SURGERY OF URO-GENITAL PROLAPSUS USING AN UNFIXED FREE PROLENE° MESH, TOT AND SACRO-SPINOUS LIGAMENT FIXATION.

Synopsis of Video

The video starts with clinical analysis of the prolapsus with vaginal eversion showing cystocoele by median and para-vaginal defect, enterocoele, high and low rectocoele.

During hysterectomy, the utero-sacral and cardinal ligaments are fixed to the vaginal angles. They are used for the sacrospinous vaginal fixation.

The high Mac Call culdoplasty is done to treat enterocoele.

Cystocoele repair is done with a Prolene° mesh, which is tailored with a V-neck shape under the bladder-neck, two lateral wings which are left free in the para-vesical fossi and a posterior tail which is left free in the vesico-uterine dissection space. The mesh is only attached to the retro-pubic insertion of pubo-coccygeus muscles.

Sacrospinous ligament fixation of the vaginal vault and rectocoele repair by Denonvilliers fascial plication and levator ani myorrhaphie are shown for posterior repair.

Stress incontinence is cured by trans-obturator tape (TOT)

The film last 29 minutes..
