Hypothesis / aims of study
One in three of all men will seek medical help for lower urinary tract symptoms in later life. While a reduced free flow rate is often indicative of bladder outlet obstruction, it does not exclude the diagnosis of detrusor under-activity. A simultaneous measurement of bladder contractility can resolve the diagnosis, and the penile cuff test provides a non-invasive estimate of isometric bladder pressure \[1\]. A non-invasive pressure-flow nomogram derived from the well-used ICS nomogram for invasive cystometry has been proposed \[2\]. However, as with the ICS nomogram the classification is categorical – obstructed, not obstructed or diagnostically uncertain. Near the centre of the nomogram a small change in pressure or flow rate could potentially change the diagnosis markedly, and this seems intuitively undesirable. The aim of this study was to propose an improved nomogram for the penile cuff test based on statistical principles.

Study design, materials and methods
We recruited 144 men in two UK institutions. All had been referred for conventional cystometry according to ICS guidelines to clarify the urodynamic cause of lower urinary tract symptoms. They were classified as obstructed or not obstructed (equivocal/unobstructed) according to the provisional ICS nomogram. All men underwent a penile cuff test. According to the standard protocol, the operator measured peak flow rate (Qmax) and the highest cuff pressure required to interrupt flow (Pcuff,int). We then constructed the new nomogram using Gaussian statistics. Outcome data
Finally, we present data from a study of 166 men who underwent TURP, and where good outcome was defined as a 50\% reduction in subjective symptoms. Using the t-statistic as a pragmatic indicator of performance, we compare the classifications according to the original categorical nomogram with those of the new probability-based nomogram.

Results
From a Gaussian distribution in two variables, we calculated the probability that a patient with given measurements of Qmax and Pcuff,int belongs to the obstructed population, and to the not-obstructed population (figure 1).

**Figure 1** The bivariate Gaussian distributions for (left) non-obstructed and (right) obstructed patients. In each case, shading shows the probability of belonging to that population.

By taking at each point the relative probability of belonging to the two populations, we constructed the new nomogram (figure 2).
The new nomogram, where shading shows the probability of being obstructed. The crossed lines are taken from the original categorical nomogram. Obstructed and not-obstructed patients are top-left and bottom-right respectively, with the other two quadrants being diagnostically uncertain.

NOTE: Resting abdominal and hydrostatic pressures give a cuff pressure of 50 cm H₂O even with no bladder contraction. We therefore have no measurements below 50 cm H₂O on which to base the nomogram, and have not shown this region.

Outcome data For comparison, the obstructed, not-obstructed and uncertain quadrants of the original categorical nomogram were assigned probabilities of 1.0, 0.0 and 0.5 respectively. Treating good and poor outcomes as two separate groups, the t-statistic shows how well the probabilities of obstruction suggested by each nomogram separate the good and poor outcome groups. Table 2 shows the relative performances; a higher value is better, and so the new nomogram performed slightly better by this criterion.

Interpretation of results
The new nomogram (figure 2) shows the properties to be expected, with a strong probability of obstruction for patients in the top-left (high pressure, low flow). The region of intermediate probability (shaded green in figure 2) is where the probabilities of belonging to the obstructed and non-obstructed populations are approximately equal. It is noteworthy that this region corresponds well with the line of separation taken from the original nomogram, and therefore reassuring that the two nomograms performed similarly.

Concluding message
We have proposed a way to make better use of the cuff test using a nomogram based on Gaussian statistics, and this can be implemented easily by computer. However, the original nomogram has the advantage of simplicity, and is perfectly acceptable where the facility to calculate statistics for the new nomogram is not available.
