigation for men suffering from nocturnal enuresis, stroke, Parkinson's disease or DM 469
III. NEUROGENIC LOWER URINARY TRACT DYSFUNCTION 470
1. INTRODUCTION 470
2. WHAT IS USUALLY EVALUATED? 470
3. SPECIAL TESTS 470
4. NEUROGENIC DETRUSOR OVERACTIVITY INCONTINENCE 470
5. DETRUSOR-SPHINCTER DYSSYNERGIA 471
6. LEAKAGE ASSOCIATED WITH CHRONICRESIDUAL/ RETENTION OF URINE ('OVERFLOW INCONTINENCE') 471
7. REPRODUCIBILITY AND RELIABILITY OF TESTS 471
8. DOES URODYNAMIC TESTING HELP TO SELECT (OPTIMAL) TREATMENT? 471
IV. PATIENT EVALUATION: CHILDREN 472
1. INTRODUCTION 472
2. NEUROGENIC BLADDER DYSFUNCTION 473
a) Myelodysplasia 473
b) Occult spinal dysraphism 474
c) Sacral agenesis 475
d) Spinal cord injury 476
e) Cerebral palsy 477
f) Tumours 477
3. ANORECTAL MALFORMATION OR IMPERFORATE ANUS 477

4. ANATOMIC ABNORMALITIES 478
a) Posterior urethral valves 478
b) Bladder exstrophy and persistent Cloacal anomalies 479
c) Ectopic ureterocele 480
d) Vesicoureteral reflux 480
e) Urethral stricture 481
5. FUNCTIONAL DISORDERS OF THE LOWER URINARY TRACT 481
a) Diurnal incontinence 481
b) Enuresis (nocturnal) 482
6. TECHNICAL CONCERNS: RELIABILITY AND REPRODUCIBILITY OF TESTS 483
V. PATIENT EVALUATION: FRAIL ELDERLY 484
1. INTRODUCTION 484
2. ROUTINE EVALUATION 485
a) Urinary urgency incontinence 485
b) Stress urinary incontinence 486
3. EVIDENCE FOR REPRODUCIBILITY AND RELIABILITY OF URODYNAMIC TEST IN THE GERIATRIC OR FRAIL ELDERLY POPULATION 486
a) Filling cystometry 486
b) Post-void residual urine 486
c) Pressure-flow studies 486
4. EVIDENCE THAT PERFORMING URODYNAMIC TESTING IMPROVES CLINICAL OUTCOMES IN THE GERIATRIC POPULATION 487
5. THE PRACTICAL INDICATIONS FOR URODYNAMIC STUDIES AND WHICH TESTS ARE NEEDED 487
a) Post-void residual urine 487
b) Uroflowmetry 487
c) Pressure-flow studies 487

V. SUBSACRAL LESIONS (CAUDA EQUINA OR PERIPHERAL NERVES) 832
C. Neurological urinary incontinence 832
I. EPIDEMIOLOGY 832
1. NEUROLOGICAL LESION BY DISEASE LOCATION 832
a) Diseases Affecting Brain/Brainstem 832
b) Diseases of the spinal cord 833
c) Peripheral nerve problems 834
d) Other 835
II. SPECIFIC DIAGNOSTICS 835
1. HISTORY 835
2. PHYSICAL EXAMINATION 836
3. URODYNAMIC TESTS 836
a) Electromyography (EMG) during cystogram 836
b) Filling parameters 837
c) Filling technique 838
d) The outlet during voiding 838
e) Bladder sensation 838
f) Complications of urodynamic testing 838
4. SPECIAL TESTS 839
a) Bladder-cooling reflex; the ice water test (IWT) 839
b) Bethanechol supersensitivity test (BST) 840
c) Electrodiagnostic tests 840
III. CONSERVATIVE TREATMENT 843
1. OVERVIEW ACCORDING TO TYPE OF LESION 843
a) Supraspinal lesions 843
b) Suprasacral lesions 843
c) Lower motor neuron lesions 843
2. SPECIFIC INTERVENTIONS 844
a) Behavioral therapy 844
b) Catheters and appliances 846
IV. PHARMACOTHERAPY 849
1. DRUGS FOR NEUROGENIC STORAGE DYSFUNCTION 849
a) Bladder relaxants 849
b) Intravesical bladder relaxants 850
c) Drugs for sphincter deficiency 854
2. DRUGS FOR TREATING VOIDING DYSFUNCTION 854
a) Alpha-adrenergic antagonists 854
b) Botulinum toxin 854
c) Cholinomimetics 855
V. ELECTROSTIMULATION 855
1. ELECTRICAL NEUROMODULATION 855
a) Anogenital Stimulation 856
b) Pudendal Nerve Stimulation 856
c) Dorsal Genital Nerve (DGN) stimulation 856
d) Posterior tibial nerve stimulation 857
e) Repetitive transcranial magnetic stimulation 857
f) Deep brain stimulation 857
2. ELECTRICAL STIMULATION OF THE PELVIC FLOOR MUSCULATURE 858
3. INTRAVESICAL ELECTRICAL STIMULATION (IVES) 858
VI. SURGICAL TREATMENT OF URINARY INCONTINENCE 859
1. SACRAL NEUROMODULATION 859
a) Hypotheses on the modes of action of neuromodulation 859
b) Treatment of neurogenic detrusor overactivity incontinence 859
c) Sacral neuromodulation for urinary retention in neurological bladder dysfunction 861
2. DENERVATION PROCEDURES FOR TREATING REFLEX URINARY INCONTINENCE DUE TO DETRUSOR OVERACTIVITY 862
a) Peripheral bladder denervation 862
b) Isolated rhizotomy of ventral and/or dorsal sacral roots 862
c) Rhizotomy of posterior sacral roots and stimulation of the anterior sacral roots 863
3. SURGERY FOR INCONTINENCE ASSOCIATED WITH POOR BLADDER EMPTYING DUE TO DETRUSOR UNDERACTIVITY 865
a) Surgical treatment of detrusor external sphincter dyssynergia 865
b) Bladder neck incision (BNI) for detrusor-bladder neck dyssynergia (DBND) 871
4. SURGERY TO INCREASE DETRUSOR STRENGTH 872
5. STRESS URINARY INCONTINENCE (SUI) DUE TO SPHINCTERIC INCOMPETENCE 872
a) Bulking agents 873
b) Autologous Sling Procedures 874
c) Suburethral tapes 875
d) Artificial urinary sphincter (AUS) 875
e) Surgery of the bladder neck 876
f) Complete bladder neck or urethral closure 878
6. SURGICAL ALTERNATIVES EXCLUDING DENERVATION PROCEDURES TO TREAT REFLEX INCONTINENCE DUE TO NEUROGENIC DETRUSOR OVERACTIVITY 878
a) Bladder augmentation using intestinal segments 878
b) Autoaugmentation by detrusor myotomy 883
c) Bladder augmentation using biomaterials 884
d) Cutaneous continent urinary diversion 885
e) Non-continent cutaneous urinary diversion 889
D. Neurological faecal incontinence 894
I. EPIDEMIOLOGY 894
II. NEUROPHYSIOLOGY OF BOWEL DYSFUNCTION 894
III. ASSESSMENT 895
IV. CONSERVATIVE TREATMENT 895
1. BOWEL PROGRAM /BOWEL CARE 895
2. SPECIFIC TECHNIQUES 896
a) Diet 896
b) Toileting 896
c) Digital rectal stimulation 896
d) Manual stool extraction 896
3. CHEMICAL STIMULANTS 896
4. ASSISTIVE TECHNIQUES FOR DEFECATION 897

a) Abdominal massage 897
b) Anal stimulation with water streams 897
c) Transanal / Transrectal irrigation (TAI) 897
5. APPLIANCE/ASSISTIVE TECHNIQUES FOR FAECAL INCONTINENCE 897
a) Anal plug 897
b) Neuromodulation /Electrostimulation/Magnetic stimulation 897
c) Quality of life 898
V. SURGICAL TREATMENT 898
1. SACRAL NERVE STIMULATION 899
2. ANTEGRADE CONTINENCE ENEMA (ACE) 901
3. DYNAMIC GRACILOPLASTY 903
4. ARTIFICIAL ANAL SPHINCTER 903
5. COLOSTOMY 906
6. POSTANAL REPAIR 907

Adult Conservative Management

I. INTRODUCTION 1103
A. UI IN WOMEN 1103
I. LIFESTYLE INTERVENTIONS 1103
1. PREVENTION 1103
2. TREATMENT 1103
a) Weight loss 1103
b) Physical activity 1104
c) Physical Forces (exercise and work) 1105
d) Smoking 1106
e) Dietary factors 1106
f) Constipation 1107
g) Other 1108
3. OTHER LUTS 1108
4. FACTORS AFFECTING OUTCOME 1108
II. PELVIC FLOOR MUSCLE TRAINING (PFMT) 1108
1. RATIONALE AND PRINCIPLES 1108
a) Biological rationale for PFMT for SUI 1108
b) Biological rationale for PFMT for UUI 1109
c) Principles of skeletal muscle strengthening 1109
d) Principles of behaviour change 1110
2. PREVENTION AND TREATMENT (PREGNANT AND POSTNATAL WOMEN ONLY) 1110
a) Is PFMT effective in the prevention of UI in childbearing women? 1111
b) Is PFMT effective in the treatment of UI in childbearing women? 1113
c) Is PFMT effective in the mixed prevention and treatment of UI in childbearing women? 1114
3. PREVENTION (OTHER WOMEN) 1116
a) Is PFMT effective in the prevention of UI? 1116
4. TREATMENT (WOMEN) 1116
a) Is PFMT better than no treatment, a placebo or a control group treatment? 1116
b) Is one type of PFMT programme better than another? 1120
c) Is PFMT better than other treatments? 1129
d) Does the addition of PFMT to other treatments add benefit? 1134
5. OTHER LUTS 1135
6. FACTORS AFFECTING OUTCOME 1136
a) Age 1136
b) Other 1136
III. WEIGHTED VAGINAL CONES (VCS) 1137
1. PREVENTION 1137
2. TREATMENT 1138
a) Are VCs better than no treatment, placebo or control treatments? 1138
b) Are VCs as effective as other treatments? 1138
c) Are VCs combined with PFMT better than PFMT alone? 1144
3. OTHER LOWER URINARY TRACT SYMPTOMS (LUTS) 1144
4. FACTORS AFFECTING OUTCOME 1144
IV. ELECTRICAL STIMULATION (ESTIM) 1144
1. PREVENTION 1152
2. TREATMENT 1152
a) Is EStim better than no active treatment (placebo, sham, control or no treatment) for treatment of UI? 1152
b) Is one type of EStim better than another in the treatment of UI? 1154
c) Is EStim better than other treatments for UI? 1154
d) Does the addition of EStim to other treatments add any benefit in the treatment of UI? 1156
3. OTHER LUTS 1158
4. FACTORS AFFECTING OUTCOME 1158
V. MAGNETIC STIMULATION (MSTIM) 1158
1. PREVENTION 1160
2. TREATMENT 1160
a) Is MStim better than no active treatment (placebo, control or no treatment)? 1160
b) Is one approach to MStim better than another? 1163
c) Is MStim better than other treatments? 1163
d) Does the addition of MStim to other treatments add any benefit in the treatment of UI? 1163
VI. SCHEDULED VOIDING REGIMENS 1164
1. PREVENTION 1165
2. TREATMENT 1165
a) What is the most appropriate bladder training (BT) protocol? 1166
b) Is BT better than no treatment, placebo or control treatments? 1167
c) Is BT better than other treatments? 1168
d) Can any other treatment be added to BT to add benefit? 1169
e) Does the addition of BT to any other treatment add benefit? 1170
f) Timed voiding 1171
3. OTHER LUTS 1171
4. FACTORS AFFECTING OUTCOME 1172
a) Age 1172
b) Other 1172
VII. COMPLEMENTARY AND ALTERNATIVE MEDICINES 1172
VIII. SUMMARY AND RECOMMENDATIONS 1173
1. SUMMARY 1173
2. RECOMMENDATIONS FOR PRACTICE 1173
a) Lifestyle Intervention 1173
b) PFMT (principal recommendation) 1173
c) PFMT (other recommendation) 1173
IX. FUTURE RESEARCH DIRECTIONS 1174
a) Lifestyle Intervention: 1174
b) Pelvic floor muscle training (PFMT) 1175
c) Vaginal cones (VC) 1175
d) Electrical stimulation (EStim) and magnetic stimulation (MStim) 1175
e) Scheduled voiding regimes, especially bladder training (BT) 1175
B. PELVIC ORGAN PROLAPSE (POP) 1175
I. LIFESTYLE INTERVENTIONS 1176

1. PREVENTION 1176
a) Quality of data 1176
b) Results 1179
c) Summary 1181
2. TREATMENT 1181
II. PHYSICAL THERAPIES 1181
1. PREVENTION 1181
a) Quality of data 1181
b) Results 1181
c) Summary 1182
2. TREATMENT 1182
a) Quality of data 1182
b) Results 1185
c) Summary 1186
d) Recommendations 1186
III. PESSARIES 1186
1. QUALITY OF DATA 1187
2. OUTCOME 1189
a) Patient reported outcomes 1189
IV. SUMMARY AND RECOMMENDATIONS 1191
1. RECOMMENDATIONS FOR PRACTICE 1191
2. FUTURE RESEARCH DIRECTIONS 1191
a) Lifestyle interventions 1191
b) Pelvic floor muscle training (PFMT) 1191
c) Pessaries 1195
C. URINARY INCONTINENCE IN MEN 1195
I. LIFESTYLE INTERVENTIONS 1196
II. PELVIC FLOOR MUSCLE TRAINING (PFMT) 1196
1. PREOPERATIVE RP PFMT 1196
2. PREOPERATIVE AND/OR POSTOPERATIVE RP PFMT, POST RP CONTINENCE STATUS NOT ESTABLISHED PRIOR TO INTERVENTION 1196
a) Preoperative PFMT instruction with postoperative home PFMT versus control 1196
b) Pre-operative PFMT instruction followed by supervised post-operative PFMT versus post-operative PFMT 1201
c) Post-operative PFMT immediately after catheter removal (no pre-operative instruction) 1201
3. POSTOPERATIVE RP PFMT FOR INCONTINENT MEN 1202
a) PFMT with digital rectal feedback (DRE) after radical prostatectomy 1202
b) PFMT with BF after radical prostatectomy 1203
c) PFMT plus or minus BF with EStim or MStim after radical prostatectomy 1204
d) PFMT compared to other interventions after radical prostatectomy 1206
4. PREOPERATIVE TURP PFMT 1206
5. PREOPERATIVE AND/OR POSTOPERATIVE TURP PFMT 1206
6. POSTOPERATIVE TURP PFMT FOR INCONTINENT MEN 1207
7. PFMT FOR OTHER LUTS 1207
a) PFMT for post micturition dribble (PMD) 1207
8. FACTORS AFFECTING OUTCOME 1207
III. ELECTRICAL STIMULATION (ESTIM) 1207
1. PREVENTION OF UI 1208
2. TREATMENT OF UI 1208
a) Is EStim better than no treatment, placebo or control treatments? 1208
b) Is one approach to EStim better than another? 1208
c) Is EStim better than other treatments? 1209
d) Does the addition of EStim to other treatments add benefit? 1209
3. OTHER LUTS 1209
4. FACTORS AFFECTING OUTCOME 1209
a) Age 1209
b) Other 1209
IV. MAGNETIC STIMULATION (MSTIM) 1209
1. PREVENTION OF UI 1210
2. TREATMENT OF UI 1210
a) Is MStim better than no treatment, placebo or control treatment? 1210
b) Is one approach to MStim better than another? 1210
c) Is MStim better than other treatments? 1210
V. SCHEDULED VOIDING REGIMENS 1210
1. PREVENTION OF UI 1210
2. TREATMENT OF UI 1210
a) Bladder training 1210
b) Timed voiding 1210
3. OTHER LUTS 1211
4. FACTORS AFFECTING OUTCOME 1211
a) Age 1211
b) Other 1211
VI. COMPLEMENTARY AND ALTERNATIVE MEDICINES 1211
1. PREVENTION OF UI 1211
2. TREATMENT UI 1211
a) What is the most effective acupuncture protocol? 1211
b) Acupuncture versus no treatment, sham acupuncture or any other treatment 1211
3. OTHER LUTS 1211
4. FACTORS AFFECTING OUTCOME 1211
VII. SUMMARY 1212
1. RECOMMENDATIONS FOR PRACTICE 1212
2. FUTURE RESEARCH DIRECTIONS 1212
a) Lifestyle interventions 1212
b) Pelvic floor muscle training (PFMT) 1212
c) Electrical stimulation (EStim) and magnetic stimulation (MStim) 1213
d) Scheduled voiding regimens 1213

3. RECOMMENDATION FOR CONTINENCE ADVOCACY (LEVEL OF EVIDENCE-3, GRADE D) 1799
V. SERVICE DELIVERY, MODELS AND ACCESSING CARE 1799
1. BACKGROUND 1799
2. NEED FOR SERVICES 1800
3. MODELS OF CARE 1800
a) Single specialist 1801
b) Nurse specialist or advisor 1801
c) Multidisciplinary resource and referral centre 1802
d) Primary care 1803
e) Other service models 1804
4. RECOMMENDATIONS FOR SERVICE DELIVERY, MODELS AND ACCESSING CARE 1807
VI. PROFESSIONAL EDUCATION 1807
1. BACKGROUND 1807
2. MEDICAL EDUCATION 1808
a) Generalists (family physicians/general practitioners/primary care physicians) 1808
b) Specialist physicians 1809
3. NURSING PROFESSIONALS 1809
a) Generalist nurses 1809
b) Specialist nurses 1810
c) Nursing assistants 1811
4. PHYSIOTHERAPY AND OTHER ALLIED HEALTH PROFESSIONALS 1811
5. IMPACT OF CLINICAL GUIDELINES 1812
a) Audits and assessments of guidelines 1814
6. RECOMMENDATIONS FOR PROFESSIONAL EDUCATION (GRADE D) 1815
VII. PRIMARY PREVENTION 1815
1. BACKGROUND 1815
2. POPULATION-BASED PREVENTION 1815
3. PREVENTION OF UI IN OLDER ADULTS 1816
4. PREVENTION OF FAECAL INCONTINENCE 1817
5. RECOMMENDATIONS FOR PRIMARY PREVENTION (GRADE C) 1817
REFERENCES 1818
APPENDIX 1. Drectory of continence organizations 1826

Committee 22
Economics of Urinary & Faecal Incontinence, and Prolapse

I. INTRODUCTION 1831
II. BACKGROUND 1831
1. PERSPECTIVE 1831
2. COUNTRY SPECIFIC ECONOMIC ISSUES 1833
3. COSTS AND TIME 1833
III. TYPES OF ECONOMIC ANALYSIS 1834
1. OVERVIEW 1834
a) Cost of illness (COI) 1834
b) Cost minimization analysis (CMA) 1834
c) Cost consequence analysis (CCA) 1834
d) Cost-effectiveness analysis (CEA) 1834
e) Cost-utility analysis (CUA) 1834
f) Cost benefit analysis (CBA) 1834
g) Summary 1834
2. DETAILS OF DECISION ANALYSIS 1835
a) Steps in a decision analysis 1836
b) Decision Tree 1837
c) Markov Model 1838
3. STATISTICAL ANALYSIS 1838
4. BUDGET IMPACT ANALYSIS 1838
IV. PRACTICAL ASPECTS OF ECONOMIC ANALYSIS IN THE CONTINENCE FIELD 1839
1. HEALTH OUTCOME MEASURES SUITABLE FOR USE IN ECONOMIC ANALYSES 1839
a) Incontinence specific outcomes 1839
b) Health Status and Quality of Life Measures 1839
c) Health value 1839
2. "DO IT YOURSELF" - HOW TO CONDUCT A COST UTILITY ANALYSIS: THE COMMITTEE'S RECOMMENDATIONS 1840
V. SUMMARY OF RECENT ECONOMIC ANALYSES 1841
1. SURGERY FOR STRESS INCONTINENCE 1841
2. SURGERY FOR URGE INCONTINENCE 1843
a) Studies regarding Botulinum Toxin A Injections (Botox A) 1843
b) Sacral nerve stimulation 1844
3. OUTPATIENT CONSERVATIVE THERAPIES 1846
4. PHARMACOTHERAPY OF URINARY INCONTINENCE 1847
a) Economics of pharmaceutical therapies 1847
5. COST IMPLICATIONS OF INCONTINENCE IN NURSING HOME SETTING 1850
6. LONGITUDINAL BURDEN OF DISEASE STUDIES 1850
7. PROLAPSE TREATMENTS, COST IMPLICATIONS 1853
8. FECAL INCONTINENCE 1854
a) Cost of illness 1854
b) Prevention 1854
c) Treatment costs 1855
VI. SUMMARY AND FUTURE RESEARCH PRIORITIES 1858
VII. APPENDIX – SEARCH STRATEGIES 1858
REFERENCES 1858

Committee 23
Research Methodology

I. INTRODUCTION 1865
1. LEVELS OF EVIDENCE 1865
2. PRIMARY GUIDING ETHICAL PRINCIPLES 1865

3. INFORMED CONSENT IS AN ETHICAL CORNERSTONE OF HUMAN SUBJECT RESEARCH 1866
4. SPECIFIC INFORMED CONSENT IS REQUIRED FOR RESEARCH PARTICIPATION. 1866
5. THE INVESTIGATOR HAS AN ETHICAL RESPONSIBILITY TO TAKE RESPONSIBILITY FOR ALL ASPECTS OF THE RESEARCH 1866
6. ENSURING PARTICIPANT SAFETY IS PARAMOUNT 1866
7. HIGH QUALITY DATA MANAGEMENT IS KEY TO PROVIDING VALID AND ETHICAL RESEARCH RESULTS [41] 1867
8. USEFUL WEBSITES 1867
9. FINANCIAL CONFLICTS OF INTEREST 1867
II. DEFINING THE RESEARCH QUESTIONS 1867
III. EXPERIMENTAL STUDIES 1867
1. RANDOMIZED CONTROLLED TRIALS 1867
a) Simple randomization 1868
b) Block randomization 1868
c) Stratified randomization 1868
d) Parallel Group Trials 1868
e) Crossover Trials 1868
f) Non-inferiority trials 1869
g) Equivalence trials 1869
h) Superiority trials 1869
2. NON-RANDOMIZED CONTROLLED CLINICAL TRIAL(S) 1869
3. PRAGMATIC AND EXPLANATORY TRIALS 1869
4. DRUG TRIALS ARE CATEGORIZED ACCORDING TO THE FOLLOWING DEFINITIONS [30, 50] 1870
a) Phase I studies 1870
b) Phase II studies 1870
c) Phase III studies 1870
d) Phase IV studies 1870
5. BIAS, BLINDING AND EFFECTS ON VALIDITY 1870
a) Blinding 1870
b) Unblinded trials 1870
c) Single blind trial 1870
d) Double blind trials 1871
IV. ELIGIBILITY CRITERIA 1871
V. SAMPLING STRATEGIES 1871
VI. DATA COLLECTION 1872
a) Baseline data 1872
b) Observations 1872
c) Tests 1872
d) Follow-up 1872
e) Quality of life measures 1872
f) Socioeconomics 1872
VII. OUTCOME MEASURES 1872
1. PRIMARY OUTCOMES 1872
2. SECONDARY OUTCOME 1873
3. TYPES OF OUTCOME MEASURES 1873
VIII. SATISTICAL CONCERNS 1874
1. SAMPLE SIZE CONSIDERATIONS 1874
2. SAMPLE SIZE CALCULATION 1874
3. THE TARGET DIFFERENCE 1875
IX. ANALYSIS 1875
X. REPORTING RESEARCH RESULTS 1877
XI. SPECIAL CONCERNS FOR SPECIFIC STUDIES 1878
1. BEHAVIORAL AND PHYSIOTHERAPY TRIALS 1878
a) Terminology 1878
b) Behavioral interventions 1878
c) Lifestyle interventions 1878
d) Physiotherapy 1878
e) Biofeedback 1879
f) Conservative interventions/treatments 1879
g) Reporting of trial characteristics 1879
h) Adherence vs effectiveness 1880
i) Adverse events and cost 1880
j) Outcome measures 1880
k) Specific and non-specific effects 1880
l) Power calculations and number of participants 1880
m) Long term studies 1881
2. EXPERIMENTAL DEVICES AND MATERIALS 1881
a) Randomisation 1881
b) Adoption by clinicians 1881
c) Recruitment procedures 1881
3. SURGICAL STUDIES 1882
4. PHARMACOTHERAPY TRIALS 1883
XII. COST ANALYSIS 1884
XIII. RECOMMENDATIONS FOR SPECIFIC PATIENT GROUPS 1884
1. MEN WITH LUTS 1884
2. WOMEN WITH LUTS 1885
a) Hormonal effects 1885
b) Obstetric History 1885
c) Pelvic Organ Prolapse 1885
3. FRAIL OLDER AND DISABLED PEOPLE 1886
4. CHILDREN 1886
5. NEUROGENIC POPULATIONS 1887
a) Classification 1887
b) History and evaluation 1887
c) Urodynamics 1888
6. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY FAECAL INCONTINENCE 1888
7. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS) 1888
8. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE 1888
XIV. CONCLUSIONS 1888
REFERENCES
