Most children are expected to achieve daytime dryness by the age of three [86]. However, some children take longer to become dry and some (e.g.
children with learning and physical disabilities) may never reach this goal. These children usually require absorbent products to contain leakage.

Aspects of assessment that are particularly important regarding bodyworn products for children are presence of faecal incontinence, day / night incontinence, level of independence with toileting, and use of aids (e.g. callipers).

To date there has been only one study of absorbent products for children and this has compared the diaper design with the newer pull-up design [87]. Sixty-one children with physical and / or learning disabilities tested five diaper products and five pull-up products, each testing each product for one week. The children were randomised to receive either the pull-up or diaper group first and individual products were tested in random order within each design arm. Parents completed a product performance questionnaire and a pad leakage diary to record wet weights and severity of leakage. Parents were asked to state their preference for a design for day and night use.

Findings indicated that generally, the diaper products performed similarly to each other and so did the pull-up products, although there were some statistically significant differences between products within each of the two design groups. Overall diapers were preferred for night-time use by the majority of parents. By contrast, 40% of parents preferred pull-ups for daytime use and these were found to be particularly appropriate for older children and those who were attempting independent toileting, provided they did not have faecal incontinence and did not wear callipers or adapted footwear. Diapers were more suitable for children who were dependant on carers and / or had faecal incontinence, and wore callipers or adapted footwear. The authors recommended that both diapers and pull-ups should be supplied for children, with pull-ups (which are about 50% more expensive than diapers) being provided for selected children during the daytime.

a) Summary and recommendations

Diapers and pull-ups meet different needs of children and both should be made available to children with disabilities, dependent on assessment (Level of Evidence 3 / Grade of Recommendation C).

b) Research priorities

Comparison of washable and disposable bodyworn products.

11. PADS FOR FAECAL INCONTINENCE

Most absorbent products are designed for urinary incontinence. No studies comparing available absorbent products for faecal incontinence were found. Bliss et al. [88] reported preliminary findings of a survey of the use and evaluation and suggested modifications of absorbent products for faecal incontinence by 188 community-living persons with the problem. Forty-five percent of persons used an absorbent product for FI. Ninety-eight percent of those with UI and FI used the same type of product for both. Suggested improvements in product designs included having better odour control, fit, and ability to stay in place; a clearer distinction between the front and back of a pantiliner or pad; adding wings for greater absorbency; and making them flushable, cooler feeling, wider and longer in the rear and more absorbent but less bulky. For mild faecal incontinence, especially when faeces remain between the buttocks without soiling underwear, persons have used a small disposable gauze surgical dressing placed between the buttocks. This product was more acceptable than a pantiliner or pad to some men [88] (Level of Evidence 2).

a) Recommendations

• A disposable gauze dressing that can be placed between the buttocks maybe acceptable for men with light faecal incontinence (Level of Recommendation C).

b) Research priorities

• Better designs of products are needed for light and moderate FI (with and without UI).

12. GENERAL RECOMMENDATIONS ON PAD SELECTION

• Individuality: No study has ever identified one product that worked best for all testers: needs and priorities vary. Accordingly, users are advised to try a variety of products when possible (Grade of Recommendation B).

• Brand differences: The individual product brands within a design group often exhibit a wide range of performance and acceptability for individuals, and it cannot therefore be assumed that pads of different brands but broadly similar design will be equally acceptable or effective (Grade of Recommendation B).

• Combinations of designs: Absorbent products vary greatly in price and performance and suitability for individual needs. Users may therefore find combinations of designs preferable and cost-effective. For example, women might use pull-ups (expensive, but discreet and good for leakage) for going out, and inserts (cheap, less good for leakage) for staying at home. Men might use disposable diapers for daytime, and washable terry-towelling products for night-time (Grade of Recommendation B).

• Freedom from leakage: In general, pads containing superabsorber should be selected in preference to those without (Grade of Recommendation B). Nobody wants their pad to leak but compromises have to be made: the pad needed to contain a person’s most severe accident may be substantially more bulky and expensive than is needed most of the time. Some users choose to
**Tolerate a higher risk of pad leakage in exchange for being able to use cheaper, smaller (more discrete) pads. The balance of priorities for a given user should be investigated in making product selections (Grade of Recommendation C).**

- **Comfort and skin health**: In general, pads containing superabsorber should be selected in preference to those without (Grade of Recommendation B). Shaped pads should usually be selected in preference to unshaped (Grade of Recommendation C).

- **Staying in place**: No product is effective if it slips from position. Inserts should be used with pants, preferably mesh pants (Grade of Recommendation B). Robust, stretch (e.g. cotton / lycra) pants may also help to provide a snug fit and minimise leakage. Shaped pads are preferable to rectangular (Grade of Recommendation C).

- **Ease of putting on and taking off**: The ease of putting on and taking off should be considered, especially for caregivers and for incontinent users with reduced mobility or dexterity (Grade of Recommendation C).

- **Aesthetics and discretion**: A possible preference for small, more discrete pads (even if they are more likely to leak) should be considered, especially for those wishing to wear close fitting clothing (Grade of Recommendation C). The possibility of plastic backing materials rustling noisily should be considered (Grade of Recommendation C).

- **Independence and lifestyle**: The ability of a user to change his / her own pad should be considered (Grade of Recommendation C): those able to change their own pad can often manage with a smaller (less absorbent) one than those reliant on a caregiver. Users who travel should consider in their choice of product(s) the practicalities of carrying a supply of pads, disposing of used ones, and dealing with laundry (Grade of Recommendation C).

- **Costs**: Cost issues should be approached with caution (Grade of Recommendation C). Expensive pads do not necessarily work better than cheaper ones. Cheaper pads do not necessarily save money. If pads leak more they may have to be changed more frequently and / or lead to higher laundry costs. More pad changes will mean increased caregiver workload. However, more absorbent pads will not necessarily reduce pad consumption rates: pads are often changed according to ward or personal routine.

### 13. RECOMMENDATIONS RELATING TO WASHABLE PADS

- **Laundry issues**: Access to good, reliable washing and drying facilities should be checked before washable products are introduced (Grade of Recommendation B). Laundry – especially of bedpads – can be heavy work, beyond the capability of frail incontinent people or their caregivers. The number of washable products needed per user depends on laundry turn-around times. Drying times for washables can be long and expensive, especially for bodyworns for heavy incontinence and for bedpads.

- **Personal preferences**: Personal preferences (of both users and caregivers) with regard to choosing between washable and disposable products should be taken into account carefully (Grade of Recommendation C). Some users prefer the chore of laundering washables to anxiety over whether their next consignment of disposables will be delivered on time. Washables generally require less storage space than disposables. Discreet disposal of disposables can be a challenge. The possibility of using a mix of disposable and washable products should be considered (Grade of Recommendation C). Some users who choose disposables when at home prefer washables when travelling because of the space that disposables occupy in luggage and the possible inconvenience of disposal. Others use washables at home and disposables when away as they see the balance of disadvantages and advantages differently.

- **Personalisation of products**: In institutions, the chore of personalizing washable products and sorting them after each laundry cycle should be considered before they are introduced (Grade of Recommendation C). Washable bodyworns are often personalised to particular users. In institutions this means marking products with users’ names and sorting them after laundry, an extra task for caregivers. Washable bedpads are not usually personalised.

- **Staining**: Washable products should not usually be used by those with faecal incontinence – beyond occasional light smearing – because of staining (Grade of Recommendation C). Skin sprays andointments may stain washables too.

- **Costs**: Cost comparisons between washable and disposable products should be made with caution (Grade of Recommendation C). Key factors are: local arrangements (mostly laundry and transport costs); the durability of the products (which depends on how carefully they are used and the criteria for deciding when they should be replaced); the costs of ordering, transporting and disposing of disposables; and product purchase costs. Much of the cost of washables is encountered with the initial capital outlay for stock. This also represents a commitment to use the products for an extended period and so expensive mistakes can be made if it transpires that a better product was / has become available. It will usually be wise to experiment with samples of a variety of alternative products before committing to major purchases.
SHEATHS

Close-fitting penile sheaths (sometimes called condom catheters, uridomes or external catheters) are commonly used male incontinence devices and they are used in combination with a urine drainage bag. They are suitable for males who are experiencing moderate to heavy urine loss, or have limited mobility and are experiencing frequency and urgency and may even be considered in combination with intermittent catheterisation (IC) for males who are leaking urine as a consequence of bladder emptying problems. Sheaths may not be suitable for males who are experiencing confusion, considered psychologically vulnerable or have decreased sensation through spinal cord injury [89], [90], [91]). There is strong opinion expressed in the literature that suggests assessment, selection and use of penile sheaths and the accompanying urine drainage systems needs to be undertaken with the guidance, education and monitoring of health professionals who have a knowledge of continence products. Failure to do so, according to this expert opinion [90], [92], [91]), may result in serious penile trauma, impaired penile skin integrity and leakage of urine.

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important in relation to sheaths include: physical, mental, cultural, gender and socio-economic factors. This incorporates assessment of the cognitive and dexterous ability of the male or carer to apply the sheath and empty the drainage bag, the integrity of the penile skin, length and circumference of the penis and whether it is retracted, or retracts on sitting or bending down, history of latex or adhesive allergy and, most importantly, recognition that the assessment from the health professional needs to be ongoing. It is also important to assess factors known to encourage or discourage sheath usage. Expert opinion [93], [90], [94]) suggests factors that encourage usage include: level of reimbursement, cultural expectation, resonance with masculine image, and ability to keep urine off the skin when the skin integrity is at risk because of incontinence. Factors which they suggest discourage usage include: ignorance of product efficacy by professionals and consumers and embarrassment between carer and client.

An effective sheath is one that stays securely in place for an acceptable period of time, is leak-free, comfortable to wear, easy to apply and remove, avoids skin damage and channels the urine effectively into a urine drainage bag.

1. PRODUCT CATEGORIES AND FEATURES

Sheaths come with a variety of features (Figure VII-1) of which the following are the most important to consider in making selections:

- Material: sheaths may be made from latex, silicone rubber or other synthetic polymers. Some men will be allergic to latex.
- Size: most sheaths are supplied in a range of lengths and sizes. Most companies supply them with diameters in the range of about 20 – 40 mm, in 5-10 mm increments.
- Adhesive: the adhesive may be integral to the sheath (one-piece systems) or come as a separate strip or spray (two-piece systems). Some men will be allergic to some adhesives.
- Applicator: some sheaths come with an applicator intended to help users and carers to put the sheath on.
- Anti-kinking / twisting features: some sheaths come with features intended to improve drainage by reducing kinking and twisting at the distal end, near the connection to the drainage bag tube.
- Anti-blow-off features: some sheaths come with features intended to reduce the likelihood of the sheath blowing off at high urine flow rates, for example, at the beginning of a void (eg the distal end of the sheath may be thickened and bulbous to stop the internal walls sticking to one another between voids).
- Connection to the drainage bag: some sheaths come with features intended to increase the ease and security of connection to the drainage tube (eg a push ring or ridge at the end of the outlet tubing)
- Retracted penis features: with or without specific features intended to accommodate a retracted penis (eg a shorter sheath or a wider adhesive seal).
- Durability: some sheaths are intended for use over a limited time period (eg 24 h) while other (generally, more robust) designs are intended for extended wear.
- Transparency: some sheaths are transparent allowing for observation of the condition of the skin along the shaft and glans of the penis.

2. QUALITY OF DATA

Some controlled comparative evaluations of different sheaths have been performed; one extensive market survey to identify the needs and priorities of sheath users; and two studies comparing sheaths with other product categories (versus indwelling urethral catheter, and versus absorbent pads). Other studies report on the problems encountered by various groups of sheath users.

3. RESULTS

Although many men use sheaths successfully, problems have been reported in the literature. In a study on an unspecified number of spinal cord injured men, Golji [95] found that 15% experienced side effects or complications when using sheaths. These were irritative, allergic or compressive in
nature. Jayachandran et al. [96] reported similar experiences with six incontinent men of widely varying aetiology and highlighted the importance of ensuring that the sheath does not become twisted near the distal end to avoid stagnation of urine and the risk of UTI. They also stressed the importance of good genital hygiene to avoid problems with infections. In a study of 94 men on medical / surgical wards, Hirsh et al. [97] found that none of the 79 who were judged as co-operative and able to manage their sheaths properly developed UTI (mean period of use, 21.2 days). By contrast, eight of 15 patients who tended to tug and kink the drainage tube attached to their sheath developed UTI within a mean of 9.6 days. In a retrospective study, Johnson et al. [98] compared the frequency of UTI in users (mean period of use, 35 months) and non-users of sheaths amongst 64 elderly men on an extended care unit. He found that 63% of users but only 14% of non-users developed UTI. No difference was found between men who did and did not tug and kink their tubing. Ouslander et al. [99] reported that 40% of 30 nursing home sheath users (mean period of use, 35.9 months) developed at least one UTI. The need for proper fitting of the sheath and regular monitoring of the skin integrity of the penile shaft, glans penis and prepuce of males who are regular sheath users has been highlighted in two articles that report a combined total of eight cases of fibropithelial polyps of the glans penis and prepuce of which six had a history of long term sheath use [92] [100].

A trial to compare sheaths and indwelling catheters in terms of infection, risk and patient satisfaction has been reported by Saint et al [101]. This was a prospective, randomised, unblinded, controlled trial which compared one type of sheath drainage with one type of indwelling urethral catheter using a small group of participants (N=75) across several locations in one hospital. There are important limitations of the study, including the low numbers drawn from a specific population, and the lack of comment on the changing / care routines associated with the sheaths and catheters. After making adjustments for age, mental score, history of UTI and history of catheterisation the conclusions of the study were that for males without dementia the use of sheaths has the potential to reduce infection compared to indwelling catheters and is more acceptable to patients in terms of comfort and pain. For males with dementia no significant difference in infection rates was found.

There has also been a cross-over trial [47] comparing sheaths with absorbent pads when used by men with moderate to severe UI (N=61). Products were used for two weeks each and the Kings Health
Questionnaire was used as the primary outcome measure. Scores for the sheath system were significantly better than for the pads on most domains and the number of men preferring sheaths was significantly higher than for pads.

Nichols and Balis [102] reported the results of a survey undertaken for marketing purposes of an international cohort of 216 men who had used sheaths for at least three years, and their carers. Their responses to 19 brands of sheath were gathered using a questionnaire in the form of a Likert scale. It was found that catheter security (presumed to mean staying in place and freedom from leakage) was the most important issue for both wearers and carers, followed by comfort and ease of application and removal.

There have been a number of comparative evaluations of different sheaths. Peifer and Hanover [103] reported on an evaluation in which 20 men compared a new branded sheath system that consisted of three ed parts: a tubular sheath impervious to urine with a drainage tube connection at one end and a ring at the other; an undergarment with a frontal opening through which the penis is extended; and a ring-like collar which is used to keep the sheath and penis in the correct position, with the variety of external sheaths they had previously been using. The participants were a convenience sample identified through pharmacy medication files. In all, 32 men were approached and 20 consented, all experienced users of urinary sheaths. A questionnaire was developed to test the participants pre and post intervention. The new sheath – which was used for a week – proved more popular with the participants: it was judged to provide superior security (13/20 experienced increased dryness by day; 10/20 by night), and considered easier to apply (19/20) and remove (20/20).

In a multi-centre study involving 35 men (age range 22-87y; mean age, 54y; 34 living in their own homes), the UK Medical Devices Agency [104] compared four latex sheaths: two with integral adhesive; and two in which the adhesive was supplied as a separate strip. They found the products with integral adhesive to be more successful in both overall performance and ease of application. Fader et al. [21] conducted a multi-centre study to compare all six sheaths with integral adhesive on the UK market in 1998. Five were made from latex, one from silicone rubber. Four were supplied with an applicator, two without. Fifty-eight men (age range 26-88y; mean age 53y) were given the opportunity to try each sheath in turn for one week. The silicone rubber sheath was found to be significantly better than four of the other sheaths in overall performance (p<0.01). The ease with which a sheath could be put on was found to be the best predictor of overall performance. Surprisingly, sheaths with an applicator were found to be unacceptable to a significantly higher proportion of subjects than sheaths without an applicator (p=0.0001). Subjects found that the silicone sheath fell off / blew off significantly less frequently than two of the other products (p<0.01).

Pemberton et al [94] report a randomised prospective open crossover design trial to test user preference for an established one-piece silicone rubber self-adhesive sheath with a new one-piece silicone rubber self-adhesive sheath in a study sponsored by the distributor of both products. To be included the males had to be currently using at least one, one-piece urinary sheath, per day. Fifty-three males from seven centres participated in the trial and were each given 10 sheaths of each product. Data from the 44 participants who had evaluated at least three of each product were analysed. No reason was given for why nine males did not complete the trial. The data shows that there were some problems with both products, however, it is difficult to understand why the new product was preferred, as the report does not mention any differences in the features of the two products.

Watson & Kuhn [105] describe a crossover study with six male participants that found the choice of leg bags may influence the performance of penile sheaths. Goldyn, Buck and Chenelly [106] conducted an exploratory study on 10 patients in an extended care hospital to consider the efficacy of a brand name external sheath and a hospital constructed sheath. The brand name sheath was found to be more secure and the preferred nursing choice but it was recognised that the hospital-constructed sheath was useful for patients with fragile skin and limited mobility. A study by Saint et al. [107] provided further evidence (although low level) to support the importance of security and comfort to sheath users. Using questionnaires, they interviewed a convenience sample of 104 older men (response rate = 90%) and surveyed 99 nurses (response rate = 92%) about the relative merits and problems of sheaths and indwelling catheters. The study population was drawn from a university-affiliated Veterans Affairs Medical Centre in the USA. The patients using the sheaths were more likely to believe their product was comfortable (p = 0.04) and less likely to believe it was restrictive (p = 0.002) or painful (p = 0.008) than those using an indwelling catheter. This viewpoint was supported by the nurses surveyed, the majority of whom (no numbers given) believed that sheaths were more comfortable and less restrictive than indwelling urinary catheters for male users, but required more care time because they fell off or leaked.

4. SUMMARY

For incontinent males, sheath drainage can provide a good alternative to pads. However, the increased risk for complications such as local skin breakdown, bacteriuria and infection - especially in the frail confused elderly male – should be borne in mind (Level of Evidence 2). Also, there is the risk of urinary retention if the condom twists or the external band is
too tight, leading to poor drainage to the urine bag (Level of Evidence 3). Sheaths with integral adhesive are more popular with users and easier to apply than those with separate adhesive strip (Level of Evidence 2/3). Secure fixation and the ease with which a sheath can be put on are the best indicators of its overall performance (Level of Evidence 2). Sheath applicators are often ineffective and unpopular (Level of Evidence 2). There can be considerable differences in performance between products with somewhat similar designs (Level of Evidence 2).

5. GENERAL POINTS FROM THE LITERATURE, INCLUDING EXPERT OPINION

- Prior to applying the sheath, ensure any remaining adhesive or barrier cream is removed from the penis and that it is thoroughly washed with soap and water and thoroughly dried.
- Trim long pubic hairs to prevent them being caught up in the adhesive.
- Protective skin wipes can be used to protect the skin, but make sure the skin has dried properly before applying the sheath.
- Leave a gap at the end of the sheath between the glans penis and the drainage tube to avoid trauma to the glans / prepuce. However, make sure the gap is not too large such as to cause kinking or twisting of the sheath [108].
- After the sheath has been applied, snip any reinforced ring or unrolled section of sheath sitting at the bottom of the shaft of the penis.
- Penile sheath removal should not be rushed and is made easier by gently rolling it off while bathing the penis in warm soapy water.

6. RECOMMENDATIONS

- Since there can be considerable differences in performance between products of similar design, men should be given the opportunity to experiment with different products before making a final selection (Grade of Recommendation B).
- The key performance characteristics which should be considered in selecting products are: security (ie ability to keep a leak-proof seal and channel urine to the drainage bag without leakage) and ease of putting the sheath on and taking it off (Grade of Recommendation B).
- In general, sheaths with integral adhesive (one-piece systems) should be selected rather than those in which the adhesive is supplied separately (two-piece systems) (Grade of Recommendation C).
- It should not be assumed that a sheath applicator will make sheath application easier: often it does not (Grade of Recommendation B).
- Potential sheath users should be asked if they have an allergy history and regular users should be routinely checked as their latex allergy status can change over time and with continued use. (Some health settings are moving to reduce or eliminate latex usage whenever possible and some manufacturers have moved to offer non-latex sheaths) (Grade of Recommendation C).
- Sheath users should be monitored for skin health, tissue damage and UTI (Grade of Recommendation C).
- When possible the external sheath rather than indwelling urethral catheter should be the urinary collection device of choice. (Grade of recommendation B).

7. PRIORITIES FOR RESEARCH

- Although products are continually being developed, changed, withdrawn and released, comparison studies that are controlled and use multiple sites to achieve larger numbers are recommended to further evaluate the effectiveness of the variety of sheaths available.
- More comparative studies of the risks of complications between the use of sheaths, pads and catheters are required.
- Since leg bag features may influence the performance of the sheath, further evaluation of design features claimed to reduce twisting and kinking at the drainage bag connection site and increase ease and security of connection to drainage bags is required.
- Well designed studies to generate and validate procedures to help identify the type of sheath most likely to suit an individual are needed.

VIII. URINE DRAINAGE BAGS AND ACCESSORIES

Urinary drainage bags are attached to an indwelling catheter or penile sheath to collect and store urine. Features of effective drainage bag systems include ease of operation of all components (connectors, taps, and support devices), comfort and discreetness.

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important regarding urine drainage bags are patient / carer dexterity [90] [109], and eyesight. Both are necessary to manage the urinary drainage bag system, including using the outlet tap to empty the drainage bag. It is also important to assess the patient’s preferred and usual mode of dress [90] [109]; for example, a male whose preferred mode of dress is shorts will want a drainage system that is not visible and allows easy access for emptying.

1. PRODUCT CATEGORIES AND FEATURES

Urine drainage bags fall into two major categories:
Leg / body worn bags come with a variety of features of which the following are the most important to consider in making selections:

- **Volume:** most bags have a volume in the range of 350-750 ml, but some are bigger.
- **Material:** most bags are made from transparent PVC (polyvinyl chloride) but PVDF (polyvinylidene fluoride, less noise from rustling), polyethylene or rubber / latex may be used.
- **Sterility:** bags may or may not be supplied sterile.
- **Wear position:** bags may be designed for wearing over the knee, across or down the thigh, down the calf, or against the abdomen.
- **Attachment / suspension system:** most leg bags are attached to the leg with straps, which are usually made from latex or a (usually elasticated) fabric. A variety of hooks, loops, buttons / button holes and Velcro may be used to secure straps and to attach bags to straps. Some bags are designed to be suspended around the waist. Some straps and suspension devices can be bought separately from bags, but they are generally not suitable for use with all bags (Figure VIII-1).
- **Connecting tube:** bags come with a variety of connecting tube lengths (eg the length required for wearing a bag on the calf will be greater than that for the thigh). With some products the tube can be cut to the preferred length.
- **Drainage tap:** Drainable bags come with a variety of drainage tap designs (Figure VIII-2).
- **Sampling port:** bags may or may not have a sampling port in the drainage tubing for taking urine specimens.
- **Comfort features:** some bags come with features intended to increase comfort – most commonly, a fabric backing against the skin to reduce sweating.
- **Discretion features:** some bags come with features intended to increase discretion – most commonly, internal welds between the front and back faces to reduce bulging and / or sounds caused by a large volume of liquid moving about as the user mobilises.
- **Anti-kinking / twisting features:** some bags come with features intended to improve drainage by reducing kinking and twisting in the connecting tube.
- **Infection reduction features:** some bags come with features intended to reduce the risk of infection for the self-carer and cross-infection between bag users by care givers. Such features may include; a non-return flap valve, designed to help reduce reflux of urine up the tubing when the bag is moved by users or carers, a sampling port and / or a tap with an outlet sleeve which allows the overnight bag to be connected to the body worn bag. This linkage provides a mechanism to maintain a closed catheter drainage system designed to minimise the risk of cross-infection by reducing the handling of the catheter. Having connected the night bag to the leg bag sleeve, the leg bag tap is opened and urine flows freely from the sheath or catheter through the leg bag into the night drainage bag. Pre-sealed drainage systems to prevent breaking the closed system are also available, and these could be beneficial in reducing time to bacteriuria [110].

Night drainage bags are usually held on a suspension system away from the body. They may be connected directly to the catheter or sheath or they may be connected to the drainage tap of the leg / body worn bag to avoid the need for repeated connections and disconnections with the catheter or sheath (Figure VIII-3) ie a closed-link system. They usually have a capacity of 2000-4000 ml and come with a variety of design features many of which are similar to those for leg / body worn bags. Night drainage bags are available as non-drainable bags (NDB) i.e. without a tap for single use as well as with a variety of drainage tap designs for emptying and reuse. Glass bottles are also available for high volume or overnight urine drainage. It has been suggested that current standard drainage tubing / bag designs evacuate the bladder sub-optimally, leading to retention of residual urine. Outflow obstruction can be caused by the development of air-locks in the dependent curls of tubing. A new drainage tubing design which incorporates a coiled downward-spiral-shaped configuration has been reported to eliminate air-lock obstruction [111] in experimental and clinical studies. However the importance of this in relation to infection requires further study.

2. **QUALITY OF DATA**

Several controlled comparative evaluations of urine drainage bags and suspension systems have been performed, as well as a small number of studies addressing infection and cross-infection issues There are also two case-controlled studies which have investigated the purple urinary bag syndrome.

3. **RESULTS**

a) **Evaluations of urine drainage bags**

A randomized cross-over design compared use of a standard latex drainage bag with a cloth covered bag in 42 men with post prostatectomy incontinence [112]. Each bag was tested for about 4-5 days, and complete data were provided by 30 individuals. People with known latex allergy were excluded. Measures included adapted questionnaires for Leg Bag Evaluation and Skin Health. A statistically significant preference was found for the
cloth covered bag with a main effect (F= 36.614, df = 1.28, p<0.01) as well as an effect related to the order provided (F= 8.398, df = 1.28, p<0.01). That is, those who used the cloth bag first had a stronger preference for it than those allocated to the latex bag first. The cloth backed bag seemed to have several positive features, including comfort under the bag and cloth straps, flexible adjustable tubing, and taps that did not cause urine spillage on fingers. But these bags had a tendency to slip down and pull on the catheter. Two persons using the latex bags had minor skin irritation, one a rash related to the straps pulling on hairs on the leg and the other minor redness and swelling which resolved within 24 hours.
Kennedy et al. [113] tested the performance of ten different drainage bags in a simulation study involving 40 subjects (mostly health-care staff) which focused particularly on taps. Significant differences (p<0.05) were found between many pairs of bags with regard to each of the performance aspects studied: ease of tap opening and closing, ability to empty the bag without urine wetting fingers; and how easy the tap mechanism was to understand. Taps comprising caps or bungs were found to be particularly fiddly and messy to use.

In a study which focused primarily on the cross-infection risks associated with leg bags, Wilson and Coates [114] evaluated four leg bags. Each of ten long-term catheterised patients was invited to try each bag for a week in turn. The authors concluded that no one bag suited every patient; rather, each was liked by some users. The popularity (or otherwise) of many features was a matter of personal preference. Adverse comments mostly related to the tap (difficult to operate, opened accidentally, causing leakage) and the straps.

The UK Medical Devices Agency [115] evaluated all 14 sterile 500 ml leg bags on the UK market in 1995 in a multi-centre study involving 83 test subjects (58 men, 25 women). About half (44) lived in their own homes and almost all the rest in nursing/residential homes. Subjects were divided into pairs matched for sex, mobility, manual dexterity and dependency and each pair was offered each of the 14 bags (seven each) to try for a week in turn. Preferences varied but the main concerns of users consistently focused on taps (many subjects found many taps difficult to operate), straps (discomfort was common) and the minimisation of leakage (through faults in bags and/or connectors; onto the fingers when emptying; or by the tap accidentally opening in use). The most popular bags tended to perform well in these three respects.

In a multi-centre study involving 34 men (age range 27-84y; mean age 55y; all sheath users) Fader et al. [116] evaluated all seven non-sterile 500-700 ml leg bags on the UK market in 1997. Twenty-five of the men lived in their own homes and the rest in residential/nursing homes or long stay wards. Conclusions were substantially similar to those for the earlier MDA study.

Some international standards have been developed which provide general advice on bag performance and test methods [53]. These standards can be useful to laboratories asked to advise on bulk buying choices.

**b) Urine drainage bag suspension systems**

Little research has been undertaken on urinary drainage bag suspensions apart from a study by Thelwell et al. [117]. Thelwell et al. conducted a cross-over study using 52 subjects (20 men, 32 women). This study compared four suspension systems for fastening leg bags with the leg straps they had used prior to the study. Each subject evaluated each product for a week in turn and recorded their findings on a weekly questionnaire. Again, difficulty of application, comfort, discreteness and cost were key issues. However, there is suggestion in the literature that urinary drainage bag suspensions have an important role to play not only in the comfort and security of the wearer but in the prevention of urinary tract infection regardless of whether the drainage system is connected to a sheath or an indwelling catheter.

Munnings and Cawood [118] report the findings of a pilot study designed to evaluate the use of a belly bag of 1,000ml capacity and worn 24 hours a day, thus eliminating the need to use two separate bags and reducing the number of times the closed system is broken. Twenty-nine patients from a variety of areas from within an acute care setting who were using continuous catheter drainage systems were invited to participate, with 27 of the participants completing the study. All agreed to wear and then compare the belly bag with their previous leg and night drainage bag system. Worn around the waist, the belly bag is not positioned below the bladder: the manufacturers claim that the pressure of the bladder muscles is sufficient to ensure that urine flows through the catheter from the bladder into the bag. The residual pressure of the bladder is reported to be around 10-25cm H2O, while the manufacturer asserts that a pressure of only 6cm H2O is necessary to ensure the urine drains into the bag. Following education of how to use the drainage bag, users were given a questionnaire designed to facilitate comparison between the previous drainage system used and the belly bag. This was followed up with a telephone call. All agreed the belly bag was an improvement over their previous system of leg and overnight drainage bags, and found it more convenient, comfortable and less likely to cause pain with movement.

It has been suggested that current standard drainage tubing/bag designs evacuate the bladder sub-optimally, leading to retention of residual urine. Outflow obstruction can be caused by the development of air-locks in the dependent curls of tubing. A new drainage tubing design which incorporates a coiled downward spiral shaped configuration has been reported to eliminate air-lock obstruction [119] in experimental and clinical studies. However the importance of this in relation to infection requires further study.

There is opinion in the literature that positioning standard drainage bags below the bladder in a
manner that averts kinking will prevent reflux of urine, and associated infection [120], [121], [122]. When doing so care must be taken not to increase traction or friction [109]. This can be achieved with the use of supports specially designed to divert accidental pulling on the catheter or sheath. When using these support systems allowance should be made for penile erection and tumescence [109].

The drainage system for indwelling catheters should be positioned off the floor to reduce the risk of cross infection [120], [121], [122]. Some sterile and unsterile leg bags come with a variety of tubing lengths or tubing that can be cut according to the needs of the individual, and leg straps that can be adjusted to allow positioning of the bag on the thigh or calf. Night bags - even if the tubing can be cut - rely on uniform stands or hangers to ensure that they are off the floor. Roe et al [123] raised the issue of poorly designed support systems for night bags. Expert opinion suggests that this still remains an issue.

c) Infection and cross-infection issues for management of urine drainage systems for indwelling catheters.

Usage of urinary catheters and their drainage systems increases the risk of urinary tract infection and cross infection (See Section XII.2.h). There is evidence to suggest that catheter associated infections are reduced with the use of closed urinary drainage systems. A randomised controlled trial was reported by Platt et al [124]. This trial compared the incidence of infection (measured as $10^5$ cfu/ml in catheter urine or drainage bag urine) between patients who were catheterised using sealed junction catheters (i.e. catheters pre-connected to a drainage bag using a sealed junction), and those catheterised using unsealed junction catheters (i.e. unconnected catheters and drainage bags), in a hospital setting with a median period of catheterisation of three days. For subjects not taking antibiotics, sealed junctions showed less infection than unsealed (p<0.01). For subjects taking antibiotics there was no difference in infection rates between sealed junctions and unsealed junctions. The infection rate appeared to be consistently lower in the subjects taking antibiotics than the ones not taking antibiotic but no statistical significance tests of this effect were reported.

Maintaining a ‘closed’ system has since become an important tenet for avoidance of urine infection both particularly in acute care but also in long-term care. This has led to the introduction of products designed to maintain a ‘closed’ system. In the UK the ‘link’ system is advocated whereby legbags are designed with a connector to attach to a night drainage bag, thereby obviating the need to disconnect the legbag from the catheter in order to connect a night bag. Use of non-drainable (single-use) night bags is also recommended in the UK (RCN 2008) presumably to reduce the cost of using a new (and more expensive) drainable night bag every night and also to avoid the practice of cleaning and re-attaching drainable night-time bags. However it should be noted that this ‘link’ system is not completely ‘closed’ (because the night bags are still disconnected and reconnected every night – albeit at the legbag tap rather than at the catheter) and the legbag may still be disconnected at the catheter junction for other purposes such as bladder instillations.

If a ‘link’ system is not in use then whenever a legbag needs to be changed to a nightbag the bag will need to be disconnected at the catheter junction. The bag (leg or night) may then be replaced (or more commonly) will be cleaned and reused. As yet there have been no studies to compare the use of the ‘link’ system with a conventional disconnection system.

The number of days that a legbag may be safely (or acceptably) left in place before it is replaced is unknown. There is little research to support the common practice of changing drainage bags every five to seven days (or any other particular change regime). The practice appears to be based upon expert opinion, anecdotal evidence and manufacturers’ recommendations. The five to seven day practice seems to be challenged by a study by Rogers et al. (1996) [125], of biofilm progression, which showed that it took only four days for colonization in the bladder model to extend all the way to the drainage bag (Royal College of Nursing, 2008).

A prospective study of catheter use in the US, of 43 long-term catheter users, indicated that drainage bags were changed less often than either commonly reported, or Rogers et al. suggest. In that study, drainage bags were replaced an average of every 23.5 (95% CI 21.1-25.9) days, during their six months’ participation in the study [126].

Of interest is the study outlined by Keerasuntpong et al. [127] which was a randomized controlled study that compared the incidence of catheter-related urinary tract infections in a group of 79 hospitalised patients whose catheter bag was changed every three days with that for a group of 74 patients who had their bag changed at the time of the catheter change or if the bag became faulty. A urine sample for culture was obtained for each participant every seven days, on the day the catheter was removed or on the day the participant was suspected of having an infection. The findings suggest that urinary drainage bags could be left for longer than three days but the authors were reluctant to define how long as the sample size was considered too small to rule out a false-negative result. They recommended additional study.
Single use drainage bags, including non-drainable urine bags (NDB), were recommended in England’s Royal College of Nursing Catheter Guidelines (2008) for all sites of care (hospital based and community living patients). Only one study was found of this product. Hardyck and Perrinovich (1998) [128] described a retrospective home care trial of a NDB in 63 elderly patients, comparing with the same persons who had used a typical drainable bag (DB) in the previous months. The non-drainable bag was replaced when full, but no information was given about the capacity of the bags, the mean number of bags used per day or how often they were replaced. Fewer UTIs (and hospitalizations) were reported with the NDB, 71 (2) versus 1395 (27) in the DB. Unfortunately the methodology was flawed in several ways. Counts of UTIs were reported though the timeframes were vastly different, with a mean of 44.4 months for DB prior to the intervention period and a mean of 8.8 months for NDB. UTI diagnosis was determined by mailed questionnaires to 82 home care patients and information from nurses, physicians, and patients as well as chart information reviewed by the physicians. Comprehensiveness or completeness of the chart data extraction was not described. Additional analysis comparing matched timeframes of 16 months for a subsample of 15 (and 5 more within 2 months either direction) indicated that the mean number of UTI related hospitalizations in the NDB group was significantly higher: 12.1 (SD 8.87) as compared with 2.8 (SD 4.74) in the DB group (Wilcoxon rank test p<0.005). The matched pairs were selected based on whether the NBD was used for at least a month and chart data were available. Given questions on the methodology, it seems that a well designed randomized trial is needed, but no such study was found.

There is no evidence to support the practice of adding in situ antiseptic agents to drainage bags to reduce catheter-associated infection. A paper by Thompson et al. [129] which was primarily looking at the effectiveness of hydrogen peroxide instilled into closed drainage bags in reducing infection in drainage bags and in catheters also raises the question of whether catheters are infected primarily via drainage bags or vice versa. This prospective randomised study in a hospital setting involved daily sampling for bacteriuria (See Section XII.2.h for further discussion of outcome measures for catheter-associated infection) in catheters (≥10^5 cfu/ml) and drainage bags (≥10^3 cfu/ml) and identifying the infecting bacteria species. In a sample size of 688, infection was found in 68 catheters and 78 bags. Although bag contamination was 8% in the H_2O_2 group and 16% in the control group (p<0.001) there was no significant difference in catheter bacteriuria (11% and 9%, respectively). One of the reasons given in the paper for questioning whether the drainage bag is the main source of catheter infection was that 77% of the bags in this study were contaminated later than the catheters.

Best practice guidelines to prevent infections associated with short term indwelling urethral catheters are available. The most recent of these, the EPIC 2 guidelines, were revised in 2005 and reported by Pratt et al. [122]. Designed to prevent short term, indwelling urethral catheter associated infection in NHS Hospitals in England, the guidelines are based upon a series of systematic reviews that include the best available evidence (experimental and non-experimental research as well as expert opinion). These guidelines recommend a closed catheter system where drainage bags are changed according to the manufacturer’s recommendations (5-7 days) or the patient’s clinical need. The guidelines also recommend that antiseptic or antimicrobial solutions are not added to urinary drainage bags.

Recommendations for acute care settings were issued by the Society for Healthcare Epidemiology of America (SHEA) in 2008 [130] addressing system wide infrastructure preventive activities. These include use of written guidelines, complete documentation, surveillance for catheter-associated UTI (CAUTI), education and training of personnel related to catheter insertion and management, and appropriate insertion technique. The authors noted that decreasing catheter use and duration are central to preventing bacteriuria and CAUTI. Suggestions were given for organization-wide strategies, such as reminder systems for review of catheter continuation, automatic stop order processes, ward rounds to enhance communication and review, catheter related protocols like post operative duration, and systems for data reporting. Guidelines from SHEA for preventing infection in long-term care facilities were updated also in 2008 [131].

d) Long-term management of urine drainage systems and reuse of components

The quandary for health professionals involved in the education and support of clients, who are self-managing and often financing their long term indwelling catheter drainage systems while living at home, is that they are aware that many of them are leaving the bags on for much longer than the manufacturers recommend and are often washing the bags out with a variety of solutions and reattaching the bags directly to the indwelling catheter. The reuse of drainage bags is often not a matter of choice but necessity in developing countries. In a survey of 28 continence nurses who were members of ICS, a majority (68%) said they advised their community dwelling patients to reuse drainage bags [132]. A number of reasons were given, such as cost of bags, evaluation of risk in the patient, policies, guidelines, and ability to do the procedure. While advice varied, most suggested a solution of water mixed with vinegar, household bleach, or dishwashing detergent.

There is a paucity of studies that have explored long-term self-management of urinary catheter drainage systems in a community setting. Moreover,
practices may vary considerably in parts of the world where catheter supplies are not routinely provided by prescription, as in the UK, or in developing nations where supplies are scarce. More research in this area is needed to provide guidance to clinicians. Implications involve cost, aesthetics, and environmental waste, particularly when single use non-drainable bags are used.

Madigan & Neff [133] undertook a literature review (50 studies) that explored the complications and long term management of long term indwelling catheters used for urinary retention and incontinence. Their recommendation in relation to management of drainage bags was that closed drainage systems were preferred best practice. However they also indicated that leg and bed bags may be used for up to four weeks if the system is broken daily to allow daily bag decontamination with a diluted (1:10) bleach solution. This recommendation appears to be based on the following two trials, one of which involved 54 participants sampled from an acute care rehabilitation centre and one involving 14 community dwelling participants.

Dille et al [134] report a randomised group parallel study with a pre-test and multiple post-tests utilised to determine the safety of a four week re-use of vinyl leg and bed bags compared to the usual practice of one week when de-contaminated daily with a procedure that utilised dilute bleach (sodium hypochlorite, 1:10 bleach to water). This study was based on previous research in which daily decontamination of drainage bags was done as compared with replacing with new sterile bags each day [135]. Set in an acute rehabilitation unit, 54 participants (18 female and 36 males) completed the four week data collection period. Randomised by the flip of a coin, 28 participants were in the experimental group and 26 in the control group. All participants had an indwelling catheter and were using a leg bag during the day and a bed bag at night. Both groups received identical daily bag decontamination and weekly bag and urine cultures. A standard of 0 to 100 cfu/mL was used to measure bag decontamination effectiveness and the urine cultures were processed by the Associated Regional and University Pathologists Inc. No significant differences were found between groups and the authors concluded that it is safe and cost effective to reuse vinyl bags for four weeks as opposed to the previous practice of one week, if the protocol for daily decontamination described is used. This study does not compare the practice of washing out the drainage bags with the chlorine solution either weekly or for a period of four weeks with a closed urinary catheter system to determine if that would result in fewer UTI’s.

Rooney [136] reported a study of 14 people with neurogenic bladders living at home. They changed from using daily sterile leg bags to non-sterile leg bags which were washed out after use each day with a dilute chlorine solution. Nine participants were on Foley catheter drainage and five were using sheaths. Bedside urine collection bags were used by all participants at night and there was no change made to the standard practice of rinsing the overnight bag with water each morning and recapping the drainage tubing. While the steps of the procedure were described, no information was given on who did the decontaminating, i.e., patients/caregivers or both. The study ran for three months including a preliminary baseline phase of one month. No comment was made on whether the non sterile bags were changed. There were no asymptomatic UTI infections during the study and urine samples with bacteriuria (>105 cfu/ml) did not increase. However the sample was very small and no statistical tests were applied to the results.

\(e\) Urinary drainage bag features intended to reduce the risk of cross infection

The cross-infection risks of leg bags (particularly via the tap or sampling port) have been studied by Glenister [137] and by Wilson and Coates [114]. In her study Glenister [137] concluded that designs in which the tap and outlet spouts were most widely separated were most effective at preventing contamination of the hands with urine. Wilson and Coates [114] studied sampling ports and contamination of leg bag spouts. They suggested that the night connector tubing attached to the taps on the four leg bags in their study made decontamination difficult.

A small comparative study of two sets of closed system bags with a double non-return valve and two set of bags with a single non-return valve - all inoculated with Escherichia Coli and using simulated laboratory conditions in two separate microbiological laboratories blinded to each other - found that the colonisation of a simulated bladder was significantly delayed when the double non return valve was used [138].

\(f\) Purple urine bag syndrome

There are occasional reports in the literature of purple discoloration in urine drainage bags – termed, purple urine bag syndrome (PUBS) – and there is considerable debate and diversity of opinion over the cause and significance of the phenomenon. Two case controlled studies were found. Tsumura et al. (2008) [139] compared five persons with PUBS to 10 without it. Urine sugar, serum amino acids, and leukocytes were similar, but the PUBS group differed in having a high alkaline urine in combination with bacteriuria. An earlier study had showed similar results with a high urinary pH. Mantani et al [140] conducted a case controlled study on 26 patients in three long-term wards. Fourteen (two men and 12 women) had exhibited PUBS while 12 (four men and eight women) had not. The clinical, microbiological and bacteriological backgrounds of the subjects in the two groups were compared to identify possible causes of PUBS. The findings of both studies suggest that urine that is alkaline and has a high
bacterial yield are most likely to exhibit PUBS. There is no evidence to suggest detrimental effects on patients' health or functioning of the drainage system. However, the smell can be very distressing.

Studies which have compared leg bags and catheter valves are reviewed in Section 12.

4. SUMMARY

Taken together, published studies agree that the main factors to consider in selecting leg bags are the ease of tap operation, the comfort of suspension systems and the minimisation of leakage (Level of Evidence 2). Bags in which the tap and outlet spout are widely separated are most likely to be effective at preventing contamination of the hands with urine and cross-infection (Level of Evidence 3). There is high level evidence from studies – predominantly in acute care settings - to support the use of closed urinary drainage systems (Level of Evidence 2).

5. GENERAL POINTS FROM THE LITERATURE, INCLUDING EXPERT OPINION

Provision of clearly presented information based on the best evidence available is needed for clinicians, carers and patients as many aspects of caring for a urinary drainage bag system are supported by scant or conflicting evidence or by custom.

There is agreement that the hands must be cleansed and clean non-sterile gloves put on prior to caring for the urinary drainage bag system and that, on completion of handling the system, the gloves must be discarded and the hands cleansed again [141], [122].

There is also mention of confusion arising for clinician, patient and carer because of the many different designs of urinary drainage bag taps, and the regularity with which such features are changed [142]. Manufacturers should ensure that the instructions and accompanying literature that they develop for their urinary drainage bag systems are clearly presented and easily understood [142] in a format which is convenient to retain and refer to.

6. RECOMMENDATIONS

In making urinary drainage bag selections particular attention should be focused on: the ability of the user to operate the tap; comfort (especially of the straps); freedom from leakage (especially from the welds and the tap); and discretion (especially visibility beneath clothing) (Grade of Recommendation B).

The patient’s individual needs and personal preferences should determine the use of leg / suspension / attachments and position of where the bag is worn (Grade of Recommendation C)

Maintain closed urinary drainage system for indwelling urinary catheterisation where the system is only broken to change the sterile bag according to manufacturer’s recommendation or in a shorter period of time if clinically indicated. (Grade of recommendation A).

7. PRIORITIES FOR RESEARCH

Jones, et al [141] identify many of the issues concerning the handling of urinary drainage bag systems that require further research, including the issue that has already been discussed above, of how long a closed urinary drainage system can be left unbroken before the urinary drainage bag is changed. Jones et al [141] also suggest research is needed into:

• How often and how drainage bags should be emptied?
• If a closed urinary drainage bag link system is used, does the night bag that is connected to the leg bag need to be sterile or can it be a reusable one?
• If a reusable night urinary drainage bag can be used, how should it be cared for when not in use?
• What is a reasonable method to dry reusable bags after they have been washed?
• Establishing whether the incidence of UTI is increased in hospital, community or residential aged care settings when urinary drainage bags in closed drainage systems are changed at different intervals (eg the time of catheter change rather than weekly).
• Determining in own home settings whether a closed catheter drainage system is more effective at preventing urinary tract infections than reusable non-sterile urinary drainage.
• Determining which method of cleaning non-sterile urinary drainage systems is most effective and acceptable to patients.

IX. BODYWORN URINALS

1. FEMALE BODYWORN URINALS

Pieper [143] has reviewed the many attempts to design bodyworn urine collection devices for women. The major challenge is in achieving a comfortable and aesthetically acceptable leak-proof seal with the body. Various designs have sought to achieve this by holding a collection device over the urethral meatus with the help of suction, straps, adhesive or close-fitting underwear. While none have found widespread success and usage, they are available commercially in some countries.

2. MALE BODYWORN URINALS AND DRIBBLE CONTAINERS

The urine collection devices most commonly used by men are sheaths (see Section VIII) but a variety of other products such as pubic pressure urinals are available. They comprise a ring-shaped opening or cone-shaped component which is worn around the
penis (and held firmly against the pubis by means of a belt and straps) and channels urine to an integral collection bag (Figure IX-1). Such devices are not widely used but they can be effective for individuals whose penis is too retracted for a sheath to be suitable. There are no published evaluations of these products.

They should be fitted by a specialist: a good fit is crucial for comfort and to avoid leakage. It is also important that the wearer / carer understands how to use the device and the importance of skin care. The wearer / carer will need good manual dexterity to manage the device. Several urinals will be needed to use in rotation, allowing each to be properly washed and dried between periods of use.

Dribble pouches are also available for light incontinence (Figure IX-2) but there are no published evaluations of these products.

3. PRIORITIES FOR RESEARCH

There is a need for leak-free, comfortable and aesthetically acceptable body-worn urine collection devices for women and improved (in these respects) products for men.

Female mechanical devices are designed to prevent urinary leakage in different ways and fall into three main categories: those that are applied over the urethra at the external meatus; those that are placed within the urethra (intraurethral devices) and those that are inserted into the vagina (intravaginal devices). Both designs of urethral device are intended to occlude the urethra and the intravaginal devices are intended to provide some support to the bladder neck and possibly some compression to the urethra. These devices are also known as occlusive devices and are primarily used by women with
stress incontinence. There is a recently updated Cochrane review of these devices [144].

General guidelines on patient assessment for product selection are discussed in Section II. Aspects of assessment that are particularly important regarding mechanical devices are high levels of motivation and acceptability of the concept of use, good cognition and good manual dexterity. They should probably be avoided by those with skin sensitivity or if avoidance of urinary tract infection is a priority.

1. DEVICES THAT OCCLUDE AT THE EXTERNAL MEATUS

Urethral occlusion devices have been developed to block urinary leakage at the external urethral meatus (Figure X-1). Several devices have utilized either adhesive or mild suction to achieve occlusion. In addition to the simple barrier effect, compression of the wall of the distal urethra has been hypothesized to contribute to continence.

Miniguard (Uromed Inc., but no longer available) is an angularly shaped foam device which utilizes an adhesive hydrogel to adhere to the peri-meatal area. The device is single use, removed prior to voiding, and disposable. FemAssist (InsightTM Medical Corp., but no longer available) is a hat-shaped silicone device, which adheres by applying an adhesive gel to the edge of the device, squeezing the central dome and creating a vacuum. The device is then placed over the urethral meatus and, upon release, the meatal mucosa is drawn up into the device and the urethral lumen is occluded. It may be worn for up to four hours or until voiding, after which the device is washed in hot soapy water and reapplied. A petroleum based lubricant is applied prior to device use. The device is removed for voiding and re-utilized for up to two weeks.

a) Quality of data and results

Miniguard: Eckford et al. [145] studied the efficacy of a single application of this device during a one hour pad test and reported that 25% of patients were continent, 50% were improved, but 25% had worse incontinence. Brubaker et al. [146] enrolled 411 women to their study; 390 used the device, and 346 completed the study. Results showed significant improvement in symptoms. The incontinence impact scores decreased from a mean of 41.0 (out of 300 – high scores worse) to a mean of 10.5 at 17 weeks. Twelve hour pad test showed mean urine loss decreased significantly from 15.8 to 6.9 ml and incontinence episodes from 4.9 episodes per week to 2.4 episodes at week 17. Symptoms of vulvar irritation or lower urinary tract discomfort occurred in a small percentage of subjects but it was generally transient, and only three women discontinued using the device for this reason. There were no statistically significant differences in the proportion of subjects reporting urinary tract infection during device use compared to beforehand. The authors concluded that the device was safe and effective (Level of Evidence 3).

Fem Assist: Versi et al. [147] studied 155 women with stress or mixed incontinence, of whom 133 attempted to use FemAssist and 96 enrolled in a four-week study. Their mean pad test loss fell from 27 g to 9.4 g (p<0.001) and 49% were dry. Symptomatic cure was more likely in those with mild incontinence. Of the nine women who had a positive pad test (>2 g) without the device, five were dry (<2 g) with the device (p<0.05). VAS scores showed a significant improvement for the symptom of stress incontinence (p<0.05). QoL scores improved significantly by 38% (p<0.05) for the IIQ and 29% (p<0.01) for UDI (Level of Evidence 3).

Moore et al. [148] reported on 57/100 recruited women who completed a one-month trial. Reduction of incontinence was statistically significant on pad testing, which revealed that 47% of the patients became continent and 33% had more than 50% benefit compared to baseline, while 9% had worse leakage. Those with severe baseline leakage were as likely to respond as those with mild or moderate pad test loss. Women with stress, urgency or mixed incontinence appeared to respond equally well. Dropouts included 13% who were unwilling to utilize the device (Level of Evidence 3).

Tincello et al. [149] in a 3-month prospective study involving 27 women with urodynamic stress incontinence found the median (range) loss with and without the device was 4.9 (0-65) ml and 21 (1-94) ml respectively (p<0.01); and 20 patients were
less wet when using the device. Discomfort was greater among the women with a greater loss. The acceptability correlated negatively with discomfort ($r = -0.53$) and negatively with embarrassment ($r = -0.39$); 15 patients (56%) reported that they would use the device in the long-term (Level of Evidence 3). Tincello et al. [150] later reported on 41 women using the device over a three month period, but 10 declined to participate, six withdrew before two weeks, 10 failed to attend two week follow-up and 11 did not attend three month follow-up. Only two completed the study. There was no difference in pad test or voiding diary grades. The authors concluded that the device had low acceptability and was ineffective, and could not be recommended for non-surgical management of stress incontinence (Level of Evidence 3).

**CapSure:** Bellin et al. [151] reported on 88/100 completers after 12 weeks, with 82% elimination of leakage on pad test, 91% continent on provocative stress test (single cough assessment of leakage), and 48% dry and 40% improved on urinary diaries. Pad test leakage decreased from 6.67 g (range 0.55-25.95 g) to 0.19 g (range, 0-2.5 g) by week 12. Five patients withdrew secondary to vaginal irritation and three due to poor device fit (Level of Evidence 3).

Shinopoulos et al. [152] carried out a multi-centre study enrolling 100 women with stress incontinence who wore the device for 12 weeks. Eighty-four women completed the study. Mean pad weights reduced from 6.7 g at baseline to 0.19 g by week 12. Complications affected seven patients, including urethral / vaginal swelling and vulval abrasion, but none of the affected patients withdrew from the study. The IQOL tool showed significant mean improvement from 62.3 to 90.4.

**b) Summary**

External urethral occlusive devices were found to be of varying efficacy, with minimal morbidity. Efficacy of the combined studies reveals a continence rate of approximately 50% dry and two-thirds of patients improved, but this data is from open studies (typically pre-test / post-test with no control group) and there have been no randomised controlled trials. Devices achieve occlusion either by blocking at the meatus or compressing the distal urethral lumen and adherence to the peri-meatal area is essential to success. However, the method and degree of adherence is also the determining factor for the type and severity of local irritation. Patient selection based on motivation, appropriate anatomy, and manual dexterity, in combination with efficacy and morbidity will determine overall satisfaction. There is no data which compares one extra-urethral device to another, or to other categories of products. Cost comparisons for disposable versus short-term reusable devices are not available. Efficacy for different grades of incontinence has not been established. The objective degree of continence improvement in the clinical laboratory (pad and stress tests) is greater than in community use (diaries). The devices tested in these studies are no longer available and there are no external urethral devices currently on the market.

**d) Priorities for research**

Further research on the development and role of devices which block urinary leakage at the external urinary meatus, with a focus on improving patient acceptability is recommended. One half of patients utilizing these devices in monitored studies were dry and two-thirds of the patients were improved with minimal morbidity. These devices may have a future role in the algorithm of conservative treatment based on patient acceptance, availability and cost, especially in those patients with mild or moderate stress incontinence, for occasional or intermittent use and/or for those who prefer to avoid pads or surgery.

2. **INTRAURETHRAL DEVICES**

Urethral inserts are silicone cylinders that are self-inserted or removed at the patient’s discretion. They are intended for day-time use, especially during vigorous physical exercise. While some women manage exercise incontinence by limiting fluid intake before or during exercise, by choosing sports that allow frequent bathroom access, or wearing absorbent pads, 20% to 40% of women cope with leakage by ceasing exercise [153]. These devices have external retainers or flanges to prevent intravesical migration and proximal balloons to hold the device in place. They act by causing occlusion either in the urethra itself or at the external urethral meatus [154].

The FemSoft (Rochester Medical Corporation) is the only urethral insert currently distributed. It has a soft, compressible, mineral oil-filled silicone layer with an insertion probe. Before insertion, the fluid distends the proximal end of the cylinder, as the user pushes the device (guided by the insertion probe) into the urethra, fluid transfers automatically to the distal end, allowing the device to pass through the urethra. Once in place, fluid flows back to the proximal end to hold the device in place. None of these devices are recommended for reuse after removal. The FemSoft Insert is currently packaged in a box of 28 inserts and each box is priced at $49.95. The Viva [155], Reliance and other intra-urethral devices mentioned in this sub-section, are not currently marketed.
The objective efficacy measurements utilized were the one-hour pad test, voiding diary and quality of life questionnaires. There have been no randomized control trials.

Nielsen et al. [155] [156] and Peschers [157] studied the Viva device. Peschers et al. screened 53 patients with USI and 21 patients accepted treatment with the two sphere device. During a four month study, the investigators analyzed subjective improvement and performed pad-weight and cough tests. The authors reported that 67% of patients had improvement in symptoms. Nielsen et al. [155] studied forty women who tested two variants of the device (with one or two spheres) each for two weeks in a cross-over study. They then continued with what they judged to be the better plug in period three (two months). Only 45% (18/40) completed this period but almost all (17/18) were reported to be subjectively and objectively continent or improved. Six women developed urinary tract infections and two of these had retained a plug in the bladder.

Staskin [158] reported on a four month study of 135 of 215 patients who utilized a disposable balloon tipped urethral insert made from thermoplastic elastomer, inflated with an applicator on insertion and deflated by pulling a string at the meatal plate for removal during voiding (Reliance, Uromed Corp., but no longer available). Eighty subjects discontinued the device prematurely, mostly because of discomfort and inability or unwillingness to use the device. Miller et al [159] and Sand et al [160] then reported on 63 of the 135 patients from the above cohort who utilized the device for one year.

The Reliance device provided 72% complete dryness with 17% improvement on diary, and 80% complete dryness and 15% improvement on pad weight testing in the study by Staskin et al. [158], and 79% complete dryness and 16% significant improvement on objective pad weight studies consistent with the improvement in subjective diaries (p<0.0001) for Miller et al. [159]. In the Miller study the patients reported improved comfort and ease of use over time. Sensation of device presence decreased from 35% at week one to 7% at 12 months. The volume of urine lost during exercise decreased from a median of 20g (range 4.9-80.2g) without the insert to 2.6g (1.3-6.8g) when the insert was worn (p=0.03). On a 5-point scale, in which 1 represented very comfortable and 5 very uncomfortable, subjects rated the mean comfort for the sessions performed with the insert in place as 2.1.

Treatment for positive urine cultures was undertaken in 20% of symptomatic and 11% of asymptomatic patients, 39% of patients had positive cultures which were not treated and 30% had negative cultures at all monthly intervals for the four month study. The main reason for drop-out was discomfort [158]. One or more episodes of gross haematuria (24%), cystoscopic findings of mucosal irritation at four or at 12 months (9%) and asymptomatic bacteruria (30%) on monthly cultures were also documented [159].

Robinson et al [161] carried out a small randomised controlled trial comparing the NEAT device (intra-urethral device with expandable tip) with the Reliance device. Twenty-four women (mean age 51 years) entered the study and there were eight withdrawals. Devices were randomly allocated and tested for four months. Improvement was reported for 6/8 women (NEAT) and 5/8 women (Reliance) when compared to baseline. There were no significant differences in the number of women improved, in mean reduction in urine loss, or in leakage scores between the two groups.

Boos et al. [162] reported in an abstract, a randomized prospective parallel group trial comparing the Reliance intra-urethral insert with the FemAssist external meatal occlusive device. Assessments at baseline, one month, and three months included subjective efficacy, seven day diary, and pad test (1 hour). Fifty-three females were randomized to the FemAssist and 49 to the Reliance device. There were some initial problems with sizing the Reliance. Once this was corrected, 40.8% (20) of women were subjectively dry and the remainder improved on completing the trial. Of women using the FemAssist, 28.3% [15] were dry, 60.4% [32] were improved, 9.4% [5] were no better and only one subject was made worse with device use. Problems experienced were few and minor with no serious adverse events. The conclusion was that both devices are efficacious, the FemAssist was more comfortable, but required a greater degree of user skill to achieve control of leakage (Level of Evidence 2).
Recent studies have investigated the efficacy of the FemSoft which is the only intra-urethral device which is currently available. Dunn et al. [153] measured pad weights during four standardized aerobic sessions during which six subjects were randomly assigned to exercise twice with the insert and twice without it. The medians of the averaged pad weights for the two different types of sessions were compared. Median urine loss during standardized exercise sessions decreased from 20g (range, 4.9 to 80.2g) without the device to 2.6g (range, 1.3 to 6.8g) with the device (p=0.03). Five women used the device at home during unsupervised exercise; one subject had urinary tract infection. At the end of three months, satisfaction and comfort were rated high on a 5-point scale. The conclusion was that the FemSoft urethral device is an effective, safe, and comfortable treatment for exercise incontinence in women (Level of Evidence 3).

Results from a prospective three-year study, (FDA post-approval device safety data submitted by Rochester Medical Corporation, 2002 unpublished), for evaluation of the long term effect of the device involved 41 subjects. Of the group, nine women were 65 years or older (22%, 9/41); 80% were post-menopausal with 24 women (59%) being on hormone replacement. Thirty-eight, (93%) used absorbent products to contain urine leakage prior to enrolment. A total of 66 follow-up visits took place with an average participation period of 4.2 years. Seven patients withdrew in the third year, three due to non-study related health problems and one because of dissatisfaction due to urge symptoms. Two were lost to follow up. There was a significant difference in the rates of incontinence at the three-year follow-up between users and non-users of the device: 0.83 versus 2.64 episodes per day, according to voiding diaries. The difference in urine loss during pad weighing tests was also significant. There were 24 reported adverse events in the 41 subjects enrolled. None of these events required medical intervention except for antibiotic prescription in cases of urinary tract infection. The 24 events included: bacteriuria (11); symptomatic UTI (3); urinary symptoms (3); device performance problems (2); irritation (2); and migration (1).

In 33 women a total of 38 cystoscopies were performed at three years. Only one patient was reported to have an abnormal finding, but this was due to mucosal irritation produced by an indwelling Foley catheter during one hospitalization for a problem unrelated to the device. Patient satisfaction had not changed over the follow-up time interval. The Quality of Life questionnaire (I-QoL) scores at three years were compared to those at 12 months and there was improvement from the baseline of 60.6 to 74.0. No safety concerns concerning urethral integrity were identified after the three years of continuous use. The incidence of urinary tract infections, given the high number of insertions and removals, was considered low risk (Level of Evidence 3).

b) Summary

Intraurethral devices have demonstrated high efficacy, but have been associated with urinary tract infection, hematuria and discomfort. Bacteruria, without symptomatic infection, was similar to extraurethral device use, which approaches screening urinalysis data [146] or may be similar to the rates seen with self catheterization. Device migration into the bladder, which requires endoscopic removal is the most serious reported problem. Long-term results are limited. Patient and clinician acceptance of this form of therapy has also been limited and there is currently only one intraurethral device on the market. High cost is also a factor that probably precludes more widespread application but ‘occasional’ use, for example during exercise may be helpful and affordable for some patients. Good hand dexterity is necessary to use the device (Level of Evidence 3).

c) Recommendations

Intraurethral occlusive devices may be considered for women with stress incontinence but they are invasive devices with high cost and have had limited evaluation. They may be most appropriate for intermittent and occasional use (such as during vigorous exercise) (Grade of Recommendation C).

d) Priorities for research

It is important that new devices - particularly invasive ones - are evaluated by randomized trials and comparing to control approved devices. Long-term follow-up results are needed to demonstrate the effects of such devices on the urethra and / or bladder and will determine the real value and safety of devices that initially have been adopted enthusiastically.

Further development and study of the use of intraurethral devices for the treatment of urinary incontinence is recommended. In particular assessment of their cost-effectiveness and effects on quality of life, when used intermittently or for particular activities, is recommended.

3. INTRAVAGINAL DEVICES

Support of the bladder neck to correct urinary stress incontinence has been achieved, with varying success, utilizing traditional tampons, pessaries and contraceptive diaphragms, and intravaginal devices specifically designed to support the bladder neck.

a) Quality of data and results

1. TAMpons / PESSARIES

Nygaard [163] performed a prospective, randomized, single blind, and laboratory based study testing 18 patients (age 33-73) with three 40 minute standardized aerobic sessions, utilizing a Hodge pessary, a super tampon, or no device. Urine loss was determined by a change in the weight of the pad worn while exercising. Statistical analysis of the log of urine loss revealed that women lost
significantly less urine when exercising with either the pessary or the tampon than when exercising with no device. Continence rates were 6/14 cured and 2/14 improved with tampons, 4/10 improved with a diaphragm (Level of Evidence 2).

2. Diaphragms / Pessaries

Realini et al, [164] analyzed the benefit for one week, in 10 selected patients of a coil-type diaphragm ring, which was softer than a pessary, utilizing diaries and a two hour pad test. They also gave an overall subjective evaluation of their experience. Urodynamic findings were essentially unchanged by wearing diaphragm rings. Four of the 10 women experienced clinically significant improvement in the amount of urine lost during pad tests, number of leaks per week, and overall assessment response (Level of Evidence 3).

Suarez et al. [165] included urodynamic testing in his evaluation of a contraceptive diaphragm in 12 patients. Complete resolution of SUI was achieved in eleven of twelve patients (91%) but two of them withdrew from the study because of associated discomfort from the diaphragm, therefore, complete resolution of SUI was achieved in 9/12 patients (75%) (Level of Evidence 3).

Bhatia et al. [166] reported on the urodynamic effects of the Hodge pessary on 30 women aged 29 to 71 with a history of UI. With the pessary, 24 of the 30 patients became continent when tested in supine position with a full bladder, three of the 24 patients lost urine with coughing in the standing position and demonstrated a positive cough profile despite the presence of the vaginal pessary. Uroflowmetry data show that the vaginal pessary did not produce any obstruction to the free flow of urine and suggested this is a modality to predict the outcome for bladder neck support surgery.

Richter et al (2010) [167] compared use of a pessary (ring or dish) with behavioural therapy (pelvic floor muscle training plus strategies for active use of muscles to prevent stress and urgency incontinence), compared with combined treatment in a randomized controlled trial of 446 women with stress incontinence. Outcomes were measured at 3, 6 and 12 months. There were small differences between groups at 3 months with slightly better results in terms of bothersome incontinence symptoms for the behavioural therapy group than the pessary group. Combined treatment was not significantly better than behavioural therapy alone and difference between groups were not sustained at 12 months.

The long-term discontinuation rates of ring pessaries (including the Introl device – see below) was investigated by Sarma et al (2009) [168]. A retrospective review of the notes of 273 women was carried out and found a surprisingly high rate of complications (93 (56%) of the 167 women who were successfully using a pessary at 4 weeks subsequently developed problems such as bleeding, extrusion, discharge and pain). The majority of women discontinued use of the pessary over time. It is therefore important that further studies of pessary use should include long-term follow-up results. Gorti et al (2009) [169] surveyed clinicians about use and follow-up of pessary placement and concluded that patients should be followed up at 6-12 monthly intervals.

3. Intra-vaginal devices designed specifically to support the bladder neck

Included in this category are:

1. Removable reusable intra-vaginal ring, composed of silastic, and constructed with two prongs which are placed behind the symphysis to support the bladder neck (Introl, no current distributor).

2. Single-use disposable devices: (i) A clam-type device composed of polyurethane foam, which is folded up upon its long axis and placed into the sagittal plane in the vagina, and when moistened, its dimensions expand by 30% and create a supportive cushion under the urethrovesical junction (originally called the Conveen Continence Guard, now known as Contrelle Activgard); (ii) A version of the expanding polyurethane design, with similarities to a tampon, (Conveen Continence Tampon, Coloplast, Denmark (no longer available) (Figure X-3); (iii) An expanding polyvinyl alcohol sponge (Ladycon, Home Care Engros, Norway); (iv) a simple surgical foam cylinder with draw-string e.g. Rocket stress incontinence device (Rocket Medical PLC)

Figure X-3: A female intravaginal occlusive device.
4. **Reusable intra-vaginal ring (INTROL)**

A pilot laboratory study was carried out by Biswas [170], the developer of the device, employed a straining cystogram. Eighty-six percent of the patients were continent with the device in place on cystogram. Following this study, the number of device sizes was increased from eight to 25. Evaluation studies followed examining efficacy, safety and satisfaction. Davila [171] initially demonstrated that 83% of patients were dry on pad weight test. Later [171], the researchers enrolled seventy women (53 completed) aged 24-76, 29 with stress, and 24 with mixed incontinence in a one month study. A statistically significant reduction in incontinence was noted on pad testing (stress mean 46.6-16.6 g; mixed, mean 31.9-6.8 g) and in bladder diary (stress, mean 28.6-7.8 losses per week; mixed, mean 30.2-15 losses per week). QoL scores (I-QoL) improved in both groups. With the device in place, urodynamic testing indicated normalization of urethral function without evidence of outflow obstruction. Subjects found the device comfortable, easy to use and convenient. Side effects included five urinary tract infections and 23 cases of vaginal soreness or mild irritation (Level of Evidence 3).

Moore et al. [148] detailed problems with both sizing and efficacy. Of the 80 recruits, four could not be fitted, and 11 did not satisfy all entry criteria. Of the 65 participants, 39 (60%) withdrew; 20 for distorted vaginal anatomy which made fitting difficult, five for lack of efficacy, four for constipation, and ten for unrelated patient events. In the remaining 26 patients, pad test weights decreased from a baseline median of 19g to 2g (p<0.001), 62% were continent, and 15% were >50% improved, and wished no further therapy. Moore et al. commented that the device was difficult to fit in women who have had multiple vaginal surgeries or were oestrogen deficient. Long-term follow-up showed that 18 of 26 (from the original 65) continued to wear the device at six months (interim dropouts being due to concurrent illness in half, the remainder had declining efficacy). Of these, 78% continued to wear the device for a minimum follow-up of two years (Level of Evidence 3).

In a separate study of patients with mixed incontinence by Moore et al. [148], five of 21 recruits never wore the device home, leaving 16 participants. A further two did not reach week four, because of poor efficacy or inability to fit the device. In the 14 who reached week four, the median number of leaks/day declined from 4.3 to 1.0 (p=0.002). Median pad weight loss fell from 53g to 7g. (p=0.012). Cystometry showed an increase in maximum bladder capacity (p<0.05) and a modest reduction in severity of detrusor overactivity, with no evidence of outflow obstruction. Three women discontinued because of poor efficacy or a poorly fitting device, leaving 11 of 16 participants (69%) at week eight, when median pad weight decreased to 2 g (Level of Evidence 3).

Kondo, et al. [172] found no urinary flow obstruction with the device in place. Urine loss decreased from 20.6 to 4.8 g per hour (p<0.001) on the 60-minute pad weight test. Twenty two patients (29%), reported complete continence, and 39 (51%) had decreased severity of incontinence by more than 50%. Minor adverse effects occurred in 26% of the patients. According to the global usefulness rating which was employed, 62 patients (81%) had some or maximum benefit (Level of Evidence 3).

5. **Reusable intravaginal hollow tampon (CONTIFORM)**

The Contiform intravaginal device was first tested in 2003 and although significant benefit was shown only 20% of participants were completely dry on 24 hour pad test [173]. In 2007 Allen et al. [174] enrolled 65 women to test the device and fitted 52 devices. 37 women completed the protocol (4 weeks testing). Urine loss on pad testing was significantly reduced from a median of 6.6g to 2.2g and there were significant improvements on the Incontinence Impact Questionnaire and Urinary Distress Inventory. Seven patients were unable to insert the device and two were shown to have residual urine over 100ml, but overall the authors concluded that the device was well tolerated.

6. **Disposable intra-vaginal devices**

Thyssen et al. [175] tested the Continence Guard in 26 women with stress incontinence before and after one month’s use: four women discontinued the treatment because of discomfort or difficulties in using the device 9 (41%) were subjectively cured of incontinence, 10 (45%) improved while three (14%) claimed unchanged incontinence. With the device in place all had decreased leakage at the 24-hour pad weighing test and unchanged urodynamic tests. No vaginal or urinary infections were found (Level of Evidence 3).

Thyssen et al. [176] reported on 19/22 women with stress incontinence, subjectively and objectively cured or improved in a short-term study, and who then continued the treatment with the device for one year. All 19 completed the study, 13 (68%) were subjectively dry, (26%) were improved and one (5%) reported unchanged incontinence. All but one had decreased leakage at the 24h pad test, and 67% a greater than 50% decrease. Subjectively cure was 41%, and 36% were dry on 24 hour pad test. Overall reduced leakage was statistically significant (p<0.0005) No significant changes were found in the other urodynamic measurements, specifically, urinary flow rate.

Sander et al. [177] found subjective cure in 11/55 women (20%) and improvement in 27/55 (49%) was reported. Results of the 24-hour pad test and mean leakage and epi-sodes in the voiding diary significantly decreased. After three months, 58% of the 55 patients desired to continue device usage. There was a highly significant improvement in QoL scores using the IIQ, as well as two additional
incontinence-related quality of life questionnaires. Responses to the SF-36 general health questionnaire showed no significant changes.

Hahnet al. [178] reported on 121 women, in a four week study. Patients dropped out because of vaginal irritation (25%), other product-related reasons (6%), lack of time (6%), or failure to complete a user questionnaire. Of the remaining 90 (mean age 47.5), 85 performed a 24 hour pad test, which showed that baseline leakage of 42 ml/24h decreased to 14 ml/24h (p <0.001). Of these, 39 (46%) were continent. The device was considered unpleasant by 8%, and caused some local discomfort in 62% on direct questioning: 75% of these wished to continue using the device. The authors noted that older women (age 56-65) tolerated the device and appeared more motivated to continue. Coexistent atrophic vaginitis and the use of topical oestrogen was not discussed.

Thyssen et al. [179] reported on 94 women recruited in a cross-over study, which compared two versions of the same device; the Conween Continence Guard (CCG) and the Contrelle Continence Tampon CCT. 62 women (66%) completed the study with withdrawals mainly due to discomfort or for unknown reasons. Both devices reduced leakage significantly but the CCT was significantly better than the CCG. Few side-effects were reported. Thirty-two women continued the treatment for one year or more with 63% preferring the “tampon” type design for its ease of use.

The report on the polyvinyl sponge by Glavind [180] was an acute laboratory study of only six women utilizing a pad test measurement during 30 minutes of aerobic exercise. Without the vaginal sponge the patients had a mean loss of 7g (range 2-18g) during exercise. With the vaginal sponge in situ there was no leakage.

Two papers have been published recently on the Tipi device (ConTIPi Ltd. Israel) [181] [182]. This device has a resin core with support ‘poles’ covered with a soft nylon mesh that stretches between the arms of the poles to act as a suburethral sling. Ziv et al. [183] recruited 60 women with severe stress incontinence to test the product. A seven day ‘control’ period was followed by a 28 day device usage period. There was no control arm or comparison product. Pre-weighed pads were used during the test period and the primary end point was the percentage of women achieving at least a 70% reduction in pad weight gain from the control period to the last 14 days of usage. Ten women withdrew from the study during the test period, four for device related reasons. Using intention to treat analysis 85% of women achieved at least 70% reduction in pad weight gain. The most common adverse events reported were mild and included genital tract discomfort, pain and spotting with blood; the only report of a moderate event was of candidiasis. The authors conclude that the device is easy to use, well-tolerated and effective.

Farage et al (2011) used a similar evaluation design with 57 women who had at least seven episodes of SUI per week. After a baseline period the women identified the best TIPI among a selection of three device sizes. The fitting period was followed by 14 days of device usage for up to 12 hours daily. The results of the 57 intention to treat population shows that 75% of the patients had at least a 60% reduction in SUI episodes, the subjective perspective of patients with regard to the severity of their incontinence improved and the results show also an improvement in the quality of life (statistically significant for: feeling frustrated, impact on social activities and impact on recreational activities). The authors stated that the device is safety in daily use and a nonsurgical alternative in the therapy for SUI.

b) Summary

Support of the bladder neck resulting in improved continence is possible with intravaginal devices without evidence that they cause significant lower urinary tract obstruction or morbidity, but the evidence is limited (Level of Evidence 3).

Studies performed in the acute setting, regardless of the device type, demonstrate better performance than diary based studies performed over time. Efficacy appears to be higher in patients with minimal to moderate urinary leakage.

Relatively high drop-out rates in monitored studies, during which patient support is provided, indicates the need for proper patient selection and patient and provider education, but may also indicate limitations in product efficacy, difficulties in application or other factors such as discomfort (Level of Evidence 3).

c) Recommendations

Intra-vaginal support devices may be considered as a treatment option when managing women with stress urinary incontinence, dependent upon the availability of product, patient ability to manage the product (particularly manual dexterity) patient acceptance, and cost (Grade of Recommendation C).

d) Priorities for research

Long-term results are not available and studies comparing these therapies to other forms of conservative therapy or surgery are needed.

4. OVERVIEW OF MECHANICAL DEVICES FOR WOMEN

a) Overall summary

The recently updated Cochrane review of mechanical devices for urinary incontinence in women [144] review found seven trials that met their criteria and concluded that the role of such devices is questionable. The authors state that there are indications...
that using mechanical devices might be better than no treatment but that the evidence was weak and that there was insufficient evidence to recommend any specific device or to show that mechanical devices are better than other forms of treatment.

In this section we have attempted to review all available evidence including many trials that did not meet Cochrane criteria. Most trials were open pre-test post-test trials with no comparators and the strength of this evidence is relatively weak. Although most trials showed positive effects on symptoms, this was often combined with relatively high drop-out rates and unwanted effects, such as discomfort, skin irritation or urinary tract infection.

Although many products have appeared on the commercial market, few have stood the test of time and are currently marketed – there are no external urethral devices available and there is only one intra-urethral device. There are at least two intra-vaginal devices available on the market and these may have potential to be more acceptable to women because of their similarities to familiar tampons. The relative lack of market success for these products may indicate low efficacy and unwanted effects, but may also reflect their relatively high cost compared to pads which are the main alternative.

b) Overall recommendations

It is possible that some of the mechanical devices currently marketed are effective and acceptable to a minority of women and, given that they are relatively non-invasive (with the exception of intra-urethral devices), they may be suggested to patients for consideration and testing, particularly for short-term or occasional use.

c) Overall priorities for research

The substantial withdrawal rate and the frequency of unwanted events indicates that there is a need to establish efficacy of these devices (compared to no treatment) over longer time periods (more than a year), with careful identification of unwanted effects.

There is also a need to compare devices with simple, cheap devices. The Cochrane review recommends an intravaginal tampon as a suitable comparator.

There are indications that the devices may best be used occasionally or intermittently for specific activities and there is a need for this type of use to be tested, possibly compared to the most common alternative - an absorbent pad.

As these devices aim to prevent urine leakage there is also potential for testing their efficacy compared to other treatments such as pelvic-floor exercises or surgery.

XI. MECHANICAL DEVICES FOR MEN WITH URINARY INCONTINENCE

Male mechanical devices aim to prevent urine leakage by compressing the penis. A variety of designs are available but occlusion is usually achieved with either a clamp or a peri-penile strap (Figure XI-1). Such devices have the potential advantages of low cost and simplicity compared with a sheath and drainage bag. However there is potential for tissue damage and these devices should be used with caution.

Careful assessment is necessary for use of these devices because there is potential for damage to the penis from ischaemia (restriction of blood to the penis). Such devices should be fitted by a trained health professional and subject to regular review. Use should be limited to men who are assessed as being cognitively intact, are aware of bladder filling, have normal genital sensation and intact penile skin, have sufficient manual dexterity to open and close the device (Moore 2004) and are motivated and willing to use such a device.

Figure XI-1: A penile clamp.

1. QUALITY OF DATA

The use of penile compression devices is described only rarely in the literature [184] [185] and is usually referred to as a last resort where other forms of management have failed or been judged inappropriate. There has only been one published evaluation [186].

2. RESULTS

Moore et al. [186] evaluated three different devices (Timms C3 penile compression device; Cunningham clamp; and U-Tex male adjustable tension band) in a cross-over study in which twelve men with stress urinary incontinence following radical prostatectomy tried each device in turn. Each of the devices significantly (p<0.05) reduced mean urine loss (measured using a 4h pad tests) compared with baseline measurements. There was some objective or subjective improvement in continence for
each of the 12 men with at least one of the devices, although none completely eliminated urine loss when applied at a comfortable pressure.

Ten of the 12 men rated the Cunningham clamp positively; two, the C3; and none, the U-Tex. However, the C3 and U-Tex allowed good cavernosal artery blood flow while the Cunningham clamp significantly reduced it. Overall Moore et al. concluded that, used correctly, the Cunningham clamp can be an effective method of controlling urinary incontinence (although it should be noted that complete control i.e. no leakage, was not achieved) in men with stress urinary incontinence who are cognitively intact and aware of bladder filling, and have normal genital sensation, intact penile skin and sufficient manual dexterity to open and close the device.

Expert opinion and anecdote suggest that penile clamps may be more successful when used for short periods, for example when undertaking activities such as swimming or jogging. Such activities may not only exacerbate incontinence but also preclude the use of bulky and/or absorbent products.

3. SUMMARY

Male mechanical devices can partially control urinary leakage (but not eliminate it at comfortable levels of use) but are likely to lead to reduced cavernosal artery blood flow and therefore care must be taken to ensure regular removal or release (Level of Evidence 2).

4. RECOMMENDATIONS

- Male mechanical devices may be considered for selected men with stress urinary incontinence who are cognitively intact and aware of bladder filling, and have normal genital sensation, intact penile skin and sufficient manual dexterity to open and close the device (B).
- The devices should be fitted by a trained health professional and reviewed regularly (Grade of Recommendation C).
- The devices may be considered for short-term use when undertaking sport or other activities, as an adjunct to management with other products (Grade of Recommendation C).

5. PRIORITIES FOR RESEARCH

- There is a need for mechanical devices for men which are discreet, easy to use and which prevent leakage without risk of tissue damage.

XII. CATHETERS

Urinary catheters can provide an effective way of draining the bladder in either the short-term or long-term, by intermittent or indwelling catheterisation, where alternative strategies are unsuitable or unsatisfactory. However, indwelling catheters are rarely completely trouble-free and the risk of catheter-related complications is high, with substantial detrimental impact on patients, carers and healthcare services. It is generally agreed that catheter use should be avoided wherever possible and only adopted for those for whom alternative strategies are unsuitable or unsatisfactory, after careful assessment of the patient and their particular problem [187].

This section examines the characteristics of urinary catheters, and provides a critical review of existing evidence to guide decision-making on choice of catheters, equipment and management strategies to minimise associated risks. Specific issues relating to short-term catheterisation are addressed, but the main focus of the section is on long-term management of bladder dysfunction, by intermittent catheterisation (least invasive) or indwelling catheterisation (most invasive). An overview of factors influencing choices of catheterisation strategy is provided in Table XII-1. Detailed discussion of key issues is provided under the following headings: user characteristics, catheter characteristics, associated risks/problems, catheter management.

The bulk of research evidence on catheter use relates to short-term catheterisation. In particular there are numerous trials which focus on catheter-associated urinary tract infection since this is well recognised as a major source of healthcare associated infection. The quality of data is very variable and many studies are limited by being underpowered and by other design issues, including poorly defined outcome criteria and highly selected study populations. Much less research has addressed intermittent or long-term indwelling catheter-related issues and guidance to healthcare practitioners remains largely based on expert opinion. Some of the difficulties in conducting research on use of continence products are discussed in Section III. Further discussion related specifically to catheters is provided within the following sections.

1. INTERMITTENT CATHETERISATION

Intermittent catheterisation (IC) is the act of passing a catheter into the bladder to drain urine via the urethra, or a catheterisable channel such as a Mitrofanoff diversion. The urine can be drained into a toilet, urinal, plastic bag, or other reservoir. The catheter is removed immediately after drainage. This technique avoids many of the problems associated with indwelling catheters. Intermittent catheterisation may be carried out using a sterile technique in some care settings, but clean intermittent catheterisation (CIC) or clean intermittent self-catheterisation CISC [188] is widely accepted as a safe technique for people who are self-caring in their own homes. Since some studies do not distinguish between CIC and CISC, the term CIC has been adopted to cover both throughout the following section. CIC provides much greater convenience than urethral catheterisation, without unacceptable
Table XII -1: Catheter choices. Catheters should only be considered where there is no satisfactory, non-invasive alternative to manage bladder drainage. *(Grade of recommendation in brackets)*

</table>
increases in infection rate, and has become a method of choice for management of bladder drainage for neurogenic and non-neurogenic bladder dysfunctions where urinary retention is a significant symptom and not easily remedied by other relatively simple means, eg TURP for prostatic obstruction. CIC can be taught to people of all ages, including the very elderly and children as young as four years old, with parental supervision [189] [190]. CIC can also be taught to carers, where this is an acceptable procedure to both patient and carer.

a) Quality of data

The majority of research evidence on intermittent catheterisation relates to catheter-associated urinary tract infection (CAUTI) and catheter materials and coatings. The most frequent complication of CIC is urinary tract infection (UTI) but it is unclear which catheter types, techniques or strategies, affect its incidence. There is wide variation in practice and important cost implications for using different catheters, techniques or strategies. Two relevant Cochrane reviews were identified; ‘long-term bladder management by intermittent catheters in adults and children’ [191]; and ‘urinary catheter policies for long-term bladder drainage’ [192]. The objective of the first review was to examine which intermittent catheter types, techniques or strategies, affect the incidence of UTI. Fourteen trials were included but sample sizes were small and attrition of participants was problematic. Definitions of outcome variables and follow-up periods differed, making it difficult to draw clinically useful conclusions. Several of the trials were more than 10 years old and were typically less rigorous in design and analysis. The authors concluded there is insufficient evidence to state that incidence of UTI is affected by use of sterile or clean technique, coated or uncoated catheters, single (sterile) or multiple use (clean) catheters, self-catheterisation or catheterisation by others, or by any other strategy. The objectives of the second review [193] were to determine if certain catheter policies are better than others in terms of effectiveness, complications, quality of life and economics. Comparisons included type of catheterisation (intermittent, indwelling urethral and indwelling supra-pubic) and antibiotic prophylaxis. Seven trials were included but all were small and confidence intervals were wide. There was limited evidence which indicated that prophylactic antibiotic therapy was associated with reduced episodes of bacteriuria (asymptomatic and symptomatic) in subjects using intermittent catheterisation. In both reviews, the trials which met the inclusion criteria were limited by small sample sizes and methodological weaknesses. A third review on ‘catheter policies for management of long-term voiding problems in patients with neurogenic bladder’ [194], which aimed to assess the effects of different types of urinary catheter (IC): in managing the neurogenic bladder, found there were no trials that met the inclusion criteria. Other research in this area is dominated by retrospective reviews of bladder management outcomes of patient cohorts. Long-term follow-up studies are almost exclusively of patient groups with neurogenic bladder disorders. Small scale, comparative studies of new products are common and are often industry-sponsored. Quality of life issues are vitally important for continence product users but studies are often limited by outcome measures predominantly based on user satisfaction, in the absence of clear criteria. Few studies have directly compared CIC with other methods of bladder drainage.

b) User characteristics:

CIC is a commonly recommended procedure for people with incomplete bladder emptying not satisfactorily managed by other methods. CIC can be appropriate for post-void residual urine volumes of 100ml or more in:

- Patients with neurological disorders that result in urinary retention problems, including failure to empty the bladder, incomplete emptying, detrusor sphincter dyssynergia.
- Patients who have difficulty emptying the bladder after surgical procedures, if outflow obstruction occurs either in the short or long-term.
- Patients who accumulate a build up of residual urine caused by detrusor overactivity and inadequate bladder emptying.
- Acute urinary retention (most commonly in men).
- Management of urethral stricture.
- Emptying the bladder following continent urinary diversions such as a Mitrofanoff diversion.
- CIC may be a practical option for patients who are:
  - Sufficiently motivated to manage their bladder drainage by this technique.
  - Sufficiently dexterous to perform the technique. An appropriate level of manual dexterity is essential but generally if people can write and feed themselves they have sufficient dexterity [195].
  - Sufficiently cognitively aware to adhere to a regime and empty the bladder at appropriate time intervals to prevent bladder over-distension and preserve upper urinary tract function.
  - Unable to perform the technique themselves but willing to accept the procedure from a caregiver.

Most men require some form of lubrication to aid catheterisation, which can be on the catheter surface or instilled into the urethra [196] (Level of Evidence 3). For those with preserved urethral sensation, a local anaesthetic gel may be needed. Many female patients also use a catheter lubricant / anaesthetic gel although some choose not to. In developing
countries, where resources are limited (or sometimes through patient choice), patients sometimes use plain water as lubricant [197] (Level of evidence 4). Some may benefit from adaptive equipment. An occupational therapist reported [198] on how a specially constructed penile trough (to hold the penis in a fixed position) allowed catheterisation with just one hand in a person with multiple brain injuries.

Regular bladder drainage is important to avoid potential damage to the upper urinary tract from urine reflux and raised intravesical pressure from build up of residual urine. Patients require individualised care plans to help identify appropriate catheterisation frequency, based on discussion of voiding dysfunction and impact on quality of life, frequency-volume charts, functional bladder capacity, and ultrasound bladder scans for residual urine. Some people need to catheterise several times per day, others less frequently. Catheterising frequently enough to avoid residual urine greater than 500ml is a general rule for adults but further guidance is also provided by urodynamic findings, detrusor pressures on filling, presence of reflux, and renal function. Disabilities such as blindness, lack of perineal sensation, tremor, mental disability and paraplegia do not necessarily preclude individuals from mastering the technique if they have sufficient manual dexterity [195]. Learning the technique may require more sessions for people with physical disability, such as MS, and cognitive impairment can contribute to less adherence over time [199]. Lack of motivation is the most common reason for failure, often linked to difficulty managing the technique or adhering to the required regime.

Children at school need a multi-professional assessment which may include a continence advisor, paediatric community nurse or school nurse, the child’s consultant, the child and parents. With adequate training, suitable facilities and supportive teaching staff many children are able to carry out CIC themselves either on a toilet or from a wheelchair. CIC has been shown to be a viable therapeutic option for children with a large post-void residual urine volume in the absence of any neurological abnormality [200]. Intermittent catheterisation has also been shown to be an effective technique for elderly patients with post-void residuals more than 50% of the bladder capacity, resistant to other treatment [201]. In a group of 21 patients (mean age 76.5 years), 12 mastered the technique of CIC, with the remainder catheterised by their partners or nurses. Urinary continence was restored, urgency, frequency and nocturia decreased and UTI rate diminished, resulting in improved quality of life.

In a study in a 110-bed hospital, a bladder scanner was introduced to decrease unnecessary catheterizations using either a straight catheter (in-out) or an indwelling catheter [202]. Staff members were educated on the use of the new scanner in conjunction with an algorithm to guide decisions on treatment. Fourteen per cent (11) of the 79 scans resulted in catheterization, and there was an 80% decrease in catheterizations in 47 persons unable to void, based on clinical observation during a one month period. Most of those who required catheterization were surgical patients. There were three in-out catheterizations and eight indwelling catheters were inserted, more were female (73%), and over age 75 (p=0.035).

Advantages of intermittent over indwelling catheterisation include:

- Greater opportunity for individuals for self-care and independence.
- Reduced risk of common indwelling catheter-associated complications.
- Better protection of the upper urinary tract from reflux.
- Reduced need for equipment and appliances e.g. drainage bags.
- Greater freedom for expression of sexuality.
- Potential for improved continence between.

c) Catheter characteristics

Types and characteristics of catheters used in intermittent catheterisation vary considerably so evaluation and selection of products is complex [191]. Plain uncoated catheters, typically clear plastic polyvinyl chloride (PVC), are packed singly in sterile packaging. As per industry standards, all disposable catheters are intended for one time use, but PVC catheters are frequently cleaned and reused by individual users because of cost or concern about environmental issues. Recently, to address environmental concerns related to single use catheters, a new PVC-free catheter was created and evaluated by 173 persons in comparison to the standard PVC one [203]. Both catheters had a hydrophilic coating. No significant differences were found. Some health care professionals make a distinction between ‘single-use’ (i.e disposed of after insertion) and ‘single patient use’ (cleaned and re-used by the same patient for a limited period of time, such as one week). Where products are used in ways which differ from manufacturers’ guidance, both patients and health care professionals should recognise their personal, professional / legal responsibilities. In some countries, including the US, there are very clear governmental directives that catheters identified as single-use devices should not be re-used in any setting. US patients should be provided with an adequate number of catheters to use a sterile catheter for each catheterisation, and patients and carers must be informed that catheters are identified for single use only. However, not everyone in the US using IC has the federal insurance program (Medicare), which began paying for single use catheters on April 1, 2008 at the rate of up to 200/month [204] [205]. In one US study of 34 IC users [206], many said they
did not have adequate insurance reimbursement for single use catheters, and 35% cleaned and reused catheters.

Most uncoated intermittent catheters are used with separate lubricant, although this is a matter of personal choice. Cleansing for re-use (where this occurs) varies from being washed with soap and water, boiled, soaked in disinfectants, or microwaved. Cleaned catheters are air dried and then stored in a convenient container (often plastic containers / Ziploc bags or paper bags). Metal catheters made from silver or stainless steel can be sterilized by heat or chemicals and may be used repeatedly for longer periods than other reusable materials.

Coated catheters are single use only (they are not currently suitable to be cleaned and reused) and are designed to improve catheter lubrication, ease of insertion and convenience. Coated catheters may reduce urethral trauma and CAUTI although good quality research evidence remains limited. The most common coatings are hydrophilic (which require the addition of water to the catheter to form a lubricious layer) or pre-lubricated (whereby the catheter is supplied pre-packed with a coating of water soluble gel). There are also several pre-lubricated products with an integrated collection bag (all-in-one) which gives flexibility for the user and are efficient for hospital use. Not all CIC users like this type of bag; thus trying several types of catheters for various activities, such as when home or when away, can help in decisions about what is best for the person [206].

Intermittent catheters range in size from 6-20 Ch, with most common sizes being 10-12 for females and 12-16 for males (Figure XII -1). Intermittent catheters are generally around 40cm long (male length) and are more rigid than indwelling catheters to aid insertion. A variety of aids to assist catheterisation are available (Figure XII -2).

Some women find a stiffer catheter easier to handle and some designs are slightly curved and made only in female length (around 18cm) to accommodate their requirements. A new compact catheter of 7cm was as effective in 23 of 24 women in removing residual urine as 20cm catheters [207]. Some manufacturers produce conveniently packaged ‘catheter-sets’ where the catheter is already attached to a urine containment pouch inside the pack and a non-touch, clean technique is facilitated by holding the catheter inside the bag and gradually advancing it from the bag during insertion. Catheter designs may include a protective tip to help reduce the transfer of bacteria from the distal region of the urethra further into the bladder. Patients should have the opportunity to try different catheters and choose which best suits their needs and lifestyle. Different catheters / packs may be appropriate at different times e.g. when added convenience for quick and efficient use and disposal is important, such as going to work or on holiday.

An effective intermittent catheter should have the following characteristics:

- Smooth for comfort, but sufficiently firm for easy insertion and maintenance of lumen patency.
- Minimal friction on insertion or removal.
- Smooth edges to catheter eyes to avoid tissue trauma on frequent catheterisation.
- Shaped for easy passage through urethral contours.
- Easy to hold and manipulate for those with limited dexterity.
- Easy to identify correct end for insertion and for drainage, for those with visual impairment.

Although there is an increasing range of intermittent catheter types on the market - including many pre-lubricated products with integrated collection bags - the quality of evidence for clinical benefit is poor. De Ridder et al [208] conducted a prospective, randomised, parallel, comparative trial of a hydrophilic coated catheter with an uncoated PVC catheter with
123 male spinal cord injured (SCI) patients. Only 57 completed the 12 month study but fewer patients with the coated catheter experienced one or more medical complications higher in persons with indwelling catheters, for pressure ulcers and days in the hospital, and kidney stones, though infrequent, were higher at times. Psychosocial outcomes also did not favour IC users, and each measure (satisfaction with life, perceived health status, and participation in society) was lower than the other groups, though not significantly so. The authors said that better understanding of psychosocial issues could be attained though prospective studies, as other factors than bladder management might affect quality of life.

1. Urinary tract infection

It is difficult to know the prevalence of UTI associated with intermittent catheterisation as reports vary widely and definitions of UTI are inconsistent, sometimes based on bacteriuria alone (asymptomatic) and sometimes on symptomatic UTI (with or without clearly defined criteria). In a study of 41 European centres serving children with spina bifida, although most centres had established protocols for diagnosis and treatment of UTI, no consensus was identified for common protocols [215]. Other variations found included methods of evaluation, catheterisation techniques, frequency of urinalysis / culture, administration or not of prophylactic antibiotics, and the patient group studied (including gender, functional ability, behavioural and personal hygiene factors).

In a prospective study of 128 SCI patients, where the incidence of UTI was calculated as the number of episodes per 100 person-days, the overall incidence of UTI was 0.68. The rate for males using CIC was 0.41, compared to 2.72 for those using an indwelling catheter [216]. Biering-Sorensen et al. [217] studied 77 SCI patients on CIC after five years and found that 81% had been treated for at least one UTI, 22% had two-three UTIs/year and 12% had four or more per year. The technique of intermittent catheterisation used does not seem to be a risk factor and despite different catheterisation techniques used, the number of episodes of clinically significant nosocomial urinary infections and the mean species turnover remains similar [218] (Level of Evidence 2).

In the Cochrane review cited above [191], the primary outcome measure was catheter-associated infection (definition of infection as used in the trial reports). Fourteen trials met the inclusion criteria but too little data could be entered into a metaanalysis to produce meaningful data summaries. Based on the available data, the authors concluded that there appeared to be no clear difference between various methods of catheterisation (sterile catheterisation techniques, clean catheterisation with a single-use sterile catheter, or clean catheterisation with a clean reused catheter). Whilst the outcomes of this review raise questions over efficacy and cost-effectiveness of expensive coated catheters it is clear that further
robust research is needed. All sample sizes in the trials were small and only two included statistical power calculations, although they were unable to achieve their predicted sample sizes. Most studies suffered from high attrition rates and several reports were more than 10 years old. The challenges of obtaining sound data in this clinical area continue to hinder the accumulation of evidence to help guide healthcare practitioners. A common difficulty is in the establishment of robust outcome measures. UTI remains the most clinically important primary outcome variable but bacteriuria/positive urine culture is not clinically relevant unless accompanied by symptoms. Symptoms themselves may present in vague and imprecise ways, especially in elderly and/or SCI patients where symptoms can be masked or unclear.

Since the Cochrane review two further studies have compared hydrophilic versus plastic IC catheters and examined the effect on UTI [219]. In a community study of patients with spinal cord injury (45 participants completed) Cardenas and Hoffman found no differences in the incidence of symptomatic UTI between the groups, although the number of antibiotic treated UTIs was significantly smaller in those using hydrophilic catheters. Regression analysis showed that women were more likely to have UTIs than men and it is noteworthy that there were twice the number of women in the control (plastic catheter) group compared to the hydrophilic group (N=11 versus N=5).

Cardenas and other co-workers also carried out a randomized trial of hydrophilic or plastic IC catheters in SCI patients in hospital. This study demonstrated benefit from the hydrophilic catheter during initial early rehabilitation with a delay in the first symptomatic UTI [220]. Fifteen North American SCI centres took part, and 224 patients were randomized to the catheter type within 10 days of beginning IC, and were followed either in the hospital or rehabilitation then, when discharged to the community, for up to 3 months more, for a total of up to 6 months. This delay in first UTI resulted in a daily risk reduction of 33% and during the initial institutional time the UTI rate decreased by 21% (p<0.05) in the hydrophilic group. However, no differences were found between the two groups in the incidence of UTI over the whole study period.

A Cochrane review on urinary catheter policies for long-term bladder drainage [221] reported limited evidence that prophylactic antibiotic therapy was associated with reduced episodes of bacteriuria (asymptomatic and symptomatic) but all trials were small and confidence intervals were wide. The authors caution that possible benefits from prophylaxis must be balanced against possible adverse effects such as the development of antibiotic resistant bacteria.

In order to improve rigorous clinical evaluation of current and innovative products for CIC, more epidemiological data on user populations and characteristics of catheter use is needed. A recent Canadian national survey of intermittent catheterisation practices following SCI [222], reported on 912 responses to a 36-item self-report postal questionnaire. Fifty five per cent of respondents used intermittent catheterisation regularly, with users forming a significantly younger group than non-users (p=0.001). The majority of users (73%) used a clean technique. The remaining 27% reported using a sterile technique. Uncoated catheters were used most commonly; 74% only used uncoated catheters; 15% used hydrophilic coated catheters; and 11% reported using both types. These notable differences may be partially related to patient education, costs to patients and health insurance funding constraints. The majority of uncoated catheter users used their catheter only once (53%) but a further 30% used their catheter more than nine times. The mean frequency of self-reported CAUTIs in the past 12 months (symptomatic but not necessarily confirmed by laboratory evidence) was 2.6, with females experiences significantly more infections than males (p=0.003). Although the use of hydrophilic coated catheters was associated with a lower rate of CAUTI (2.46 versus 2.62 for those using uncoated catheters), this difference was not reported as statistically significant. However UTI rates are multi-factorial and are unlikely to be fully accounted for by the variables investigated. A significant relationship between number of catheterisations per day and CAUTI rates was identified, with those who catheterised only once a day having the highest rate of infections (p=0.03). This is consistent with previous suggestions that increasing the time that colonised urine is present in the bladder is associated with increased infection rates [208]. It is interesting to note that, while extra fluid intake was positively related to reduced rate of CAUTI (p<0.001), catheter re-use, catheter disinfection and antibiotic prophylaxis were not significantly associated with CAUTI rate. Clearly there are potential limitations in this study as with any which employs self-report methodology. These include self-selection of respondents, accuracy of recall and quality of information provided, but the large number of respondents and the degree of internal consistency reported by the researchers provide credibility to these results.

Several studies have sought to determine whether the antibacterial effects of cranberry extract will reduce or eliminate bacteriuria and pyuria in patients using intermittent catheterisation, particularly in SCI populations [223] [224]. In a randomised, double-blind, placebo-controlled study of 48 SCI patients living in the community and using intermittent catheterisation or external urine collection device, participants ingested 2g concentrated cranberry extract in capsule form or placebo daily for 6 months [224]. There were no differences between groups with respect to number of urine specimens with bacterial counts >10^4 cfu/ml, types and numbers of different bacterial species, numbers of urinary leukocytes, urinary pH, or episodes of symptomatic infection.
2. Tissue trauma, strictures and other complications

Long-term follow-up studies have examined other complications associated with intermittent catheterisation and found urethral trauma to be common [225] [226]. Urethral bleeding is frequent in new patients and has been noted to continue to occur in up to 30% on a long-term basis [226] [227], however risks of tissue trauma may be reduced with newer catheter products which are designed to reduce friction. Consequently the outcomes of older studies need to be considered with caution. The withdrawal frictional force was compared between two hydrophilic coated catheters and one uncoated catheter in a prospective, randomised, participant-blinded, crossover trial by Stensballe et al [228]. Forty participants completed the study and it was interesting to note that while one coated catheter (SpeediCath) exerted a lower mean withdrawal force than the other catheters, the second coated catheter (LoFric) exerted a significantly higher mean friction force than both the other catheters. Both hydrophilic coated catheters were associated with less microscopic haematuria than the uncoated catheter. Similarly, there was a lower incidence of microscopic haematuria reported in two of the coated catheter groups compared to uncoated catheters in trials included in the Cochrane review [191]; 0.31 versus 0.65 [229]; 6/14 (43%) v 11/14 (78%) [230]. Trauma of the urethra, especially in men, can cause false passages. Treatment for false passages in SCI patients by six weeks indwelling catheter use and five days antibiotics, has been reported to be effective [231] (Level of Evidence 3). The false passages had disappeared on cystoscopy and CIC could be restarted.

It has been claimed that the long term risk of urethral stricture formation may be less when hydrophilic coated catheters are used [232]. The degree of urethral inflammation, measured by urethral cytology in two groups using CIC (one using ordinary PVC catheters with lubricant; the other using hydrophilic coated catheters), showed significantly less urethral inflammation in the hydrophilic coated catheter group. Although this data suggests some benefit in using hydrophilic coated catheters to minimise stricture formation in the long-term comparative studies are limited. One recent follow-up study of 31 females with spina bifida, using CIC for a median of 15 years, examined risk of urethral lesions. There were few problems reported (only on 20 occasions in a total of 459 patient-years), despite long-treatment periods and use of non-coated PVC catheters [233].

The relative importance and cost-effectiveness of hydrophilic catheter coatings has not been adequately addressed in large scale studies to date. Hedlund et al. [234] in their review of 28 CIC studies, called for a prospective, randomized, long-term, multi-centre study to address clinical benefit and cost effectiveness. Data on patient characteristics should include age; gender; diagnosis of bladder dysfunction; reason for CIC; physical and mental disability; manual dexterity; and previous treatments. Effect parameters should include number of catheterisations; urinary tract infection (symptomatic or asymptomatic); early and long-term urethral complications; patient satisfaction, preferences; and drop-out rates. Robust studies of this nature are still awaited.

3. Other complications

Formation of bladder stones has been found to be associated with long-term use of CIC in a number of studies [235] (Level of Evidence 2). Barroso et al. [236] reported an increased risk of developing bladder calculi in children performing CIC based on the records of 403 children. Stones were diagnosed in 28 patients. The incidence was slightly higher in those with a Mitrofanoff conduit but was not influenced by bladder augmentation (Level of Evidence 3). A retrospective study of 140 SCI patients, followed up from 1987 to 2003, identified 27.9% of patients diagnosed with epididymo-orchiditis. This problem was more common in patients using CIC compared to indwelling catheterisation (42.2% v 8.3%, P= 0.03). Multivariate analysis showed CIC to be an independent risk factor for epididymo-orchiditis, with SCI patients in this study subject to a 7-fold higher risk (OD 6.96; 95%CI, 1.26-38.53) [213]. While the risk of cancer in long-term indwelling catheter users is known, (see section 12.2.10 below) squamous cell cancer in persons with intermittent catheters has been reported also in at least eight cases. A number of factors may be involved including leukoplakia, bacteriuria, trauma from the catheter and squamous metaplasia, a premalignant change [237].

e) Catheter management

1. Education, support and quality of life (QoL)

Good education of all involved in CIC, good patient compliance, use of an appropriate catheter material, and good catheterisation technique have been identified as the most important measures to prevent adverse complications [209]. Factors affecting adherence to self-catheterisation procedures have been explored, addressing both initial mastery of technique and both short-term adherence and long-term adherence [238] [239]. Time taken to build confidence is variable and may range from days to years [239]. General determinants of adherence related to knowledge, complexity of the procedure, misconceptions, fears, shame, motivation, quality and continuity of professional care.

CIC may affect both sexuality and sexual activity [240] and sensitive support and teaching are needed. An emotionally negative response can occur, which requires individualized teaching in a relaxed, supportive environment [240]. Adequate information combined with thorough teaching and good
communication can help new CIC users gain initial acceptance and adherence to the procedure [239]. Some women are not able to locate the urinary meatus, and they may not be comfortable in learning and thus require additional coaching, encouragement, practice and support [241] [206] [240]. Other anatomical issues need to be considered as well, such as redundant prepuce in some males, false urethral passages, and bladder spasms [242]. In addition, lack of adequate bathroom accessibility, especially in public places, can be a major barrier to adherence [242] [206].

Integration of the CIC regime into everyday life was a recognised difficulty and for younger patients, in particular, availability of materials, physical impairments and resistance to ‘sickness role’ were factors which could also compromise adherence. Qualitative research studies using a grounded theory approach have identified similar factors influencing variations in quality of life (see also section XII.4). These include sex; lifestyle; frequency of duration of carrying out CIC; technical difficulties; type of catheter; comorbidities; and individual predispositions [241].

In the large scale Canadian survey above [222] 71% reported that CAUTIs had negatively impacted on their QoL score (a 10-point scale). Several significant variables associated with CAUTI and QoL were determined. Interestingly, time lost from social activities was more strongly associated with compromised QoL than actual number of infections or days lost from work. In another study in 41 persons with SCI, treatment success correlated positively with the Qualiveen QoL measure. Success criteria involved clinical symptoms of continence, lack of autonomic dysregulation (dysreflexia), and urodynamic testing for adequate bladder storage capacity (> 360 mL) and detrusor pressure (< 40 cm water) [243].

Twenty two teenagers and young adults with myelomeningocele were interviewed about psychosocial factors related to CIC [244]. Deciding when to disclose CIC use was important in relation to peer support and friendships, and many wished they had done so at an earlier age, with the help of an adult. In fact everyone in a group needed to appreciate the need to avoid gossip. Those not in wheelchairs found it harder to convince others of their need to use CIC. In healthcare settings, many wanted to perform self-catheterisation instead of staff doing it. Information about sexual function was desired by many. An Internet based qualitative study in the US aimed at discovering issues and problems in long-term CIC users [206] found key concerns related to use of bathrooms that were dirty and inaccessible and a lack of knowledge of options in supplies and/or insurance coverage. Other themes involved knowing the body, practising intermittent catheterization, hassles, and adjustment in making intermittent catheterization a part of life. Experienced CIC users explained how they made adjustments to include CIC in daily life by paying attention to their routines.

More education may be provided to catheter users through the Internet in the future. In a study using 18 articles written for persons with spinal cord injury (based on suggestions from patients and rehabilitation nurses), consumers were satisfied with the information and scored this approach as 8.02 on a 1-10 scale with 10 as being most satisfied [245]. Information was available in English and Spanish. Utilization during the 13 month study, scored as “hits” on the website, was far more frequent in the Spanish language materials (n=811, 70%) than “hits” for the English materials (n=351, 30%). Examples of article content in both languages included cranberry juice and UTIs, cleaning the drainage bag, types of urinary management and only in English, latex allergies and catheter use, autonomic dysreflexia, and sexuality.

2. Catheter cleaning for re-use

Where catheters are cleaned for re-use they may continue to be used many times, up to weeks or even months. However, health professionals and users need to recognise their personal responsibilities and liabilities in supporting this approach since manufacturers’ guidance will normally relate to single use only (see also Section XII.1.c). Questions over how long the same catheter may be safely re-used require further examination, and may be particularly important in developing countries, where access to new supplies may be limited [246]. Methods of cleaning or re-sterilising include soaking in a variety of antiseptic solutions or boiling water or microwave sterilisation. In a study which compared three home cleaning methods used by patients performing CIC, all of the following were found to be effective: 0.6% hydrogen peroxide; bleach in a 1:4 solution with tap water; and betadine in a 1:2 solution with tap water [247]. None of the cleaned catheters showed detectable bacterial growth for 48 hours after the cleaning procedure was performed (Level of evidence 4). Lavallee et al. [248] also compared the effectiveness of hydrogen peroxide, vinegar, dishwashing detergent, and tap water alone to clean catheters contaminated with Pseudomonas aeruginosa and Escherichia coli. They also examined the effect of immediate rinsing and drying before cleaning. Results indicated that rinsing and drying immediately after use was the most effective at reducing bacteria to near zero (Level of evidence 4). Microwave sterilization has been advocated by some, but has not been adequately evaluated. A study by Sherbonty, et al. [249] showed that even where standardized instructions (both verbal and written) were provided, microwave sterilization techniques by patients performing CIC varied considerably. Many patients surveyed did not follow the study instructions recommending sterilizing used catheters on a daily basis, cleaning with soap
and water and air drying before inserting into a microwave oven on a paper towel. Microwaving on a high setting for six minutes on a rotation table was recommended together with a heat sink – a cup of water in a microwave-safe container placed in the microwave to absorb extra heat. Catheter melting was reported by 63% and was significantly associated with the absence of a rotation table. If microwaving is to be accepted as an appropriate sterilization method then users must be provided with a standardised, evidence-based, protocol to follow. A recent study reported the development of titanium dioxide-coated catheters for CIC which were easily sterilized under certain light sources and were shown to be safe in experimental studies [250]. Preliminary clinical analysis with 18 volunteers was also promising.

f) Comparisons between intermittent and indwelling catheterisation

A systematic review of risk factors for UTI in adults with SCI reported evidence of fewer infections in patients using intermittent catheterisation compared to indwelling catheterisation [251]. Twenty two studies met the inclusion criteria for evaluation but the authors noted that many had important methodological deficiencies. Intermittent catheterisation has also been shown to be associated with fewer UTIs compared to indwelling catheterisation in elderly patients after surgical repair of hip fractures [252] and in a comparative study of patients at a hospital department of urology [253].

g) Catheter use over time in persons with SCI

Bladder management methods in 24,762 patients were tracked for over 30 years, using the US National Spinal Cord Injury Database, yielding the results summarised in Table XII-3 [168]. Surveys were completed every five years to evaluate catheter use at discharge from rehabilitation. In addition, continued use in the same individuals was evaluated 30 years later in follow up data with 12,984 to determine changes in use over time.

Table XII-2 provides some guidance on patient education and troubleshooting for CIC.

Guidance for common problems:

• Catheter will not go in at first attempt – relax for a while and try again a bit later; lubricate catheter (eg dipping in water or gel); if necessary seek professional guidance.

• Catheter inserted into vagina by mistake – withdraw, wash and re-insert.

• Catheter will not come out – leave for a few minutes, relax and try to ‘let go’, cough gently and withdraw catheter.

• UTI – report changes in urine (eg blood, sediment, smell). Know how to recognise signs of symptomatic infection and seek treatment and review of CIC technique.
At discharge from rehabilitation, condom catheter use decreased gradually (35% in 1972 to 1.5% in 2001) while clean intermittent catheterization increased from 13% in 1972, peaked in 1991 at 56%, and fell slightly to 50% in 2001. Indwelling catheter use initially decreased during this time (33% in 1972 to 17% in 1991) but increased somewhat to 23% in 2001. In follow up data, the great majority of those originally using an indwelling catheter stayed with it, i.e., 71% after 30 years. However, most persons using CIC or condom drainage did not continue to use them, and only 20% and 35%, respectively, did so after 30 years. This indicates that despite CIC being the bladder drainage method of choice, individuals with SCI might use indwelling catheters if not able to manage CIC (Level of Evidence 3).

Patel et al. [254] examined the outcomes of different forms of urinary drainage for men with acute urinary retention. After a short period of indwelling urinary catheterisation patients were taught to use CIC (34 men). Patients who failed this were re-catherised and taught to manage a valve or failing this a leg bag (16 men) and then discharged home. The CIC group had a higher rate of spontaneous voiding (56% v 25%) and a lower incidence of UTI (32% v 75%). At TURP 20% in the CIC group had a UTI compared to 69% in the indwelling catheter group. Patients using CIC preferred it and had fewer complications. The authors concluded that CIC was well accepted by those patients who were able to manage the technique, resulted in fewer UTIs and should be considered in patients presenting with acute retention.

In a recent 2-week prospective study of intermittent catheterisation versus indwelling urethral catheterisation in older female patients in a rehabilitation setting, 81 females >65 years with post-voiding residual volume persistently >300 ml were randomized to one of two groups [255]. Both groups demonstrated similar success in regaining bladder function and similar rates of bacteriuria. The authors concluded that intermittent catheterisation was justified in managing this patient group, particularly since indwelling catheters were deemed to hinder rehabilitation and adversely affected quality of life.

An RCT of 72 women post-urogynecological surgery (stress UI or pelvic organ prolapse) compared intermittent catheterization (CIC) with supra-pubic catheterization (SPC) [256]. The length of hospital stay was decreased significantly (Mann-Whitney p=0.003) with CIC (median 5 days, range 2-19) as compared with SPC (median 6 days, range 2-15). The days of catheterization also decreased significantly (Mann-Whitney p=0.01) with CIC (mean 4, SD 26, median 2) as compared with SPC (mean 5, SD 36, median 4), but the differences were viewed as limited clinically. Post-op UTIs were higher in the CIC group (13 versus nine in the SPC group), but not significantly (Fishers' exact p=0.44). Of note, the CIC group had the opportunity to void much sooner than the SPC group because the latter were on straight drainage for 48 hours post-operatively as hospital policy, and this may have had an impact on the results and clinical relevance.

In a prospective RCT of CIC versus supra-pubic catheterisation (SPC) for post-operative bladder care following hysterectomy in 40 women there was no significant difference in the length of bladder care between the two groups [257]. Bacteriuria was higher in the CIC group at days 3 and 5 (p=0.05 and 0.004, respectively) although it is unclear whether there was evidence of symptomatic infection. However, there was a higher incidence of symptoms / problems arising from the SPC site, of which 23% were shown to have a positive wound swab. The authors concluded that despite a higher rate of bacteriuria, the high incidence of site problems with SPC could be avoided by CIC. The technique of CIC was seen to be more acceptable to patients (p=0.009); allowing fewer disturbances at night (p=0.006); greater freedom to lead a normal life during the day (p=0.000); and less anxiety / embarrassment (p=0.005) compared to SPC. However, in a study of 43 persons with tetraplegia who were on artificial ventilation comparing IC and SPC, SPC users had significantly fewer urological complications and better quality of life, as measured by the ICIQ-SF (3 items), but not significantly better [258].

**h) Summary**

CIC is the preferred method of urinary drainage in patients with neurogenic bladder dysfunction and others with problems of bladder emptying who are...
capable of performing the procedure and who find it acceptable. It can be taught to patients of all ages who have sufficient manual dexterity and motivation to manage the technique. Urinary tract infection is the most frequent complication and the most important preventative measures for all complications are good education of all involved in CIC management, good patient compliance and support, use of an appropriate catheter material and good catheterisation technique. Difficulties in carrying out the procedure such as physical and technical difficulties, embarrassment, time involved and lack of appropriate public facilities may deter users from adhering to the regime. Hydrophilic-coated catheters confer benefits in terms of comfort and minimised tissue trauma compared to non-coated catheters (Level of evidence 2/3) but evidence of benefit in relation to urinary tract infection is less clear.

The available data on intermittent catheterisation does not provide convincing evidence that any specific technique (sterile or clean), catheter type (coated or uncoated); method (single use or multiple use), person (self or other), or strategy is better than any other for all clinical settings. This reflects lack of reliable evidence rather than evidence of no difference. Currently clinicians will need to base decisions about which technique and type of catheter to use on clinical judgment, in conjunction with patients. Differential costs of catheters / techniques may also inform decision making.

In particular, CIC has been shown to have benefits over indwelling catheterisation in the following ways:

- Avoidance of common problems associated with LTC use such as catheter leakage and / or practical management of drainage systems
- Avoidance of complications linked to bacterial biofilm formation, including catheter encrustation and blockage. Strong evidence for reduced risk of CAUTI is less clear.
- Maintenance of some level of bladder capacity and muscle tone by allowing the bladder to fill periodically, compared to free drainage by indwelling catheter.
- Less urethral inflammation (measured by cytology) than urethral indwelling catheterisation (Level of evidence 2/3).
- Lower incidence of bladder calculi than indwelling catheterisation (Level of evidence 2/3).

2. INDWELLING CATHETERISATION

Indwelling catheters (Figure XII-3) may be used in the short-term to manage an acute need for controlled bladder drainage or as part of a long-term management strategy (Table XII-1).

Catheters may be inserted into the bladder urethrally (UC) or suprapubically (SPC) through an incision in the abdominal wall. The continued requirement for indwelling catheterization should be reviewed at regular intervals and the catheter removed promptly if no longer necessary, since catheter use is associated with a number of risks. The major complication associated with short-term, indwelling catheters used in acute care, is nosocomial (healthcare acquired) catheter-associated urinary tract infection (CAUTI), which can lead to life-threatening bacteraemia in vulnerable groups and may also contribute to reservoirs of antibiotic resistant microorganisms [187] [122] [259]. Long-term catheters (LTC) are also associated with increased risk of CAUTI and a further range of problems including: recurrent blockage due to encrustation by mineral deposits; meatal tissue damage - often caused by excessive weight from heavy drainage bags; frequent bladder spasm with potential expulsion of the catheter; formation of bladder calculi; and potential for long-term neoplastic changes in the bladder (although further long-term studies are needed to establish this risk).

Although for some patients an LTC catheter can provide satisfactory management of bladder problems and greater independence, others experience pain and discomfort with a catheter in situ and / or, are distressed by the impact of a catheter on their body image and sexuality. Intermittent catheterisation (See Section XII.1) is less invasive and is generally associated with fewer risks.

a) Quality of Data

Nine Cochrane reviews relating to short and long-term indwelling catheter use were identified. Five reviews on short-term (<14 days or other temporary
short-term use as defined by trialists) catheter issues included: types of urethral catheters for management of short-term voiding problems in hospitalised adults [260]; policies for bladder management[192]; the role of prophylactic antibiotics [221]; use of alpha blockers for acute retention prior to a trial without a catheter [261] and policies for removal of short-term indwelling catheters [262]. The objective of the first review [260] was to determine the effect of type of indwelling urethral catheter on the risk of UTI. Twenty-three trials - comparing different types of standard catheters or a standard catheter with an antiseptic catheter (silver alloy or impregnated with silver oxide), or an antibiotic impregnated catheter (either minocycline and rifampicin, or nitrofurazone) - met the criteria. The reviewers concluded that currently available evidence suggests that silver alloy catheters prevent asymptomatic bacteriuria in the short-term catheterised patient, although trials are generally of poor quality (Level of evidence 2/3). They also recommended that further economic evaluation is required to confirm that reduction of infection compensates for the increased cost of the silver alloy catheters. Catheters impregnated with antibiotics were also beneficial in reducing bacteriuria in hospitalised adults catheterised for less than a week but data were too few for those catheterised longer. However, it is important to note that although bacteriuria is a commonly used outcome measure in CAUTI studies there is much debate over the clinical utility of this measure. Many studies fail to distinguish between asymptomatic bacteriuria and symptomatic infection. This is discussed further in Section XII.2.h.3.

The second review [192] included 14 trials which reported on comparisons between SPC and UC for short term (up to 14 days). Higher relative risks scores were found for UC related to more bacteriuria (RR 2.60; 95% CI 2.12 to 3.18), more frequent re-catheterization (RR 4.12; 95% CI 2.94 to 7.56) and increased discomfort (RR 2.98; 95% CI 2.31 to 3.85) (Level of Evidence 1). The third review [221] included six parallel group RCTs and reported weak evidence that antibiotic prophylaxis reduced the rate of symptomatic UTI in female surgical patients, compared to antibiotics given when clinically indicated. The review of policies for catheter removal [262] reported suggestive, but inconclusive, evidence of benefit from midnight removal of the catheter (larger volumes at first void) and shorter hospital stay after early rather than delayed removal.

In the fifth Cochrane review [261] use of alpha blockers prior to a trial without a catheter for acute retention was evaluated. This treatment is believed to relax smooth muscle in the prostate which would improve urine flow and decrease the need for recatheterisation. Five clinical trials were involved, in four trials ranging from 24-72 hours prior to catheter removal in most persons (up to eight days in one trial). In the other study, the drug was given for eight days. Results overall were mixed, with two trials favouring the treatment and two favouring placebo, and thus there was limited but positive evidence that this was helpful. There were some side effects, such as hypotension and headache, but this was similar in the placebo groups. Further research was suggested.

Of the four Cochrane reviews relating to long-term catheter use, a review of 400 articles for comparative methods of using catheters for neurogenic bladder management, updated in 2011 [194] failed to find any trial that met the inclusion criteria. A second review [263] to compare types of indwelling catheter for long-term use (defined as >30 days) found only three trials which met the inclusion criteria. One trial compared antiseptic impregnated catheters with standard catheters and two compared different types of standard catheter. The authors reported ‘an astonishing lack of evidence for this clinically highly relevant problem’. Since the included studies were very small and showed methodological weakness, the authors concluded that the available evidence was insufficient as a reliable basis for practice and catheter choice remains largely based on clinical experience. In the third Cochrane review on ‘urinary catheter policies for long-term bladder drainage’ [264], seven trials met the inclusion criteria. All were small, with wide confidence intervals. No appropriate trials addressed comparisons between: indwelling UC and SPC; UC and intermittent catheterisation; or SPC and intermittent catheterisation. Evidence pertaining to whether antibiotic prophylaxis is better than antibiotics given when clinically indicated, was insufficient as a basis for clinical practice.

A fourth new Cochrane review for long-term catheter care involved washout policies for the management of long-term catheters in adults [265] which examined five trials, four of which were poorly reported or designed. Two crossovers compared group differences not sequential treatments in individuals, and two parallel groups provided limited value. One trial with a strong methodology had a small sample size. No differences were found in three studies in which solutions were compared: saline, acidic, and antibiotic. Unfortunately, there was not enough evidence overall to conclude that washouts were of benefit. Larger size samples in full randomized trials are needed.

There was little research to judge the value of catheter clamping prior to removal, and one (non-Cochrane) systematic review [266] of postoperative clamping in three clinical trials in 224 surgical patients (mostly women) was inconclusive. In two studies, clamping in comparison with free drainage was not effective in reducing UTI (not defined) or retention post removal. Time to first void decreased in one study. Recatheterisation and length of stay were measured in one study each, and were not different between groups. More recently in a trial in Sweden, 113 persons >50 years with short term
catheters post hip fracture were randomized to clamping or free drainage [267]. The primary outcome was the time to normal voiding, with a median of 6 hours (Q14-Q38) in the group with clamping and four hours (Q13–Q37. 25) in the group with free drainage. This difference was not significant, nor were groups different related to recatheterization or length of hospital stay.

Overall long-term catheter care practices remain poorly supported by research evidence. This is at least partially due to difficulties in conducting trials in long-term catheterised populations for a variety of reasons, many of which have been discussed in earlier sections (See Sections XII, XII.1 and XII.1.d).

The impact of long-term catheters on users’ quality of life (QoL) is a very important issue which has not been studied adequately. No Cochrane reviews have dealt with this topic directly, although several reviews have included issues with an impact on QoL such as catheter related complications and comfort. One RCT addressed education needs of catheter users. Other studies include a small number of prospective cohort studies, with the remainder being retrospective studies and case series reports, providing evidence at Level 3. Much relevant research uses qualitative research methodologies, aimed at understanding the nature of long-term catheter-related issues and patient concerns. Measures of QoL used commonly rely on a single question of quality of life or satisfaction on a 3- or 10-point scale. Validated QoL instruments, such as SF 36 are not only infrequently used, but are likely to lack sensitivity for the specific issues which concern catheter users. There is one device-specific measure for long-term catheter users [268], recently validated in two small samples for internal consistency reliability and content validity (expert review) [269]. Factor analysis yielded three subscales related to management, interpersonal, and psychosocial issues. Work in this area is continuing.

b) Prevalence of indwelling catheters use

1. Decreasing acute care use

Short-term catheterisation is common in acute care settings, with up to 25% of patients receiving a catheter during their hospital stay [270] [187]. Recently a change in the US, whereby CAUTI will not be reimbursed during hospital stays [271], has triggered a number of studies designed to reduce the use and duration of indwelling catheters in acute care, and subsequently the number of associated infections. A popular approach is a “bundle” in which several evidence-based strategies are grouped and implemented in a system-wide approach. Analysis of cause and effect are incorporated into the bundled activities, and checklists are often used to address the issues in methods (procedures), people, environment, and equipment [272].

In one study [273], in a community hospital’s 22 bed intensive care unit (ICU), a bundled approach was used to decrease catheter use with a checklist, a decision algorithm and criteria based guidelines. A fishbone diagram helped the nurses to identify the (historical) reasons for extended catheter device days (duration of use) and to plan the intervention. The device days decreased significantly from 4.72 (SD 7.67) in 124 persons to 2.98 (SD 3.17) in 83 persons, p=0.38, t = -2.10, df 176, n=83). Similar results were found in an inner city ICU with 21 beds [274] with duration of catheter use decreasing from 312 days/month to 239 days/month. CAUTI events decreased as well, from 4.7/month in the 11 previous months, to zero during the six months’ intervention. Also, a multidisciplinary team was successful in using a bundled approach and decreased catheter use by 56% and the duration of device days by 71% [275]. In a hospital in Brazil [276], the CAUTI rate went from 10 to 3.3/1000 catheter days after an intervention that bundled several activities in the previous year. Settings in rehabilitation [277] [278] and in an emergency department [279] have also been able to decrease catheter use and CAUTI by effective surveillance and an interdisciplinary approach.

Requiring documentation for the reason for catheter placement is critical to reducing unnecessary use. In one study with emergency room physicians [280] education and guidelines for placement contributed to an increase in appropriate indications for catheter use (72.6% to 82.2% post intervention), and unnecessary catheterizations decreased significantly from 16.4% to 13% (p=0.018). Inappropriate catheter use (30%) in a hospital study in Italy with 461 patients [281] was linked with older age, not having had surgery, conscious state, comorbidities, the length of time the catheter had been used, and the hospital ward. In the only randomized (and patient blinded) trial related to interventions to decrease catheter use in acute care [282], automatic stop orders for inappropriate catheter indications were successful in decreasing catheter duration in 392 patients. For those randomized to stop orders, catheter duration was lower at 3.7 days, compared with 5.0 in usual care (mean difference -1.3; 95% CI= -2.1, -0.6). Likewise, inappropriate catheterizations were lower in the stop orders group at 2.2 versus 3.9 in usual care (mean difference -1.7; 95% CI= -2.2,-1.2). CAUTI and recatheterisation rates did not differ.

Simple approaches such as checklists and stop reminders have also been effective in decreasing catheter use. In one study testing a checklist [283] catheter duration decreased significantly in five acute care hospital units from 402 to 380 pre/post intervention (p=0.047), and CAUTI went down from 2.88 to 1.46/1000 catheter days (NS). Compliance with the checklist varied from 50-100% but provider surveys indicated most viewed the checklists as relevant, easy to use, and were satisfied with them. An educational intervention on issues related to infec-
tions and notification of the continued catheter presence [284] also successfully decreased catheter use and the CAUTI rate. A simple chart reminder sticker related to removing the catheter when not needed [285], resulted in a significant increase in appropriate indications and a decrease in CAUTI in a hospital setting.

In a study of an educational strategy to use reminders with or without structured education, Gokula and colleagues (2007) [286] reported a 14% reduction in the number of inappropriately catheterized elderly patients in emergency departments, following a staff education program and the use of an indications checklist attached to each catheter kit. The intervention also enhanced documentation about catheter use. In another study, the total duration of catheter use and number of days of inappropriate catheter use was significantly less for patients randomized to an intervention that required staff in three hospitals in Canada to remove the patient's catheter if six criteria for appropriate catheterization were not met [282]. Saint and colleagues (2005) [287] reported a similar outcome from a simple reminder to assist hospital staff to remember which patients had catheters. Using a pretest-posttest design, two of the four wards were assigned to the intervention group, and two served as controls. The researchers found that of 5,678 patients, the average duration of catheter use decreased by 7.6% in the intervention group and increased by 15.1% in the control group (p=0.007). Similarly, Voss (2009) [288] reported a reduction from 33% catheter use to 15.3% (p=0.0006) in acute care older patients after the implementation of a protocol designed to enhance clinician awareness of the appropriate use of catheters and the parameters for catheter removal.

A systematic review of reminders and stop orders for catheter use in acute care settings [289] indicated a benefit in the rate of CAUTI, which was reduced by 52% (p=0.001), duration of use decreased by 37%, and 2.61 fewer catheter days’ use in treatment versus control groups. Stop orders were more effective than reminders.

Empowering nurses to remove catheters when not indicated was also successful in a quality improvement project [290]. Daily prevalence of catheter use decreased from 24% to 17%. However, in an anonymous survey of 164 nurses [291] 54% said they were not comfortable removing a catheter without a physician’s order, but 74% remind the physician daily of the presence of the catheter.

2. PREVALENCE OF CATHETERS AND CAUTI

Despite the increase in research in preventing CAUTI, many hospitals do not have systems in place for prevention. Based on a large survey to 600 non-governmental hospitals and 119 VA hospitals in the US [292], only about 1/3 of the respondents stated that they use antimicrobial catheters or bladder scanners, and surveillance data were not tracked for catheter placement by 56%, nor duration of use by 74%. Catheter reminders were used by only 10%.

The prevalence of LTC use in home care or community care settings varies widely and can be more difficult to determine. A large scale survey of 4010 older people (>65 years) receiving home care in 11 European countries, found a mean prevalence of LTC use of 5.4%, ranging from 0% in the Netherlands to 23% in Italy [228]. In another large study of 1004 frail older women living in the community the reported LTC prevalence rate was 38.1% [229]. Duration of use can be for many years. In a US sample of 43 community dwelling long-term catheter users, who each provided data over a six months’ period, mean use was 11.7 years (ranging in months from 1-589; median 8.8 years). Twenty persons had used it over 10 years [126].

There is evidence that older patients aged 65 years or more are often catheterised inappropriately [293] [294] [295]. Gokula et al. [294] surveyed a 10% random sample of patient charts from 2845 elderly patients who received an indwelling catheter during hospital admission in one year. Less than half the selected charts recorded an appropriate indication for catheterisation. An explicit reason for catheter insertion was documented in only 13% of charts and there was no written order for catheterisation in 33% of the charts. Only 18% had documented care plans for catheter removal. Expert opinion and experience suggests that even when there is an appropriate clinical reason for initial catheterisation, patients may remain catheterised unnecessarily if medical and nursing staff fail to review ongoing need (Level of Evidence 3). Problems of inappropriate catheter use may be compounded when patients are transferred from one clinical setting to another without adequate information on why the person was catheterised [296]. Wald et al [297] reported that 32% of patients catheterised during treatment for hip fracture in their study were discharged to nursing homes with the catheter still in place.

The prevalence of catheterized patients in nursing homes is generally higher than in people living at home and has been reported to be around 9% in the UK [298], but there may be considerable variation between homes [299]. In nursing homes in the US, it has been estimated that between 7-10% of the residents have an LTC [300], although figures vary from state to state. More recent data from analysis of a US National Nursing Home Survey [301] and a point prevalence study of nursing home-associated infections in the Department of Veterans Affairs nursing home care units [302] demonstrated similar prevalence. Tsan et al. [302] reported a prevalence of 10.7% for indwelling urethral catheters and 2.46% for suprapubic catheters amongst a nursing home population of 11,475 in 133 care home units.
There is some evidence of decreasing rates of urinary catheterisation in some places. A retrospective cohort study of the use of urine collection devices in skilled nursing facilities (SNFs) in five US states examined the characteristics of 57,302 patients who remained in an SNF for one year in 2003 [303]. The prevalence of indwelling catheterisation was 12.6% at admission and 4.5% at annual assessment (p<0.001). Paraplegia, quadriplegia, multiple sclerosis and comatose state were strongly associated with LTC use. Male residents were more likely to use a catheter at every assessment, as were obese patients; individuals with diabetes mellitus, renal failure, skin conditions, deep vein thrombosis, aphasia or end-stage disease; and those taking multiple medications.

A qualitative study of catheter use in 14 UK care homes (skilled nursing) [304] found that catheter use was higher in homes which were task-centred rather than patient-centred, and / or where patients were inappropriately given residential care when skilled nursing was actually needed. In contrast, the homes with lower rates of catheter use (6% or < versus 9% or >) were more proactive related to catheter removal (many of which had been “inherited from the hospital”), and they actively promoted toileting and mobility. Both groups had similar staffing and believed their approaches enhanced patient dignity.

Duration of catheter use in home settings varies widely, with a median of 3-4 years and some individuals using them over 20 years [305] [306]. Management regimes for continence problems in older people continue to demonstrate a predominance of containment strategies, using pads and catheters [307] and consequently unwarranted use of LTCs for incontinence continues in many places despite known catheter-associated risks.

In view of the considerable cost, and morbidity and mortality associated with the use of catheters, health services should consider adopting similar successful strategies, incorporate such information into their policies and ensure that education on catheters forms part of staff’s continuing education.

c) User characteristics

Short-term catheterisation (usually defined as up to 14 days) is most commonly used:

• During surgical procedures and post-operative care.
• For accurate monitoring of urine output in acute illness.
• Instillation of medication directly into the bladder.
• For relief of acute or chronic urinary retention.

Long-term indwelling catheters - routinely changed and replaced, often over many months or years - may be required to aid those who have difficulty emptying their bladder due to obstruction or neurological disorders, where intermittent catheterisation is not a satisfactory option. LTCs may also be used to provide supportive care for those with severe incontinence who cannot manage otherwise, are terminally ill, or need treatment to heal skin lesions or surgical wounds affected by the presence of urine.

Long-term catheterisation is most commonly used to help manage:

• Bladder outlet obstruction (BOO), where patients are unsuitable for - or waiting for - surgical relief.
• Chronic retention, often as a result of neurological injury or disease (where intermittent catheterisation is not possible).
• Debilitated, paralysed or comatose patients (in presence of skin breakdown and infected pressure ulcers).

Intractable urinary incontinence where catheterisation enhances the patient’s quality of life (as a last resort when alternative non-invasive approaches are unsatisfactory or unsuccessful).

d) Routes of catheter insertion

For some patients the insertion of an indwelling catheter suprapubically (SPC) into the bladder, through the abdominal wall, offers advantages over the urethral route (UC). SPC may be necessary following urethral or pelvic trauma but also offers advantages in acute and long-term care. In frail elderly men, and / or those prone to infection e.g. diabetes mellitus, SPC can be preferable to a urethral insertion to avoid urethritis, orchioepididymitis and prostatitis [107]. Strategies to support the SPC may be required (e.g anchoring to the abdominal wall with a BioDerm tube holder) to prevent traction and potential displacement of the catheter or balloon [308].

Advantages of SPC compared to UC are:

• Avoidance of risk of urethra trauma to men and women during catheter insertion and withdrawal.
• Avoidance of risk of urethral destruction / necrosis from pressure caused by the weight of poorly supported catheter bags, expulsion of the catheter (particularly in neurologically impaired women), or sitting on the catheter in wheelchair bound women.
• Ease of access to entry site in patients with reduced mobility, who are wheelchair bound, have restricted hip mobility, or experience urethral pain.
• Facilitation of post-surgical trial of voiding (by temporarily clamping the drainage tubing).
• Greater freedom for expression of sexuality, although this may be counteracted by perceptions of altered body image.
• Reduced risk of contamination where faecal incontinence is a problem.
SPC insertion is generally contra-indicated in patients with haematuria of unknown origin, bladder tumour, or small contracted or fibrotic bladders which may have resulted from long-term urethral catheterisation on free drainage. In obese or immobile patients the traditional SPC stoma site may become concealed by an apron of excess anterior abdominal wall fatty tissue which can lead to sub-optimal care by both patient and carer. SPC is an effective and well-tolerated method of bladder management for many SCI patients [309] [310] [311]. In Sheriff et al’s study [309] the general level of satisfaction with SPC was very high with 70% of patients awarding a satisfaction score of 9/10 and 95% awarding 7/10 or more. It is of interest to note that in 18% of cases, an SPC was inserted following the request of the patient, having heard about this form of bladder management from others. A review of current literature on SPC in the neuropathic bladder, by Feifer & Corcos [311] identified some notable differences between early studies and more recent reports. Problems and complications of SPC identified in earlier studies of SCI patients were less common in the more recent investigations, in which patients were managed with anti-cholinergics, frequent catheter changes and volume maintenance procedures.

Recent studies demonstrated similar morbidity profiles to clean intermittent catheterisation. In one retrospective study from 2010 [312] comparing 85 persons with neurogenic bladder prior to SPC use, and after a mean of 65.3 (± 48.0) months with SPC, anti-cholinergic medicine and bladder clamping (with a valve) did not seem to be needed to preserve detrusor compliance nor renal function. Bladder capacity did decrease significantly, though, and renal function deteriorated in three persons, two of whom were on anticholinergics and none used clamping. Complications were reported by 62.6%, including recurrent blockage (19.2%), surgery for bladder stones (12.1%), and CAUTI (28%). 3.6% had septicaemia or were hospitalized for CAUTI. In another retrospective study of 179 men with SCI comparing indwelling urethral catheters (UC) and suprapubic catheters (SP) [313] complication rates were similar for UTIs, recurrent bladder/renal calculi and cancer. However, those with UC had higher urethral and scrotal complications and SP users suffered from leakage from the urethra and/or SP tube site. Individualizing care management was suggested.

Although SPC has gained wide acceptance for bladder drainage and many regard SPC insertion as a simple procedure, it is not without risks. The initial insertion of the SPC requires a minor surgical procedure which presents a potential risk of injury to adjacent structures to the bladder, especially the small and large intestines with resultant peritonitis [314] [309]. Other complications of initial SPC insertion include misplacement [315] [316] [317], displacement to the peritoneal cavity and sepsis, [318] and incisional hernia [319] [320]. There are a number of SPC techniques for insertion described in the literature and training models have been developed to facilitate teaching [321]. Some modern catheter insertion kits employ the initial introduction of a guide wire into the bladder, to facilitate accurate positioning of the catheter introducer. However, where patients are at high risk of bowel injury (eg previous abdominal surgery or small fibrotic bladders which do not expand well at cystoscopy), some authorities recommend introduction of the SPC by percutaneous technique using intraoperative ultrasonography combined with flexible cystoscopy [322] [323]. In low risk patients nurse specialists may undertake first insertion of an SPC, according to agreed policy and protocols [324]. Subsequent SPC changes can be competently managed by skilled nurses [325].

e) Catheter characteristics

An effective indwelling catheter should have the following design characteristics:

- Retained in the bladder effectively, yet easily removable without trauma to tissue.
- Soft ‘tip’ within the bladder to avoid pressure damage to the mucosa.
- Effective drainage while minimising risk of bladder mucosa being ‘sucked’ into drainage channel.
- Conforms to shape of urethra.

Despite some notable efforts to improve catheter design, the original Foley design has changed very little over the years and remains the most common. However traditional drainage systems may fail to drain the bladder to completion, due to potential outflow obstruction caused by air-locks within the curved, redundant drainage tubing segments. A novel, spiral-shaped, drainage tubing design has recently been reported which appears to optimize flow and minimize residual urine [119]. Adding more eyeholes has been suggested to reduce residual urine [326] and in a case report, leakage [327]. Further evidence of efficacy is awaited.

f) Catheter materials

An ideal catheter material requires the following properties:

- Soft for comfort.
- Causing minimal tissue reaction or friction.
- Sufficiently firm for easy insertion and maintenance of lumen patency in situ.
- Elastic recoil so that an inflated balloon can deflate to almost its original size.
- Resistant to colonisation by micro-organisms and to encrustation by mineral deposits.

Catheters are made of a variety of materials includ-
ing polyvinyl chloride (PVC) or other plastic, latex rubber with or without a coating, silicone or metal. Plastic catheters are relatively cheap to manufacture, have a thin wall and relatively large lumen, and are designed for short-term use (in situ up to 14 days). Latex catheters are restricted to short-term indwelling use (and commonly avoided where possible) because of potential discomfort due to high surface friction, vulnerability to rapid encrustation by mineral deposits from the urine and the implication of latex allergic reactions in the development of urethritis and urethral stricture [328] [329] [330] [331] [332] [333] or anaphylaxis [334].

Attempts to minimise friction during catheterisation and to reduce tissue reactions have led to the coating of latex catheters with tightly bonded materials designed to provide a smoother, less irritant surface which also minimizes absorption of water by the latex (and subsequent changes in internal and external catheter diameters). Polytetrafluoroethylene (PTFE or teflon) coated latex catheters are sometimes used for medium-term use (catheter can remain in situ up to 28 days) but the materials known to cause least friction and tissue reaction are silicone elastomer and hydrophilic polymer-coated catheters, or all-silicone catheters [335] (Table XII-4). These materials are therefore recommended for long-term use (i.e. expected to remain in situ for 14 days or more, and changed regularly for a new catheter as part of a long-term strategy of care). LTC materials are also less vulnerable to rapid colonisation by bacteria and encrusting by mineral deposits than short-term catheter materials. There is evidence that silver-alloy coated catheters can help to reduce risks of CAUTI in the short-term (where bacteriuria is used as the outcome measure) (See Section XII.3.a), but no currently available material or surface coating is completely immune to microbial colonisation.

Inflation of silicone catheters with water can sometimes lead to water loss from the balloon over time, which with an associated risk of the catheter falling out [337]. Consequently some manufacturers recommend filling the balloon with a 10% aqueous glycerine solution, or to fill the balloon with the full 10mL, knowing that 1/4 to 1/2 could be lost over time [336].

Most catheter materials are suitable for either UC or SPC, however not all UC catheters are also licensed for SPC. Suprapubic catheter removal is sometimes associated with trauma of tracts or stoma site where overgranulation has occurred, with bleeding and patient discomfort [338] [335]. This can be a particular problem with catheter materials such as all-silicone, which are prone to hysteresis, leading to balloon clogging on deflation. This problem may also occur with hydrophilic coated catheters but is less common [339] [340]. Management of this and other catheter-related problems is considered below in Section XII.2.k.

The main finding of a recent Cochrane Review of types of indwelling urinary catheters for long-term bladder drainage in adults [263] was a remarkable lack of evidence for this clinically, highly relevant problem. Despite consideration of 11,000 abstracts and 74 full papers, only three trials met the inclusion criteria. Since these were very small and showed methodological weakness, the authors concluded that there was insufficient evidence to provide a reliable basis for clinical decision-making and catheter choice remains largely based on clinical experience.

**g) Catheter size – catheter gauge, length and balloon size**

Indwelling catheters are formed either by building up layers through dipping and coating on a shaped ‘former’ or by a process of extrusion of a single material. Catheter size is measured in Charrière (Ch) – also called French gauge (Fr) - which refers to the circumference of the catheter shaft in millimetres. Internal diameter varies depending on the manufacturing method, with the extrusion process resulting in a catheter with relatively thinner

walls and a larger lumen for the same Charrière size. A size 12Ch catheter made by dipping and coating will have an external diameter of around 4mm and an internal diameter of around 2mm or less. Urinary flow rates are related to the internal diameter of the catheter but 12-16Ch catheters (usual sizes for adults) easily drain normal quantities of urine, including larger volumes produced by diuresis [341]. Although larger sizes may be needed following urological procedures where blood clots and other debris are a problem, large catheters are generally associated with increased bladder irritability and spasm [113], and with potential blockage of para-urethral glands and tissue damage, including urethral strictures. Therefore large catheter sizes should be avoided wherever possible. It is not known whether large catheters contribute to CAUTI, but the smallest size to maintain good drainage and prevent urethral and bladder neck trauma is recommended [342] further research may be needed to determine best practices [343]. Small balloon sizes are recommended for all patients (10ml for adults and 2.5-5ml for children) to minimise the risk of discomfort and bladder irritation. Larger balloons tend to sit higher in the bladder with potential for increased residual urine volumes to collect below the catheter eyes. Larger balloons are also associated with increased risk of meatal tissue damage caused by bladder spasm and possible expulsion of the catheter with a fully inflated balloon.

The most common sizes of SPC catheters for adults are also 12-16Ch. Some SPC kits provide a specific catheter in the kit and therefore dictate the sizes available; others allow the insertion of a range of Foley catheters. Since the catheter is inserted into the bladder via an artificial stoma it is possible that slightly larger sizes may be better tolerated than for UC although there is no research evidence to support this.

The standard male length catheter (41-45cm) is available to males and females but a shorter female length (25cm) can be more comfortable and discrete for some women. The female length catheter should not be used for males as inflation of the balloon within the urethra can result in severe trauma. In one case series report [344] six boys, aged <1 month to 16 years suffered damage to the bulb or prostatic urethra due to inflation within the urethra. Three required suprapubic catheters, and all healed without further complications. Insertion to the bifurcation of the catheter – that is, until only the inflation and drainage ports were visible - was advised to prevent this. Paediatric catheters are usually approximately 30cm long.

**h) LTC-associated risks / problems: catheter-associated urinary tract infection (CAUTI)**

The urinary tract is recognised as the commonest site for nosocomial infection in hospitals and nursing homes, accounting for between 21% and 45% of all healthcare-associated infections [345] [346] [65] [347] [302] [348]. National nosocomial infection surveillance systems monitor CAUTIs and provide guidance for benchmarking [349]. The presence of an indwelling catheter is a key risk factor in around 80% of nosocomial UTIs. The risk of bacteriuria increases by 5-8% per day of catheterisation [350] [351] [352] and virtually all LTC patients are likely to be bacteriuric within four weeks [342]. A majority of microorganisms derive from the patient’s own colonic and perineal flora or from the hands of health-care personnel during catheter insertion or management [187]. Access is gained in two ways: (1) extraluminally during catheter insertion or via the periurethral space; (2) intraluminally following breaks in the closed system or contamination of urine in the drainage bag. The comparative importance of these routes is difficult to determine, but animal models have demonstrated rapid colonisation via the extraluminal route following a break in the closed system, compared to the extraluminal route (32-48 hours v 72-168 hours respectively) [353]. However, clinical studies have shown that colonisation will occur even when strict infection control practices are adhered to [354].

Indwelling catheters rapidly become colonised by micro-organisms which form a strongly adherent biofilm on catheter and drainage equipment surfaces. Biofilm formation begins by deposition of a conditioning layer of proteins, electrolytes and other organic molecules from the urine which may then mask catheter surface properties designed to inhibit colonisation. Micro-organisms attached to catheter surfaces divide to form micro-colonies, ultimately developing a complex three-dimentional structure, including fluid filled channels through which the biofilm members receive nutrients, diffuse away wastes and send chemical signals to each other [356]. Catheter biofilms commonly comprise mixed communities of micro-organisms embedded in a matrix of host proteins and microbial exopoly-saccharides [357], [358] (Figures XII-4, XII-5 and XII-6). Microorganisms growing as biofilm are less susceptible to antimicrobial therapies than free-living organisms and are a major source of resistant, nosocomial pathogens [187] [359] [259]. Decreased susceptibility arises from multiple factors including; physical impairment of diffusion of antimicrobial agents, reduced bacterial growth rates; and local alterations of the micro-environment that may impair activity of the antimicrobial agent [356]. The close proximity of cells within a biofilm can facilitate plasmid exchange and the spread of antimicrobial resistance [355].

**1. Antibiotic use**

Hospitalized patients are likely to be on antibiotics for other causes than an indwelling catheter, which also might be present. In one study in an acute care setting, [360] catheterized patients on antibiotics...
antibiotics use, in particular with fluoroquinolone. The researchers’ model predicted that decreasing CAUTI in hospitals with high rates (75th percentile or >) could reduce antibiotic use by 2.1% and 0.4% for fluoroquinolone.

2. PREVALENCE OF CAUTI

The majority of research on the risks of CAUTI has been conducted in acute care settings where catheters usually remain in place for less than 14 days and many patients’ health is already compromised by co-morbidities [362]. A series of reports from the International Nosocomial Infection Control Consortium (INICC) provided rates of CAUTI in intensive care unit (ICU), using the methodology of the US National Nosocomial Infections Surveillance system. The rates per 1000 catheter days were: Brazil 9.6 [363] and Peru 5.1 [364]. Overall, in 13 limited resource countries implementing INICC infection control guidelines for education and surveillance (Argentina, Brazil, Colombia, Costa Rica, Cuba, El Salvador, India, Macedonia, Mexico, Morocco, Philippines, Peru, and Turkey) the CAUTI rates dropped from 8.2 to 6.9 per 1000 catheter days [365]. A later report in ICUs in Cyprus, Greece gave a rate of 2.8/1000 catheter days [366]. From the U.S. National Healthcare Safety Network (NHSN) [367] from January 2006 through December 2008, the pooled mean CAUTI rate in ICUs ranged from 3.1 to 7.4 /1000 catheter days, depending on the type of specialty unit. Surveillance was suggested for a minimum of three months, based on a pilot study describing the protocol and surveillance tool used in six hospitals caring for elderly people in Scotland [368].

Less is known about the prevalence of CAUTI in long-term and home care settings or about the potential for reduction of CAUTI and improved cost benefits in the LTC population [352]. Encouragingly, in a recent U.S. study in North Carolina home health and hospice populations, [369] the CAUTI rates have decreased over 11 years of surveillance. The rate of catheter-associated UTI decreased in home health from 4.2/1000 catheter days in 1998 to 0 in 2008, and in hospice patients from 2.35/1000 catheter days in 1999 to 0 in 2008. Infection control specialists trained the persons collecting data, and presumably the rates reflect symptomatic CAUTI. However, in a hospital study of U.S. Veterans with spinal cord injury and disorder, [348] the rate was higher (8.9/1000 catheter days), reflecting greater risk. In a similar population of 100 inpatient and outpatient veterans with chronic catheters, candiduria was present in 17%, and all but one had an indwelling catheter. This was of concern due to the likelihood of reoccurrence of this microorganism [370].

In the multi-national survey of 4010 older people (>65 years) receiving home care in 11 European countries, the risk of a UTI was found to be 6.5 times greater for catheterised individuals than for non-catheterised [371]. Prevalence of a UTI amongst
1004 frail older women living in the community was 21% in catheterized women compared to 10% in non-catheterized subjects (p>0.001) [372]. Furthermore, catheterised subjects were more likely to die within a year (RR1.44; 95% CI 1.01-2.07). Tsan et al’s point prevalence survey [302] of Nursing Home acquired infections found 13.2% of 11,475 residents had an indwelling urinary catheter. Of those, 13% of residents with a UC and 9.5% of those with a SPC had a UTI. In catheterised SCI populations the overall rate of urinary tract infection has been quoted as about 2.5 episodes per patient per year [373]. Although randomized trials are lacking there is some evidence of reduced rates of bacteriuria and CAUTI with SPC, condom catheters and intermittent catheterisation compared to UC [373] [374] [302].

Bacteraemia resulting from CAUTI invariably represents a serious complication which may occur in approximately 4% of catheterised patients with bacteriuria in acute care settings [375] [376] [377]. In their review, Saint et al. [375] statistically pooled results from several prospective studies on short-term indwelling catheterization (in which the definition of bacteriuria varied between studies, ranging from >103 cfu/ml to >105 cfu/ml) and estimated (Level of Evidence 2) that:

- 26% of patients (not receiving systemic antibiotics) with a short-term, standard non-coated indwelling catheter in situ for between two and 10 days will develop bacteriuria.
- 72% of patients developing bacteriuria will remain asymptomatic and not require treatment.
- 24% of those developing bacteriuria will develop a symptomatic UTI without bacteraemia.
- 4% with bacteriuria will develop bacteraemia.

This data is interesting since it provides supporting evidence that bacteriuria remains asymptomatic in a majority of catheterised patients. However, it can be difficult to generalize such data from acute care contexts to other practice settings. Unfortunately, few epidemiological studies or comparative catheter evaluations are conducted on long-term catheterised patients in community settings.

3. Outcome measures and criteria for CAUTI

Interpretation of the literature on CAUTI is often confused by the range of definitions and outcome measures used. In this chapter, the terms symptomatic infection and asymptomatic bacteriuria have been employed to distinguish as clearly as possible between symptomatic and asymptomatic conditions. However many studies make little or no distinction between these states, referring to both as infection. This can be particularly confusing when attempting to interpret results in terms of the magnitude of infection-related problems, clinical importance and implications for services and individuals.

Bacteriuria is commonly used as a surrogate outcome measure for the clinically more important outcomes of symptomatic UTI. Although symptomatic infection is far less common than asymptomatic bacteriuria, the frequency of catheter use produces considerable overall morbidity and mortality [378] for patients and high costs to healthcare services [377], often including unnecessary antibiotic drug therapy which may then become a major source of antibiotic resistant pathogens. Asymptomatic bacteriuria can lead on to symptomatic infection, but not necessarily. Questions about the significance of long-term asymptomatic bacteriuria in its own right (e.g. effects of chronic tissue inflammation) are currently unanswered.

In non-catheterised patients the criterion for ‘significant’ bacteriuria is commonly accepted to be >10^5 cfu/ml but since growth of micro-organisms in catheterised patients is rapid, many authorities consider >10^2 or 10^3 cfu/ml in a urine sample collected from the sampling port of the catheter, to be indicative [187] [342] [110]. Most definitions of symptomatic UTI [379] are based on those used for non-catheterised patients and include significant bacteriuria. For catheterised patients, these include presence of pyuria (>10wbc/mm3 plus one or more clinical signs and symptoms for which no other aetiology is apparent: fever, suprapubic or flank discomfort, bladder spasm haematuria, changes in mental state, or malaise / lethargy. Pyuria alone is not diagnostic of UTI. [110]. For SCI patients signs and symptoms may also include increasing spasticity and / or worsening autonomic dysreflexia (usually manifested by increase in blood pressure, headache, sweating above the SCI lesion, flushing below the SCI lesion) [380] or a “sense of unease” [110]. Elderly persons may have atypical or generalized symptoms [284]. In a study of the validity, accuracy and predictive value of UTI signs and symptoms in person with SCI using intermittent catheters, [381] cloudy urine had the highest accuracy (83.1%) and leukocytes in the urine was the most sensitive (82.8%). Fever was the most specific (99%) but least sensitive (6.9%) symptom. Moreover, patients might be better at identifying when they do not have UTI, as positive predictive value was 32.6% and negative predictive value was 82.8%.

However, commonly used criteria for symptomatic urinary infection have been questioned by Tambyah and Maki [362] in a prospective study of 1497 newly catheterised patients. No significant difference in reported symptoms of pain, urgency, dysuria and fever was found between patients with a catheter-associated infection and those without, nor was there statistical evidence that peripheral leukocytosis was predictive of infection (p=0.14) (Level of Evidence 2). The criterion for bacteriuria (catheter-associated infection) in this study was >= 10^3 colony forming units (cfu/ml urine). This finding raises further questions over the selection of the most appropri-
ate outcome measures in studies of CAUTI. Indeed concerns have also been raised over current UTI criteria for non-catheterised populations, particularly for elderly groups, including nursing home residents. Consensus criteria (e.g. Loeb criteria 2001) have been found to be limited in terms of sensitivity, specificity and predictive value by Juthani-Mehta et al. [382] and these authors have called for clearer identification and evaluation of evidence-based clinical criteria associated with laboratory evidence of UTI. A further complication to difficulties in confirming ‘best criteria’ for UTI and CAUTI is the variation in the clinical and scientific definitions required for specific populations, for research purposes or to meet stipulations for reimbursement from governments and medical agencies. Asymptomatic bacteriuria might be treated inappropriately, as described in a study in which 32% were treated (53 of 164 episodes of bacteriuria) [383] further confounding the definitions of CAUTI that include treatment with antibiotics. It is important that efforts to resolve these issues are progressed as quickly as possible to provide greater clarity in the interpretation of existing research, the design of new studies and the application of clinically important findings.

### 4. Reducing the Risk of CAUTI

Risk factors which are independently predictive of increased risk for CAUTI have been identified in a number of large prospective studies of short-term catheterised patients [187] (Table XII-5). There is evidence that females have a substantially higher risk than males (relative risk: RR 2.5-3.7), and 1.3-2.2, p=0.001 in an ICU setting [384]. But the greatest risk is associated with prolonged catheterisation > six days (RR 5.1-6.8). A recent retrospective cohort study of 35,904 undergoing major surgery reported that 86% of patients had a perioperative indwelling catheter [385]. Multivariate analysis showed that postoperative catheterisation for longer than two days was associated with increased risk of UTI.

Use of a preconnected drainage bag may be of value in preventing CAUTI in acute care settings. A prospective study in the UK of 205 patients in three medical wards over two periods, each of about six months’ surveillance, [386] compared use of preconnected bags with the usual bags. The CAUTI rate was 41% lower in the group with the preconnected bags, with rates of 37.8/1000 catheter days for the usual bags, compared with 22.4/1000 catheter days in the intervention group (RR 0.59 (0.35-0.99) 0.04.

In Japan, a prospective observational study in five hospitals evaluated risks in persons with catheters >3 days, using a Cox proportional hazards model [387]. Risks were significantly associated with two practices in this study of 555 inpatients, not using a pre-connected closed system (RR 2.35, 95% CI 1.20–4.60, p=0.013) and the lack of daily cleaning of the perineum (RR 2.49, 95% CI 1.32–4.69, p=0.005).

Although there is some evidence to suggest there may be a reduced risk of CAUTI when SPC is employed compared to UC, the data is limited, studies are often small and most catheterisations are for post-operative care in acute care settings. One large scale point prevalence study of nursing home acquired infections in >11,000 residents [302] reported that 9.5% of residents with a SPC had a UTI compared to 13% of those with a UC. These data just fail to demonstrate a statistically significant difference between UC and SPC (one-sided, Fisher’s exact test; p=0.066). A review of five published RCTs comparing SPC with urethral catheters

Table XII-5: Risk factors for catheter-associated infection based on prospective studies and use of multivariate statistical modelling (adapted from Maki & Tambyah 2001)[187].
following colorectal surgery [388] reported that sample sizes were small, catheters were used short-term and there was no apparent difference in the duration of catheterisation between the two techniques. Significant UTI was defined in different papers as bacteriuria with either $>10^4$ or $10^5$ organisms or cfu/ml. Frequency of UTI was less in the SPC group in three of the studies, with no significant difference in the other two. The SPC groups reported less pain and discomfort than the urethral groups and SPC was preferred by those patients who experienced both. The authors concluded that the results favoured SPC over urethral catheterisation as UTIs are reduced, particularly in females, and the ability to attempt normal voiding is facilitated, particularly in males (Level of Evidence 2).

Much of the recent research on reduction of risk of CAUTI has centered on the development of catheters with antimicrobial surfaces, such as silver. Silver ions are bactericidal [389], non-toxic to humans when applied topically, and have been used successfully in other areas of infection control such as burn wounds. Silver is also purported to have broad spectrum activity against Gram-positive, Gram-negative, aerobic and anaerobic organisms. Early silver-coatings incorporated silver oxide into the external surface of the catheter material only, but efficacy against CAUTI was limited [390]. Subsequently, silver-alloy coatings were developed to provide an integral coating on both internal and external surfaces and promote a slow release of silver ions. Other developments have been directed towards impregnation of catheter materials with antibiotic or antiseptic agents such as nitrofurazone [391] [392] [393] [394]; minocycline and rifampicin [395]; chlorhexidine, silver sulfadiazine, triclosan [396] and others. Although a large number of studies (both laboratory models and clinical studies) have attempted to examine the potential benefits of antimicrobial catheters, most have used bacteriuria - rather than symptomatic UTI - as a surrogate endpoint. Most reports were either prospective cross-over studies [397] or prospective surveillance of outcomes associated with introduction of new catheter types, in comparison with historical or baseline outcomes associated with previously used catheter types [398] [399] [400]. Almost all have examined short-term catheter use in acute care settings.

A recent Cochrane review [260], designed to determine the effect of type of indwelling urethral catheter on the risk of UTI, examined 23 trials, comparing different types of standard catheters or a standard catheter with an antiseptic catheter (silver alloy or impregnated with silver oxide); or an antibiotic impregnated catheter (either minocycline and rifampicin, or nitrofurazone). The reviewers commented that trials were generally of poor quality but concluded that current evidence suggests silver alloy catheters prevent asymptomatic bacteriuria in the short-term catheterised patient (Level of Evidence 1). They recommended that further economic evaluation is necessary to confirm the extent to which reduction of clinically important infection compensates for the increased cost of the silver alloy catheters. Catheters impregnated with antibiotics were also found to be beneficial in reducing bacteriuria in hospitalised adults catheterised for less than a week, but data were too few for patients catheterised longer.

An earlier systematic review of antimicrobial urinary catheters to prevent CAUTI in hospitalized patients [401] identified 12 randomised or quasi-randomised trials of silver-alloy coated (n=9) or nitrofurazone-coated catheters (n=3) compared to standard silicone or latex catheters. Pre-post study designs were excluded. No study addressed symptomatic UTI and therefore analysis was based on bacteriuria. Although all studies indicated some benefit in prevention or delay of onset of bacteriuria the effect size varied substantially between studies. Variations were related to catheter type, patient characteristics, control group bacteriuria rate and year of publication (i.e prevailing clinical conditions at the time of the study). Post enrolment exclusions, absence of intention to treat analysis, highly selected study samples and lack of data on clinically meaningful end-points, all limited the ability to draw definitive conclusions on efficacy. The authors concluded that, according to fair-quality evidence, antimicrobial catheters can prevent bacteriuria in hospitalised patients during short-term catheterisation (Level of Evidence 1), but trial results are highly context dependent. The relevance of results to other institutions or patient groups depends on the similarities between settings with respect to a range of variables, including: background bacteriuria rate, baseline catheter type, local catheter use and maintenance practices, patient groups and patterns of antimicrobial usage. The authors cautioned that older data may lack current relevance, particularly where background rates of bacteriuria have changed notably in the intervening period. Although there is evidence that antimicrobial-coated catheters prevent bacteriuria during short-term catheterisation, there is a lack of corresponding data to demonstrate clinical benefit [402]. Further well-designed and adequately powered randomised trials, with clinically relevant endpoints are needed to clarify comparative clinical utility and economic value.

In contrast to the majority of trials of silver-coated latex catheters Srinivasan et al [403] found no significant reduction in bacteriuria with silver-impregnated silicone catheters despite similar performances in vitro. However, outcomes may have been affected by notable differences in the study groups in this prospective, cross-over study. The authors drew attention to the fact that not all silver products are of the same and clinical trials of new products remain critically important. Any potential advantages of silver alloy catheters (or other antimicrobial catheters)
for LTC patients remain uncertain, although clinical experience suggests some benefits for individuals with frequent symptomatic infections. It is not known whether argyria (deposition of silver in the skin) may be a potential problem for long-term care patients or whether silver-resistant mutants may be selected by repeated exposure [404] [405].

A common concern over the use of antimicrobial impregnated catheters is that elution of sub-inhibitory levels of the antimicrobial agent into the urine may induce resistance in resident organisms with prolonged catheter use [406]. Antiseptic agents are generally considered more likely to confer resistance to surface colonization than antibiotics and not to select for infection with antimicrobial drug resistant bacteria. Alternative approaches to inhibiting biofilm development include development of catheter surfaces which reduce protein absorption [407]; inflation of the balloon with a biocide solution, such triclosan, which then diffuses throughout the catheter material and into the surrounding area [408] [409]; or efforts to disrupt matrix or glyocalyx components with agents such as heparin [410], and colonization with a competing benign organism. Bacterial interference with E. coli 83972 was attempted in 13 CIC users with SCI, [411] [110], and eight were successfully colonized in 19 three-day attempts. Monthly urine cultures (until colonization was lost in the urine) indicated a reduction in symptomatic UTI rate per year, 0.77 per patient year as compared with 2.27 per patient year prior to the study.

Relatively few studies have examined the cost benefits of different catheters. Those that have tend to rely heavily on assumptions that a certain proportion of patients with bacteriuria will develop the clinically important outcomes of symptomatic UTI or bacteraemia. The focus of economic studies generally falls on acute care settings and, as discussed earlier, it can be difficult to generalise results from one practice setting to another. Practitioners and/or institutions who are considering introducing a new product (e.g. catheter type) for a majority of their patients on the basis of claims of improved cost-effectiveness from clinical research studies, are advised to look carefully at the similarities and differences between their own local practice (and patient groups) compared to that described in the research. Economic studies are frequently required to make assumptions about certain data (e.g. increased length of hospital stay for CAUTI) which is then applied to an economic model. (?Cross ref to economics chapter). Such assumptions may or may not be applicable in local settings.

Numerous trials of oral antibiotics, antimicrobial bladder washes, drainage bag solutions and topical disinfectants all lead to the common conclusion that bacteriuria and UTI may be suppressed temporarily at best, but resistant organisms are highly likely to emerge [357]. The application of devices to secure catheters in place, to prevent a ‘to and fro’ pistoning effect that could favour invasion of catheter tracts by microorganisms, has been shown to reduce the incidence of catheter-related blood stream infection in central venous catheters. Only one prospective, randomised trial has examined a similar device for urinary catheters (StatLock) [380]. Although the study in 118 SCI patients failed to achieve statistically significant results the authors reported a clinically important reduction in the rate of symptomatic UTI of 45% and called for further larger scale trials. They also noted the polymicrobial nature of infections including the presence of a Candida species in more than 20% of infections.

5. TREATING CAUTI: antibiotic use

Some studies have suggested that methenamine hippurate may have a beneficial effect in preventing bacteriuria in patients requiring short-term catheterisation during and post-surgery. However, a Cochrane review [393] designed to address this issue concluded there is not enough reliable evidence to conclusively support its use for urinary prophylaxis and identified a range of methodological limitations in existing studies. Caution is needed in translating research on reducing CAUTIs in short-term catheters to LTCs but treatment of asymptomatic bacteriuria is not recommended in either for either group. Urine cultures should be obtained before initiating treatment to permit selection of specific therapy for the infecting organism and the extensive use of broad spectrum therapy should be avoided [412].

Studies of LTC patients can be difficult given the relatively high proportion of disabled or elderly patients, many of whom are very frail. However, routine use of prophylactic antibiotics in LTC patients is not supported by research evidence and has been shown to favour the emergence of resistant organisms [110]. In a double-blind, cross-over study of 34 elderly nursing home patients with urethral catheters [413] subjects were randomised to receive antibiotic prophylaxis (200mg/day norfloxacin ) or placebo for three months, followed by cross-over. Urine cultures were obtained once monthly. Episodes of UTI, catheter-related complications (obstruction, encrustation, leakage, suprapubic pain, inflammation of meatus, haematuria and side effects of treatment were monitored weekly. Symptomatic UTI was defined as bacteriuria >105 cfu/ml and (i) a temp>38.5°C for two days in the absence of other clinical sources of infection or (ii) flank pain or unexplained mental disturbance or abdominal discomfort. Only 23 patients completed the study and although norfloxacin failed to reduce asymptomatic bacteriuria, there was a significant reduction in symptomatic UTIs (1 v 12, p<0.02) and a decrease in catheter-associated complications of obstruction and leakage (p<0.05).

Of the 11 patients who did not complete the study, six died (of non-infectious causes), one died of septic shock and four were withdrawn. However, norfloxacin
treatment was also strongly associated with the acquisition of gram-positive norfloxacin resistant flora (RR 4.66, 95% CI 2.47-8.80), and there was a rapid recolonisation by norfloxacin-sensitive, gram-negative bacteria on cessation of treatment. Overall the study concluded that norfloxacin failed to prevent bacteriuria in long-term catheterised patients and favoured the emergence of quinolone-resistant organisms, although there were some clinically observable benefits in some patients.

Similarly there is little strong evidence of benefit in prophylactic antibiotics prior to re-catheterisation and it is not routinely recommended [110]. One RCT in which 70 residents in a long-term care home were allocated to a treatment group (1gm IV meropenem given 30 minutes before re-catheterisation) or control group (no antibiotics) showed no significant differences in urine cultures at 3, 7, 14 or 28 days [414].

When catheterised patients are prescribed a course of antibiotics for symptomatic infection a common question from healthcare practitioners is whether the catheter should be changed to a new one prior to starting antibiotics. There are concerns that this may allow time for a new biofilm to become established on the catheter within a few hours (and provide a source of re-infection) before the antibiotics have taken effect. In contrast, the 2009 International Clinical Practice Guidelines from the Infectious Diseases Society of America suggest a catheter change if the catheter had been in place for at least two weeks and was still needed. The rationale was that this would facilitate resolution of symptoms and decrease risk of bacteriuria and CAUTI [110]. There is little research to guide practice but in one RCT of 54 nursing home residents managed by long-term catheterisation, subjects were randomised to undergo catheter replacement, or no catheter replacement, before antibiotic intervention for clinical diagnosis of UTI [216]. Clinical outcomes (reduction in polymicrobial counts, time to achieve afebrile status and clinical status at 72 hours) were significantly better among subjects randomised to catheter change immediately before institution of antibiotics (Level of Evidence 2). Replacement of the catheter, in patients suspected of having a UTI, prior to collecting a urine sample for culture and sensitivity testing has also been shown to reduce the number of pathogens identified, the number of antimicrobials prescribed and laboratory costs [415]. There is evidence that certain bacterial strains may be particularly difficult to eradicate. In a prospective study of infection in catheterised nursing home patients a single genotype of P.mirabilis was shown to persist in the urinary tract despite many changes of catheter, periods of non-catheterisation and antibiotic therapy [416].

Cranberry juice has long been advocated as a treatment for urinary tract infection and there is some evidence of decreased symptomatic infections in some study populations, but not in catheterised persons [417]. However current evidence to date is limited to non-catheterised patients and caution needs to be applied in extrapolating results to catheterised patients.

i) LTC-associated risks and problems: recurrent catheter blockage

Recurrent catheter encrustation by mineral deposits, leading to catheter blockage occurs in up to 50% of LTC users, with resultant increased costs to services and patients [418] [419] [420] [421]. Heavy encrustation on external surfaces of the catheter tip and balloon can also cause painful tissue trauma on catheter removal. The major components of encrustation are calcium phosphates and magnesium ammonium phosphate (struvite) (Figures XII-7 and XII-8) which precipitate from the urine, most commonly under alkaline conditions.

The precipitation of different ionic species (ie Ca++, Mg++, and phosphates) is influenced by their ionic concentrations in the urine. In addition, the urinary pH at which different ions precipitate from the urine varies, not only for different ions, but also between individuals and at different times [422] [423]. These factors contribute, at least in part, to individual variability in terms of susceptibility to catheter encrustation and time to blockage. Catheterised patients can usually be classified into ‘blockers’ or ‘non-blockers’ [418] [424] where ‘blockers’ are those individuals who experience recurrent catheter blockage within a few days to a few weeks. Early recognition of recurrent ‘blockers’ facilitates proactive care through appropriate catheter change regimes [424]. Urine from recurrent blockers tends to have a very narrow ‘safety margin’ between ‘voided’ urinary pH and the pH at which crystallisation (or nucleation) occurs. This margin is much wider in non-blockers [425]. Precipitates occur most commonly under alkaline conditions caused by the presence of urea-splitting micro-organisms such as Proteus mirabilis, in the catheter biofilm [426] [424] [427] [425].

1. Reducing catheter encrustation — catheter materials

The majority of research on catheter encrustation comprises experimental, laboratory-based studies addressing current and / or potential catheter material surface properties in relation to bacterial adhesion and encrustation. Encrustation may sometimes take place in the absence of infection [428] and is influenced by catheter surface properties, including roughness and irregularity, hydrophobicity and wetability, charge, polymer chemistry and coatings. None of the currently available long-term catheter materials is resistant to biofilm formation and encrustation. In a series of laboratory studies of 18 types of catheter materials, using a model of the catheterised bladder, none resisted biofilm formation by a clinical strain of P.mirabilis [429] [430]. Relative times to catheter blockage were: silver-coated latex 17.7h; hydrogel-coated latex 34h; silicone-coated latex 38h;
all-silicone 47h. However, the authors note that the internal diameter of the coated latex catheters was much smaller than for the silicone catheters (1.5mm compared to 2.5mm).

This finding was confirmed [409] in tests with five types of catheters (pure silicone, silicone-coated latex, hydrogel-coated latex, hydrogel/silver-coated latex, and nitrofurazone silicone) colonized with P. mirabilis 108 cfu/mL and a urine pH of 8.5. All had heavy encrustation by 24h and were blocked within 40h. There are implications for coated catheters, such as silver, because the bacteria can continue to grow even when attached to the crystalline biofilm, which shields them from the silver. To keep the pH from rising, antimicrobials need to get into the urine.

Targeting P. mirabilis infection for treatment as soon as it is introduced into the urinary tract may be beneficial in preventing recurrent encrustation and blockage [431]. While this organism, which is harboured in the intestines, may not cause problems in the urinary tract of a healthy person, it has many characteristics that negatively impact the bladder of a catheterized person who has an already inflammatory process taking place. These include: four adhesins that help make it stick to the bladder and catheter, a protective capsule, several secretions that promote extraction of host nutrients, quick migration capacity, and a powerful urease [431]. The ability of P.mirabilis to evade the host’s immune response make it a very difficult organism to treat. For example, a structure in the membrane called LPS contributes to virulence and can cause hypotension, fever, DIC and shock. Another component (migration factor Cmf) improves swarming [432].

Although it is not possible to examine the effects of polymer surface properties on microbial adhesion and formation of catheter encrustation in detail here, recent studies have shown that strongly electron donating surfaces are less prone to adhesion by P.mirabilis than more hydrophobic materials [433]. Some copolymer, polyurethane blends are associated with less microbial adherence and improved resistance to encrustation in an artificial bladder model [434]. The effect of iontophoresis produced by passing an electric current through silver electrodes attached to catheters has also been shown to inhibit bacterial growth [435]. Another potentially promising innovation is the use of the anti-septic agent triclosan in the catheter balloon [408] [436] [437]. In laboratory models of the catheterised bladder infected with P.mirabilis, silicone and latex-based catheters, with balloons inflated with triclosan, drained freely for seven days compared to 24h for controls inflated with water. Triclosan became impregnated throughout the silicone catheter material and strongly inhibited the formation of the crystalline biofilm. However, latex-based catheters required a higher concentration of triclosan (>1mg/ml) than silicone catheters to produce similar inhibitory effects on P. mirabilis. Diffusion through the latex balloon occurred but the latex-based catheter did not become impregnated with triclosan throughout. The potential benefits of triclosan in catheter balloons now needs to be tested in clinical trials but it is also important to note that not all microbial species responsible for CAUTIs are sensitive to this biocide and emergence of resistant strains is a common concern [437].

2. REDUCING CATHETER ENCRUSTATION – INTERVENTIONS

A number of studies have employed in vitro models of the catheterised bladder to examine the influence of urinary composition on bacteria growth and encrustation, and the ability of acidic irrigations to reduce encrustation build up. There is good evidence from laboratory studies that increased fluid consumption (leading to lower concentration of encrustation components) increases the time to catheter...
blockage [438]. Increasing citrate concentration in fluid intake and urinary output (eg through drinking orange juice or other fruit juices such as lemon or lime) has also been shown to increase time to catheter blockage (see below). Cranberry juice has frequently been advocated to reduce UTIs, microbial adherence and biofilm development but an in vitro study by Morris and Stickler [439] drinking cranberry juice did not produce urine which was inhibitory to the development of P. mirabilis biofilms and catheter blockage, although increased fluid intake was beneficial. Although some studies have claimed drinking cranberry juice can decrease urinary pH in healthy volunteers [440], this is unlikely to be accomplished in catheterised patients, in the presence of continued ammonia production by the action of urease-producing micro-organisms [441].

Urease inhibitors, including acetohydroxamic acid (1.0mg/ml) and fluorofamide (1.0microg/ml), have been shown to restrict the increase in urinary pH of P. mirabilis infected urine from 9.1 to 7.6, in a simple physical model of the catheterised bladder [430]. Significant reductions in precipitation of calcium and magnesium salts were also noted but the impact of possible side-effects remains unclear, and therefore clinical potential is uncertain. Clinical studies on the prevention or management of catheter encrustation are extremely limited and only two relevant studies addressing the use of urease-inhibitors were identified. One early clinical study [442] examined oral administration of a urease inhibitor (acetohydroxamic acid) to five patients who required frequent catheter changes (>1 every 2 weeks) due to encrustation and blockage. The dose was based on body weight (eg. 250mg three times daily for patients between 50-70kg). The degree of encrustation decreased significantly during therapy (p<0.05) and the authors reported minimal adverse side effects experienced by patients, but acknowledged the potential for more severe side effects to occur. A subsequent double-blind, RCT of acetohydroxamic acid in the palliative treatment of infection-induced urinary calculi, demonstrated lowered urinary pH in urine infected with P. mirabilis but the side effects were unacceptable to patients [443] (Level of Evidence 1).

An alternative approach to reducing catheter encrustation, aimed at increasing the ‘safety margin’ between urinary pH and the nucleation pH (pHn) (i.e. the pH at which crystals of calcium and magnesium are formed in the urine) warrants further clinical investigation. In laboratory studies using models of the catheterised bladder, the pHn of the urine was shown to increase when urine concentration was decreased and also by addition of citrate to the urine [438]. In models supplied with urine containing citrate at 1.5mg/ml or above, catheter drained freely for the seven day experimental period. Drinking 500ml pure orange juice per day can achieve concentrations of citrate of up to 1.2mg/ml urine [423] and further clinical evaluation of the effects of increasing a patient’s fluid intake with citrate containing drinks is awaited. Viable cell counts of P. mirabilis in the model suggest that results were unlikely to be due to direct effects of citrate on the growth of metabolism of P. mirabilis in the catheter biofilm, but rather on the process of mineral crystallization.

Recent research provides more evidence. In a recent randomized six week crossover trial of citrated drinks in 24 persons with catheter blockage [444], it was demonstrated that the pHn could be significantly increased. The highest level of change was with lemon juice, with a “safety margin” of 0.84 (95% CI 0.63, 1.04), followed by fluid intake 0.57 (95% CI 0.37, 0.78), and potassium citrate 0.41 (95% CI 0.20, 0.61). Overall, the safety margin for the drinks was significant (p<0.001) when controlling for the three groups. Each participant, who had experienced at least three blockages within four weeks previously, received all three drinks. Baseline 24 hour urines were obtained after each week, allowing for a washout period between the one week drink consumption for each arm of the study. The lemon juice concentration was 60mL/1 litre of water, potassium citrate was 6 g/1 litre, and the fluid intake was also 1 litre additional. Participants were instructed to consume the drinks each day in addition to their usual fluid intake and they tracked their intake and output during the study. This study provides additional evidence that optimal and consistent levels of fluid intake could minimize catheter blockage or increase the interval between changes, in persons with persistent encrustation and blockage.

The reduction of encrustation and corresponding extension of ‘catheter life’ by regular instillation of an acidic catheter maintenance solution into the catheter has been advocated by some researchers, particularly where frequent catheter changes for recurrent blockage are difficult and / or unacceptable to patients. Solution G (Suby G) and Solution R (Table XII-5) have been shown to be effective in in vitro models of the catheterised bladder [445] [446] [447] and in vitro models of struvite stone chemolysis [448]. In response to concerns over potential damage to the bladder mucosa from acidic catheter maintenance solutions, Getliffe et al. [446] advocate the use of small volumes of solution so that less enters the bladder. Under controlled laboratory conditions smaller volumes of acidic solutions (Suby G) (50ml), retained in the catheter for 15 minutes, were shown to be as effective as the commonly available commercial standard of 100ml. Getliffe et al. also showed that two sequential washouts with 50ml were more effective than a single washout.

There is relatively little clinical evidence to draw on in this area and outcomes remain to be tested in well-controlled clinical trials. Most clinical studies are small-scale and descriptive although both Getliffe [424] and Kunin et al. [418] compared groups of ‘blockers’ and non-blockers’ to identify
characteristics of recurrent ‘blockers’. One small-scale, comparative trial of Suby G, Solution R and saline catheter ‘washouts’ in 14 older female patients [449] reported a higher incidence of red-cells in the retrieved washout fluid with Suby G compared to saline (mean incidence of 28% and 14%, respectively. However, increased shedding of uroepithelial cells was present in the retrieved washout from all three solutions suggesting this was at least partially related to the physical process of administration. This issue was previously raised by Elliot et al. [450] who also demonstrated increased uroepithelial shedding following washouts with up to 60ml saline 0.9%; chlorhexidine 0.02% or noxythiolin 2.5%.

A more recent RCT with 73 community dwelling individuals, which aimed to compare weekly catheter flushes with saline or an acidic solution, with no flushes, reported the mean time until catheter removal was very similar between groups. Importantly, there was no evidence of detrimental effects, such as increased risk of symptomatic infection, from breaking the closed system in order to apply catheter flushes. Urinary pH did not change over the study time; at baseline the mean was 6.3 (SD 1.04), range 5-8.5. However, the study was underpowered and subjects were only followed for a maximum of eight weeks, or until the catheter was changed three times, or a symptomatic UTI developed. There were considerable difficulties with recruitment of patients and target numbers fell short within each group (Level of Evidence 2) [358]. A sample of 400 per group, 1200 in total, was estimated posthoc, as giving sufficient power for future research in this area [451]. Other clinical studies have focused on chemolysis of infection stones (principally composed of struvite). Stronger acidic solutions such as Solution R have been shown to dissolve fragments of struvite renal calculi following lithotripsy [452] but potential benefits may be outweighed by the greater risk of inflammatory tissue reactions when used as a catheter maintenance solution. Renacidin solution is approved for kidney stone disintegration in the US but although it may be effective for recurrent catheter blockers, there is no published research evidence of its use in this group.

Overall, methodological issues make it difficult to draw robust conclusions on the effectiveness of acidic solutions in managing catheter blockage. It is unlikely that any currently available strategies will completely prevent catheter encrustation and a more practical aim is to extend catheter life to a period which is acceptable to users and manageable by healthcare professionals. Early detection of impending blockage by determination of usual length of catheter-life [424] or by application of a sensor device designed to detect early stages of P. mirabilis biofilm formation [453] are likely to remain the main stays of management.

### j) LTC-associated risks and problems: urethral trauma, bladder calculi and bladder cancer

#### 1. URETHRAL TRAUMA

Urethral trauma and discomfort can occur during catheterisation but may be minimised by using a sterile lubricant or anaesthetic gel [454], however clinical practice remains variable. More studies have considered the use of lubricants for male catheterisation but few have considered the procedure for women or for supra-pubic catheterisation [455]. A recent randomised, double-blind study with 62 alert, cooperative females requiring urethral catheterisation, demonstrated that the group receiving lignocaine gel had a significantly lower median procedural pain score compared to the group receiving a water-based lubricating gel [456]. It is not clear whether cleaning the urinary meatus prior to insertion is needed, based on two small trials (Level of Evidence II). In one study, 0.05% chlorhexidine gluconate or sterile water was tested in a home care sample (N=20), with four urine specimens cultured over two weeks. No difference was found, and no one developed a symptomatic CAUTI [457]. In the other study of 60 women receiving outpatient gynaecological surgery, [458] povidone-iodine was compared with water. No significant differences in bacteriuria or symptomatic CAUTI were found in comparing urine samples just prior to insertion and 24 hours later.

#### 2. BLADDER CALCULI

Most long-term follow up studies of LTC use have addressed SCI populations. Indwelling catheters (UC and SPC) have been significantly associated with increased risk of bladder calculi formation in SCI patients, compared to intermittent catheterisation [460] [235]. In a retrospective cohort study of 457 patients, controlled for variable follow up times by regression analysis, both UC and SPC were significantly associated with increased risk of bladder calculi formation compared to intermittent catheterisation IC (hazard ratio 10.5; p<0.0005 and 12.8; p<0.0005) respectively [461]. This increased risk was independent of age, sex, level and degree of injury but calculi were no more likely to form with SPC than UC (hazard ratio 1.2, p=0.6). Another case series of SPC in 118 patients with neurogenic bladders [462] found common complications were bladder calculi (25%), particularly associated with high urinary pH and urethral leakage (10%). Bladder calculi-free rates at five and 10 years were 77% and 64% respectively, falling to 50% at 20 years.

Where SPC has been compared to CIC the main difference appears to be in a lower incidence of bladder calculi in the CIC group. A prospective comparison of long-term outcomes between 34 quadriplegic patients managed by SPC (mean period 8.6 years) and 27 paraplegic patients managed with CIC (mean period 9.9 years) reported no significant
difference between groups in respect of symptomatic UTI, renal stone, degree of bother and overall satisfaction [310] but there was a significantly increased incidence of bladder stones in the SPC group. However a recent review of current literature [311] (56 studies), concluded there were variations between older and more recent studies. More recent studies showed morbidity profiles to be similar for SPC and CIC, where patients were managed by anticholinergic medications, frequent catheter changes and volume maintenance procedures. A dedicated catheter clinic established to aid the management of patients having problems with LTC, reported the majority of patients were elderly with chronic disabilities. A significant proportion of those with catheter encrustation and blockage (45% of 147 patients) were shown to have formed bladder calculi [463].

3. BLADDER CANCER

A number of retrospective, cohort reports of SCI patients have linked bladder cancer with long-term indwelling catheterisation [464] [465] [466]. The reported incidence of squamous cell and transitional cell carcinoma associated with chronic indwelling catheterisation varies widely between studies but Groah et al. [466] in their follow-up of 3670 subjects, calculated that patients with SCI and an indwelling catheter were 25 times more likely to develop bladder cancer than the general population (Level of Evidence 3). For SCI patients without an indwelling catheter, the risk of bladder cancer was 15 times that of the general population. Since SCI patients are already at increased risk of developing bladder cancer compared to non-SCI groups, the influence of an indwelling catheter on bladder cancer requires further clarification, including the potential relationship between duration of catheterisation and cancer development. Bladder calculi have been identified as an independent risk factor for bladder cancer by some authors [464].

Most reports have grouped UC and SPC together as indwelling catheters but a small number of case study reports have drawn attention to long-term risks of carcinoma within the cystostomy tract with SPC, with or without further extension into the bladder [467] [468] [469]. However, in a retrospective analysis of screening biopsies for bladder malignancy in 36 patients with SPC for more than 12 years, Hamid et al. [470] found no tumours in the screened group although histological findings were frequently abnormal (Level of Evidence 2). These authors raise concerns over the interpretation of screening cystoscopy and biopsy in this population and note the importance of the distinguishing between histological changes and confirmed cancers when interpreting study results. Recently published guidance on management and prevention of catheter-associated urinary tract infection, based on an extensive survey of the literature, includes a recommendation that patients with urethral catheters in place for 10 years or more should be screened annually for bladder cancer [471] (Grade of Recommendation C).

k) Catheter management strategies

Although guidelines and protocols for catheter-care practices are abundant, relatively few practices are supported by research evidence and even fewer by evidence from randomized controlled trials. For example, in the ‘Guidelines for prevention of healthcare associated infections in primary and community care’ commissioned by the UK’s National Institute for Clinical Excellence [472], of 29 recommendations relating to urinary catheterisation only six were Grade A (directly based on Level 1 evidence); with one each at Grades B and C. The remaining 21 were all grade D, being based on evidence from expert groups or clinical opinion.

1. GUIDELINES

In 2009, the U.S. Healthcare Infection Control Practices Advisory Committee issued through the Centers for Disease Control and Prevention (CDC) updated Guideline for Prevention of Catheter Associated Urinary Tract Infections [342]. This guideline, which updated the 1982 Guideline, expanded information about catheter related issues, including intermittent, condom, suprapubic, and chronically catheterised long-term users. The recommendations made by this committee for preventing catheter-associated urinary tract infections, based on systematic review of the best available evidence, address the following issues:

- who should receive an indwelling urinary catheter
- catheter insertion
- catheter maintenance
- quality improvement programs to achieve appropriate placement, care, and removal of catheters
- administrative infrastructure required
- surveillance strategies

This new guideline recommended selected practices at grade B based on level of evidence of 1 or 2. Therefore, many topics were judged as “no recommendation/unresolved issue” due to a lack of evidence.

2. QUALITY INDICATORS AND REGULATOR INITIATIVES

It is well established that guidelines alone do not change practice. Further efforts should be directed to disseminating evidence-based guidelines about catheter care through education and the use of quality indicators and regulatory initiatives. Regulation that is accompanied by the use of evidence based quality indicators has a powerful influence on the quality of care. Quality indicators are defined as quantitative measures reflecting a professional
care standard which are used as guides to monitor and evaluate the quality of important patient care and support service activities. The ACOVE (Assessing Care of Vulnerable Elders) suite of quality indicators has been designed to measure the quality of care for vulnerable elders [473]. It incorporates one quality indicator to guide measurement of the quality of care related to catheter use.

"IF a VE has clinically significant urinary retention, and a long-term (> 1 month) urethral catheter is placed, THEN there should be documentation of justification for its use, BECAUSE treatment of certain underlying causes(s) of urinaryretention (e.g., treatment of constipation or bladder outlet obstruction) may carry less risk than long-term urinary catheterization" [473].

Another attempt to ensure the appropriate use of catheters is the use of assessment protocols. For example, regulation for long-term care settings in the USA mandates that all newly admitted Medicare/Medicaid funded residents receive an assessment using a standardized form called the Minimum Data Set (MDS). A further level of assessment is triggered when/if a resident is newly incontinent and the Resident Assessment Instrument Minimum Data Set is completed (RAI-MDS). This assessment information in turn, acts as a prompt for staff to design an individualized care plan based on direct contact with residents, appropriate staff, and through use of observation, interviews and record reviews. The MDS and RAI are now used in a number of other countries, including Canada and Iceland, and other countries have developed their own assessment instruments. Ideally, these assessment instruments should prompt staff to enquire about whether the residents’ catheter is medically warranted, and to identify catheter related problems, and care plans should contain information about an individualized catheter care plan (including the frequency of catheter changes and ongoing maintenance). This assessment process is strengthened in the USA by its link to quality indicators. Specifically, long-term care facilities are required to use information from the residents’ comprehensive assessment to provide assurances that:

- Catheters are used for only medically valid reasons;
- Catheters are removed as soon as clinically warranted;
- Efforts are applied to restore or improve bladder function as much as possible; and
- Efforts are made to prevent infection while the catheter is inserted (U.S Dept of Health and Human Services, 2004).

It remains to be seen if these measures will reduce catheter rates in long-term care, and how they will impact day-to-day catheter use and catheter care. However, similar regulatory approaches should be considered by government and health agencies in other countries.

3. Catheter change procedures and catheter comfort

Indwelling catheters can cause substantial patient discomfort but although anecdotal information on the discomfort experienced by many catheterised patients is readily available, there is a general lack of published evidence from research studies. Further investigation and guidance to practitioners is needed. Catheter-related pain or discomfort can occur as the catheter is passed, in situ and on removal. Local anaesthetic lubricant gels are commonly used to aid the insertion of indwelling catheters in males and protect the sensitive urothelium from trauma [474]. Similar use of anaesthetic gels is generally recommended for females although the procedure may be less consistent in some places and where only small amounts of lubricant are applied to the catheter tip this may be insufficient to coat the urethra adequately. There is little research evidence to underpin clinical practice in this area although the NICE guidelines on infection control [472] recommend: ‘an appropriate lubricant from a single-use container should be used during catheterisation to minimise trauma and infection’. The choice of lubricating gel is usually left to practitioners but not all gels containing anaesthetic agents (eg lidocaine) are suitable for both urethral and suprapubic use. One prospective, randomized, double-blind, controlled trial of plain lubricant versus lidocaine gel prior to female catheterisation in an accident and emergency department found no significant differences in pain ratings, based on lubricant type or catheter size amongst 100 women recruited to the trial [475]. Anaesthetic gels may be contraindicated in patients with damaged or bleeding urethral membranes and should be used with caution in those with cardiac conditions, hepatic insufficiency and epilepsy [476]. Lubricants which contain chlorhexidine have been reported to trigger anaphylaxis in a small number of patients during catheter insertion and consequently a careful history is required to screen for sensitivities [477] [96].

In a study with 45 infants (2-24 months) who needed urethral catheterization, random assignment was made to either a topical lubricant (control), topical and intraurethral lubricants, or topical and intraurethral lidocaines [478]. Infants with the lidocaine had less distress, but the lidocaine did not eliminate the distress totally.

Catheterization in males can be difficult at times, and different approaches can be used, including a Coude catheter, various guide wires or filiform catheters, and other techniques performed by urologists. Research in this area is needed to compare different practices and associated risks [479].

Catheters can be painful when in situ. In one study at a US Veterans Affairs Medical Centre, 42% of
catheterised patients reported it was uncomfortable, with 48% complaining it was painful, and 61% stated it restricted their activities of daily living [107]. In one small sample of 43 community dwelling persons with long-term catheters, pain was reported by 24 (54%) [126]. Causes of pain were bladder spasms, position of the catheter, or related to catheter changes. Three had pain all the time, but 21 of 24 persons had it intermittently. If bladder spasm is the cause of pain when a catheter is in situ a low dose of an anticholinergic medication can help [480]. Other helpful approaches include treating constipation if present, ensuring that the catheter is the smallest size to provide adequate drainage, and ensuring that the drainage bag is well supported to prevent dragging on the catheter. Attention to the catheter position is needed to prevent kinks or twists in tubing and ensure that the catheter straps are not blocking urine flow [481]. Blockage in urine flow can cause bladder distension resulting in increases in hydrostatic pressure and bleeding points which open the way to bacteria, already present, to cause a symptomatic infection [210].

Bladder discomfort related to an indwelling catheter can exacerbate post-operative pain by mimicking overactive bladder syndrome that is resistant to conventional opioid therapy. Sub-lingual oxybutinin has been shown to be an effective treatment for pain after radical retropubic prostatectomy, with significant reduction in other pain relief requirements [482]. Cuffing of the catheter material on balloon deflation (see below) and / or encrustation of the catheter by mineral deposits may cause pain during catheter removal. Encrustation is discussed further in Section 12.2.9 and management of these problems is also discussed below.

4. EDUCATION OF HEALTHCARE PROVIDERS

Educational approaches should ensure that all healthcare practitioners have the necessary knowledge and skills to care for individuals with a catheter. Some research however, points to gaps in healthcare practitioners’ knowledge about what catheter to select, and how to minimize and manage ongoing problems[483]. Mody and colleagues (2010) [484] assessed nursing home healthcare workers’ knowledge and awareness of recommended catheter care practices, and found significant discrepancies between their knowledge and research-based recommendations. Respondents were drawn from seven community-based nursing homes in the USA and included nurses and nurse aids.

Twin surveys were sent to healthcare providers in Minnesota to determine their level of knowledge about catheter use. The physicians (N=635) reflected awareness of the indications for catheter use, and about 1/3 said they remove them sooner. However, about 30% were unsure about how to prevent UTI [485]. Nurses (N=370) were aware of catheter indications, but some were likely to approve of catheter use in the ICU (for whatever reason) and of the value of silver coatings on catheters [485]. Both studies had low response rates, of 9% and 4% physicians and nurses, respectively. Another survey to 333 persons, (70% RNs and 27% unlicensed assistants) indicated that there was a need for more education related to catheters [486]. Incorrect practices involved not securing the catheter (75%) and not knowing when to replace the catheter (74%). The response rate was 54%, and about half of those surveyed had less than two years work experience.

An audit of education given to nursing students in Greece indicated that there was a need to upgrade teaching methods [487]. Proficiency was impaired by a lack of attention to preparing the patient (including emotional and practical aspects), old textbooks, outworn traditions, little or no instruction on troubleshooting and a lack of sophisticated methods for teaching (e.g. DVDs showing the procedure).

An audit of adherence to standards of nursing care in one UK Trust related to catheter practices in patients’ homes [488]. All nurses surveyed (N=25) indicated they would change the catheter every 12 weeks unless there was a reason to do this more often; no data were provided on the percentage with 12 week changes. Though a closed system was advocated by all nurses, washouts were performed by 75% and sampling ports for urine samples were used by 28%, and the rest used a clean drainage bag. A similar audit was conducted in a hospital setting [489]. Continuing catheter care was well documented at 98%, but 11% were missing details on insertion.

5. CATHETER CHANGE FREQUENCY

Protocols on indwelling catheter change frequency vary widely from monthly to up to three months if the catheter is trouble-free. In the absence of clear supporting evidence this remains an area of controversy amongst clinicians with advocates of early change believing this to reduce the incidence of complications while others argue that frequent changes increase the risk of infection, trauma and long-term histological changes. However, very sparse evidence suggests that CAUTI might be less when the catheter is changed every 4-6 weeks, rather than only when it blocks, or with planned changes of every two weeks [490].

SPC changes can be competently managed by skilled nurses [325], often in the patient’s own home, but the new catheter should be inserted as quickly as possible whilst the track is still easy to follow. A delay of only a few minutes can result in partial obliteration of the tract [491]. It is also possible to insert the new catheter too far through the bladder so it enters the urethra with resultant trauma when attempts to inflate the balloon are made. Careful observation of the length of catheter external to the abdomen and the angle of protrusion prior to catheter change can
help to ensure correct positioning of the new catheter [492]. Dressings around the stoma site are not normally required unless there is excessive discharge, causing staining and / or sticking to clothing.

While nurses do not usually order catheter insertions, and there may be times when delay in a clinically appropriate catheterisation is harmful to certain patients. A new protocol and algorithm was thus developed by nurses, physicians and other key stakeholders in an orthopaedic unit of a large urban hospital to facilitate catheter insertion in certain defined situations [493]. Indications, such as spinal column injury, and contraindications were depicted in a diagram to identify when to stop, consider the issues (e.g., neutropenia), and when to insert the catheter.

Urinary catheter ‘deflation cuff’ formation can be a problem in both SPC and UC, causing difficulty in removal and great discomfort to patients. Evidence suggests deflation cuff formation can be a particular problem for all-silicone SPCs. A retrospective study of 113 patients cared for by community nurses showed that 30% of nurses had experienced problems changing catheters in the previous 12 months [494]. In vitro studies have confirmed increased retention force and resistance to withdrawal caused by cuff formation and although cuffs can form with other catheter materials (eg hydrogel coated-latex) the retention force is less than with all-silicone material [339]. It has been suggested that slow deflation may enhance the probability of the silicone balloon returning to its pre-inflation shape [340]. Alternatively, reinsertion of 0.5-1ml water is sufficient to fill the catheter inflation lumen and eliminate the balloon cuff. Subsequent use of lubrication with gentle removal of the catheter has been well-tolerated by patients and produced virtually no trauma.

6. PERSONAL HYGIENE AND INFECTION CONTROL

Meatal cleansing by simple washing with soap and water during routine bathing or showering is recommended (Level of Evidence 1) [495] [496]. No consistent reduction in bacteriuria has been demonstrated by any other meatal cleansing regimes, using povidone-iodine solution or cream, chlorhexidine, polymicrobial creams, 1% silver sulfadiazine or antiseptic lubricating gels, compared to routine bathing or showering [374] [122]. Effective handwashing by healthcare professionals, carers and patients, before and after handling catheters and drainage equipment is generally accepted to be the most important component of any infection control strategy. Healthcare professionals and formal carers should also wear gloves. Catheters and drainage equipment are commonly supported in position by tapes, Velcro and other securing devices (eg CathSecure, StatLock)

More securement devices are now on the market providing choices for long-term users, in particular. Consideration should be given to usual activity, clothing, size of the person (e.g. thighs) and the weight of the bag it would support. All, but especially those using adhesives, need to be comfortable, easy to use, and gentle to the skin [497]. These securement devices are designed to control post-operative bleeding, maintain surgical anastomoses in the lower urinary tract, and prevent urethral erosion or trauma and accidental dislodgement from traction [498]. The importance of these in reducing risks of CAUTI and the mechanism involved are not well-established [380] (See also section XII.2.h).

7. URINE COLLECTION — CATHETER VALVES

Urine may drain continuously from the bladder into a drainage bag attached to the catheter (See Section XIII) or intermittently via a catheter valve. The valve is a small device connected to the catheter outlet in place of a bag. Closure and opening the valve allows bladder filling and intermittent drainage rather than continuous drainage into a bag. Valves are available in a variety of designs (Figure XII-9) ranging from simple inexpensive types used for up to a week, to more expensive, complex, forms which last longer and which may permit one handed action. However, valves are not available or licensed in all countries.

Most valve designs can be attached to a drainage bag at night to allow free drainage while the patient sleeps. A valve can provide a discreet alternative to conventional urine drainage bags and may offer improved maintenance of bladder tone and capacity for appropriate patients. A spigot is not a suitable alternative to a valve since it must be removed from the catheter to allow drainage thereby breaking the ‘closed system’. Patients must be able to manipulate the valve mechanism and empty the bladder regularly to avoid overfilling, with accompanying risks of back pressure on the upper urinary tract. Valves are generally inappropriate for patients with poor manual dexterity, poor bladder capacity, detrusor overactivity, ureteric reflux, renal impairment or cognitive impairment. There is relatively little research-based literature on catheter valves with much of the evidence supporting beneficial effects derived from the level of expert opinion. Concerns
over possible increased risk of infection associated with valves have not been realised although there is a paucity of research in this area. A lack of knowledge on valves may interfere with their use in appropriate situations; therefore, a full assessment is required to determine whether the person is a good candidate for a catheter valve using a systematic process, such as an algorithm [499].

The flushing mechanism resulting from bladder filling and emptying may be expected to contribute to reduction in problems of encrustation and blockage. One study was found that provides new evidence as to how a catheter valve might do this [500]. The laboratory study involved four experiments with a bladder model and artificial urine cultured with Proteus mirabilis. Manual valves were opened every two or four hours with continuous drainage at night, followed by experiments with automatic valves timed to open for five minutes every two to four hours around the clock for seven days. All experiments were compared with continuous drainage of urine. Analysis of variance showed that all models controlled by valves during the daytime (12 h) took significantly more time to block (62.6 versus 35.9 h, p=0.039) than 24 hour continuous drainage. Experiments were done with automatic valves which ran 24 hours day every two or four hours, and time to blockage extended to 119.8 h versus. 50.7 h, and 159.8 h versus. 44.7 h, respectively.

There is stronger evidence of benefits in terms of patient comfort and independence since this is a common finding in most studies. Five studies comparing a catheter valve with standard drainage (leg bag) were identified: three were cross-over designs, with 28, 16 and 18 subjects respectively [501] [502] [503] (Level of Evidence 3); two randomized their sample of 100 subjects to either catheter valve or standard drainage [504] [505] (Level of Evidence 2). None of the studies identified any significant difference in urinary tract infection and a majority found a high level of preference or acceptability of catheter valves (>72%). There were no differences in reported incidence of bladder spasms or discomfort; however, there was a higher incidence of nocturnal frequency and episodes of bypassing with valves. It was suggested that a combination of a valve during the day and free drainage at night through an open valve connected to a drainage bag could be an appropriate management strategy.

Several studies have evaluated a single valve design [506] [507] but only one has compared a broad range of valve designs [508]. Fader et al undertook a comparative evaluation of the seven catheter valves available on the UK market in 1996. Each valve type was tested for one week by between 19 and 36 subjects, followed by completion of a product evaluation questionnaire. Performance scores (and costs) varied widely between products but critical characteristics were: being easy to manipulate, leak-free, and inconspicuous. The authors concluded that prescribers need to be aware of the strengths and limitations of different valves for appropriate product selection (Level of Evidence 3). A more recent development concerns the design of a prototype, novel, automatic valve system for LTC patients [509] which may be helpful for patients who lack sufficient dexterity to manage a manual valve. In summary:

- Catheter valves provide a well-accepted system of bladder emptying for suitable patients who are able to manipulate the valve mechanism and empty the bladder regularly to avoid overfilling (Level of Evidence 2).
- There is no evidence of increased risk of urinary tract infection with valves compared to conventional drainage systems (Level of Evidence 2).
- Valves may promote maintenance of bladder tone and capacity (Level of evidence 4).

8. MAINTAINING EFFECTIVE CATHETER DRAINAGE

Use of urinary catheters is rarely completely trouble-free. Catheter drainage can be compromised by a variety of factors from simple causes such as kinked tubing or the position of the drainage bag, to bladder spasm, pressure of a constipated bowel on the adjacent urethra, suction of bladder mucosa into the catheter eye, or blockage by blood clots, mucous or encrustations formed by deposits of mineral salts. The algorithms in Figures XII -10 to XII-12 combine current evidence-based knowledge and expert opinion to provide some guidance on trouble-shooting common problems.

9. RECURRENT CATHETER ENCRRUSTATION AND BLOCKAGE

Factors affecting persistent catheter encrustation leading to recurrent blockage have been discussed earlier in section XII.2.i. The day to day management of recurrent catheter encrustation and blockage is largely a nursing responsibility but there are few options available. Maintenance of dilute urine by a suitably high level of fluid intake has been shown to reduce encrustation in laboratory studies [438] and increased urinary citrate concentration produced by drinking orange juice or other fruit juices may also be beneficial [438]. However the amounts required may be relatively high and clinical studies are needed to assess benefits and possible detrimental side effects e.g on bowel behaviour. Use of a catheter valve in suitable patients may also help reduce build up of encrustation by facilitating periodic flushing but clinical evidence is currently unavailable. In a majority of patients a characteristic pattern of 'catheter life' can be identified with careful record-keeping of three or more catheter episodes [424] [418] [510]. This may allow pro-active strategies of care designed to change the catheter before likely blockage. However, very frequent catheter changes can be unsuccessful or
Figure XII-10: Troubleshooting long-term catheter problems: urine does not drain (N = No; Y = Yes). (Always have a spare catheter available)
Unacceptable for some patients, as well as being costly in terms of health service resources [420]. In a study of planned catheter changes [511], based on observation of the intervals for three changes, urinary pH, and visual encrustation, unplanned changes decreased significantly from 46 the year prior (n=39) to 30 during the 12 months post intervention (n=21, p<0.01). The major impact on quality of life related to catheter problems decreased from 39% to 5%, though satisfaction with care management did not change much.

An alternative strategy is the regular prophylactic instillation or irrigation of the catheter with an acidic ‘catheter maintenance’ solution to dissolve mineral deposits. In older literature the term ‘bladder washout’ appears but as the aim is to wash the catheter, rather than the bladder, ‘catheter maintenance solution’ is a more appropriate term. A range of commercially available catheter-maintenance solutions is indicated in Table 12-6, although these are not necessarily available in all countries. Support for irrigations is strongly divided between those claiming benefit for specific patients who experience very frequent blockage and those who consider any break to the closed system to increase risks of infection. Research evidence is primarily derived from laboratory models of the catheterised bladder. The few clinical studies which have addressed this issue have been limited by methodological deficits and small sample size.
THE INFLATION BALLOON DOES NOT DEFLATE

PROBLEM

Blocked deflation channel?

Faulty valve or syringe

? constipation, present - may cause pressure on the inflation channel

consult local policy for further advice or seek medical help

ACTION

- try to remove or dislodge debris blocking the deflation channel by gently 'milking' the catheter along its length
- try to remove or dislodge debris by inserting a few drops of sterile water into the inflation channel (no more than 1-2ml) with a sterile syringe

- try a different syringe, withdraw water very slowly or leave syringe in place, the water may seep out over a period of time
- insert the needle of a sterile 10ml syringe into the balloon drainage channel just above the inflation valve. If the valve is faulty the water may be withdrawn gently via the syringe

try to relieve constipation

do not cut the catheter
- it may recoil inside the urethra

do not cut the inflation valve off
- if the balloon does not deflate it will no longer be possible to try alternative simple methods

do not attempt to burst the balloon by over-inflating it
a cystoscopy will be required to remove fragments!
remaining fragments may result in formation of calculi

Record problem, actions and outcome.
Record catheter details, lot number etc and report to manufacturer

Figure XII-12: Troubleshooting long-term catheter problems: the inflation balloon does not deflate.
1) Levels of evidence relating to catheter-associated risks and complications

- All currently available catheter materials are subject to bacterial biofilm formation (Level of Evidence 1).

- Silver alloy coated catheters are associated with a statistically significant reduction in incidence of asymptomatic bacteriuria in short-term catheterised, hospitalized adults (studies of varying quality included) (Level of Evidence 1). There is less robust data to show that silver-alloy catheters reduce symptomatic infection (Level of evidence 4). Silver oxide coated catheters are not associated with a statistically significant reduction in bacteriuria (Level of Evidence 2).

- Antimicrobial catheters can prevent bacteriuria in hospitalized patients during short-term catheterization (<14 days) (Level of Evidence 1). Trial results are highly context dependent and the effectiveness of specific antimicrobial preparations may be limited to specific groups of microorganisms. Potential toxicity and/or antimicrobial resistance is unknown (Level of Evidence 2).

- There is little evidence to guide the precise timing of antibiotic cover (when required) for catheter change. One study has shown that clinical outcomes (i.e. reduction in polymicrobial counts in urine, time to achieve afebrile status and clinical status at 72 hours) are significantly better among subjects randomised to catheter change immediately before institution of antibiotics (Level of Evidence 2).

- A majority of health services have clear policies on the use of antibiotics, designed to limit unnecessary use. Current evidence does not support routine use of antibiotic cover during catheter changes unless the patient’s condition renders them particularly at risk (Level of evidence 4).

- Meatal cleansing by simple washing with soap and water (i.e. not with antimicrobial agents) during routine bathing or showering is recommended (Level of Evidence 1).

- Recurrent urinary catheter blockage caused by encrustation occurs in 40-50% of all long-term catheterised patients (Level of Evidence 2). In the majority a characteristic pattern of ‘catheter life’ can be identified (Level of Evidence 3).

- Evidence from in vitro models of the catheterised bladder indicates that i) dilute urine; ii) high urine citrate content (> 1.5mg/mL) reduce risk of blockage (Level of Evidence 2).

- Evidence from in vitro models of the catheterised bladder indicates that acidic ‘catheter maintenance’

¹ Available in the UK pre-packed in a sterile delivery devices designed for instillation into a urinary catheter. ² Renacidin**R** is approved in the USA for kidney stone disintegration only. Although it may be effective in certain situations for persistent catheter blockers, there are no supporting studies.

- Saline is widely available
solutions may have a role in dissolving encrustations in persistent blockers (Level of Evidence 2). There is insufficient evidence from RCTs to assign an in vivo level of evidence.

• Suprapubic catheterisation (SPC) is an appropriate alternative to urethral catheterization for many patients following appropriate risk assessment (Level of Evidence 1).

• There is some evidence for a reduction in catheter-associated infection in SPC use during short-term catheterisation (Level of Evidence 2), compared to urethral catheter insertion. However, there is no corresponding evidence for long-term catheterisation.

• Patient comfort, quality of life and satisfaction with SPC is generally good compared to urethral catheters (Level of Evidence 1).

• Catheter valves provide a well-accepted system of bladder emptying for suitable patients who are able to manipulate the valve mechanism and empty the bladder regularly to avoid overfilling (Level of Evidence 2).

• There is no evidence of increased risk of urinary tract infection with valves compared to conventional drainage systems (Level of Evidence 2).

m) Urinary catheters versus other care strategies

Very few studies have compared urinary catheterisation with other strategies to manage urinary incontinence, not least because of the difficulties in recruiting to and conducting robust trials. For male patients who do not have problems with retention of urine external urine collection systems are an option (See Sections VII, VIII and IX). One recent prospective, randomized, blinded, controlled trial on men >40 years in a US Veterans Affairs Medical Centre reported that the use of condom catheters was less likely to be associated with bacteriuria, symptomatic UTI or death than the use of indwelling catheters [101]. Patients reported that condom catheters were more comfortable (P=0.02) and less painful (P=0.02) than indwelling catheters.

A small number of studies have attempted to examine preferences for different urinary incontinence treatments in long-term care. In a descriptive, comparative study of preferences for treatments for frail older adults, residents in long-term care facilities were interviewed and groups likely to serve as proxy decision makers were surveyed (family members of residents and nursing staff) [512]. Forced choice comparisons of continence treatments were measured. Although there was wide variation within and between groups, most preferred non-invasive strategies (diapers and prompted voiding) to invasive strategies including indwelling catheterisation. Older adults stated they would choose a treatment based, in part, on feeling dry, being natural, not causing embarrassment, being easy, and not resulting in dependence. Similar results, showing urinary catheterisation as the least favoured choice, were found in a study of 117 medical inpatients aged 80 years or over, their physicians, nurses and family members [513].

3. CATHETER-RELATED QUALITY OF LIFE

Use of a LTC is often a last choice for bladder management when other options such as CIC, for males a sheath (condom) catheter, or other voiding treatments like Credé procedure, are either unsatisfactory or no longer practical. Catheter users must deal with a variety of problems that disrupt their daily activities and negatively affect QoL, such as CAUTI, blockage, leakage and catheter dislodgment. In addition, the visibility of a catheter or drainage bag can contribute to shame or stigma, and urine odour can be embarrassing. A catheter can also be a reminder of vulnerability associated with illness / mortality and a symbol of a loss in control of bodily function. Yet catheter users also acknowledge catheter-associated benefits of freedom from wetness, convenience, and utility in promoting urine drainage. While this section focuses on long-term catheter use, even short-term catheters can have a detrimental impact on QoL. For instance in a study of short term catheter use prior to surgery for acute urinary retention, leaking, blocking, urgency, and pain at the penis or during erection were all reported [514].

Studies of QoL issues commonly utilise qualitative research methodologies, such as phenomenology or grounded theory approaches (see also Section XII.1.e). In-depth interviews with catheter-users and carers provide important insights into aspects of ‘living with a catheter’ and contribute research based evidence to support development of effective care strategies. Measurement of QoL and the impact of factors which may affect it is complex. Most validated QoL instruments fall into one of two groups: i) generic measures designed to encompass domains including physical, mental and social wellbeing; ii) disease specific measures designed to measure change in QoL resulting from treatment. For those people whose urinary symptoms are managed by products or devices, including catheter users, it is particularly difficult to assess the impact of the product on QoL. This is partially because changes are more likely to be related to improved management of ongoing symptoms rather than actual change in symptoms, and partially because QoL is also dependent on the underlying disease process.

Much of the literature on LTC use involves people with neurogenic bladder, particularly those with spinal cord injury (SCI) or multiple sclerosis (MS). Thus, QoL in catheter users must be considered from a perspective of how the disease and the device affect the individual’s life. For instance, in one postal survey of 230 people with SCI, the factors
which had most impact on QoL were social activities and accomplishments, including employment, attending school, and other activities. There was no association between QoL and different bladder drainage methods [515]. A particular problem for people with spinal cord injury or disease is autonomic dysreflexia (AD), an autonomic nervous system syndrome causing symptoms which include severe hypertension, headache and sweating. A blocked urinary catheter can be a common cause. AD can be a serious problem requiring emergency medical attention, but lack of knowledge and awareness of the risks by some health care providers can cause high levels of anxiety for SCI patients [516] [305] (Level of Evidence 3).

There is currently one instrument measuring quality of life in people with indwelling urinary catheters [269] though this measure was validated in two small samples. Further development and validation are ongoing in the US and in the UK (Level of Evidence 3).

The published literature addressing QoL in catheter-users is small, and is commonly limited to reports addressing levels of satisfaction with a device. Studies which include a broader perspective of QoL are discussed below under the following headings: changes in bladder management, embarrassment, sexuality, catheter-related pain, catheter adjustment, and self-management.

a) Changes in Bladder Management

Changes in bladder management are often made to promote QoL but there are trade offs that require weighing up the pros and cons of various methods. People sometimes switch from CIC to an indwelling catheter - despite the inherent problems with an indwelling catheter - because quality of life might be improved. In particular, women with cervical spinal cord injury (SCI) may need an indwelling catheter because of difficulties in transferring to the toilet, limited hand dexterity, or dependence on caregivers [517]. Moreover, many people have used different bladder drainage methods over time. In one study, of 30 long-term catheter users, 80% of the sample had used another form, and 33% had used two or three different types [518]. In another small study with a sample of 11, 100% had used another method, and 27% had used two or three other types [306]. Reasons for non-compliance with CIC in relation to QoL or satisfaction have been addressed in Section XII.1.e and in some studies comparing drainage methods (Level of Evidence 3).

Two studies provided additional evidence of how changes in bladder drainage methods are made to improve their quality of life. In a retrospective study assessing compliance with bladder management, 50 new spinal cord injury (SCI) patient records were reviewed after admission, discharge, and follow up from 1994-1997 [517]. Of 38 patients on IC at hospital discharge, 20 (52%) were back to UC at follow up. Six of 10 females on IC had resumed UC. Reasons for not continuing with IC were: the need to depend on caregivers, poor hand functioning, spasticity, incontinence (despite anticholinergic drugs), and for females with cervical injury, toileting inconvenience (Level of Evidence 3). In contrast, a retrospective chart review and follow up questionnaire was used with 236 SCI injured people (at least 10 years post injury) between 1956-1990 [519]. An 85% response rate was achieved in the sample, with 82% males who had tetraplegia (47%) or paraplegia (53%). Although 46% changed their bladder management method over time and 28% considered the method a problem, in 58% of those who had tetraplegia, the use of CIC went up from 11% at discharge to 36%. Suprapubic tapping decreased from 57% to 31% and Crede increased from 5% to 19%. CIC alone, or with other methods, was the most common method (Level of Evidence 2).

b) Embarrassment

Embarrassment and a sense of lack of bladder control are two major catheter-related issues that are ongoing problems for many people. In one study at a US Veterans Affairs Medical Centre, 30% of catheterised patients surveyed found the indwelling catheter embarrassing, and 61% stated it restricted their activities of daily living [107]. The catheter is placed in a position in the body normally considered ‘private’, yet health care providers frequently need access to the site to provide care. Also, the force of urine flow is something that catheter users must deal with on a daily basis. In a qualitative phenomenological study of 14 people with long-term catheters, people told stories of how getting wet in public was embarrassing and how the force of the urine was like water that had built up pressure [516]. They used the metaphor of “flowing water” to describe the force of urine flow, the weight of the drainage bag, and the sound of urine sloshing around in the bag.

Living with the catheter was described in one qualitative study [305] as a swing back and forth between stigma, when it contributed to embarrassment or shame, and acceptance when it was working right and did not cause problems. The catheter became a source of embarrassment during catheter changes, bag emptying, and when it leaked or spilled in public. Individuals used planning and great care when going out (e.g. mapping out the toilets) to prevent urine accidents. They were bothered also by their lack of bodily control, the monotonous care, and how it was a reminder of their condition and mortality (Level of Evidence 3).

Catheter related embarrassment is a common experience stemming from exposure to the opposite sex, the visibility of the urine bag, and unpredictability of urine accidents [520] [521] [305]. Breaches in privacy were identified in two qualitative studies of the lived experience of catheter use [522]
To care providers, catheters may seem commonplace, but male / female sensitivities may occur during catheter care, particularly catheter changes, including men who are embarrassed by a female care provider [520]. Embarrassment can be minimized by providing privacy during catheter changes and same sex care providers when possible [522] [305] [523]. Acknowledging the embarrassment that exists if the nurse is of the opposite sex paradoxically may diminish the vulnerability [305]. Humour is often used by care providers, catheter users, and caregivers, and a professional approach by the health care provider may help the catheter user accept the situation [522] [305] [523] (Level of Evidence 3).

A few studies have examined QoL issues related to practical aspects of living with the catheter, such as managing the drainage bag (See Section VIII). While most people who are self-caring cope with the management of their catheter drainage system, many find them restrictive and report a negative impact on QoL. In a small pilot study based on a postal questionnaire to LTC catheter users (n=59) [525] almost 25% of respondents stated that wearing a bag had a major negative affect on everyday living. Concealment of the bag was one of the most important concerns raised (89%). Keeping the urine drainage bag covered and its visibility minimized can help reduce embarrassment and the stigma related to using a catheter. The visibility of the bag can be considered demeaning and it exemplifies a loss of bladder control [305] [523]. Moreover, if a bag is unreliable, and springs a leak for instance, it contributes to vulnerability. Even using a catheter for a short time can be an assault to one’s dignity. In a study in post-operative short-term catheter use, people complained about feeling “on display” and objectified [522] (Level of Evidence 3).

c) Sexuality

In a study of experiences of 25 men with prostate cancer, many of whom were treated with a urinary catheter, subjects reported the catheter contributed to feelings of shame, excess hospital visits for complications, and with other treatments for cancer, an end to sexual activity [526]. Men viewed healthcare professionals as having responsibility for medical decisions and they alone felt responsible for the catheter, micturition, and sexual life (Level of Evidence 3).

Issues related to sexuality were dominant in several other studies. Using a catheter compounded changes in sexual life caused by illness or injury [521] [524]. In one study, catheter users complained that care providers did not provide enough information about sexuality and how to adapt to a catheter [524]. Despite some care provider’s reluctance to address these issues, sexual health should be a part of assessments [527], and information about sexual activity should be provided proactively, while recognizing that some catheter users will wish to engage in sexual intercourse and others will not (Level of Evidence 3-4).

In a study of 20 men in Nigeria with prostate-related obstruction, who used an indwelling catheter from 1-36 months, [528], negative changes in self-esteem and sexuality (manhood) were reported. However, family and friends were instrumental in providing support and encouragement, including financial help and transportation to the hospital. The underlying disease may also impact on sexuality. For instance, a urinary catheter complicates sexual activity in people with spinal cord injury (SCI). Moreover, men may have changes in sexual performance related to ejaculation, erectile function, and arousal [529]. For females with SCI, experimenting with positions, lubrication, and preventing pruritic may be helpful in sexual activity [529] (Level of Evidence 2). For people with SCI, sex-related autonomic dysreflexia (AD) occurs most often in people who suffer from AD during bladder or bowel care [530] (Level of Evidence 2). Autonomic dysreflexia is an autonomic nervous system syndrome that occurs in people with spinal cord injury or disease. Symptoms include severe hypertension and excruciating headache as well as sweating and goosebumps. It can be a serious problem—even life-threatening—requiring emergency medical attention, yet it is sometimes ignored or disregarded by health care providers [516]. A blocked catheter is also a frequent cause of AD. In a qualitative study [524], several people complained that care providers did not know much about AD and often dismissed their anxiety and concerns (Level of Evidence 3).

Promoting sexual health for persons with catheters [531] requires awareness of self (especially in relation to sexuality), training for health care providers, open communication, and advocacy for and validation of patients’ experiences.

d) Catheter-related Pain

Pain related to catheter use is not always recognized although anecdotal information suggests that many people find a urethral catheter uncomfortable (see also Section XII.2 k.3 on catheter comfort and catheter change procedures). In Saint et al’s study [107] 90% of catheterised patients surveyed reported they found the indwelling catheter uncomfortable or painful, and in a study of 43 community dwelling persons [126] 54% reported catheter-associated pain, and in a sample of 20 men who used a catheter for prostate obstruction, 35% had pain [528]. Sometimes women complained about the pain because of sitting on the catheter or sores in the vaginal area [516], however it is unclear whether sores or skin irritation are related to latent sensitivity, friction, or wetness or a combination. Bladder spasms, CAUTIs, blockage, and dislodgement can all contribute to catheter-associated pain, as well as insertion and removal procedures [532] [523] [516].
(Level of Evidence 3). Pain arising from AD in SCI patients can result from catheter blockage and has been discussed above.

e) Adjustment to a Catheter

Adjusting to living with a catheter may take a considerable time. In Roe’s study [533] participants reported it had taken them up to a year. Similar lengths of time are commonly reported in anecdotal evidence. An educational booklet for catheter wearers has been shown to significantly improve knowledge and acceptance of the catheter [534]. Though the implications for this type of intervention are positive (Level of Evidence 1-2), the sample was small (n=45) and the study has not been replicated. The core category identified in a study using a grounded theory approach to examine older people’s experiences of living with a LTC was ‘all about acceptance’. Two further categories defined as ‘at ease’ and ‘unease’ reflected the extremes of their experience and these were mediated by ‘interaction with others’ [535]. The presence of a catheter can affect the individual’s view of their own body and such shifts in body image can cause some people to exclude themselves socially. New catheter users (both urethral and suprapubic) may resist the “intrusion of the catheter” prior to acknowledging the need for it [536]. Qualitative studies have shown that although some people felt ill prepared for a catheter, and even viewed it as distasteful, most learned to accept the device over time [536] [523]. Catheter-users have described their changed perceptions of the body and of how they learned to pay attention to urine flow to prevent catheter related problems. Though most acknowledged feeling vulnerable because of disruptions caused by the catheter, they noted also that keeping urine flowing was critical to their wellbeing [537] (Level of Evidence 3).

Health care providers need to provide proactive support and education about the catheter and its care, particularly since some catheter users are uncomfortable in asking for help or support. Male / female sensitivities can interfere; for example, a woman might be disinclined to talk about her catheter with her son [536] [523] (Level of Evidence 3).

Guiding and supporting an individual’s adjustment to living with a catheter involves promoting dignity, supporting the changed body image so that the catheter becomes a part of self (and almost not noticed), and learning self-management and self-care, and in planning for active life in the community. It is essential that catheter users know how to select suitable equipment. Simple advice such as not using a coloured catheter in the summer when white clothing would allow it to show can be very helpful. Knowing where toilets are and planning for outings (rehearsing) can prevent urine accidents [516] (Level of Evidence 3). Ambulatory females who use a belly bag need to face the toilet when emptying the bag. Since this position is associated with male toileting rather than female it can sometimes cause embarrassment. Some women may prefer to use a unisex toilet where possible.

While adjustment takes time, emotional distress with the catheter can swing back into the picture at any time if problems develop. Depending on whether the device is working well or not, people can move back and forth between acceptance and estrangement from the catheter [305] when the problem in the background emerges and brings the issue once again to the foreground [538] (Level of Evidence 3). Learning to live with a catheter involves recognizing that the benefits can outweigh the problems [524], watching for signs of problems, and adjusting to the interpersonal and sexual changes [536] (Level of Evidence 3).

f) Self-management

Self-monitoring, a component of self-management, involves awareness of what to notice and related measurements or observations [539]. Self-monitoring urine flow was found to be helpful in preventing or minimizing catheter-related problems in a pilot study with 11 community-based individuals over a six months’ time [306]. In this study, a 3-day urinary diary of intake and output was combined with an educational program, individualized to the interests of participants. Most participants said they learned to pay attention to urine flow, through observing continuous drainage into the drainage bag, increased awareness of the urine colour, position of the catheter, and by monitoring the consistency of their fluid intake [306]. Health care providers can help catheter users to learn to manage their catheter themselves, (i.e. self-care) by identifying where they are in the process of learning self-care and by working with them [536] (Level of Evidence 3).

g) Summary

Most published studies of patients with indwelling catheters have focussed on short-term catheters (<14 days) in hospitalised patients and relatively few have compared different modes of catheterisation (urethral, suprapubic, intermittent). The main subject of research on catheter use has been the risk of catheter-associated infection and the surrogate outcome measure of bacteriuria (asymptomatic) is commonly employed. However, there are important questions over the appropriateness of this as an outcome measure. Although there is clear evidence to support a small proportion of catheter care procedures (indicated below) the majority of procedures are based on clinical experience and expert opinion. Long-term studies are difficult to carry out for a variety of reasons (not least the frailty of many long-term catheterised patients) and there are relatively fewer studies based on community dwelling patients. RCTs may not be the most appropriate or pragmatic design for these groups. Although there are now a number of Cochrane reviews relating to
long-term catheter use it is clear that the quality of studies available frequently precludes drawing robust conclusions.

The published literature on SPC use is still relatively small, with much of it based on single centre cohort or case studies, or on short-term post-operative care following surgical procedures (not necessarily related to lower urinary tract symptoms). The majority of reports on SPC for long-term bladder drainage focus on the management of neurogenic bladder. Robust conclusions are often difficult to reach given the relatively short follow-up time frame of many studies and the lack of precise definitions of key outcome measures such as measurement of infection. Overall the risks associated with short and long-term use of indwelling catheters are common to both urethral and SPC insertions, including CAUTI, tissue trauma, catheter encrustation leading to blockage, formation of bladder calculi and historical changes.

Quality of life measures, including evaluation of psychometrics, need to be developed further and tested in this population, which may have different needs than others with incontinence. Studies of incontinent people that include catheter users should present data in ways that give the reader information about this sub-population. Sensitivity and a proactive stance from care providers could prevent or minimize some of the stigmatizing effects of the catheter, including those related to privacy needs, dignity, and sexuality. Further product development may help catheter users attain a higher quality of life. Additional research on the effects of self-management/self-care may provide direction for teaching that could contribute to a higher quality of life for catheter users.

4. OVERALL RECOMMENDATIONS RELATING TO CATHETERS

a) Intermittent catheters

• Clean intermittent catheterisation (CIC) is a treatment of choice for those with ongoing bladder emptying problems and residual urine > 100ml who are able to manage the technique (Grade of Recommendation A).

• CIC technique can be taught to all ages of people with appropriate motivation and manual dexterity (or to a carer where this is acceptable to both parties). Appropriate education and ongoing support is needed (Grade of Recommendation C/D).

• Frequency of catheterisation needs to be based on individual need, to prevent over-filling of the bladder (Grade of Recommendation C).

• An external lubricant or lubricant-coated catheter is recommended to minimise urethral trauma (Grade of Recommendation C).

b) Indwelling catheters

• Indwelling catheters should only be used after alternative management strategies have been considered and rejected as unsatisfactory (Grade of Recommendation A).

• Duration of catheterisation should be minimal (Grade of Recommendation A).

• A closed drainage system should be maintained to reduce risk of catheter-associated infection (Grade of Recommendation A).

• Asymptomatic bacteriuria should NOT be treated with antibiotics (unless urological instrumentation is planned) (Grade of Recommendation B).

• Routine urine culture in an asymptomatic patient is not recommended (Grade of Recommendation C).

• Silver-alloy catheters should be considered for short-term catheterised patients to reduce the risk of catheter-associated infection (Grade of Recommendation A) but further economic evaluations are required to determine cost-benefit to institutions.

• Catheter materials designed for long-term use (all-silicone, silicone or hydrogel-coating) should be used where a catheter is expected to be used long-term (i.e. >14days) (Grade of Recommendation B).

• Meatal cleansing with plain soap and water (not with antimicrobial agents) is recommended (Grade of Recommendation A).

• Addition of disinfectants to drainage bags, bladder irrigation and antibiotic prophylaxis are NOT recommended as routine infection-control measure (Grade of Recommendation A).

• If an indwelling catheter is being considered, SPC should be considered alongside UC, following appropriate risk assessment (Grade of Recommendation B).

• UC and SPC insertion should be carried out only by appropriately trained and skilled practitioners using aseptic technique (Grade of Recommendation C).

• UC and SPC catheters and drainage bags should be adequately supported to prevent meatal or cystostomy damage from traction (Grade of Recommendation C).
• In patients with recurrent catheter encrustation and blockage, careful monitoring should be undertaken to identify a characteristic pattern of ‘catheter life’ and instigate pre-emptive catheter changes prior to likely blockage (Grade of Recommendation C).

c) Catheter valves

• A catheter valve can provide an effective means of catheter drainage following appropriate patient assessment (Grade of Recommendation B).

• A combination of a valve during the day and free drainage at night through an open valve connected to a drainage bag could be an appropriate management strategy (Grade of Recommendation D).

5. PRIORITIES FOR RESEARCH

a) General

• Despite much published research (primarily on short-term catheter use in acute care settings), catheter studies have been hampered by methodological weaknesses. There is a need for agreement on key criteria to permit robust comparisons between studies: (i) criteria for symptomatic UTI, (ii) significant bacteriuria in a catheterised patient and its clinical/research usefullness (iii) standardised time frames for following patients in studies of catheter-associated infection eg 48h, 5 days, 7 days, 14 days 21 days etc (iv) documentation of the use of antibiotics prior to and during a study eg preoperatively in surgery or commencement of antibiotics for other conditions during the study, (v) patient follow-up to include post catheter removal.

• A standardised definition of UTI should be adopted as the primary outcome variable. At present the most recent CDC/NHSN surveillance definition of health care-associated UTI is an example [379]. Although criteria for both symptomatic UTI and asymptomatic bacteriuria are defined by the CDC/NHSN, it should be recognised that definitions are applicable to non-catheterised populations and specific to acute care settings and additional definitions apply to catheterized patients [342].

• Moreover, definitions which distinguish between asymptomatic and symptomatic infection in catheterized patients can be prone to coding errors. Inappropriately treated asymptomatic bacteriuria confounds the errors [540] and contributes to a lack in knowledge of effective ways to treat symptomatic CAUTI [541].

• Better adherence to CONSORT guidelines [542] eg double blind randomization with appropriate power calculations, intention to treat analysis with inclusion of study drop-outs

• Need for clinical studies which are adequately powered to detect differences in clinically and economically important endpoints in preference to (or in addition to) more easily measured surrogate endpoints such as bacteriuria.

• Comparative studies of different patient groups eg. males and females, different age groups, patients at home and those in institutional care, including patients’ comfort, satisfaction and quality of life measures.

• Further research on the development of biomaterials that resist microbial adherence and biofilm formation and /or prevent catheter-associated bacteriuria in both long-term and short-term catheter users.

• Further efforts aimed at reduction of short and LTC use, particularly acute care and nursing home populations. Targeted areas to include evaluation and management of skin problems, and alternative measures for people with diabetes mellitus, obesity and communication problems.

b) Intermittent catheters

There is lack of evidence demonstrating the effectiveness of any particular catheter type, technique or strategy. Variations in clinical practice and growth in the use of single-use catheters (particularly coated catheters) with associated increased costs mean that large, well-designed, parallel group RCTs are needed. RCTs are difficult to conduct in this area and must focus on the most important pragmatic questions, for both clinical and cost-effective reasons. Key issues are identified below.

• What evidence is there that coated (single-use) catheters are superior to uncoated (multi-use) catheters and in what ways (e.g. infection, comfort, convenience)? Further studies are needed on the risks / benefits of single use catheterisation (new catheter used at each insertion) versus single patient use (patient cleans, stores and re-uses the same catheter for several days) for patients whose long-term bladder management is by CIC.

• To assist assessment of cost-effectiveness, it is recommended that patient acceptability / satisfaction with procedure and a measure of health state utility are measured for different situations (e.g. at home and when away from home) as a secondary outcome variable.

c) Indwelling catheters

• Epidemiological studies of CAUTI in LTC use in community care settings.

• Better prospective data on long-term sequelae of indwelling catheter use, eg ongoing symptoms, strictures, calculi, bladder cancer.
• Studies comparing catheterisation techniques eg CIC, suprapubic and urethral catheters, on CAUTI and other risks or potential benefits

• Studies to determine whether the frequency of regular re-catheterisation make a difference to CAUTI and other complications

• Studies to ascertain if there are detrimental effects on bladder tissue from persistent asymptomatic bacteriuria in long-term catheterised patients.

• Clinical evaluation of strategies to reduce recurrent catheter encrustation and blockage, including maintaining a dilute urine, increased level of urinary citrate, role of acidic ‘catheter maintenance’ solutions.

• Further development of catheter materials resistant to microbial biofilm formation, new approaches to disruption of the biofilm, or alternatives to catheterisation.

d) Catheter valves

• Clinical investigation of effect of catheter valves on incidence and frequency of catheter encrustation and blockage.

• Cost-effectiveness studies of disposable versus re-useable valves.

• Studies designed to demonstrate if catheter valves promote maintenance of bladder tone and capacity.

• Further examination of combination management strategies such as valve during the day and free drainage overnight.

e) Quality of life

• Identification of appropriate quality of life indicators/criteria and measures for catheterised patients.

• Development of a quality of life measurement instrument including both subjective measures and objective measures, including factors such as: frequency of catheter blockage, catheter-associated infection, hospitalization, unplanned catheter changes, adequacy of equipment, knowledge about self care, interaction with caregivers in catheter management.

• Case study analyses to maximise evidence gained through clinical experience and expert opinion, particularly where opportunities for formal research are likely to be unrealistic.

XIII. PRODUCTS FOR PREVENTING OR CONTAINING FAECAL INCONTINENCE

The broader issues of conservative management of faecal incontinence are dealt with comprehensively in chapter 16 while this chapter deals with products for preventing or managing faecal incontinence. They fall into three main categories:

• Products that aim either to prevent or contain leaked stool.

• Products that seek to prevent or mask the offensive odour that occurs from leaked stool or flatus.

• Products for preventing or treating perianal skin damage associated with faecal incontinence (one of the primary complications of faecal incontinence and an important part of care).

Products dealing with skin health and odour are covered in Sections XIV and XV, respectively, while products for preventing or containing faecal incontinence are covered in this section (apart from absorbent pads, which are included in Section VI).

1. PRODUCTS TO PREVENT OR CONTAIN LEAKED STOOL

There is little knowledge about product management for people suffering with faecal incontinence. Peden-McAlpine et al. (2008) [543] show in their study the experiences of ten women with faecal incontinence. They show how a number of strategies, such as: bathroom rituals, eating habits or fiber supplements belong to the management strategies of the affected, so that they may actively participate in a normal public life. The use of aids is also a major strategy as Bliss et al. (2011) [544] also show. More than 1/3 of those questioned (189 participants) would no longer pursue their activities, when they had no aids at their disposal. Thereby, those who suffer seriously with faecal incontinence resort to absorbent aids, particularly to pantiliners from the range of feminine hygiene products. First and foremost of importance for the study participants was odour control, however, when asked about their satisfaction with various aspects of the product, they ranked odour control as the worst.

Products fall into three groups:

• Plugs to prevent leakage of faeces.

• Devices to channel faeces from the rectum into a storage container.

• Absorbent pads to contain leaked faeces (see Section 6).

An anal plug (Figure XIII-1) consists of a foam, cup-shaped plug that is collapsed and held by a film for insertion; the plug opens when the film comes in contact with the moist rectal mucosa [545] [546]. It is inserted like a suppository using a lubricant gel. It has a string for removal or it can be expelled by raising intra-abdominal pressure and pushing like during normal defaecation. The anal plug has been used mainly by community living people, both adults and children, who are independent in managing faecal incontinence and toileting. Another type
of experimental anal plug consists of a balloon at the end of a catheter connected to a notification device. The catheter is intended to be inserted into the rectum by the user and the inflated balloon acts as the anal plug; there are also vent holes on the distal tip of the catheter (Figure XIII-2). The disposable, double lumen, balloon-cuffed rubber catheter has an infra-red photo-interrupter sensor that is connected to a pager [547]. When faeces enter the rectum, a photosensor signal is sent to the pager which then notifies the person to inflate the balloon. Before a bowel movement, the balloon is deflated and the catheter is withdrawn. To prevent ischemic bowel damage, patients are advised to deflate the balloon for 10-15 min every 3-4 hours.

By contrast, devices for channelling faeces from the rectum to a storage container are used primarily by people who are acutely ill, critically ill, confined to bed, or in long-term care institutions and receive assistance in incontinence management and toileting by caregivers [548] [549] [550] [551] [552]. These devices do not prevent faecal incontinence and are used primarily for preventing or treating skin damage associated with faecal incontinence. They include rectal tubes, catheters, trumpets, and pouches.

Rectal tubes and catheters are inserted into the rectum and drain faeces through openings at their proximal end into a collection bag (Figure XIII-3). Sometimes a balloon slightly distal to the proximal tip is inflated with the aim of preventing leakage of faeces around the catheter and to retard inadvertent expulsion of the tube during defaecation [549]. This arrangement works best with liquid stool which is most likely to be able to flow without blocking the drainage lumen [553] [552]. Bowel management programs often include daily saline irrigations through the rectal catheter to maintain liquid consistency of stool and catheter patency. Differing amounts and frequency of irrigation have been reported (300 to 900 ml). Cutting the tip of the catheter off at an angle to facilitate drainage of stool of thicker consistency has been reported [554]. A rectal tube / catheter is contraindicated in patients who have intestinal mucosal disease, immunosuppression, gastrointestinal bleeding or bleeding tendencies, recent myocardial infarction or prostate surgery [555] [554]. Use of a rectal tube with or without inflating the balloon is controversial because of concerns of perforating the rectum, damaging the anal sphincter or rectal mucosa, stimulating intestinal secretion worsening diarrhoea and thus incontinence [553] [554] [556]. Critically ill patients, who often receive a rectal tube, may be at greater risk for intestinal ischemia and rectal damage because they experience shunting of blood from the gastrointestinal tract during shock or low perfusion states.

A rectal trumpet is a nasopharyngeal airway that is inserted into the rectum and connected to a collection bag at its distal end. The flange end of the trumpet is inserted into the rectum [557] (Figure XIII-4). A possible advantage of the rectal trumpet over a rectal tube is that it is shorter and has less contact with the rectal mucosa, so limiting the area of possible damage. Other limitations are similar to those for the rectal tube / catheter regarding risk of expulsion from forceful valsalva movements and dislodging during linen changes or from tugging on the collection bag [557]. Nasopharyngeal airways that can be used as a rectal trumpet are produced by several manufacturers.

An external anal pouch consists of a pliable wafer, which has an opening at its centre, an adhesive on the body side, and a collection bag on the other. The wafer adheres to the perianal skin (Figure XIII-5).
The bag has a resealable port at its distal end through which faeces can be drained without the need to remove the wafer from the skin. The port can also be connected to a larger, gravity drainage bag. Some pouches have a small folded flap that allows flatus to escape so that it doesn’t inflate and rupture the bag. The pouch avoids the risks of rectal or sphincter damage associated with the rectal tube or trumpet. If used without the additional drainage bag, it can collect leaked stool of any consistency without clogging.

A limitation of the rectal pouch is difficulty in applying it on people who have a small space or severe oedema between the anus and vagina or scrotum. Other reported disadvantages include difficulties in maintaining the seal (especially when the perianal skin is already damaged); break of the seal when repositioning the patient; and skin tears by traumatic removal of the adhesive [557] [551].

An intra-anal stool bag is composed of a latex bag (20cm non-extended, to 26cm extended) that is inserted into the anus and an adhesive attachment (10 cm in diameter) applied perianally [558] (Figure XIII-6). There is a cut-out on the ventral urinary side of the adhesive wafer.

Aspects of patient assessment that are relevant to products to prevent or contain leaked stool include the following: a) physical characteristics (e.g. some anal plugs may be too large to fit smaller sized children), b) dexterity (e.g. some degree is needed to insert or remove an anal plug), c) mobility (e.g. rectal catheters are mainly used for patients who are in bed versus ambulatory), d) nature of incontinence (e.g. bowel catheters will require irrigation when stool consistency is not loose or liquid in order to remain patent; and e) personal priority and lifestyle (e.g., some persons will wear an anal plug on certain occasions such as when swimming, despite discomfort).

2. QUALITY OF DATA

Since the previous review there have been two observational studies in which the anal plug has been evaluated. One study was of adults [559] and
the other of children [560] bringing the total number of published evaluations of anal plugs for controlling faecal incontinence to ten. There was one study of the anal catheter plug (Procon, AnaTech, El Paso, TX). Six reports included children of which two studied children exclusively [561] [562]. The study designs were one randomized clinical trial, four repeated measures (cross-over), one pre-post design, two prospective cohort studies, one cross-sectional survey, one case series, and one case report. One study did not specify the manufacturer of the anal plug studied [560], one study [561] compared plugs of two manufacturers (Coloplast, Denmark and Med.SSE-System, Germany) and all other studies of anal plugs evaluated products from the same manufacturer (Coloplast). There has also been one published evaluation of a rectal trumpet using a case series design [557] and one each of an external anal pouch and an inter-anal stool bag in which no comparison group or pre-post measures were included.

3. RESULTS

a) Anal Plugs

Most evaluations of anal plugs have involved relatively small cohorts of ambulatory subjects. The largest sample had 48 subjects and 26 of 31 persons in the intervention group who wore the anal plug completed the study [563]. The aetiologies of faecal incontinence varied across studies and included spina bifida, imperforate anus, spinal injury, post-surgical incontinence, sphincteric injury, and obstetric trauma. Faecal incontinence was measured by self-report using a daily stool diary in six studies [563] [562] [547] [545] [546] [564]. A questionnaire/survey was used in one descriptive [565] and one repeated measures study [561]. The main reported outcome measures were: the number of episodes of faecal incontinence per number of anal plugs used due to self removal or need for defecation [545]; the number of patients experiencing no faecal incontinence [564] [562] [561] [546] [560] or improved faecal incontinence [546] while using the plug; score on a 10-point visual analogue scale for control of faecal leakage, [559]; the number of patients able to retain 150 ml of viscous fluid while using the plug [564]; and the change in a faecal incontinence severity score [563] [547]. The percentage of participants lost to follow-up ranged from 10% [545] to 80% [564].

The effectiveness of the plug in preventing faecal incontinence in adults ranged from 83% [564] to 38% [562] (Level of Evidence 3). Bond et al [563] conducted a randomized clinical trial of the effectiveness of an anal plug that included 31 adults and children with spina bifida in the treatment group and 17 adults and children in a control group; 84% of the treatment group and 100% of the control group completed 12 months of follow-up. There was no statistical difference in the faecal incontinence severity score between the group wearing an anal plug and the one that did not; however, the study was determined to be underpowered to detect differences. Norton and Kamm [546] compared two anal plugs for two weeks each in random order in a cross-over design. Of the 20 adults (16 female) participating, 10 (50%) were continent, and 9 (45%) withdrew after trying the first plug. Three anal plugs were compared by 10 adults for one week each in a cross-over design in an earlier study by Mortensen and Humphreys [545]. Continence was achieved in 83% of anal plug uses overall. Faecal incontinence occurred in 18%, 19% and 15% of uses when Plug 1, 2 or 3 were worn, respectively. Only one subject withdrew from the study. In a pre-post comparison of an anal catheter plug, seven of 18 adults (39%) with various aetiologies of faecal incontinence and a Cleveland Clinic FI severity score >7 completed a 14-day wear period [547]. The mean (standard deviation (sd)) faecal incontinence score during wear of the anal plug (5.2 (3.0)) was less than half that before its use (12.7 (3.6)). Thirty middle-aged patients (aged 63 (52-70) years (mean (range)) with intractable FI of various aetiologies tested the anal plug for three weeks; the score for control of faecal leakage on a visual analogue scale (1= very poor to 10= extremely good) was 9 (median) after 1 and 3 weeks of using the plug [559]. Christiansen & Roed-Petersen [564] reported that 86% of persons were able to retain 150 ml of viscous fluid while an anal plug was inserted.
In the study of children only, 38 children (ages six to 15 years) after anorectal malformation repair compared two anal plugs (one made of polyurethane and one of polyvinyl alcohol) for three weeks each in a random order in a cross-over design. Approximately two-thirds (61%) completed the study. Twelve children (32%) were completely continent using either plug and five (13%) reported “total failure.” Two or fewer soiling accidents occurred in 74% using the polyurethane plug, and in 65% using the polyvinyl alcohol plug [561].

In a study of 20 children and adults with spina bifida, average age 12 years (range = 4-29 years), the weekly number of episodes of FI soiling decreased from 4 (0-28) to 0 (0-8) (median (range)) after using the anal plug [560]. A survey of adults and children showed that a higher percentage of children tolerated using an anal plug over a longer period of time [565]. Five of eight (63%) adult survey respondents who had faecal incontinence of various aetiologies stopped using an anal plug immediately while three used it periodically for 12 to 20 months. Two of seven child respondents stopped anal plug use immediately while five (71%) used it weekly for an average of 2.5 years.

The most common reported problems associated with wearing an anal plug included discomfort and failure to retain the plug. Despite efficacy, approximately two-thirds of the subjects in two studies [564] [546] said they would not continue to wear the plug due to discomfort. Discomfort occurred in 10% to 12% of the times that one of the three anal plugs were worn in another study [545]. In more recent studies, 23% and 33% of subjects reported discomfort [563] [560] and 23-25% withdrew from studies because of pain [562] or discomfort [560]. More men than women withdrew from one study because of discomfort [559]. Adults who experience discomfort do not seem to adapt over time [559]. After three weeks of wear, adults reported a score on a ten-point visual analogue scale for comfort while inserting the anal plug was 7 (5-9) and while removing it was 8 (7-10) (median (range)). There was no association between comfort of the plug and anal-rectal sensitivity during anal-rectal physiology tests in adults [546]. Children seem to experience less discomfort than adults while wearing the anal plug. [561] [559]. Approximately 20% of children reported that insertion of the polyvinyl alcohol plug was painful while 17% found removal of the polyurethane plug to be painful; one child experienced bleeding on removal of this second plug. Rectal bleeding also occurred in adults but infrequently [545].

Failure to retain the anal plug was reported by 13% of subjects in two studies [563] [562] and was noted by one child in the paediatric study as a reason for withdrawal [561]. The size of any plug tested was too large for six children in one study [561]. Twenty-seven of 30 adult subjects preferred a small size anal plug [559]. Other tolerance problems were fairly uncommon. In one study, adults rated all three anal plugs that were evaluated as relatively easy to insert. Two plugs were difficult to remove in only 5% and 6% of uses, respectively, while the third was difficult to remove in 23% of uses [545]. Other reported problems were feeling a need to defecate [546], inconvenience or difficulty in managing [546] [547], and local irritation [565].

b) Rectal Trumpet

One case series study evaluated the use of a rectal trumpet in 22 acutely or critically ill patients with faecal incontinence and perineal skin damage [557]. For 90% of the subjects, the skin damage had been caused by wearing a rectal pouch immediately prior to the study. Subjects used the trumpet for periods varying between 36 hours and 16 days (mean 6.5 days; sd 4.4 days). The reasons for any discontinuation of use were reported. Outcome was determined using a daily questionnaire completed by patients’ nurses and the health of the perianal skin was noted by subjective assessment. No standardised definitions or criteria for restoration of skin integrity or healing of skin damage were reported. Two subjects were lost to follow up. Faeces were successfully diverted to and contained by the collection bag in all patients. Recovery from skin damage was reported in 7 (39%) patients and partial healing of skin in the remaining 11 (61%). Discomfort on insertion was noted for 41% of subjects (Level of Evidence 3).

c) Rectal Catheter Systems

Closed rectal catheter and collection bag systems specifically designed for extended use and diversion of faeces are commercially available, primarily for acutely-ill or bed-ridden patients (Flexi-Seal™ and Flexi-Seal™ Signal™ Faecal Management System, Convatec A Bristol Myers Squibb Company; Princeton, NJ; Actifo Indwelling Bowel Catheter (formerly Zassi® Bowel Management System); Hollister, Inc., Libertyville, IL; Dignicare® and Dignishield™ Stool Management Systems, Bard Medical). The catheters of these systems typically contain a retention cuff that collapses to assist with insertion (US FDA approved for up to 29 days) and a port for irrigation. In one system (Acti-flo) there is also a collapsible zone below the cuff that resides in the anus to allow normal anal sphincter function during use and a second port for sampling intestinal fluid. A third catheter has an inner balloon that can be inflated to serve as an anal plug to promote retention of an enema, for instance (Kim, US Patent 5 569 216, apparently not currently commercially available).

Six studies evaluated use of a rectal catheter system. Three studies used one type of catheter while the other three studies used three different types of systems. One study was of children [566]. The designs included a prospective single cohort in four studies [548] [567] [549] [566], a pre-post descriptive design [568], and a retrospective case-matched
pre-post design [569]. The largest sample size was 106 in the retrospective chart review whereas sample sizes in the prospective studies were relatively small, ranging from 20 to 42 subjects. In the studies of adults, subjects were burn patients in two studies [567] [569] and acutely or critically-ill patients in three studies [548] [568] [549]. In three studies, irrigation of the catheter with saline, a combination of lactulose and saline irrigation or use of an enema was used to keep the stool liquid and the rectal catheter patent [567] [569] [549].

In only two studies was the effectiveness of the rectal catheter system in reducing faecal incontinence reported (Level of Evidence 3). In the one paediatric study, 31 children (11 females) participated. Eight families refused to stop using the rectal catheter to complete an incontinence diary without use of a catheter. Two children had balloon extrusions and three were noncompliant resulting in their study withdrawal. The mean number of daily faecal incontinence episodes as reported on a daily diary decreased from 3 to 1.5 in males and from 1.6 to 1.1 in females (p<0.05 for both) [566]. Three children experienced no improvement of faecal incontinence. In the one adult study, 39 of 42 subjects (62% female) with diarrhoea in intensive care units in seven hospitals completed the study. There was up to 29 days of follow-up. Varying degrees and types of leakage around the rectal catheter were reported in 71% of 198 assessments; 35% of these leakages extended to pads on the bed or beyond [548]. Seven (17%) of subjects had difficulty retaining the rectal catheter. Section 6.11 discusses use of a small gauze dressing for absorbing small amounts of stool leakage and a moisture barrier as skin protective strategies that might also help prevent damage from stool leakage around a rectal catheter. Skin damage from the tape holding the catheter in place and rectal bleeding are other reported but uncommon complications [567] [548].

The effect of a rectal catheter on various outcomes associated with stool leakage has also been studied. Two studies reported costs savings in terms of reducing laundering of soiled bed linens. One study reported that the number of bed linen changes in burn patients with diarrhoea decreased eight-fold and dressing changes in hospitalized or burn patients decreased in half after a bowel system was introduced [567]. A multi-site study of 146 bedridden patients in the U.S. showed that one catheter (Holistier, Inc) reduced the rate of bed linen changes (1.2 changes per day) more than another (1.7 per day) (Convatec). Estimates of cost savings based on staff time and laundry costs was almost $14 USD per patient per day [570].

Other outcome measures of rectal catheter use included urinary tract infections, incidence of skin / soft tissue damage or infections, prevalence of pressure ulcers, and number of linen changes (Level of Evidence 3/4). In a retrospective review of medical records, approximately twice as many burn patients had skin / soft tissue or urinary tract infections before a bowel catheter system was introduced than after (p<0.01) [569]. A prospective study of acutely and critically-ill patients showed that 41% who had normal skin in the perineum or buttocks at baseline maintained normal skin during use of the bowel catheter, 44% with some degree of skin damage improved, and 8% had worsened skin condition [548]. The percentage of intensive care unit patients with a stage II or greater pressure ulcer was observed to be less at nine months after use of a bowel catheter was introduced. The total number of patients observed was not reported. The length of time during which the prevalence of pressure ulcers was determined prior to catheter use was also not reported [568].

The condition of the rectal mucosa was observed endoscopically in 40 patients total across three studies; the evaluations were not blinded or independent and did not use a rating scale [548] [567] [549]. All endoscopic observations were reported as being normal after rectal catheter use. Few complications associated with use of the rectal catheter system were reported in one study. Leakage around the rectal catheter seemed to be the most frequent problem. Catheter expulsion occurred in a small number of patients and skin damage from trying to secure the tube occurred only in one patient. Altered rectal sphincter function occurred using one of the catheters [549]. As the catheters are used more widely in clinical practice, there are more case reports of complications including rectal or lower gastrointestinal bleeding and need for blood replacement, mucosal pressure necrosis, fistula, and autonomic dysreflexia [571] [572] [573] MAUDE http://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfmaude/search.cfm. (Level of Evidence 3).

d) Anal Pouch

One case series study evaluated the use of an external anal pouch (Technoline, Concordia, Moderna, Italy) in 120 nursing home or hospitalized patients (65 men, 55 women, ages 45-96 years) [574]. The nursing home residents (n = 92) were bedridden and had faecal and urinary incontinence or were treated for constipation for rectal enemas that drained into the pouch. Ten had a pressure ulcer. They used the pouch for four weeks or more. Acute care patients (n = 28, of which 10 were in the intensive care unit) had diarrhoea and were temporarily bedridden. Forty-five patients who had surgery of the perineal area received a pouch to collect post-surgical drainage for up to three days. In the nursing home residents free of pressure ulcers, no new ulcers developed. In those with a pressure ulcer, healing occurred in five residents, ulcer diameter was reduced by 50% in three residents, and there was less than 50% reduction in two residents. Of the nursing home and acute
An internal anal stool bag (Terumo Corp., Tokyo, Japan) was applied to five bedridden patients (3 female, 2 male) aged 68-90 years [558]. Persons were administered a bisacodyl suppository prior to insertion of the stool bag into the anus to control excretion of faeces. The bag was successful in collecting stool 50% of the time (Level of Evidence 3). The bag was removed after each stool was collected.

Bliss and Savik (2008) [88] carried out a study, to examine the use of a surgical dressing to absorb a small leak of feces. These anorectal dressings can be placed between the buttocks. Of 28 people who had faecal incontinence, 27 had used the dressing and 23 of them wanted to continue to use it. 79% reported no skin complications, and 80% of the participants rated their confidence in its effectiveness as very good to good. Use of the dressing lessened anxiety about faecal soiling in 81% and was thought to improve quality of life in 76%. The authors stated that new types of absorbent products will become available.

4. SUMMARY

- An anal plug can successfully prevent faecal incontinence but it is associated with high levels of discomfort, more so in adults than children (Level of Evidence 3).
- A rectal catheter system diverts faeces to a collection bag and promotes healing of damaged perineal skin but requires liquid stool consistency to remain patent. Some catheter systems enable irrigation of the rectum to maintain liquid stool consistency.
- Non-blinded and non-independent endoscopic observations suggest the rectal catheter does not cause rectal mucosal damage during the recommended length of use (≤ 29 d in the US). As rectal catheter usage increases in clinical practice, case reports of complications have become evident; among the common ones reported are perianal skin damage, rectal bleeding, and mucosal pressure necrosis. (Level of Evidence 3).
- A rectal trumpet can successfully channel faeces to a collection bag and there is some evidence that it can thereby enable damaged perianal skin to recover but it has been associated with discomfort and its safety has not been determined (Level of Evidence 3).
- An external anal pouch and an internal anal bag can be used to collect stool (Level of Evidence 3) but the adhesive wafers used to adhere them can cause skin damage upon removal. The internal anal bag has been primarily used when a bowel movement is induced using a suppository.

5. RECOMMENDATIONS

- Anal plugs may be tried but many patients are likely to use them on a limited basis or reject them due to discomfort (Grade of Recommendation C).
- The use of a rectal trumpet (i.e. a nasopharyngeal tube inserted into the rectum) in patients with loose / liquid stool consistency offers an alternative to the rectal pouch when pouch adherence is a problem and may preserve perianal skin integrity or facilitate healing (Grade of Recommendation C). The safety of the rectal trumpet has not been determined, but it suggests a lower risk due to its shorter length than a standard, longer rectal tube (Grade of Recommendation C).
- Use of a standard rectal tube with and without an inflatable balloon for faecal diversion is indicated primarily for non-ambulatory patients with liquid stools (Grade of Recommendation C).
- Use of an anal pouch attached to a drainage catheter to divert liquid stool is recommended, but there is a risk of skin damage. For this reason it is not recommended in cases where skin is already damaged or the need for faecal diversion is less acute (e.g. where stool is more formed) (Grade of Recommendation C).

6. PRIORITIES FOR RESEARCH

- Development of an anal plug that is more comfortable and tolerable.
- More rigorous evaluation of anal plugs using larger subject cohorts and more objective outcome measures over longer periods of use.
- More rigorous evaluation of rectal tubes / catheters and trumpets using larger subject cohorts and more objective outcome measures (e.g. for assessing health of the rectal mucosa) over longer periods of use.
- Development and evaluation of an external anal pouch that is easy to apply and remove, adheres to skin better and, perhaps, even promotes healing of damaged skin to which it would be applied. Further evaluation of an internal stool bag with similar adherent properties (as recommended for the external anal pouch) is needed.

XIV. SKIN HEALTH AND CONTINENCE PRODUCTS

1. BACKGROUND

The skin of an incontinent individual will be regularly exposed to contact with urine and / or fea-
ces and damage to the skin is the main physical health consequence of urinary and faecal incontinence. The majority of current knowledge about the effects of urine and faeces on skin has been obtained from studies with pads or pad materials on animals, healthy infants, and on body areas such as the forearm or back of adults. Where clinical trials have been conducted, they have usually been on infants and rarely on adults using pads. Skin irritation within the pad occlusion area is usually termed diaper dermatitis in infants. In adults the term perineal dermatitis (PD) has commonly been used, but more recently it has been proposed that incontinence-associated dermatitis (IAD) is a better term because affected skin areas are not confined to the perineum [575] [576]. A consensus panel in 2005 defined IAD as ‘erythema and oedema of the surface of the skin, sometimes accompanied by bullae with serous exudate, erosion, or secondary cutaneous infection [577] and this term and definition has been widely used since then [578] [575] [579]. More recently IAD has been classed as a sub-category of ‘moisture-associated skin damage’ (MASD) which includes intertriginous dermatitis and peristomal and periwound moisture-associated dermatitis [579] [580].

Literature reviews and consensus papers

There has been considerable interest in IAD over the last few years, particularly with regard to its definition and aetiology and there have been three review/consensus papers on the subject [578] [575] [579] and one focusing on the prevention and treatment of IAD [581].

a) The role of urine and faeces in skin irritation

Prolonged exposure to water alone has been shown to cause hydration dermatitis [582] [583] and prolonged occlusion of the skin (as within a continence product) has been demonstrated to reduce skin barrier function [584] and significantly raise microbial counts and pH [585] [586]. Repeated wetting and drying makes the skin more vulnerable to substances that are usually innocuous, e.g., bile salts [587] [588]. A product that simply maintains wet and occluded skin (even without the additional constituents of urine and faeces) is therefore likely to cause skin irritation and increase skin permeability to other irritants.

Using a hairless mouse model Buckingham and Berg [589] examined the role of faeces in the aetiology of diaper dermatitis. They identified proteases and lipases as the major irritants and noted that these faecal enzymes not only irritated the skin directly but also increased the susceptibility of the skin to other irritants such as bile salts. The irritant effect of faeces was virtually eliminated by heating, which destroys enzymes, and was restored by the replacement of specific enzymes [e.g. lipase and protease]. Skin damage appeared dependent on the concentration and length of exposure to enzymes in faeces [590].

A similar mouse model was used by the same researchers to examine the role of urine in the aetiology of diaper dermatitis [588]. They found that the irritant potential of urine by itself was minimal over short periods (48 hours) but after continuous exposure (10 days), skin damage became apparent. The researchers also measured skin permeability and found that continuous exposure to urine greatly increased skin permeability (more than 15 fold) compared to occluded skin or skin exposed only to water.

However, the combination of urine and faeces caused significantly higher levels of irritation than urine or faeces alone. The authors concluded that the presence of faecal urease results in the breakdown of urinary urea causing an increase in pH, which increases the activities of faecal proteases and lipases leading to skin irritation. The role of microorganisms - which comprise approximately 50% of the solid component of faeces - in skin damage is unresolved. Microorganisms on the skin of infants with and without diaper dermatitis were similar [591]. Zimmerer et al. [592] sampled the microflora of the skin after pre-loading with pre-wetted patches containing urine and found that the microbial counts were significantly higher for wet patches relative to the dry patch controls. It was nearly impossible to establish infection with the opportunistic organism, Candida albicans, on normal skin without complete occlusion of the site [593]. Therefore, it is thought that bacterial or fungal infection is secondary to alterations in the skin barrier that allow penetration of the microorganisms [594].

Zimmerer et al. [592] examined the role of skin wetness in the development of diaper dermatitis by using the volar forearms of adult volunteers. They aimed to determine the effects of wet and dry diaper materials on skin health with respect to friction, abrasion damage, permeability and microbial growth. Pre-wetted patches of baby diapers were placed on the volar forearms of adults for two hours and then the skin was subjected to friction and abrasion. The coefficient of friction for the ‘wet’ skin was significantly higher than for ‘dry’ skin although increased fluid loading of wet patches did not further increase skin friction. Similarly, skin hydrated with a wet patch showed a significant increase in skin abrasion damage relative to a dry patch. Again, variations in the fluid loading of the patch did not produce significant changes in abrasion damage.

Although the volar forearm is most commonly used for skin experimentation, it has not been shown to be a valid model for the skin exposed to an incontinence pad, i.e. buttocks and groins. Schnetz and colleagues [595] demonstrated that trans-epidermal water loss (TEWL) measurements (used to measure both skin barrier function and excess water in the skin) from the volar forearm did not correlate with those taken from the face, although the left and
right side of the face showed good correlation. The researchers concluded that TEWL measurements for the study of facial cosmetics should be taken from the face rather than the forearm. Similarly, studies using the volar forearm may not be valid for the buttocks and groin. Skin in the perianal area was shown to be more sensitive to faecal irritation than that on the inner arm [596].

Recently Fader and colleagues (2010, 2011) [597] [598] reviewed the literature on measurement of TEWL for assessment of overhydrated skin and found that there was a lack of standardization in all components of the method including the analysis and interpretation of findings [597] and they describe the development and testing of a more valid and robust method and compare measurements made on younger and older women and on volar forearm and hip skin. The authors conclude that age did not significantly affect measurements but those made on the hip were consistently higher and more variable than those made on the forearm. It is recommended that the forearm is used for future work.

Berg [588] analysed the aetiological factors contributing to infant diaper dermatitis and developed a model (Figure XIV-1) to show its development and resolution. However, the applicability of this model to adults with incontinence has not been tested, and other factors such as low mobility and prolonged pressure - which are common in frail, older adults - are not accounted for in this model. In addition, this model assumes the presence of urinary and faecal incontinence, which is much less common in adult populations than urinary incontinence alone.

b) Prevalence of incontinence-associated dermatitis / perineal dermatitis

Incontinence-associated dermatitis (IAD) has been defined most recently as “an inflammation of the skin occurring with or without erosian or secondary cutaneous infection”. Perineal dermatitis (PD) is an inflammation of the skin characterized by redness, tissue breakdown or denudement, vesiculation, oozing, crustling, soreness, itching, and in its more severe form, pain and fungal patches [599] [600] [575] within the pad area. In the largest study of assessment records of more than 59,000 residents in 510 nursing homes located in 31 US states, Bliss et al. [601] reported a prevalence of perineal dermatitis of nearly 6%. In studies with smaller sample sizes and other populations, perineal dermatitis (Table XIV-1) has been shown to affect about a quarter to a half of patients.

Recently there has been further clinical evidence supporting the role of faeces in the development of IAD. Bliss et al. (2011) [544] studied the development of IAD in 45 critically ill adults in three critical care units. Most (76%) were male and all were free of IAD at the start of the study. IAD developed in 36% of patients and the median time to onset was 4 days (range 1-6). Severe IAD (denudement) occurred in 9% of the observed time. Frequent incontinence of loose or liquid stools and diminished cognitive awareness were significant independent risk factors for development of IAD sooner.

Shigeta and colleagues (2011) [610] studied the skin of 100 older Japanese patients in a nursing

Figure XIV-1: Berg's model of diaper dermatitis (1987).
home who had faecal and/or urinary incontinence and wore absorbent products. Multivariate logistic regression analysis showed that the presence of diarrhoea was an independent risk factor.

Bliss et al. [611] prospectively investigated the development of IAD using assessment data of 1,850 elders who were free of IAD at admission to a nursing home. The preliminary report showed that at three months after admission, faecal incontinence alone and double incontinence were significant predictors of IAD, but urinary incontinence alone was not a significant risk. The prevalence of IAD appears to be influenced not only by the type of patient (nursing home versus hospitalized) but also by the type of incontinence and whether or not a skin damage prevention program is followed.

Few studies report the severity of PD. In a prospective surveillance study of 981 nursing home residents with incontinence of urine and/or stool over six weeks, the most common anatomical locations of PD were the buttocks (73% of those with PD) and perianal area (70%) followed by the genitalia, scrotum and groin (36%) and thighs (24%) with the smallest percentage near the sacrum (9%). Approximately one-third of residents had PD in more than one location. Mild PD was by far the most common (69% of residents); severe PD affected only 8% of residents [616].

c) Pressure ulcers and incontinence

The role of urinary and faecal incontinence in the development of pressure ulcers is uncertain. Studies aiming to identify risk factors for the development of pressure ulcers have generally found that the presence of both urinary and faecal incontinence was a risk [617] [618] [619] [620], but some studies have only found faecal rather than urinary incontinence to be a risk factor [621] [622]. Pressure ulcer risk assessment scales all have a sub-scale of incontinence or moisture-level, and the main mechanism for the development of pressure ulcers has been thought to be the increased friction and increased vulnerability to abrasion of wet skin.

Some researchers have used pressure ulcer classification systems, such as those published by the National Pressure Ulcer Advisory Panel (NPUAP) or the European Pressure Ulcer Advisory Panel (EPUAP), to measure skin health. The validity and reliability of most of these tools have not been established. Doughty et al [623] and Bethell [624] described numerous other limitations of pressure ulcer staging systems and despite recent revisions of the NPUAP and EPUAP staging systems, many of the shortcomings still apply. The reliability of the EPUAP staging score (which is a modified version of the NPUAP score) has been tested recently in three studies using photographs of pressure ulcers. These photographs included ‘moisture lesions’ (defined as lesions resulting from prolonged exposure of the skin to excessive fluid because of urinary or faecal incontinence, profuse sweating or wound exudate). A high degree of reliability for classification of moisture lesions was found amongst 44 pressure ulcer experts (Kappa = 0.80) [625]. However, inter-rater reliability was found to be much worse (Kappa = 0.37) when photographs were viewed by 473 non-expert nurses [626] and subsequently in
a European study of 1,452 non-expert nurses from five European countries (Kappa = 0.36). The authors concluded that better descriptors needed to be incorporated into the EPUAP system and more education was needed.

An education tool aimed at improving skills in pressure ulcer classification (the PUCLAS education tool) was developed by a workgroup of the EPUAP and was tested by Beeckman and colleagues [627] in a randomised controlled trial. 1217 nurses from Belgium, the Netherlands, UK and Portugal participated. At baseline 45% of skin photographs were classified correctly and results were significantly improved in the intervention group who received the PUCLAS education tool (63% classified correctly) compared to the control group (53% classified correctly). Furthermore the proportion of correct assessments for IAD was 71% in the intervention group and 36% in the control group. The authors conclude that the PUCLAS tool improved pressure ulcer classification.

However there is still debate regarding the validity of separately classifying IAD from pressure ulcers particularly when skin damage occurs over bony prominences. To investigate the validity of classifying moisture lesions, Houwing et al. [628] examined the histology of 14 biopsy samples of damaged patient skin. Skin damage was classified using the EPUAP system: 12 were moisture lesions, one was a grade 4 pressure ulcer (extensive tissue destruction / necrosis) and one was a combination of a moisture lesion and a grade 1 pressure lesion (non-blanchable erythema). Both pressure ulcers had a histological pattern suggesting ischemic pathology; the histology of the moisture lesions, however, was either of an ischemic or irritation pattern. Because of the overlap in histology patterns of some of the moisture lesions and the pressure ulcers, the authors concluded that there is no justification for classifying moisture lesions separately from pressure ulcer lesions. This finding requires further study as there are several limitations of their study. First, the true aetiology of the skin damage and the veracity of the EPUAP classification were not determined; some moisture lesions seem to be partially over a bony prominence so that a mix of pressure and moisture damage cannot be ruled out, which might explain the mixed histology patterns. Secondly, the moisture lesions and the pressure ulcer were both described as having blanchable erythema.

Identification of moisture lesions as distinct from pressure ulcers is sought as a way to solve the tension between inadequate prevention / treatment of a pressure ulcer and inappropriate use of costly prevention relieving devices / measures. It is also of importance in determining care quality. Pressure ulcers are deemed as quality indicators in many countries and are considered to be preventable. Facilities may not be allowed to charge for the care and treatment of patients who develop pressure ulcers and may also be fined. The ‘correct’ classification of IAD and pressure ulcers therefore has financial and reputational implications.

Fader et al. [629], examined the effects of absorbent continence pads on mattress interface pressures using an articulated model or “phantom” as the subject and found that the presence of a pad significantly and substantially (around 20%) increased the peak pressures recorded between the buttocks and the pad / mattress. Peak pressures were frequently found at the locations of pad creases and it was considered that pad folding and compression may contribute to raised interface pressures. It is therefore possible that continence product use contributes to the formation of pressure ulcers by raising interface pressures.

Black et al. (2011) [579] have categorized IAD as distinct from pressure ulcers as shown in Table XIV.2

2. CLINICAL STUDIES OF THE IMPACT OF PRODUCTS AND PRODUCT MATERIALS ON SKIN HEALTH

In the 1980s, product manufacturers introduced diapers with super-absorbent polymers (SAP), which were designed to reduce skin wetness, buffer pH and reduce urine / faecal contact in order to help prevent diaper dermatitis. This led to clinical and laboratory studies to evaluate the efficacy of diapers with different materials, in particular, super-absorbent polymers (SAP) compared to those without, and compared to conventional washable diapers.

a) Quality of data

There are three types of studies testing the effects of different products or product materials on skin health: (i) clinical trials of normal infants wearing diapers; (ii) laboratory wet patch testing of adult forearms with diaper or continence pad patches; and (iii) clinical trials of adult absorbent pads containing different materials. The infant diaper studies were randomised controlled trials with large samples and blind measurement of outcomes. It should be noted that these studies were carried out by industry-employed staff. The infant and laboratory studies used a probe comprising two hygrosensors and thermistors (an evaporimeter) placed on the ‘wet’ skin to measure trans-epidermal water loss (TEWL), an indicator of skin hydration level. However, there is uncertainty about the optimum procedures for measuring TEWL, and different procedures and outcomes were used in the studies, making it difficult to compare results. Probably the most important threat to the validity of these studies is the selection of products or materials used in the study. None of the studies adequately described the products used - in particular, regarding their total absorbency. Thus it is possible that an alternative explanation for the fairly consistent findings that disposable pads with
SAP perform better on skin outcome measures may be that those with SAP simply had greater absorbency than those without.

b) Results

1. Clinical studies of infant diapers

Campbell and colleagues [630] conducted four clinical studies involving 1,614 infants randomly assigned to either disposable diapers with SAP, disposable diapers without SAP or washable cloth diapers. Disposable diapers with SAP were associated with significantly reduced skin wetness as measured by TEWL, lower pH and lower ratings of diaper dermatitis when compared to the two other diaper products (Level of Evidence 2).

Lane et al., [631] randomised disposable diapers without SAP and disposable diapers with SAP to 149 newborn infants and assessed their skin condition seven times over a 14 week period. Skin rash ratings were significantly lower for infants wearing diapers with SAP at only one time period (14 weeks) (Level of Evidence 2).

Davis and colleagues [632] assessed 150 infants over 15 weeks in a cross-over study involving four different disposable diaper types, two with different levels of SAP and two with different levels of fluff pulp only. Both diapers containing SAP were associated with significantly less skin wetness and significantly lower pH. Clinical skin ratings showed significantly lower ratings for the SAP-containing pads compared to the lower weight fluff pulp pad, but not compared to the higher weight fluff pad (Level of Evidence 2).

2. Laboratory studies of diaper patches

Wilson and Dallas [633] used the adult normal forearm skin model to compare patches taken from 16 different infant diapers. They found that disposable diapers containing SAP left the skin significantly drier than washable diapers and disposable diapers without SAP (p<0.01). Disposable diapers without SAP did not differ significantly from reusable diapers and there were no significant differences between products within any of the three groupings (Level of Evidence 2).

However, in a subsequent study involving 20 disposable and washable adult incontinence pads incorporating a similar range of materials to the baby diaper study Dallas and Wilson [634] found significant differences between products within each of the three product groupings but not between groupings (Level of Evidence 2). Grove et al. [635] used a similar approach to compare three infant diapers and found a significant difference in skin wetness between two that contained similar quantities of SAP (p<0.001). The one in which the SAP was in a layer near the water-proof backing kept the skin dryer than that in which it was near the coverstock. The third diaper – which had a microporous (breathable) backing kept the skin significantly dryer than each of the other two (p<0.001) (Level of Evidence 2).

3. Clinical studies of adult absorbent products

There has been one clinical study of adult incontinent patients comparing underpads with and without SAP, diapers with and without SAP and washable cloth underpads and which used skin condition as the primary outcome variable [22]. This study included 166 incontinent patients (urine, faeces or both) from three acute care facilities who were divided into the five groups. It is unclear whether randomisation to group occurred by patient or by facility. One facility used the washable cloth underpads only for their patients. Other patients tested either diapers or underpads and crossed-over from without SAP to with SAP products after six weeks. Skin measurements were made for colour, integrity and symptoms using rating scales. Both blind and non-blind measurements were made.

Findings were rather complex and difficult to interpret and no corrections for multiple comparisons

Table XIV-2: Differentiation of IAD Versus Stage I and II Pressure Ulcers
appear to have been made. Overall there were no differences in skin measurements between the diaper and underpad groups but - for some measurement sub-groups - differences were found with mean colour scores being significantly higher (worse) in the without-SAP diaper group and the washable cloth underpad group. Blinded ‘worst’ skin colour scores were highest for without-SAP diapers and washable cloth underpads and lowest for with-SAP products. Overall the findings supported the favourable effects of SAP on skin health but, as with the infant diaper studies, total absorbency of the products was not reported (Level of Evidence 2).

Hu et al. [66] randomised an unnamed range of disposable insert pads with mesh pants to 34 nursing home residents who were matched (based on incontinence severity) with 34 residents who received the usual reusable cloth diaper product. Skin condition was rated at baseline and after the five week intervention period by a blinded nurse researcher. Skin condition was reported to be significantly better in the disposable pad group (Level of Evidence 2).

More recently Beguin and colleagues (2010) [636] tested a modified diaper design (incorporating a top layer of specialised cellulose – beneath the top sheet – to maintain skin pH, and air-permeable side panels to minimise skin occlusion) in a small study of 12 patients using a pre-post test design. Skin pH was significantly lower when patients used the modified diaper and 8 out of 12 patients had resolution of pre-existing skin lesions. A larger more robust trial would be needed to establish any important clinical benefit.

3. CLINICAL STUDIES OF SKIN-CARE PRODUCTS AND NURSING PRACTICES TO MAINTAIN OR IMPROVE SKIN HEALTH

The skin of incontinent people requires frequent cleansing to remove urine and / or faeces. Soap and water is in common use [637] but it is known that repeated exposure to anionic surfactants (common in soaps) results in skin irritation [638] [639]. In addition, the action of washing is also considered likely to contribute to mechanical damage of the stratum corneum.

Cleansing of skin soiled with urine and / or faeces should occur immediately if possible or promptly after episodes of incontinence [640] [641] [642] [643] [644] [579] [575]. In addition, an individualised schedule for cleansing the perineum according to patients’ needs or preferences [645] [646] [575] [579] or at routine intervals, such as daily or at bath time [647] [576] [640] [642] [648] has been recommended (Level of Evidence 3).

The practice of cleansing or wiping the perineum front to back is recommended as standard practice in the literature - particularly for women [649] [650] [651] [652] [653]; this recommendation is based on the physiological rationale of lowering presumed risk of contaminating the urethra with faecal bacteria and subsequent urinary tract infection [653]. One retrospective study of pregnant women found a significantly higher association of urinary tract infections in women who self-reported they wiped back to front (25.8%) than among those who wiped front to back (18.5%) [654] (Level of Evidence 2).

To minimize friction damage of the skin during the perineal cleansing process, gentle cleansing and patting dry the skin [655] [656] rather than rubbing or using a soft cloth is recommended by clinical experts [616] [657] [576] [643] [644] [658] [659] [659] (Level of evidence 4).

However there is some evidence that drying the skin by patting may be less effective than gentle towel drying or drying with a hair dryer [660]. Damp skin is more vulnerable to friction damage and special care may therefore be needed to ensure that the skin is dry. For already damage skin, there are clinical anecdotes of using a small hand-held hair-dryer set on a low and cool setting rather than drying with a cloth. Further research into cleaning and drying techniques and products is encouraged.

Alternative cleansers are available which have been formulated with the intention of overcoming some of the limitations of soap and water. Although over-hydration of skin is detrimental, an excessively dry stratum corneum develops cracks and fissures and can be as ineffective a barrier as an over hydrated one [583]. Soap has a high pH (9.5-11) [661] and under laboratory conditions skin that has been exposed to high pH solutions has been found to have increased stratum corneum swelling and other signs of skin damage. However, there is a lack of controlled clinical trials comparing standard (high pH) soap with pH neutral soap or cleansers.

Many modern cleansers are designed to be used without water [i.e. ‘no-rinse’] and are designed to provide a less aggressive skin environment than soap (e.g. lower pH) but this may compromise their effectiveness in cleaning the skin of urine and faeces. This question has been addressed by Ronner et al, (2010) [662] who compared soap and water and a no-rinse cleanser in terms of their ability to remove escherichia coli and staphylococcus aureus. This laboratory study employed volunteer volar forearms and found low level and comparable levels of residual bacteria on the skin.

The use of topical products aiming to prevent or treat skin irritation is common but there is a lack of standardisation in definitions and descriptions of products, which makes comparisons difficult. Products such as ‘moisturisers’ or ‘barriers’ may be applied to the skin after cleansing, and some cleansers also incorporate moisturisers. The aim of moisturisers (also known as emollients) is to hydrate the skin by reducing trans-epidermal water loss through occlusion (e.g. petrolatum), by drawing
water into the stratum corneum by the addition of a humectant (a hygroscopic substance, e.g. glycerol) or by adding water in the applied water-miscible product. These modes of action are often combined in the same product, but there are exceptions - such as petrolatum - which only work by occlusion [663]. Some products are designed specifically to prevent penetration of water into the stratum corneum (‘barrier’ products) such as liquid skin sealants containing polymers, and may allow trans-epidermal water loss whilst preventing external water penetration. Simple occlusive products such as petrolatum may also act as barrier products to water but also occlude trans-epidermal water loss.

The application of skin barriers is recommended on areas that would come in contact with leaked urine and / or faeces. In general these areas include the buttocks and perianal area, groin, and inner thighs. Community-living persons report leaking small amounts of faeces that remain between the buttocks. Clinically, nursing staff have observed seepage of faeces around a rectal catheter in hospitalized patients. In both groups, perianal skin protection is important, and skin barriers are recommended (Level of evidence 4).

Topical creams are commonly used to prevent and treat dermatitis but controlled experiments to assess efficacy on human and animal skin have produced equivocal results. Ghadially et al. [663] showed that barrier recovery (measured by TEWL) on experimentally irritated skin was accelerated by the application of petrolatum and De Paepe K et al. [664] showed similar results using a different moisturising cream. Hannuksela and Kinnunen [665] showed that treatment with moisturisers prevented the development of irritation in an experiment involving frequent skin washing with liquid detergent. However, Gabard [666] was unable to demonstrate significant acceleration of barrier recovery to chronically irritated skin following application of different moisturisers using a chronic irritation model and also found that some creams enhanced irritation.

The efficacy of barrier products in preventing water penetration of the skin has been tested in laboratory settings. Vinson and Proch [667] applied wet patches with a water-soluble marker to skin coated with three different barrier products and measured dye extracted from the skin by absorbance spectrophotometry. One multiple barrier product performed significantly better than a petrolatum-based and an allantoin-based protectant. Waring and Hoggarth [668] used a Chromameter to measure skin colour change after staining skin with a water-soluble dye, covering it with a barrier product and washing the skin. Petrolatum products were found to be more effective barriers than dimethicone-based products. In a later study, Hoggarth et al. [669] investigated the barrier function and skin hydration properties of six skin protectants when applied to the volar forearms of 18 healthy volunteers. The researchers found that each had different performance properties with the water-in-oil products containing petrolatum performing better than the oil-in-water products containing dimethicone for protection against irritation or maceration. However the dimethicone products had higher hydration properties compared to the petrolatum products. Overall the water-in-oil petrolatum-based product was the only product to be efficacious for all performance variables. A limitation of some petrolatum-based moisture barriers compared to a non-alcohol barrier film for individuals wearing absorbent pads or briefs is that the petrolatum-based products have been shown to transfer from the skin onto the absorbent product and reduce fluid update by 54% to 90%. [605]. However this has not been tested in clinical trials and the effects of different topical products on the leakage performance of absorbent pads is unknown.

Other practices that may affect skin health include frequency of pad changing. Increasing pad changing may reduce skin wetness by application of a dry pad and may therefore benefit skin health. Increased pad changing is commonly recommended to prevent or treat dermatitis particularly in infants [670] Level of Evidence 4.

a) Quality of data

Several studies of skin cleansing and / or moisturising / barrier products to prevent perineal dermatitis have been limited by being uncontrolled [614] [671] [604] [672] and of small size and lacking adequate power calculations [673] [674] [602], or not including any clinical outcome measures [673]. Measurement of dermatitis may also have been compromised by reactive hyperaemia on skin areas subject to pressure. Only four randomised controlled trials of a skin cleansing regimes to prevent perineal dermatitis could be found, and two RCTs of products to treat dermatitis. Two trials focused on the costs of barrier products use. In addition there was one randomised crossover trial of pad changing frequency.

b) Results

1. Skin cleansing / moisturising products to prevent dermatitis

Byers et al. [673] compared four different cleansing / moisturising regimes including soap and water using a multiple cross-over design. Despite having a very small sample size (n = 12 elderly women) they found statistically significant differences in TEWL, pH and erythema between some of the regimes, and soap and water was found to be the least effective product for skin health. No clinical outcomes were measured and differences in outcomes were small (Level of Evidence 2).

Beeckman et al, 2011 [609] randomised 141 nursing home residents to receive standard cleansing with pH neutral soap and water with the use of a
3-in-1 perineal care washcloth impregnated with a 3% dimethicone skin protectant over a period of 120 days. Skin health was measured using the IAD 3% dimethicone skin protectant over a period of 3-in-1 perineal care washcloth impregnated with a four skin damage prevention regimens. In three of homes to compare the cost and effectiveness of Bliss et al. [616] randomly selected 16 nursing film to $1.40 per day for the more frequently applied $0.26 per day for the less frequently applied barrier included in the cost analysis, costs increased from nursing staff labour to apply the barrier products was accounted for. There was no control group receiving no skin treatment and therefore it was not possible to establish the efficacy of using cream as treatment per se (Level of Evidence 2).

Cleansing products

Cooper and Gray [657] randomised 93 long-term elderly subjects to skin cleansing with soap and water or with a foam cleanser over a 14 day period and blindly assessed perineal skin photographs at zero, seven and 14 days. The skin of 37% of subjects using soap and water remained ‘healthy’ compared to 66% of subjects using the foam cleanser. However, statistical analysis was not carried out (Level of Evidence 3).

Lewis-Byers et al. [658] randomised 32 nursing home residents with incontinence to a soap and water or no-rinse cleanser regime over a period of three weeks. No significant differences in skin condition were found but no power calculations were included (Level of Evidence 3).

Taken together, the evidence from these trials indicate that specialised cleansers may be better than soap and water for skin health, although there is still a need for further robust clinical trials. Reported staff opinion tends to favour specialised cleansers rather than soap and water and there may also be cost savings [614] [673] [674] [658] although the reliability and validity of the health economic analyses carried out to date has been questioned by Beeckman (2009) [581].

Costs of barrier products to prevent dermatitis

Zehrer et al. [605] compared the cost and efficacy of three incontinence skin barrier products in 250 nursing home residents from four facilities. A polymer-based barrier film was used either once daily or three times weekly, and one of two petrolatum ointments was used after each episode of incontinence. Residents were monitored for skin damage for six months. There were no significant differences in effectiveness among the various barrier film and ointment protocols of care. Time and motion measures were used to determine the costs of the products and associated nursing labour. Daily cost of barrier product ranged from $0.17 for the barrier film applied three times per week to $0.76 for a petrolatum ointment applied after each episode of incontinence. When nursing staff labour to apply the barrier products was included in the cost analysis, costs increased from $0.26 per day for the less frequently applied barrier film to $1.40 per day for the more frequently applied petrolatum ointments (Level of Evidence 3).

Bliss et al. [616] randomly selected 16 nursing homes to compare the cost and effectiveness of four skin damage prevention regimens. In three of the four skin prevention regimens, a moisture barrier ointment or cream of different compositions (43% petrolatum; 98% petrolatum; and 12% zinc oxide + 1% dimethicone) was applied after each episode of incontinence, while in the fourth, a polymer-based alcohol-free barrier film was applied three times per week. All regimens used a pH-balanced, moisturizing cleanser of the same manufacturer as the barrier. Time and motion measures were documented for the amount of skin care products used, the number, type, and time of caregivers performing IAD prevention care, and the number and type of supplies used. Compared to the three regimens in which a barrier was applied after each episode of incontinence, the use of a regimen in which a barrier film was applied three times weekly had significantly lower costs for the barrier product, labour associated with barrier application, and total cost which included products, labour, and supplies. There were also savings in total product (cleanser and barrier) and total labour costs. The total cost was lowest for the regimen using the barrier film compared to the other regimens in which a barrier needed to be applied after each episode of incontinence. The total cost savings ranged from $0.40 to $0.85 per episode of incontinence (Level of Evidence 2).

Although both these studies demonstrated cost savings when using barrier-film products such savings are dependent on relatively infrequent application of the barrier-film product. This may be achieved by assigning product application to care staff on particular shifts but uncontrolled use of such products may be expensive.

2. Skin products to treat dermatitis

In a double blind controlled trial of 64 subjects, Anthony et al. [675] compared the efficacy of cream formulated to treat dermatitis (Sudocrem) with zinc cream BP. Thirty subjects showed inflammatory lesions of the buttocks and a significantly greater proportion of subjects allocated to Sudocrem showed reduction in skin redness at both seven days and 14 days. No differences were found in the prevention of inflammatory lesions between the two groups. Skin measurements were made over the ischial tuberosities but the effect of reactive hyperaemia was not accounted for. There was no control group receiving no skin treatment and therefore it was not possible to establish the efficacy of using cream as treatment per se (Level of Evidence 2).

Baatenburg de Jong & Admiral [676] determined the cost of treating moderate to severe IAD in 39 nursing home patients in the Netherlands randomly assigned to treatment with a non-stinging barrier film or zinc oxide oil. The barrier film was applied every 48 - 72 hours for less severe skin damage and 24 - 48 hours for more severe damage. Zinc oxide oil was applied twice per day and after each episode of incontinence. Both barriers reduced IAD but the no-sting barrier film was significantly associated
with reduced severity of skin redness and skin loss, although skin assessments were not blinded. The cost per day of the nursing staff labour in the regimen using the barrier film was €68.58 (sd = €23.61) compared to €88.20 (sd = €22.88) in the regimen using the zinc oxide oil. The total cost (including barrier, labor and supplies) per day of the regimen using the barrier film (€76.13, sd = €25.48) was also less than for the regimen using the zinc oxide oil (€102.96, sd = €23.25) (Level of Evidence 2).

3. Pad changing frequency

Fader et al. [629] investigated the effect of different frequency of night-time pad changing on 81 incontinent nursing / residential home subjects from 20 homes. Following a two week baseline period, subjects were randomised by home to pad changing at 22.00 and 06.00 for four weeks followed by 22.00, 02.00 and 06.00 for four weeks, or vice versa. Blinded skin measurements of instrumental erythema (using an erythema meter), visual rating, trans-epidermal water loss and pH were made at baseline and during the last two weeks of each regime with instrumental erythema measurements used as the primary outcome variable. Trans-epidermal water loss measurements were significantly higher when pads were changed less frequently (22.00 and 06.00) indicating that skin was wetter. No other significant differences were found. However, five subjects developed stage II pressure ulcers in the less frequent pad changing regime compared to none in the frequent pad changing regime. Although more frequent pad changing did not demonstrate less dermatitis / erythema, the pressure ulcer findings - though non-significant - make it unwise to conclude that less frequent pad changing does not damage skin health (Level of Evidence 2).

4. SUMMARY

- Incontinence-associated dermatitis is a common problem amongst absorptive product users (Level of Evidence 2).
- Skin wetness overhydrates skin and potentiates the effects of other irritants (Level of Evidence 2).
- Faecal incontinence is more irritating than urinary incontinence, but the combined effects of urine and faeces are particularly damaging to skin (Level of Evidence 2).
- Absorbent pads containing super absorbent polymers are associated with reduced skin wetness (Level of Evidence 2).
- Wet skin is more vulnerable to friction and abrasion injury (Level of Evidence 2).
- Pressure ulcers are associated with urinary and faecal incontinence (Level of Evidence 2).
- Bodyworn absorbent products may raise interface pressures measured under the buttocks (Level of Evidence 3).

- There are indications that skin cleansers may be more cost-effective than soap and water (Level of Evidence 3) and may be better for skin health (Level of Evidence 2).
- Barrier skin products may impede water penetration into the stratum corneum (Level of Evidence 3).
- A regular and structured skin care regimen using topical preparations such as moisturisers or barrier creams is associated with a low incidence of perineal dermatitis (Level of Evidence 4).
- More frequent pad changing has not been shown to prevent dermatitis, but less frequent pad changes may be associated with pressure ulcers (Level of Evidence 3).

5. RECOMMENDATIONS

- Absorbent pads with SAP should be selected in preference to those without (Grade of Recommendation B).
- Absorbent pads should be changed regularly to minimise skin wetness (Grade of Recommendation C).
- Patients with faecal or double incontinence should be changed as soon as possible after incontinence has occurred to prevent the development of dermatitis from protease and lipase activity (Grade of Recommendation B).
- Patients should be washed gently at times of pad change with either soap and water or cleansers. Cleanser may be less time-consuming than soap and water (Grade of Recommendation C).
- Skin barrier products should be applied to areas that potentially come in contact with leaked urine and/or faeces (Grade of Recommendation D).
- Barrier products may be applied to skin within the pad area to reduce water penetration of the skin (Grade of Recommendation C).
- Buttock and sacral areas should be protected using topical skin barrier products, containment products or diversion devices in patients vulnerable to IAD or pressure ulcers (Grade of Recommendation C).

6. PRIORITIES FOR RESEARCH

- Controlled randomized trials that investigate the effectiveness of skin care products or skin care regimes to prevent or treat perineal skin damage due to urinary and faecal incontinence are recommended. Trials which
aim to test the comparative effects of different cleansing regimes, different barrier products and use of barrier products compared to careful cleansing are needed in particular. Such studies should determine appropriate sample sizes using power analyses. Analyses need to be powered to distinguish effects on participants with faecal or double incontinence. Objective measures from instruments, standardized clinical assessments, and patient symptom ratings should be included.

- Laboratory-based studies on healthy volunteers are recommended to help select products and establish potential efficacy of products before undertaking RCTs.
- Further work is needed to examine the relationship between IAD and pressure ulcers, in particular the potential and/or methods to discriminate between them, including use of biomarkers and technology.
- Studies to identify markers or ways of discriminating between pressure ulcers and IAD are required. Trials to test the comparative effectiveness of different skin cleansing regimes are needed as are trials to determine whether skin barrier products deliver benefits over careful cleansing alone and, if they do, which work best.

**XV. ODOUR CONTROL PRODUCTS**

Fear of smelling is a major concern that preoccupies many people suffering from incontinence and it is an issue that has been raised in several qualitative studies that have explored the subjective opinion of the patient eg [677] [678] [5]. Accordingly, there is a demand for products which will mask odour or, preferably, prevent it.

**1. PRODUCTS FOR URINARY INCONTINENCE**

Fresh, infection-free urine smells only slightly but bacterial action on urea over time yields pungent smelling ammonia.

A variety of anti-microbial solutions are available for washing such products as hand-held urinals or for treating urine spillage onto soft furnishings such as carpets. They aim to prevent smell by destroying the bacteria responsible for break down of urea. There are no robust published studies that have sought to evaluate such products. Another approach is to mask the smell of stale urine using a strong but (hopefully) pleasant smelling liquid. There are no robust published studies on such products either but anecdotal evidence suggests that, in time, the masking smell comes to be associated with the incontinence that it is intended to disguise. Several companies supply products (washable bedpads, carpets, chairs, clothing and bed linen) made with fabrics that have been treated with anti-microbial agents intended to reduce the smell of any urine on or in them. However, again, there have been no robust published studies to investigate efficacy.

One of the 12 disposable bodyworn pads for lightly incontinent women evaluated by Clarke-O’Neill et al. [18] was treated with a lavender scent but it was not found to perform significantly better than the other products in terms of preventing smell. However, the scent was appreciated by 18% of the 50 test subjects, who commented favourably on it.

**2. PRODUCTS FOR FAECAL INCONTINENCE**

Odour associated with faecal incontinence may occur from involuntarily leaked stool or flatus. In a study with subjects eating a self-selected diet, Moore et al. [679] identified the volatile chemicals primarily responsible for faecal odours as the methyl sulphides: methanethiol, dimethyl disulphide, and dimethyl trisulphide. Hydrogen sulphide was thought to make a smaller contribution. In a subsequent study with persons consuming a bolus of pinto beans and lactulose (a non-absorbable carbohydrate) Suarez et al. [680] attributed the odour of flatus to the sulphur compounds, hydrogen sulphide, methanethiol, and dimethyl sulphide. The intensity of the odour in flatus was related to the concentration of the sulphur-containing compounds: the ability of the human nose to recognise malodorous odour appears to be related to the amount of gas expelled [680]. Different states of health and gastrointestinal function, diet composition, relative concentrations of sulphide gases and, possibly, short chain fatty acids or ammonia are expected to contribute to the odour of faeces and flatus [679] and [680].

There are several commercially available devices that are designed to absorb the odour of flatus. One such product originally called the “Toot Trapper” and renamed the “Flatulence Filter” (UltraTech products, Inc., Houston, TX, USA) is a cushion or pad (which can be placed directly against the anus) that is lined with activated charcoal. Both the cushion and pad are encased in either a washable or a disposable cover. There are similar products by other manufacturers (e.g., Flat-D by Flat-D Innovations, Inc., Iowa, USA and GasMedic underair pads by Dairiair and manufactured by ECVC, Greenville, NC, USA). Pads comprising fabric covered activated charcoal that can be worn next to the anus or attached to a brief (GasMedic underair pad by Dairiair and Flat-D, Flat-D Innovations, Inc., Cedar Rapids, IA). There is also underwear (briefs) entirely made of covered activated carbon cloth (Underease protective underwear (UltraTech Products, Inc., Houston, TX). Ohge et al. [681] compared the effectiveness of
11 devices containing activated carbon in six normal adults (50% female) under controlled conditions in absorbing odoriferous rectal gases. Five types of seat cushions, four types of pads, and two types of briefs (one that held a pad next to the anus and one made of activated carbon fiber fabric) were tested. A mixture gas comprising 100 ml of nitrogen with traces of hydrogen sulphide (40 ppm), methyl mercaptan (40 ppm) and hydrogen (5,000 ppm) was instilled into the rectum of the subjects via a rectal tube. Since hydrogen does not react with charcoal, the amount of unabsorbed sulphide was determined from the ratio of sulphide to hydrogen collected from the pantaloons relative to the ratio in the instilled gas. The subjects wore mylar pantaloons that were sealed at the thighs and waist with elastic bandages to reduce convection to the air.

The subjects' clothing, apart from any device, absorbed approximately 22% of sulphide gas. The cushions absorbed an amount comparable to usual clothing, 20%. The various pads and the brief with an attached pad held near the anus absorbed 55-77% of the rectal gas. The underwear made of charcoal fabric was the most effective and removed nearly all (95-99%) of the sulphide gas. The charcoal fabric briefs are reusable and the charcoal is allegedly regenerable with heat. There are no reports of any odour absorbing devices being evaluated in persons with faecal incontinence. In vitro studies showed that each device had the capability of absorbing the rectal gases and that their performance efficiency depended on contact between the charcoal element and gas. Briefs entirely made of activated charcoal fabric appear to provide the greatest surface area for contact with malodorous rectal gas. The absorption of odorous gas by clothing suggests that washing outer clothing as well as underwear is important to reduce odour.

Some products aim to reduce the amount of malodorous flatus that is produced. Administration of the probiotic, Lactobacillus plantarum, (5 x 10^7 cfu/ml) in a randomized trial of 60 patients with IBS significantly reduced flatulence (by half in 44% of patients). Only 18% of the placebo group reported reductions of flatulence [682]. Although administration of charcoal, yucca and zinc acetate reduced the percentage of episodes of malodorous gas [683], there are inconsistent findings about reductions in flatulence from ingesting activated charcoal in humans [165] [684]. Two clinical trials involving small sample sizes (19 and eight persons, respectively) showed that the over-the-counter product, Beano, which contains α-galactosidase, reduced flatulence frequency in normal persons following the ingestion of beans [685] [686]. A significant reduction in cumulative breath hydrogen excretion over an 8-hour period after α-galactosidase versus placebo suggests α-galactosidase reduces flatus production [686]. Although Ganiats et al., 1994 [685] reported a significant decrease in flatus using 240 galactosidic units (GalU), Di Stefano reported that effects of 1200 GalU but not 300 GalU were significantly different from placebo. One GalU is the amount of galactosidase that releases 1 μmol of galactose from its substrate in one minute [686]. Differences in the test diet or lack of adequate statistical power may explain these differences since neither study reported a power analysis. Although a reduction in the amount of intestinal gas produced may decrease the volume of odour, it may not decrease its potency or perceived odour.

A few products are available that aim to prevent, absorb, or control odour associated with involuntarily leaked stool or flatus associated with faecal incontinence. These include cushions and pads that absorb odour as well as probiotics and enzymes, which aim to reduce production of malodorous gas.

3. RECOMMENDATIONS

- Briefs made of activated charcoal fabric are recommended over pads or cushions containing activated charcoal for absorbing odoriferous rectal gas (Grade of Recommendation C).
- Since some pads absorb up to 75% of gas, there may be value in offering patients who have smaller amounts of gas the opportunity to compare pads and briefs for themselves. (Grade of Recommendation D).
- For those persons experiencing stool leakage due to flatus, over-the-counter α-galactosidase containing products, which reduce flatus frequency, can be tried in an attempt to reduce FI frequency (Grade of Recommendation B).
- Washing of outer as well as under clothing after flatus is recommended to reduce odour due to absorption of gas by clothing (Grade of recommendation of C).

4. PRIORITY FOR RESEARCH

- Investigation of whether probiotics or changes in dietary intake can modulate or reduce the odour of flatulence or leaked faeces.
- Development of an absorbent product that can reduce the odour of leaked faeces while protecting the skin.
- Investigation of the efficacy of anti-microbial agents in textile products (soft furnishings and bedding) for reducing odour associated with urinary and faecal incontinence.

I. LITERATURE SEARCH

A systematic review of the literature using online databases Scopus, Medline/Pubmed, Embase, Biosis, Cinahl, Pycninfo, Psychlit, ERIC, Cochrane Library, Web of Knowledge, and CNKI (China National Knowledge Infrastructure) was conducted. The focuses of the searches were from 2008 to March 1, 2012, although literature from the preceding 15 years was also searched to ensure thorough coverage. The following search terms were used in various combination: awareness, consumer, education, urinary incontinence, faecal incontinence, continence promotion, health education, public education, population-based prevention, health promotion, help-seeking, care seeking, continence nurse, continence advisor, public awareness, prevention, primary prevention, pelvic organ prolapse, interstitial cystitis, bladder pain syndrome, painful bladder syndrome, allied health care professionals, self-care practices, outcome measures. There was significant overlap between the searches made on different databases, as would be expected. Non-English language guideline references were noted, but excluded from the review unless they contained an English-language abstract providing sufficient information.

II. INTRODUCTION

Contidence promotion, education and primary prevention involves informing and educating the public and health care professionals that urinary and fecal incontinence can often be prevented, can be treated successfully in most cases, and can always be managed. Other bladder disorders, with links to incontinence, such as bladder pain syndrome/interstitial cystitis and pelvic organ prolapse, can also be treated and managed successfully and are often included in continence awareness programs. The Fourth International Consultation on Incontinence (ICI) Continence Promotion, Education & Primary Prevention Committee stressed the importance of all health care professionals promoting primary prevention of continence [1]. It was acknowledged that this would require raising the level of community awareness, providing public education as well as addressing health care professionals’ education. While some advances have been made, these strategies remain a priority.

Taboos surrounding disorders of the bladder and bowel are gradually lifting in most cultures [2]. Two decades ago it was almost impossible to discuss urinary incontinence in the media. Today, in many countries, government funded initiatives and practice guidelines have been developed in the area of urinary and faecal incontinence [1,3,4]. Around the world, expert panels have suggested that urinary and fecal incontinence be combined through a multidisciplinary approach to further research priorities. Thus, there have been advances in promoting awareness of both of these conditions. Popular magazines, local and national papers, radio, and television, regularly cover topics of men and women relating to urinary incontinence in most developed countries. Many countries have run national or local public awareness campaigns, often spearheaded by a national continence organization. Many also have confidential “help lines,” which can be accessed anonymously. The internet provides a convenient source of health information for a growing number of consumers. Some experts believe that persons with incontinence might get valuable advice and comfort by using interactive services such as internet “chat rooms.” However, in many developing countries, accessible public information and campaigns relating to continence are limited or non-existent. Though information may be available in principle on the internet, access to the internet may itself be limited.

This chapter updates previous ICI chapters on four areas: continence awareness and promotion, service delivery, professional education, and primary prevention along with the recommendations in each area. The majority of information available relates primarily to urinary incontinence (UI) and faecal incontinence (FI) and less to bladder pain syndrome/interstitial cystitis (BPS/IC) and pelvic organ prolapse (POP). The first section reviews continence awareness by discussing health promotion and help-seeking (care-
These conditions are prevalent but often ignored by medical guidelines and care pathways. Finally, since IC and POP) including the development and use of cation of professionals in these areas (UI, FI, BPS/
continence care. The third topic reviewed is the edu-
fessional attitudes and knowledge about it. The sec-
tion on the effectiveness of changing public and pro-
awareness of incontinence, there is minimal informa-
tion on building public and health care professional
Although there is a great deal of published informa-
tion is provided on continence promotion programs
and management, with goals of eliminating stigma,
and promotion frameworks can be used to plan and eval-
benefits
of
prevention
primary prevention
tertiary prevention efforts directed at individuals,
communities and populations with, or at risk of de-
veloping, incontinence. Efforts to promote continence awareness may be enhanced by adopting evidence based theories and methods from the field of health promotion. Health promotion frameworks can be used to plan and evaluate the effectiveness of strategies and programs used to promote continence. When planning health promotion interventions, consideration needs to be given to the demographic features of target groups including age, gender, culture, language and socio-economic background [6].

1. RAISING AWARENESS AND UNDER-STANDING

The main reason to educate consumers – individuals with, or at risk of, incontinence and their family members or informal caregivers – is to increase awareness of incontinence and the benefits of prevention and management, with goals of eliminating stigma,

Promoting help-seeking, and reducing suffering [7,8,9]. While in some countries there is strong govern-
mental support, much of the health promotion ef-
fort related to continence issues is undertaken by the many professional bodies, non-governmental contin-
ence organizations, and advocacy groups listed in
Appendix I. Health education activities can involve
educational, health-care, and community service
providers, and may include a range of components
including materials that are accessible, comprehen-
sible, trustworthy, and culturally sensitive, formal
and informal health advice systems such as including a hotline, online support and health care professional
learning systems [10].

Consumer education is a critical component of effec-
tive continence promotion. This includes both gen-
eral information about UI[11] and methods to identify
potentially modifiable risk factors for UI [12]. Patients
with UI have a wide variety of ideas and attitudes
about why they leak urine [13]. Knowledge about
specific aspects of UI is often limited, indicating an
area for improved consumer education.

Consumer knowledge about FI is also generally limit-
ed. A recent study found that many patients had a sign-
nificant emotional component to their experience of FI
and that knowledge about the terms used to describe
the condition was often limited [14]. A United States
(USA) Public Broadcast (PBS) Second Opinion medi-
cal television program was develop to educate con-
sumers about FI and attempts to dispel the stigma of
this condition (www.iptv.org/video/detail.cfm/12719/
sopt_20101018_fecal_incontinence_api).

The Internet is frequently searched for health infor-
mation, and coverage of relevant health topics is
growing. This method of acquiring health informa-
tion is widely accessible, anonymous and informal,
with estimates indicating that around 20% of USA
adults use the internet for this purpose [15]. Since
one-quarter of adults do not go online, the percent-
age of health information seekers is 59% among the
total U.S. adult population (http://pewinternet.org/
Reports/2011/HealthTopics/Summary-of-Findings/
Looking-for-health-information.aspx). Thus, access-
ing information about incontinence has become
much easier in the age of digital technology, espe-
cially for internet users with a higher literacy level
[10]. A 2011 Google search for “urinary incontinence”
and “faecal incontinence” yielded about 4.8 million
and 311,000 websites respectively; “interstitial cysti-
tis” - 2.2 million sites, “bladder pain syndrome” –
105,000 sites and “pelvic organ prolapse” – 382,000
sites. These figures are all two to three times greater
than a similar search in 2008. Many of the sites were
related to non-government organizations such as the
International Continence Society (ICS), the Nation-
al Association For Continence (NAFC), the Simon
Foundation, the Interstitial Cystitis Association (ICA),
and the International Foundation for Functional Gas-
trointestinal Disorders (IFFGD).
In light of the reluctance of those affected by stigmatized illnesses such as incontinence to seek treatment or to ask health care professionals for information, the Internet may prove to be a useful tool for consumer education and public health outreach [16,17]. In a national survey of internet users in the USA, Berger et al[18] found a trend among people with a stigmatized illness such as UI to be more likely to report that internet use increased their communication with a health care provider and utilization of health care. The quality of these materials can vary widely and providers should help interested patients to navigate resources that provide accurate information. A recent study showed that most websites that provide UI information are not certified by any accrediting body [19]. There were also differences observed between sites run by professional organizations, educational and government agencies, and companies either for profit or non-profit.

Among those who do not use the Internet, 60% are aware of publicly available Internet access points within their community [20]. However, people with low levels of education and low socioeconomic status are less likely to use the Internet [21]. Research has questioned the quality of continence information on the internet and suggested that validation is needed [22]. Healthcare professionals can assist patients in finding reliable information sources by providing details of reputable web sites [23].

The Internet has changed the way many people access health information, and has much to offer as a means of health education and raising awareness. But Internet access is far from universal, especially in developing nations and among older and poorer sections of society in developed nations. Thus, it is important that more traditional awareness-raising and education methods are still used, such as information posters, leaflets and booklets distributed through health outlets such as clinics and pharmacies, and articles in the popular media. In both developing nations and in countries with limited health systems and dispersed populations, more innovative techniques have been successfully used for health education, such as dissemination of information through community nursing infrastructures and lay health workers.

Social network sites may be the future source of information for consumers. Sajadi and Goldman[24] used the word “incontinence” to search for information on Facebook, Twitter, and YouTube, to evaluate its usefulness. Their conclusion was that social networks have insufficient useful incontinence content, especially from healthcare professionals and incontinence organizations. However, they recommended that medical professionals and societies target these avenues to reach and educate consumers.

3. HELP-SEEKING (CARE-SEEKING) BEHAVIOR

Estimating the prevalence of incontinence problems is difficult due to different definitions of incontinence, different populations and different data collection strategies,[25] and this lack of clarity regarding baseline prevalence of incontinence undermines efforts to determine the proportion of those affected that seek help. Despite the considerable impact of both UI and F1 on quality of life (QoL), it is clear that many people never seek help for their incontinence, although the precise level of under-reporting is difficult to determine [26,27]. Perhaps of more concern is a recent comparison of HSBs in two surveys conducted sixteen years apart (1991 and 2007) which revealed that there had been virtually no increase in the proportion of women seeking help for lower urinary tract symptoms (LUTS) [28].

Qualitative research has described a process that takes place and influences the decision to seek treatment (or not), whereby consumers affected by incontinence, or other chronic, non-life-threatening conditions, weigh the perceived costs and benefits of treatment (in terms of discomfort and inconvenience as well as financially) against the effect of the condition on QoL [29].

Instead of seeking care, individuals with UI and F1 alter their lifestyle and develop elaborate “self-care” practices (e.g., stopping exercising, use of protective products, dietary and fluid changes) to conceal and/or manage symptoms and improve QoL [30,31,32,33]. Data from focus groups of women showed self-reliance and the development of personalized strategies to alleviate symptoms [34]. Some patients have been known to make major changes in their lives (e.g., quitting their jobs). Surveys have also revealed extensive use of coping mechanisms for overactive bladder (OAB) symptoms of urgency and frequency (e.g., toilet mapping) [35].

Several studies have estimated levels of help-seeking for specific consumer groups. An integrative literature review of HSB for UI symptoms among non-institutionalized women of all ages indicated that less than 38% of women sought help for their UI symptoms [36]. Age, type, and severity of UI, and embarrassment have been found to be significantly related to seeking care [37,38,39].

Kinchen and colleagues [26] noted that women with UI waited more than a year before seeking help from a health care provider or professional [26]. This delay is in line with a European survey that reported that consumers wait from 2 to 11 or more years before seeking treatment [40]. Huang et al[41] reported that fewer than 50% of women in the USA with clinically significant UI reported seeking treatment. This was despite the fact that all women in this study had health insurance to cover such services and had continuous access to a primary care provider. Only 12% of women with UI attending obstetric and gynaecology clinics in Turkey had sought help for their incontinence [42]. Shaw and colleagues[43] surveyed adult women attending primary care practices in United Kingdom (UK) and of those who noted UI symptoms (n=3273), only 15.8% of women with
stress UI, 32.3% of those with urge UI, and 33.7% with mixed UI had sought help for urinary symptoms during the preceding 12 months. Rizk[44] found that of women affected by UI in the United Arab Emirates (UAE), only 30.9% had sought medical advice.

Surveys of individuals with FI also indicate a lack of HSB. In 2010, the IFFGD conducted an online survey to help explain what it is like to live with and manage FI from the point of view of those who experience the condition (http://www.aboutincontinence.org/pdfs/319-IFFGD%20Incontinence%20Survey%20(9-11).pdf). A total of 142 individuals completed the survey, responders were recruited primarily from the IFFGD websites. Ninety-seven (68%) of the survey responders indicated they had never been diagnosed by a physician, giving reasons such as “too embarrassed to bring it up” and “feel I can manage the condition on my own.” Of the 32% who had mentioned their FI problems to a physician, the physician implied there is not much to be done about it or it is a normal part of aging.

a) Barriers to seeking care

Understanding the barriers and reasons why people do or do not seek treatment for incontinence is hampered by the ethnic homogeneity of the existing data, which has been derived mostly from white populations, and there is a lack of comparisons with ethnic and minority populations. The strategies for promoting HSB need to be culturally appropriate to the populations of interest [45,46,47]. Rates of HSB for UI amongst minority groups may relate to a number of factors such as access to care, socioeconomic factors and access to or comprehension of health education campaigns or materials [48,49,50].

Help-seeking behaviour is dependent upon awareness and understanding [51] and lack of knowledge has been a significant barrier to people seeking help for continence issues. Furthermore, HSB for UI, FI, BPS and POP may be different depending on the person’s culture, ethnicity, gender and socioeconomic groups.

Questionnaires have been developed and validated which can be used to assess consumer knowledge about UI and POP [52]. In 2008, a study (n = 126) found that white women had greater knowledge of UI than non-white women while both groups of women had higher levels of knowledge of UI compared to POP [53]. Using this instrument, research has shown that there appear to be important differences in health literacy about these conditions in different racial and ethnic groups.

Another study found that Korean American women living in America tend to rely on information and social support from family and friends rather than seeking professional advice for UI [54]. The women in this study sought help less frequently, had less knowledge and more negative attitudes towards UI than other community members. It was suggested that these factors influenced help-seeking in this group of women [55].

In certain parts of the world, cultural factors can affect the experience of incontinence and HSB and the gender of the health care provider may be a barrier. Knowledge of continence issues in UAE women was researched by Rizk and Hassan [56]. It was found that UAE women perceive continence problems to be neurological or “senile” disorders rather than related to childbirth or menopause. Quantitative data was derived from a community-based descriptive cross-sectional study conducted in Sri Lanka from 2006 to 2007 with 1,718 married women, aged 15-49, of whom 9.8% reported problems of stress UI [57]. Although incontinence affected outdoor activities, sexual life, and sense of wellbeing, women did not consider it a health problem, rarely discussed it with others, and rarely sought treatment. Barriers to help-seeking included fear of vaginal examination, shame and embarrassment, and belief that stress UI was a natural consequence of aging and childbirth. Within all cultures, embarrassment or shyness may prevent some women from seeking care for UI [58,59,60,61]. These have been shown to impact help-seeking in Middle Eastern women, where both UI and FI are underreported. In the UAE, cultural attitudes and inadequate public knowledge, and male health care providers have been identified as barriers to seeking health care for women, despite the effect on QoL. Rizk[44] found that women affected by UI in the UAE, were troubled by their inability to pray (90%) and to have sexual intercourse (33.3%). Saleh[62] found similar results when surveying women in Qatar who reported that UI interfered with their ability to pray (64%) because of lack of cleanliness and need to void, and 47% reported that UI interfered with marital relationships. El-Azab and colleagues[63] found that encouragement from husbands, severe UI and the desire to be able to pray were associated with an increased likelihood of HSB [63].

Rizk and colleagues (2001) investigated the prevalence and HSB of UAE women with FI (n = 400, mean age 37.9) and also found that many did not seek medical advice because they were too embarrassed to consult their physician and preferred to discuss the difficulty with friends (64.7 %), assumed that FI would resolve spontaneously (47.1 %), felt it was normal (31.3 %), or they chose self-treatment as a result of low expectations of medical care (23.5 %). As with UI, women with FI were bothered by the inability to pray (92.2 %) and to have sexual intercourse (43.1 %).

These studies reinforce the need for different strategies to be targeted to cultural and minority groups with low levels of HSB for UI and FI. In addition, public education efforts related to UI should not just focus on older adults [64]. An earlier study of high-school and college age athletes in the USA found that more than 25% of the young women surveyed...
experienced UI during strenuous physical activity, but 90% had never reported their symptoms to anyone [65]. A recent study of nulliparous female athletes also found that young women have low levels of HSB for UI [66]. This study found that UI issues occurred particularly during training and to a lesser extent, during competition in women of varying competitive levels ranging from high school to elite level athletes. The prevalence rates of UI in nulliparous women in recent studies have varied from 28% to 52% and are influenced by the type of athletic activity. A 2011 study found a lower prevalence rate of UI in women playing volleyball compared to higher rates occurring in women performing track and field, soccer and gymnastics [66].

Barriers to seeking help for continence issues that have been frequently identified in the literature include embarrassment, social stigma and the mistaken belief that incontinence is inevitable, untreatable, and/or a normal part of aging [67]. The authors of a Swedish study suspected that lack of knowledge, worries about different procedures and negative expectations may be important factors in reducing the desire to seek treatment among even those most severely affected [68]. Embarrassment and fear of humiliation have been identified as the major factor influencing reluctance to seek help among women with long-term UI [69]. Among women affected by UI in the UAE, reasons for not seeking help included embarrassment (38.2%), choice of self-treatment (38.2%) and assuming that UI is normal (23.3%) because of low expectations from medical care [37x299] and/or a normal part of aging [67]. The authors of a Swedish study suspected that lack of knowledge, worries about different procedures and negative expectations may be important factors in reducing the desire to seek treatment among even those most severely affected [68]. Embarrassment and fear of humiliation have been identified as the major factor influencing reluctance to seek help among women with long-term UI [69]. Among women affected by UI in the UAE, reasons for not seeking help included embarrassment (38.2%), choice of self-treatment because of low expectations from medical care (38.2%) and assuming that UI is normal (23.3%) [44]. Among women with gynaecological cancers who experience concomitant LUTS, the failure to seek help for the latter symptoms has been attributed to a perception that the LUTS were not serious enough symptoms to warrant attention and lack of awareness of treatment options [70].

Advice given by physicians can affect a patient’s ability to change health behaviours [71]. Opportunities to promote continence can present themselves during other health screening activities (e.g., yearly physical examination) [72]. While health care professionals may enable people to seek help, those who have a lack of interest in incontinence can negatively affect HSB in consumers [73,74].

Other initiatives to promote HSB can include providing written information [75]. Continence health promotion information provided in a brochure [76] and in a computer based program,[77] have been found to improve HSB. However, language, level of education and cultural factors may also be barriers to seeking help [78]. Consideration should be given to health literacy in target populations and this will affect the ability to read and understand health information in written formats. Poor health literacy results in lower rates of health seeking behavior [79].

The Boston Area Community Health (BACH)[80] population-based random epidemiological survey of urologic symptoms (n=5503) indicated that the stigma of UI also includes other LUTS. They reported that OAB symptoms of urgency and frequency were linked to social interruption, loss of socially-expected control of the body, not understanding the nature of the bladder problem, and the need to mix private behavior and public space. The stigma of OAB and UI was correlated to whether the problem was perceptible (i.e., odor, or observation of trips to the bathroom or soiled clothes) or concealed. Men reported feeling stigmatized for being seen making frequent trips to the bathroom and feared being viewed as impotent. Women feared being stigmatized based on having an unclean body and a compromised social identity. Like others, Hispanic individuals wanted to keep urinary symptoms a secret from others.

Surprisingly, the perception that incontinence is not important or serious enough to warrant treatment has even been found to affect HSBs in women with recurrent UI following surgery for UI and POP [81]. Women with POP have also reported that fear and embarrassment are barriers to seeking help. Symptoms such as nocturia have been linked with serious consequences such as falls and associated morbidity in older adults. Bladder and bowel incontinence is a deviation from social norms, which in most cultures there are defined complex and sensitive rules and behaviours for bladder and bowel emptying [82,83]. If incontinence occurs in adulthood, it can cause a decrease in self-esteem and feelings of not being “normal.”[84] These perceptions, which can affect help-seeking, are shared by the public as well as by many health care providers [85].

b) Gender-specific disparity

The impact of UI may also differ depending on gender but little is known about gender differences in HSB. Teunissen and colleagues [86] interviewed independently living patients (56 men, 314 women) 60 years and older with uncomplicated UI. Men reported higher impact scores than women, despite the fact that incontinence was less severe in men. The most important effect of incontinence reported in men was “being out of control,” while most women considered “feeling compelled to take several precautions” to be the most important consequence of UI. Researchers in Egypt interviewed 353 patients attending clinics at hospitals in Alexandria, Egypt [87]. They found differences in men and women as women suffered from at least one negative impact on their social lives compared to men. The impact of symptoms on QoL appeared to be the main trigger for seeking help for UI in both men and women. Women had fewer hospital admissions and hospital days and less use of diagnostic procedures and surgery.

There is very limited data on ways to improve men’s awareness of bladder and bowel health [88]. Gender specific health disparity may exist as men tend to be less proactive in HSB for UI. There is a need
for gender specific strategies to address this [89]. Men with LUTS have been found to seek help less frequently than women [90]. Consumer surveys conducted over a 5-year period by the USA continence advocacy group, the NAFC, indicated that only 26% of respondents (18% of men and 33% of women) reporting bladder control symptoms had discussed them with a doctor [91]. However, a study into the prevalence of UI in men in the USA found that while a low proportion of men with continence issues sought help, those who did, consulted their doctor within 12 months of the onset of symptoms, a shorter period than the length of time taken by women to seek help [92]. Men are more likely to seek help for LUTS if they have had advice from others or received information in the media, rather than seeking help as a result of their symptoms [93].

In certain parts of the world, the gender of the health care provider may be a barrier. Doshani et al[94] explored views and experiences of South Asian Indian women with UI and found that feelings of embarrassment were present, especially with male health care providers.

c) Symptom impact and bother

The level of perceived bother (physical, emotional and/or economic) associated with incontinence also affects HSBs. A number of studies have found that those affected by incontinence are not necessarily so bothered by it as to want to seek professional help. In Japan, it has been found that 55% of elderly continent people do not consider incontinence a bother [95].

Of women with UI attending obstetric and gynaecology clinics in Turkey, 53% were found not to be bothered by their incontinence [42]. In a population-based study in Sweden (a supplement to a comprehensive survey of public health and general living conditions), a postal questionnaire comprised of 12 questions on UI received a response rate of 64.5% from 15,360 randomly selected residents (aged 18–79 years) [68]. The prevalence of UI was 19% (when defined as “any leakage”) and most considered their problems to be minor. Only 18% of those with UI desired treatment. Of the 17% who had reported severe problems that interfered with daily life, 42% did not want treatment.

A recent study by Visser and colleagues[39] showed that older adult women, who did not consult a general practitioner (GP) about incontinence symptoms, were more often younger and had lower levels of distress due to their urogynaecological symptoms, but the main reason for not seeking help was they did not consider their symptoms to be severe enough [39]. An internet survey in the USA, the UK and Sweden, noted that in men and women who reported LUTS less than a third of respondents reported seeking treatment [96]. Rates of bother were greater for those who reported multiple storage, voiding and post-micturition LUTS (men 83%, women 89%) and correlates of treatment seeking across genders included bother due to weak stream, incomplete emptying, perceived daytime frequency, nocturia and urgency.

With chronic problems like UI, FI, POP and BPS/IC, it is important to understand what triggers the consumer to consult a health care provider [83]. Yet factors that lead those affected to seek help for continence issues remain less well researched than those that prevent help seeking. Women with stress UI are more likely to seek help when there is severe leakage that is having a significant impact on their QoL [97]. The importance of the effect of UI on QoL is supported by Brazilian research [98]. An American study suggests that worsening severity of UI, along with increasing age and not being obese, were associated with an increased likelihood of help seeking [99]. Older people may be keen to seek help if they are concerned that a health issue, such as incontinence, impacts on their ability to remain independent and living in the community [100].

In conclusion, the most commonly reported reasons for not seeking help for incontinence are lack of knowledge and awareness, embarrassment, a perception that incontinence is not sufficiently important to warrant treatment or is “normal” either at certain stages of life or in association with childbirth or certain illnesses, and low expectations of the effectiveness of treatments offered. The more serious the impact of incontinence is on QoL, the greater the likelihood of seeking help, but this will be balanced against the perceived disadvantages of treatment in terms of cost, discomfort or inconvenience.

4. CONTINENCE PROMOTION PROGRAMS

Continence promotion programs vary across countries and cultures, but share the same aim of increasing awareness and understanding of incontinence. Efforts to raise awareness of continence issues need to consider the following:

Target population - Continence promotion programs need to consider age, gender and culture of target populations. It is necessary to consult with target groups when planning programs in order to meet the needs of these groups and to enhance HSB [101].

Target issues - A continence promotion program needs to address risk factors and management options in different target groups. Community-based interactive continence promotion workshops conducted in a recent cohort study in Canada were shown to be well-received by participants and the interventions changed knowledge, attitudes, skills, and appeared to increase rates of HSBs [102]. A similar study showed that improved understanding about UI and POP was associated with improved QoL scores among women who attended a nurse-led educational workshop [103].

Promotional material – Newman [104] reported on a mail survey of 1,500 women, noting that most of the 422 respondents wanted more information regarding UI, and while they may not be equipped to fully
understand the problem, they expect doctors, nurses, medical professionals, retail outlets, medical supply companies, and mail order houses to provide the information, including information through consumer advertising.

Communication and expectations – Health care professionals may launch campaigns or seminars to increase practice revenues. Commercial companies often fund public campaigns in order to sell their products, whereas continence organizations may be driven by missionary zeal or organizational growth. Regardless of motivation, care should be taken to avoid raising public expectations beyond what the services or products can deliver [105].

a) Creating public awareness

In the area of UI, building awareness among the general public has usually been attempted via the media. The USA National Institutes of Health, in partnership with the American Urogynecological Society, American Urological Association, American Foundation for Urologic Disease, NAFC, Society of Urologic Nurses and Associates and the Simon Foundation for Continence, launched a national awareness campaign in 1997. The Let’s Talk About Bladder Control for Women awareness campaign (http://kidney.niddk.nih.gov/kudiseases/pubs/bcw_zz/index.htm) offered easy-to-read booklets explaining the symptoms, types and causes of poor bladder control, as well as treatment options. The materials were designed to encourage and enhance communication between and among women and their health care providers. Free consumer and health care provider kits were available through a toll-free phone number. In 2007, the USA National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), National Institutes of Health (NIH) State of the Science Conference Statement on Prevention and Fecal and Urinary Incontinence in Adults paved the way for the 2011 national campaign, Let’s Talk about Bowel Control (www.bowelcontrol.nih.gov). In 2001, the NAFC in the USA produced and disseminated continence awareness public service announcements (PSAs) to 380 television media markets, including Hispanic outlets. In the UK, the Bladder and Bowel Foundation (BBF), supported by the pharmaceutical industry, has conducted a lengthy campaign to raise awareness of OAB and to encourage HSBs (www.bladderandbowelfoundation.org/?p=1550). The campaign has featured advertisement of a toll-free information line on television, in the print media and on public transport. The BBF also provides informational leaflets on a variety of continence-related topics and a website containing a great deal of information as well as a directory through which visitors can locate their nearest continence professionals and clinics. Another UK organization, Education and Resources for Improving Childhood Continence (ERIC), offers courses for school nurses on how to deal with school children with UI, as well as children with medical issues (http://www.telegraph.co.uk/education/primaryeducation/5956231/Pupils-start-school-still-in-nappies.html). In Australia, the government has provided a high level of support to continence promotion activities via the National Continence Program [106,107,108]. These are just a few examples of campaigns conducted by organizations to bring awareness to lower urinary tract conditions.

Media campaigns should use multiple channels to ensure the broadest coverage [109]. Channels can include print media, television and radio, while the Internet, phones, and other mobile devices are also effective outreach channels [110]. Specialised age and health publications offer potentially valuable channels for dissemination of continence advice. At a more local level, a useful channel for dissemination can be the use of posters and brochures placed in medical offices, hospitals, seniors’ centres, pharmacies and churches and direct presentations to the public, such as at senior citizen’s centres [111] or retirement communities [112]. In many cultures, an effective strategy for reaching the public is through an informed journalist. Journalists often use a “media hook,” an interesting story that will take priority over other news on the television, radio or newspaper. In addition, having a spokesperson affected by incontinence or finding a celebrity who is willing to speak for the cause can help [82]. These individuals can act as “influence leaders.”

The Japan Continence Action Society held a “Toll Free Telephone Clinic” and callers were asked how they heard about the line. The responses in 2006 were: 30% from television, 16% from the web, 11% from a newspaper, 9% from a book, 6% from a friend, 5% from a brochure, 3% from a magazine and 20% other and/or unknown. A UK campaign [113] found that newspapers were by far the most common source of information, followed by radio. However, with the growth of the Internet and social media, print campaigns may no longer be the most effective avenue for awareness.

Roe [114] suggested that local initiatives on the availability of services and how to access them, as well as health education information on UI, may be particularly effective in raising public awareness and should supplement national campaigns. Awareness raising materials include pamphlets, self-care instructions, visual aids, pictographs, posters, banners, decals and advertisements in newspapers, magazines, newsletters, CD and films. Muller [115] believed that the change related to increased public awareness and HSB for continence care is likely to fuel the demand for innovation in technology and products. The Simon Foundation for Continence developed an innovative community education initiative, The Bladder Health Mobile. The goal of this initiative was to provide education, increase public awareness, and promote early diagnosis and proper treatment of UI and other bladder control problems [116]. However, it was never launched due to a lack of funding.

Health literacy related to UI is an important issue,
and is a potential target for additional consumer education. Raising awareness of health problems and providing information on terms used to describe symptoms assists in promoting HSB [117]. The words “continence” or “incontinence,” “interstitial cystitis,” or “painful bladder syndrome,” or bladder pain syndrome and “pelvic organ prolapse” are poorly understood [118] and simpler terms may achieve greater public recognition in many languages and cultures. The use of “overactive bladder” in advertising has increased reporting of the condition to primary care professionals in the USA. Palmer and Newman [74] reported on a USA health promotion project conducted in 2000 to determine the needs of senior citizens concerning bladder control issues. Focus groups of older adults attending health seminars in urban, community and church settings were conducted. The primary objective of the project was to determine the understanding of older adults in the areas of general health and their beliefs surrounding the problem of UI. The 82 participants were predominantly African-American women representing all socio-economic levels. Seniors expressed confusion when asked if “overactive bladder, bladder control issues and UI” were the same condition. An evaluation of Australia’s National Continence Management Strategy in 2006 noted that recognition of the barriers to help-seeking and identification of the most appropriate terminology and key messages would strengthen awareness raising strategies [106,119].

In the UK, campaigns and consumer literature often avoid clinical terms in favor of lay terms that focus on the need to go to the toilet often, worrying that one may not make it to the toilet on time or have “leaking” of urine or feces. In the area of bowel disorders such as FI, it is felt that people find it difficult to find the right words to discuss their symptoms [85]. The IFFGD in the USA has found that people will often report having diarrhea to their physician. If the physician or nurse does not question the patient any further regarding the ability to control gas, liquid or solid stool, the incontinence may not be discovered.

Lack of understanding about terminology and physiology may lead to difficulties with communication between patients and providers. A survey of 138 women attending continence clinics in the UK, Australia, and Italy found that over 20% of women were unsure of the meaning of basic continence terminology commonly used by health care providers [120]. Terms tested in this study included “daytime frequency, nocturia, urgency, urge UI, stress UI, and hesitancy.” Two recent studies highlight the confusion and lack of knowledge about LUTS. Smith and colleagues [121] study of focus groups with women who experienced OAB, showed that there were high levels of misunderstanding about symptoms and physiology, and miscommunication between patients and providers. The finding was more pronounced among the older women in this study. Senejian and colleagues[118] corroborated this finding and recommended that public health campaigns about UI and other pelvic floor disorders need to use terminology targeted to the basic understanding of consumers.

Some researchers have targeted health literacy of patients undergoing urodynamic testing [122]. Theoretically, this may help to improve understanding of the procedure and reduce patient anxiety. This particular study did not reveal significant differences in overall satisfaction between the group that received this additional information and those who did not. A similar study revealed that after reading this type of material, most women (78.1%) felt they understood the indications for urodynamic testing [123]. However, fewer felt they understood what the procedures would involve (68.2%) or that they had enough information about the tests (64.9%). Many patients still expressed anxiety or embarrassment about the procedure. Additional research will be needed to determine how best to deliver this type of information to improve patient experiences.

b) Program evaluation

Evaluating the effectiveness of health promotion programs is notoriously difficult. Evaluation methods should be established prior to developing the continence promotion program. Evaluation should include quantitative measurements and qualitative measures. Open-ended questions may be more sensitive than “direct satisfaction” questions [124]. Health promotion evaluation methods include process evaluation, impact evaluation and outcome evaluation.

Research-based evidence for the effectiveness of programs aimed at raising awareness of continence issues or at improving help-seeking behaviors is rare [125]. A number of studies have considered the effectiveness of leaflets or brochures in raising awareness of UI and of treatment options and while generally supportive of such information, the evidence is contradictory in some areas and far from conclusive. In a good quality study of 1,175 participants, Wagg et al [126] reported that a self-help standard treatment leaflet is as effective as structured help from a continence nurse in reducing bothersome urinary symptoms in women. A small Australian study considered an information leaflet to have influenced the HSBs of people with UI who had received it, but these were people who were identified in a primary care setting and had already reported a UI problem [127]. A similar study found that individuals given a continent education package, which included a Continence Educational Brochure, helped to improve the health-seeking behaviours of participants who were bothered by UI symptoms [128]. Within 3 months following the education, of the 111 participants who were bothered by UI symptoms, 49 participants (44.1%) indicated that they had discussed the issue of bladder or bowel problems with a health care professional, but this could have been either directly because of the information contained in the brochure or because of
information contained in the leaflet. But there is research that indicates that education alone may not improve a person’s understanding or experience with specific medical care. A study that investigated the effectiveness of detailed educational materials, about the urodynamic tests given to women undergoing these investigations, did not significantly improve their experience [129]. A Swedish population-based study found that the distribution of a brochure on UI to the general public was well received and can be an efficient method to spread knowledge and encourage self-management [130].

In France, the effect of direct health education was evaluated in a randomized study in sheltered accommodation for the elderly [131]. Twenty centers were randomized to either a single one-hour health information meeting or control group. During a 30-minute talk, a nurse encouraged people to visit a physician if they had urinary problems. A questionnaire three months later found that the experimental group was much more likely to have had treatment if they were incontinent (41% vs. 13% controls). Similarly, knowledge and symptoms were found to have significantly improved three months after a 2.5 hour nurse-led workshop for women with UI and POP [132].

A health promotion project called ‘Dry Expectations’ was developed and implemented in six ethnically diverse, predominantly minority, and inner city senior centres in the USA in 1996 [111]. The program was designed to address an older population. The project consisted of three phases: orientation and training of key staff members/peer educators at the centres (train-the-trainer model); educating seniors through four one-hour weekly sessions involving visual aids and completion of bladder records and quizzes; and follow up sessions with senior staff/peer educators to reinforce the previous training. The program was very well received by the participants and approximately 80% felt they had more control over their bladder by the end of the last session.

The interventions that are most effective in reaching the public and triggering the desired behaviour seem to vary between countries and cultures. Television and newspapers work best in Singapore, with a “cured” patient bearing testimony to former suffering and its alleviation having the most impact. In the USA, television advertising targeting OAB, funded primarily by pharmaceutical companies, has yielded a significant response. Nationwide television reaches more people than the circulation of any single newspaper or the distribution of a booklet through physician offices. In March 2008, Japanese National Television broadcast a program about UI during “golden time” (2000 to 2045 hours). The audience rating was 15.6%, the highest in a year (usual rating 12%), and more than 500 calls were received in one night, requesting repeat broadcast and more details about treatment. However, the Internet is rapidly becoming the most effective and quickest way to reach the largest number of people. But there are cultural differences in the how online health information is used, as well as the types of sites users prefer to surf [110].

5. RECOMMENDATIONS FOR CONTINENCE PROMOTION AND AWARENESS (GRADE D)

Based on the literature reviewed in this section, the following recommendations can be made:

- Continence awareness should be part of mainstream and on-going health education and advocacy programs with emphasis on eliminating stigma, raising awareness of effective treatments, promoting HSB and improving QoL.
- Continence awareness programs should include education, health-care, and community service providers.
- Research is needed to provide higher levels of evidence on the effectiveness of continence promotion programs to include:
  - Identification and understanding of barriers to HSBs
  - Translation of promotion research into improved clinical practice and identification of methods by which this occurs.
  - Effectiveness and impact of consumer education initiatives.

IV. CONTINENCE ADVOCACY

1. BACKGROUND

Advocacy is defined as the act or process of defending or maintaining a cause or proposal. Advocacy, as it pertains to incontinence, involves assisting individuals in finding necessary health care and treatment. Organisations consisting of professional and public members promote continence advocacy as a core mission.

There is little doubt that incontinence is a common problem that often goes unreported, with those affected anxious to conceal the problem and reluctant to discuss it. Misconceptions fuel this reluctance, such as the widespread belief that incontinence is normal in some circumstances, especially in women following childbirth or in both sexes after a certain age. Incontinence is associated with a very strong stigma that sets it apart from most other health problems and will inevitably influence behaviours. Whereas many formerly stigmatized health issues such as cancer and women’s health are more openly discussed today than previously, incontinence remains for the most part shrouded in silence [133,134]. Yet the effect of incontinence on self-image, emotional well-being and QoL cannot be underestimated. Lowered self-esteem, shame, embarrassment, despair and depression are often reported; incontinence can
affect the ability to form or maintain personal relationships, leading to isolation [135,136,137,138].

In such circumstances, there is a need among the general public for better awareness and understanding of bladder and bowel problems, and of the services and treatments that are available. There is also a need for both practical and emotional support to those affected and for advocacy on their behalf in pursuit of development in treatments and services. In response to these needs, continence advocacy organizations have emerged in many countries.

2. CONTINENCE ADVOCACY WORLDWIDE

A central goal of most continence advocacy organizations is the raising of public awareness and understanding of the types of incontinence, the risk factors for incontinence and treatments, services and management products available. These organizations provide a valuable voice for an often unheard consumer population in political and health-care governance, development and planning processes. In recent years, consumers and clinicians have been involved in identifying and prioritizing important areas of research relating to incontinence in order to inform research development and funding decisions [139,140]. In addition, through advocacy organisations, the consumers of health care have become more closely involved and influential in the activities of clinical professional organisations.

Another major role that has been adopted by many continence organizations is the direct provision of information support to those affected by incontinence and to caregivers. The types of information provided include background information about symptoms, risk factors and conditions, treatments and management strategies, and availability of, and access to, health and social services. Such information is provided through a variety of sources, including regularly produced magazines, internet-based information resources, telephone support lines (often staffed by qualified nursing or counseling staff), and printed media such as leaflets and booklets on a wide variety of topics. Other innovative strategies have included outreach work through travelling information roadshows and events [116]. Organisations also provide emotional supports to people with incontinence by putting them in touch with others similarly affected either through direct contact at meetings or through internet discussion forums.

For the Fifth International Consultation on Incontinence, forty-seven continence organisations in twenty-eight countries were identified, with an additional two international consumer-based organisations (Appendix 1). Continence organisations vary in scale and in nature, from small consumer or clinician groups that focus on quite specific bladder symptoms or conditions, to large and well-funded national organisations that address bladder problems generally. Often the founding and development of such organisations has resulted from the dedication of a small group of sufferers consumers, clinicians or both, who have worked tirelessly to promote awareness and understanding of incontinence among the public or colleagues and to provide better services and supports to those affected. They represent a wide diversity of models, including consumer-led, company-sponsored, consumer-only, professionals-only, and organisations which have deliberately set about trying to bring together all relevant stakeholders in a relatively democratic model. In every part of the world, these organisations play a dynamic role in building both public and professional awareness of this underserved and underreported condition.

a) Funding

The degree of funding available inevitably affects the level of work that organizations can undertake. Whereas in some countries, such as Australia, relatively strong governmental support has been provided for the work of continence support organisations, in other countries such as the USA and UK, financial support has come for the most part through charitable donations from individuals and foundations, or through the support of the pharmaceutical industry and continence products manufacturers. Most continence organisations are poorly capitalized, being either under- or unfunded (i.e., run by volunteers) and are held together initially by either a dedicated consumer advocate or an energized healthcare professional. In most cases, this professional is a urologist or nurse whose patient population includes persons with UI. In developing countries, where the need for improved awareness, support and services is often greatest, the availability of funding for continence advocacy work is particularly challenging.

Lack of funding limits the work of continence organisations, and searching for funding can present a considerable burden in terms of time and skills for an organisation’s paid or voluntary staff. The very source of funding can present additional challenges: in most parts of the world, organisations are at least partially, if not totally, dependent upon funding from pharmaceutical and product manufacturers. In order to avoid a perceived or real conflict of interest, organisations are well advised to have clear and robust policies dictating the nature of their relationships with commercial entities, to declare their arrangements fully and, if possible, to ensure that they are not dependent for funding upon only one company.

b) Collaboration

Within countries, some previously separate consumer-led organisations have merged with clinician-led organisations in order to make best use of funding available and to prevent duplication of efforts [133]. In other countries there may be good reasons why this is not possible, while in some circumstances there is merit in the independence of groups focusing on specific areas within the continence field. However, both within countries and internationally, there is much to be gained from the networking and cooperation of organisations.
Duplication of effort in the production of materials and other activities can often be avoided, and although it may not be practical to develop global and uniform strategies for continence promotion and public awareness, much can be learned from the positive and negative experiences of other organisations in other countries. For instance, in 1998, the Asia Pacific Continence Advisory Board member countries including Thailand, Korea, China, Hong Kong, Taiwan, Malaysia, Indonesia, India, Philippines, Singapore and Pakistan joined to develop continence promotion programmes that collaborated with health care professionals and the general public. Their mission was to develop strategies to increase awareness and reduce the social burden of UI in the Asia Pacific Rim.

In addition, the cooperation and coordination of continence organisations on an international level can result in more effective engagement with influential international clinical and research organisations. Professionals (e.g., urologists, urogynaecologists, gynaecologists, geriatricians, primary care practitioners, physiotherapists, nurses) and professional organisations have been instrumental in promoting awareness of continence in all care settings. The International Continence Society (ICS) established the Continence Promotion Committee (CPC) to promote education, services and public awareness about incontinence throughout the world, and to facilitate communication, exchange of information and partnerships between continence organisations, health care professionals, governments, and industry. The CPC’s multinational and multidisciplinary representation, which includes representatives of continence organisations from around the world, aims to identify broad issues through an international forum that can facilitate translation at the local and national level. Each year at the ICS’s annual meeting, the CPC holds workshops around various themes that have a broad national focus, such as prevention, GP education and promotional strategies. Its relevance, as is the case with each of the national organisations, is to recognize the interface between continence management and continence awareness and promotion. The CPC is also promoting continence awareness through the hosting of public forums in conjunction with the ICS annual meeting and sponsorship of the yearly World Continence Week.

The level of evidence on the impact of national organisations increasing continence awareness is Level 3.

3. RECOMMENDATION FOR CONTINENCE ADVOCACY (LEVEL OF EVIDENCE-3, GRADE D)

Based on the literature reviewed in this section, the following recommendations can be made:

- Research is needed on the activities or effectiveness of organisations that target consumers or the general public.

V. SERVICE DELIVERY, MODELS AND ACCESSING CARE

1. BACKGROUND

There has never been a comprehensive examination of an optimal service or model for delivery of continence care. It is not known whether academic, specialist-led centres will achieve better and more cost-effective results than primary care clinics, domiciliary services or any other model. However, most experts believe that female UI is initially most effectively diagnosed and managed by primary care providers compared to specialist services. A large cross-sectional community mail survey of women with UI in France, Germany, Spain, and the UK found that many women actually prefer to be treated for UI by primary care providers, despite easy access to specialized services [141]. Appropriately trained continence nurses and physical therapists can provide high quality UI care for women; women are satisfied with care provided by continence nurses [142,143,144]. In 2000, the UK Department of Health issued guidance on continence services that outlined a good practice model to achieve more responsive, equitable, effective continence services [145].

In the USA, the primary sources of care for the majority of Medicare patients (primarily an elderly population) are family physicians and primary care physicians [146]. Less than 1 person in 1000 is admitted to an academic, medical centre hospital [147]. Thus, in the USA, elderly persons with UI and FI will probably be seen by primary care physicians for initial assessment. This is unlikely to address the needs of developing countries (such as the Asia Pacific area or in Africa) where dissemination of expertise to rural communities and isolated community health care workers is more logical. Continence services are being implemented in several countries using shared teaching and educational resources through co-operative arrangements of the respective Continence Foundations. Thus, the general practitioner (GP) or family physician plays an important role in the first line treatment of UI that may be treated successfully with conservative treatments in the majority of patients [148,149].

In fact, UI is often a complex and multi-faceted problem, particularly in frail or dependent individuals, and it may require input from a wide variety of disciplines to tackle it effectively. Drennan and colleagues [150] interviewed thirty-two caregivers about their strategies for managing a person with UI and dementia. They recommended that professionals, especially those in primary care, could be more proactive in questioning patients about incontinence and toileting habits to identify counter-productive and harmful strategies. Symptoms typically associated with incontinence may also be indicative of other conditions, as evidenced by the urgency and frequency symptoms of BPS [151,152]. The ICI Committee 19 addresses Bladder Pain Syndrome. While it may not be practical for all specialties to work in close prox-
nity, there is a need to consider carefully specialist roles, responsibility, and which protocols will guide appropriate referrals and ensure good collaboration. It is important that there are neither gaps nor overlaps in the service.

Although some might see multidisciplinary relationships as the ideal, the reality is not always smooth. In some situations, rivalries and competition between disciplines and medical specialties is evident. This may be because of competition for patients and revenue, or because of disputes over the demarcation of the scope of different disciplines (such as the boundary between urology and gynaecology, or between nursing and physiotherapy).

Implementation of integrated service mandates can be challenging due to infrastructure limitations and other barriers. For example, despite national recommendations for multidisciplinary integrated continence services in the UK, audits indicate that this requirement is not yet being met [153,154,155].

2. NEED FOR SERVICES

There are no studies directly comparing the effectiveness of specific delivery systems for continence care. In certain cases, enthusiasts have conducted research, and results may not generalize to the wider setting. Others have combined the expertise of multidisciplinary teams to maximize service delivery. The level of evidence on service delivery models is 4.

A Japanese survey of over 1,000 caregivers of elderly incontinent people in the community found that more than 80% of caregivers are female and over half were more than 60 years old [95]. The caregivers felt that incontinence caused problems with the home getting dirty (10%), extra laundry (9%), need to wake at night (7%), and not being able to leave their homes because of incontinence (9%). When asked what kind of government service they wanted, caregivers replied “health training” (10%), “knowledge about incontinence” (10%), and “supply of a portable toilet” (3%). Only 6% wanted the government to send them professional caregivers and only 4% desired referral to a specialist physician.

Knowledge and attitudes about UI and care certainly may influence consumer choices. Some studies suggest that as QoL worsens, care-seeking increases [156]. In some cultures, particularly those where living with extended family is more common, UI may be viewed as a family issue rather than a disorder affecting just one family member [157]. Family support is often seen as an important component when dealing with UI [158].

Buckley and Lapitan[159] conducted an online survey of 1,040 community-dwelling adults in the UK to examine attitudes and behaviours related to care-seeking for UI, FI, and nocturnal enuresis [159]. Overall, 75% said they would turn to their GP for help. However, a surprising 23% said they did not know where to turn for help. This confirms that there are still major needs for continence promotion and consumer education at the community level.

This can create a dilemma and raises many questions. Should health care professionals attempt to persuade or educate people who do not see UI as a problem that it is an abnormal condition? Should a patient who is “not bothered” by symptoms be treated because the partner or caregiver requests the physician’s assistance? This is concerning as Rodriguez, et al.[160] found that physicians underestimated the degree to which patients were bothered by their symptoms 25% to 37% of the time. Is lack of bother genuine or simply a defense against having to tackle an unpleasant problem? Does early intervention prevent later deterioration in symptoms? Does delay in treatment mean that success rates are lowered? There is scant evidence on any of these issues or on the most acceptable way of providing help.

Using narrative analysis of structured patient interviews, Bradway and Strumpf[161] found that women with UI who sought professional care were more likely to “tell a story,” describe UI as having a negative impact on their sense of self, were older, Caucasian, were in ‘good or excellent’ self-reported health, and had suffered from UI longer compared to those who did not seek care [161]. They also confirmed that many women found that UI impairs their sexual health and intimacy.

In contrast, some studies have shown that compared to general health care, many women prefer to take a more active role in their care for UI. In a survey of 265 Norwegian women with UI, O’Donnell and Hunskaar found that 60% of women wanted to be actively involved in their UI care decisions compared to only 38% for their general health care needs [162]. However, this may also be influenced by the context of care and the education level of the patient [163]. The findings are not universal, and may be more associated with a desire for adequate clinical information rather than a desire to make active treatment decisions [164].

It is the impression of all members of this committee that due to the high percentage of people not seeking help for UI (for all the above mentioned reasons), health care professionals must develop the concept of a “reaching-out” service and to actively provide service for incontinence care. This means promoting awareness, openly discussing and actively detecting UI, while providing simple and efficient therapy. While not all patients with voiding disorders (e.g., bothersome lower urinary tract symptoms including urgency, frequency, nocturia, poor stream and hesitancy) have incontinence, many of these patients will also benefit from a service that will provide assessment, education and relevant treatment prior to the potential onset of incontinence.

3. MODELS OF CARE

Continence care was defined by the Canadian Continence Foundation as “all measures directed
toward the prevention, improvement and or management of UI” (http://www.canadiancontinence.ca/pdf/en_dec2000vol_1.pdf). Models of care for the frail elderly with UI are covered by Committee 11: Incontinence in the Frail Elderly. A report on continence care services worldwide noted that services were scattered, inconsistent and considerable discrepancies exist in their funding. It was concluded that there is a need for accessible (and affordable) continence care and multidisciplinary teamwork [165]. Models of service delivery for FI, BPS/IC and POP have not been defined.

The provision of continence care and services in each country will depend on the organisation and infrastructure of its health services. It is difficult to make specific recommendations that will apply in such a variety of contexts. In addition, UI is so widespread and affects men and women of all ages who receive medical care from a variety of health care providers (e.g., PCP, family physician, geriatrician, gynaecologist, nurse practitioners). This means that there will seldom be one point of entry to continence care. There has been little systematic assessment of continence services aimed at identifying an optimal service. It is not known whether academic, specialist-led centres will achieve better and more cost-effective results than primary care clinics, domiciliary services or any other model. There are no studies directly comparing the effectiveness of specific delivery systems for continence care. A range of service delivery models is described below. The level of evidence on service delivery models is Level 4.

a) Single specialist

This is a service led by a consultant or specialist physician (urologist, gynaecologist or urogyaecologist), often focused around the “urodynamic unit” providing medical or surgical treatment. This is the most common model in developed countries; the best of them have a nurse continence advisor or continence nurse specialist as an integrated part of the service.

b) Nurse specialist or advisor

In some health systems, both UI and FI have traditionally been seen solely as a nursing problem, with little interest or input from other members of a multidisciplinary medical team. Except for a few isolated areas, the main intervention has been trying to help individuals and caregivers cope with symptoms, rather than attempting to treat the underlying cause of the UI. For example, in the UK, it is common for an elderly person presenting with UI to be referred directly to the district nurse “for assessment for pads and pants,” with no physical examination or further investigation considered.

There are many examples of nurse-directed models of incontinence care described in the literature. Farrell and colleagues [166] studied a modification of UI care that involved step-wise care delivery, including a continence advisor and nurses, which were found to be as effective as the traditional medical model. In countries such as Australia, New Zealand and the UK, a national network of Continence Nurse Advisors (CNAs) or Continence Nurses liaise, integrate services, and guide individuals through the referral route most appropriate to meet their needs. The efficacy of Continence Nurse Practitioners (CNPs) in the UK was reported by Matharu and associates [167] who studied four hundred and fifty (450) women over 40 years of age who underwent urodynamic studies in the UK after seeing a trained CNP. In patients diagnosed with bladder overactivity, the CNP had prescribed drug therapy to 79% of patients and pelvic floor muscle training (PFMT) to 64.8%. In those with urodynamic stress UI, 88% had appropriately been prescribed PFMT. Nursing assessment has the potential to assign patients the correct conservative treatment thereby shortening waiting times for urodynamics and specialist assessment.

There is more evidence that treatment of incontinent community-dwelling individuals by a “continence nurse” is beneficial in terms of clinical outcomes [168]. Jeffrey and colleagues [144] assessed the clinical effectiveness and patient satisfaction with nurse-led, telephone follow-up of women with lower urinary tract symptoms. Participants were offered telephone follow-up with a nurse instead of a conventional outpatient appointment. Suitability for this option was decided by the doctor who saw the woman at her last visit. In total, 116 women received “telephone consultations” and the mean overall satisfaction score was 77 (maximum score was 100). Only 16 patients (17%) did not prefer telephone follow-up to a clinic visit. The authors concluded that nurse-led telephone follow-up is associated with high satisfaction and has the advantages of consistent follow-up by the same clinician, convenience to the patient and cost-savings [144]. Shaw, Williams, and Assassa [169] conducted a postal survey of people in the UK receiving services for UI by CNPs. Participants expressed satisfaction with nurse-led services because of the interpersonal, technical, communication and information-giving skills of the nurses.

The nurse continence advisor (NCA) may be independent, but is usually associated with community/area health centres, where they may have variable professional support from GPs and family physicians. Continence nurses often work in both hospital and community settings, and the service is focused on primary care. This is particularly true for district nurses. Key roles include patient assessment and implementation of conservative management strategies where appropriate and facilitation of patient access to incontinence product subsidies or schemes.

The Department of Health in the UK has commissioned an evaluation of different models of nursing services, with and without specialist NCAs. It was found that where there is a continence nurse incontinent people are more likely to receive a tar-
targeted referral to specialists such as an urologist, are more likely to have had investigations such as urodynamic testing and are more likely to receive appropriate treatment and care for their UI. These patients were also more likely to report satisfaction with the service. In contrast, there are still concerns that general nurses continue to "contain the problem" instead of promoting continence, despite acknowledging its importance [170].

Unfortunately, there is often still an emphasis on containment and simple management of UI rather than on active therapy. Part of this may be due to cost, which has been shown to be lower for containment compared to active continence evaluation, promotion, and treatment [171]. Even in this case, provision of care may be substandard. An audit of the continence services in the UK revealed that rationing of pads and absorbent products was widespread, with most patients limited to four pads per day [172]. In addition, 59% of the continence services surveyed provided pads for children under the age of four, which is outside of the published national guidelines. This indicates a need for improved implementation of continence services with regard to use of pads and products.

In a series of studies performed in Leicestershire UK, the short and long-term outcomes of a new CNP-led service for urinary symptoms (three and six months after implementing the program) were examined and evaluated [173,174,175]. Williams, et al.[175] reported on a randomized, controlled study (RCT) of 3,746 community-dwelling individuals greater than 40 years of age (61% women) who had incontinence, frequency, urgency, and nocturia all impacting QoL. The experimental group was comprised of 2,958 patients. The standard care was the control group (n=788) who accessed GP services and existing continence services in the area. The experimental group received an 8-week primary intervention package by the CNP (21 generalist nurses who trained as CNPs). The CNPs delivered evidence-based behavioral interventions using predetermined care pathways in four visits over an 8-week period. Interventions included advice on diet, fluids, bladder training, pelvic floor muscle awareness and healthy eating. Individuals whose symptoms persisted after primary intervention were offered urodynamic testing. The CNP led service had a 10% higher cure rate than standard care with statistically and clinically significant reductions in urgency, frequency, nocturia and UI. In addition, QoL improvements were greater in users of the CNP-led service and higher levels of patient satisfaction were achieved. This is the first study to show the effectiveness of nursing services on urinary storage symptoms (rather than simply incontinence) and associated QoL. The authors noted that the public health value of a 10% reduction in symptoms is substantial when applied to such a common problem.

An additional number of studies support the efficacy of specialist NCA in the delivery of community continence care [148,176,177,178]. In the USA, urology nurses have been trained as “teachers” to successfully implement behaviour modification programs to groups [179]. Nurses may also play an important role in the evaluation and management of POP, a condition which is often associated with concomitant UI [180].

Regional continence nurses have also been successfully incorporated into primary care practices, however they need to be given both the authority and opportunity for interactions. A survey of 22 district continence nurses found that having regularly scheduled appointments with patients who were actively involved in their assessment and management led to the best nurse provider satisfaction and sense of professionalism [181].

In the USA, there has also been an increase in nurses who specialize in dealing with patients with pelvic floor disorders including UI, FI, POP and BPS/IC/PBS, although there are no academic or clinical proficiency requirements in order to be considered a CNP or “continence nurse specialist.” Those nurses who do specialize in continence care have obtained their knowledge and skills through self-motivated activities [182]. Masters prepared or educated “advanced practice registered nurses” (APRNs) have become increasingly interested in, and knowledgeable about, the assessment, diagnosis, and treatment of people suffering with UI. These nurses are developing a nursing subspecialty in the care of individuals with UI and related pelvic floor dysfunction, providing comprehensive assessment and treatment (drug and conservative therapy), and acting as educators and researchers [183].

A 2000 study in the USA demonstrated significantly improved outcomes for three clinical problems, UI, depression, and pressure ulcers, when advanced practice gerontological nurses worked with nursing home (NH) staff to implement scientifically-based protocols [184]. In addition to working with NHs to provide resident evaluation as physician extenders, this research indicates that this service model using an APRN can be an effective link between current research-based knowledge about clinical problems and NH staff. This study also showed that consistent educational efforts with staff and NH residents demonstrated that interventions could improve or stabilize the level of UI in this population.

c) Multidisciplinary resource and referral centre

Multidisciplinary clinics, as service models, have been shown to provide comprehensive continence care. In multidisciplinary clinics, such as a “Pelvic Floor Clinic,” the gynaecologist, urologist, colorectal surgeon, and continence nurse work together [185]. Some pelvic floor clinic staffing models also include physical therapists (PTs) and registered dieticians.
An Australian study took all community referrals of those who had been incontinent for at least two months and had at least one episode in the preceding two weeks to a continence clinic [186]. Patients were randomized to conservative treatment or control, with a crossover design. Patients were asked subjective questions about embarrassment, odor, depression, family relationships, isolation, and laundry, on a 4-point scale ranging from no effect to major effect upon life. The questionnaire was completed at the start, and at 2, 4, 8, and 12 months. Seventy-eight patients entered the study and 87% improved with treatment (versus 41% controls). Fifty-two percent were moderately or severely embarrassed at the start of the study period, but at 4 months, only 17% were. Depression decreased from 49% to 22% and isolation from 28% to 12%. Odor and the use of extra laundry also decreased. All benefits were maintained at 12 months. Controls did not improve on these items until crossed over to active treatment, despite feeling better. The authors conclude that conservative treatment in a multidisciplinary community clinic improves continence and well-being.

The Continence Foundation of Australia (CFA), funded by the Australian Government, employs CNAs to answer the National Continence Helpline and to provide advice to consumers and health professionals, including referral advice [187]. Evaluation of this service indicated availability and uptake of information, as well as increased traffic to the Bladder and Bowel website and the National Public Toilet Map. There had also been a general increase in the number of consumers seeking help for their incontinence.

An expansion of this service provision is exemplified by the National Centre for Continence in Israel, which aims to provide an integrated service [188]. The Center’s professional team not only treats incontinent patients, but also educates GPs and nurses who come from pre-selected peripheral/outlying clinics. They also provide ongoing support and advice as well as a pathway for tertiary referral. A local team (GP and nurse) is also selected to be in charge of promotion, detection and treatment of incontinence at the clinic. They later become “in charge” of incontinence in their region. This model allows national distribution of continence services with support from the resource centre and provides interdisciplinary exchange, as well as maximum co-operation between Medical Centres and community health services. The national centre is funded by government and industry to provide a “Hotline” for the public, to promote education programmes in nursing and medical schools, hospitals and NHs, and to develop guidelines for diagnosis and management of incontinence by primary healthcare staff.

Multidisciplinary services should initially focus on a step-wise approach to evaluation and management. This need not be limited to tertiary level centers, but can be incorporated into care in local communities when providers with expertise are available [189].

The multidisciplinary model has also been used for delivery of community-based services. One model used a combination of clinic and home visits, multidisciplinary care delivery to targeted client groups, and use of multidisciplinary tools and provider education [190]. Overall, a generalist approach was found to be most effective in this study, although this may depend on the community context and other factors. The model shown in Figure 1 combines an academic center and community services. Although it was proven feasible, there were significant challenges due to funding and infrastructure [191]. This program in Canada is ongoing, and additional research will be needed to assess overall outcomes.

**d) Primary care**

Although primary care practitioners can certainly do a large portion of general continence care, the literature notes barriers to care provision and poor adherence to evidence-based recommendations [192,155]. This precludes efficient delivery of continence care and prevents appropriate first-line treatment. Cohen and colleagues [193] found that, among primary care providers, only 25% initiated a discussion of incontinence with their patients. In their cohort, older patients were less likely to be asked about incontinence compared with younger patients. Findings from a USA survey indicate that the majority of primary care practitioners were unlikely to ask about UI [194]. Forty percent recommended pad use for treatment, and only 17% were aware of clinical practice guidelines. The identical situation exists in other countries such as in Europe and Canada [195,196]. Although most primary care practitioners recognize that UI is common, only a minority have an organized plan for its evaluation and management, and report feeling very comfortable dealing with UI. Ten years ago, attempts by the U.S. Agency for Health Care Policy and Research, now known as the Agency for Healthcare Research and Quality (AHRQ), to use physician group interventions to raise awareness through UI guidelines failed to improve screening and management rates in the primary care setting [197]. There have been other innovative methods used to increase UI screening. Yazdany [198] prospectively randomized patient charts (n=88) to receive a chart-alert sticker (“Do you leak urine?”) that reminded resident physicians to ask about UI in their general gynaecology clinics. Overall, the rate that resident physicians inquired about incontinence increased with the alert-sticker from 4% to 34%. This method may be more easily implemented in electronic health records.

Many countries have sought to shift the provision of primary care from doctors to nurses in order to reduce the demand for doctors and improve healthcare efficiency. A Cochrane review found that quality of care is similar for nurses and doctors, since nurses tend to provide more health advice and achieve higher levels of patient satisfaction compared to doctors [142]. A RCT in the Netherlands compared usual care for UI in GP clinics to those that included
a nurse specialist [199,200]. Short-term outcomes revealed better continence rates in those patients seen in clinics that involved care by the nurse practitioners. However, the results were not sustained at the one-year follow-up, and both groups had equivalent continence outcomes. A focus group analysis with the nurse practitioners revealed that they felt competent to provide the needed services and appreciated by the patients [201]. In addition, they felt they added value to the practice, particularly since many of the GPs were seen as lacking interest in UI. Overall, the results do suggest a benefit from this type of multidisciplinary care delivery. Future research will be needed to determine if long-term outcomes can be maintained and if the model may have other unmeasured benefits, such as better cost-effectiveness.

Therefore, primary care practitioners may not be the most appropriate professional to manage UI, and this committee’s recommendations include a care delivery model (see Figure 2) based on a chronic care approach that has been used successfully in other chronic conditions (e.g., diabetes, CHF, asthma) [202].

There are many factors that can persuade health care planners about the importance of adequate investment in community continence services. The prevalence and the number of incontinent people is likely to increase with an aging and increasingly dependent population and many frail, disabled or elderly people are incontinent for reasons extraneous to the urinary system (such as poor mobility, an inappropriate physical environment or lack of an individualised care regime). It is often best to provide an initial assessment for such individuals in their usual surroundings and to reserve hospital or clinic (specialist or academic) referral for those who do not respond to simple measures such as treatment of constipation, modifying a diuretic medication, or provision of accessible toilet facilities. A number of guidelines have suggested an algorithmic, step-wise approach to UI assessment and treatment, and many conservative treatments have a good success rate in primary care [203,204,205,206].

e) Other service models

In a structured literature review, Chin and colleagues found that primary care clinics for continence led by nurses and allied health professionals were common across the world [207]. Although there were a number of differences that were culture specific, there were also a number of key factors that predicted high quality care across all cultures. These included identification and recruitment of appropriate patients, improving access to care, enhancing engagement with primary care providers, using small teams with adequate training, developing structured referral lines,
and working to employ evidence-based practices including guidelines and treatment protocols.

Group intervention models for delivering first-line treatment for UI is feasible [208,112,209] and may be an equally effective and potentially cost-saving approach to this form of therapy [210]. Even simple group education about UI in general, may improve self-care among postmenopausal women with the condition [11]. Another study has shown that non-medical lay instructors can be taught how to instruct patients in proper pelvic floor muscle exercises [211]. This train-the-trainer model may be useful to help disseminate behavioural therapy on a more widespread basis.

Education of other professionals who interact with UI patients, but do not themselves provide direct health care, may also be quite useful. For example, improved education about UI and other lower urinary tract disorders among teachers may help improve not only their own continence health, but that of their students as well [212].

Many consumers seek information from the Internet, although the quality of materials can be highly variable. Some websites include an interactive component, including e-mail of other communication methods that allow users to interact with a health educator or other professional [213]. Computerized education methods have been developed to disseminate consumer education materials about UI [214]. Usability was considered good and these methods may help disseminate continence promotion materials.

1. **Acute or Sub Acute Care to Community**

Patients with UI who receive care in acute care hospitals have been shown to lack appropriate care because of the lack of knowledge amongst acute care nurses about assessment or management of UI [215]. Nursing education must change to improve this situation. The value of tackling this is shown in a retrospective review of 6,773 episodes of care in 54 medical facilities [216]. The discharge destination was altered by the presence or absence of UI – 57% versus 82% respectively being discharged home, and 29% versus 12% being discharged to a NH or other health care venue. In addition, the time in rehabilitation was 185.6 days for those with UI compared with 156.8 days without UI, and geriatric costs in evaluation and management were higher in the UI group. The level of functional independence and motor function also impacted outcome.

Continence promotion, education and treatment may occur in a variety of clinical settings, particularly in relation to other associated clinical conditions. For example, UI occurs commonly after acute stroke. Rehabilitation nurses who work with post-stroke patients could play an important role in continence care, however research shows this may not happen.

---

**Figure 2. Proposed Continence Care Delivery Model**
regularly. A recent multinational qualitative study examined a focus group of rehabilitation nurses in the UK, Sweden and China [217]. They found that only a superficial assessment of continence was routinely performed by most nurses in this setting. The authors noted a focus on containment and social continence although process models of practice were seen in all countries. Other studies have corroborated these findings and reveal the emphasis in the rehabilitation setting is containment rather than continence promotion or active therapy [218]. The results highlight a need for systematic assessment and development of patient-centered care plans.

Heart failure is another common clinical condition, particularly among older adults, that is frequently associated with UI. A recent study of 182 heart failure patients with at least monthly UI revealed that 83% had not asked for help with their incontinence symptoms and 64% were interested in learning more [219]. Many patients, particularly those with comorbid diabetes, were contemplating changing their behaviors and seeking care.

Clinical care around the time of pregnancy and delivery is another potential time for patient education and interventions aimed at preventing or treating UI [220]. Studies have shown that women are generally very receptive to this type of clinical education in the post-partum interval [221]. Additionally, women who were instructed in pelvic floor muscle exercise by a PT during the immediate post-partum period were more likely to continue the exercises at one year after delivery compared to controls [222]. However, in many cases, this opportunity is missed due to lack of training on the part of care providers. A study of nurse midwives in Australia found that the majority do not assess for UI in the peripartum period [223]. In addition, the survey respondents indicated a lack of guidelines for nurse midwives.

2. Elder services (Long term care or nursing homes)

There is growth worldwide in the use of APRNs “continence” specialists practicing in home care and LTC settings, providing expert consultation in UI and related disorders [183,182]. Many have developed innovative approaches to management of UI in NHs. Bucci [224] developed the CHAMMP (Continence, History, Assessment, Medications, Mobility, Plan) tool to educate NH staff in the USA on a comprehensive continence assessment and to assist in implementation of individualized plans of care. The CHAMMP program improved one facility’s Quality Measure Indicator Report. ICI Committee 11 discusses services for frail elders.

Many older adults rely on home care services for a variety of health care needs, including UI. The methods used to implement and deliver services can differ a great deal depending on the care model used in a particular region. Implementation of guidelines is felt to be an important part of this process [225]. This allows care providers to try to put evidence into direct practice. A recent study examined 19 home care agencies in the Netherlands to determine if the quality of care systems influenced outcomes [168]. Most models included designation of the continence nurse and documenting UI-related actions on the patient care record. However, no differences in clinical outcomes were observed in this study of 155 home care teams. The authors concluded that additional research examining specific implemented practices would be required in the future.

Even within the long-term care setting, the focus is too often on containment and use of pads or absorbent products compared to active continence promotion or treatment. A recent Cochrane review supported this finding, and noted that none of the studies reviewed focused on attempts to maintain continence in facility residents [226].

One new innovative model has described the development of individualized continence profiles for use with NH residents [227]. This may help NH staff identify residents who may benefit from various forms of assessment and interventions. Another model has worked to involve NH residents more actively in their fluid intake and continence care. After a 12-week intervention, overall hydration status improved and time spent in wet diapers decreased significantly in a cohort of 153 NH residents who participated in the intervention [228]. Education of staff was felt to be important to the observed success in this study. Within the context of ‘person-centered care,’ there is a growing need to develop and encourage bladder rehabilitation and prevention with a proactive focus, particularly for older adults [229]. This may help to expand the focus beyond containment only in this population.

Another study found that the best performing long-term care facilities in terms of UI care generally utilized a multidisciplinary process improvement team [230]. In addition, more were likely to use a clinical practice guideline in evaluation and management compared to the poorer performing facilities.

Data have shown that a nurse’s level of knowledge and attitudes about UI may influence care within the NH environment [231]. Overall perceptions about physical functioning in older adults may also impact this issue in hospitalized patients [232]. Physical functioning is a complex entity and nurses in this focus group study identified system-level approaches that could be used to prevent additional functional decline in their patients.

Education specifically targeted at family caregivers may also be important in the promotion of continence for community dwelling older adults. A recent report by Jackson and colleagues [233] used focus groups of family caregivers and health care professionals to identify the types of materials and methods of delivery preferred by participants [233]. Most wanted printed materials such as summary brochures or fact sheets with answers to frequently asked questions.
Electronic materials were not as readily desired in this study.

Distance learning techniques have been successfully used to teach and implement programs and strategies for management of UI in NH [234]. This training method might help to improve dissemination of information, particularly in rural and otherwise underserved communities in more remote locations.

3. MODELS IN DEVELOPING NATIONS

Continence services are a relative luxury, to which countries with a low per capita income are unlikely to devote scarce resources, especially while other population health issues have precedence.

The potential demand for UI services in developing nations far outstrips the resources that are available. The provision of services will depend on dedicated healthcare professionals with support by government or industry, and by a local continence organisation to educate a new generation of service providers who will carry the services to remote communities. Increased use of advanced communication technologies can help to disseminate continence promotion materials among nurses and other health professionals worldwide [235].

In some instances, consideration will have to be given to cultural and social mores and taboos. For example, Ethiopia’s Health Minister has stressed the need to develop rural health services to reduce the incidence of fistula and to have first time mothers examined by Traditional Birth Attendants (TBAs). The ICI Committee 18, Vesico vaginal fistula in the developing world, addresses service for this specific condition. It is planned that TBAs will be trained to identify high-risk women and thereby divert expenditure from high cost physicians and urban health services to training community health workers and to health education. Attitudes on female circumcision, contraception and women’s health, matters that are often decided by their husbands, obviously have much wider implications than just continence care.

4. RECOMMENDATIONS FOR SERVICE DELIVERY, MODELS AND ACCESSING CARE

Making recommendations for interdisciplinary and multidisciplinary models for continence advocacy and service delivery remains a rather elusive goal. Although there have been more publications since the last ICI, there has been little evidence of substance generated. Implementation is quite difficult, funding is often limited, and there are few studies on outcomes. Based on the literature reviewed in this section, the following recommendations can be made:

- There is a need to move beyond the theory and work on research about the practice of continence care delivery and education. We recommend a care delivery model based on a chronic disease approach. (Grade D)
- There needs to be an increased emphasis on non-physician models of care (nursing, nurse practitioner, continence advisor, physiotherapy, physician assistants, etc.). (Grade C)
- Despite the proliferation of guidelines, there is increasing evidence that practicing clinicians are not following them. Implementation models should be developed on how to translate guidelines into practice. (Grade C)
- There still appears to be a shortage of physician specialists in continence care (urology, gynaecology, etc.) which needs addressed. (Grade D)

VI. PROFESSIONAL EDUCATION

1. BACKGROUND

With the continued advances in health care, increasing public pressure to provide high quality evidence-based care, limited time for health professionals to update their knowledge and the recognised ineffectiveness of passive ‘lecture style’ education provision, the need for new models to change health care providers behaviour is essential. Nowhere is this more relevant than in the provision of care for those with UI and FI, where educational provision has been inconsistent at best.

Professional education is a key component in the provision and care of individuals with UI and FI. In their state-of-the-science statement on the prevention of faecal and UI, Landefeld et al [8] identified that education of health care providers alone is insufficient to improve detection and treatment of UI and FI. However, they recognise that in order to appropriately detect and evaluate incontinence professional education is required along with outreach and practice-based resources. To date, the education and training of those involved in the provision of continence care has been poor.

There is limited literature on the educational preparation and ongoing training of those health care professionals engaged in continence promotion, care, and referral and even less on the evaluation of education programmes in terms of educational or practice outcomes. It has long been recognised that professional education with reference to UI and FI remains only a small part of the basic training of physicians, nurses, or allied health professionals and on-going training is largely ‘ad-hoc’ with huge variation in the types, content and quality of such training. An early survey in the UK found minimal attention given to incontinence in both medical and nurse training, and a key recommendation for improving continence care was an increase in the quality and quantity of professional education [236]. This has clearly not occurred. While educational initiatives have been undertaken, they remain fragmented and inconsistent internationally. Most notable is the absence of evidence demonstrating an impact of professional or public education on the burden of suffering posed by OAB and UI. The
ICS has established an Education Committee to promote, organise and co-ordinate all educational advances undertaken under the auspices of the ICS. Details are available on the ICS website (www.icsoffice.org).

There is a paucity of published work on professional education on UI or FI. Similarly there are few studies addressing the effectiveness of education in improving the knowledge of learners, or on whether improved knowledge impacts patient outcomes. Information has been building since the publication of the ICI chapter in 2009,[1] but the level of evidence on the effectiveness of professional education remains at Level 4. This section will examine the available evidence on the effectiveness of professional education on incontinence for different groups of health care professionals.

2. MEDICAL EDUCATION

a) Generalists (family physicians/general practitioners/primary care physicians)

Physicians (general, primary care, and family physicians) have been viewed as having a gate-keeping role in continence provision since they are often the most likely first point of contact when consumers seek formal help for their incontinence. Most physicians have received little education or formal training about incontinence, fail to screen for it, and view the likelihood of successful treatment as low, so most avoid the topic with patients. At the same time, there are no data confirming the benefits of screening as a method to reduce the burden of suffering from UI. A postal survey noted that only 18% of respondents said providers asked them to complete a questionnaire about bladder control during routine office visits, and a majority (69%) felt it would be very helpful in prompting discussion if their physician or health care professional provided a form for them to check off symptoms of incontinence [104].

Traditionally, UI and FI have formed only a very small part of the undergraduate medical curriculum. Education on UI has usually been fragmented across different organ systems, with training scattered between gynaecology, urology, and geriatric medicine. Bladder and pelvic floor anatomy is poorly covered in preclinical training and relevant physiology is rarely mentioned. A survey of urology residency directors, medical student educators in urology, and urology applicants identified UI as one of the eight most commonly cited topics to be included in a core urology curriculum [237]. Minimal training is provided on paediatric continence issues.

Recent studies have shown that there has been an overall decline in the amount of time devoted to urologic education in most medical school curricula [238]. Surveys have shown that general levels of knowledge about common conditions such as haematuria and OAB are low. In addition, respondents indicated a low likelihood of seeking urologic consultation for many conditions. A similar study found that exposure to issues of pelvic floor dysfunction in women was extremely limited in medical education, with more than 80% of medical students receiving no formal training in this area during the first two years of training [239]. This represents a critical shortfall in training, particularly since many patients with genitourinary problems will initially present to a primary care provider for evaluation and management.

A survey of program directors for internal medicine residency training programs in the USA was conducted to determine whether they felt their residents should master thirteen core competencies identified to be central to the health care of women (including UI) [240]. Although almost all felt this was an important goal, there was a large discrepancy in whether they actually achieved this level of learning. This indicates there is still a wide educational gap among primary care physicians who are often the first portal into the organized health care community for patients with UI.

There is very little available literature on knowledge among family doctors on FI. A study has recently been undertaken to explore GP awareness of surgical treatment options for FI [241]. A postal questionnaire was mailed to 1,100 GPs in the Yorkshire region in the UK, and a response rate of 48.5% was achieved. The questionnaire assessed basic knowledge of FI and treatment options. Overall knowledge was poor, with the majority unaware of available investigations, treatments and specialist centres. The authors recommend better communication between specialist centres and GPs, as well as CME programme implementation.

There is growing evidence to suggest that traditional 'lecture style' medical education is ineffective in changing physician behaviour and, ultimately, patient outcomes [242]. More innovative teaching methods are clearly required. Levine and colleagues [243] used a train-the-trainer model to evaluate the management of a number of common geriatric conditions including incontinence. This model involved training, by an expert faculty, a team of non-expert peer educators. These peer educators used a toolkit to conduct small group learning sessions, which were evaluated immediately after and 6 months after the education sessions. The model used principles of knowledge translation and active teaching using tool kits based on guidelines to train geriatricians. Results showed statistically significant improvements in self-reported knowledge, attitudes and office-based practices. The study concluded that modest changes in practice in relation to geriatric conditions were achieved using this peer-led approach. While such evaluations are promising, these models are difficult to sustain and costly. Perhaps most importantly they point to the need to use innovative teaching methods to ensure that educational efforts actually make a difference.
Web-based training and the use of standardized patient case studies has become very popular in medical education and has been successfully incorporated into residency training programs. In one recent project, training about UI was included with a number of other geriatric syndromes [244]. In fact, those internal medical residents who received the information via web-based methods had better overall test results than those who completed paper-based training.

Some models of physician education have incorporated training on UI into modules on quality care. For example, the Assessing Care of Vulnerable Elders (ACOVE) project in the USA includes UI as one of the target conditions. A recent study looked at implementation of this information into community-based physician education within practice groups [245]. These authors found that dissemination of this information was well received by primary care physicians, and some intended to make changes in their practice related to this new knowledge. Similar studies have also found that primary care physicians specifically educated about UI assessment and interventions were more likely to recommend care for UI to their patients [246,247]. Large-scale dissemination of information using these types of training models might ultimately help improve access to care.

b) Specialist physicians

There is little new published evidence on medical specialist training in the form of effective training interventions. Specialist training in incontinence is not always adequate. Both UI and FI still may be perceived as exclusive to “super-specialists,” potentially alienating colleagues.

Even among subspecialists, training may not be ideal. A survey of 163 urodynamic services in the UK found that half the respondents felt their training in urodynamics was inadequate [248]. Marsh and colleagues [249] surveyed 100 gynaecologists and urologists in the UK and found widespread inconsistent and inappropriate diagnosis of PBS/IC [249].

Increased use of advanced surgical technology has led to greater need for procedure specific training. Examples include use of laparoscopic and robotic techniques for treatment of POP. Some of these procedures have a steep learning curve and require additional training for surgeons [250]. Structured training and curricula have been developed for a variety of surgical procedures used to treat UI and POP [251]. Inclusion of this training in residency will lead to increased numbers of physicians who are qualified to offer this type of care to patients suffering from UI. A variety of models have been developed to help teach some basic skills such as cystoscopy or methods for grading the degree of POP. One option includes the use of cadaver labs [252]. Others have used inanimate objects to replicate the female pelvis and teach basic anatomic concepts [253,254]. Script concordance models have been developed to assess clinical reasoning skills related to care for UI in older adults [255]. This may allow better measurement of clinical practice behaviours for this condition.

Ongoing education and utilisation of evidence-based training with incorporation of guidelines has been suggested as a way to maintain high quality standards of treatment, particularly for surgical care of UI [256].

In the USA, there has recently been a push to develop sub-certification for specialists who care for women with UI and associated pelvic floor disorders [257]. This has involved cooperation between the certifying boards in both urology and obstetrics and gynaecology. The field of ‘female pelvic medicine and reconstructive surgery’ has recently been approved by the relevant certifying boards. This means there will soon be a separate board examination in this field. Continued emphasis on quality education for specialist physicians is needed worldwide [258]. A study of gynaecologists in Germany found that most considered their specific post-graduate training in urologic issues and urogynaecology to have been inadequate. The vast majority of general gynaecologists in this study referred their patients with voiding or incontinence issues to subspecialists in urology or urogynaecology.

3. NURSING PROFESSIONALS

Nurses have a significant role to play in the area of incontinence since they are the largest single group of health care professionals around the world and are often the first to become aware that the patient is experiencing incontinence. Cheater and colleagues [25] found that in the UK, an average community nurse case load will comprise approximately one-third of patients with UI. There have been a number of recent studies that explore the use of new innovative methods of education provision for nurses. Rogalski [259] reports a persisting lack of educational emphasis on common symptoms like UI and recommends a curriculum model based on existing guidelines and best available evidence, which could address this shortfall and would increase the quality of continence service provision.

a) Generalist nurses

There are significant gaps in knowledge and clinical practice adoption related to both UI and FI, although nurses worldwide have played a major role in developing new information and testing interventions [260]. Although nurses can provide effective interventions in the area of UI, there is limited research on effective interventions for FI.

Innovative methods of improving knowledge among nurses have undergone recent evaluation. An important study undertaken by Cheater and colleagues [261] adds to the debate by examining the value of audit and feedback, and educational outreach, which in the past has often focused on doctors’ behaviours rather than nurses’. In this study, the researchers
undertook a cluster-randomized trial to evaluate 194 nurses in 157 family practices with 1,078 patients with a diagnosis of UI. They found that when compared to educational materials alone, there were no improvements in care for either educational outreach or audit and feedback (all groups did improve, but differences between groups were not significant). McConnell et al. [73] described how advanced practice nurses learned evidence-based approaches to managing complex cases, including incontinence, in NH residents. Advanced practice nursing skills include evidence-based assessment and diagnosis for implementing management. The authors suggest that such practices can enhance both student and facility outcomes, although no systematic evaluation was undertaken.

Ostaszekiewski [262] describes a nursing leadership model to enhance continence care in older adults. Evaluation of the program suggests improved management and assessment of incontinence for individuals sustained after a two-year period. Leadership programs have proved effective in a number of areas in nursing provision. Within these more recent studies, the use of innovative methods of knowledge transfer and education are beginning to be adopted, and such methods used in other areas of professional education may be well suited to UI and FI.

Education related to UI may often be linked to training about other concomitant disorders or conditions. For example, training on prevention and treatment of pressure ulcers or dermatitis may include significant components related to UI [263, 264, 265]. Training about improved mobility in the geriatric population has also shown this educational link [266]. This can help to disseminate information about continence care and promotion to a wider audience of nurses who have direct patient contact.

Although APRNs may have good levels of knowledge and positive attitudes about treating UI in women, many have difficulty applying this directly to practice in the clinical setting [267]. These authors suggest that there needs to be increased exposure to these topics in clinical experiences during training for graduate nurses.

Programs have focused on nurse education for continence care in specific settings, such as the NH [268]. Competency-based UI education with use of case examples has been used successfully in the training of generalist nurses [269]. Experiential activities have also been used with good results [270].

b) Specialist nurses

Educational courses on incontinence are available for nurses in the UK, USA, Europe and Australia, and are beginning to appear in Asia, notably Hong Kong and Singapore. These courses vary from two to four weeks of face to face didactic courses to distance learning courses lasting 12 months that lead to a post-basic nursing certificate and, in some cases, post-graduate degrees.

In the UK, education programs are documented at the Association for Continence advice website (http://www.aca.uk.com/education_modules.php) and comprise information on 1 day courses, as well as diploma courses, degree modules and masters level study. Such databases of courses offer an excellent overview for students and providers. Likewise, the CFA (http://www.continence.org.au/pages/continence-courses.html) is an excellent resource for nurses to access information and be linked to educational organisations that provide a variety of programs which focus on or incorporate both UI and FI in the curriculum. Many can be continued through to post-graduate tertiary education. A number of these programs can be undertaken externally and therefore are popular with nurses in rural and remote areas, as well as students of nursing who practice in other countries. Clinical support is arranged to complement the theoretical components.

Internationally, there is inconsistency in the provision of specialist education to prepare nurses to practice as experts in the field of incontinence. Innovative web-based learning programs incorporating modern information and communication technology (e-learning) may offer one way of providing standardized programs of study to practitioners.

Beitz and Snarponis [272] describe their innovative on-line learning program which includes continence nursing. They feel that such teaching strategies are acceptable to nurses. As with physicians, it is unlikely that improving nursing knowledge alone will translate into improved clinical practice or into the ultimate goal of improved patient outcomes.

Jha, Moran, Blackwell, and Greenham [273] conducted a small study in the UK that showed improvements in both knowledge and attitudes of nurses who undertook a specially designed, full-time, 3 month program that included a continence module.

The level of knowledge about UI within the general nursing community appears to be less than ideal in both the USA [274, 275, 276] and Sweden [277]. Many non-specialist nurses (referred to as general nurses) desire, and have a need for, more education about what they can do to better manage incontinent patients. Moreover, the QoL of the incontinent NH resident is often more dependent upon the skill, education, and attitudes of the nursing aide than of the qualified nursing staff.
Improved education of school-based nurses regarding normal bowel and bladder habits of children may help to improve pediatric continence and promote healthy elimination patterns [278]. Although 61% of school nurses surveyed reported they had never received training on the topic, many (43%) had been asked to provide information to their teacher colleagues.

In the USA, although there are a growing number of nurses who are developing expertise caring for incontinent patients, there are no academic or clinical proficiency requirements to be considered a “continence nurse practitioner or specialist.”[279] In 1993, the Wound, Ostomy, and Continence Nurses Society developed the first certification program for continence care nurses in the USA. This nursing organization recently published a position statement on the role of continence nurses [280]. The Society of Urologic Nurses and Associates certifies different educational levels of nurses in the area of urology and in urodynamic testing. The norm is that most “continence” nurses in the USA obtain their knowledge and skill through self-motivated activities.

Recently, there has been some debate about the need to provide special education and credentialing to non-baccalaureate nurses regarding UI and associated conditions [281]. However, to date, most of the focus on UI education has been at the baccalaureate and advanced degree levels.

Other discussions have focused on whether specialty training in wound, ostomy and continence nursing should be at the doctoral level. In the USA, the new Doctor of Nursing Practice (DNP) degree may help to fill this training gap [282].

A study of 231 vulnerable elders with complex disease and enrolled in a ‘Special Needs Plan’ in the USA were shown to benefit from a nurse care management program with nurse practitioners in addition to physician care, as opposed to those who received care from a physician alone [247]. The model has continued to develop and requires further evaluation. A smaller study[168] in the Netherlands demonstrated that there were short-term benefits following referral to a continence nurse, however these benefits were not sustained long-term. Both studies demonstrate the need to further evaluate the effectiveness and sustained benefits of specialist continence nurses. A Cochrane Review[142] that explored the substitution of doctors with nurses showed similar patient health outcomes, at least in the short-term, over the range of care investigated.

Albers-Heitner and colleagues[283] evaluated the cost-effectiveness of involving UI nurse specialists in primary care compared to care-as-usual by GPs [283]. From 2005 until 2008, an economic evaluation was performed alongside a pragmatic multicenter RCT comparing patients with UI receiving care by nurse specialists with patients receiving care-as-usual by GPs in the Netherlands. One hundred eighty-six adult patients with stress, urgency, or mixed UI were randomly allocated to the intervention and 198 to care-as-usual; they were followed for 1 year. Main outcome measures were ‘QALYsocietal’ (Quality Adjusted Life Years based on societal preferences for health outcomes), the EuroQol-5D, ‘QALYpatient’ (based on patient preferences for health outcomes) (EuroQol VAS), and ‘Incontinence Severity weighted Life Year’ (ISLY) based on patient-reported severity and impact of UI (ICIQ-UI SF). Health care resource use, patient and family costs, and productivity costs were assessed. Compared to care-as-usual, nurse specialist involvement yielded slightly more favorable cost-effectiveness results. Based on these results, the authors recommended adopting the nurse specialist intervention in primary care.

c) Nursing assistants

There is also a need to address the training of nursing assistants (NAs) and aides, particularly in the long-term care setting. In the USA and many other countries, one concern is the high turnover rate among first-line caregivers in institutional and homecare settings, making it difficult to maintain desired training levels. Nursing assistants are often the people providing ‘hands-on’ incontinence care, and yet they often have the least training. Certainly, in terms of published evidence, there are few reports of efforts to train NAs. A cross-sectional study via postal survey to gather self-reported data from nurses and NAs in NHs was conducted in Taiwan [284]. Results indicated UI-related knowledge scale and practice behaviors differed significantly in both groups. The authors recommended that enhancing staff competence in incontinence care was needed in both levels of nursing to improve NH residents with UI. Educational efforts, particularly in the NH setting, must involve not only professional nurses, but NAs and other staff, as well. A study of nurses’ knowledge about UI in NHs that used a standardized examination about UI and associated care demonstrated that professional nurses answered about two-thirds of questions correctly, but that baseline knowledge among NAs and aides was much lower [285].

4. PHYSIOTHERAPY AND OTHER ALLIED HEALTH PROFESSIONALS

Physiotherapists or physical therapists (PTs) have long played a part in continence care and the management of UI. In some countries, patient self-referral to specialised PTs has become commonplace. Physiotherapist’s involvement in UI appears to be either on the basis of individual interest or through association with women’s hospitals or obstetric departments, rather than as part of a general physiotherapy practice [286]. As such, they tend to be highly motivated and enthusiastic.

Generalist PTs have been encouraged to be more aware of the risk factors for incontinence in males and females, to identify patients with risk factors for incontinence and to assist them
in seeking further advice or treatment. The “Red Flags” Project conducted in 2005 was a collaborative effort of the Australian Government’s National Continence Management Strategy and the Australian Physiotherapy Association’s Continence and Women’s Health Group to enhance HSB in people with incontinence visiting generalist PTs.

Throughout the world national physical therapy organizations have established continence physiotherapy sub-groups [287]. The International Organisation of Physical Therapists in Women’s Health represents over 20 member countries with PTs practicing continence and women’s health physiotherapy and offers professional development programs. A number of specialist continence PTs also treat men and children. Universities in many countries offer short courses or post-graduate continence education programs to PTs that may range from post-graduate degree courses to Masters and PhD programs [288].

The Scope of Practice for continence PTs may include PFM training, bladder training, management of sexual dysfunction, anorectal dysfunction and treatment of pelvic pain syndromes, FI and male continence issues.

Pharmacists have a variety of roles to play in continence care. In Australia, they have been avid consumers of continence education programs. In 2004, the Pharmacy Guild launched an educational and promotional program for their members with appropriate outcome evaluation measures. The public sees pharmacists as important and approachable sources of health information, especially information on medicines that may cause or exacerbate UI and FI. Many retail pharmacies display health promotion literature on a range of subjects, including UI. Pharmacists may also advise the consumer on appropriate continence products. Educational seminars for pharmacists are generally well received. There are a growing number of CME programs for pharmacists on the Internet, either through new products or through sites such as www.worldwidelearn.com.

Regulatory issues are often linked not only to quality of care, but also to reimbursement for clinical care and services. Reimbursement policies for services frequently determine which professionals are able to provide continence care. In the Netherlands, for example, the government pays for up to 14 visits to a PT for incontinence therapy. In the USA, patient’s visits to a PT are typically restricted by the need for referral and cost.

5. IMPACT OF CLINICAL GUIDELINES

In the past several years, there has been an explosion in the rate of development and publication of clinical guidelines for UI and associated conditions. Since the last ICI, at least 20 different guidelines or consensus recommendations have been published regarding UI and associated conditions. Many of these have been developed by professional organizations focused on urologic, gynaecologic, geriatric, or related fields. Some have been created and disseminated on behalf of national governing bodies. Several older guidelines have recently been updated using evidence-based methodology.

Most of the guidelines target physician practice, although some do include recommendations specific to PTs, nurses, or other health care professionals. Different guidelines focus on specific clinical areas, and some are gender specific. Some only examine issues related to either the assessment or the treatment of UI. Some of the treatment-centered guidelines are specific for either surgical therapy or conservative therapy. Others look at clinical conditions in specific patient populations including those with underlying neurological disorders, women with POP, or patients who have previously undergone surgical treatment for UI. There can be some confusion, particularly when guidelines present conflicting or even contradictory recommendations about specific issues of evaluation or management. Table 1 summarizes many of the recently published guidelines.

Guidelines have also been developed for different care settings. In the USA, the Centers for Medicare and Medicaid Services (CMS) issued F-Tag 315 in 2005. This guideline provides recommendations for bladder management in the long-term care setting. Nursing journals have published recommendations on ways to enhance implementation and compliance with the U.S. government regulatory guidelines [289].

Some guidelines have focused on education rather than on care delivery. The International Urogynaecological Association (IUGA) issued a set of guidelines specific for training in the area of female pelvic medicine and reconstructive pelvic surgery [290]. Other professional organizations have issued similar information under the headings of ‘consensus statements,’ ‘recommendations,’ and ‘curricula.’

Many of the published guidelines focus on younger, healthy, community dwelling adults. Guidelines for evaluation and treatment of UI and FI in children and the elderly population or those with significant comorbidity need to be developed. These will need to take into account issues such as cognitive impairment, which can influence continence status in older adults [291]. Fung [292] in a study in a large academic Veterans Affairs medical centre in the USA, used guidelines to develop condition-specific computerized templates to serve as guides for clinicians to ask questions and perform elements of a physical exam for two specific medical conditions:

UI and falls. This study demonstrated that a set of templates can be developed within an existing electronic health record system that can be used to prompt a clinician to obtain elements of a history and to perform physical examination.

In 2006, a national UK guideline was produced on UI in women [293]. Within the document, the area of surgeons’ competence is discussed; however, there is no mention of other care providers’ education and training (including GPs, nurses, physiotherapists, etc.). In order for services to be delivered effectively, primacy needs to be given to practitioners education and training in such documents.

**a) Audits and assessments of guidelines**

A number of recently published studies have examined the degree to which clinicians actually follow published guidelines. Many of these have focused on primary care providers.

A postal survey of Dutch general practitioners found that most adhered to guidelines when making the diagnosis of UI [199]. However, implementation of other measures and treatments were less robust. At least 25% reported difficulty adhering to the guideline due to lack of time, staff, diagnostic tools, competency in care delivery, and perceived low motivation on the part of patients. Others have questioned the utility of this specific guideline when viewed from the perspective of urologists [294]. They proposed future research to determine if recommendations for referral to specialists are adequate and if they will be implemented in a manner that will benefit patients. Another study with Dutch general practitioners identified therapeutic nihilism among the physicians and low motivation on the part of patients as major barriers to guideline implementation [86]. Other barriers included lack of time, difficulty explaining therapeutic options, limitations in patient mobility, and increased patient comorbidities.

A survey of primary care clinicians in the UK revealed that 56.8% agreed or strongly agreed that the NICE guideline on UI in women reflected their current practice [295]. However, more than half of clinicians indicated that they had not changed their practice to be fully compliant with the guideline. In another study, general practitioners in the UK identified knowledge limitations, time constraints, and access to resources on UI as important barriers to better implementation of the guidelines [296].

Adherence to guideline recommendations may also be less than optimal among specialist providers. Ismail [297] examined records of women undergoing sling surgery for treatment of stress UI at an academic medical center in the UK [297]. Only 45.3% of the patients had documentation in the medical record that they had previously tried conservative therapies. Documentation of underlying risk factors was highly variable. A similar study among urologists in Spain showed that compliance with guideline recommendations was less than ideal [298].

Rovner et al [299] examined published literature to determine the degree of adherence to the 1997 American Urological Association guidelines for the surgical treatment of stress UI in women [299]. They found that none of the 90 articles examined actually met all of the guideline criteria, although most complied with at least half of the recommendations. This directly influences the quality of literature available for evidence-based reviews and development of future guidelines.

Some components of guidelines may be particularly difficult to implement. For example, the NICE guideline recommendation that women undergoing PFMT should have a pelvic examination with assessment of muscle contractions may be challenging to perform in a busy clinical practice [300].

Studies have also examined the degree of awareness and adherence to guidelines among specific patient populations. Ismail reported on the results of a survey of 223 women in the UK who had recently delivered their first child [297]. According to the NICE guideline, these women should have been taught pelvic floor muscle exercises in the antenatal period. Although 95% reported awareness of the importance of the exercises, many did not have accurate information and only a small minority actually practiced them.

Guideline recommendations are not without controversy. In a retrospective database analysis of 6,276 women, Agur et al [301] noted that of women felt to have pure stress UI based on history alone, at least 25% were found to have other forms of voiding dysfunction based on urodynamics [301]. They concluded that the recommendation in the NICE guideline to avoid urodynamic testing in women with pure stress UI symptoms might be unwise and could miss other important findings, which could influence care.

Recent audits in the UK have shown that the mandate to develop and implement integrated continence care services has not been met [153,302,155].

There is even more limited data on whether adherence to guidelines actually leads to substantive changes in measurable continence outcomes [302]. In cases where organized services were available, overall quality outcomes were better compared to areas where these services were not offered [303].

A recent audit of the NICE guideline in the UK revealed that patient age may be associated with differential implementation of guideline recommenda-
tions for UI evaluation and treatment [304]. In this study, data from 7,846 women treated at either acute hospitals or primary care trusts in the UK, revealed that elderly women were significantly less likely to receive guideline compliant care compared to younger women. Actual levels of adherence by the care providers varied widely depending on the specific recommendation being evaluated. Levels of guideline adherence also appeared to differ between specialists providing care in acute hospital settings compared to general practitioners in the primary care trusts. In response to this finding, a recent editorial analysis asked rhetorically if lack of adherence to published guidelines for UI may actually represent a form of ageism on behalf of clinical providers and patients [305].

DuBeau et al[306] assessed the knowledge and attitudes of NH staff (including directors of nursing and nursing home surveyors) following revised USA government guidelines on continence care (Tag F315 - http://www.cms.hhs.gov/transmittals/downloads/R8SOM.pdf) [306]. They used a questionnaire in a convenience sample of 558 staff attending workshops. The authors report striking deficiencies in knowledge amongst staff and identified managerial structures as barriers to guideline implementation. They suggest such barriers need to be overcome in order to improve the quality of continence care.

Realistically the likelihood of obtaining adequate independent funding for effective professional education on UI and FI is unlikely in the current economic climate.

6. RECOMMENDATIONS FOR PROFESSIONAL EDUCATION (GRADE D)

Based on the literature reviewed in this section, the following recommendations can be made:

- There remains a need for rigorously evaluated continence education programmes which adhere to defined minimum standards for continence specialists and generalists, utilizing web-based and distance learning techniques alongside audit and feedback, train-the trainer models and leadership models, as well as traditional methods.

- Models of education content delivery (professional and patient education) are changing with technology with increased emphasis on Internet, web modules, etc. There needs to be ongoing quality control that includes maintenance of accuracy, methods of delivery, etc.

- There is a need for research on the most effective means to educate professional groups on continence issues. Specifically, there is need for research on:
  - The effectiveness of innovative teaching methods in improving knowledge and practice.
  - Translation of research into improved clinical practice and identification of methods by which this occurs.

- Mechanisms for increasing professional motivation to acquire education and improve performance.

VII. PRIMARY PREVENTION

1. BACKGROUND

Urinary incontinence is a highly prevalent and chronic condition that can often be prevented by addressing modifiable risk factors through primary prevention [307]. Although the evidence base for FI, PBS/IC, and POP is more limited than that for UI, the conditions share many similarities with respect to risk and treatment, suggesting that similar benefits may derive from population-based strategies [1].

Primary prevention refers to efforts directed to an individual, community or population level, to promote protective health behaviours in order to reduce the risk of these conditions. Since the Fourth ICI, there continues to be an increasing body of evidence linking incontinence with other conditions. These links provide opportunities to benefit from cooperative efforts with other health promotion initiatives. Primary prevention of UI using behavioral modification programs, including lifestyle changes (e.g., weight loss, diet modification) has been investigated in at-risk populations, including older women, childbearing and obese women, and women with diabetes. Obesity and diabetes have now been recognized as independent risk factors for UI [307]. ICI Committee 12: Adult Conservative Management reviews the evidence base for prevention of UI and POP in those persons with associated known risk factors and includes the levels of evidence for the respective interventions. Reference has also been made to prevention in other chapters, including ICI Committee 11: Incontinence in the Frail Elderly. Consequently, the focus of this section will be on the principles of population-based prevention, its application in other health conditions, and suggestions for translation into preventative programs for incontinence.

2. POPULATION-BASED PREVENTION

Recent research has predicted that due to population increases and a rise in the number of older adults, there will be a worldwide increase in the prevalence of UI by 20% by 2018 [308]. This has led to repeated calls to boost efforts to provide better continence education, promotion and prevention strategies throughout the world [235].

Prevention strategies should include education about lifestyle factors and behaviours that increase the probability of incontinence, the normal functioning of the urogenital and gastrointestinal tracts, expected age-related and developmental changes, healthy bladder and bowel habits,
and how to find the appropriate treatment providers [309]. A meta-analysis of physical activity programs found that behavioural interventions (such as goal setting, exercise prescription and self-monitoring) were more effective in increasing levels of physical activity than cognitive interventions (described as health education and the provision of information) [310]. Interventions for UI and FI (e.g., lifestyle changes, bladder and bowel training, PFMT) may also be better suited to behavioural rather than cognitive interventions. In addition, programs developed to raise awareness of continence issues should consider targeting a range of groups, including people of different cultures, ages and genders [106]. Consideration should also be given to targeting specific groups, including those who are socio-economically disadvantaged, as they may be hard to reach through population-based programs [311].

In 2011, the CFA launched a population-based campaign titled “Pelvic Floor First” to address concerns regarding the negative impact of some forms of physical activity on pelvic floor health. The campaign sought to raise awareness of pelvic floor related bladder and bowel health issues and to educate people at risk of UI and FI. Fitness instructors taught ways to minimise strain on the pelvic floor muscle when exercising. The campaign consisted of a dedicated web page (http://www.pelvicfloor-first.org.au), on-line and printed education materials, screening tools for men and women, referral information and accredited on-line training for fitness professionals. Health consumers could also obtain information materials from the web page as well as links for further support from continence health professionals and the Australian National Continence Helpline.

Community based continence education workshops have been found to increase knowledge of continence issues and continence related QoL in women. In a study of 51 women who attended a 2.5 hour workshop, there was an increase in continence knowledge that was sustained for three months after the workshop [103]. The authors conclude that learning self-management strategies are important to improve pelvic floor health and that education in a public forum may be beneficial for these patients.

In 2011, a panel of experts released a consensus statement, A Healthy Bladder [312]. This follows from consensus work conducted that has examined the evidence base for preventative strategies for incontinence,[313,314] reiterating the ongoing need for primary prevention efforts to be addressed not only by healthcare professionals, but also by policymakers and funding bodies.

Consideration should be given to the setting in which the health promotion program is to be delivered, such as schools, work places, community groups and health care institutions [315]. It is acknowledged that while some nations are successfully implementing primary prevention strategies, others have yet to effectively implement secondary prevention measures, such as assessment and management of continence conditions [316]. In Australia, the UK and the U.S.A, continence organisations have received additional support from national governmental departments and agencies resulting in greater resources being applied to preventative and continence promotion programs.

Evaluation and research are essential components of population-based prevention programs[317] and it is necessary to include funding for these as part of the program.

The WHO has stressed the importance of intersectoral collaboration involving governments, local communities and the private sector in efforts to tackle the effects of obesity and lack of physical activity upon chronic health conditions (http://www.who.int/dietphysicalactivity/en/). This type of collaboration may assist in spreading the cost of preventative programs for incontinence. A proposed diabetes population based prevention program found that governments are often reluctant to commit to high expenditure programs when the results may not be apparent until a considerable time later [318]. If a preventative program was developed for a combination of chronic health conditions, such as diabetes and incontinence, there may be economies of scale that would make funding such a program more attractive to governments, particularly when there is evidence that bladder changes and UI can be reversed if diabetes is prevented.

There have been a number of population-based prevention programs throughout the world that have been developed to reduce the incidence of obesity and chronic health problems by promoting physical activity and daily consumption of fruits and vegetables. An evaluation of a program in Australia to increase fruit and vegetable consumption in children found that increased parental knowledge as a result of the program was the strongest predictor of fruit and vegetable intake [319]. Evaluation of data from these programs is likely to benefit researchers and practitioners planning continence prevention programs for adults as well as children. The evidence for population-based prevention strategies remains at Level 4, Grade C.

3. PREVENTION OF UI IN OLDER ADULTS

Older adults are a heterogeneous group, and therefore preventive strategies for older adults need to take into consideration the well aged as well as the frail aged. It is important to involve older people and upcoming generations in health promotion research and health promotion intervention programs targeted at older people [320]. Promoting self-efficacy, such that the individual has a belief that they have the capacity and skills to im-
prove their own health, has been used in research on prevention of older, well-educated women with UI [321]. Self-efficacy improves the ability to cope with symptoms and is linked to motivation, knowledge of the benefits of making changes, and adherence to behavior change [322,323]. Self-efficacy over UI may be enhanced if women are taught self-monitoring techniques, such as adjusting fluid and caffeine intake, resolving constipation, PFMT, and monitoring voiding intervals. Self-efficacy measures, such as the Geriatric Self-Efficacy Index for Urinary Incontinence can be used to determine adherence to behavioral programs developed for the prevention and management of UI [6].

Community continence education of older adults has been advocated in several studies. A descriptive cross-sectional study conducted in China found that community-dwelling older persons often expressed negativity toward UI [158]. They considered UI as shameful, their own fault, and not preventable. Despite these feelings, they indicated that UI was not a sufficiently serious problem to justify treatment. In addition, nearly half of the nurses surveyed reported ignoring the initial onset of UI. Findings from this study indicated a great need for UI education for community-dwelling older persons and community nurses [158]. A similar conclusion, that the need for education, was drawn from a cross-sectional descriptive study of 182 community-dwelling Korean American women [324].

Workshops can be an effective tool for population-based prevention education in older women. Tanenbaum [102] carried out a quasi-experimental prospective cohort study to evaluate the effectiveness of an interactive continence workshop. Ninety incontinent women, ages 55 to 87, were involved in this study. The interventions significantly increased knowledge and attitudes about the condition (94%). Sizeable proportions of participants either initiated self-treatment strategies, such as pelvic floor muscle exercises, scheduled toileting or dietary change (43%), or sought consultation with a health care provider (42%). The authors concluded that interactive continence workshops can promote self-management and consultation seeking among older women with incontinence. Incontinence-related knowledge, attitudes, self-perceived skills and intentions for seeking care improved after attending the workshops [102]. A behavioural modification program delivered to a group of women over 55 years of age reported the preventive effects of increasing pelvic floor muscle strength and increasing time between voids upon continence status, suggesting that preventive strategies are effective in older women [309,325].

Correlations have been found between poor general health and severe UI and/or FI in frail older people [326]. There are a number of strategies (e.g., mobility training, progressive strength training, balance and walking exercises), combined with behavioral interventions (e.g., pelvic floor muscle exercises) that may be successful in improving UI in this population. A systematic review of 3 RCTs and 4 quasi-experimental studies aimed to identify conservative interventions for reducing UI in non-institutionalized frail older adults [327]. With 683 participants involved (75% female), the studies concluded that multi-component behavioral interventions, including pelvic floor muscle exercises and bladder training, can improve UI frequency. However, there is need for more RCTs to demonstrate the efficacy of multidimensional treatments to guide clinical practice in the prevention and management of UI in frail older adults. (LOE 2)

4. PREVENTION OF FAECAL INCONTINENCE

While it appears that people are seeking help more readily for UI, the problem of FI remains under-reported,[241] especially in older people,[328] and few physicians ask patients about it in those persons at-risk [329]. A variety of risk factors associated with FI is reported by Committee 16: FI: Conservative Treatment. Analysis of studies on FI is hampered by a lack of standardised terminology with regards to stool consistency, gas leakage and frequency of incontinent episodes [314,330,331]. In order to be all inclusive, search terms for FI were expanded to include additional terms, (stool consistency, gas leakage, frequency of incontinent episodes, flatus, coprocrasia). However, there were fewer matched papers about this area. Only an RCT in China revealed that PFMT is effective on the prevention of coprocrasia by sphincter preservation operation on mid-lower rectal cancer. One hundred and fifty-one participants who received the surgery were randomized to two groups. Intervention group (n=75) received PFMT for six months but the control group (n=76) did not. The results from 1, 3, and 6 month follow-ups showed that PFMT contributed a positive effect against the development of FI [332]. (LOE 2) While acknowledging that prevention of FI is important, it is recognized that more research is needed to determine the effectiveness of population-based interventions that focus on the risk factors of FI.

5. RECOMMENDATIONS FOR PRIMARY PREVENTION (GRADE C)

Based on the literature reviewed in this section, the following recommendations can be made.

- Primary prevention studies should not be limited to individual interventions, but also test the impact of population-based public health strategies.
- More high quality, randomised controlled trials are needed to strengthen the effectiveness of population-based primary prevention intervention.

patients are living longer and are at greater risk for developing a range of conditions, including urinary and faecal incontinence, as well as prolapse. In order to compete for precious healthcare resources, in this contracted global economy, continence clinicians must construct robust health economic analyses of any new treatments if we hope to see these new treatments implemented for the benefit of our patients. In this chapter we present a summary of the appropriate methods, then present a critical analysis of recent publications.

I. INTRODUCTION

Since writing the first chapter about the economics of incontinence in the initial report of the ICI in 1999, our knowledge about this subject, along with the number of treatment options, has increased substantially. The global economic crisis that began in 2008 has led to contracting budgets, both for individuals and governments, and a heightened interest in maximizing value. Economic tools are useful for understanding the value equation. Often economists are called on to enumerate the costs and benefits, and payers are increasingly using these tools to determine what treatments should be provided in order to maximize their population’s health.

The first ICI report focused on stress, urge and mixed incontinence. The last report also included pelvic organ prolapse and faecal incontinence. We have developed, in part due to the ICI, better data for understanding how to manage these conditions. For example, stress incontinence can be readily cured by a variety of conservative and surgical options, but the benefit may decay over time. Similarly, pharmaceutical companies have developed new anticholinergic treatments for the overactive bladder, but these may require prolonged administration with longstanding drug costs. Such pharmacotherapy needs to be accompanied by bladder training, which also requires patient compliance to achieve success. The immediate benefit of Botox injections is well documented, as is the fall off in efficacy over time.

The good news is that this new information is making its way into the economic analyses. The bad news is that economic analyses are becoming more complex and harder to evaluate. Because of their unique aetiologies, it is more accurate to talk about the subtype of incontinence, making the blanket term of “the economics of incontinence” less applicable. This chapter takes account of these considerations, and is arranged according to incontinence subtype.

In the last five to ten years, the “aging” of the post WWII baby boomers is changing the consumption of health care resources. The median lifespan of a woman in OECD countries is now 83 years, and rising, with similar enhanced lifespan in men. Thus
More importantly, this places an important duty upon researchers to describe explicitly where, when and how the costs were calculated. Researchers in one country need to be able to extract as much economic information as possible from the research carried out on a particular condition in other countries, to save “re-inventing the wheel” whenever possible.

Patients often observe very different “costs” for health care goods and services. In health care, we often think of cost as the amount to produce the good, whereas a charge represents the stated amount on a bill, which often includes profit for the manufacturer. Therefore, different accounting systems can yield very different cost estimates. For example, most of the hospital accounting systems in the U.S. focus on billing and payments. The charges listed on the bill usually overstate costs, on average by a factor of three, and are rarely paid in full by the payer. For example, in a study of the costs of surgery for female fecal incontinence in the US,[4] hospital “charges” were defined as the amount on the hospital bill, but the hospital “costs” were defined as the amount that the hospital actually received in payment. Only after understanding this definition can one make sense of the fact that hospital “charges” for FI surgery rose from $48 million to $57 million over 3 years, but the hospital “costs” increased only slightly from $23 to $24.5 million over the same 3 years [4].

In the U.S., many researchers prefer to use payments as the estimate for cost. Researchers have developed imperfect methods for adjusting charges with a hospital-specific ratio of costs to charges to better estimate costs [5]. Charges, however, are not always available. Integrated health care systems, including Canada and the U.K, do not routinely generate bills. For these systems, researchers have developed methods for generating pseudo-bills and cost estimates [6-8].

Many cost determination methods are used. Most analyses include a combination of “gross costing” and “micro costing” [9]. These terms are similar to the phrases “top-down” and “bottom-up”. Accounting and billing systems use activity based micro-costing methods, whereby detailed estimates of time and products (inputs) are combined with unit costs to estimate total costs. Micro-costing (or “bottom-up”) is challenging to perform because a single inpatient stay or outpatient procedure might have hundreds or thousands of inputs. For example, Morris et al[10] performed over 3621 observations to determine expenditure on urinary faecal or mixed incontinence in a one month study of 29 patients in a sub-acute care facility. Even when there is just a single input, such as a tablet, the cost can vary by location or the time of purchase if prices fluctuate.

At the other end of the spectrum, gross cost methods (“top-down”) identify a limited number of important characteristics such as the Health Care Resource Group (HRGs) in the U.K., Diagnosis Related Groups (DRGs) in the U.S or Australia, and length of stay. However, DRG costing lack precision and can be problematic because this method does not track the actual treatment activities, but are based on an average treatment. For example, in Australia the DRG for Tension Free Vaginal Tape and Colposuspension is the same. In the section of this chapter on Sacral Nerve Stimulation (SNS) for faecal incontinence, the costs for temporary stimulation and permanent implantation vary considerably between Spain[11], Italy[12] and the UK[13] as shown in Table 1.

Accounting systems are limited in that they always report the health care payer’s costs or charges. If researchers want to estimate societal costs, which are often of most interest,[9, 14] one must include both provider-incurred costs and patient-incurred costs. This distinction is important for urinary incontinence, since most providers do not pay for routine care (e.g., pads and protection). These costs are usually incurred by individuals, and in the year 2000 the routine care costs in the U.S. were $1347 per person for urinary incontinence and $1554 for people with OAB [15].

Thus the conclusion drawn by a researcher may be heavily dependant upon their perspective. For example, a study from the USA analysed Medicare claims for the treatment of urinary incontinence among women aged 65 or older for 3 years (1992, 1995, 1998) including outpatient, inpatient and emergency department visits [16]. Such Medicare claims nearly doubled over the time frame, from $128 million to $234 million, largely due to increased numbers of women treated by office visits and ambulatory (day only) surgery for items such as collagen injections. When the per capita changes were analysed, and inflation was considered, costs had actually declined by 15%. However, the editorial comment following this article points out that Medicare claims have a payer’s perspective, do not quantitate pad usage, and cannot record pharmacotherapy for urge incontinence. Since we know that overactive bladder is more common as age increases, such pharmacotherapy is likely to be increasingly important in the over 65 age group, so that the conclusion of a 15% drop in per capita Medicare expenditure is not likely to be valid representation of costs in general. The editors pointed out that the article was mainly representative of patients with stress incontinence as a result. Such methodological issues are important.

In the example described above, the “perspective” that the researchers used was that of Medicare claims. In other words, Medicare was the “payer”, not
the patient. This highlights the fact that costs can be evaluated from several different perspectives. The four most commonly used perspectives are (1) overall society costs, which includes all aspects of care and treatment (which this committee recommends), (2) the payer, such as Medicare, (3) the provider, such as a hospital or managed care plan and (4) the patient. In general, health economists prefer that a societal perspective (include all costs) is used [9, 14]. This facilitates comparison of the cost of illness across different countries. The problem is that different countries use different frameworks for reimbursing some or all of the costs of various conditions, so that international comparisons remain controversial.

2. COUNTRY SPECIFIC ECONOMIC ISSUES

From the perspective of a patient, large costs are often incurred when paying for routine care products, treatments, and long-term care. These patient costs vary by country. For example, in Sweden and Spain, the government (tax based) health insurance covers routine care products. In the UK, age-dependant patient subsidies are available for pads. In Germany and Spain, pad costs are reimbursed if prescribed by a doctor [17]. In Australia, low-income patients can apply for a subsidy to reimburse most of their routine care products, but more wealthy patients must pay all costs. In the USA, such products are rarely covered and can be very expensive [17].

The degree of government subsidy to the patient varies greatly by country. In the UK, most patients use the National Health Service (NHS) so that all office visits, tests, outpatient visits and surgical treatments are free to the patient. Pharmacotherapy does attract a small out of pocket payment for each drug. In Italy and Sweden pads are reimbursed, but not in Germany. Pads are not routinely subsidized, only at the discretion of the local Care Trust. In Australia, about 70% of patients only have government insurance, similar to the UK NHS, but 30% of patients also have private insurance so that inpatient treatments attract a rebate from their health fund. In the USA, adults over age 65 and those with a disability are covered by the Medicare program. This provides coverage for inpatient, outpatient and pharmacotherapy, although patients are generally responsible for sizable co-payments and nursing home care is capped. Those not covered by Medicare often have private insurance or Medicaid (a health insurance program for people with low incomes); nonetheless about 48 million Americans lack any insurance.

In the Netherlands, all legal residents are obliged to purchase a basic health policy (the purchase of a complementary policy covering extra health services remains voluntary). The choice of health insurer and type of health plan is free. The government establishes what is in the basic package and under what conditions people are entitled to care.

In regards to long term care benefits for those in residential care, considerable variation occurs. In the USA, Medicare and Medicaid benefits are time limited for re-imbursements to nursing homes and other assisted living facilities. Usually, after several months, benefits stop and payment must come from private insurance or the patient’s pocket. In Australia, low income patients who have no private superannuation (pension fund) can receive the “old age pension” which covers fully funded long term care, albeit in lower-calibre facilities than would be chosen by those who could afford better (similar to the Netherlands system). In Japan, generous long term benefits are provided to long term institutional residents, so that out of pocket payments are reduced.

3. COSTS AND TIME

Costs change over time and researchers need to account for temporal changes in their analysis. The easiest way is to present the costs in a specific year (e.g., 2012). Costs borne in past years should be inflated. In many countries, the governments track and publish inflation indices. In the US, inflation is represented in the Consumer Price Index (e.g., www.stats.bls.gov). In the UK, the Health Service Cost Index or the Retail Price Index, published by the NHS Executive, Leeds, UK, can be used to adjust the costs of health care services (www.statistics.gov.uk).

Caution is needed because general inflation relates to the cost of a consistent set of goods over time, e.g., the goods must be of the same quality over time, and thus the costs observed five years ago can be observed today. If so, then the inflation index is informative. However, medical goods change rapidly as does their quality. For example re-usable laparoscopic equipment has been replaced by disposable equipment that is usually more expensive, and the newer drugs for OAB are generally more expensive. This makes it difficult to determine whether any change in price is due to inflation or due to (real or perceived) improvements in quality. Thus, just inflating costs from many years ago can be misleading. Consequently, many researchers recommend against using price indexes that are developed specifically for medicine because these indexes do not take quality into account. Researchers must also be cognizant of the fact that the published success rates for various treatments change over time. For example, in Adang et al. [18] dynamic graciloplasty is portrayed as having a stable success rate over time in the treatment of faecal incontinence (see Figure 1). In fact, we now know that dynamic graciloplasty has a very poor success rate over 10 years, so that the estimated data shown below in Figure 1 from 1998, is no longer accurate.

In addition, many continence treatments have costs that extend into the future. Drug treatments require that patients take drugs in the future. People have time preferences for money and future costs should be discounted to represent the present value. Controversy exists about the appropriate discount rate [19-21] but most international studies use a discount rate of 3% per annum. See Adang et al. [18] for example.
In summary, defining and measuring costs in health care can be imprecise. Often there is variation across regions and time. This variation needs to be taken into account in the economic analysis and the easiest way is to conduct sensitivity analysis to investigate how different cost estimates can influence the results. By this we mean re-running the analysis with different input parameters. As we describe in the next section, explicitly describing these contextual issues is crucial for interpreting results.

III. TYPES OF ECONOMIC ANALYSIS

1. OVERVIEW

A typology of economic analysis for health and medicine has emerged over the past few decades. This section reviews these studies.

a) Cost of illness (COI)

As already described, COI studies summate the costs related to a condition for a given population. The costs are annualized for a given year (i.e., 2012). A COI is a descriptive analysis. However, COI studies provide little information to decision makers about how to allocate scarce resources for treating conditions, because there is no attempt to measure the “value” of the relevant treatments.

b) Cost minimization analysis (CMA)

CMA compares the costs of alternative health care strategies, assuming that the benefits of the alternatives are equivalent. When the two treatments are truly equivalent in their risks, outcome, and an individual’s preference for them, then a cost minimization analysis is sufficient; the cheapest intervention is to be preferred.

c) Cost consequence analysis (CCA)

CCA is a variation on cost-minimization analysis, which involves assessing whether a new treatment results in a greater decrease in health care utilization than another treatment. Thus costs of the intervention are compared to health care utilization, such as the cost per hospitalization averted. There is a naturally appealing rationale for conducting this analysis. Unfortunately, when examined in detail, this rationale boils down to an analysis of whether the new treatment saves money in comparison to the alternative treatment. Accordingly, a cost-utility or cost-benefit analysis provides many advantages over a cost consequence analysis.

d) Cost-effectiveness analysis (CEA)

CEA refers to the broad class of calculations where the effectiveness measure is a general health outcome. CEAs with narrowly focused health outcomes (e.g., incontinence episodes) have well-known limitations. Most notably, the use of narrowly focused health outcomes will miss other important effects. For this reason, there has been widespread agreement on the use of quality adjusted life years (QALYs) as the preferred health outcome in cost-effectiveness analysis. In the US, CEA has become synonymous with cost-utility analysis.

e) Cost-utility analysis (CUA)

CUA refers to a CEA when QALYs are used as the outcome measure. Gold et al.[9] and Drummond et al.[14] have published texts that discuss standard techniques for conducting a CUA. In health and medicine, the CUA is considered to be the gold standard. Utilities capture all potential benefits of an intervention and allow comparisons with other health conditions, making cost-utility analysis a powerful research tool.

Compared to other medical fields, we have insufficient data on utilities in incontinence or on the effect of treatment or change in incontinence severity upon cost utility measures, to date.

Data in a CEA and CUA are represented by an incremental cost-effectiveness ratio (ICER). The ICER represents the average cost of the intervention group minus the average cost of the control group. This amount is then divided by the average utility of the intervention group minus the average utility of the control group (see Section IVb).

f) Cost benefit analysis (CBA)

Involves measuring the benefits in dollars. When everything is measured in dollars, optimal choice can be easily found by addition and subtraction. However, it is difficult to measure benefits in dollars, and many researchers and policymakers are averse to placing a dollar value on life. CBA is rarely used in health.

g) Summary

COI and cost-minimization analyses are simple, yet limited economic tools. Most new treatments offer ad-
2. DETAILS OF DECISION ANALYSIS

Decision analysis is a tool that can be used to summarize effectiveness data, costs data, or combine both cost and effectiveness data in a CUA. The value of decision analysis is highlighted by a multi-site clinical trial by Albo and colleagues [23] that compared Burch colposuspension to fascial sling for stress incontinence. They concluded that the fascial sling yielded a higher rate of successful treatment, measured as a composite outcome, but also resulted in greater morbidity. Even in well-designed multi-site clinical trials, the results may be ambiguous. Decision analysis may be used to overcome this ambiguity. Decision analysis is a quantitative probabilistic tool for resolving problems when there is uncertainty with regards to treatment options.

There are two primary decision analytic methods (see below); each has its strengths and weaknesses. The starting point with any decision analysis is a clinical question, such as how to treat women with stress urinary incontinence or how to treat patients with faecal incontinence (see Fig 2 below from Dudding et al., 2008 [13]). The question should fully and fairly address the clinical questions. One might develop add on questions, such as how to treat women who had surgical failure or sacral nerve implants that become infected or in which leads migrate, but it is often best to address these more specific questions as part of the broader decision analysis.

A benefit of decision analysis is that researchers can combine data from multiple clinical trials and marry that data to observational information (e.g., long-term follow-up data). Decision analytic tools are flexible and can be used to identify the treatment that maximizes quality of life. One can also use the same model to address issues of cost-effectiveness. Hence, one of the first tasks in the decision analysis is to identify the primary outcome. Outcomes such as quality adjusted life years (QALYs), that can reflect treatment and disease, are recommended. By using QALYs, one can overcome conflicting data—for example, the finding that vaginal slings have higher success rates but also greater morbidity. As is discussed elsewhere in this chapter, QALYs value all aspects of quality of life and include mortality. Next, the researcher must

![Figure 2. Decision tree for SNS treatment of faecal incontinence modified from Dudding et al (2008) with permission [13]](image-url)
determine whether the model will include cost information or not. Some decision analytical models focus only on outcomes, while others add cost data to address resource allocation questions.

By combining data from multiple sources, decision analysis can be used to model lifetime costs and benefits. Researchers are often asked to identify the treatment(s) that maximizes lifetime benefits or lifetime cost-effectiveness. Randomized trials, while the gold standard for assessing causation, are time limited, often following participants for less than five years. Decision analysis can extend such data to consider future events, such as surgical failure rates, nursing home admission or life expectancy. Decision analysis can also be used to understand whether the analysis differs by perspective. Payers, providers and patients all have different perspectives, and decision analysis makes it relatively easy to consider each of these perspectives and whether they differ from a society perspective.

a) Steps in a decision analysis

Decision analysis can be boiled down into five steps. The first step involves identifying the structure of the problem and this requires the listing of all decision alternatives, all clinical outcomes, and a sequence of events. After completing step one, step two involves assigning probabilities to all chance events (e.g., death). Step three involves quantifying the benefits (e.g., QALYs) for all outcomes. The fourth step involves the mathematical calculation of expected utility for each strategy (or this can be taken from published data). Step four will often identify the preferred strategy. The final step involves conducting sensitivity analysis to check that the model is robust across a range of clinically meaningful possibilities.

Every decision model involves some assumptions. Frequently, assumptions are needed to incorporate clinical trial data in the model. For example, a common assumption is that the effect shown in a clinical trial is generalizable to the broader population—treating women with TVT will result in effects like those seen in Lier and colleague’s paper[24] (discussed later in the chapter). Some assumptions may seem trivial, but it is best to delineate each assumption along the way. Published decision analysis should include a table of assumptions along with other data inputs; frequently this is the first table in the decision analysis.

The clinical question and the structure of the problem (step 1) should provide guidance on the decision model. Frequently decision trees are used because they are simple and address the question at hand. Decision trees are so named because they look like a tree with a trunk, branches and leaves. For example see Figure 3, taken from a study of Botox therapy versus clam augmentation cystoplasty by Padmanabhan et al[25], to be discussed later in this chapter.While decision trees are easy to describe and conduct, it is hard to include changes over time in the analysis. Diseases often change over time and people may transition into and out of different health states over time. One strength of Markov models is their ability to include these time-related transitions. We will discuss decision trees first and then Markov models in more detail afterwards.

Figure 3. Decision tree for Botox treatment of severely refractory neuropathic DO patients, modified from Padmanabhan et al (2011) [25]. * indicates the treatment algorithm continues along the augment pathway
b) Decision Tree

In a decision tree, there is a distinction between a decision node and a chance node. A decision node is a point where a choice is made by the decision maker (typically a physician or patient). For example, for a woman with stress incontinence, the choice to operate (yes or no) would be represented with a decision node. A choice must have at least two options and more than two choices are permitted. However, each choice must be mutually exclusive. A patient cannot choose both operation and no operation. A chance node is a point where chance determines fate. For example, the decision maker chooses to operate or not operate, and hopefully the treatment is successful, but treatment success or failure is a chance node. Not only must chance nodes be mutually exclusive, but they must also be collectively exhaustive (one of the chances must happen and the sum of probabilities for all of the chances must add to 100%).

In addition to chance and decision nodes, there are terminal nodes. These nodes are the final outcome for the pathway taken. Sometimes understanding the nodes makes more sense when looking at the pictorial representation. Figure 4 shows a hypothetical decision tree for treating a patient with stress incontinence. In this hypothetical situation, we structure the model to have two options: surgery or drugs. It is overly simplistic in that we do not differentiate between drugs.

The main choice is surgery versus medical management. Surgery carries some risks—a small probability of operative death, for example, in the case of clam cystoplasty for refractory detrusor overactivity. The decision nodes are represented by squares while chance nodes are represented by circles. The terminal nodes are cure, no cure, operative death or non-adherence, which is the same as no cure. This is a hypothetical decision model, and most decision models are much more complex. Clearly this model could be expanded to include behavioral treatment and each decision node could be expanded to consider all relevant alternatives (autologous sling, Burch colposuspension, tension-free vaginal tape, trans-obturator tape).

For the next step in the decision model, one must include probabilities at each chance node. We must identify the probability that the disease is cured after operation. Researchers should review the published literature to find this probability and ideally some information about the distribution around this probability (e.g., probability = 58% with a 95% CI 51-68%).

After including probabilities, one must place values next to the terminal nodes. These values must be a single outcome and QALYs are preferred, although life years (unadjusted for quality) are used for some diseases. With outcomes and probabilities, one can then "run" the decision tree. Because there is one decision node with two options, we will be computing expected values for the two options. Running the model involves starting at each endnode and working left or backwards. The expected value for the surgical survival node is 3.8 QALYS. (Figure 5)

The expected value for the surgical operative death node is 0. When we combined a 10% chance of operative death (0 QALYS) and a 90% chance of survival (3.8 QALYS), we find the expected value of surgery is 3.42 (Figure 6). If we do the calculation for the lower branch, we get the expected value for drug therapy is 3.76 QALYs. Because 3.76 > 3.42, we would recommend surgery over drugs IF the sensitivity analysis shows this result to be robust. The decision tree in the example focuses on QALYs for UI treatment and it ignores cost differences, but it could be easily modified to include cost information.

c) Markov Model

The decision tree, as shown above, assumes the chance of events is stable over time. Our knowledge about urinary incontinence suggests otherwise. A person, for example, could get surgery for stress incontinence, but over time we need to include the potential for surgical failure. Markov models are good
for incorporating changes in health states over time. At their core, Markov models are mathematical techniques, derived from matrix algebra, that describe the transitions a cohort of patients make among a number of mutually exclusive health states over time. The model works by cycling to make new calculations for each period of time.

The pictorial depiction of a Markov model is typically shown as a decision state. Figure 7 shows a very basic four-state Markov model. At each period in time, a person has to be in one and only one of the states. But with each change in time (cycle), the person can move to another state, shown with arrows, depending on the possible states and a probability. If the person dies, they are shown to enter the death state. The person cannot leave this state.

Some aspects of the Markov model construction are similar to a decision tree. Setting up the model is quite similar. One must identify the health states and the transition probabilities. What is quite different is that one must determine the cycle length—the rate at which you allow people to change states. The cycle length should be a clinically meaningful period of time and this choice is also frequently affected by the availability of data. There may be publications showing annual failure rates for surgery and so one could choose an annual cycle. For a Markov model, one needs to know the value for each state. Again, QALYs is the preferred metric. When the model runs, the program keeps track of the amount of time each person spends in each state. Transitions to other states are handled by transition probabilities (i.e. the likelihood of cure or failure). Decisions, such as the decision to change from one treatment to another, can affect transition probability. Models can use cohort simulations where a large hypothetical cohort of patients is run through the model. This does not provide information on the distribution of expected values. Monte Carlo simulations run each patient through the model a large number of times (e.g., 10^4). In doing so, this provides a distribution and variance information on patients.

With Markov models, sensitivity analyses remain a crucial step to test the robustness of the model. Recent advances in sensitivity analyses and in the graphical presentation of data general require the use of specific software. Although some people program Markov models into a spreadsheet, such as Excel, both Tree Age and Decision Maker software, are well known for their ability to streamline decision analysis and provide many advanced features that would be very difficult in Excel.

3. STATISTICAL ANALYSIS

In the last ICI chapter, we discussed alternative statistical techniques, but did not discuss bootstrapping, which has become quite common in cost-utility analysis, especially in analyses alongside clinical trials. Bootstrapping is a method of resampling that enables researchers to estimate parameters based on the observed sampling distribution. It is particularly useful when estimating the confidence intervals for the incremental cost-effectiveness ratio (ICER). The ICER involves dividing the mean difference in costs by the mean difference in utilities. Statistical software can easily determine whether two samples have different costs or different utilities (e.g., t-test). But software cannot easily calculate the confidence interval around the ratio of these two differences. Bootstrapping involves randomly drawing cases from the sample and replacing the case back in the sample. Resampling is done until the original sample size is met. The same process is then done again and again, typically 4000 times. Thus, by resampling, the analyst can calculate the ICER 4000 times, thereby providing a distribution around the ICER.

4. BUDGET IMPACT ANALYSIS

Providers and payers often have priorities that are not directly addressed by a cost-effectiveness analysis from a societal perspective. Budget impact analysis (BIA) was developed to inform a decision maker on how alternative technology will affect their budget. A BIA will often focus on the decision maker’s costs and over a short time frame (e.g., 1-3 years). Other parameters in the model, such as patient characteristics or input costs, can also be tailored specifically for the
decision maker. Making decision based solely on a BIA can lead to suboptimal societal results. Hence, scientists advocate that a BIA be done in conjunction with a CEA so that decision makers are informed about the broader social implications of their decision. The International Society for Pharamacoconomics and Outcomes Research (www.isPOR.org) has created guidelines for conducting a BIA and these can be found on their website.

### IV. PRACTICAL ASPECTS OF ECONOMIC ANALYSIS IN THE CONTINENCE FIELD

#### 1. HEALTH OUTCOME MEASURES SUITABLE FOR USE IN ECONOMIC ANALYSES

There are a number of health outcomes that are used in economic evaluations of incontinence. These include disease-specific outcomes, health status and health value (e.g., QALY). Each is discussed in turn.

**a) Incontinence specific outcomes**

Cost-Effectiveness in Health and Medicine[9] recommends using QALYs as the effectiveness measure in the CEA. However, the panel also notes that analysts can use a clinical outcome measure. For incontinence, clinical outcome measures include 24-hour pad test, a voiding diary, or urodynamics. These outcomes are attractive for clinicians because they often use these measures in clinical practice.

Clinical outcomes can be very valuable in identifying when a treatment is efficacious. However, using clinical outcomes in a CEA yields results that are limited in scope. A treatment might have improved a person’s quality of life, but had little effect on the clinical outcome measure. In this case, the results would be biased. In addition, a CEA with a clinical outcome measure might not be comparable to another CEA with a different clinical outcome measure. A clear advantage of cost utility analysis is that QALYs can be generalized beyond incontinence. For this reason, QALYs and CUAs are the gold standard.

**b) Health Status and Quality of Life Measures**

There are a number of frequently used and highly regarded general health status measures, such as the SF-36, the Sickness Impact Profile and the Nottingham Health Profile, which describe a person’s current health state. Instruments that assess how a person perceives or feels about their health state are called quality of life (QOL) measures.

Chapter 5 in this book reviews generic and disease – specific quality of life measures, which are useful for understanding the effects of a treatment. However, because they cannot be used to create QALYs they are of limited value in economic analysis. An example of an exception is the SF-36 for which Brazier et al. [26] have created a utility scoring system known as the SF-6D.

**c) Health value**

Although there are several ways of measuring the value of a health state, the most common are willingness to pay (WTP) [27] and the quality-adjusted life year (QALY). We focus on QALYs as they represent the current standard for measuring health value in cost utility analysis.

QALYs denote the relationship between the value of a given health state and the length of time a person lives in that health state. The value of a given health state is measured in ‘utilities’, where ‘utilities’ represent preferences for a given health state.

To understand utilities, consider the following: most people would prefer to be healthy over a given time rather than suffer constant urinary or fecal incontinence. Utility measurement refers to valuing these preferences on a perfect health-death scale with endpoints of 1.00 and 0.00, where 1.00 is perfect quality of life (best imaginable) and 0.00 is death equivalent quality of life. For example, the measured utility for urinary incontinence may be 0.60. If treatment improves this to 0.70, then the value of the treatment is 0.70 – 0.60 = 0.10. If this utility gain is maintained over time, say for 10 years, then the gain is 0.10 x 10 = 1.00 QALY. Because utilities are measured on an absolute scale (perfect health to death), they can be used across different health states and therefore can be used to compare the effect of interventions in different health fields, or different interventions within the same field. For example, the QALYs gained from treatment for incontinence could be compared with those gained from treatment for depression. Where treatment costs (including costs to the patient) are known, the treatment providing the lowest incremental cost-per-QALY gained is preferred as this ensures society gains the greatest benefit from the health care dollar.

Direct and indirect methods have been used to elicit utilities [28]. The most common direct elicitation methods for valuation include time trade off (TTO), standard gamble (SG), and the visual analog scale (VAS). For description of these methods, see our previous chapter in this ICI series [29].

#### 1. INSTRUMENTS MEASURING UTILITIES SUITABLE FOR QALY CALCULATION

Multi-attribute utility (MAU) instruments can be used instead of the direct elicitation methods. Simply, a MAU-instrument decomposes HRQoL into health domains (e.g., mobility and emotions). Respondents provide estimates for each attribute, which are then “valued” and summarized into a utility. The three most commonly used MAU instruments are Quality of Well Being Scale (QWB), Health Utilities Index (HUI) and EQ5D (as reviewed by Hawthorne & Richardson[30]).

**Quality of Well-Being Scale (QWB)**

The QWB has three dimensions (Mobility, Physical Activity, and Social Activity), with 3–5 levels each,
and 27 illness symptoms [31]. The QWB requires trained interview administration (15–35 minutes), although a shorter version is available; a self-report version is under development. The upper boundary is 1.00, lower boundary is 0.00.

Health Utilities Index (HUI)

The HUI uses 12 items that measure 8 domains (Vision, Hearing, Speech, Ambulation, Dexterity, Emotion, Cognition and Pain). The upper boundary is 1.00, lower boundary is –0.36.

EQ5D

The EQ5D was developed by the Euroqol team from 7 European countries [32, 33]. It has 5 items measuring Mobility, Self-care, Usual Activities, Pain/Discomfort and Anxiety/Depression. The upper boundary is 1.00, lower boundary is –0.59. This has become a very popular instrument in clinical trials because it has been widely used in many languages and it is very brief.

A recent study [34] tested the effect of stress urinary incontinence on quality of life, as measured with the EQ5D. Investigators in the Stress Urinary Incontinence Treatment (SUIT) study, a 12-month, prospective, observational, multicenter study multicity in four European countries, described the association of SUI symptoms with the EQ5D among 3762 women seeking treatment for symptoms of SUI. Participants had a mean age of 58 years, mean body mass index of 27.7 kg/m2, and had at least one comorbidity in addition to UI. The health state index scores were significantly and independently influenced by the presence of comorbidities affecting quality of life, total number of stress and urge incontinence episodes. In summary, the number of incontinence episodes and type of UI had a significant impact on the EQ-5D index score.

SF-6D

Whenever SF-36 raw scores are available, SF6D utilities can be computed [26]. The SF-6D measures physical functioning, bodily pain, mental health, physical role, emotional role, social functioning, and vitality. The endpoints for the SF-6D are 1.00, and 0.30 for the worst possible health.

The 15D

The 15D was created in Finland. It has 15 items, measuring Mobility, Vision, Hearing, Breathing, Sleeping, Eating, Speech, Elimination, Usual Activities, Mental Function, Discomfort & Symptoms, Depression, Distress, Vitality and Sexual Function [32]. The upper boundary is 1.00, lower boundary is +0.11.

The 15D is a generic, comprehensive, standardized, self-administered measure of HRQOL that can be used both as a profile and single index score measure [35]. The single index score (15D score) on a 0-1 scale and representing the overall HRQOL, is calculated based on population-based preference or utility weights. The 15D scores are shown to be highly reliable, sensitive and responsive to change, and valid for deriving quality-adjusted life years (QALYs) gained for resource allocation purposes. The 15D score is sensitive to urinary incontinence in a cross-sectional study [36, 37] and is sensitive to change in incontinence severity following intervention [24, 38]. A recent population-based survey of over 3700 Finnish adults found that increased severity of urgency and urgency urinary incontinence is associated with statistically significant decreases in the total 15D score and on all 15D dimensions (p<0.001 for all) [36].

The Assessment of Quality of Life (AQoL)

The Assessment of Quality of Life (AQoL) includes five dimensions: Illness (not used in utility computation), Independent Living, Social Relationships, Physical Senses and Psychological Well-being [39]. The upper boundary is 1.00, lower boundary is –0.04.

The Rosser Index has two dimensions measuring disability and distress, and measured 29 health states. Values (magnitude estimation) were from a convenience sample of 70 respondents [40]. A revised version in the early 1990s included discomfort as an additional dimension [40]. Administration requires a trained interviewer. The upper boundary is 1.00, and the lower boundary –1.49, which means that health states worse than death are permitted.

Note that many people with incontinence are not cognitively able to complete a MAU or go through a standard utility elicitation process. Some of the MAUs, such as the HUI3, have been validated for use with proxies. Although not always possible, if proxies are expected then proxies should be gathered for all cases, even those patients who complete the utility measure themselves, so that the method is applied in a standard, consistent fashion.

2. “DO IT YOURSELF” - HOW TO CONDUCT A COST UTILITY ANALYSIS: THE COMMITTEE’S RECOMMENDATIONS

The cost utility analysis (CUA) now represents the gold standard for medical decision making. Therefore, the remainder of this section highlights ten key issues that must be addressed in a CUA. These ten principles, summarized below, comprise an appropriate minimum standard for performing and reporting cost utility analyses. The principles were identified from guidelines established by the Panel on Cost-Effectiveness in Health and Medicine convened by the United States Public Health Service [9]. Each principle should be explicitly addressed in every study.

a) The Research Question must be clearly stated. All CUA results must compare at least two different treatments or interventions. One of these should include the current standard practices. For example, when comparing surgeries for stress incontinence, one of the comparators should be a longstanding method, avoid comparing two new methods side by side.
b) The **Time Frame** over which costs and benefits are measured should be long enough to capture the economic impact of an intervention and future health outcomes. Pharmacology studies of 12 weeks duration give very little real economic information, and surgical complications/ failures seldom emerge in less than 1-2 years.

c) **Perspective**: The choice of perspective should be clear. Total society perspective (all payers) is the gold standard. Other perspectives, such as the payer or patient perspective, may be useful but must be stated clearly.

d) **Probabilities** are needed for each “chance” event, such as chance of cure or chance of an adverse event. The best sources of probabilities come from meta-analyses of randomized clinical trials, or if not available use data from individual clinical trials.

e) **Costs**: Units of expense and unit costs should be described in detail. Information on the source (e.g., charges, payments) and year of the cost data should be presented. If the costs were inflated and/or converted from another currency, then this must be described.

f) **Outcome Measure**: Measures of effectiveness depend on the type and objectives of analysis. Quality adjusted life years are the gold standard, as described previously in this chapter.

g) **Analytic Model**: Each intervention being assessed must be described and possible courses of events identified, including the expected course of disease, treatments, complications, and outcomes. This may be performed using a spreadsheet/ clinical trial path, or Decision Tree, or Markov Model.

h) **Discounting**: Since the value of both costs and benefits may decrease over time, discounting is used to calculate the present value of money and health states that will occur in the future. Future costs and utilities should be discounted to present value; 3 % per year is a recommended starting point.

i) **Incremental Analysis**: The purpose of a CUA is to describe the relative value of one health care strategy compared to another. An incremental cost-effectiveness ratio (ICER) is the incremental cost divided by the incremental effectiveness of intervention a compared to intervention b, and is calculated as follows.

\[
\text{ICER} = \frac{\text{Average Cost}_{\text{intervention A}} - \text{Average Cost}_{\text{intervention B}}}{\text{Average Utility}_{\text{intervention A}} - \text{Average Utility}_{\text{intervention B}}}
\]

Averages should be used rather than other measures of central tendency, such as medians, because it is important to include the effect of outliers. The leverage of the outliers should be tested in a sensitivity analysis.

j) **Sensitivity Analysis**: A sensitivity analysis should allow the reader to understand whether the conclusion of the analysis would hold true if either the Costs or the Probabilities (of cure or complications) were to vary substantially. For example if one treatment costs €5,000 and has a cure rate of 90%, and the second treatment costs €2,000 with a cure rate of 80%, then the ICER will assess whether the resultant benefit in QALY/ Quality of Life makes the first treatment worthwhile.

Having reached this conclusion, the researcher should then vary the costs and the cure rates in the model, to see how much variation in real life would be allowed yet still maintain a valid conclusion.

Documenting these boundaries helps define the conditions under which a treatment is preferred. Researchers are developing innovative methods for conducting sensitivity analyses. Probabilistic models that use simulations are becoming more common, although they can be computationally complex. Some journals require probabilistic sensitivity analyses.

V. SUMMARY OF RECENT ECONOMIC ANALYSES

Two trends stand out while reviewing the recent literature. First, many studies are choosing relatively short time frames. This makes it difficult to project the long-term economic consequences. Second, a number of studies are claiming that one treatment is dominant with very small differences in parameter estimates. This raises questions about whether one treatment is non-inferior.

1. **SURGERY FOR STRESS INCONTINENCE**

Previous reports from this ICI committee[41] on the cost-effectiveness of surgical treatment for stress incontinence can be summarized as:

- minimally invasive surgery (TVT, injectable therapy) are likely to be cost-effective compared to more invasive surgeries like the Burch colposuspension
- studies are limited by poor longer-term data on the effectiveness of less invasive procedures, lack of primary and/or generalizable data on costs, clinical outcomes and utilities and not using a accepted and generalizable outcome (cost per QALY or cost per “cure”)
- there is a need for longer-term follow-up data from methodologically rigorous randomized trials to provide a better data to estimate the relative benefits and cost implications
Since the last ICI meeting in 2008, few cost-effectiveness analyses of surgical interventions for stress incontinence which systematically compare costs and outcomes within an RCT framework have been published.

In late 2008, the U.S Urinary Incontinence Treatment Network group estimated costs for incontinence management, health-related quality of life, and willingness to pay for incontinence improvement in women electing to have surgery for stress urinary incontinence [42]. This cross-sectional study included 655 incontinent women enrolled in the Stress Incontinence Surgical Treatment Efficacy Trial (SISTER), a randomized surgical trial. Baseline out-of-pocket costs for incontinence management were calculated by multiplying self-report of resources used (supplies, laundry, dry cleaning) by national resource costs (in 2006 USD). Post-treatment costs were given in a later report.

Health-related quality of life was estimated with the Health Utilities Index (HUI) Mark 3. Participants estimated willingness to pay for 100% improvement in incontinence. Potential predictors of these outcomes were examined by using multivariable linear regression. Mean age was 52 ± 10 years, and mean number of weekly incontinence episodes was 22 ± 21. Mean (SD) and median (interquartile range) estimated personal costs for incontinence management among all women were $14 ± 24 and $8 (interquartile range $3, $18) per week, and 617 (94%) women reported any cost. Costs increased significantly with incontinence frequency. Mixed leak cost more than pure stress incontinence.

The mean and median Health Utilities Index Mark 3 scores were 0.73 ± 0.25 and 0.84 (interquartile range 0.63, 0.92). Women were willing to pay a mean of $118 ± 132 per month for complete resolution of incontinence, and willingness to pay increased significantly with greater expected incontinence improvement, household income, and incontinent episode frequency. Urinary incontinence is associated with high costs, with women reporting expenses of nearly $750 per year out of pocket for incontinence management. Women were also willing to pay a lot - nearly $1,400 per year - for incontinence cure, reflecting the high degree of bother of the condition. Incontinence was also associated with a significant decrement in quality of life.

Subak et al (2010)[43] then studied 491 women who completed 24 months of the Stress Incontinence Surgical Treatment Efficacy Trial (SISTER) who underwent Burch colposuspension or sling surgery. Self-reported out-of-pocket incontinence management costs were measured at 24 months post-operatively. Women quantified the resources used for management of UI including number of supplies for UI and additional laundry and dry cleaning needed each week. Total costs for management of UI were estimated by multiplying these resources by national resource costs (2006 USD). The analysis combined both treatment groups to examine the effects of change in UI over 24 months on cost. Univariate and bivariate changes in cost were examined using Wilcoxon signed rank test. Potential baseline predictors of change in cost were examined using multivariate mixed models adjusting for age, ethnicity, baseline BMI, annual income, ≥3 UTIs, POP-Q stage, fecal incontinence, diabetes, prior non-surgical UI treatment, menopause, smoking, treatment group, and accounting for site clusters.

The mean (±SD) age of participants with complete resource use data at baseline and 24 months was 53 ± 10 years. The mean weekly UI frequency was 23 ± 21 episodes at baseline, which decreased by 86% at 24 months (P<0.001). Mean weekly cost was $14.88 ± $25 (median $8.42) at baseline which decreased to $4.10 ± $14 (median $0.09) at 24 months (P<0.001). The proportion of women reporting any cost decreased from 95% at baseline to 50% at 24 months (P<.0001). There was a similar reduction in weekly cost for both treatment groups (-$10.83 for Burch vs. -$10.73 for sling; P=0.49). In multivariable analyses, cost decreased by $0.96 ± $0.23 per week for each decrease of 7 UI episodes per week (P<0.001) and was strongly associated with greater improvement in UDI and IIQ scores and decreased 24-hour pad weight (P<0.001 for all). In summary, incontinence management costs decreased by 73% ($580 per woman per year) and were strongly and independently associated with decreasing UI frequency 24 months following Burch or sling.

Lier and colleagues [24] performed a within trial cost-utility analysis in a randomized trial of trans-obturator tape (TOT) compared with tension-free vaginal tape (TVT) in the surgical treatment of stress urinary incontinence (SUI) among 194 women in Canada. Cure was assessed by objective pad tests. They assessed costs in 2007 Canadian dollars from the public-payer perspective, i.e. 807$ Can for surgical kits, plus day only surgical costs and 12 months of care costs. The 15D utility instrument was used to measure QALYs. At 1 year post-surgery, 81% of TOT patients were dry on 24 hour pad test, versus 77% of TVT patients; 15% of the TOT had groin pain (versus 6% of TVT) but whether this contributed to medical costs over 12 months was not clear. The TOT group had a non-significant average saving of $1133 (95% CI -2793; 442), or 17%, with no difference in average QALYs between groups (95% CI -0.02; 0.01). TOT was cost-saving in over 80% of sensitivity analyses, suggesting that TOT would be cost-effective compared with TVT in the treatment of SUI. However, longer-term assessment of clinical and economic outcomes are needed to confirm the finding and observe for effectiveness, surgical complications, and re-treatment.

Jacklin et al [44] published a decision tree/Markov model in 2010 which proposed to consider the cost
utility of second line treatment for women with stress incontinence who had failed PFMT. The Markov model was controversial, because patients were expected to have either duloxetine or a TVT and then be followed up for 2 years, there was no opportunity for patients not responding to duloxetine to progress to a TVT. However patients failing the initial TVT were able to have a repeat TVT. The purpose of the article was to employ recently published long term followup data for duloxetine (as initial studies only reported to 12 months, with 68% of women estimated to continue therapy, but recent studies showed much poorer continuation rates, i.e. 9% and 8% at 12 months and 2 years). No actual QALY data for the TVT patients were cited from the literature, and QALY date for duloxetine patients was cited from a small study [45].

Unsubstantiated assumptions were made about the QALY loss associated with adverse events from duloxetine therapy. An 8 week course of duloxetine cost £30 (which would be very low cost for this medication in most countries), a TVT cost £2,044. They concluded that TVT is a cost effective second line therapy, but duloxetine, although cheaper, is not cost effective because of high discontinuation rates and lower efficacy. One of the authors was part funded by NICE, a second author had previously been funded by the manufacturers of duloxetine.

Patel et al. [46] compared the operating/bedstay billing costs in 45 patients from South Carolina having surgery for stress incontinence with or without prolapse, who had either commercial mesh kits, or segments of prolene mesh that were sewn in by the surgeon, with or without biomaterials during 2007-2008. Operative billing sheets including operative time, hospital "cost", bedstay time, and the insurance billings were reviewed. Surgeon payment was not included. The definition of cost is unclear and may represent hospital charge rather than cost. In both pure stress incontinence or coexistent prolapse, the surgeon-made prolene mesh operations were less expensive than the surgical kits, not surprisingly. No efficacy data or QALY data were included.

In our last report, Wu et al. [47] had very recently performed a methodologically excellent cost-effectiveness analysis of Burch colposuspension compared with TVT for stress incontinence, using a Markov model to compare costs (2005 USD) and QALY’s (measured by the Health Utilities Index) over 10 years from a health care system perspective. In this well done study using state-of-the-art methods, Burch colposuspension was not cost-effective compared with TVT. However, if the tension-free vaginal tape failure rate was to increase over time, Burch may become cost-effective, reinforcing the need for long-term follow-up in surgical trials and cohorts.

In our last chapter, we reported a study regarding open vs. laparoscopic colposuspension by Dumville et al [48], which the Committee pointed out was a good example of the importance of evaluating costs over a long time frame to allow cost effectiveness to emerge. In the initial economic analysis of the two procedures at 6 months, healthcare costs were higher for the laparoscopic arm than for the open Burch arm (£1805 vs. £1433; differential mean cost £372; 95% CI 274, 471) due to increased theater costs. QALYs were slightly higher in the laparoscopic arm relative to the open arm (0.005; 95% CI -0.012, 0.023). The ICER was £74,400 at 6 months. At 24 months, higher mean QALY’s persisted in the laparoscopic arm and modeling showed the ICER was reduced to £9300. While laparoscopic colposuspension was not cost effective compared with open colposuspension during the first 6 months following surgery, it may be cost effective over 24 months.

In the last report, we discussed the multicentre RCT of Manca et al (2003) [49] who assessed the cost effectiveness of TVT with open colposuspension for primary stress incontinence at 6 months, in 344 women from 24 centres in the UK and Ireland. The EQ-5D was used to measure QALYs. The TVT had lower mean costs and higher mean QALYs at 6 months, which persisted over 95% of sensitivity analyses. The 2 year and 5 year follow-up of this study has since been published but no further economic analysis appears to have been reported.

2. SURGERY FOR URGE INCONTINENCE

a) Studies regarding Botulinum Toxin A Injections (Botox A)

Three studies comparing Botox A with other treatments have been published since our last report. Wu et al (2009) from the USA performed a Markov model analysis of Botox A versus anticholinergic medication [50]. The model was conducted over a two year time frame, and assumed that 33% of patients would comply with anticholinergic therapy over this time. The Botox treatment cycles were more expensive (US$ 4,400) than the anticholinergic medication (US$ 2,560), but the Botox was more effective (QALY gain 1.63 versus 1.50), yielding an ICER of $14,377.

Wefer et al (2009) from Germany evaluated Botox A injections in 214 patients with neuropathic detrusor overactivity [51]. 300 IU of Botox were injected in each patient (which is common practice in neuropathic DO, but varies from some clinical practice in idiopathic DO which 200IU are often given). The injections were given as inpatients. Pad costs per day were reduced from €2.11 per day to €1.05, and medications for urinary tract infection fell by half (from €162 per annum to €80 per annum). Unfortunately no QALY measurements were performed.

Robinson et al. (2010) [52] undertook a Markov model study comparing Botox with percutaneous tibial nerve stimulation (PTNS), over a 2 year time frame for refractory idiopathic detrusor overactivity. Repeat botox injections were assumed to occur every 8 months; 20% of patients were assumed to perform clean intermittent self-catheterization for 4 months.

1843
QALY data was assumed from the literature. PTNS was cheaper than Botox (£1,700 versus £4,067) and had a lower ICER (£50,133 versus £111,953) but neither would satisfy UK NICE guidelines for cost-effectiveness (i.e. not less than £30,000 per QALY).

Padmanabham et al (2011) from USA performed a decision tree analysis of Botox injections versus Clam Cystoplasty[25] (which is an arguable model, since Sacral Nerve Stimulation has largely overtaken clam cystoplasty in the western world). Nevertheless, this was a group of severely refractory neuropathic DO patients, who were performing clean intermittent self catheterization (CISC) but still had upper tract dilatation.

In a heterogeneous group of patients, also including patients with urinary retention and chronic pelvic pain, a one year SNS treatment reduced 92% of output. During the two year period, SNS was not cost-effective (1.73 vs 1.63 QALYs) than Botulinum Toxin A. The base case scenario included a staged implant procedure for SNS using the tined lead, and office injections of 200 units Botulinum Toxin A.

Sacral Nerve Stimulation (SNS) is a minimally invasive FDA approved second line treatment for refractory overactive bladder (OAB) dry and wet. Currently five papers describe different aspects of cost analysis and cost-effectiveness of SNS, some with comparison to other treatment strategies for OAB [53-57].

Aboseif et al[53] in the U.S.A. retrospectively reviewed the costs related to SNS for a period extending from one year pre- to one year post-implantation. In a heterogeneous group of patients, also including patients with urinary retention and chronic pelvic pain, a one year SNS treatment reduced 92% of outpatient doctor visits and diagnostic and therapeutic procedure costs, along with a 30% reduction in drug costs [53]. This however did not include the costs of the neuromodulation implant itself, nor the surgical implantation costs. QALYs were not ascertained.

A cost analysis evaluation was also conducted in a large multicenter cohort study in France,[56] which included 190 OAB wet patients and neuropathic DO, as well as another 85 patients with OAB wet plus faecal incontinence (double incontinence). Treatment costs included insertion of preliminary tined leads under GA as an outpatient then permanent implant as an inpatient, with Botox injections given as an inpatient. Health-related travel costs were also included in the analysis, which extended from the pre-test evaluation, over the temporary stimulation procedure until two years after the implant procedure.

The median overall cost per OAB wet patient for the first two years was €16,403, which was on average €8,525 more per patient compared to patients on alternative treatments, which comprised conservative measures (medication and diapers/pads), botulinum toxin injection, enterocystoplasty or urinary diversion. Importantly, devices and hospital stays accounted for 40% and 52% of the total cost respectively. Although the authors provided a limited cost-effectiveness analysis over the two year period, the interpretation of the results are difficult because of the heterogeneity of the study population, surgical procedures and the lack of clear descriptions of the cost-effectiveness parameters. Their data, however, suggest that SNS for OAB wet is not cost-effective over the two years period. This is in agreement with the data from Siddiqi et al[57] (see below), and not surprising since the initial costs are very high due to the device costs. Interestingly, their data suggest that SNS may be cost-effective even in the short term for patients with double incontinence [56]. This deserves attention in future research.

Siddiqi et al [57] performed a cost-effectiveness analysis of SNS vs intravesical Botulinum Toxin A in patients with idiopathic “OAB wet” in the US. A two year period was chosen for evaluation because no long-term data were available for Botulinum Toxin A. The base case scenario included a staged implant procedure for SNS using the tined lead, and office injections of 200 units Botulinum Toxin A. For the SNS strategy, no data were provided on the procedure (local vs general anesthesia; outpatient vs inpatient clinic). The relevant base case estimates are provided in Table 2. Based upon their Markov decision model, the base case SNS treatment was more expensive ($15,743 vs $4,392) but also more effective (1.73 vs 1.63 QALYs) than Botulinum Toxin A. During the two year period, SNS was not cost-effective with an ICER of $116,427 [57]. As stated above, the relevance of a cost-effectiveness analysis over a two years period with a costly implant device is questionable.

Two cost-effectiveness studies have considered the longer term, comparing SNS and Botulinum Toxin A in the Netherlands[55] and Spain [54]. The parameter estimates are provided in Table 2. In the Netherlands, Leong et al. (2011)[58] showed that SNS becomes cost-effective from the fourth year post-implant on, given an ICER threshold of 40,000€/QALY [55]. These data are based upon two procedures under general anesthesia (1) a staged SNS procedure involving a tined lead test phase in the operating theatre on an outpatient basis, followed by an inpatient stay for device implant; (2) inpatient stay for Botulinum Toxin A injection in the operating theatre.
These data are in agreement with the Spanish study by Arlandis et al.,[54] which showed SNS to be cost-effective from five years post-implant on, given an ICER threshold of 30,000€/QALY. These results are based on (1) a staged SNS procedure involving a tined lead test phase; (2) 100 units Botulinum Toxin A. No further data were provided on the procedure (inpatient vs outpatient; local vs general anesthesia). In both studies,[54, 55] several estimates or assumptions had to be made due to the lack of long-term data beyond 1 year for Botulinum Toxin A injections and 5 year for SNS therapy, such as therapy transition rates after failure and drop out rates. To what extent these data are reliable and valid is currently unknown.

Furthermore, both studies quote a one year success rate for SNS of 90%, based upon Van Voskuilen et al,[59] that describes the effect of SNS in 39 patients with OAB over 15.5 months follow up. However, in that study 10 patients were lost to follow and were excluded from the analysis. Therefore the 90% success rate

</table>
may be an overestimation, and the worst scenario, considering the ten lost to follow up patients as failures would give a 61% success rate. How this would influence the cost-effectiveness evaluation is unknown. A similar consideration applies for the 5 years success rate of 70% based upon Van Kerrebroeck et al[60] which considers patients lost to follow up as last observation carried forwards.

Sensitivity analyses for several parameters estimated by expert opinion have been performed. In the Netherlands, SNS over a 5 years period remained cost-effective (ICER < € 40,000/QALY) when the estimated dropout rate of 4.3% for both treatments was changed to 2% or 6%, and when utility value for incontinence was changed from 0.73 to 0.80. SNS was no longer cost-effective over 5 years in the following cases:

a. when Botulinum Toxin injections were done under local anesthesia (which is common practice in several countries),

b. when the Peripheral Nerve Evaluation test for SNS screening is used (because of the lower success rate of 55% compared to 75% for Tined Lead screening),

c. when bilateral testing is done

d. when the new and smaller stimulator (Interstim II) is used [55].

Because there is no standard protocol of Botulinum Toxin A injection, a different protocol using 200 units every 14 months was evaluated in the Arlandis study, which proved cost-effective on the ICER < € 30000/QALY threshold [54].

3. OUTPATIENT CONSERVATIVE THERAPIES

An important study regarding the baseline “cost of illness” for women with stress or urge leak was detailed in our last chapter (Subak et al.[61]).

A more recent study of the “Cost of Illness”[62] included 528 women with UI weekly or more enrolled in the Reproductive Risks for Incontinence Study at Kaiser population-based study. Similar to the prior studies, routine care costs were calculated with the use of national resource costs ($2005). Potential predictors of these outcomes were examined by multivariable linear regression. Among women with weekly UI, 69% reported incontinence-related costs. Median weekly cost was $1.83 (25%-75% interquartile range [IQR], $0.50, $5.23) and women spent a mean of >$250 per year out-of-pocket for UI routine care. Costs increased with incontinence severity (P < .001) and body mass index (P < .001) were 2.2-fold higher for African American versus white women (P < .0001) and 42% higher for women with mixed versus stress incontinence (P < .05).

Since costs for incontinence management increase with leakage severity, data are needed to explore whether effective treatment will be associated with decreased incontinence costs.

Recently, Subak et al.[63] performed a planned secondary analysis among overweight and obese women, who were enrolled in a clinical trial of a weight loss intervention. The purpose was to estimate the effect of a decrease in incontinence frequency on incontinence management costs [63]. The study included 338 obese and overweight women with at least 10 weekly urinary incontinence episodes at baseline. They enrolled in a randomized clinical trial to determine the effect of an 18-month weight loss and maintenance intervention compared to a structured education program, upon the frequency of incontinence.

Quantities of resources used for incontinence management, including pads, protection, additional laundry and dry cleaning were reported by participants. They estimated direct costs for urinary incontinence management (“cost”) by multiplying resources used by national resource costs (in 2006 U.S. dollars). For the total cohort (combined randomization groups), mean (±SD) age was 53 ± 10 years and baseline weight was 97 ±17 kg. Mean weekly urinary incontinence frequency was 24+18 at baseline, which decreased by 37% at 6 months and 60% at 18 months follow-up (both P<0.001).

At baseline, adjusted mean cost was $7.76 ± $14 per week. Costs increased significantly with greater incontinence frequency. Mean cost decreased by average of 54% at 6 months and 81% at 18 months (both P < 0.001). In multivariable analyses, cost independently decreased by 23% for each decrease of 7 urinary incontinence episodes per week, 21% for each 5 kg of weight lost, and was strongly associated with greater improvement in UDI and IIQ scores at 18 months (P < 0.001 for all). In this cohort of obese and overweight women enrolled in the clinical trial, management cost for urinary incontinence decreased by over 80% at 18 months ($327 per woman per year) and was strongly and independently associated with decreasing incontinence frequency. This suggests that effective incontinence treatment will be associated with decreasing costs of incontinence management.

Although not primary data, Imamura et al (2010) published a comprehensive review of the cost effectiveness of non-surgical treatments for women with stress incontinence [64]. In this report, a group of senior clinicians and other experts obtained funding from the Medical Research Council of the UK to evaluate 88 studies of conservative treatment involving 37 distinct treatment regimes, in a total of 9,721 participants. QALY data were taken from participants. QALY data were taken from a study by Haywood et al[65] which employed the EQ-5D [64]. In brief, the authors found that a treatment strategy of Pelvic Floor Muscle Training (more than 4 visits) along with lifestyle advice, followed by a TVT where necessary, was the least costly strategy, at £1644 per person, and was the most effective, with a cost utility of 16.20 QALY per annum. This strategy had a 70% likelihood of being the most cost effective across a wide range of sensitivity analyses.
A smaller review of cost effectiveness evaluations for pelvic floor exercise interventions, which included data from 3 older studies (from 1996, 2003, 2006) has also recently appeared [66].

In the last Chapter, we reported an abstract from Ho et al. [67] in Australia who performed a “bottom up” study of the short and long-term treatment costs of conservative and surgical management of childbirth-related stress and mixed urinary incontinence (UI). This report has now been published in full [68]. Costs of treatment episodes during conservative and surgical management were calculated for a cohort of 150 women and related to cure. At 6-13 years follow up, personal and treatment expenditure was measured using a postal questionnaire. During active treatment, patients with stress UI treated conservatively incurred a median cost of AU$658 per capita (IQR 476 – 1191 AU$) compared to a median cost of $6,870 per capita for surgical treatment (IQR 6,320 – 7,508 AU$. Similar cost difference was seen for the two treatment options in mixed incontinence. Of regular clinic attendees, 39% of conservatively treated and 78% of surgically treated patients were cured.

At 6-13 years follow up (82 women with a known address), 43 (52%) responded to the survey, of whom 46% remained cured. The median treatment cost for the total group of postnatal incontinence (irrespective of continence status) was AU$885.80 per capita per annum (IQR 338- 2,589 AU$). The costs per cure are shown in Table 3, in Australian dollars.

In response to the regulatory requirements, drug developers routinely conduct economic evaluations. In the UK, such efforts are done as part of the NICE review. In the US, developers present economic data to purchasers for post approval marketing. Many purchasers (as in Australia) have formularies, or lists of medications that they are willing to pay for, and the economic evaluation is frequently part of the request to place the new drug on the formulary.

In the next sections, we review the recent literature on the economics of drugs for incontinence and overactive bladder.

1. **Pharmacotherapy for Stress Incontinence**

Mihaylova et al. (2010) assessed the cost-effectiveness of duloxetine compared with conservative therapy in women with SUI [69]. Cost and outcome data from a 12-month, prospective, observational, multicenter, multicountry study were used (the Stress Urinary Incontinence Treatment (SUIT) study). Costs were assessed in 2007 £ from the healthcare plus patient perspective; outcomes were measured in quality adjusted life years using the EQ-5D. Duloxetine alone and with conservative treatment (not explicitly defined but varied by physician practice) were associated with incremental quality-adjusted life-years (QALYs) of about 0.03 over a year compared with conservative treatment alone or with no treatment. Conservative treatment alone did not show an effect on QALYs. Duloxetine either dominated (lower
cost and greater change in QALY) or had an incremental cost-effectiveness ratio (ICER) below £900 per QALY gained, compared with no treatment and with conservative treatment alone. Duloxetine plus conservative therapy had an ICER below £5500 (compared with no treatment or conservative treatment alone). Duloxetine compared with duloxetine plus conservative therapy showed similar outcomes but an additional cost for the combined intervention. While limited by the observational design, the study suggests that initiating duloxetine therapy in SUI is a cost-effective treatment alternative.

(NOTE: Duloxetine failed the US approval for stress urinary incontinence due to concerns over liver toxicity and suicidal events. It is approved for SUI in Europe, where it is recommended as an add-on medication in stress urinary incontinence instead of surgery.)

In a similar vein, we reported in our last chapter that Brunenberg[70] conducted a Markov model to assess the cost-effectiveness of duloxetine alone and duloxetine after inadequate response to pelvic floor muscle training [PFMT] compared with PFMT or no treatment for women 50 years of age or older, which narrowly focused upon pharmacotherapy and PFMT for stress incontinence, with no consideration of surgery.

Das Gupta and colleagues[45] also developed a model to assess the cost-effectiveness of duloxetine for moderate to severe SUI, but they assumed that drug treatment was fully effective. Thus duloxetine studies published to date have methodological limitations.

2. Pharmacotherapy for Urge Incontinence

There are five commonly used medical treatments for overactive bladder: Oxybutynin (ditropan) as a tablet or as Oxytrol patches; tolterodine (Detrol), darifenacin (Enablex), trosiptium (Sanctura), solifenacin (Vesicare), and a sixth recent introduction, Fesoteridine (not yet widely used).

Many economic evaluations are funded by drug developers and compare the investigational drug to placebo or to an older compound that has known problems with side effects (e.g., immediate release oxybutynin). In the Fourth ICI report [41] we reported one study by Ko et al. [71] who conducted an independently funded economic evaluation of five antimuscarinic drugs (in eight formats) for overactive bladder (see Figure 8). They concluded that solifenacin had the lowest costs and highest effectiveness, compared to immediate-release (IR) oxybutynin, extended-release (ER) oxybutynin, transdermal oxybutynin, IR tolterodine, (ER) tolterodine, trosiptium, and darifenacin. However, their study did not meet minimum standards for cost-effectiveness analysis [9, 14]. It also focused on the payer’s perspective (rather than a societal perspective), had a short time frame.

![Figure 8](image-url)

**Figure 8.** Decision-analysis model used to compare cost-effectiveness of antimuscarinic agents for the treatment of overactive bladder. Modified from Ko et al. (2006)[72].
of 3 months, and used complete continence as the main effectiveness measure (rather than QALYs). Given these limitations, we recommended that these results must be interpreted cautiously and that additional studies using standard methods were needed.

3. SOLIFENACIN STUDIES

Milsom et al[72] performed a cost effectiveness analysis of Solifenacin flexible dosing (5-10 mg) versus tolterodine 4 mg Sustained release in 4 Nordic Countries. The efficacy data was based upon the STAR RCT (Chapple et al, 2005[73]) and 2 other RCTs of solifenacin versus tolterodine and placebo. QALYs were not included in the original trials, but the EQ5D was estimated from original HRQOL data collected in 1997. The cost differences between solifenacin and tolterodine ranged from €6 to €127. The authors concluded that Flexible dose Solifenacin was more cost effective than Tolteridine 4 mg. This study was supported by Astellas.

Herschorn et al[74] undertook a Markov model based upon the VECTOR study, which compared Solifenacin 5 mg/ day versus Oxybutynin 15 mg / day in Canada. The withdrawal rate due to side effects of oxybutynin (19%) was much greater than that for solifenacin (3%). No QALY data was included in the original VECTOR study. Their 8 week efficacy data was projected over 1 year, which is an arguable model. Solifenacin yielded a cost saving of Can $ 1,830 per annum, giving an ICER of Can $14,000. This study was also funded by Astellas.

Cardozo et al[76] performed a decision tree analysis of solifenacin, versus fesoteridine, oxybutynin ER, propiverine, tolteridine ER and IR in the UK. In this one year model, success was individually defined for frequency, urgency and urge incontinence. The model was problematic (Fig 9), in that it assumed if the patient had no success on a drug that was only available in one dose, then the patient was given no further treatment. The original study did not include QALY data, which were calculated from willingness to pay data published by Kobelt in 1998 [77]. The calculation of QALYs from willingness to pay is not a standard methodology and created confusion among the Economics Committee members. Because oxybutynin was so much cheaper than the other drugs (20% of total costs, versus 60-70% of total costs for the other therapies), oxybutynin was dominant for 2 of the 3 outcomes.

In 2005, Getsios and colleagues[78] published a review of the economic studies for overactive bladder, highlighting many of the limitations including a lack of comparisons of drugs to behavioral training.

4. DARIFENACIN HYDROBROMIDE (ENABLEX)

Darifenacn was approved by the FDA in 2004, based on Phase II and III controlled clinical trials with over 8,800 patients. Short term efficacy (12 week) as well as longer term effects (24 and 52 week) were evaluated [79]. Abrams and colleagues [80] found that darifenacn was associated with significant improvements in quality of life as measured by the King's Health Questionnaire at 12 weeks relative to placebo. Chancellor et al. [79] found that darifenacn and darifenacn combined with a behavioral modification plan both resulted in improvements in symptoms and quality of life, as measured by the Overactive Bladder Questionnaire (OAB-q), but there were no differences between the two groups. Unfortunately, neither the Abrams nor the Chancellor study measured utilities. Besides the Ko [71] article discussed above, there is little data on the cost-effectiveness of darifenacn.

5. TOLTERODINE (DETROL)

In late 2008, Burgio et al (The UTIN group) conducted a clinical trial of 10 weeks of open-label, extended-release tolterodine alone (n = 153) or combined with behavioral training (n = 154), followed by discontinuation of therapy and follow-up at 8 months [81]. Among 237 participants completing the trial, the rate of successful discontinuation of therapy at 8 months was the same in the combination therapy and drug therapy alone groups (41% in both groups; difference, 0 percentage points [95% CI, -12 to 12 percentage points]). A higher proportion of participants who received combination therapy than drug therapy alone achieved a 70% or greater reduction in incontinence at 10 weeks (69% vs. 58%; difference, 11 percentage points [95% CI, -0.3 to 22.1 percentage points]). Women in the combination therapy group reported better outcomes over time on the UDI and the OAB-Q (both P <0.001) for patient satisfaction and perceived improvement but not health-related quality of life. They concluded that the addition of behavioral training to drug therapy may reduce incontinence frequency during active treatment but did not improve the ability to discontinue drug therapy and maintain improvement in urinary incontinence. Economic evaluations are ongoing.
Two studies evaluating the cost-effectiveness of tolterodine versus percutaneous tibial nerve stimulation (PTNS) have recently been published. In 2009, Robinson et al.[82] undertook a cost minimization study of PTNS versus tolterodine ER 4mg, involving 1-2 year follow-up, from the perspective of the NHS. In the model, the two treatments were assumed to have equivalent efficacy (based on unpublished data), and adverse effects were considered to be cost neutral. The patients having tolterodine were followed for 2 years, the duration of follow-up for PTNS was not clearly stated. Tolterodine appeared to be the cheaper treatment but alteration of the variables in the model had a large effect.

In 2010, Chen et al.[83] performed a very similar evaluation of PTNS versus tolterodine, cost-utility values were obtained from the literature [84], yielding an ICER of $70, 754 per QALY, thus PTNS was not cost effective in the treatment of OAB over a 1-year period.

6. TROPIUM CHLORIDE (Sanctura)

Besides the Ko[71] article discussed above, there is little published data on the cost-effectiveness of tropium chloride.

5. COST IMPLICATIONS OF INCONTINENCE IN NURSING HOME SETTING

Two key aspects of cost of care for nursing homes are (1) cost of nursing home admissions attributable to urinary incontinence, and (2) the treatment cost of urinary incontinence. In the last 4 years, no new studies were found regarding this aspect of the economics of incontinence, therefore our previous findings are briefly summarized.

Additional nursing home admissions cost is often a major component in the total cost of urinary incontinence. In a 2001 study [16] the cost estimate was $2.4 billion in 1995 dollars. In a 2004 study [15], the cost estimate was $4.0 billion in 2000 dollars. In a 2006 study,[85] the attributable fraction (AF) statistics from published data was shown to be $6.0 billion in 2004 dollars. The Attributable Fraction (AF) statistics are obtained by using incontinence prevalence rates for those admitted to nursing homes, as compared to those who were not admitted to nursing homes. It shows that reimbursement for treatment of UI in the community might help or delay institutionalization and offset some costs of staying in nursing homes. The AF method has been used in the economic cost of mental illness, smoking, and cancer diseases. The new estimated magnitude shows that reimbursement for treatment of UI in the community might help or delay institutionalization and offset some costs of staying in nursing homes.

Holroyd-Leduc et al. [86] conducted a population-based prospective cohort study (from 1993-1995) in over 6,500 elderly (age70) patients. After adjusting for confounders, UI was not an independent predictor for death, nursing home admission, or functional decline. Within nursing homes, labor costs are a major component of caring for incontinent patients. These costs are studied via time/motion observation, correlated with severity and type of incontinence. In 49 long-term care facilities in North Carolina, USA, it was found that the incremental labor costs (per shift) were $3.31 for patients with occasional UI and $5.61 for patients with frequent UI [87], in keeping with Morris et al[10].

Bliss et al. [88] addressed the cost/effectiveness of incontinence-related treatment of skin condition in 16 US nursing homes. Four regiments of different moisture barriers were applied. Time and motion measurements included skin products and time spent. Using acrylate barrier film spray achieved cost savings of between $854 to $1,862 per resident, with better skin protection than the use of an ointment or cream.

6. LONGITUDINAL BURDEN OF DISEASE STUDIES

For the first time in the last ICI report, we found a number of studies that measure the cost of incontinence over the long-term time frame. As pointed out by Birnbaum et al.[89], the study of “the lifetime cost of illness” is a recent area of research. These authors combined case-control methods (to calculate annual medical costs of stress incontinence, etc) with knowledge of the incidence of the conditions, assuming “steady state conditions” of the costs, to project the lifetime costs of each disorder.

As regard the impact of incontinence upon employed women, Fultz et al. [90] sent a postal questionnaire to 2326 employed women, 37% had leaked urine in the past month. The impact of incontinence upon ability to concentrate, performance of physical activities, self confidence, and ability to complete tasks without interruption increased with the severity of the leak and affected nearly 75% of all those with severe leak status. Similarly, Wu et al. [91] focused upon the work loss burden of women with OAB. The number of days absent was 15% higher among 3077 OAB employees compared to 6154 controls. OAB subjects had 4.4 more days off work than non-OAB subjects, yielding an annual excess cost of $1220 per OAB employee.

In the last chapter, Reeves et al. [92] employed a theoretical model based upon a large “EPIC” prevalence study of OAB [93] to derive the future cost burden for OAB in five European countries. They calculated an annual per capita expense of €269-706 per annum.

A more detailed analysis of OAB costs in Germany [94] that included psychiatric costs of OAB-related depression, and nursing care, indicated an annual per capita expense of €609-1170 per annum in that country.

Since the last report, this same group of authors obtained updated data for the treatment costs of “OAB wet” and “OAB dry” [95]. They also provided new data about the non-treatment costs of OAB, such as lost productivity, depression, sleep disturbance, falls
and fractures, skin infections and UTIs. The manuscript lists 23 website links that were used to access unit costs for each of the six developed countries (Canada, Germany, Italy, Spain, Sweden and UK). A summary of the costs in each country is shown in Table 4 [95], with summary data in Table 5 [95]. Overall, the annual treatment costs of OAB in six countries is shown to be approximately €3.9 billion, with additional costs for nursing home stays (€4.7 billion per year) and loss productivity due to work absenteeism (€1.1 billion per year). The estimated total cost therefore for the ≈25 million patients with OAB in these countries is €9.7 billion.

Cisternas et al [96] undertook an analysis of the economic burden of overactive bladder syndrome in Medicare beneficiaries in the USA[96]. They obtained data for all Medicare claims for patients over age 65 during 2003-2004, compared with non-OAB subjects. Multiple regression analysis was used to estimate costs attributable to OAB after adjusting for demographic characteristics and comorbidities. They used a narrow definition of OAB (detrusor overactivity, urge incontinence, frequency with polyuria) and also a broader definition of OAB (that included incontinence without sensory awareness, nocturnal enuresis, continuous leakage, etc).

Costs were based on the amount of money reimbursed to providers by Medicare (which generally yields 80% of “allowed amounts”) that includes inpatient stays, skilled nursing facilities, outpatient visits and procedures such as cystoscopy. Figure 10 shows the prevalence of the two definitions of OAB compared to other chronic conditions. The prevalence of OAB in this over 65 group was 9-14% for the two definitions.

The mean annual expenditure attributable to OAB ranged from US$825 – 1184 per subject, which comprised 9-12% of all their medical expenditure.

†Not costed
The total cost of OAB expenditure was 1.8–3.9 Billion US $ per year. These authors also considered the consequences of incontinence. For example, the OAB cohort had a higher occurrence of events such as falls/fractures (46% OAB versus 34% non-OAB; RR = 1.4) urinary tract infections (42% OAB versus 17% non-OAB, RR = 2.4), and depression (21% OAB versus 12% non-OAB, RR = 1.8) all p < 0.001. The authors pointed out that this is the first study to evaluate the treatment costs of OAB in over-65 year individuals using “real-world” Medicare claims data.

In the last 4 years, the Committee found 3 publications reporting a new trend towards conducting Internet studies of the Burden of Disease associated with OAB. Because of difficulties in achieving telephone surveys, researchers have moved towards internet surveys, however the Committee feels that such method can be subject to considerable bias.

For example, Kannan et al [97] reported an internet survey in 2009 that was actually conducted in 2006, in which 62,833 American subjects who were members of an industry-based feedback panel were questioned as to whether they had LUTS or OAB. Because of difficulties in achieving telephone surveys, researchers have moved towards internet surveys, however the Committee feels that such method can be subject to considerable bias. For example, Kannan et al [97] reported an internet survey in 2009 that was actually conducted in 2006, in which 62,833 American subjects who were members of an industry-based feedback panel were questioned as to whether they had LUTS or OAB. The survey compared 13,954 men and women with LUTS/OAB (comprising 24% of the survey population) with age matched subjects having similar comorbidities. They found that subjects with LUTS/OAB had approximately US $ 1,000 more health care costs per annum. They concluded that the projected costs of LUTS/OAB were US$ 51 Billion per annum more than age/comorbidity matched controls. However, in Discussion, the authors admitted that the study was quite biased towards subjects who were connected to the internet, yet not fully employed, i.e. having sufficient time to enroll in the Industry Feedback Panel.

A similar internet study was reported by Onukwugha et al [98], derived from the Epi LUTS study, which yielded a projected LUTS/OAB cost of 24.9 billion US$. Neither of these projected costs agrees with other cost estimates from non-internet based studies.

Finally Ganz et al [99] performed an overall estimate of the costs of OAB, which used a panel of expert urologists in Boston USA, via a Delphi technique to obtain consensus on the model. The authors accumulated all known costs for OAB, including patients in nursing homes. They projected costs based upon known projected prevalence figures, with respect to the ageing of “baby boomers” (Figure 11) showing a projected marked increase in OAB costs as this cohort “swells” the numbers of elderly in the community.

7. PROLAPSE TREATMENTS, COST IMPLICATIONS

Despite the high prevalence of pelvic organ prolapse and frequency of surgery for prolapse, there are minimal data on costs or cost-effectiveness of medical care for this condition.

In the previous chapter, we reported an important cost of illness study from 2001, regarding the annual treatment cost of surgery for pelvic organ prolapse in the U.S. [100]. Treatment costs of pelvic organ prolapse surgery were US$1,012 million (1997 US$; 95% CI 775-1,251 million). Hospitalization accounted for a majority of the total cost (71%) with the remainder being physician services (29%). Twenty-one percent of pelvic organ prolapse operations included urinary incontinence procedures (US$218 million).

The annual treatment costs of operations for pelvic organ prolapse are substantial and similar to other surgical interventions for women (breast cancer, gynecologic cancer, urinary incontinence).

In 2009, Subramanian et al. [101] estimated the rate, type and costs of surgical interventions for pelvic organ prolapse (POP) in Germany, France, and England. They identified hospital admissions for pelvic floor surgery in 2005 from national hospital activity databases in each country: the German Hospital Episode, the French Medical Care Program Information System, and the National Health Service England Hospital Episode Statistics. Costs to the payer were estimated using the Diagnosis-Related Group reimbursement rates for each country. In 2005, the number (rate) of admissions for POP surgery was 36,854 (0.87 per 1000 women) in Germany, 36,679 (1.14 per 1000 women) in France, and 28,959 (1.13 per 1000 women) in England. Admissions for POP surgery constituted 10.4%, 16.7% and 16.9% of all admissions for female genital tract therapeutic interventions in Germany, France and England, respectively. At least 20% of hysterectomies were performed for the primary indication of POP. 57.4%, 45.0%, and 40.1% of all admissions for POP surgery included a hysterectomy. The costs to payers were €144,236,557, €83,067,825, and €81,030,907 in Germany, France, and England, respectively. These data effectively document the substantial burden and costs associated with POP surgery in the three countries studied using generalizable data and appropriate methods.

A multicentre international randomized controlled trial of pelvic floor physiotherapy for mild to moderate prolapse (the POPPY study) was published as an abstract in 2011[102]. A total of 447 women were randomized to either 5 physiotherapy visits over 16 weeks, or were given written instructions about lifestyle advice re constipation, obesity etc. Although the POPSS quality of life test [103] was employed, and showed significant benefit for physiotherapy treatment, the authors had not been able to find a QALY test that was responsive to change for prolapse treatment.

In 2011, Hullfish and colleagues from the UK [104] developed a Markov model to compare the relative cost effectiveness of treatments for post-hysterectomy pelvic organ prolapse (POP), including expectant management, use of a pessary, and surgery. They used probabilities from published studies and expert consensus and generalizable national costs from national charge data from the 2007 Healthcare Costs and Utilization Project Nationwide Inpatient Sample adjusted for all payer cost to charge ratio. They could not identify published HRQOL or utility scores for POP conditions, so estimated these based on a range of 1.0 for repaired POP without complications to 0.0 for major complication or re-operation. Over a 1 year timeframe, initial pessary use was the least expensive and had the lowest QALY. Vaginal reconstructive surgery had the highest QALY. Unfortunately, the results were not presented as incremental analyses so they are difficult to interpret. Sensitivity analysis demonstrated that these baseline results depended on several key estimates in the model: probabilities of POP complications, surgery following pessary use, and late complications following surgery, utility of pessary use, and the cost of robotic assisted surgery.

In 2011, Murray et al. [105] investigated the cost of traditional anterior colporrhaphy (AC), hand-cut mesh, and mesh kit anterior vaginal prolapse (AVP) repair using a decision analysis model. The model included mean operating room (OR) times, mesh extrusion rates, and recurrence rates obtained from a meta-analysis and Medicare reimbursement for surgeon fees and office visits, and hospital costs of supplies, OR time, and room and board. Non-kit mesh repair was $3,390, AC $3,461, and mesh kit $4,678. One-way sensitivity analyses demonstrated recurrence rate of AC would need to be 28% to be cost equivalent to non-kit mesh repair and the non-kit mesh cost must be < $480 (basecase $400) to remain less expensive than AC. Mesh kit repair did not reach cost equivalence, even with an OR time of 0 minutes. Two-way sensitivity analysis comparing mesh extrusion and AC recurrence demonstrated AC is less costly if recurrence is <20% or extrusion >25%.

As per our previous report, a Cochrane review of surgeries for the management of pelvic organ prolapse emphasized the importance of CEA and CUA [106]. They observed that abdominal sacrocolpopexy is associated with a lower rate of recurrent vault prolapse and dyspareunia than the vaginal sacrospinous colpopexy yet these benefits must be balanced against a longer operating time, longer time to return to activities of daily living and increased cost of the abdominal approach. Similarly, the use of mesh or graft
inlays at the time of prolapse repair may reduce the risk of recurrence and the addition of a continence procedure to a prolapse repair operation may reduce the incidence of postoperative urinary incontinence. Yet, these benefits need to be balanced against possible differences in costs and adverse effects, which have not been assessed and, like surgical treatment for stress incontinence, are inherently appropriate for CEA since there may be differences between procedures in costs, clinical outcome and health-related quality of life.

Maher et al. [2004] performed a randomized trial of abdominal sacral colpopexy vs. vaginal sacrospinous colpopexy to treat vaginal vault prolapse among 95 women [107]. Secondary outcomes included the impact on cost (measured as Australian bed and operating theater costs) and general- and incontinence-specific quality of life. Two years after the operation, the subjective and objective success rates were similar between groups. The abdominal approach was associated with a longer operating time, a slower return to activities of daily living, and a greater cost than the sacrospinous colpopexy (P<.01). Both surgeries significantly improved the patient’s quality of life (P<.05). These data suggest that formal cost-utility analysis would be beneficial to further compare these two common procedures for pelvic organ prolapse. Additional data with generalizable costs and utility measures and long-term efficacy outcomes are needed.

In the chapter of this text regarding surgery for pelvic organ prolapse (Chapter 15), the authors give further references that provide surgical cost data for a variety of procedures, such as laparoscopic sacrocolpopexy, robotic sacrocolpopexy, versus abdominal sacrocolpopexy, and laparoscopic sacrocolpopexy versus total vaginal mesh procedures. Readers are referred to that chapter for details, however no utility measures were provided in these reports.

8. FECAL INCONTINENCE

a) Cost of illness

In the previous chapter, several cost of illness studies regarding faecal incontinence were reported. However these studies mainly employed previously collected databases[108, 109], or focused upon inpatients [10], subjects with constipation as the main complaint [108], women with faecal incontinence after obstetric injury [110]. Few conducted face-to-face direct enquiry of the personal costs of leakage of faeces[10]. Most did not employ a validated measure of severity [10, 108-110]. Deutekom et al[111] from the Netherlands did measure treatment and non-treatment costs along with the Vaizey continence score, no QALYs were measured and the relationship between cost and severity was not explored.

In 2011, Parkin et al[112] conducted personal interviews with a consecutive sample of 54 ambulatory home dwelling men (5) and women (49) patients who presented with faecal incontinence to a tertiary outpatient Unit, to collect cost data prior to the onset of treatment in relation to baseline severity as measured by St Marks score[113], maximum score 24 points.

Costs were determined by administering a 3 page questionnaire, modelled on the DBICI questionnaire for urinary incontinence[114]. Interviews were conducted face to face, taking approximately 15 minutes each. The information included basic personal hygiene costs (pads, laundry, wipes, cleansers), medication costs (loperamide, creams & stool bulk ing agents etc) and diagnostic costs (including medical attendance, anorectal physiology, colonoscopy). Following each interview, the personal hygiene items used by patients were costed from known tables compiled by visiting local pharmacies and suppliers. Costs were recorded in AUS.

The median age was 69.5 (IQR 61.5-74) and the major personal expense was for pads and personal hygiene items (median 70.89 per annum, IQR 0.63-310.68). Medicare costs included medical consultation and rebates for physiology testing and endoscopy (median $576.92 IQR). There was no relationship between these overall costs and incontinence severity. The Spearman rank correlation showed no significant relation between total personal costs and severity (r=0.21). When the costs just for pads and creams alone was evaluated, a relationship became apparent (r= 0.34, p=0.05, Figure 12).

b) Prevention

The cost effectiveness of two sphincter preserving treatments for anal fistula (anal fistula plug versus endoanal advancement flap) in the treatment of cryptoglandular fistulae to prevent faecal incontinence was studied by Adamina et al in 2010 [115]. The primary end-points were absence of drainage and fistula openings on physical examination at 6 months and absence of abscess formation at any time during follow-up.

This was a microcosting analysis of treatment costs, adjusted for inflation. Non-medical costs and lost productivity costs were not assessed, sensitivity analyses were performed. The study was flawed in that the success rates of healing in advancement flap group were lower than the majority of published studies on this technique. Cost-effectiveness was based on healing and complication rates, with no direct measurement of faecal incontinence. Use of the anal fistula plug saved $1,588 US per healed fistula.

Tan et al (2008) studied the cost effectiveness of primary sphincteroplasty versus delayed sphincteroplasty for anal sphincter injury, in the prevention of faecal incontinence [116]. They constructed a decision tree analysis over 10 years. QALYs were derived from SF36, but no direct QALY tests were measured. The primary sphincteroplasty was associated with a gain of 5.72 QALYs for a cost of £2,750,
the delayed sphincteroplasty yielded a QALY gain of 3.73 for a cost of £2,667, thus the primary sphincteroplasty was judged to be cost effective.

c) Treatment costs

Reflecting the increased use of sacral nerve stimulation (SNS) as a first-line surgical treatment for patients with faecal incontinence, recent cost-effectiveness analyses have primarily focused on this therapy. Brosa et al (2008) performed a cost-effectiveness study of Sacral Neuromodulation for the treatment of faecal incontinence[11]. In their decision tree, they employed two decision pathways, firstly, for patients with an intact anal sphincter (IAS) and secondly for patients with a structurally deficient anal sphincter (SDAS) who had previously undergone a sphincteroplasty. Two of the authors worked for the Medtronics company (international makers of sacral neuromodulation equipment), and “4 authors received an unrestricted grant from Medtronics”.

Because recent NICE guidelines recommend Sacral Nerve Stimulation (SNS) as first line therapy in patients with an intact sphincter, and as second line therapy in those with a deficient sphincter[117], their aim was to evaluate the previous scenario (no option to perform SNS) with a new decision tree that included SNS. QALYs were obtained from Deutekom et al [118], [ie for patients with faecal incontinence QALY = 0.68, for patients with no faecal incontinence QALY = 0.87]. Costs were obtained from Spanish Health Costs Database[119]. Temporary SNS evaluation cost €1,484, whilst permanent SNS cost €10,700. Other treatments in the model were more expensive, such as Dynamic graciloplasty €12,000 and Artificial Anal Sphincter €12,000 (taken from Spanish DRG figures).

The timeline for the model was 5 years, with 3% discount rate per annum. Prevalence figures and Medtronics sales forecast were used to estimate numbers of patients likely to receive SNS over the next 5 years, to perform Budget Impact Analysis. Monte Carlo simulation analysis was performed for a cohort of 1,000 patients (i.e. Bootstrapping, see Methods of this chapter) to test sensitivity.

The results of their decision tree analysis showed that patients obtained an additional symptom free year of 0.31 and 0.34 per patient per 5 years in the two pathways respectively. In patients with an intact sphincter, SNS had a cost of €16,181 per QALY gained; for those with a deficient sphincter, SNS cost €22,195 per QALY gained. Budget Impact Analysis on the basis of 75-100 expected patients per annum would yield a budget impact of 0.1% in patients with faecal incontinence.

The authors commented that dynamic graciloplasty in 123 patients yielded complications in 74% of patients with a total of 189 complications [120]. Artificial anal sphincter was performed in 112 patients with 51 patients required a total of 73 further reoperations with 41 (36.6%) subjects requiring device removal [121]. No corresponding figures for reoperation rates were given for those undergoing SNS.

Figure 12. Total personal costs vs incontinence severity St Mark’s score
The relationship between the Markov model developed in the above paper by Brosa et al [11], and a patient cohort study published by a similar group of authors [122] also from Spain in the same year, is unclear. In the paper from Munoz-Duyos et al., [122] patient level cost data is given for 57 temporary evaluations under local anaesthetic in 47 patients, giving a success rate of 61% (which is lower than many other publications). Permanent SNS devices were implanted in 29 patients, who were followed for a median of 3 years.

The study was reported on an intention to treat basis over a five-year time horizon. Only treatment costs were evaluated. The actual Markov model was not provided. Costs were not discounted. No sensitivity analysis was performed. It is unclear how the QALY were determined, as no QALY tests were administered, and data arising from calculating QALYs from SF36 were quoted as being derived from the paper by Bosa et al [11]. Thus it appears that this report from Munoz-Duyos [2008] was in some aspects a duplicate of the earlier Brosa paper [11, 122].

Despite this paper being entitled a “cost effectiveness study” there was little individual cost data given, for example, the temporary evaluation cost was £397, and the SNS permanent device cost was £10,178. Mainly, group totals of costs were given, for example, operating room costs of £26,000 for all the temporary evaluations, and £17,000 for all SNS implantations in the study group. Thus the majority of costs were associated with implantation of the permanent SNS device (due to upfront device costs).

In patients with an anatomically intact anal sphincter, SNS versus maximum conservative treatment had an ICER of €16,181 per QALY gained, well within the €30,000 per QALY threshold accepted in Spain.

In 2010, Indinnimeo et al. [12] from Italy, published a cost effectiveness study of SNS based on the decision tree model of Brosa (who was a co-author of this paper also) [11]. The decision tree parameters appeared to be identical, based on the same NICE guidelines, but cost data from the Italian NHS reimbursement list were substituted. For example, the cost of temporary evaluation of SNS was €6,400, the cost of permanent implantation of SNS was €6,400, the cost of dynamic graciloplasty was €8,760 and the cost of artificial anal sphincter was €4,620 (as shown in Table 1, earlier in this chapter).

Clinical data were obtained from published studies and from “expert” panel consensus. Note should be made that one of the authors worked for Medtronic Italia and that some data on SNS were taken from a review in which the majority of patients were implanted using an open surgical rather than percutaneous technique. Treatment success was defined as “the cessation of the patient to seek further treatment due to a satisfactory reduction of incontinent episodes with the therapy”. Measurement of success was based on outcome at 6-month follow-up and it was assumed that loss in efficacy over time for each treatment was equal. The committee felt that this may have biased the results, as generally (for example) the efficacy of sphincter repair declines with time (80% < success > at 1 year, 50% at 5 years, 20% at ten-years [123]). In contrast, loss of efficacy with SNS is more likely to occur in the first year (in the absence of device failure).

There were several difficulties regarding the design of the decision tree. Firstly, the study assumed that all patients with a structurally deficient anal sphincter should undergo sphincter repair. Structural deficiency was defined as damage up to 120 degrees in radial extent affecting partial or full length of the internal or external anal sphincter, or both.

No reference was given to sphincter function in assessing the role of sphincteroplasty.

The Committee felt that in real life, those with partial length defects or isolated internal anal sphincter defects would not be considered for sphincteroplasty; only patients with full length defects with adequate residual muscle bulk and function would generally be considered for sphincter repair.

Generally, the indications for sphincter repair or dynamic graciloplasty are end-stage faecal incontinence in the presence of a substantial muscular defect and / or neural defect of the anal sphincter. However, the Decision Tree analysis assumed that all patients (even those with intact anal sphincters) would undergo one of these operations, which seems to make the model flawed in the case of patients with an intact anal sphincter.

Secondly, the model also assumed that of those undergoing a neo-sphincter procedure, 95% would undergo dynamic graciloplasty and only 5% artificial anal sphincter. The Committee felt that artificial anal sphincter is more readily performed in current clinical practice, with the recent understanding of poor long-term outcome of dynamic graciloplasty. Only 65 DG were performed in 21 European Centres in 2011 (Personal correspondence Medtronic Inc.). Finally, the model indicates that colostomy achieved 100% continence. In practice patients may still be incontinent of mucous which can cause considerable morbidity and impact upon quality of life.

The cost utility analysis revealed an ICER (€ per QALY gained) of €28,285 in those with sphincter defects, and €38,662 in those with intact sphincters. These results were within €40,000 acceptability threshold of the Italian NHS. Their Budget Impact Analysis appeared to give a low estimate of the total number of patients being treated with SNS (that is 86 to 115 patients per year over five year period in a population of 48 million people).
Mitchell et al [2011] performed economic analysis of the use of local anaesthetic (LA) versus general anaesthetic (GA) for insertion of temporary test electrodes (single electrode helical wires were used rather than tined quadripolar leads) [124]. Because LA was used, determining the optimal site for electrode placement was based upon sensory perception of the stimulus effect, rather than motor response. However, one third of patients undergoing SNS are known to have poor sensory localization and are unable to define the exact location of the stimulus making electrode placement difficult [125].

This was a retrospective cohort study of 111 consecutive age and sex matched patients, 42% of patients had LA which cost £613, and 58% had GA which cost £743, yielding a saving of £130 for the LA cases.

All were planned as day case procedures, but 89% of LA patients went home that day versus 62% of GA cases. A greater proportion of patients had success in the GA group (77% versus 64%). The small sample size resulted in a modest effect and a large standard error with non-significant effects. Reduced cost with the LA procedure was not correlated with effectiveness, so it is difficult to make conclusions about the outcome of study.

In late 2009, Dudding et al [13] performed a cohort analysis of 70 consecutive patients treated with SNS at a single UK institution over a ten-year period [1996-2006] with subsequent followup for approximately 2 years, which was then projected over a 7 year time horizon. Unlike the previous publications, these authors collected data prospectively at the patient level for baseline cost information and evaluated actual success, failure and complications, which comprised the Decision Tree analysis (as previously shown in Fig. 2, Decision Analysis).

All of the patients had failed standard conservative therapy, and these costs were assessed at baseline, for comparison with subsequent intervention with SNS. A societal perspective was taken and sensitivity analysis was performed.

Treatment and non-treatment costs were assessed. The treatment costs were taken from UK national tariff and health resource group codes. Face to face data on routine care costs was collected but careful calculations of typical costs of pad usage, loperamide consumption, outpatient visits etc were undertaken.

The non-treatment costs were derived from publications regarding time off work [110, 126, 127] and loss of work productivity[111, 128], from non-British sources, yielding a figure of £912 per patient per annum (which may not have been applicable to the UK population studied).

QALY data were calculated from conversion of elements of the Short-form 36 questionnaire, which is a standard methodology [26], although it must be noted that the SF-36 was not designed for economic evaluations. Inconsistencies can occur with this conversion which makes it possible for a patient with a better health state to record a lower QALY value than a patient with a worse health state [129].

Because the study included a self-selected group of patients who had failed to benefit from conservative treatments, it may not be representative of all patients who undergo conservative management for faecal incontinence (many of whom do achieve success from conservative treatment).

All procedures were performed under general anaesthesia, but the costing for short stay procedures was such that this had little economic effect. The cost for temporary evaluation was £510, the cost of permanent SNS implant was £8,480. Figure 2 shows the clinical pathway with resultant success rates and complication rates of this patient cohort (earlier in this chapter). Complications occurred in nearly 20% of patients (several were mild but required some form of medical intervention); these were carefully costed in the manuscript at the patient level. The basic conservative regime cost £596 per QALY gained, and SNS cost £2159 per QALY gained. Sensitivity analysis was performed to assess robustness of the model and rates were discounted by 3.5%. Including all treatment and non-treatment costs the ICER for SNS was £25,070 per QALY gained. This equates to £1038 more per year to treat patients with SNS for a median reduction in 286 incontinent episodes (£3.63 per episode reduced). Lost productivity make up a large proportion of the total cost of faecal incontinence and this was reflected in this study. When lost productivity was included, the ICER was reduced to £12,959 per QALY gained for SNS versus conservative therapy.

In conclusion the ICER of £25,070 per QALY gained was within the £30,000 per QALY threshold recommended by the UK National Institute of Clinical Excellence as an effective use of UK NHS funding (Figure 2).

In 2009, Dudding and Nugent[130] published an abstract which compared the costs of using a permanent quadripolar tined lead electrode for temporary testing as part of a staged implant versus the single electrode helical wire as part of a two-stage procedure. This was a decision tree analysis based upon published literature, which took into account success, failure and complication rates. On an intention to treat basis of 100 patients, a saving of £27.78 per patient can be made by adopting a staged implant strategy. They concluded that a permanent quadripolar electrode should be used for temporary SNS.
VI. SUMMARY AND FUTURE RESEARCH PRIORITIES

In the four years since the last ICI consensus conference, some high quality economic analyses of surgery for stress incontinence treatments have been published. The Committee notes that evidence regarding cost utility of outpatient therapies for stress incontinence remains limited, aside from the recent economic study of obesity treatment for this condition. However the economic analysis of therapy for overactive bladder syndrome requires greater effort, to encompass longer time frames and wider use of QALYs that can yield cost utility analysis (CUA). The Committee was disappointed to find that most of the recent economic studies of anticholinergic therapy did not include collection of raw QALY data.

In the last 4 years, the implementation of Sacral Nerve Stimulation for refractory detrusor overactivity has been the subject of several economic analyses, which are indeed important. However the Committee reiterates the need to collect primary data for QALY outcomes in future studies of this technique.

In the field of prolapse, it is not yet known whether any currently available QALYs are sensitive to treatment benefit, so that CUA may still not be feasible in this area. The recent POPPY study is to be commended for including patient-level cost data and quality of life information about conservative treatment.

As regards faecal incontinence, research into Cost of Illness remains rather preliminary, so that broader more long term studies are still needed. It is encouraging to see economic analyses of Sacral Nerve Stimulation in this field as well, however more data about Cost Utility in Faecal Incontinence is urgently needed.

As regards methodology, researchers need to consider carefully how they construct the model parameters for Decision Tree Analysis and Markov Models, so that “real life” assumptions are made. The gold standard remains Cost Utility Analysis in parallel with Randomized Controlled Trials, and we urge all clinicians to consider cost and QALYs as important outcome measures.

VII. APPENDIX – SEARCH STRATEGIES

We performed a comprehensive computerized medical literature search (PubMed) for the years 2007-2012 to identify all economic, health-related quality of life and cost-effectiveness analyses published on urinary incontinence, fecal incontinence or pelvic organ prolapse. Our initial search strategy was very broad and meant to be very sensitive but not specific. We performed a search for the following Medical Subject Headings (MeSH) and keywords: cost-effectiveness analysis, health care costs, quality-adjusted life years, costs and cost analysis, sickness impact profile, or utilities and urinary incontinence, overactive bladder, fecal incontinence, anal incontinence, uterine prolapse or pelvic organ prolapse. The initial searches were reviewed to identify articles appropriate for more detailed evaluation. Inclusion criteria were: urinary or fecal incontinence or prolapse as primary disease, data on costs available. Studies were excluded when they were a review or case-report.

I. INTRODUCTION

This chapter provides general recommendations for good research practice, including principles of clinical trial design and statistical methodology. In addition, we present specific recommendations applicable to trials for certain types of treatments and certain subgroups of patients.

1. LEVELS OF EVIDENCE

Most contributions to this consultation used the Oxford Centre for Evidence-based Medicine Levels of Evidence and Grades of Recommendation (http://www.cebm.net/levels_of_evidence.asp). However, as these are not an appropriate metric for recommendations in this chapter, the Research Committee used the following categories.

- High: Supported by strong evidence (multiple strong publications)
- Medium: Supported by moderate evidence (limited/moderate level publications)
- Low: Expert/Panel opinion

The report endorses consistent use of the methodology and approved terminology that will not only facilitate incontinence research by producing high quality studies but also facilitate communication about research. Recognized published guidelines produced by the International Continence Society (ICS) [1-15] and Society for Female Urology and Urodynamics (SUFU) [16-18] are useful examples of standardized terminology that advances communication in research.

Research is defined as “systematic investigation designed to develop or contribute to generalizable knowledge” [19] and participants accept risks to advance scientific knowledge and to benefit others [20]. The aim of clinical research in functional urology and urogynaecology is to evaluate treatments intended to prevent and/or significantly reduce symptoms of lower urinary tract dysfunction. The research methodology presented herein is intended to facilitate production of high-impact, high-quality research which will provide evidence needed to inform clinical practice, stimulate other investigators, generate new research ideas, and lead to a better understanding of physiology and pathophysiology of the human health and disease.

Although it is beyond the scope of this section to review the rules of conducting human subject research in depth and extensive coverage is available elsewhere [21-25], all investigators should understand the difference between “research” and “clinical practice”. At a minimum, criteria for an ethical research study should meet the following criteria:

- the study should be well planned, scientifically sound with clearly defined aims;
- clinical research should be prospectively registered whenever possible;
- the study should be feasible with a realistic chance for completion;
- there should be a reasonable assumption that new knowledge will be provided at the end of the study; and
- there should be an expectation that the results will be published to advance scientific knowledge [21, 26].

Human subject research protocols must be approved by an Institutional Review Boards (IRB), although IRB approval should be regarded only as a minimal ethical standard for research. Ultimately it is responsibility of the investigator to ensure the research is ethically acceptable.

2. PRIMARY GUIDING ETHICAL PRINCIPLES

There are 3 primary guiding ethical principles for human research outlined by the 1979 Belmont Report on “Ethical Principles and Guidelines for the Protection of Human Subjects of Research” [27]. These principles are essential for ethical clinical research and are briefly reviewed in the following section.

a) Respect for Persons recognizes the voluntary nature of research participation and includes informed consent without undue influence.

b) Beneficence requires investigators to maximize
benefits and reduce risks to the subject. The primary concern of the investigator should be the safety of the research participant and careful consideration of the risk/benefit ratio; this includes an ongoing responsibility to monitor research and medical literature as the research proceeds. The investigator needs to critically consider within the expert medical community if there is clinical equipoise for the proposed interventions in their trial. Is one treatment no better than another? Are the research risks reasonable in relation to anticipated benefits? It is the responsibility of the investigator to ensure risks are minimized and potential benefits enhanced as well as that the knowledge gained outweighs the risks [26]. Of note, invalid research cannot be ethical no matter how favorable the risk–benefit ratio for study participants.

c) Justice requires that the benefits and risks be distributed fairly (i.e. not only using people without access to health care, prisoners, or those impaired). Justice is of particular concern in Phase I testing of pharmaceutical agents and in early investigation of surgical devices/implants. Payment offered for participation in such drug trials may be extremely attractive to poor and disenfranchised subjects. Early device studies may target countries with lax regulatory environment even if there is little intent to market the device there in the long term.

3. INFORMED CONSENT IS AN ETHICAL CORNERSTONE OF HUMAN SUBJECT RESEARCH.

Peer review of protocols by a multidisciplinary team may include members of the scientific community, clinicians, pharmacists, the public/patient groups, the legal profession and individuals who can provide an ethical perspective. Each member of this team reviews the protocol from their particular type of expertise and in doing so aids in safeguarding patient health and well-being.

4. SPECIFIC INFORMED CONSENT IS REQUIRED FOR RESEARCH PARTICIPATION.

The length and depth of detail in consent forms vary widely between institutions. In the extreme, they involve exhaustive pages of information, which explain every alternative treatment with its pros and cons in detail. A general list of requirements for a consent form includes: name of the investigators and contact numbers, a detailed description of the new treatment and its known side effects, rationale for why the new therapy may be preferred to standard therapy. A summary table of the results of previous studies using the drug can be helpful when available. A statement that the patient may decline to be in the study with no subsequent consequence to their ongoing medical care is generally provided and whether or not remuneration is expected. Additionally, there should be a statement about payment for medical care required during the course of the study if there is an adverse event associated with the intervention. An understanding that the patient will be randomly assigned to treatment should be included when relevant, written using terms that are meaningful to potential participants [28-29].

5. THE INVESTIGATOR HAS AN ETHICAL RESPONSIBILITY TO TAKE RESPONSIBILITY FOR ALL ASPECTS OF THE RESEARCH.

This will insure that the work is done rigorously and to maintain the integrity of the research [30]. International Committee of Medical Journal Editors (ICMJE) now requires that information about trial design be placed into an accepted clinical trials registry prior to participant enrollment [31]. For more information, see more extensive information available elsewhere [30, 32-35]. A list of registries acceptable to the ICMJE can be found on their website. One objective of trial registration is to reduce publication bias given that trials with positive findings are more likely to be published than those with negative findings. An important feature of one registry, clinicaltrials.gov, is a results database [36].

Consider this pragmatic, simple test to use when resolving an ethical research dilemma: “Imagine what you are preparing to do will be reported the next day on the front page of your local newspaper. If you are comfortable having colleagues, friends, and family know what you did, chances are you acted responsibly.”

6. ENSURING PARTICIPANT SAFETY IS PARAMOUNT.

An independent data safety monitor (DSM) or data safety monitoring board (DSMB) is important to evaluate the study on an ongoing basis to determine early evidence of significant harm or benefit [37-38]. Depending on the size, complexity, and risks of a trial, the DSMB is comprised of experts needed to monitor interim data to ensure the safety of the participants. The DSMB should be established prior to initiation of the trial. In addition to reviewing results of the study for safety monitoring they may evaluate interim analyses to ensure that a treatment is not producing unacceptable levels of side effects and/or efficacy [29, 37]. A priori stopping rules or boundaries are established to assess if the study should continue or be terminated due to futility (that is, no conclusion will be drawn due to low enrollment, few outcome events, or high drop out rates etc.), reaching an endpoint, or identifying increased risks. Guidelines for stopping the study should be agreed upon, prior to the start of the trial [30]. Interim analyses (in particular those based on efficacy) will have implications for the study power. Specialist statistical advice and support will be essential to address these issues [39, 40]. Investigators must not be aware of the results of interim analyses, however, since this may cause bias by influencing how vigorously any given patient is recruited into or followed up in the study, and most importantly, runs the risk of a type
Il error (ie mistakenly concluding benefit when there is none). Nevertheless, emergency procedures for unblinding a patient’s allocation are required in case of a severe side effect or concomitant serious illness where knowledge of treatment assignment is essential for patient management and safety.

7. HIGH QUALITY DATA MANAGEMENT IS KEY TO PROVIDING VALID AND ETHICAL RESEARCH RESULTS [41].

In addition, ethical conduct of research includes timely and complete reporting. Clear guidelines for authorship have been established by medical journals [42]. Beginning with the research contract, authorship rules should be established according to accepted guidelines. In general, authorship credit should be based on 1) substantial contributions to conception and design, or acquisition of data, or analysis and interpretation of data; 2) drafting the article or revising it critically for important intellectual content; and 3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

9. FINANCIAL CONFLICTS OF INTEREST

Many investigators are involved in testing new drugs or devices developed by industry and have the potential to significantly supplement to personal income. It is acceptable for investigators to receive contracted financial support to perform this research and a principled partnership between industry and investigators is essential if we are to preserve medical progress [43]. Financial conflict of interest policies have been developed due to ethical concerns about potential biases that may influence trial design, conduct, over interpretation of positive results or not publishing negative results [30, 44]. It is important that investigators do not receive money directly (personal income) from industry sponsors but rather through a research contract through an appropriate entity with research oversight capabilities. Disclosure of these relationships helps maintain scientific integrity and preserve public trust in the scientific process. This is a rapidly evolving area and investigators are encouraged to clearly understand and disclose such relationships.

An investigator’s institution may have additional definitions and reporting requirements for financial conflict of interest disclosures. There are many potential relationships between physicians and industry; it is preferable that the nature of the relationship and its financial magnitude if any, be fully defined rather than categorized (i.e. "consultant") so that the reader can appropriately assess the disclosure.

II. DEFINING THE RESEARCH QUESTIONS

The investigator(s) should take a deliberate approach to formulate the specific research question, based on a careful review of related clinical research and relevant studies that are well designed and clinically relevant. The research reviews provided by the Cochrane Incontinence Group (http://healthsci.otago.ac.nz/dsm/wch/obstetrics/cure) provide an excellent starting point for most major incontinence topics. Based on a thorough literature review, the investigator clearly describes the primary research question(s), summarizes the background information, and formulates the rationale, objectives and hypotheses for the study. The investigator(s) should formulate the simplest study design which will provide the highest quality of evidence to test the given hypothesis in a cost and time-efficient manner. Whenever possible, basic or translational research should occur as part of the clinical research study in order to advance discovering of underlying mechanisms or pathophysiology. This balance between breadth and depth greatly increases the yield of the research effort [45].

III. EXPERIMENTAL STUDIES

1. RANDOMIZED CONTROLLED TRIALS

Experimental studies have the potential to provide a higher level of evidence than observational studies. The randomized double-blind clinical trial (RCT) is considered the gold standard study design. Properly planned and executed, the RCT is the optimal approach to limiting allocation bias [46]. The study participants are assigned to a treatment group by a random (chance) mechanism that ensures adequate concealment so that neither the study participant nor the investigator can influence treatment group assignment in order to reduce allocation bias. Subject assignment must be concealed during enrollment (for example, by separating allocation from the process of recruiting subjects, and by using remote randomization such as by telephone or web-based procedures), and wherever possible treatment allocation must be concealed during the trial (for example, using blinding with or without placebo). In order to minimize bias, the randomization process must be concealed from those recruiting subjects to the trial [48-49]. This can be achieved most effectively by the use of central telephone randomization.
In drug studies, a pharmacy can maintain identical treatment drug and placebo already randomly allocated into individual subject portions. These are distributed consecutively as subjects are enrolled in the study. In some studies, blinding of subjects and health care providers may not be possible, for example in trials of some surgical procedures or health care delivery methods. In almost all cases, however, the personnel collecting outcome data should be unaware (blinded) to the subjects' treatment allocation. RCTs require ethical equipoise and are usually expensive to conduct optimally.

The purpose of randomization is to produce groups that are, on average, comparable. A per-protocol analysis retains this property only in the unlikely situation when non-compliance is unrelated both to the patient's underlying state of health and the treatment received [50]. The intention-to-treat approach in pragmatic trials retains the full benefits of randomization and has the advantage that the comparison will more closely reflect the relative effectiveness of the treatments when applied in real clinical practice, where non-compliance is a common occurrence [51].

a) Simple randomization can use computer-generated random numbers, either prepared specifically for the trial or using existing tables of random numbers where the digits of 0-9 appear with equal likelihood in each entry. Treatments are assigned to odd or even numbers. As the total number of subjects in the trial increases, the balance of numbers and characteristics of subjects between the groups improves. In small trials, however, balance is not assured by simple randomization. Appreciable imbalances in subjects per group may be particularly important in a multicenter study where imbalances in assignment can occur within individual institutions.

b) Block randomization is one method used to prevent imbalances in subject numbers assigned to each group, particularly when the number of subjects in the trial is small. With block randomization, the total sample size is divided into blocks of a given size. Within each block, the group is assigned so that there are equal numbers allocated to each group. To prevent investigators from learning the block size and being able to guess order of assignment, the block size can be varied, usually at random from a small number of alternatives. In any case, blocking prevents serious imbalances in characteristics across groups when used in conjunction with stratification as described below.

c) Stratified randomization

Most disease states have factors known to influence the outcome of treatment, for example symptom severity or gender. A form of randomization that accounts for such factors is called stratified randomization [46-47]. Stratified randomization ensures equal distribution of subjects with a particular characteristic in each group when blocking is employed within strata. Stratification is usually restricted to a small number of factors, in particular those most likely to influence outcome. Despite its complexity, stratified randomization is usually helpful in a multicenter trial, so that both the numbers of subjects in each group and the important factors influencing the outcome can be balanced within each site. An alternative method exists to cater for more factors at once, known as minimization, where the characteristics of individuals already randomized alter in a systematic manner the chances of a given subject being allocated to the different trial groups, so as to maximize the resulting balance of these factors [46-47, 52].

Although the classical RCT involves the study of parallel groups, other options are possible and may overcome some of the limitations of the classical approach [53]:

d) Parallel Group Trials

This design generally includes one group of subjects assigned active treatment and a second (parallel) group a placebo or another treatment not believed to be an active treatment. The key feature of this design is that both groups (treatment and comparison group) are assembled and followed at the same time. In clinical trials of drugs the dose of the drug tested may be either a single dose or multiple doses to determine clinical benefit and/or minimize side-effects. More complex study designs can in some circumstances be worth considering – for example, factorial trials where two or more interventions can be investigated simultaneously [54-55], and cluster randomized trials whereby groups of participants (defined by some common feature, e.g. members of the same health maintenance organization, clinic, etc.) rather than individuals are randomly allocated to the trial arms [56]. This strategy might be employed when studying an intervention requiring policy changes in an institution, with a hospital, clinic, or health care system being the unit of randomization.

e) Crossover Trials

Subjects receive both the treatment being studied and the placebo/alternative treatment, with random order of treatment assignment. The benefit of crossover studies is that they eliminate the effect of variation between groups of participants seen in parallel trials, that is each subject serves as his/her own control. Crossover studies are particularly well suited for small studies, where the course of the disease under study is believed to be stable, and where the primary objective is to measure a short-term change in the outcome (e.g. urinary symptoms) in response to treatment. The duration of treatment required before the anticipated effect may be observed is critical in determining whether the crossover study design is appropriate – too long a period time before an effect becomes evident, and the disease state may vary before the study
either amount. The clinically important difference between the standard treatment group and the control and study treatments are not large in either direction (more beneficial or less beneficial). A recent trial of midurethral sling surgery illustrates this type of study design [67].

h) Superiority trials

The most common study design for clinical trials of urinary incontinence and for many other diseases/conditions is the superiority trial where the goal is, in its most simple form, to show one treatment is better than another (or no treatment, placebo). The general approach is to establish a priori a clinically meaningful effect that you wish to detect. Once conducted, determining superiority requires that the findings permit the investigator to reject the null hypothesis that the two distributions of the treatment effect are equal, in favor of the new treatment being better than the control [58].

2. NON-RANDOMIZED CONTROLLED CLINICAL TRIAL(S)

This category includes trials in which treatment allocation is known to the investigator prior to obtaining informed research consent (for example, day of clinic appointment). This approach often results in baseline characteristics of the treatment groups being significantly different, decreasing the ability to interpretate trial results. Because of this major shortcoming, this type of study should be used rarely, if at all.

3. PRAGMATIC AND EXPLANATORY TRIALS

There is an important distinction between pragmatic and explanatory trials [68-69], and correspondingly, between intention-to-treat and per-protocol approaches to data analysis [50, 70]. This distinction has a number of facets. In pragmatic trials the interventions are designed to be as close as possible to treatment options in clinical practice (including multiple patient management choices) and entry criteria are usually relatively liberal in comparison with explanatory trials. In addition, pragmatic trials may involve a wide variety of outcome domains, including patient-completed questionnaires, and an economic evaluation of outcomes. As a result of intention-to-treat data analysis, pragmatic trials will tend to yield lower estimates of treatment differences than explanatory trials. It may be of interest to gauge the effect of treatment given full compliance; therefore, full data analysis ideally incorporates both intention-to-treat and per-protocol approaches [50]. The primary analysis, though, should follow the intention-to-treat principle.

Data from pragmatic trials are analyzed by intention-to-treat, according to the group to which subjects were randomized, regardless of the extent of compliance with the intended treatment. In explanatory trials, data are analyzed accounting for compliance. This per-protocol approach may exclude serious non-compliers, analyze data according to treatment actually received, or allow for degree of compliance in a statistical model.
At first sight, the explanatory approach appears more attractive. However, there are considerable limitations to the explanatory approach, particularly when the intention is to draw inferences from the trial to wider clinical practice (generalizability).

4. DRUG TRIALS ARE CATEGORIZED ACCORDING TO THE FOLLOWING DEFINITIONS [30, 50].

a) Phase I studies

The first studies of a drug in humans, often open label and uncontrolled, concentrating on safety and frequently but not exclusively carried out in healthy volunteers. Pharmacokinetic and tolerance information is obtained from Phase I trials.

b) Phase II studies

The first attempts to investigate treatment efficacy, often the first use of the drug in subjects and focusing on short-term outcomes. A common objective of Phase II studies is dose finding in terms of efficacy. Two sub-types may usefully be distinguished: Phase IIA studies where single treatments are considered in relation to a minimum response prior to further investigation; Phase IIB where direct comparisons are made between interventions, albeit on a small scale and not necessarily involving randomization [71].

c) Phase III studies

Large-scale, authoritative randomized studies performed once the most likely effective and tolerated treatment regimens have been established. The objective is often to establish that the intervention is suitable for registration/approval with the appropriate regulatory authority. Trials are conducted after submission of a new drug application (NDA), but before the product’s approval for market launch. Phase IIIB trials (between submission for approval and receipt of marketing authorization) may supplement or complete earlier trials, or seek different kinds of information (for example, quality of life or marketing). Phase III trials are also used to investigate the effectiveness and cost-effectiveness of various interventions – that is, non-drug including organizational issues – and not necessarily with reference to regulatory authorities. All Phase III trials should be subject to a formal sample size calculation – for instance to obtain sufficiently precise estimates of the comparisons between treatments or to have a reasonable chance (power) of detecting a difference if one exists (see section II C 7 below).

d) Phase IV studies

These investigations are usually carried out after registration/approval, to investigate the drug’s safety and efficacy in different populations. Such post-marketing surveillance studies are typically larger and simpler than regulatory studies; they may lack a control group and are often conducted using surveys.

5. BIAS, BLINDING AND EFFECTS ON VALIDITY

Bias can be introduced at many stages of a study including patient selection, randomization, assessment of outcomes, and statistical analysis and interpretation. Bias occurs because of previously conceived ideas held by those involved, which consciously or unconsciously affect their actions and observations. In addition to observer bias, an amount of observer error is inherent in outcome measures that require clinical interpretation.

a) Blinding

In order to minimize bias, research design should strive for the highest practical level of blinding. Blinding is the process by which key elements of knowledge are withheld that can otherwise lead to bias. Blinding should not be confused with concealment of allocation, referring to withholding knowledge of assignment in advance, which is a prerequisite for the validity of any trial [48, 72]. While blinding is important, its effect is lower than that of concealment of allocation [73]. In most drug studies placebo pills allow blinding of all relevant participants.

b) Unblinded trials

They are conducted in an open manner where both subjects and study investigators are aware of which treatment has been assigned. While certain types of therapy may require investigation in this manner (e.g., some surgical trials), there remains considerable opportunity for bias. Both subjects and investigators may have preconceived ideas regarding the benefits of a particular treatment that can influence the reporting of symptoms and/or their outcome.

c) Single blind trial

Commonly, in a single blind trial, ‘single blinding’ may refer to blinding the outcome assessor (but not the subject); this is common in trials in which blinding the subject is not possible (such as pelvic muscle exercise trials). It is important to specify who is blinded to which aspects of study execution, rather than using only the vague term “blinded”. Hence, in these studies the only possible blinded person is the assessor. It may be advantageous for the clinical staff to be aware of the assignment to allow them to monitor the health and safety of individuals, since the potential effects of the treatment (side effects) will often be known in advance. Single blinding ameliorates biased reporting of symptoms and/or side effects by subjects. However, clinical staff can influence data collection and change other aspects of subjects’ care when they know which study treatment subjects are receiving.
d) Double blind trials

In double blind trials, both parties who could influence outcome are unaware of group assignment. Often this is just the subjects and the clinical team responsible for their care. Selection of an appropriate external comparison group is challenging and factors unknown or not measured by the investigators may adversely influence the findings.

IV. ELIGIBILITY CRITERIA

Eligibility criteria impact every aspect of a study’s progress, from recruitment to analysis to acceptance of the study’s results by the community. Yet, in the planning phase of a study, this vital aspect is often given short shrift. Eligibility criteria will differ, depending on the main goal of a study. For a Phase I trial, designed to understand safety of an intervention, eligibility criteria should be very narrow, and should focus on minimizing risk and maximizing ability to demonstrate proof of concept. A Phase II trial, designed to test the efficacy of a treatment in a fairly ideal population, will have broader eligibility criteria, but will exclude individuals in whom it is highly unlikely a treatment will be helpful, or highly likely that a treatment might be harmful. If a treatment shows promise at this point, eligibility criteria for a Phase III trial are as broad as possible, to test the effectiveness of the treatment in as real world of a setting as possible, thus maximizing generalizability. Conclusions can only be as broad as the eligibility criteria allow. Thus, a drug found to be effective in a study that included only healthy middle-aged people can be recommended for that group, but not for older people, children, people with medical conditions, or other groups excluded by the eligibility criteria.

While some exclusion criteria are necessary to reduce risk to potential participants, it is important to include individuals in whom the treatment would likely be used once widespread. For example, in testing a new drug for urgency incontinence, that is excreted by the kidneys, it is important to exclude people with high serum creatinine levels, but equally important to include older individuals with multiple co-morbidities in specific studies, as these are also likely to benefit from a drug for urgency incontinence once released.

Particularly in longer-term studies of pelvic floor disorders, some exclusion criteria are needed to maximize potential for follow-up. Such studies often exclude people likely to move or die during the study period, people with conditions that impair adherence (such as drug or alcohol dependence, severe mental illness or homelessness) or factors that make follow-up more difficult (such as lack of a telephone). For ethical reasons, it is important to either exclude people with significant cognitive impairment (such that informed consent is impossible) or to plan a consent process with a legally authorized representative in mind. However, all exclusions impact the generalizability of the conclusions and so such trade-offs must be carefully thought through.

Additionally, inclusion criteria related to the condition of study must be considered in concert with the consideration of the primary outcome measure. If an inclusion measure defines “disease”, it is essential that the outcome measure does not include this same measure or cut-point as “success”. For example, if a surgical trial comparing two treatments for pelvic organ prolapse defines prolapse as >/= stage II (and excludes from enrollment only women with < Stage I prolapse) and the primary outcome measure defines successful treatment as prolapse at or above the hymen, then women enrolled with maximal prolapse at points 0 or -1 may be considered successfully treated when in fact, their condition has subjectively not changed. It is also important to note that a given condition, such as stress urinary incontinence, will be present or absent depending on which outcome measure is used to define it. Avoid using one outcome measure to exclude women from a study and then a different outcome measure defining the same condition as the primary outcome measure.

V. SAMPLING STRATEGIES

Every study must address its sampling strategy, that is, the selection of participants. In principle, sampling should involve random selection. In practice, however, this ideal is rarely met outside of large-scale epidemiological studies. For example, RCTs are drawn from a subset of the population, often limited to those with access to academic medical centers plus the willingness and ability to participate. Where this is the case, it is crucial to provide descriptive information about the study sample, so that its representativeness can be judged. Guidelines for reporting of RCTs include requirements to state the study population, give details of inclusion and exclusion criteria, and present clearly the numbers of eligible subjects who were not randomized and the reasons [32, 48-49].

A study may require a sample that is representative of the community overall or one representative of patient groups suffering the condition/disease. In principle, this is achieved by taking a simple random sample from a known population. In practice, a list of all eligible individuals is obtained and then a sample is drawn by a method in which each member of the population has an equal probability of selection (‘epsem’). Even in ideal circumstances, however, some sophistication on this basic method is usually desirable or necessary. For example, in stratified sampling, subjects are arranged into subgroups and the sampling is performed within each subgroup separately. This ensures that the sample is representative of the population in terms of these subgroup character-
In multi-stage random sampling, the population is first divided into primary sampling units (such as hospital, health center, or surgeon), and a sample of primary units is selected. The secondary sampling units, usually individual subjects, are selected within the primary sampling units. A special case of multi-stage random sampling is cluster sampling where all individuals within each primary unit are included. Standard procedures for sampling should be followed [56, 74].

It is important to note that, while the technicalities of random selection of subjects for a study are closely related to the random allocation of subjects in an RCT (and indeed there are similar issues in trials relating to stratification and clustering) [56], there is an important distinction in the objectives of the two procedures. First, the (ideally random) selection from the population of eligible subjects concerns the external validity or generalizability of the study findings (RCT or otherwise). Independent of this, the random allocation of subjects in an RCT is concerned with the internal validity or comparability of the trial groups. It is usually obvious whether the study can be performed at a single institution, or whether a multicenter study will be required. Single institution studies have the benefit of being less complicated from a logistical perspective. While multicenter trials are more complex to manage and are usually more expensive, they provide larger numbers of participants in a shorter period of time, and increase the generalizability of research findings.

VI. DATA COLLECTION

Although the number of questions in a single study should be limited, it is still relevant to record as many as observations as is possible without jeopardizing recruitment or retention with onerous demands. Strong consideration should be given to collection of the following data groups [16], [75].

a) Baseline data:

b) Observations:

1. Patient’s observation/Subjective measures
2. Clinician’s observation/Objective measures

c) Tests

1. Quantification of symptoms—bladder diary, and
2. Pad tests for incontinence outcomes
3. Urodynamics

d) Follow-up

e) Quality of life measures

f) Socioeconomics

It is useful to consider collection of the following variables:

- Age
- Race/ethnicity
- Gender
- Body mass index (height and weight)
- For women – obstetric history, including parity and menopausal status
- Smoking status
- Co-morbidities such as cardiovascular, respiratory and neurologic conditions and diabetes
- Medication use
- Past surgical history
- Level of education
- Mental and physical status
- Prior treatment for pelvic floor disorders, including behavioural, pharmacological and/or surgical interventions
- Sexual function

VII. OUTCOME MEASURES

Specific discussions of the most appropriate outcome measures for particular studies of incontinence and pelvic organ prolapse are discussed elsewhere in this consultation. The purpose here is to define the general concepts of primary and secondary outcomes, which are relevant to both sample size determination and data analysis. The distinction between these two sets of outcomes depends on the context of the trial, and should be decided at the planning stage of the study. Primary and secondary outcomes should not be confused with the distinction between primary and secondary analyses of trial data.

1. PRIMARY OUTCOMES

Primary outcomes are those viewed by the researchers to be of central interest. Sample size calculations are based on anticipated changes in the primary outcomes. The final study population may or may not be sufficient to allow robust comparisons of secondary outcomes. Trial results that are based on the primary outcomes can lead to responsible alterations in standards of patient care.

The number of primary outcomes in a particular trial will depend on the nature of the interventions and the number of independent domains. The number of primary outcomes is usually limited to three. Sample size calculation is based on the primary outcomes. The number and nature of outcome domains in a particular study will vary depending on the study’s perspective. Careful selection of outcome measures
that are valid and clinically relevant is intrinsic to the success of research; usually no single measure can fully express the outcome of an intervention.

2. SECONDARY OUTCOME

Secondary outcomes can be relatively large in number. They are not the focus of the main study objectives and are rarely used directly in sample size estimation. Secondary outcomes are exploratory, i.e., as hypothesis-generating exercises for which independent confirmation is essential or used to monitor: e.g., safety, side-effects, costs or patient acceptance.

3. TYPES OF OUTCOME MEASURES

Traditionally, a patient’s success after a particular treatment was reported by the physician, using subjective information that differed from physician to physician. Given the mismatch between physicians’ and patients’ perceptions of treatment effectiveness, this type of physician reported outcome measure has been largely replaced with patient-reported outcomes (PROs). The Food and Drug Administration defines a PRO as any report of the status of a patient’s condition that comes from the patient, without interpretation of the response by the clinician or anyone else.

There is emerging consensus that PROs are most appropriate when describing success or failure of therapies. However, physician-reported outcomes can yield valuable information about mechanistic effects of therapies and are also vital in developing predictive data for future use. As an example, a patient's report of a bulge is a reasonable outcome measure for a study of surgical treatment for POP. However, if, over time, women with stage II POP after treatment who were initially asymptomatic became symptomatic, it would be pertinent to include prolapse stage, as an anatomic outcome measure, in the definition of success.

Other types of physician reported outcome measures (often called “objective outcomes”), used frequently in pelvic floor disorder research, include results obtained from urodynamic testing (e.g., presence or absence of detrusor overactivity incontinence), radiologic imaging (e.g., various angles measured during pelvic ultrasonography), physical examination (e.g., the POP-Q system for assessing pelvic organ prolapse), laboratory values, biomarkers, etc., as well as tests collected by the patient but interpreted by the physician (such as pad tests and bladder diaries).

The primary types of PROs include [76].

- Disease/condition specific: measure patients’ perceptions of a specific condition.

These cannot be administered to people without the condition under study.

- Population specific: specific to a certain population (for example, women or men or elderly) with or without a given condition.

- Dimension specific: assess one aspect of health status. The primary dimensions studied include:
  - Physical function (e.g., activities of daily living)
  - Symptoms (e.g., urinary incontinence)
  - Psychological well-being (e.g., depression)
  - Social well-being (e.g., sexual function)
  - Cognitive function (e.g., mental status evaluation)
  - Role activities (e.g., household or work activities)
  - Personal constructs (e.g., body image)

- Generic measures: measure broad aspects of health which can be used to compare across populations (The SF-36 is a commonly used measure). These are often less responsive to clinically significant changes in health than condition-specific instruments.

- Utility measures: (e.g., EuroQol) incorporate preferences or values attached to individual health states. This type of instrument produces evidence for the overall value of health states to society and can be used in cost-utility analysis.

- Summary items: participants summarize an overall picture of their status in one item (for example, the transitional item queried in the SF 36: “Compared to one year ago, how would you rate your health in general now: excellent, very good, good, fair, poor?”)

- International Classification of Functioning, Disability and Health (ICF), WHO 2001

- Unified and standard language and framework for discription of health and health-related states

- Body, Individual, Society
  - Body functions and structures
  - Activities and participation

- Body functions: physiologiical and psychological functions of body systems

- Body structures: anatomical parts

- Impairments: problems in body function or structure such as significant deviation or loss
• **Activity**: execution of a task or action by an individual
• **Participation**: involvement in a life situation

While not yet in wide use, web-based resources for administering computerized adaptive tests are being developed. One example is the Patient Reported Outcomes Measurement Information System (PROMIS) system (www.nihpromis.org). Using this type of testing, researchers can lower participant burden substantially. For example, in a measure of physical function, someone who endorses inability to dress themselves would not be asked the next series of questions in a typical validated physical function questionnaire about walking or exercising; someone who endorses ability to run marathons would not be asked questions about less strenuous activities. Nascent work has begun on the use of the PROMIS system in pelvic floor disorders [77].

Investigators should strive to use validated outcomes measures whenever possible. A fully validated outcome measure is demonstrated to 1) be reproducible when administered to the same person twice, 2) yield results that align with other gold standard measures (content validity), 3) change with successful treatment (be responsive to change), and 4) measure what it is intended to measure (face validity). (A full discussion of psychometric properties needed to validate a questionnaire can be found elsewhere in this consultation.) Much progress has been made in this area over the last decade, and therefore, when planning a study, the default position should always be choosing a validated outcome tool as a primary outcome measure. However, it is important to note that just because a questionnaire is “valid” does not mean it can be used in any population in any language. Researchers must take care to use instruments in the populations for which they were intended.

**Adverse event recording and analysis** is an important aspect of outcome measures, especially when the benefits may be offset by harms. Adverse event assessment should be systematically included in every interventional study. The Clavien-Dindo system for structured reporting and analysis of surgical complications has been used in several studies comparing pelvic floor interventions[78]. In this system, complications are classified into one of four categories based on the type of therapy needed to correct the complication.

**The timing of outcome assessment** should reflect the study question. Studies reporting efficacy of incontinence treatment should follow subjects for a minimum of one year. Although early follow-up can provide important insights about adverse events, a great deal more emphasis needs to be placed on long term effectiveness. The follow-up time for a trial should be at a fixed time (for logistical reasons, this is in practice often a short time window) relative to randomization rather than when treatment was actually received, since again this is the only way of ensuring a valid comparison. The planned timing of follow-up at a fixed time relative to randomization should, however, allow for any likely delays in receiving treatment, e.g., due to surgical waiting lists.

## VIII. STATISTICAL CONCERNS

### 1. SAMPLE SIZE CONSIDERATIONS

There is no single answer for sample size determination; often the calculation proceeds around a ‘circle of specifications’ (involving, say, power, targeted difference in effect size and population available for study). Furthermore, the ideal of the target being the minimum for clinical significance cannot always be met; rather, the aim in practice is to produce a convincing argument (among the researchers themselves, and also to funding bodies and regulatory agencies) that the sample size has an adequate chance of detecting differences that are (a) feasible, and (b) worthwhile detecting in clinical terms. A common failing is selecting a target difference that is too large, often derived from differences that have been observed or published previously rather than based on considered clinical judgment. Preliminary investigations into the levels of treatment effects that patients themselves consider worthwhile should be carried out much more commonly than is the case at present.

Sample size should be calculated in the planning stage of all studies. There are many formal equations to assist in this process, details of which will not be given here [70-71, 79-80]. Rather, the emphasis for this discussion is on the concepts involved and the information required for the calculations to proceed.

### 2. SAMPLE SIZE CALCULATION

One approach to sample size calculation is based on the required precision of an estimate, which is relevant to both descriptive and analytical investigations. The basic issue is one of precision (measured by the standard error, SE) or margin of error (which depends on the SE but is more specifically defined as half the width of the 95% confidence interval [CI] around the estimate). The higher the level of precision specified in advance (i.e., the smaller the SE and the narrower the CI, the larger the sample size will need to be. However, the margin of error depends on the nature of the primary outcome variable, i.e., whether it is a continuous variable (such as maximum urinary flow rate) or a binary variable (such as the presence or absence of self-reported urgency incontinence). For a continuous variable, the variability (standard deviation) of the measure must be estimated for relevant subjects; this may
be derived from some combination of clinical experience, the literature, or a pilot study. The larger the variability, the larger the sample size required. For a binary variable, its prevalence must be estimated in the population to be studied, since the SE for such variables depends on their prevalence.

A second approach, based on power, is the most commonly used and requires that the study have adequate probability (power) of detecting a given (target) magnitude of effect. It requires similar prior information, including estimates of the variability for continuous measures and the magnitude of proportions for binary variables. In addition, it requires specification of three other quantities: the significance level, the power, and the target difference. Significance is a statistical term that tells how certain one can be that a difference or relationship exists. It does not necessarily imply that the result is clinically relevant, just that the result is likely to be accurate. The significance level, termed alpha, is conventionally, though not necessarily, set at 5%. Power is defined as the probability that the study will detect (as statistically significant at the alpha level specified) a given target difference between the groups, if such a difference exists. Power is commonly specified in the range of 80% to 90%, which implies a risk of not detecting the target difference of between 20% and 10%, respectively. For a trial involving anything other than minor risks and expenditure, a power closer to 90% than 80% would seem preferable [32], which leads to a larger sample size (as does a stricter alpha level of, say, 1%). This is most pertinent when a lack of statistical significance is obtained in a small trial, particularly when the sample size was not planned using a power calculation [47]. This is the basis for the adage that “the absence of evidence is not evidence of absence”[25]. A planned unequal allocation to the trial groups also requires an inflation of the sample size [47], as does interim analyses. By multiplying the number of significance tests performed, studies with interim analyses generally require stricter significance levels at each analytical point [50, 70].

3. THE TARGET DIFFERENCE

This is the last, and arguably the most important, quantity that must be specified for the power-based approach to sample size calculation. The target difference is defined as the minimum difference between treatment groups considered to be clinically significant. Clinical significance is an entirely different concept from statistical significance. Investigators must estimate the clinical significance as the magnitude of difference (in means or proportions) that would lead to a change in clinical management for the target group of patients. For example, a study might propose that a 20% difference in incontinence episode frequency is a clinically meaningful response. Ideally, such an assumption would be based on surveys of patient behavior but in practice the decision is often based on clinical judgement. In any case, the smaller the clinically significant target difference, the larger the required sample size. Statistical significance means that the observed difference, whatever its magnitude, cannot reasonably be considered as being due to chance. Statistical significance (denoted by the p-value) represents the strength of evidence against the null hypothesis [81]. The degree of clinical significance can be inferred only with the additional information of a confidence interval for the comparison between groups. A very large trial may achieve a high level of statistical significance with a very small effect size and therefore be of little clinical significance. A trial designed in such a way poses ethical challenges because many extra subjects are exposed to risk without meaningful benefit.

With each approach, appropriate adjustment for attrition (loss to follow-up) should be performed. This is commonly achieved by simply increasing the planned sample size in proportion to the anticipated attrition (i.e. to predict the reduced effective sample size that will be available for the analysis).

IX. ANALYSIS

The analytic plan should be consistent with study aims and the a priori analytic plan should be included at the time of the protocol entry into a clinical trials registration system. Currently, high tier journals will often request the statistical analysis plan and protocol at the time of the review of the report. This section will not contain any technical details of statistical methods, which are available in standard texts [47, 82-83], but rather will summarize concepts of data analysis.

It is established practice that the primary analyses (for both primary and secondary outcomes) of an RCT should be on an intention-to-treat basis [48, 72]. Secondary analyses incorporating non-compliance and/or which treatment was actually received may be justified in addition to the primary analyses. In practically all situations, hypothesis tests should be two-sided (i.e., allowing for the possibility that the difference could have been in either direction, that is benefit or harm), rather than one-sided. One-sided tests are only appropriate if a difference in one direction is not just unlikely, but would not be of interest, such a demonstrating only superiority of a new drug.

Regardless of the type and complexity of statistical techniques used in analysis, the general underlying principles behind hypothesis testing and estimation apply. In particular, the statistical significance of a hypothesis test should be interpreted critically. The actual p-value should be considered, rather than just whether or not it is below an arbitrary threshold such as 5% [48]; indeed, the p-value is better considered a measure of the strength of evidence against the null hypothesis, on a continuum or ‘shades-of-grey
[83-84]. The direction and magnitude of the trial comparison should be presented with an appropriate confidence interval to indicate the possible clinical significance and precision of the comparison [48, 85].

Appreciable loss to follow-up in a trial (which is not the same as adherence with intended treatment, lack of efficacy, or the observation of adverse events) may present serious problems both in terms of generalizability of the findings to the wider population and, in the case of differential loss to follow-up across treatment groups, to the validity of the comparisons. Indeed, strictly speaking any missing outcome data means that not all of those allocated to the various randomization groups can be included in the analysis [86], and this might lead to the conclusion that the term ‘intention-to-treat’ should only be used if follow-up is complete. Under current guidelines, intention-to-treat relates more to the broad strategy adopted by the researchers for data analysis [39, 87]. Results should always be accompanied by a full and clear statement of how deviations from intended treatment and missing outcome measures have been handled in the analysis. The discussion should include how missing outcome data may have affected the conclusions [86]. Sensitivity analyses can be used to test the exclusion of, or assumptions about, missing values; practical examples of such analyses are becoming more common [88]. Another design strategy, modified intent to treat (MITT), is common in drug trials. It requires the participant to take at least a single dose of the study medication in order to be included in the analysis.

It is essential that a statistical analysis plan be developed for the trial prior to implementation. The CONSORT statement provides an outline of the various stages of data analysis for RCTs [32, 72]. Here we present the underlying concepts of data analysis at a particular follow-up time relative to randomization, and considers initially the simplest case of a clinical trial with two treatment groups. Multiple treatment groups will be covered briefly, but repeated measurements of outcomes and interim analyses involve considerably more complex methods of planning and analysis, for which expert help is essential [71, 89].

- **Stage of data analysis**

  **The first stage** of data analysis is to address the representativeness of randomized subjects compared to the target population of eligible patients. The number of eligible patients who were and were not randomized should be provided, along with reasons for excluding potential study participants. This aspect of the findings of the trial will only prove useful if all eligible patients are considered: in practice there is a tendency for researchers to avoid approaching certain potentially eligible patients (selective pre-screening), for any of a wide variety of reasons, and this behavior may introduce bias in which subjects from the target population are included in the study. The presentation of this information is facilitated by use of the CONSORT flow diagram [48, 72]. Use of the CONSORT guidelines is associated with improved quality of reporting of trials generally [32]. Descriptive statistics should also be given of important characteristics of health care professionals approached for involvement in recruiting subjects to the trial, both for those taking part and those declining.

  **The second stage** of data analysis is to compare the two groups at randomization (baseline) including demographic, prognostic, and outcome variables. A common error at this point is to rely on statistical testing for these comparisons [47, 50, 70]. If the randomization procedure has been performed correctly, then any statistically significant differences in baseline characteristics are likely due to chance. Statistical testing of this kind is not a test of the comparability of trial groups; rather, it is a test of the allocation procedure [47, 50, 70]. It may be seriously misleading, particularly if lack of a statistically significant difference for a given characteristic is taken to imply comparability. Baseline comparability is best assessed by simply obtaining descriptive statistics for the groups and making a judgment as to whether any observed differences are likely to be influential or not. If differences are likely to be influential, they should be considered in the analyses. Notable exceptions to this are baseline measures of the outcome variables, which should be considered in the analysis regardless of the situation at baseline, since removing variance in the outcome measure that is purely attributable to differences between individuals at baseline has potentially marked benefits in terms of precision and power [50]. Investigators should consider stratifying the randomization on any strongly prognostic variable (for reasons of efficiency rather than bias). Since there are practical limitations as to how many variables a trial can stratify for, a technique known as minimization may also be considered [46, 74]. Any variables stratified or minimized at randomization should be allowed for in the analysis [50]. In incontinence research, variables such as prior failure of therapy in drug and surgical studies or the degree of anatomic support in surgical or injectable trials or degree/amount of incontinence might be considered important enough to stratify, or to include in the analysis if unequally distributed.

  **The next stage** of data analysis is to perform the primary (comparative) analyses for the outcome variables. First, though, it is essential to derive and report actual numeric data – even if simply in the form of descriptive statistics – rather than just reporting for instance a percentage change, even if the latter are relevant and provided as well. Graphs can be misleading, especially when subsections of the scales are magnified, and should be used to supplement or clarify the numerical data,
not to replace it. Primary outcomes should initially be analyzed by intention-to-treat comparisons of the groups as randomized, both using hypothesis tests for statistical significance and CIs for comparisons between the groups to assess clinical and statistical significance, usually adjusting for baseline measurements of the outcome variable. With a small number of primary outcomes, multiple testing is not a concern. However, when a large number of statistical tests are performed for secondary outcomes, corrections to the observed p-values should at least be considered.

The most commonly used procedure for multiple testing of many outcomes is the Bonferroni correction [47, 50, 82]. The Bonferroni correction can be conservative in reducing the risk of a statistically significant effect occurring purely by chance, at the cost of reduced power for individual outcomes. This is particularly pertinent when, as is usually the case, the outcomes are positively associated with one another. While there are alternative procedures that improve this deficiency, none of them are entirely satisfactory [50]. It is emphasized that whatever strategy is adopted to deal with multiple testing, the major errors are to rely solely on p-values rather than present confidence intervals “CIs” as well, to over-simplify the presentation of p-values to just non-significant “NS” or “p<0.05” rather than to quote the actual p-values, and above all to report selectively the results of significance tests.

Another example of a “multiplicity” is where there are more than two treatment groups, e.g., when different doses of a drug are being investigated or when more than one ‘active’ procedure is being compared with placebo [50]. Similar issues to multiple testing of different outcomes are involved here, but there are a greater variety of commonly used procedures available to deal with the central concern of finding a difference purely by chance. Standard methods for dealing with this multiple comparisons problem include the procedures attributed to Tukey, Newman-Keuls and Dunnett [90].

Secondary analyses of trial data include per-protocol analyses with adjustments using regression methods for pertinent process measures such as degree of adherence with the allocated treatments. Secondary analyses also include planned subgroup analyses, such as the investigation of different intervention effects across age, ethnic, or disease severity groups. Subgroups should be analyzed by using appropriate interaction terms in regression models [48, 70]. Using interaction terms rather than performing repeated, separate, subgroup-specific analyses considerably reduces the risk of false positive findings [91-92]. Subgroup analyses should be carried out sparingly, specified in advance (preferably with a clinical rationale), and above all should not be reported selectively [48, 92-93]. This last point relates not just to subgroup analyses but to all stages of reporting randomized trials. Pre-specification of the primary outcomes in the study protocol and analysis plan, along with clear statements about all the outcomes considered is essential to avoid selective reporting. The large volumes of data accumulated in major multicenter RCTs almost guarantee that something “significant” can be identified by “data-mining”. If not identified by the investigators as an a priori item of interest such findings should be viewed with great skepticism.

X. REPORTING RESEARCH RESULTS

Over the past decade, progress has been made in reporting research results. However, faster progress would occur if investigators would follow the reporting recommendations. As part of the “Enhancing the QUALity and Transparency Of health Research” (EQUATOR) Network project, a website was developed at www.equator-network.org. On the website, the Consolidated Standards of Reporting Trials (CONSORT) statement provides guidelines for reporting the design, detailed methods, and results of RCTs. For studies of diagnostic tests the Standards for Reporting of Diagnostic Accuracy (STARD) [94] statement fills the same role and information is also included on the EQUATOR website. Guidelines for reporting meta-analyses are described by the Quality of Reporting of Meta-analyses (QUORUM-37) and Epidemiologic research reporting guidelines are contained in STROBE, Strengthen the Reporting of Observational Studies in Epidemiology [38, 72].

The CONSORT statement is specifically designed to provide standards for reporting RCTs [48, 72]. It includes a checklist of items that should be included by authors preparing manuscripts. Adherence to these guidelines and the use of flow diagrams in particular is associated with improved quality in reporting of RCTs [95]. Errors in presentation of statistical information are extensively covered in many textbooks [47, 82]. This section will emphasize the most important points on reporting of RCTs, to ensure an objective and comprehensive presentation of the trial itself, and also to facilitate any subsequent synthesis of research evidence including formal meta-analyses of RCTs. Meta-analyses are themselves the subject of separate reporting guidelines: the QUORUM statement [96]. However, such guidelines are not a panacea [97]; deficiencies in reporting are still common [72, 98].

The CONSORT statement for reporting parallel group randomized trials have recently been updated Statements have also been issued for pragmatic trials [99-102] and noninferiority and equivalence trials. The CONSORT statement includes a checklist of items and a comprehensive set of characteristics of a clinical trial to assist investigators to write reports of their findings, journal editors and
reviewers in the review of manuscript submitted for publication and permit consumers of the literature to critically appraise articles. Clear statements about the objectives of the trial, intended study population, and planned comparisons. Subgroup or covariate analyses should be clearly specified and justified. The method of randomization should be stated, as should the unit of randomization; in most cases, this will be the individual participant but occasionally an aggregate group of subjects will be allocated jointly in a cluster randomized design [56]. Cluster randomized designs are also now the subject of separate reporting guidelines [103], and involve particular complications in terms of data analysis [104]. For all trials, specifications for the sample size calculation (primary outcomes, target differences, etc.) should be stated and justified. In addition, the precision actually obtained in a study must be presented. This requires confidence intervals as well as the observed p-values, at least for primary outcomes but preferably for all outcomes. The principal confidence intervals should be for comparisons between the groups, rather than for differences in the outcomes within the trial groups [47, 50]. Results should include a trial flow diagram, with numbers and reasons for the exclusion of eligible subjects, the number randomized, and subsequent losses to follow-up [32]. Protocol deviations should be described and explained [70]. Harms of the trial should be described for each treatment group. Finally, the discussion should include a brief summary of the trial’s findings, possible explanations for the results, interpretation of the findings in light of the literature, limitations of the trial including internal and external validity, and the clinical and research implications of the study[48].

Recommendations on Study Conduct and Statistical Methods

- The design, conduct, analysis and presentation of meta-analyses should follow QUORUM guidelines. **HIGH**
- Reporting studies of diagnostic tests, including urodynamics, should follow the STARD statement guidelines. **HIGH**

**XI. SPECIAL CONCERNS FOR SPECIFIC STUDIES**

1. BEHAVIORAL AND PHYSIOTHERAPY TRIALS

**a) Terminology**

The lack of consistent terminology severely hampers our ability to build a body of literature about conservative interventions. The terms “behavioral therapy”, “lifestyle intervention”, “conservative treatment”, “non-surgical treatment”, “physiotherapy”, “biofeedback”, and pelvic floor muscle exercise” are often used interchangeably and incorrectly to describe both the same, and different interventions. While such therapies are discussed elsewhere in this consultation, we here advance this committee’s opinion about appropriate terminology:

**b) Behavioral interventions**

According to Oxford Advanced American Dictionary the term behavioral is «the way someone behaves, especially towards other people», and behavioral science is the study of human behavior. We recommend that behavioral science be limited to studies that evaluate how people do or do not behave as desired.

**c) Lifestyle interventions**

Lifestyle interventions for UI are discussed elsewhere in this consultation and have traditionally included change in diet, intake of caffeine and carbonated soft drinks, fluid restriction, weight loss, smoking cessation and advice of increasing general physical activity level. Behavioral science can be used to understand how and why people change life-style to, for example, adhere to exercise and weight loss programs, but it should not be used as term to replace specific therapies such as physiotherapy or pelvic floor muscle training.

**d) Physiotherapy**

Physiotherapy refers to assessment, prevention and treatment given by an authorized physiotherapist (ICS physiotherapy committee www.icsoffice.org). It involves “using knowledge and skills unique to physiotherapists” and, “is the service only provided by, or under the direction and supervision of a physiotherapist” (WCPT 1999). This implies that the term physiotherapy should only be used in trials where the professional providing the intervention is a physiotherapist. We recommend describing the actual intervention instead of using the term physiotherapy: eg pelvic floor muscle training
with or without biofeedback, electrical stimulation, pelvic floor muscle training with vaginal cones or resistance device etc. This accurately describes the intervention and is neutral towards profession. Publications should report the actual profession of the interventionist (e.g., physiotherapist, general practitioner, urogynecologist, urologist, midwife, nurse, fitness instructor), rather than using the vague term, “therapist.”

e) Biofeedback

Biofeedback encompasses “a group of experimental procedures where an external sensor is used to give an indication on bodily processes, usually in the purpose of changing the measured quality” [105]. Biofeedback equipment was developed within the area of psychology, mainly for measurement of sweating, heart rate and blood pressure under different forms of stress. Today, a variety of biofeedback apparatuses are commonly used in clinical practice to assist with PFMT, and the biofeedback can be either visual, auditory or both. In many textbooks the term “biofeedback” has been used to classify a method as different from PFMT. However, biofeedback is not a treatment on its own. It is an adjunct to training. For example, it may measure the response from a single PFMT contraction or provide visual feedback during attempts to relax the muscles. Hence, a more precise terminology is PFM training or relaxation with or without biofeedback.

In addition to traditional biofeedback apparatuses, other instruments can offer valuable feedback. Vaginal and anal surface EMG, urethral, vaginal or anal squeeze pressure measurements, ultrasound and MRI can all be used to make the patients more aware of muscle function, and to enhance and motivate patients’ effort during training [106].

f) Conservative interventions/treatments

Conservative interventions include all of the above, and this term includes everything except medication and surgery. As several studies have found that more than 30% of women with pelvic floor muscle dysfunction are not able to perform a correct PFMT contraction at the first consultation [107-110] it is mandatory to report how ability to perform a correct contraction was assessed before commencing an exercise trial. Also in electrical stimulation research one should report in which way response to the stimulation was assessed.

Although there is level A, grade 1 evidence for some of the conservative interventions such as PFMT for SUI, a variety of new conservative methods to treat the condition are frequently suggested in clinical practice and in the literature. These new methods are often presented as being effective, but are usually a hypothesis based on theories, data from small experimental laboratory studies/small clinical series, or associations found in large epidemiological studies. If the clinicians like the approach, it soon enters clinical practice and textbooks without any further critical testing [113]. A model for how new therapies ideally should enter clinical practice has been proposed [114]. In this model the new idea should go through at least the 4 first stages before they enter practice:

Clinical observation and laboratory studies
- Clinical exploration
- Pilot studies
- Randomized controlled trials
- Refinement, eg dose-response issues
- Active dissemination of the method if it has proven to be effective
It is important that the patients participating in the 3 first stages before the RCT are given full information that they are participating in an experimental treatment, and that the clinician does not know if this new approach is effective. The patients also need to be informed if there are other proven effective treatments available.

g) Reporting of trial characteristics

In addition to reporting the specific type of intervention (e.g. PFMT with biofeedback compared to PFMT alone or electrical stimulation) and the profession administering the intervention, the intervention needs to be described in such detail that other investigators can reproduce the intervention. This includes:
- Ability to perform a correct PFMT contraction.
- Frequency: number of home training sessions and supervised training sessions (eg every day, 3 times/week)
- Number of repetitions and sets (eg. 12 sets x 3 times/day)
- Duration: length of each training session (eg. 20 minutes), and duration of the total training period (eg. 3 months, 6 months)
- Intensity: In exercise science, this is usually reported as % of one repetition maximum for strength training. In pelvic floor muscle training it is often described as attempts to reach maximum contractions or utilizing submaximal contractions. Another description of intensity is the holding time in seconds, eg: 6-8 sec
- Adherence: the degree to which participants follow the prescribed protocol, usually reported as a percentage of the total possible.

Educational material provided, such as DVDs, brochures and booklets should be described.

Assessment: All devices used for assessments (eg manometers, dynamometers, ultrasound and EMG) must be described in detail, and their re-
sponsiveness (ability to detect small changes), reliability and validity should be reported [111].

**h) Adherence vs effectiveness**

It is important to note that adherence is not the same as the effectiveness of a program, as it is possible to have high adherence, but still little effect of training. Hence, when reporting the effect of conservative interventions it is ideal to measure also the exposure variable that the treatment is expected to change (eg muscle strength, ability to relax etc). This variable should not be confused with the primary or secondary outcomes of the intervention (eg leakage measured with pad testing, number of leakage episodes or QoL).

In many areas of conservative interventions there are high quality RCTs, systematic reviews and meta-analysis showing statistically significant and clinically relevant differences between the intervention and the untreated control group or other interventions. Of conservative therapies, PFMT for SUI/MUI has the strongest evidence to support its use; further, the more intensive the program (more supervision, higher dosage of training) the better the effect. Therefore, when comparing new methods and innovations with established PFMT, it is important to compare the new intervention with the current best evidence, meaning the effective arm of the reported RCTs. Unfortunately it is common to compare new methods with an ineffective training protocol, thereby overestimating the effect of the new method and claiming that it is equal to or better than “the old method”. When comparing different methods the dosage also needs to be the same in both treatment arms, eg when comparing PFMT with and without biofeedback, the number of supervised sessions, length of the sessions, frequency of home treatment and duration of the intervention must be the same.

**i) Adverse events and cost**

There are few adverse effects or complications reported after conservative interventions, but they do exist, eg in electrostimulation [112], and adverse effects or lack of adverse effect, and inconvenience to the patients should be reported. Although seldom harmful, conservative treatments are time consuming and can be costly for participants and paying parties because of the need for close follow up during the interventions. Cost effectiveness studies are crucial to fully understand where conservative therapies fit in the treatment armamentarium.

**j) Outcome measures**

The need for use of responsive, reliable and valid outcome measures in research is covered elsewhere in this chapter. The RCTs published in conservative treatment have applied a huge variety of outcome measures, making systematic reviews and meta-analysis difficult or impossible to conduct. Therefore, in future research it is important to use established and recommended outcome measures. In addition to description and use of responsive, reliable and valid primary and secondary outcome measures, future studies should include description and assessment of adherence to the intervention protocol, measurement of the independent variable (the intervention; eg strength training, relaxation training) and measurement of the possible underlining mechanisms of how the treatment works. It is usually not possible to blind the participants or those providing the intervention, but the assessors of outcome should always be blinded to group allocation.

**k) Specific and non-specific effects**

There have been some concerns that the effect of conservative treatments can be attributed to non-specific effects such as the extra attention of the therapist. The role of the therapist is to educate, motivate and empower the patient to be able to perform the actual program, secure high adherence, and minimize drop-outs. In patient reported outcomes and reports on quality of life it may be difficult to separate the effect of the attention and the actual effect. However, the effect of the attention is less likely to affect outcomes such as muscle strength, urodynamic assessments, pad testing and morphological changes measured by ultrasound and MRI. To minimize bias, all assessments should be conducted by investigators blinded to treatment allocation; the logistics of this should be addressed during the planning phase of the study. In a high quality RCT, Dumoulin et al address the problem of attention in physiotherapy research [115]. Women with persistent UI, three months after childbirth were randomized to either two different training regimens or a control group receiving relaxation massage for the back and limbs for the same amount of time as the supervised training groups. 70% were cured on pad testing in both treatment groups while there was no effect on urine loss in the relaxation massage group. Participants in the massage control group had improvement in disease specific quality of life.

**l) Power calculations and number of participants**

Some of the RCTs on conservative treatments are flawed by small sample sizes, this being especially evident in electrostimulation studies and may account for negative effects caused by type II errors. It is important that future studies use results of previous published studies to make appropriate power calculations that incorporate estimates of drop-outs and loss to follow-up to decide the optimal number of participants needed. Recruiting large numbers of participants may come at the expense of the rigor of the intervention [116]. Weak interventions (eg non-optimal training dosages or
suboptimal electrostimulation parameters) are unlikely to be effective and do not yield the true effect of an intervention. In meta-analyses, adding RCTs with large sample sizes but weak and ineffective interventions, can dilute the effect of smaller RCTs with higher methodological and interventional quality [116].

**m) Long term studies**

To date there are no quality criteria for how to report long term follow-up studies or how to conduct meta-analyses of long term studies. Challenges in long term follow-up studies include cross over to the more effective treatment after cessation of the original RCT, co-interventions during the follow-up period, recurrent events (eg new pregnancy), competing events (other diseases leading to incontinence) and loss to follow up. For conservative interventions it is expected that any training effect will diminish over time if no maintenance training is conducted or the pre- or co-contraction of the pelvic floor muscles has not reached an automatic level during the original trial. In order to control for as many of the above mentioned factors as possible, it is recommended that the long term follow up study should be planned together with the original RCT. Loss to follow-up and adherence to the protocol during the follow-up period must be reported [106, 111-117].

**Recommendations for conservative treatment trials:**

- Use correct terminology to describe the intervention. HIGH
- Report details of ability to perform correct contraction, dose-response issues and adherence. HIGH
- Use recommended outcome measures with high responsiveness, reliability and validity. HIGH
- Compare new methods with the best available intervention. HIGH
- Use power calculation in planning the study. Avoid large sample sizes and weak (ineffective dosages) interventions. HIGH
- For long-term follow-up studies report cross-over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up

**2. EXPERIMENTAL DEVICES AND MATERIALS**

Surgical research presents unique challenges to efforts at optimizing patient care. It is important to create a pathway for real advances while simultaneously protecting patient safety. When new procedures are substantially different from prior operations there should be a broad based preliminary exploration leading to a comparative trial if warranted. At the same time, many minor modifications of surgical procedures are inappropriate for randomized trials and if required, surgical progress would be slowed [118].

**a) Randomisation**

It has been argued that the first patient in whom a procedure is performed should be randomized [119-120]. Alternatively, it has been suggested that case series for new procedures are allowed until the procedure finds its intended use and to avoid doing studies while those performing the procedures are on the “learning curve”. Typically, new surgical procedures for incontinence have been reported as case series [121-122]. Not only do surgical case series provide the lowest level of evidence for treatment effects, case series may be “harmful”. An accumulation of “positive” case series may present a premature certainty about benefits of a procedure and make it even more difficult to perform randomized trials [123-124]. Influential members of the surgical community may endorse a new procedure and if the procedure is considered better it may be difficult to get surgeons and patients to randomize or a trial may appear to be unethical with a “proven” procedure [119, 123, 125].

**b) Adoption by clinicians**

Therefore, devices often are widely adopted by clinicians based on anecdotal data, marketing, or small case series. This raises a unique problem for trials in this area: 1) Surgeon buy-in can be difficult to obtain as some surgeons (“early adopters”) may perceive that the newest therapy is best and thus be unwilling to randomize patients to receive the traditional therapy, 2) Other surgeons (“late adopters”) may perceive that the data available do not support use of the newest therapy and thus be unwilling to randomize patients, 3) Patients may be unwilling to be randomized to traditional therapy because they are influenced by marketing forces propelling the newest devices to the forefront, and 4) Device companies frequently modify their materials or technique recommendations; therefore, by the end of the 3-5 years it typically takes to complete the earliest outcome assessment for a surgical randomized trial, the device tested is no longer the same as the device used in the trial. Thus, the results may be discounted as being no longer applicable.

**c) Recruitment procedures**

An important area of concern in surgical and device studies is patient recruitment procedures. Both in this regard and for all components of a study, we strongly support reporting according to the CONSORT guideline for randomized trials and the STROBE guidelines for observational studies. Subjects should be enrolled in a manner that minimizes selection bias. The protocol should detail the procedure by which consecutive patients meeting
the inclusion criteria are selected. All situations in which a patient meets the inclusion/exclusion criteria but is not offered enrollment by the investigator should be documented. The number of patients who decline enrollment should be stated, along with the reasons. It is vital that clinician researchers do not “cherry pick” from their patients, that is, that they do not limit recruitment to those patients considered to have the greatest chance of cure or lowest chance of risk. The study population should be as generalizable as possible. There should be a complete accounting of all participants in the study including the reasons for subject withdrawal.

Participants must be well informed about what is known and not known about devices or procedures being tested. They should not be led to assume that because a device is on the market, it is “safe and effective”, as gaining knowledge about this is the purpose of the trial.

3. SURGICAL STUDIES

Cross-sectional studies of surgical procedures by type can provide estimates of prevalence, variation by age, race, and region as well as morbidity and mortality [126-127]. This type of information raises important health policy questions regarding physician practices, patient preferences for incontinence treatment, and differential access to and the utilization of care.

Case series are the most common study design found in the surgical literature, especially for new “innovative” surgical procedures. This is true despite the fact that case series cannot account for selection bias on the part of the patient and surgeon, non-reporting bias of failures or loss to follow-up, lack of long-term follow-up, and provide the lowest level of evidence for treatment effects. Observational studies can provide important information about effectiveness and complications of surgical procedures, and also are very helpful in designing and selecting potential randomized clinical trials.

The randomized controlled trial is the accepted “gold standard” for research of treatment effects. In all surgical specialties, there has been growing concern regarding the limited number of randomized controlled trials for surgical procedures, poor methodological standards in those that have been performed, and a perception that surgeons are reluctant to rigorously test new surgical interventions [119, 123, 128-129]. A number of reasons for the paucity of surgical trials have been suggested including the lack of a regulatory board similar to the Food & Drug Administration responsible for the development of new medications [130].

The body of literature of surgical randomized trials in pelvic floor disorders is small, though increasing. However, many RCTs have serious limitations including a sample size too small to detect differences between groups, lack of blinding of the participants and/or individuals assessing the outcomes, short follow-up, inclusion of limited number of surgeons only, poor description of the technique, and lack of standardized outcome measures. Multi-center treatment networks are useful to overcome some of these limitations.

Differential drop out after randomization (or for cohort studies, after the intervention) can introduce bias. In a large and methodologically sound randomized controlled trial comparing the tension-free vaginal tape (TVT) and colposuspension, a large number of women withdrew from the colposuspension arm after randomization [131-132]. The loss of participants after randomization introduced bias in favor of the TVT because the drop outs had less severe incontinence resulting in the colposuspension group having more severe incontinence. It has been suggested that participants were only willing to continue if they were randomized to the “new and better” TVT procedure [132-133]. Accounting for subjects “lost to follow-up” must also be detailed as per the CONSORT and STROBE recommendations. In the UK TVT RCT, drop out after surgery was similar for both procedures. In contrast, in two large study comparing two incontinence procedures performed by the Urinary Incontinence Treatment Network, randomization was done in the operating room after the patient was anesthetized and therefore no participant was lost to randomization [134],[67].

For studies of specific surgical procedures, the technique should be described in such detail that it could easily be reproduced in another study. Standardization of the procedure may vary depending on the research question [135]. Surgical trials using a small number of highly skilled surgeons are analogous to medical trials where only compliant patients are randomized, reflecting efficacy of the procedure in an ideal setting. It may be more generalizable to a mixture of skill level among surgeons in the community, and so reflect effectiveness of the procedure in usual practice [124].

Masking of participants as to their assigned intervention and those assessing the outcome is particularly important for surgical trials for incontinence because there may be enthusiasm by the patient or surgeon for a new procedure, many outcomes are based on the patient’s own assessments such as symptom and quality of life scores, and the intervention is primarily for improvement of symptoms [118].

For new surgical procedures, important issues of adequate informed consent and conflicts associated with incentives for developing, starting and using new procedures have been raised. Informed consent for a new procedure must include:
• acknowledgment that the procedure is new and has not been shown to be more effective than a traditional approach
• discussion of potential complications, especially any integrally related to the procedure or device
• disclosure that information on complications are limited, and
• disclosure that the long-term benefits are unclear [122].

Incentives for adopting new procedures prior to sufficient evidence can arise from self-interest by attracting patients to one’s practice, industry marketing, and patient desire for “cutting edge” techniques. Industry sponsorship or a surgeon’s financial interest must be disclosed.

Organizations and treatment networks have been established to address many issues related to surgical interventions. Examples include the UK National Institute of Clinical Excellence (NICE www.nice.org.uk), the Australian Safety and Efficacy Register of New Interventional Procedures-Surgical (ASERNIP-S www.surgeons.org/asernip-s), and the US treatment networks: Urinary Incontinence Treatment Network (UITN http://www.niddk.nih.gov/patient/uitn/uitn.htm) for the NIDDK and the Pelvic Floor Disorders Network (PFDN). The NICE and ASERNIP-S provide systematic reviews of new operations, assessment of effectiveness, and recommendations that the technique has sufficient data for widespread use, or that the techniques appear unsafe, or that further audit/research are required before its widespread usage. The UITN and PFDN were established to provide the infrastructure for multicenter large randomized controlled trials for incontinence and prolapse.

Recommendations for Surgical and Device Trials:

• The safety and serious side effects of new operations must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicenter cohort studies when RCTs are not practical. HIGH
• Safety and serious side effects of incontinence devices must be completely defined with adequate follow-up, especially for use of implantable devices and biologic materials, so that risks can be weighed against efficacy. HIGH
• Valid informed research consent is required in all trials of surgical interventions, which is separate from the consent to surgery. HIGH
• We recommend ongoing research into the usefulness of pre- and post-operative predictive testing (such as urodynamics, ultrasound, MRI, etc) in surgical trials. HIGH
• Reports of successful treatment should be limited to subjects with a minimum (not mean) of one year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated. HIGH
• Randomization for surgical trials should occur at the time of surgery to minimize drop-outs and switch of procedure HIGH
• Long-term follow-up of RCT cohorts in an observational cohort is recommended. HIGH

4. PHARMACOTHERAPY TRIALS

Although many RCTs have been published in recent years on pharmacotherapy for urinary incontinence a great deal more remains to be learned. The trials have almost all been limited to 8-12 weeks of treatment giving very little information about long term safety and efficacy of drug therapy. Inclusion criteria are often stringent, such that the study population of healthy middle-aged people bears little resemblance to the patients for whom providers wish to prescribe medication. There is less than adequate information about special patient groups—men, children, neurogenic patients, and especially the frail elderly. Because incontinence creates such an impact on the older population, good studies to define the utility and safety of drug therapy are greatly needed in this group.

An issue of special relevance in trials of pharmaceutical agents (although germane to other treatment modalities) is the controversy regarding placebos in clinical trials. Regardless of whether a drug is effective or not, simply giving a drug to a patient may produce a beneficial response. To assess if a drug has an effect over and above the placebo response, it is usually tested against an inactive substance (placebo). In incontinence studies, the placebo effect may be quite large, anywhere from 30-50% in recent published studies. To account for this, investigators and regulators have generally demanded a placebo arm in most clinical trials of medication. While this may be acceptable to participants for short trials, it is neither ethical nor feasible to withhold treatment for longer periods of time. Further, clinicians and patients generally want to know how a new drug compares with established treatment.

Masking, while desired in all types of trials, is especially important in pharmacological trials. Further, it is feasible to do in such trials (as opposed to surgical or conservative interventions, in which masking may not always be possible) and thus should be prioritized. However, the identical appearance of two pills does not guarantee that participants will be unaware of group assignment. Side effects
common with anti-cholinergic therapy, such as dry mouth, may unmask participants. Studies should assess the degree to which masking was successfully maintained.

Recommendations for Pharmacotherapy Trials

- As effective drug therapy is available for most forms of incontinence, active drug comparator arms are recommended for most trials. **HIGH**
- Very little is known about the safety, efficacy and tolerability of drug therapy beyond 12 week trials. A concerted effort is needed to create this type of information base. Long-term follow-up of RCT cohorts in an observational cohort is recommended **HIGH**

### XII. COST ANALYSIS

Economic and health policy outcomes are gaining increasing importance, as policy makers deliberate the values of different therapies. The financial burden on the health care system, the patient and patient’s family of various treatment options makes cost an important outcome to measure. We recommend that cost analyses be planned with clinical studies whenever possible. Costs may be influenced by economic and political factors that are subject to change at any time; however, when basic units of work, time, and resources are carefully defined, models of costs remain useful even if market forces change in an unforeseen manner.

In health and medicine, economic analyses are descriptive and/or comparative. Descriptive data include the socioeconomic cost caused by the disease and its current treatment, whereas comparative data provide an economic evaluation of different treatment strategies and interventions where costs are compared to health outcomes.

There are several relevant types of cost analysis, some of which require a high level of expertise to conduct:

- **Cost of illness analysis** (COI) typically quantifies the burden of medical expenses (direct costs) and the resulting value of lost productivity (indirect costs) attributable to a specific condition such as an illness or injury [136], [132].
- **Cost effectiveness analysis** (CEA) measures the costs and consequences of two or more diagnostic or treatment pathways related to a single common effect or health outcome. It then summarizes the results in ratios that demonstrate the cost of achieving a unit of health effect for different types of patients and for variations of the intervention [137], [133].
- **Cost utility analysis** (CUA) is a form of cost effectiveness analysis in which particular attention is paid to the quality of health outcome related to treatment. In CUA, health effects are expressed in terms of quality-adjusted life years (QALYs) [138], [107]. A QALY is a measure of health outcome that assigns to a given period of time a weighting that corresponds to the health-related quality of life during that period, and then aggregates these weights across time periods. The QALY is important because it considers both quantity and quality of life.

- **Cost benefit analysis** estimates the net social benefit of an intervention by comparing the benefit of the intervention with the cost, with all benefits and costs measured in dollars [24], [134]. Health outcomes are converted into monetary values using “willingness to pay” (the value an individual would pay for reduction in illness severity) or “risk of death” or “human capital” methods (an individual’s value to society based on productivity or future wages) [139-140], [135-136].

Recommendations on Cost Analysis in Incontinence:

- Cost analysis should be incorporated into clinical studies whenever possible [137]. **HIGH**

### XIII. RECOMMENDATIONS FOR SPECIFIC PATIENT GROUPS

#### 1. MEN WITH LUTS

When considering men with LUTS, one must consider some unique factors which may influence urinary tract symptoms independently of any intervention, and so confound any data. These are the presence of the prostate gland which can cause bladder outlet obstruction (BOO), and the rarity of sphincter incompetence except in men who have undergone surgery for benign or malignant prostatic disease. For short term outcomes after intervention studies, these factors are unlikely to be relevant, but longer term follow up, and large observational or epidemiological studies may need to take these factors and changes over time into account when analyzing data. The prostate gland may complicate research outcomes as a result of outflow obstruction (either at baseline, or development of a new problem during follow up studies). Also, for patients with prostate cancer (either at the time of enrolment, or during follow up of longer studies), it is likely that both the disease, and the treatment given (surgery or radiotherapy) may alter urinary tract function and symptoms independently of any intervention in the study and thus confound the outcomes. Overall, about 2/3 of men with LUTS have urethral obstruction and over 50 % have detrusor overactivity, al-
though a much smaller number have urinary incontinence due to detrusor overactivity [141].

If prostate size is considered to be a variable that could affect outcomes, measurement of prostate volume should be made before and after treatment. The method used to measure volume and its reliability and validity should be provided if available or their absence indicated. Any associations between outcomes and change in prostate size should be tested for using appropriate methods and reported. Consideration should be given to stratifying participants by prostate volume when there is suspicion that response to therapy may be size dependent.

Insofar as about 2/3 of men with LUTS have bladder outlet obstruction (BOO), any research protocol in men should consider inclusion of a method to screen for it. At the least, maximum free urinary flow rates and measurement of post-void residual urine should be recorded before and after treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. Synchronous pressure-flow studies are generally desirable and should be included whenever feasible. Several pressure-flow nomograms have been proposed to diagnose obstruction in men. The ICS nomogram is recommended and it is important to specify which if any nomogram is being used [142].

**Recommendations for Research in Men:**

- Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a potentially important variable, or to change during the intervention and follow up. **HIGH**
- Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. **HIGH**
- Participants should be stratified by prostate size at randomization when size is considered to be a potentially important determinant of treatment outcome. **LOW**

2. WOMEN WITH LUTS

a) **Hormonal effects**

Our knowledge of hormonal influences on the lower tract remains limited. Recent RCTs and prospective cohort studies have demonstrated that hormone replacement therapy (HRT) does not improve or may worsen incontinence [143-145]. It therefore seems appropriate that information about menstrual and hormonal status should be an integral part of the baseline history. New studies designed to examine the influence of hormones on incontinence (if considered ethical by an appropriate review board) should include details of hormonal status (premenopausal, postmenopausal without HRT, post-menopausal with HRT), the route and type of HRT (oestradiol only, combined sequential, combined continuous), and whether or not oophorectomy has been performed.

b) **Obstetric History**

The influence of vaginal childbirth on the structure and function of the female pelvis is the focus of much recent and ongoing research but the complex interactions remain incompletely understood. While it is clear that childbirth, and particularly vaginal childbirth increases the risk of incontinence and pelvic organ prolapse, the potential effect of further childbirth on previous or current treatments of incontinence (especially surgery) has yet to be determined.

Potentially confounding variables include: number and route of deliveries (vaginal/Cesarean), use of forceps or vacuum, infant birthweight and head circumference, duration of second stage of labor, use of episiotomy and any vaginal or perineal trauma, and epidural anaesthesia. The importance of these variables will depend upon the specific study design; for randomised studies the allocation process should balance these between groups, but consideration should be given to stratifying or minimizing the randomization against one or more of these important factors, depending on the exact intervention. For epidemiological or observational research each of these factors should be collected and included in univariate and multivariate analyses.

c) **Pelvic Organ Prolapse**

The effect of pelvic organ prolapse on lower urinary tract function remains poorly understood. Pelvic organ prolapse may potentially affect lower urinary tract function by obstruction of the urethral outflow, and thereby mask sphincter weakness (so called “occult” stress incontinence). Emerging evidence suggests that prolapse may contribute to the symptoms of OAB and correction of the prolapse may modulate these symptoms. Thus, it is important to include assessment of pelvic organ prolapse in incontinence research on women. A validated assessment method for prolapse should be used to identify the stage of prolapse; the Pelvic Organ Prolapse Quantification System (POP-Q) [9] is recommended. Research protocols should be developed, either excluding women with prolapse severity beyond a specified stage, or the analysis plan should include stratification for stage of prolapse in randomization, and adjustment for prolapse stage in any analysis. For larger studies where regression analyses are planned, stage of prolapse should be considered a mandatory factor for inclusion. Prolapse should be graded at the same time as the outcome assessment for incontinence and LUTS is performed.
Recommendations for research in women:

- Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. **HIGH**

- High quality, symptom and bother scores (e.g., ICIQ-FLUTS, KHQ, PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes. **HIGH**

- Standardized assessment of pelvic organ prolapse (by POPQ) should be performed before treatment and at the time of other outcome assessments in all research where prolapse and continence outcomes are being assessed. **HIGH**

- Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests. **HIGH**

- Assessment of the impact of treatment on sexual function should be performed with other outcome assessment when appropriate. **MEDIUM**

3. FRAIL OLDER AND DISABLED PEOPLE

There are a number of unique and pertinent research issues for this population.

In the frail elderly, important variables include:

- **Demographic information:** Advancing age, white race, and women [145-148] are associated with an increase risk of incontinence and each of these variables should be adjusted for in most analyses.

- **Medical Conditions:** Medical conditions related and unrelated to the lower urinary tract have been shown to increase the risk of incontinence in older women and are especially important to assess in the frail older population [147, 149-151]. Prior hysterectomy has also been suggested as a potential risk factor for incontinence in older women [152-153].

- **Medication Inventory:** Certain medications may exacerbate incontinence and therefore a complete medication inventory is essential [151, 153-155].

- **Physical function:** Mobility is often impaired in the frail elderly and impacts urinary control [156], therefore mobility should be assessed using validated instruments such as the Barthel Orcats or ADL scales [156-157]. Data on walking aids or wheelchairs, gait speed, and manual dexterity may also be collected.

- **Cognitive function:** Cognitive function impairment and/or dementia increase the risk of incontinence [158]. The Mini-Mental Status Scale Examination [130] assesses global cognitive function, and the Confusion Assessment Method (CAM) [159] is a standardized assessment for delirium. A battery of neuropsychological tests to measure subtle impairments in cognitive function include the Buschke Selective Reminding Test (verbal learning and memory) [160], the Digit Symbol (incidental memory, visual scanning and motor speed) [161], and the Trails A (attention and visual) [162].

Outcome measures should be selected for applicability to the frail elderly. Commonly used self-reported measures of frequency of urinary symptoms, severity, or level of bother may not be possible in the cognitively impaired frail elderly patient. Similarly, voiding diaries that have been shown to be valid and reliable in assessing urinary frequency, nocturia, and incontinence episodes by type [138, 162-164] may not be feasible or reliable. Motivated and trained staff, caregivers, or family members may be able to adequately collect diary data; however, this has not been validated.

In nursing home or inpatient settings, **wet checks by staff** at set intervals have been used in a number of studies. There are limitations to the measurement including visually determining what is “wet” because of new absorbent materials and staff reports not always being reliable or valid, due to underreporting [165-166]. To overcome the limitation of defining wetness and underreporting, 24-hour **pad weighing tests** [167-168] may be used. Pad weighing tests and wet checks are feasible and can provide important outcome data if staff is well trained and checks are often [14]. New outcome measures specific to the frail older population such as increased socialization or decreased caregiver burden need to be developed.

4. CHILDREN

The conduct of clinical research in children is generally more difficult than in adults. Four overriding issues separate pediatric research from the general recommendations. First, physiology varies widely within the group referred to as “children”, differs from adults, and changes with time. Because children are growing, any treatment, especially pharmacological and surgical therapy, may affect them profoundly in the long term. This is particularly true of the immature brain, nervous system and other incompletely developed systems. Second, compliance with therapy is more complicated as children may depend on caregivers to administer treatment in many studies. Third, reporting of symptoms and outcomes may be difficult. Symptoms reported by a caregiver may not be interpreted in the same way as the child. Finally, the issue of informed consent is complex with children.
Urinary incontinence in children falls into four main categories: neurogenic (myelomeningocele and other less common neurogenic etiologies), monosymptomatic nocturnal enuresis, detrusor overactivity, and dysfunctional voiding without neurologic disease. This issue of age groups is most crucial in children with myelomeningocele. These children are often on medication beginning at a very young age and continuing for many years; the long-term safety of medications in children must be established in all age groups. Therapy for other causes of incontinence in children tends to start at a later age, by which time size is the main difference between children. We recommend that clinical studies have long-term (five years or more), open label extension arms to monitor safety, particularly focusing on normal growth and development and the effects on treatment of liver and central nervous system function.

Assessment of compliance with therapy is always difficult, and even more so with children. Compliance with voiding diaries, a significant issue in the adult population, may be even more problematic with children. The social and family interactions between the child and parent or carer can influence the accuracy of data collection and treatment compliance, both positively and negatively.

Outcome measures are not as well developed in children as in adults. Validated, age-specific symptom and disease-specific quality of life instruments must be developed for the pediatric population. Early efforts in this area have been reported for dysfunctional voiding [169] and daytime incontinence [170]; much more work remains to be done. Invasive urodynamics can be used when deemed appropriate (specifically in the neurogenic population); however, the test-retest reproducibility of urodynamic investigations in children is still under investigation.

Recommendations for Research in Children:

- Long-term follow-up is of critical importance in the pediatric population in order to ascertain the effect of a treatment on normal growth and development. **HIGH**
- Research is needed to develop standardized outcome measures including validated, age-specific symptom and disease-specific quality of life outcome measures. **MEDIUM**

5. NEUROGENIC POPULATIONS

**a) Classification**

Classification of NLUTD has three primary aims—to aid in discriminating or identifying an unknown underlying neurological disease process, to characterize the nature of the dysfunction so as to develop a treatment plan, and to assess the risk of secondary effects (e.g., on the upper tract) which may influence the necessity and aggressiveness of treatment. The latter two are clearly relevant to research in neurogenic incontinence and must be reflected in study design and patient description.

It is difficult to find a classification system of NLUTD as a base for research that is satisfactory for each of the three aims. The published systems have been reviewed in detail [171]. Both the disease process and the site of the neurologic lesion(s) are relevant in the study of NLUTD, yet even this information is inadequate to predict the functional characteristics for an individual patient. There is no one method that meets the broad needs of classification in this group. Typical or classic cases are often well described but it is especially difficult to describe mixed and incomplete lesions. Thus, classification systems necessarily oversimplify or become extremely cumbersome. Finally, it must be acknowledged that the complexity of neurologic diseases and variations in individual behavior almost always call for a customized approach to therapy, further complicating research in the neurogenic patient. All of these factors complicate study design as it becomes difficult to create workable inclusion and exclusion criteria that apply to other than a narrow segment of the neurogenic population. Ideally a broad population of potentially relevant participants would be enrolled in research studies with full characterization of both the neurologic condition and the nature of the lower urinary tract dysfunction so as to allow for subgroup analysis.

**b) History and evaluation:**

Study planning is best undertaken with the cooperation of urologist, neurologist, and other clinicians, who have a specific interest and special training in the neurogenic patient. Baseline data collected by history in subjects with neurogenic lower urinary tract disorders should include:

- bladder volumes by diary or examination (maximum voided or catheterized volume, post voiding residual urine, total capacity);
- mechanism of bladder evacuation: normal (volitional), spontaneous involuntarily ("reflex"), Credé, sterile intermittent catheter (SIC), clean intermittent catheter (CIC), intermittent catheter by second person, or suprapubic or urethral catheter;
- use of external appliances (e.g., diaper or pad use, condom catheter, urethral catheter, suprapubic tube);
- the typical time span of continence (continence interval) following last bladder evacuation and maximal continent bladder volume.
- bowel function, sexual function, and specific neurologic deficits
- the evolution of the condition of (changes in)
the upper tract should be included in the outcomes evaluation of treatment for NLUTD. Where possible these factors should be controlled for in analyses, and stratified for in randomization for interventional studies, or patients with certain factors should be excluded. The details will depend on the research question to be asked.

c) Urodynamics:

Baseline urodynamics are recommended for research studies of neurogenic incontinence, because the symptomatic response is usually of lesser relevance, compared to objective response in NLUTD, especially where NDO or reduced compliance is involved in the dysfunction. Neurogenic disorders commonly cause complex and generalized lower tract dysfunction, often with combined bladder and urethral sphincter abnormalities.

Recommendations for Research in Populations Affected by Neurogenic Lower Urinary Tract Dysfunction:

- Detailed urodynamic studies are recommended for classification of neurogenic lower urinary tract disorders in research studies because the nature of the lower tract dysfunction cannot be accurately predicted from clinical data. Videourodynamic studies are preferred but are not mandatory. LOW
- An area of high priority for research is the development of a classification system to define neurogenic lower urinary tract disorders. Relevant features could include the underlying diagnosis, the symptoms, more precise documentation of the neuromuscular lesion by clinical neurophysiologic testing, and the nature of the urodynamic abnormality. LOW

6. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY Fecal INCONTINENCE

- High quality, validated, symptom and bother scores (e.g., ICIQ-BS, Wexner score, FQIL, Manchester Questionnaire, FISI) should be employed when assessing outcomes HIGH
- Due to the high concordance of faecal and urinary incontinence, and the potential for urinary incontinence therapy to affect bowel function, data on faecal incontinence should be collected at the outset and during trials of urinary incontinence whenever practical. HIGH

7. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS)

- Broader entry criteria should be used to reflect the full spectrum of the BPS/IC patient population. MEDIUM
- The primary endpoint of BPS/IC trials should be patient driven and the Global Response Assessment is recommended. A wide spectrum of secondary endpoints will be useful in defining the effect of treatments. MEDIUM

8. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

- A validated standardized assessment of prolapse (eg POP-Q) should be used for baseline and outcome assessments. HIGH
- Complete reporting of outcomes including a validated assessment of anatomy, functional status, and complications is essential. HIGH
- Complications/adverse events (especially for mesh) must be explicitly and completely defined.
- Long term outcomes (> 2 years) of intervention studies are needed HIGH

XIV. CONCLUSIONS

The 2012 Consultation examined and classified available data in order to determine the level of evidence that supports our care of incontinent patients. This committee’s contribution was to provide guidance to facilitate high quality research for the next Consultation. All quality research, be it prospective or retrospective, clinical or preclinical, begins with a clear research question and benefits from detailed planning—establishing a clear and relevant hypothesis, developing a trial of appropriate magnitude to accept or reject the hypothesis, and defining methods of adequate sensitivity and specificity to produce credible data.

5th International Consultation on Incontinence

Recommendations of the International Scientific Committee:

Evaluation and Treatment of Urinary Incontinence, Pelvic Organ Prolapse and Faecal Incontinence

and the Members of the Committees

INTRODUCTION

The 5th International Consultation on Incontinence met from February 23rd – 25th 2012 in Paris and was organised by the International Consultation on Urological Diseases and the EAU, in order to develop consensus statements for the diagnosis, evaluation and treatment of urinary incontinence, faecal incontinence, pelvic organ prolapse and bladder pain syndrome.

The consensus statements are evidence based following a thorough review of the available literature and the global subjective opinion of recognised experts serving on focused committees. The individual committee reports were developed and peer reviewed by open presentation and comment. The Scientific Committee, consisting of the Chairmen of all the committees then refined the final consensus statements. These consensus statements published in 2013 will be periodically re-evaluated in the light of clinical experience, technological progress and research.

Annex 1: Bladder Charts and Diaries
Annex 2: International Consultation on Incontinence Modular Questionnaire (ICIQ) - ICIQ UI SF (short-form)
The consultation agreed to use the current International Continence Society definitions (ICS) for lower urinary tract dysfunction (LUTD) including incontinence, except where stated. These definitions appeared in the journal Neurourology and Urodynamics (2002; 21:167-178 and 2006; 25:293) or can be viewed on the ICS website: www.icsoffice.org

The following ICS definitions are relevant:

1. Lower Urinary Tract Symptoms (LUTS)

LUTS are divided into storage symptoms and voiding symptoms.

**Urinary incontinence** is a storage symptom and defined as the complaint of any involuntary loss of urine. This definition is suitable for epidemiological studies, but when the prevalence of bothersome incontinence is sought, the previous ICS definition of an "Involuntary loss of urine that is a social or hygienic problem", can be useful.

Urinary incontinence may be further defined according to the patient’s symptoms

- **Urgency Urinary Incontinence** is the complaint of involuntary leakage accompanied by or immediately preceded by urgency.
- **Stress Urinary Incontinence** is the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing.
- **Mixed Urinary Incontinence** is the complaint of involuntary leakage associated with urgency and also with effort, exertion, sneezing and coughing.
- **Nocturnal Enuresis** is any involuntary loss of urine occurring during sleep.
- **Post-micturition dribble** and **continuous urinary leakage** denotes other symptomatic forms of incontinence.

**Overactive bladder** is characterised by the storage symptoms of urgency with or without urgency incontinence, usually with frequency and nocturia.

2. Urodynamic Diagnosis

- **Overactive Detrusor Function**, is characterised by involuntary detrusor contractions during the filling phase, which may be spontaneous or provoked.

The overactive detrusor is divided into:

- **Idiopathic Detrusor Overactivity**, defined as overactivity when there is no clear cause
- **Neurogenic Detrusor Overactivity** is defined as overactivity due to a relevant neurological condition.

**Urodynamic stress incontinence** is noted during filling cystometry, and is defined as the involuntary leakage of urine during increased abdominal pressure, in the absence of a detrusor contraction.

3. Bladder Pain Syndrome *

- **Bladder pain syndrome** is defined as an unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptom(s) of more than 6 weeks duration, in the absence of infection or other identifiable causes.

4. Pelvic Organ Prolapse

- **Uro-genital prolapse** is defined as the symptomatic descent of one or more of: the anterior vaginal wall, the posterior vaginal wall, and the apex of the vagina (cervix/uterus) or vault (cuff) after hysterectomy. Uro-genital prolapse is measured using the POP-Q system.
- **Rectal prolapse** is defined as circumferential full thickness rectal protrusion beyond the anal margin.

5. Anal Incontinence *

- **Anal incontinence**, defined as “any involuntary loss of faecal material and/or flatus” and may be divided into:
  - **Faecal incontinence**, any involuntary loss of faecal material
  - **Flatus incontinence**, any involuntary loss of gas (flatus)

* To date, these definitions are not included in the current ICS terminology
The following phrases are used to classify diagnostic tests and studies:

- **A highly recommended** test is a test that should be done on every patient.
- **A recommended test** is a test of proven value in the evaluation of most patients and its use is strongly encouraged during initial evaluation.
- **An optional test is a test** of proven value in the evaluation of selected patients; its use is left to the clinical judgement of the physician.
- **A not recommended test** is a test of no proven value.

The recommendations are intended to apply to children and adults, including healthy persons over the age of 65. These conditions are highly prevalent but often not reported by patients. Therefore, the Consultation strongly recommends case finding, particularly in high risk groups.

The main recommendations for this consultation have been abstracted from the extensive work of the 23 committees of the 5th International Consultation on Incontinence (ICI, 2012).

Each committee has written a report that reviews and evaluates the published scientific work in each field of interest in order to give **Evidence Based** recommendations. Each report ends with detailed recommendations and suggestions for a programme of research.

The main recommendations should be read in conjunction with the management algorithms for children, men, women, the frail older person, neurogenic patients, bladder pain, pelvic organ prolapse, and anal incontinence.

The **initial evaluation** should be undertaken, by a clinician, in every patient presenting with symptoms/signs suggestive of these conditions.

### 1. History and General Assessment

Management of a disease such as incontinence requires caregivers to **assess** the sufferer in a holistic manner. Many factors may influence a particular individual's symptoms, some may cause incontinence, and may influence the choice and the success of treatment. **The following components of the medical history are particularly emphasized:**

#### a) Review of Systems:

- Presence, severity, duration and bother of any urinary, bowel or prolapse symptoms. Identifying symptoms in the related organ systems is critical to effective treatment planning. It is useful to use validated questionnaires to assess symptoms.
- Effect of any symptoms on sexual function: validated questionnaires including impact on quality of life are a useful part of a full assessment.
- Presence and severity of symptoms suggesting neurological disease

#### b) Past Medical History:

- **Previous conservative, medical and surgical treatment,** in particular, as they affect the genitourinary tract and lower bowel. The effectiveness and side effects of treatments should be noted.
- **Coexisting diseases** may have a profound effect on incontinence and prolapse sufferers, for example asthma patients with stress incontinence will suffer greatly during attacks. Diseases may also precipitate incontinence, particularly in frail older persons.
- **Patient medication:** it is always important to review every patient's medication and to make an assessment as to whether current treatment may be contributing to the patient's condition.
- **Obstetric and menstrual history.**
- **Physical impairment:** individuals who have compromised mobility, dexterity, or visual acuity may need to be managed differently

#### c) Social History:

- **Environmental issues:** these may include the social, cultural and physical environment.

---

**I. HIGHLY RECOMMENDED TESTS DURING INITIAL EVALUATION**

This section primarily discusses the **Evaluation of Urinary Incontinence** with or without **Pelvic Organ Prolapse (POP) and Anal Incontinence.**
Lifestyle: including exercise, smoking and the amount and type of food/fluid intake.

Desire for treatment and the extent of treatment that is acceptable

Patient goals and expectations of treatment

Patient support systems (including caregivers).

Cognitive function: all individuals need to be assessed for their ability to fully describe their symptoms, symptom bother and quality of life impact, and their preferences and goals for care. They must be able to understand proposed management plans and to discuss, where appropriate, alternative treatment options. In some groups of patients formal testing is essential e.g. cognitive function testing for individuals for whom the clinician has concerns regarding memory deficits and/or inattention/confusion, and depression screening for individuals for whom the clinician has concerns about abnormal affect. Proxy respondents, such as family and caregivers, may be used to discuss history, goals of care, and treatment for individuals with dementia, but only if the individual is incapable of accurate reporting or weighing treatment decisions.

Mental status

Obesity (BMI)

Physical dexterity and mobility

Examination of the perineum and external genitalia including tissue quality and sensation.

Vaginal (half-speculum) examination for pelvic organ prolapse (POP)

Bimanual pelvic and anorectal examination for pelvic mass, pelvic floor muscle function, etc

Stress test for urinary incontinence.

c) Pelvic examination:

d) Neurological testing (see chapter on assessment)

3. Urinalysis

In patients with urinary symptoms a urinary tract infection is a readily detected, and easily treatable cause of LUTS, and urine testing is highly recommended. Testing may range from dipstick testing, to urine microscopy and culture when indicated.

Conclusion

For simple treatments, particularly non-invasive and inexpensive therapies, management may start without the need for the further investigations listed below.

II. RECOMMENDED FURTHER ASSESSMENT PRIOR TO, OR DURING, SPECIALIST ASSESSMENT

The tests below are recommended when the appropriate indication(s) is present. Some recommended tests become highly recommended in specific situations.

This section should also be read in conjunction with the relevant committee reports.

1. Further Symptom and Health-Related QoL Assessment

In patients with urinary symptoms the use of a simple frequency volume chart or bladder diary (examples in Annex 1) is highly recommended to document the frequency of micturition, the volumes of urine voided, incontinence episodes and the use of incontinence pads.

a) General status:

- Mental status
- Obesity (BMI)
- Physical dexterity and mobility

b) Abdominal/flank examination: for masses, bladder distention, relevant surgical scars

d) Other Treatment Planning Issues:

a) General status:

- Mental status
- Obesity (BMI)
- Physical dexterity and mobility

b) Abdominal/flank examination: for masses, bladder distention, relevant surgical scars

Conclusion

For simple treatments, particularly non-invasive and inexpensive therapies, management may start without the need for the further investigations listed below.

II. RECOMMENDED FURTHER ASSESSMENT PRIOR TO, OR DURING, SPECIALIST ASSESSMENT

The tests below are recommended when the appropriate indication(s) is present. Some recommended tests become highly recommended in specific situations.

This section should also be read in conjunction with the relevant committee reports.

1. Further Symptom and Health-Related QoL Assessment

In patients with urinary symptoms the use of a simple frequency volume chart or bladder diary (examples in Annex 1) is highly recommended to document the frequency of micturition, the volumes of urine voided, incontinence episodes and the use of incontinence pads.

a) General status:

- Mental status
- Obesity (BMI)
- Physical dexterity and mobility

b) Abdominal/flank examination: for masses, bladder distention, relevant surgical scars

d) Other Treatment Planning Issues:

a) General status:

- Mental status
- Obesity (BMI)
- Physical dexterity and mobility

b) Abdominal/flank examination: for masses, bladder distention, relevant surgical scars

Conclusion

For simple treatments, particularly non-invasive and inexpensive therapies, management may start without the need for the further investigations listed below.

II. RECOMMENDED FURTHER ASSESSMENT PRIOR TO, OR DURING, SPECIALIST ASSESSMENT

The tests below are recommended when the appropriate indication(s) is present. Some recommended tests become highly recommended in specific situations.

This section should also be read in conjunction with the relevant committee reports.

1. Further Symptom and Health-Related QoL Assessment

In patients with urinary symptoms the use of a simple frequency volume chart or bladder diary (examples in Annex 1) is highly recommended to document the frequency of micturition, the volumes of urine voided, incontinence episodes and the use of incontinence pads.
The use of the **highest quality questionnaires** (Grade A, where available) is recommended for the assessment of the patient’s perspective of symptoms of incontinence and their impact on quality of life.

The ICIQ is highly recommended (Grade A) for the basic evaluation of the patient’s perspective of urinary incontinence, with other Grade A questionnaires recommended for more detailed assessment. **Further development is required in the areas** of pelvic organ prolapse, bladder pain syndrome, and for specific patient groups, as only Grade B questionnaires are currently available (see Annex 1).

### 2. Renal Function Assessment

Standard **biochemical tests for renal function** are recommended in patients with urinary incontinence and a possibility of **renal impairment**.

### 3. Uroflowmetry

**Uroflowmetry** with the measurement of post void residual urine is recommended as a screening test for symptoms suggestive of urinary voiding dysfunction or physical signs of POP or bladder distension.

### 4. Estimation of Post Void Residual Urine (PVR)

In patients with **suspected voiding dysfunction**, PVR should be part of the initial assessment if the result is likely to influence management, for example, in neurological patients.

### 5. Imaging

Although **routine imaging is not recommended**, imaging of the lower urinary tract and pelvis is **highly recommended** in those with **urinary symptoms** whose initial evaluation indicates a possible co-existing lower tract or pelvic pathology. Initial imaging may be by ultrasound, or plain X ray.

**Imaging of the upper urinary tract is highly recommended in specific situations. These include:**

- Haematuria,
- Neurogenic urinary incontinence e.g. myelodysplasia, spinal cord trauma,
- Incontinence associated with significant post-void residual,
- Co-existing loin/kidney pain,
- Severe pelvic organ prolapse, not being treated
- Suspected extra-urethral urinary incontinence,
- Children with incontinence and UTIs, where indicated
- Urodynamic studies which show evidence of poor bladder compliance.

**In anorectal conditions**, anal US or MRI prior to anal sphincter surgery is highly recommended, when obvious anatomic defects are not evident. Defaecating proctography or dynamic MRI is recommended in suspected rectal prolapse which cannot be adequately confirmed by physical examination.

### 6. Endoscopy

Although **routine cysto-urethroscoopy is not recommended**, LUT endoscopy is **highly recommended**:

- When initial testing suggests other pathologies, e.g. haematuria
- When pain or discomfort feature in the patient’s LUTS, these may suggest an intravesical lesion
- When appropriate in the evaluation of vesicovaginal fistula and extra-urethral urinary incontinence (in childbirth fistulae, endoscopy is often unnecessary).

**In anorectal conditions**, proctoscopy or flexible sigmoidoscopy should routinely be performed in the evaluation of patients with faecal incontinence. Colonoscopy, air contrast barium enema or CT colography is highly recommended in the presence of unexplained change in bowel habit, rectal bleeding or other alarm symptoms or signs (see Basic Assessment chapter).

### 7. Urodynamic Testing

**a) Urodynamic evaluation is recommended**

- When the results may **change management**, such as prior to most invasive treatments for UI and POP,
- After **treatment failure**, if more information is needed in order to plan further therapy,
- As part of both initial and long-term **surveillance** programmes in some types of neurogenic lower urinary tract dysfunction,
- In “complicated incontinence” (for details please see relevant subcommittee reports).
b) The aims of Urodynamic Evaluation are

- To reproduce the patient’s symptoms and correlate these with urodynamic findings
- To assess bladder sensation
- To detect detrusor overactivity
- To assess urethral competence during filling
- To determine detrusor function during voiding
- To assess outlet function during voiding
- To assess residual urine

These tests are recommended in the presence of unexplained diarrhoea or when Crohn’s disease is suspected.

III. OPTIONAL DIAGNOSTIC TESTS

1. Additional Urodynamic Testing

Video-urodynamics may be useful in the management of UI in children, in patients who fail surgery and in some neurogenic patients, to obtain additional anatomical information. Both US and X-ray imaging can be used.

If a more detailed estimate of urethral function is required, then the following optional tests may give useful information:
- Urethral pressure profilometry
- Abdominal leak point pressures
- Video-urodynamics
- Electromyography

If initial urodynamics have failed to demonstrate the cause for the patient’s incontinence then the following tests are optional:
- repeated routine urodynamics
- ambulatory urodynamics

2. Pad Testing

Pad testing is an optional test for the routine evaluation of urinary incontinence and, if carried out, a 24 hr test is suggested.

3. Neurophysiological Testing and Imaging

The information gained by clinical examination and urodynamic testing may be enhanced by neuro-physiological testing of striated muscle and nervous pathways.

Appropriately trained personnel should perform these tests. The following neuro-physiological tests can be considered in patients with peripheral lesions prior to treatment for lower urinary tract or anorectal dysfunction.
- Concentric needle EMG
- Sacral reflex responses to electrical stimulation of penile or clitoral nerves.

Pudendal nerve latency testing is not recommended.

Further imaging of the central nervous system, including spine, by myelography, CT and MRI may prove useful if simple imaging, for example by spinal X-rays in patients with suspected neurological disease, proves normal.

4. Further Imaging

Cysto-urethrography, US, CT and MRI may have an indication:
- Suspected pelvic floor dysfunction
- Failed surgery, such as recurrent posterior vaginal wall prolapse or failed sling surgery
- Suspected fixed urethra

5. Cysto-urethroscopy

This is an optional test in patients with complicated or recurrent UI (e.g. after failed SUI surgery)

6. Anorectal physiology testing

Anorectal manometry is useful to assess resting and squeeze anal pressures.
3. Management Consensus statements

The consensus statements are derived from the detailed work in the committee reports on the management of incontinence in children, men, women, the frail elderly and neurological patients, as well as those with obstetric fistula, pelvic organ prolapse, bladder pain syndrome, and faecal incontinence. The management of incontinence is presented in algorithm form with accompanying notes.

The Consultation recognises that no algorithm can be applied to every patient and each patient’s management must be individualised. There are algorithms for

I. Urinary Incontinence in Children
II. Urinary Incontinence in Men
III. Urinary Incontinence in Women
IV. Fistulae
V. Pelvic Organ Prolapse
VI. Urinary Incontinence in Neurological Patients
VII. Bladder Pain Syndrome
VIII. Faecal Incontinence in Non-Neurological Patients
IX. Faecal Incontinence in Neurological Patients
X. Urinary and Faecal Incontinence in Frail Older Men and Women

These algorithms are divided into two for groups I to III, VII and X. The two parts, initial management and specialised management require a little further explanation.

Although the management algorithms are designed to be used for patients whose predominant problem is incontinence, there are many other patients in whom the algorithms may be useful such as those patients with urgency and frequency, so-called “OAB dry”

The algorithms for initial management are intended for use by all clinicians including health care assistants, nurses, physiotherapists, generalist doctors and family doctors as well as by specialists such as urologists, geriatricians and gynaecologists. The consultation has attempted to phrase the recommendations in the basic algorithms in such a way that they may be readily used by clinicians in all countries of the world, both in the developing and the developed world.

The specialised algorithms are intended for use by specialists. The specialised algorithms, as well as the initial management algorithms are based on evidence where possible, and on the expert opinion of the 400 healthcare professionals who took part in the Consultation. In this consultation, committees ascribed levels of evidence to the published work on the subject and devised grades of recommendation to inform patient management.

It should be noted that these algorithms, dated December 2012, represent the Consultation consensus at that time. Our knowledge, developing from both a research base and because of evolving expert opinion, will inevitably change with time. The Consultation does not wish those using the algorithms to believe they are “carved in tablets of stone”: there will be changes both in the relatively short term and the long term.

Essential components of basic assessment

Each algorithm contains a core of recommendations in addition to a number of essential components of basic assessment listed in sections I to III.

- General assessment
- Symptom assessment
- Assessment of quality of life impact
- Assessment of the desire for treatment
- Physical examination
- Urinalysis

Joint decision making

The patient’s desires and goals for treatment: Treatment is a matter for discussion and joint decision making between the patient and his or
her health care advisors. This process of consultation includes the specific need to assess whether or not the sufferer of incontinence wishes to receive treatment and, if so, what treatments he or she would favour. Implicit in this statement is the assumption that the health care provider will give an appropriate explanation of the patient’s problem and the alternative lines of management, and the indications and the risks of treatment. The assumption that patients almost always wish to have treatment is flawed, and the need to consult the patient is paramount.

In each algorithm, treatments are listed in order of simplicity, the least invasive being listed first. This order does not imply a scale of efficacy or cost, two factors which need to be considered in choosing the sequence of therapy. The order is likewise not meant to imply a suggested sequence of therapy, which should be determined jointly by the treating health care provider and the patient, considering all the relevant factors listed above.

In the initial management algorithms, treatment is empirically based, whilst the specialised management algorithms usually rely on precise diagnosis from urodynamics and other testing.

The assumption is made that patients will be reassessed at an appropriate time to evaluate their progress.

**Use of Continence Products**

The possible role of **continence products** should be considered at each stage of patient assessment and treatment, and if treatment is not (fully) successful, subsequent management.

- **Firstly**, intermittent catheterisation or indwelling catheter drainage often have a role to play in addressing urinary retention.
- **Secondly**, assisted toileting using such devices as commodes, bedpans, and handheld urinals may help to achieve dependent continence* where access, mobility and/or urgency problems undermine a patient’s ability to maintain independent continence*, be it urinary and / or faecal.
- **Finally**, containment products (to achieve contained incontinence*) for urine and / or faeces find an essential role in enhancing the quality of life of those who:
  - Elect not to pursue treatment options
  - Are awaiting treatment
  - Are waiting for treatment to take effect
  - Are unable to be (fully) cured

Further guidance and care algorithms on which products might be suitable for a given patient are given in Committee 20.

1. **Initial assessment should involve a detailed investigation of voiding and bowel habits using bladder/bowel diaries and structured and validated questionnaires.**

The child’s social environment and general and behavioural development should also be formally assessed and recorded. Physical examination should be done to detect a palpable bladder, faecal loading and exclude anatomic and neurogenical causes. Urine analysis and culture is sufficient to exclude the presence of infection. If possible, the child should be observed voiding.

**Referrals for specialist treatment are recommended for children who have complicated incontinence associated with:**
- Recurrent and febrile urinary infection
- Voiding symptoms or evidence of poor bladder emptying
- Urinary tract anomalies
- Previous pelvic surgery
- Neuropathy or neuropathic origin
- Bowel dysfunction not responsive to treatment
- Comorbid behavioural (e.g. ADHD and ODD) and emotional disorders.

- **Initial treatment is recommended for the remaining patients who have:**
  - Nocturnal enuresis without other symptoms (mono-symptomatic enuresis).
  - Daytime symptoms of frequency, urgency, voiding postponement, straining, interrupted voiding, urgency incontinence with or without night-time wetting.

2. **Treatment**

- **Initial treatment for mono-symptomatic nocturnal enuresis** should include:
  - parental and child counselling and motivation
  - review of bladder diary with attention to night-time polyuria
  - a choice between either bed wetting alarm (Grade A) and anti-diuretic hormone analogues of desmopressin (Grade A). It may be a parental and child choice if advantages and disadvantages are well explained.

- **Daytime incontinence** should be managed holistically including:
  - counselling, timed voiding, behaviour modification and bowel management when necessary (Grade B);
  - antimuscarinics may be used if there are symptoms that suggest bladder overactivity (Grade A).
Initial Management of Urinary Incontinence in Children

HISTORY/SYMPTOM ASSESSMENT
- Nocturnal enuresis (monosymptomatic)
- Daytime ± Nighttime wetting ± Urgency / frequency

CLINICAL ASSESSMENT
- General assessment (see relevant chapter)
  - Physical examination: abdominal, perineal, ext. genitalia, back/spine, neurological
  - Assess bowel function -> if constipated, treat and reassess
  - Urinalysis ± Urine culture -> if infected, treat and reassess
  - Assess post-void residual urine by abdominal examination (optional: by ultrasound)

PRESUMED DIAGNOSIS
- MONOSYMPTOMATIC NOCTURNAL ENURESIS
- URGENCY INCONTINENCE
- RECURRENT INFECTION
- DYSFUNCTIONAL VOIDING

TREATMENT *
- Explanation/education
- Enuresis Diary
- Alarm
- Desmopressin

SPECIALISED MANAGEMENT
- At any stage of the patient’s care pathway, management may need to include continence products
1906

I. URINARY INCONTINENCE IN CHILDREN

B. SPECIALISED MANAGEMENT

Two groups of children with “complicated” incontinence should have specialist management from the outset (Fig. 2).

- Children whose incontinence is due to, or associated with, urinary tract anomalies and neuropathy.
- Children without urinary tract anomalies, but with recurrent febrile infection and, proven or suspected, lower urinary tract dysfunction.

Children who fail the basic treatment, but who have neither neurogenic nor anatomical problems, should also receive specialist management. Children with comorbid behavioural and emotional disorders require referral to mental health services, as compliance and treatment outcomes are lower. Assessment and treatment should follow evidence-based practice parameters and guidelines.

1. Assessment

- As part of further assessment, the measurement of urine flow (in children old enough), together with the pelvic ultrasound estimate of residual urine and appearance of the bladder wall and rectum are highly recommended. An evaluation of the upper urinary tracts with ultrasound is also highly recommended. Those who do not improve with treatment and have neither neurogenic nor anatomical problems should be reassessed using micturition charts, symptom scores, uranalysis, uroflowmetry and residual urine determination.

If there are recurrent and febrile infections, upper tract imaging and possibly a VCUG should be considered. However, endoscopy is rarely indicated.

- Urodynamics should be considered:

  - If the type and severity of lower tract dysfunction cannot be explained by clinical findings.
  - If invasive treatment is under consideration, for example, stress incontinence surgery if there is sphincteric incompetence, or bladder augmentation if there is detrusor overactivity.
  - If upper tract dilatation exists and is thought to be due to bladder dysfunction. Invasive urodynamic studies are generally not recommended if the child has normal upper tract imaging and is to be treated by noninvasive means.
  - Spinal imaging (US/X-ray/MRI) may be needed if a bony abnormality or neurological condition is suspected.

2. Treatment

The treatment of incontinence associated with urinary tract anomalies is complex and cannot easily be dealt with in an algorithm. In many children more than one pathophysiology demands treatment. If there are complex congenital abnormalities present, the treatment is mostly surgical and it should be individualised according to the type and severity of the problem (please see Children's Committee Report).

Care should be given by specialist children’s nurses and therapists.

- Initial treatment should be non-surgical.
  - For stress urinary incontinence (SUI): pelvic floor muscle training (Grade C).
  - For suspected bladder overactivity (OAB): fluid/voiding regimes and antimuscarinics (Grade A).
  - For voiding dysfunction: timed voiding, voiding re-education, pelvic floor muscle relaxation (+/− biofeedback), intermittent catheterisation (when PVR >30% of bladder capacity) (Grade B/C).
  - For bowel dysfunction: high fibre diet and laxatives as appropriate.

The child’s progress should be assessed and, if quality of life is still significantly impaired, or if the upper urinary tracts are at risk, surgical treatment is likely to be necessary.

- If surgical treatment is required, then urodynamic studies are recommended to confirm the diagnosis.
  - For SUI, sling surgery, bulking agent injection and AUS may be considered.
  - For DO/poor compliance, botulinum toxin (for DO, and off-label) and bladder augmentation may be performed.
  - If the child cannot do IC then a Mitrofanoff channel may be needed.
Specialised Management of Urinary Incontinence in Children

**EXPERT HISTORY & PHYSICAL EXAMINATION**

**CLINICAL ASSESSMENT**

**DIAGNOSIS**

**TREATMENT** *

- **STRESS URINARY INCONTINENCE**
  - Pelvic floor muscle training
  - AUS
  - Sling
  - Bulking agent injection

- **DETRUSOR OVERACTIVITY / POOR COMPLIANCE**
  - Fluid/voiding regime
  - Antimuscarinics
  - Bowel management
  - Botulinum toxin
  - Bladder augmentation

- **VOIDING DYSFUNCTION**
  - Timed voiding
  - Pelvic floor relaxation ± biofeedback
  - Pharmacotherapy
    - Antimuscarinics
    - α-blockers
  - Intermittent cath.
  - Bowel management
  - Antibiotic if infection

- **ANATOMICAL CAUSES OF URINARY INCONTINENCE**
  - Correct anomaly (see: surgical treatment in children)

* At any stage of the patient’s care pathway, management may need to include continence products
II. URINARY INCONTINENCE IN MEN

A. INITIAL MANAGEMENT

1. Initial Assessment should identify:

➤ Complicated incontinence group

Those with pain or with haematuria, recurrent infections, suspected or proven poor bladder emptying (for example due to bladder outlet obstruction), or incontinence following pelvic irradiation or radical surgery, are recommended for specialised management.

Poor bladder emptying may be suspected from symptoms, physical examination or if imaging has been performed by X-ray or ultrasound after voiding.

➤ Four other main groups of men should be identified by initial assessment as being suitable for initial management.

• Those with post-micturition dribble alone,
• Those with overactive bladder (OAB) symptoms: urgency with or without urgency incontinence, together with frequency and nocturia
• Those with stress incontinence (most often post-prostatectomy),
• Those with mixed urgency and stress incontinence (most often post-prostatectomy)

2. Management

➤ For men with post-micturition dribble, this requires no assessment and can usually be treated by teaching the man how to do a strong pelvic floor muscle contraction after voiding, or manual compression of the bulbous urethra directly after micturition. (Grade B)

➤ For men with stress, urgency or mixed urgency / stress incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, scheduled voiding regimes, behavioural therapies and medication. In particular:

• Lifestyle interventions (Grade D)
• Supervised pelvic floor muscle training for men with post radical prostatectomy SUI (Grade B)
• Scheduled voiding regimes for OAB (Grade C)
• Antimuscarinic drugs for OAB symptoms with or without urgency incontinence (Grade B) if the patient has no evidence of significant post-void residual urine
• α-adrenergic antagonists (a-blockers), can be added if it is thought that there may also be bladder outlet obstruction. (Grade C)

➤ Should initial treatment be unsuccessful after a reasonable period of time (for example, 8-12 weeks), specialist advice is highly recommended.

Clinicians are likely to wish to treat the most bothersome symptom first in men with symptoms of mixed incontinence.
Initial Management of Urinary Incontinence in Men

**Initial Management**

**HISTORY**
- Post-micturition dribble

**Clinical Assessment**
- General assessment (see relevant chapter)
- Urinary symptom assessment and symptom score (including frequency-volume chart and questionnaire)
- Assess quality of life and desire for treatment
- Physical examination: abdominal, rectal, sacral, neurological
- Urinalysis ± urine culture → if infected, treat and reassess
- Assessment of pelvic floor muscle function
- Assess post-void residual urine

**Assessment**
- Complicated incontinence
  - Recurrent or “total” incontinence
  - Incontinence associated with:
    - Pain
    - Haematuria
    - Recurrent infection
    - Prostate irradiation
    - Radical pelvic surgery

**Mixed Incontinence**
- Treat most bothersome symptom first

**Urgency Incontinence**
- Presumed due to detrusor overactivity
  - Urethral milking
  - Pelvic floor muscle contraction

**Stress Incontinence**
- Presumed due to sphincteric incompetence

**Specialised Management**

**Failure**
- At any stage of the patient’s care pathway, management may need to include continence products
The specialist may first reinstitute initial management if it is felt that previous therapy had been inadequate.

1. Assessment

- Patients with “complicated” incontinence referred directly to specialised management, are likely to require additional testing, such as cytology, cystourethoscopy and urinary tract imaging.

If these tests prove normal then those individuals can be treated for incontinence by the initial or specialised management options as appropriate.

If symptoms suggestive of detrusor overactivity, or of sphincter incompetence persist, then urodynamic studies are advisable in order to arrive at a precise diagnosis, prior to invasive treatment.

2. Treatment

When basic management has failed and if the patient’s incontinence markedly disrupts his quality of life then invasive therapies should be considered.

- For sphincter incompetence the recommended option is the artificial urinary sphincter (Grade B). Other options, such as a male sling, may be considered (Grade C).

- For idiopathic detrusor overactivity, (with intractable overactive bladder symptoms) the recommended therapies are: Botulinum toxin A (Grade B), neuromodulation (Grade C), and bladder augmentation (Grade C).*

*Note: At the time of writing, botulinum toxin for idiopathic DO is being used “off-label”.

- When incontinence has been shown to be associated with poor bladder emptying and detrusor underactivity, it is recommended that effective means are used to ensure bladder emptying, for example, intermittent catheterisation (Grade B/C).

- If incontinence is associated with bladder outlet obstruction, then consideration should be given to surgical treatment to relieve obstruction (Grade B). α-blockers and/or 5α-reductase inhibitors would be an optional treatment (Grade C). There is increased evidence for the safety of antimuscarinics for overactive bladder symptoms in men, chiefly in combination with an α-blocker (Grade B).
Specialised Management of Urinary Incontinence in Men

**HISTORY/SYMPTOM ASSESSMENT**

**Post-prostatectomy incontinence**
- Consider urodynamics and imaging of the urinary tract
- Urethrocystoscopy (if indicated)

**Incontinence with urgency / frequency**
- With coexisting bladder outlet obstruction
- With coexisting underactive detrusor (during voiding)

**“Complicated” Incontinence:**
- Recurrent incontinence
- Incontinence associated with:
  - Prostate or pelvic irradiation
  - Radical pelvic surgery

**CLINICAL ASSESSMENT**

**STRESS INCONTINENCE**
- Due to sphincteric incompetence

**MIXED INCONTINENCE**
- Treat major component first

**URGENCY INCONTINENCE**
- Due to detrusor overactivity (during filling)

**TREATMENT**

- If initial therapy fails:
  - Artificial urinary sphincter
  - Male sling (see chapter 13)
  - α-blockers, 5ARI
  - Correct anatomic bladder outlet obstruction
  - Antimuscarinics

- If initial therapy fails:
  - Botulinum toxin A
  - Neuromodulation

- If initial therapy fails:
  - Intermittent catheterisation
  - Antimuscarinics

- Consider:
  - Urethrocystoscopy
  - Further imaging
  - Urodynamics

- Correct anomaly
- Treat pathology

*At any stage of the patient’s care pathway, management may need to include continence products*
III. URINARY INCONTINENCE IN WOMEN

A. INITIAL MANAGEMENT

1. Initial assessment should identify:

 ➢ “Complicated” incontinence group.
Those with pain or haematuria, recurrent infections, suspected or proven voiding problems, significant pelvic organ prolapse or who have persistent incontinence or recurrent incontinence after pelvic irradiation, radical pelvic surgery, previous incontinence surgery, or who have a suspected fistula, should be referred to a specialist.

 ➢ Three other main groups of patients should be identified by initial assessment.
• Women with stress incontinence on physical activity
• Women with urgency, frequency with or without urgency incontinence
• Those women with mixed urgency and stress incontinence
Abdominal, pelvic and perineal examinations should be a routine part of physical examination. Women should be asked to perform a “stress test” (cough and strain to detect leakage likely to be due to sphincter incompetence). Any pelvic organ prolapse or urogenital atrophy should be assessed. Vaginal or rectal examination allows the assessment of voluntary pelvic floor muscle function, an important step prior to the teaching of pelvic floor muscle training.

2. Treatment

 ➢ For women with stress, urgency or mixed urinary incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, PFMT), scheduled voiding regimes, behavioural therapies and medication. In particular:
• Advice on caffeine reduction (Grade B) and weight reduction (Grade A)
• Supervised pelvic floor muscle training (Grade A), supervised vaginal cones training for women with stress incontinence (Grade B)
• Supervised bladder training (Grade A) for OAB.
• If oestrogen deficiency and/or UTI is found, the patient should be treated at initial assessment and then reassessed after a suitable interval using vaginal oestrogens. (Grade B).
• Antimuscarinics for OAB symptoms with or without urgency incontinence (Grade A); duloxetine* may be considered for stress urinary incontinence (Grade B)
PFMT should be based on sound muscle training principles such as specificity, overload progression, correct contraction confirmed prior to training, and use of the Knack for 12 weeks before reassessment and possible specialist referral.
Clinicians are likely to wish to treat the most bothersome symptom first in women with symptoms of mixed incontinence. (Grade C).

 ➢ Some women with significant pelvic organ prolapse can be treated by vaginal devices that treat both incontinence and prolapse (incontinence rings and dishes).

* Duloxetine is not approved for use in United States. It is approved for use in Europe for severe stress incontinence (see committee report on pharmacological management for information regarding efficacy, adverse events, and ‘black box’ warning by the Food and Drug Administration of the United States).
Initial Management of Urinary Incontinence in Women

**HISTORY**
- Incontinence on physical activity
- Incontinence with mixed symptoms
- Incontinence / frequency with urgency

**Complicated incontinence**
- Recurrent incontinence
- Incontinence associated with:
  - Pain
  - Haematuria
  - Recurrent infection
  - Significant voiding symptoms
  - Pelvic irradiation
  - Radical pelvic surgery
  - Suspected fistula

**CLINICAL ASSESSMENT**
- General assessment (see relevant chapter)
- Urinary symptom assessment (including frequency-volume chart and questionnaire)
- Assess quality of life and desire for treatment
- Physical examination: abdominal, pelvic and perineal
- Cough test to demonstrate stress incontinence if appropriate
- Urinalysis ± urine culture -> if infected, treat and reassess *if appropriate*
- Assess oestrogen status and treat as appropriate
- Assess pelvic floor muscle function
- Assess post-void residual urine

**PRESUMED DIAGNOSIS**
- Stress incontinence: presumed due to sphincteric incompetence
- Mixed incontinence: treat most bothersome symptom first
- OAB - with or without urgency incontinence: presumed due to detrusor overactivity

**TREATMENT**
- Life style interventions.
- Pelvic floor muscle training for SUI, MUI, or OAB
- Bladder retraining for OAB
- Antimuscarinics (OAB ± urgency incontinence) or Duloxetine** (SUI)

**SPECIALISED MANAGEMENT**
- Other adjuncts, such as electrical stimulation
- Vaginal devices

**Failure**

*At any stage of the patient’s care pathway, management may need to include continence products*
III. URINARY INCONTINENCE IN WOMEN

B. SPECIALISED MANAGEMENT

1. Assessment

Women who have “complicated” incontinence (see initial algorithm) may need to have additional tests such as cytology, cystourethroscopy or urinary tract imaging. If these tests are normal then they should be treated for incontinence by the initial or specialised management options as appropriate.

- Those women who have failed initial management and whose quality of life is impaired are likely to request further treatment. If initial management has been given an adequate trial then interventional therapy may be desirable. Prior to intervention urodynamic testing is highly recommended, when the results may change management. It is used to diagnose the type of incontinence and therefore inform the management plan. Within the urodynamic investigation urethral function testing by urethral pressure profile or leak point pressure is optional.

- Systematic assessment for pelvic organ prolapse is highly recommended and it is suggested that the POP-Q method should be used in research studies. Women with co-existing pelvic organ prolapse should have their prolapse treated as appropriate.

2. Treatment

- If urodynamic stress incontinence is confirmed then the treatment options that are recommended for patients with some degree of bladder-neck and urethral mobility include the full range of non-surgical treatments, as well as retropubic suspension procedures, (Grade A) and bladder neck/sub-urethral sling operations; (Grade A). The correction of symptomatic pelvic organ prolapse may be desirable at the same time.

For patients with limited bladder neck mobility, bladder neck sling procedures, (Grade A) injectable bulking agents (Grade B) and the artificial urinary sphincter (Grade B) can be considered.

- Refractory urgency incontinence (overactive bladder) secondary to idiopathic detrusor overactivity may be treated by botulinum toxin A (Grade C)*, neuromodulation (Grade A) or bladder augmentation (Grade C).

- Those patients with voiding dysfunction leading to significant post-void residual urine (for example, >30% of total bladder capacity) may have bladder outlet obstruction or detrusor underactivity. Prolapse is a common cause of voiding dysfunction.

* At the time of writing, botulinum toxin is being used “off-label” and with caution.
Specialised Management of Urinary Incontinence in Women

HISTORY/ SYMPTOM ASSESSMENT

- Incontinence on physical activity
- Incontinence with mixed symptoms
- Incontinence with urgency / frequency

CLINICAL ASSESSMENT

- Assess for pelvic organ mobility / prolapse
- Consider imaging of the UT/pelvic floor
- Urodynamics (see notes)

URODYNAMIC STRESS INCONTINENCE (USI)

- Mixed INCONTINENCE USI/DOI
  - Treat. most bother-some symptom first

DIAGNOSIS

- Bladder outlet obstruction
- Underactive detrusor

TREATMENT *

- If initial therapy fails:
  - Stress incontinence surgery
  - bulking agents
  - tapes and slings
  - colposuspension

MIXED INCONTINENCE USI/DOI

- If initial therapy fails:
  - Botulinum toxin
  - Neuromodulation
  - Bladder augmentation

DETURSOR OVERACTIVITY INCONTINENCE (DOI)

- Correct anatomic bladder outlet obstruction (e.g. genito-urinary prolapse)
- Intermittent catheterization

INCONTINENCE associated with poor bladder emptying

- Correct anomaly
- Treat pathology

“Complicated” incontinence:
- Recurrent incontinence
- Incontinence associated with:
  - Pain
  - Haematuria
  - Recurrent infection
  - Voiding symptoms
  - Pelvic irradiation
  - Radical pelvic surgery
  - Suspected fistula

Consider:
- Urethrocystoscopy
- Further imaging
- Urodynamics

* At any stage of the patient’s care pathway, management may need to include continence products.
In the developing world fistulae are often a consequence of poor peri-natal care. The epidemiology, aetiology, diagnosis, treatment and prevention have been described in detail during the recent International Consultation on Obstetric Fistula.

In contrast to the field of obstetrical fistulae where the numbers of patients are high, the prevalence of non-obstetrical fistulae seems to be much lower. The published series have small patient numbers, are usually retrospective and have a low level of evidence. The published obstetrical series show impressive numbers and demonstrate the level of skill that many of the fistula surgeons have obtained while working in difficult and isolated situations.

Both committees are convinced that obstetric fistula surgeons in the developing world and reconstructive pelvic surgeons in the developed countries can learn a lot from each other.

**PART I: OBSTETRIC FISTULA**

**INTRODUCTION**

Epidemiological studies on obstetric fistulae are inadequate.

The incidence of fistulae is expressed per 1,000 deliveries and would appear to be between 0.1% rising to 1.5 per 1,000 pregnancies in rural areas.

The major risk factors appear to be age at first marriage, short stature, pregnancy with a male child rather than a female child, failure to attend ante-natal care, low socio-economic status, low social class, lack of employment and illiteracy.

The consequences of obstetric fistulae include divorce (16-92%), social isolation, worsening poverty, malnutrition, sexual dysfunction and mental illness (including anxiety/depression), insomnia, general ill health and thoughts of worthlessness and suicide.

**ASSESSMENT**

Early detection of fistulae could improve by examining all women after their delivery or Caesarian section who suffered prolonged labour and who are at risk of developing an obstetric fistula.

Associated pathologies should be actively searched for and should be taken into account in the treatment plan: all components of the 'obstructed labour injury complex' should be examined.

Classification of fistulae is recommended. Although many classification systems exist, the committee recommends the use of the Waaldijk classification, since it is supported by the largest amount of data. It involves precise measurements of the distances between the external urinary meatus and the distal edge of the fistulae, together with the widest diameter of the fistulae. Fistulae are classified into types 1, 2 and 3. Type 3 fistulae are those fistulae other than vesico-vaginal fistulae (VVF) and include recto-vaginal fistulae (VVF) and uretero-vaginal fistulae. (Grade C)

The formal classification of the fistulae should be done under anaesthesia when the patient is on the operation table, just before surgery.
MANAGEMENT OF NEW AND ESTABLISHED VVF

Management of VVF depends on whether the fistulae is diagnosed within two or three months of its occurrence or whether the woman presents late with an established fistula. (Algorithm 1)

Early fistulae (less than 75 days after obstructed labour). There is evidence that early catheter care will result in the cure of a significant minority of VVF. (Grade C)

Established fistulae (>75 days after obstructed labour) and those that fail catheter treatment should be treated surgically by a fistula surgeon. (Grade C)

TREATMENT

If catheter drainage fails, then fistula repair will be necessary. There are certain principles behind fistula repair:

- Necrotic tissue must be removed prior to fistula repair.
- Fistula repair must only be undertaken by a properly trained surgeon.
- Adequate post-operative care is essential.
- Proper follow-up should be arranged.

A vaginal approach under spinal anaesthesia is preferred.

A tension-free single layer closure of the bladder wall and closure of the vaginal wall in a separate layer are advocated. A Martius flap in primary obstetric fistula repair is not recommended.

In principle most fistulae can be dealt with by vaginal approach, but an abdominal approach can be useful in some cases (e.g. concomitant reconstructive procedures). Advanced training and surgical skills are prerequisites for treating this type of fistula.

When reporting on outcome after fistula repair, authors should make a clear distinction between fistula closure rates and post-operative stress incontinence rates and the time at which the follow-up was organized.

Prevention of post-operative stress incontinence must be added to the surgical procedure if the urethral closing mechanism is involved. This can be done by a good repair of the pubocervical fascia and refixation or by adding a sling procedure.

MANAGEMENT OF THE COMPLICATIONS OF VVF

The complications of vesico-vaginal fistulae are many but include:

- Persistence or recurrence of urinary incontinence
- Persistence of lower urinary tract symptoms or occurrence of new lower urinary tract symptoms, including overactive bladder
- Urinary tract infections
- Upper urinary tract symptoms, including loin pain
- Dyspareunia and sexual dysfunction
- Infertility
- Neurological symptoms
- Psychological problems and mental illness

INTRODUCTION

Iatrogenic urogenital fistulae are known complications of pelvic surgery and oncological treatments such as radiotherapy, chemotherapy or a combination of both. In the oncological context, fistulae may also occur as a result of primary or recurrent malignancy. The development of fistula following radiotherapy for primary treatment should trigger a search for evidence of tumour recurrence (Grade D).

- Urogenital fistulae are more frequent in women who have undergone hysterectomy.
- The risk of injury to the bowel or urinary tract and of subsequent fistula formation is higher in women with malignant disease undergoing radical surgery than in women with benign disease undergoing simple surgical procedures.
- Several modifications to conventional radical hysterectomy have been described, although they have not consistently been shown to mitigate the risk of urinary fistula postoperatively.
- Data on exenterative surgery are inconsistent, although the risk of fistula formation may be higher following exenteration for recurrent disease as compared to that following radical hysterectomy for the primary treatment of malignancy.
- The rate of visceral injury and fistula formation is inconsistently reported following laparoscopically assisted radical hysterectomy, but may be somewhat higher than following open surgery.
- Local ablative treatments applied in gynaecological oncology, whilst apparently relatively low risk as single treatments, may carry considerable risk for fistula formation when repeated.
- The rate of fistula formation following radiotherapy for gynaecological cancer appears to be of the same order as that following surgical treatment.
- The risk of fistula formation following radiotherapy for locally recurrent malignancy is higher than following its use in primary disease.

ASSESSMENT OF FISTULAE

- Leakage of stool, urine, or possibly both is the hallmark sign of a fistulae. The leakage is usually painless, may be intermittent if it is position dependent, or may be constant. Unfortunately, intraoperative diagnosis of a GU or GI injury is made in only about half of the cases that result in fistulae.
- CT and cystoscopy appear more consistent in the confirmation and location of possible intestino-vesical fistulae, than other investigations (Grade C).
- Level 3 evidence indicates that the routine use of cystoscopy with dye testing at gynaecological surgery has high sensitivity, specificity and negative predictive value in the detection of ureteric injury, although false positive tests do occur. The clinical and cost-effectiveness of routine cystoscopy remains to be established. (Grade C)
- Ureteric injury or fistulae may be suspected in patients following pelvic surgery if a fluid leak or pelvi-calyceal dilatation occurs postoperatively. (Grade D)
- Uretero-arterial fistula may be suspected in patients presenting with haematuria with a history of relevant pelvic surgery and indwelling ureteric stent. (Grade D)
- Elevated levels of creatinine in drainage fluid following pelvic surgery are suggestive of a urinary tract injury. (Grade D)

MANAGEMENT OF VESICOVAGINAL FISTULAE

The literature relating to surgical fistulae is extensive, but of limited quality.

- The use of neoadjuvant or adjuvant therapies is likely to be associated with a greater risk of fistula development than the primary treatment alone.
- The most common non-obstetric causes of fistulae involving the gastrointestinal tract are diverticular disease, Crohn’s disease, malignancy and radiotherapy.
Attention should be given as appropriate to skin care, nutrition, rehabilitation, counselling and support prior to and following fistulae repair. (Grade D)

Perioperative antibiotic prophylaxis should follow local policies. (Grade D)

There is no benefit from mechanical or laxative bowel preparation prior to colonic surgery; it is reasonable that this recommendation be extrapolated to apply to fistulae surgery. (Grade B)

There is no proven benefit to delayed repair of vesicovaginal fistulae; the timing of repair should be tailored to the individual patient and surgeon requirements, but can be undertaken as soon as any oedema, inflammation, tissue necrosis, infection are resolved. (Grade B)

There are no high quality data to indicate greater cure rates for any one technique as compared to others; level 3 evidence indicates similar success rates for vaginal and abdominal, and for transvesical and transperitoneal approaches. (Grade C)

Surgeons involved in fistulae surgery should have appropriate training, skills, and experience to select an appropriate procedure for each patient. (Grade D)

The majority of vesico-vaginal and all urethro-vaginal fistulae can be repaired vaginally, regardless of aetiology. (Grade C)

Where concurrent ureteric re-implantation or augmentation cystoplasty are required, the abdominal approach is necessary. (Grade D)

A variety of interpositional grafts can be used in either abdominal or vaginal procedures, although there is little evidence to support their use in any specific setting. (Grade C)

Conventional and robotically-assisted laparoscopic approaches have both been shown to be feasible in selected cases; the indications for, or optimal patient for these techniques is not yet clear. (Grade C)

A period of continuous bladder drainage is crucial to successful fistulae repair; there are no high level data to support any particular type, route, or duration of catheterisation; current practice suggests: 10-14 days for simple and/or post-surgical fistulae; 14-21 days for complex and/or post-radiation fistulae. (Grade D)

RADIATION FISTULAE

Whilst diversion is used more widely in radiation-associated fistulae of all types as compared to non-radiated fistulae, there is low level evidence that repair procedures can achieve successful fistulae closure and continence in appropriately selected cases. (Grade C)

Where urinary and/or faecal diversions are required, attempts should be made to avoid using irradiated tissues wherever possible, and to minimise the potential for anastomotic complications. (Grade C)

There is low level evidence to support the use of interposition grafts when repair of radiation-associated fistulae is undertaken. (Grade C)

In patients with intractable urinary incontinence from radiation-associated fistulae, where life expectancy is very short, ureteric occlusion might be considered; there is insufficient evidence to recommend any particular technique. (Grade D)
MANAGEMENT OF IATROGENIC VESICOVAGINAL FISTULAE

HISTORY

Leakage of urine from vagina/perineum

Clinical examination
Urethro-cystoscopy
Imaging (Xray/CT/MRI,US)
Evaluate upper urinary tract

CLINICAL ASSESSMENT

Assess fistula closure & assess continence status

At any stage of the patient’s care pathway, management may need to include continence products

PRESUMED DIAGNOSIS

VVF

Primary simple

Consider catheter 4-12w

Vaginal repair
Consider timing
Martius flap optional

Primary complex

Vaginal repair or other approach
Consider timing
Use interposition flaps

Recurrence

Vaginal repair or other approach
2-3 months
Martius flap or Interposition flaps

Post-irradiation

Vaginal repair or other approach
6-12 months
Martius flap

MANAGEMENT *

* At any stage of the patient’s care pathway, management may need to include continence products
MANAGEMENT OF FISTULAE INVOLVING BOWEL

• There is limited evidence to support a non-surgical or conservative surgical approach in colo-vesical fistulae where there are minimal symptoms or evidence of limited bowel involvement. (Grade C)

• There is only limited low level evidence to support a non-surgical approach in colo-vesical fistulae associated with diverticular disease; nevertheless, in the frail elderly, or in patients who have limited symptoms of urinary infection or urinary diarrhoea it is reasonable to consider a trial of conservative management. (Grade D)

• A one-stage approach to surgery for intestino-vesical fistulae is appropriate in many cases, but should be limited to those patients whose nutritional state is good, and where there is no evidence of additional intra-abdominal pathology (e.g. severe inflammation, radiation injury, advanced malignancy, intestinal obstruction) or major co-morbidity. (Grade B)

• A laparoscopic approach to one-stage management has been shown to be feasible, although there is no high level evidence to allow comparison of outcomes with open surgery. (Grade D)

MANAGEMENT OF URETERIC FISTULAE

• Surgeons undertaking complex pelvic surgery should be competent at identifying, preserving and repairing the ureter. (Grade D)

• Ureteric stents are not required as prophylaxis against injury during routine gynaecological surgery, while their role in more extensive surgery remains to be established. (Grade B)

• Most upper urinary tract fistulae should be initially managed by conservative or endoluminal techniques where such expertise and facilities exist. (Grade B)

• Persistent ureterovaginal fistulae should be repaired by an abdominal approach using open, laparoscopic or robotic techniques according to availability and competence. (Grade D)

• For patients with ureteric fistulae associated with advanced pelvic cancer and poor performance status, palliation by nephrostomy tube diversion and endoluminal distal ureteric occlusion is an option. (Grade C)

MANAGEMENT OF URETHRO-VAGINAL FISTULAE

Recommendations

• Urethrovaginal fistulae are preferably treated by a vaginal approach. (Grade C)

• A variety of autologous tissue interposition techniques have been described, but their value remains uncertain. (Grade C)

• Urethrovaginal fistulae repair may be complicated by stress incontinence, urethral stricture and urethral shortening necessitating long-term follow-up. (Grade C)
Management of Iatrogenic Ureteric Fistulae

HISTORY

Extra-urethral vaginal urinary leakage and/or signs of ureteric obstruction

CLINICAL ASSESSMENT

Clinical examination
Urethro-cystoscopy
Imaging (Xray/CT/MRI, US)
Evaluate upper urinary tract obstruction

PREVIOUS DIAGNOSIS

Ureterovaginal fistula

MANAGEMENT *

Endoluminal technique (stenting, nephrostomy) for at least 6 weeks

Unable to stent (initially)...

Re-evaluate for fistula closure, ureteric obstruction

Persisting fistula or ureteric obstruction

Healed

Ureteric reimplantation (open, laparoscopic or robotic)

* At any stage of the patient’s care pathway, management may need to include continence products.
Pelvic organ prolapse includes urogenital and rectal prolapse. Treatment for pelvic organ prolapse should be reserved for symptomatic women, except in rare, selected cases.

1. ASSESSMENT

Symptom enquiry may reveal a variety of symptoms. Symptom severity may not correlate with the severity of the anatomical changes.

Physical examination should:
- define the severity of maximum anatomical support defect,
- assess pelvic floor muscle function and
- determine if epithelial/mucosal ulceration is present.

Post void residual should be measured; nearly all elevated post void residuals resolve with treatment of urogenital prolapse. Imaging of the upper tract is indicated when treatment of vaginal prolapse beyond the hymen is observation only (i.e. no pessary or surgery).

2. MANAGEMENT

- **Observation** is appropriate when medically safe and preferred by the patient (Grade C).

- **Pelvic floor muscle training may:**
  - reduce the symptoms of urogenital prolapse (Grade A), although topographic change is not expected
  - prevent or slow deterioration of anterior urogenital prolapse (Grade B)

- **Pessaries**, when successfully fitted, may improve protrusion symptoms (Grade B). Regular follow up is mandatory. **Support pessaries** that concurrently treat stress incontinence should be considered when appropriate.

- **Local oestrogens** may benefit hypoestrogenic women for the prevention and/or treatment of vaginal epithelial ulceration (Grade C).

- **Reconstructive surgery** should aim to optimise anatomy and function (see full text for grades of recommendation for specific surgical techniques). Pre and postoperative pelvic floor muscle training may promote quality of life and fewer symptoms after surgery for urogenital prolapse (Grade C).

- **Obliterative surgery** is reserved for selected women who agree to permanent vaginal closure (Grade B).
Management of Pelvic Organ Prolapse
(including urogenital prolapse and rectal prolapse)

HISTORY

Bothesome pelvic organ prolapse

Symptoms Screening: assess bothersomeness, frequency and severity of urinary, ano-rectal, genital and sexual symptoms
- Urinary: PVR, cough stress test, urinalysis.
- Physical Examination: Sufficient to determine the site and severity of prolapse and detect other significant findings
  - Selective use of urodynamics when results would alter planned treatment
  - Selective use of upper tract imaging when observation is planned
- Ano-Rectal: Endoscopy, lower GI tract imaging

CLINICAL ASSESSMENT

Complex or recurrent prolapse

INVESTIGATION BY SPECIALIST

UROGENITAL PROLAPSE WITH OR WITHOUT OTHER PELVIC SYMPTOMS

Observation
Lifestyle interventions
Pelvic floor muscle training
Pessary
Reconstructive surgery
Obliterative surgery

RECTAL PROLAPSE WITH OR WITHOUT OTHER PELVIC SYMPTOMS

Observation
Lifestyle interventions
Transperineal surgery
Transabdominal surgery

MANAGEMENT *

Specialist management

* At any stage of the patient’s care pathway, management may need to include continence products
Patients with known neurological disease often need evaluation to exclude bladder dysfunction, not only if symptoms occur, but as a standard assessment as neurogenic bladder has a high prevalence in this disease (for prevalence figures see chapter).

A possible neurological cause of "idiopathic" incontinence should always be considered. Diagnostic steps to evaluate this include basic assessments, such as history and physical examination, urodynamics and specialised tests.

Incontinence in neurological patients does not necessarily relate to the neurologic pathology. Other diseases such as prostate pathology, pelvic organ prolapse, might have an influence. These have to be ruled out.

Extensive diagnostic evaluation is often useful and necessary to tailor an individual treatment based on complete neurofunctional data. This may not be needed in every patient e.g. patients with suprapontine lesions or in patients where treatment will consist merely of bladder drainage due to bad medical condition or limited life expectancy.

There is often a need to manage bladder and bowel together.

The management of neurological urinary incontinence depends on an understanding of the likely mechanisms producing incontinence. This can in turn depend on the site and extent of the nervous system abnormality.

Therefore neurogenic incontinence patients can be divided into those having:

- peripheral lesions (as after major pelvic surgery) including those with lesions of the cauda equina (e.g. lumbar disc prolapse);
- sacral spinal cord lesions involving the sacral micturition centre
- suprasacral spinal cord lesions (suprasacral infrapontine spinal cord lesions);
- central lesions of the brain or brain stem (stroke, Parkinson’s disease).

History and physical examination are important in helping distinguish these groups.

Patients with peripheral nerve lesions (e.g. denervation after pelvic surgery) and patients with spinal cord lesions (e.g. traumatic spinal cord lesions) should get specialised management (A).

Initial treatment for patients with incontinence due to suprapontine pathology, like stroke; need to be assessed for degree of mobility and ability to cooperate. Initial recommended treatments are behavioural therapy (C) and anti-muscarinic drugs for presumed detrusor overactivity (A). Continence products (B) or catheters (C) may be necessary for non-cooperative or less mobile patients.
Initial Management of Neurogenic Urinary Incontinence

**HISTORY, level of lesion**
- Peripheral nerve lesion (e.g. radical pelvic surgery)
- Sacral cord/cauda equina lesion (e.g. lumbar disc prolapse)
- Suprasacral infrapontine and pontine lesions (e.g. trauma, multiple system atrophy)
- Suprapontine cerebral lesion (e.g. Parkinson's disease, stroke, multiple sclerosis)

**CLINICAL ASSESSMENT**
- Further history
- General assessment including of home circumstances
- Urinary diary and symptom score
- Assessment of functional ability, quality of life and desire for treatment
- Physical examination: assessment of sensation in lumbosacral dermatomes, anal tone and voluntary contraction of anal sphincter, bulbocavernosus and anal reflexes, gait, mobility, contractures, hand function.
- Urine analysis + culture (if infected: treat as necessary)
- Urinary tract imaging, serum creatinine: if abnormal to specialised management
- Post void residual (PVR) assessment by abdominal examination or optional by ultrasound

**PRESUMED DIAGNOSIS**
- Stress urinary incontinence due to sphincter incompetence with negligible PVR
- Urinary incontinence due to detrusor overactivity
- Urinary incontinence associated with poor bladder emptying (significant PVR)
- With negligible PVR

**MANAGEMENT**
- Behavioural modification
- External appliances
- Intermittent catheterisation **with or without**
- Antimuscarinics

**Failure**

- Depending on cooperation and mobility:
  - Behavioural modification,
  - Antimuscarinics,
  - Continence products,
  - Indwelling catheter

Specialised management preferable for more "tailored" treatment

*At any stage of the patient’s care pathway, management may need to include continence products
**Some patients omit IC through personal choice or inability to self catheterise
VI. URINARY INCONTINENCE IN NEUROLOGICAL PATIENTS

B. SPECIALISED MANAGEMENT

I. ASSESSMENT

- Most patients with neurogenic urinary incontinence require specialised assessment: urodynamic studies should be used with videourodynamics if available when surgical interventions are planned or when the “bladder may be unsafe”.

- Upper tract imaging is needed in some patients and more detailed renal function studies will be desirable if the upper tract is considered in danger: high bladder pressure, upper urinary tract dilatation, recurrent or chronic upper tract infection, (major) stones, (major) reflux.

- In patients with peripheral lesions clinical neurophysiological testing may be helpful for better definition of the lesion.

II. TREATMENT

Also for specialised management conservative treatment is the mainstay (A). Management of neurogenic urinary incontinence has several therapeutic options. The algorithm details the recommended options for different types of neurological dysfunction of the lower urinary tract. The dysfunction does not necessarily correspond to one type/level of neurological lesion but must depend mostly on urodynamic findings. One should always ascertain that the management is urodynamically safe (low pressure, complete emptying). It is recommended to look at urinary and bowel function together if both systems are affected, as symptoms and treatment of one system can influence the other and vice versa (A).

As therapeutic approaches can differ in various neurological diseases, the most prevalent diseases are discussed separately in the chapter.

III. TREATMENT MODALITIES (often in combination)

- Conservative
  - Intermittent catheterisation (A)
  - Behavioural treatment(C)
  - Timed voiding (C)
  - Continence products (B)
  - Antimuscarinics(A)
  - Alpha 1 adrenergic blockers (C)
  - Intravesical electrical stimulation (C)
  - Bladder expression (B)
  - Triggered voiding (C)
  - Indwelling catheter (C)

- Surgical treatment
  - Artificial sphincter (A)
  - Bladder neck Sling (B)
  - Sub-urethral tapes (D)
  - Bulking agents (D)
  - Bladder neck closure (D)
  - Stents intravesical (B)
  - TUI sphincter (B)
  - Botulinum toxin for : sphincter(C) detrusor (A)
  - Sacral deafferentation (B)
  - Sacral anterior root stimulator (B)
  - Enterocystoplasty (B)
  - Autoaugmentation (D)
Specialised Management of Neurogenic Urinary Incontinence

**LEVEL AND EXTENT OF LESION, HISTORY AND CLINICAL ASSESSMENT**

- Peripheral nerve lesion (e.g. radical pelvic surgery)
- Conus cauda equina lesion (e.g. lumbar disc prolapse)
- Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)
- Suprapontine cerebral lesion (e.g. Parkinson’s disease, stroke, multiple sclerosis)

**SPECIALISED ASSESSMENT**

- Urodynamic testing (usually videourodynamics)
- Urinary tract imaging

**DIAGNOSIS**

- Stress UI due to sphincteric incompetence
- Incontinence associated with poor bladder emptying due to detrusor underactivity / sphincter overactivity
- UI due to detrusor overactivity

**CONSERVATIVE TREATMENT**

- Timed voiding
- Ext. appliances
- Artificial sphincter
- Bladder neck sling
- Antologous sling
- Bulking agents
- Bladder neck closure
- (Synthetic midurethral tapes)**

**SURGICAL TREATMENT**

- Stents intraurethral
- TUI sphincter
- Botulinum toxin to sphincter *
- Artificial sphincter
- Bladder neck sling
- Antologous sling
- Bulking agents
- Bladder neck closure
- (Synthetic midurethral tapes)**

**Stoma/diversion may be an option in selected cases**

*At any stage of the patient’s care pathway, management may need to include continence products
I. DEFINITION

Bladder Pain Syndrome in the absence of a universally agreed definition, the European Society for the Study of Interstitial Cystitis (ESSIC) definition is given along with the definition of the American Urological Association

- **ESSIC**: Chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent urge to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.

- **American Urological Association Guideline Definition**: An unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than 6 weeks duration, in the absence of infection or other identifiable causes.

II. BLADDER PAIN SYNDROME (BPS)

1. NOMENCLATURE

The scientific committee of the International Consultation voted to use the term “bladder pain syndrome” for the disorder that has been commonly referred to as interstitial cystitis (IC). The term painful bladder syndrome was dropped from the lexicon. The term IC implies an inflammation within the wall of the urinary bladder, involving gaps or spaces in the bladder tissue. This does not accurately describe the majority of patients with this syndrome. Painful Bladder Syndrome, as defined by the International Continence Society, is too restrictive for the clinical syndrome.

Properly defined, the term Bladder Pain Syndrome appears to fit in well with the taxonomy of the International Association for the Study of Pain (IASP) (see below), and focuses on the actual symptom complex rather than what appears to be long-held misconception of the underlying pathology.

Bladder Pain Syndrome

Bladder pain syndrome is the occurrence of persistent or recurrent pain perceived in the urinary bladder region, accompanied by at least one other symptom, such as pain worsening with bladder filling and day-time and/or night-time urinary frequency. There is no proven infection or other obvious local pathology. Bladder pain syndrome is often associated with negative cognitive, behavioural, sexual, or emotional consequences as well as with symptoms suggestive of lower urinary tract and sexual dysfunction.

2. HISTORY / INITIAL ASSESSMENT

Males or females whose symptoms meet the requirements of the definition of bladder pain syndrome should be evaluated. The presence of commonly associated disorders including irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia in the presence of the cardinal symptoms of bladder pain syndrome also suggests the diagnosis. Abnormal gynecological findings in women and well-characterized confusable diseases that may explain the symptoms must be ruled out.

The initial assessment consists of a frequency/volume chart, focused physical examination, urinalysis, and urine culture. Urine cytology, cystoscopy, and urodynamic evaluation are recommended if clinically indicated and/or the diagnosis is in doubt. Patients with urinary infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and microscopic or gross haematuria are evaluated with appropriate imaging and endoscopic procedures, and only if findings are unable to explain the symptoms, are they diagnosed with BPS.

Grade of recommendation: C
3. INITIAL TREATMENT

- patient education,
- dietary manipulation,
- non-prescription analgesics,
- stress reduction,
- pelvic floor muscle relaxation techniques comprise the initial treatment of BPS. In the patient with findings suggesting pelvic floor dysfunction, pelvic floor muscle physical therapy with myofascial trigger point release and intravaginal Thiele massage is often an effective therapeutic intervention.

The treatment of pain needs to be addressed directly, and in some instances referral to an anaesthesia/pain centre can be an appropriate early step in conjunction with ongoing treatment of the syndrome.

Treatment should be focused on the most bothersome or distressing symptom(s).

⇒ When conservative therapy fails or symptoms are severe and conservative management is unlikely to succeed,
- oral medication, or
- intravesical treatment can be prescribed.

It is recommended to initiate a single form of therapy and observe results, adding other modalities or substituting other modalities as indicated by degree of response or lack of response to treatment. Grade of recommendation: C

4. SECONDARY ASSESSMENT

⇒ If initial oral or intravesical therapy fails, or before beginning such therapy based on clinician judgment, it is reasonable to consider further evaluation which can include urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anaesthesia.

Findings of detrusor overactivity suggest a trial of antimuscarinic therapy.

The presence of a Hunner’s lesion suggests therapy with transurethral resection, fulguration of the lesion, or direct steroid injection into the lesion. Distention itself can have therapeutic benefit in 30-50% of patients, though benefits rarely persist for longer than a few months. Grade of recommendation: C

5. REFRACTORY BPS

⇒ Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive modalities. Many of these are best administered within the context of a clinical trial if possible. These may include neuromodulation, intradetrusor botulinum toxin, oral cyclosporine A, or clinical trials of newly described pharmacologic management techniques. At this point, most patients will benefit from the expertise of an anaesthesia pain clinic.

⇒ The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urinary stream.

- Urinary diversion with or without cystectomy has been used as a last resort with good results in selected patients.
- Augmentation or substitution cystoplasty seems less effective and more prone to recurrence of chronic pain in small reported series. Grade of recommendation: C
Bladder Pain Syndrome

SYMPTOMS

Pain, pressure, or discomfort perceived to be related to the bladder with at least one other urinary symptom (e.g., frequency, nocturia)

BASIC ASSESSMENT

History Symptom tools.
Frequency/volume chart
Focused physical examination
Assess pelvic floor muscle function
Urinalysis, culture

“Simple BPS” conservative management
- Stress reduction
- Patient education
- Dietary manipulation
- Non-prescription analgesics
- Pelvic floor muscle relaxation

Urinary infection

“Complicated BPS”

Incontinence
Urinary infection
Haematuria
Gynaecologic signs/symptoms

Consider:
Urine cytology
Further imaging
Endoscopy
Urodynamics
Laparoscopy

 Treat other conditions as indicated

1st LINE RX

Pain management is a primary consideration at every step of algorithm
Patient enrollment in appropriate research trial is reasonable option at any point
Evidence supporting neuromodulation, cyclosporin A, and botulinum toxin for BPS indication is limited. These interventions are appropriate only for practitioners with experience treating BPS and willing to provide long-term care post-intervention

BPS requiring more active intervention

2nd line treatment (no hierarchy implied)

Consider, if not done previously:
Cystoscopy under anaesthesia with bladder hydrodistension
Fulguration, resection or steroid injection of Hunner’s lesion

Improved with acceptable quality of life:
Follow and support

3rd line treatment

4th line treatment (no hierarchy implied)

Neuromodulation
Bladder botulinum toxin
Cyclosporin A

NOTE the only FDA approved therapies are DMSO and pentosan polysulfate

5th line treatment

Consider:
Diversion with or without cystectomy
Substitution cystoplasty

1932
Patients with faecal incontinence present with a variety of symptom complexes. As many people are reluctant to admit to having faecal incontinence, it is important to proactively enquire about it, especially in known high risk groups (such as older community-living individuals, post partum women who might have had an obstetric injury, and patients with loose stools).

- **History** will include bowel symptoms including loose stools, severity and types of incontinence, systemic disorders, neurological disorders, and anorectal surgeries (e.g., haemorrhoidectomy), obstetrical history for women, medications, diet, chronic straining, cognitive status, and effects of symptoms on quality of life.

- **Types of incontinence:** urgency faecal incontinence, often a symptom of external anal sphincter dysfunction; *flatus incontinence* (leakage of rectal gas) may indicate rectal sensory impairment and/or internal anal sphincter dysfunction; and *soiling after defaecation*, typically related to a defect in the internal sphincter or poor closure of external sphincter due to rectal prolapse or stage III/IV haemorrhoids.

- **Physical examination** will include anal inspection, abdominal palpitation, a brief neurological examination, digital rectal examination and usually proctosigmoidoscopy or colonoscopy.

- **Further diagnostic testing** needs to be considered if the patient has symptoms such as an unexplained change in bowel habit, weight loss, anaemia, rectal bleeding, severe or nocturnal diarrhoea, or an abdominal or pelvic mass and bowel pathology when organic conditions such as cancer, inflammatory bowel disease (IBD), a recto-vaginal fistula, full thickness rectal prolapse, or cloacal deformity are suspected. **Condition specific management** is indicated for these patients.

Reversible factors (such as inadequate access to toilets and side effects of medications resulting in loose stools) should be assessed and addressed at the outset.

**II. INITIAL INTERVENTIONS**

- Initial management can often be performed in primary care. After environmental factors and local or systemic pathology have been excluded, **initial interventions include**:
  - Discussion of **options** and **goals** of management with the patient
  - Provision of patient or caregiver **information** and **education** (Grade A)
  - Adjustment of **diet** and fluid advice, **fibre** intake (Grade A)
  - Establishing a **regular bowel habit** (Grade C) or **urgency training** if relevant (Grade C)
  - **Anti-diarrhoeal** medication can help if stools are loose (Grade B)
  - **Rectal Irrigation** to achieve complete rectal evacuation of faeces (Grade B)
  - Use of **continence products** including various types and sizes of absorbent pads, briefs, etc., to contain leaked faeces and prevent skin damage
III. SECONDARY INTERVENTIONS

- If initial interventions fail to improve symptoms after 8-12 weeks, consideration should be given to referral to an **incontinence specialist** (e.g., gastroenterologist, continence nurse, advisor physiotherapist, or colorectal surgeon) for other interventions or further assessment.

- **Pelvic floor muscle training (PFMT)** – contraction of pelvic floor muscles multiple times per day to improve strength of contraction and increase awareness of anorectal muscle function. (Grade C)

- **Biofeedback therapy** – behavioural treatment designed to enhance the strength of sphincter contraction and improve rectal sensation using specialised equipment. Biofeedback therapy can be combined with PFMT to improve strength. (Grade B)

IV. SECONDARY ASSESSMENT

- A variety of anorectal investigations, including manometry, anal ultrasound, and possibly MRI, defaecography, and neuro-physiological testing can help to define structural or functional abnormalities of anorectal function and guide management if initial and/or secondary interventions are ineffective

V. TERTIARY REFERRAL, SURGICAL OR MULTI-DISCIPLINARY CONSULTATION

- **Faecal** incontinence that fails to respond to initial and secondary management requires specialised consultation by a gastroenterologist, colorectal surgeon, urogynaecologist, and/or a multi-disciplinary team.

RESEARCH RECOMMENDATIONS

- Data should be collected on faecal incontinence whenever practical as part of research on urinary incontinence.

- Development of techniques for diagnosing FI and its severity using new and available technologies

- Well designed and adequately powered studies are needed to evaluate all treatment modalities currently available including
  - Effectiveness of lifestyle modifications including weight loss, exercise, modifying diet and eating pattern and supplementing dietary fibre as primary and adjuvant management strategies
  - Comparative effectiveness trial comparing instrumented biofeedback training to neuromodulation for the treatment of FI
  - Effectiveness of tibial nerve stimulation

- Studies are needed to develop interventions for supporting coping and self-management of faecal incontinence, odour, and urgency and increasing care seeking
INITIAL MANAGEMENT OF FECAL INCONTINENCE

**Initial Clinical Assessment**
- History
- Physical exam
- Medication and diet review
- Assessment of impact on quality of life
- Proctosigmoidoscopy and/or colonoscopy

**Address Reversible Factors**
- Toilet access, medication side effects, loose stools, etc.

**Initial Interventions**
- Discussion of options, goals of management
- Education of patient and/or caregiver
- Diet and eating pattern modifications, dietary fibre supplements
- Medications (loperamide)
- Bowel habit training
- Rectal irrigation
- Continence products such as pads for containment
- Active case finding or patient presents with faecal incontinence

**Secondary Interventions**
- PFMT +/-
- Biofeedback
- Continence products such as an anal plug

**Secondary Assessment**
- Manometry and/or Ultrasound
- Possible additional tests
  - MRI
  - Defaecography
  - Neuro-physiology testing, etc.

**Continence Specialist**
- Tertiary referral, surgical and/or multi-discipline consult

**Condition Specific Assessment and Management**
For cancer, IBD, impaction, full thickness rectal prolapse, recto-vaginal fistula, cloacal deformity

**Active case finding or patient presents with faecal incontinence**
The reader is referred to the relevant sections on “Dynamic Testing” and “Conservative Treatment for Faecal Incontinence.” In general, patients referred for surgical management of faecal incontinence must either have failed conservative therapy or not be candidates for conservative therapy due to severe anatomic or neurological dysfunction.

Prior to surgical management of faecal incontinence, the integrity of the anal sphincter complex should be assessed. This assessment is best performed with endoanal ultrasound, though pelvic MRI may also be useful. Ancillary tests include anal manometry, electromyography, and defaecography.

- Patients with rectal prolapse, rectovaginal fistulae, and cloacae often have associated faecal incontinence. Initial therapy should be directed at correction of the anatomic abnormality (in the case of rectovaginal fistula or cloaca, this surgical repair may include overlapping sphincteroplasty.) If the patient has persisting faecal incontinence, she should undergo repeat assessment, including especially endoanal ultrasound.

### II. SPECIALISED MANAGEMENT

The surgical approach to the incontinent patient is influenced by the presence and magnitude of an anatomic sphincter defect. If no defect is present, or if the sphincter defect is minimal, options include SNS and injection therapy.

- For patients with moderate sphincter defects, sphincteroplasty, SNS or injection therapy can each be considered. For patients with large sphincter defects (>120 degrees), sphincteroplasty is likely the best option, though a PNE trial for SNS can be considered.

- Patients with sphincter defects of greater than 180° or major perineal tissue loss require individualised treatment. In some cases, initial reconstruction can be performed. Should incontinence persist, alternatives include stimulated muscle transposition, artificial anal sphincter implantation, or sacral nerve stimulation.

### III. SALVAGE MANAGEMENT

For patients who remain incontinent following sphincteroplasty, repeat endoanal ultrasound should be undertaken to reassess the status of the repair. If no defect is present, or if the sphincter defect is minimal (<30 degrees), options include SNS and injection therapy. If there is a large persisting sphincter defect, repeat sphincteroplasty can be considered.

Patients who have failed sacral nerve stimulation can be considered for injection therapy or sphincteroplasty if a sphincter defect is present. Other alternatives include stimulated graciloplasty and implantation of an artificial anal sphincter.

Patients who fail surgical therapy for faecal incontinence, or who do not wish to undergo extensive pelvic reconstruction, should consider placement of an end sigmoid colostomy. While this procedure does not restore continence, it does restore substantial bowel control and appears to improve social function and quality of life. Novel therapies can also be considered under protocol: PTNS, the magnetic anal sphincter and sling procedures.

### IV. SPECIAL SITUATIONS

Individuals with severe spinal cord dysfunction (due, e.g., to injury or congenital abnormality) should be considered for an Antegrade Continence Enema (ACE) procedure or colostomy.

---

*At any stage of the patient’s care pathway, management may need to include continence products*
Patients with known neurological disease may present with symptoms related to neurologic bowel dysfunction – difficulty in defaecation, constipation and faecal incontinence which disturb their activities of daily living and quality of life. Many have permanent impairments and functional limitations and disabilities, which are due to neurological deficits and complications.

**I. INITIAL ASSESSMENT**

- **History taking:** this includes
  - Neurological diagnosis and functional level
  - Previous and present lower gastrointestinal (LGIT) function and disorders
  - Severity of neurogenic bowel dysfunction
  - Current bowel care and management including diet, fluid intake, medications affecting bowel functions
  - Co-morbidity / complication e.g., urinary incontinence, autonomic dysreflexia, pressure ulcers, sexual dysfunction
  - Patient's satisfaction, needs, restrictions and quality of life
  - Environmental factors and barriers and facilitators to independent bowel management.

- **Physical examination:**
  - Cognitive functions; motor, sensory and sacral reflexes – voluntary anal sphincter contraction, deep perianal sensation, anal tone, anal and bulbocavernous reflexes
  - Spasticity of the lower limbs
  - Abdominal palpation for faecal loading and rectal examination

**FUNCTIONAL ASSESSMENT:**
- hand and arm use, fine hand use, mobility – maintaining body position, transfer and walking ability.

**ENVIRONMENTAL FACTORS ASSESSMENT:**
- toilet accessibility; devices for bowel care and mobility; caregivers’ support and attitude;

**II. BASIC INVESTIGATIONS:**

- Stool exam, plain abdomen XRay

**III. INITIAL TREATMENTS**

- **Patient education and goals-setting** - complete defaecation on a regular basis and faecal continence based on right time, right place, right trigger and right consistency
- **Adequate fibre diet and fluid intake;** appropriate trigger according to preservation of sacral (anorectal) reflex – digital rectal stimulation; suppository and enema; if no anorectal reflex, manual evacuation; abdominal massage can also be helpful
- **Prescribe medications** – stool softener, laxative, prokinetic agents, anti-diarrhoea drugs as necessary
- Assistive techniques may be necessary for
  - defaecation – irrigation
  - for incontinence – anal plug

The diagram does not apply to management in acute neurological patients that need regular bowel emptying.
**Initial Management of Neurogenic Faecal Incontinence**

**History, level of lesion**
- Sacral cord/cauda equina lesion (e.g. lumbar disc prolapse). Peripheral nerve lesion (e.g. radical pelvic surgery)
- Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)
- Suprapontine lesions (e.g. Parkinson)

**Clinical Assessment**
- History taking including diagnosis, pre-morbid bowel function and sensation and their disorders, current bowel and bladder programme, co-morbid diseases/disorders, QOL and needs
- Physical & neurological examination including cognitive function, voluntary anal contraction, sensation, sacral reflexes, digital rectal examination, abdominal palpation for faecal impaction
- Functional assessment including hand and arm use, fine hand use, balance, transfer and walking
- Environmental factors assessment including toilet accessibility, assistive device, caregivers' support and attitude
- Basic investigation: stool exam, plain film abdomen in selected patients (diarrhoea, impaction not felt on rectal examination)

This assessment will give basic information but does not permit a precise diagnosis of neurogenic bowel dysfunction

**Presumed Diagnosis**
- Incontinence due to sphincter incompetence
- Incontinence due to lack of cognitive function, sensory awareness disorders, unable to control by voluntary anal contraction
- "False incontinence" due to faecal impaction

**Treatment**
- Manual evacuation: Assistive device – anal plug, mini-enema, transanal/transrectal irrigation
- Digital rectal stimulation: Chemical stimulant: suppository, mini-enema, stool softener, laxative; given by patient/caregiver
- Faecal disimpaction incl. enemas and transanal/transrectal irrigation

Patient education, adequate fibre diet and fluid intake; regular bowel care, preferably ± 3 times a week

Specialised management preferable for more "tailored" treatment

* At any stage of the patient's care pathway, management may need to include continence products
Some patients with neurogenic faecal incontinence will need specialised assessment, especially if initial management is unsuccessful to look for comorbidity and certainly before performing invasive treatment.

Do not assume that all symptoms are due to neuropathy, e.g. women with neurological pathology might have had childbirth injury to the sphincter.

Special investigations: manometry, endoanal ultrasound, (dynamic) MRI, (needle) EMG. These specific bowel functional tests and electro-diagnostic tests must be considered optional as their value in neurological pathology is not sufficiently demonstrated so far.

Management of neurological incontinence does not include very extensive treatment modalities and many conservative interventions are still empirical.

Also for specialised management, conservative treatment for neurological faecal incontinence is the mainstay.

Transanal irrigation (C)

Electrical stimulation sphincter, (C)

Percutaneous neuromodulation: further research is required

Surgical management of neurogenic faecal incontinence has different options which need a very strict patient selection.

Antegrade Continence Enema ACE (C)

Graciloplasty (C)

Artificial sphincter (C)

Sacral Anterior Root Stimulation SARS (C)

Botulinum Toxin (C)

Neuromodulation (C)

It is recommended to look at urinary and bowel function together if both systems are affected, as symptoms and treatment of one system can influence the other and vice versa (A).

As therapeutic approach can differ in different neurological diseases, the most prevalent diseases are discussed separately in the chapter.
Specialised Management of Neurogenic Faecal Incontinence *

Primary assessment, history, level and extent of lesion, clinical assessment

- Sacral cord/cauda equina lesion (e.g. lumbar disc prolapse). Peripheral nerve lesion (e.g. radical pelvic surgery)
- Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)
- Suprapontine lesions (e.g. Parkinson)

SPECIALISED ASSESSMENT

- Functional bowel testing / functional imaging
- Consider neurophysiological testing and anorectal manometry.

DIAGNOSIS

Faecal Incontinence through loss of bowel sensation, sphincter deficiency or severe rectal prolapse

Faecal impaction

Faecal disimpaction

CONSERVATIVE TREATMENT

- Transanal irrigation
- Electrical stimulation of sphincter,
- Percutaneous neuromodulation : further studies

Failure consider

SURGICAL TREATMENT

- ACE
- Graciloplasty
- Artificial anal sphincter
- SARS
- Botulinum Toxin for anal sphincter spasticity
- Neuromodulation

Failure consider

ACE = Antegrade Continence Enema
SARS = Sacral Anterior Root Stimulation

Stoma/diversion may be an option in selected cases

* At any stage of the patient’s care pathway, management may need to include continence products
There is no reason to suspect why interventions which have proven efficacy in the community dwelling elderly should not also be effective in frail older people. Clinicians should, however, take due regard of the practicality, potential benefits and dangers of employing any single intervention in this population. Frail older people do require a different approach addressing the potential role of co-morbid disease, current medications (prescribed, over the counter and/or naturopathic), and functional and cognitive impairment in urinary and faecal incontinence. The extent of the investigation and management should take into account the degree of bother to the older person and/or caregiver, the goals for care, the degree that the older person is able to undertake any intervention and the overall prognosis and life expectancy. Effective management to meet the goals of care should be possible for most frail older people.

**I. HISTORY AND SYMPTOM ASSESSMENT**

- Active case finding for urinary and faecal incontinence should be done in all frail older people (Grade A). History should include comorbid conditions and medications that could cause or worsen incontinence. Physical examination should include a rectal examination for faecal loading or impaction (Grade C), functional assessment (mobility, transfers, manual dexterity, dressing and undressing ability, ability to toilet) (Grade A), a screening test for depression (Grade B), and cognitive assessment (to assist in planning and management, (Grade C)). The mnemonic DIPPERs (see urinary and faecal incontinence algorithms) covers some of these comorbid conditions. Note that urogenital atrophy does not, in itself, cause urinary incontinence and should not be treated for this purpose (Grade B). The patient and / or caregiver should be asked about the degree of bother of urinary incontinence and/or faecal incontinence (Grade B); goals for urinary and faecal incontinence care (dryness, decrease in specific symptoms, quality of life, reduction of comorbidity, lesser care burden) (Grade B); and likely cooperation with management (Grade C).

- Evaluation for bowel “alarm” symptoms (rectal bleeding, positive blood screening from stool studies, obstructive symptoms, recent onset of constipation, weight loss, and a change in stool calibre) will need more extensive evaluation (Grade A).

- Urinalysis is recommended for all patients, primarily to screen for haematuria (Grade C). Treatment of otherwise asymptomatic bacteriuria/pyuria is not beneficial (Grade C), and it may cause harm by increasing the risk of antibiotic resistance and severe adverse effects. e.g., *Clostridium difficile colitis* (Grade C).

- Stool studies may not be needed in all patients with faecal incontinence. Patients with diarrhoea, especially those with more acute onset diarrhoea, may need to be tested for infectious causes of their diarrhoea. Other stool studies could involve testing for malabsorption syndromes.

- The utility of the Clinical Stress test in this population is uncertain (Grade D).

- Wet checks can assess urinary incontinence frequency in long-term care residents (Grade C):

  A post voiding residual volume (PVR) test is impractical in many care settings and there is no consensus for the definition of what constitutes a “high” PVR in any population. A PVR measurement is not recommended in the routine initial assessment of frail older people with urinary incontinence.

- However, there is compelling clinical experiential evidence for PVR testing in selected frail older people with: diabetes mellitus (especially long standing); prior urinary retention or high PVR; recurrent UTIs; medications that impair bladder emptying (e.g., opiates); severe constipation; persistent or worsening urgency urinary incontinence despite antimuscarinic treatment; or prior urodynamics showing detrusor underactivity and/or bladder outlet obstruction (Grade C). Treatment of contributing comorbidity may reduce PVR. Trial with catheter may be considered for PVR > 200-500 ml if the PVR is felt to contribute to UI or urinary frequency (Grade C).

- **Nocturia** Assessment of frail elders with bothersome nocturia should identify potential underlying causes including nocturnal polyuria (by bladder diary/frequency-volume chart or wet checks; oedema on examination) (Grade C), primary sleep problems (e.g., sleep apnoea); and low voided volumes (e.g., from high PVR).

- Stool impaction/loading. If suspected on digital rectal examination, an abdominal x-ray may be necessary to further evaluate the degree and location of impaction/loading in frail older adults.
II. CLINICAL DIAGNOSIS

The most common types of Urinary Incontinence in frail older people are urgency, stress, and mixed urinary incontinence. Frail older people with urgency urinary incontinence also may have detrusor underactivity and high PVR (without outlet obstruction). There is no evidence that antimuscarinics are less effective or cause retention in this situation (Grade D).

The most common types of faecal incontinence in frail older people are related to urgency and passive leakage. Passive leakage can refer to leakage, seepage and staining following bowel movements that are not associated with faecal urgency and may also occur with faecal impaction. Because constipation and impaction often contribute to faecal incontinence in older adults, these are considered separately in the algorithm.

III. INITIAL MANAGEMENT

- Initial treatment should be individualised and influenced by goals of care, treatment preferences and estimated remaining life expectancy, as well as the most likely clinical diagnosis (Grade C). In some frail older persons the only possible outcome may be containment; management with continence products, especially for people with minimal mobility (require assistance of >2 people to transfer), advanced dementia (unable to state their name), and/or nocturnal urinary and faecal incontinence.
- Conservative and behavioural therapy for UI includes lifestyle changes (Grade C), bladder training for more fit alert persons (Grade B), and prompted voiding for frailer, more impaired older people (Grade A).
- For the select cognitively intact older person with UI or FI, pelvic floor muscle therapy can be considered, but there are few studies (Grade C). Antimuscarinics may be added to conservative therapy of urgency UI (Grade A-C, depending on agent).
- For the select cognitively intact older with FI, biofeedback may be considered, but few studies exist among frail older adults.
- Alpha-blockers may be cautiously considered in frail men with suspected prostatic outlet obstruction (Grade C). All drugs should be started at the lowest dose and titrated with regular review until either care goals are met or adverse effects are intolerable.
- DDAVP (vasopressin) has a high risk of severe hyponatraemia in frail older persons and should not be used outside specialist centres (Grade A).

- Improving stool consistency can be done with dietary fibre and supplementary fibre in older adults (Grade C). In older adults with diarrhoea, loperamide may be considered at low doses to improve stool consistency. However, close monitoring for constipation and impaction is needed.

IV. ONGOING MANAGEMENT AND REASSESSMENT

Optimal urinary and faecal incontinence management is usually possible with the above approaches. If initial management fails to achieve the desired goals the next steps are reassessment and treatment of contributing comorbidity and/or functional impairment.

V. SPECIALISED MANAGEMENT

If frail older people have either other significant factors (e.g., pain, haematuria, bowel “alarm” symptoms), UI or FI symptoms that cannot be classified as urgency, stress, or mixed or overflow or other complicated comorbidity which the primary clinician cannot address (e.g., dementia, functional impairment), then specialist referral should be considered. Referral may also be appropriate when there is been insufficient response to initial management. The type of specialist will depend on local resources and the reason for referral: surgical specialists (urologists, gynaecologists, colorectal surgeons), gastroenterologists, geriatricians or physical therapist (functional and cognitive impairment); or continence nurse specialists (homebound patients). Referral decisions should consider goals of care, patient/caregiver desire for invasive therapy and estimated remaining life expectancy.

Age per se is not a contraindication to UI or FI surgery (Grade C), but before surgery is considered, all patients should have:

- evaluation and treatment for any comorbidity, medications, and cognitive or functional impairments contributing to UI that could compromise surgical outcome (e.g., dementia that precludes patient ability to use artificial sphincter) (Grade C)
- adequate trial of conservative therapy, including pharmacological therapies where relevant (Grade C)
- discussion (including the caregiver) to ensure that the anticipated surgical outcome is consistent with goals of care in the context of the patient’s remaining life expectancy (Grade C)
- urodynamic testing or anorectal manometry, because clinical diagnosis may be inaccurate (Grade B)
- preoperative assessment and perioperative care to establish risk for and to minimize common geriatric post-operative complications such as delirium and infection (Grade A), dehydration and falls (Grade C).
Management of Urinary Incontinence in Frail Older Men & Women

**HISTORY/SYMPTOM ASSESSMENT**
- Active Case Finding in all Frail Elderly people

**CLINICAL ASSESSMENT**
- Delirium
- Infection
- Pharmaceuticals
- Psychological
- Excess urine output
- Reduced mobility
- Stool impaction (and their factors)
- Avoid overtreatment of asymptomatic bacteriuria

**CLINICAL DIAGNOSIS**
- * These diagnoses may overlap in various combinations, e.g., Mixed UI, DHIC (see text)

**INITIAL MANAGEMENT** *
- (if Mixed UI, initially treat most bothersome symptoms)

**ONGOING REASSESSMENT and MANAGEMENT**

**URGENCY UI**
- Lifestyle interventions
- Behavioural therapies
- Consider trial of antimuscarinic drugs

**SIGNIFICANT PVR**
- Treat constipation
- Review medications
- Consider trial of alpha-blocker (men)
- Catheter drainage if PVR 200-500 ml, then reassess (see text)

**STRESS UI**
- Lifestyle interventions
- Behavioural therapies (See text)

If insufficient improvement, reassess for and treat contributing comorbidity ± functional impairment

If continued insufficient improvement, or severe associated symptoms are present, consider specialist referral as appropriate per patient preferences and comorbidity (see text)

**UI associated with:**
- Pain
- Haematuria
- Recurrent symptomatic UTI
- Pelvic mass
- Pelvic irradiation
- Pelvic / LUT surgery
- Prolapse beyond introitus (women)
- Suspected fistula

* Other

* At any stage of the patient’s care pathway, management may need to include continence products
Management of Faecal Incontinence in Frail Older Men & Women

**HISTORY/SYMPTOM ASSESSMENT**

- Assess, treat and reassess potentially treatable conditions, including relevant comorbidities and ADLs (see text)
- Assess QoL, desire for Rx, goals for Rx, pt & caregiver preferences
- Targeted physical examination (cognition, mobility, neurological and digital rectal examination)
- Urinalysis
- Consider bowel diary and clean checks, especially if nocturia is present. PVR is specific patients (see text)

**CLINICAL ASSESSMENT**

Rx reversible causes:
- Delirium
- Infection
- Pharmaceuticals
- Psychological
- Excess stool output (diarrhoea)
- Reduced mobility
- Stool impaction (and their factors)

**CLINICAL DIAGNOSIS**

**Urgency FI**
- Lifestyle interventions
- Behavioural therapies
- Biofeedback
- Improve stool consistency

**Constipation/Faecal Impaction**
- Treat constipation (osmotic laxatives) if impacted, Glycerine or Bisacodyl suppositories. Phosphate enemas if severe.
- Review medications that may contribute to constipation
- Consider biofeedback if dyssynergic defaecation is suspected

**Passive FI**
- Lifestyle interventions
- Behavioural therapies
- Biofeedback
- Improve stool consistency

If insufficient improvement, reassess for and treatment of contributing comorbidity ± functional impairment

If continued insufficient improvement, or severe associated symptoms are present, consider specialist referral as appropriate per patient preferences and comorbidity (see text)

* At any stage of the patient’s care pathway, management may need to include continence products
4. Recommendations for Further Research in Epidemiology

1. Longitudinal study designs are needed to: (i) estimate the incidence and remission rates of urinary incontinence (UI) anal incontinence (AI) and pelvic organ prolapse (POP) and to (ii) describe the natural course of these conditions and (iii) to investigate risk factors and possible protective factors. In addition similar studies regarding other lower urinary tract symptoms (LUTS) should be initiated.

2. Although there is today more information regarding prevalence, incidence, and other epidemiological data in developing countries further information is still needed. It is recommended that fundamental research regarding prevalence, incidence and other epidemiological data in developing countries should be encouraged, and tailored to the cultural, economic and social environment of the population under study.

3. Some potential risk and protective factors deserve more attention. For example, the role of pregnancy and childbirth in the development of UI, AI and POP must be studied in a fashion that links population-based methods to clinical assessment of pregnancy, delivery and birth trauma and follows women over many years. Such a design is necessary because the effect of pregnancy and childbirth may become clear only years later when the woman is older and because the woman will not then be able to report the exact nature of the tear, episiotomy, etc.

4. There should be more emphasis on the associations between UI, AI and POP and specific diseases like stroke, diabetes, and psychiatric diseases.

5. The variation of disease occurrence in groups of different racial origin yet similar environmental exposures, lend support to the presumed genetic influence on the causation of UI, AI and POP. This again provides circumstantial evidence for a genetic contribution to pelvic floor muscle disorders since most of these studies have been unable to control for heritability in relation to the complex interaction of environmental factors.

The aetiology of UI, AI and POP is widely recognised to be multifactorial, yet the complex interaction between genetic predisposition and environmental influences is poorly understood. Genetic components require further investigation. Twin studies provide a possible means of studying the relative importance of genetic predisposition and environmental factors. By comparing monozygotic female twins with identical genotype, and dizygotic female twins who on average share 50 percent of their segregating genes, the relative proportions of phenotypic variance resulting from genetic and environmental factors can be estimated. A genetic influence is suggested if monzygotic twins are more concordant for the disease than dizygotic twins whereas evidence for environmental effects comes from monozygotic twins who are discordant for the disease.

5. Recommendations for Further Basic Science Research

1. Integrate data from reductionist experiments to inform the formulation of better systems-based approaches in the investigation of the pathology of the lower urinary tract (LUT), the genital tract (GT) and the gastro-intestinal tract (GIT).

2. Encourage greater emphasis on basic research to characterise tissues receiving relatively little attention: ie the lower gastrointestinal tract; the bladder neck and urethra.

3. Generate improved experimental approaches to investigate the pathophysiology of the LUT and GIT by:
   • developing fully-characterised animal models
   • using human tissue from well-characterised patient groups.
   • developing emerging areas such as: tissue engineering; protein structure modelling

4. Use genome-wide bioinformatic surveys to generate testable hypotheses regarding the physiological and pathophysiological functions of the LUT and GIT

5. Develop centres of excellence in LUT and GIT research
   • integrate expertise from university departments, academic medical units and industry
   • encourage translational approaches to research.
   • develop inter-institutional research-training programmes to allow new researchers the opportunity to better interact and exchange ideas
6. Recommendations

Continence Promotion, Education and Primary Prevention

Continence promotion, service delivery, education, and primary prevention involves informing and educating the public and health care professionals that urinary and faecal incontinence are not inevitable, but are treatable or at least manageable. In addition, other bladder disorders such as bladder pain syndrome and pelvic organ prolapse can be treated successfully. Progress continues to be made in the promotion of continence awareness through advocacy programmes and public access to information on a worldwide basis. Professional education of these conditions has increased. However, screening and help-seeking behaviour have not noticeably improved. Published studies focus on developing better models of existing service provision and education, rather than testing new strategies to increase screening. There have been advances in primary prevention of urinary incontinence.

CONTINENCE AWARENESS AND PROMOTION

- Continence awareness should be part of mainstream and on-going health education and advocacy programmes with emphasis on eliminating stigma, raising awareness of effective treatments, promoting help-seeking behaviour and improving QoL.
- Continence awareness programmes should include education, health-care, and community service providers.
- Research is needed to provide higher level of evidence on the effectiveness of continence promotion programmes to include:
  - Identification and understanding of barriers to help-seeking behaviours
  - Translation of promotion research into improved clinical practice and identification of methods by which this occurs.
  - Effectiveness and impact of consumer education initiatives.

CONTINENCE ADVOCACY AND MODELS OF SERVICE DELIVERY

- There is a need to move beyond the theory and work on research about the practice of continence care delivery and education. We recommend a care delivery model based on a chronic disease approach.
- There needs to be an increased emphasis on non-physician models of care (nursing, nurse practitioner, continence advisor, physiotherapy, physician assistants, etc.).
- Despite the proliferation of guidelines, there is increasing evidence that they are not being followed by practicing clinicians. Implementation models should be developed on how to translate guidelines into practice.
- There still appears to be a shortage of physician specialists in continence care (urology, gynaecology, etc.) and this needs to be addressed. (Grade D)
- Research is needed on the activities or effectiveness of organisations that target consumers or the general public.
PROFESSIONAL EDUCATION

• There remains a need for rigorously evaluated continence education programmes which adhere to defined minimum standards for continence specialists and generalists, utilising web-based and distance learning techniques alongside audit and feedback, train-the trainer models and leadership models as well as traditional methods.

• Models of education content delivery (professional and patient education) are changing with technology with increased emphasis on internet, web modules, etc. There needs to be ongoing quality control that includes maintenance of accuracy, methods of delivery, etc.

• There is a need for research on the most effective means to educate professional groups on continence issues to include:

○ The effectiveness of innovative teaching methods in improving knowledge and practice.

○ Translation of research into improved clinical practice and identification of methods by which this happens.

○ Mechanisms for increasing professional motivation to acquire education and improve performance.

PRIMARY PREVENTION:

• Primary prevention studies should not be limited to individual interventions, but also test the impact of population-based public health strategies (Grade C)

• More high quality randomised controlled trials are needed to strengthen the effectiveness of population-based primary prevention intervention.

7. Recommendations for Clinical Research Methodology

PART I: RECOMMENDATIONS ON STUDY CONDUCT AND STATISTICAL METHODS

The role of quality RCTs as providing the strongest level of evidence in incontinence research should be fully acknowledged by researchers, journal reviewers, and editors. HIGH

Careful attention to the planning and design of all research, especially RCTs, is of the utmost importance. HIGH

Appropriate expertise in biostatistics and clinical trial design should be employed at the design phase of a RCT and thereafter on an ongoing basis. HIGH

The design, conduct, analysis and presentation of RCTs must be fully in accordance with the CONSORT Statement. HIGH

The design, conduct, analysis and presentation of observational studies should follow STROBE guidelines. HIGH

The design, conduct, analysis and presentation of meta-analyses should follow QUORUM guidelines. HIGH

Reporting studies of diagnostic tests, including urodynamics, should follow the STARD statement guidelines. HIGH

PART II: RECOMMENDATIONS ON RESEARCH CONDUCT

RECOMMENDATIONS FOR CONSERVATIVE TREATMENT TRIALS

Use correct terminology to describe the intervention. HIGH

Report details of ability to perform correct contraction, dose-response issues and adherence. HIGH

Use recommended outcome measures with high responsiveness, reliability and validity. HIGH

Compare new methods with the best available intervention. HIGH

Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions. HIGH

For long-term follow-up studies report cross-over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up.

1948
• The safety and serious side effects of new operations must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicenter cohort studies when RCTs are not practical. HIGH

• Safety and serious side effects of incontinence devices must be completely defined with adequate follow-up, especially for use of implantable devices and biologic materials, so that risks can be weighed against efficacy. HIGH

• Valid informed research consent is required in all trials of surgical interventions, which is separate from the consent to surgery. HIGH

• We recommend ongoing research into the usefulness of pre- and post-operative predictive testing (such as urodynamics, ultrasound, MRI, etc) in surgical trials. HIGH

• Reports of successful treatment should be limited to subjects with a minimum (not mean) of one year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated. HIGH

• Randomisation for surgical trials should occur at the time of surgery to minimize drop-outs and switch of procedure. HIGH

• Long-term follow-up of RCT cohorts in an observational cohort is recommended. HIGH

• Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. HIGH

• Participants should be stratified by prostate size at randomization when size is considered to be a potentially important determinant of treatment outcome. LOW

• Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. HIGH

• High quality, symptom and bother scores (e.g., ICIQ-FLUTS, ICIQ-SM, KHQ, PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes. HIGH

• Standardized assessment of pelvic organ prolapse should be performed before treatment and at the time of other outcome assessments in all research where prolapse and continence outcomes are being assessed. HIGH

• Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests. HIGH

• Assessment of the impact of treatment on sexual function should be performed with other outcome assessment when appropriate. MEDIUM

• Long-term follow-up is of critical importance in the paediatric population in order to ascertain the effect of a treatment on normal growth and development. HIGH

• Research is needed to develop standardised outcome measures including validated, age-specific symptom and disease-specific quality of life outcome measures. MEDIUM

• Detailed urodynamic studies are recommended for classification of neurogenic lower urinary tract
disorders in research studies because the nature of the lower tract dysfunction cannot be accurately predicted from clinical data. Videourodynamic studies are preferred but are not mandatory. LOW

- An area of high priority for research is the development of a classification system to define neurogenic disorders. Relevant features could include the underlying diagnosis, the symptoms, more precise documentation of the neuromuscular lesion by clinical neurophysiologic testing, and the nature of the urodynamic abnormality. LOW

### III: POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS)

- Broader entry criteria should be used to reflect the full spectrum of the BPS/IC patient population. MEDIUM

- The primary endpoint of BPS/IC trials should be patient driven and the Global Response Assessment is recommended. A wide spectrum of secondary endpoints will be useful in defining the effect of treatments. MEDIUM

### IIIg: POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

- A validated standardised assessment of prolapse (eg POP-Q) should be used for baseline and outcome assessments. HIGH

- Complete reporting of outcomes including a validated assessment of anatomy, functional status, and complications is essential. HIGH

- Complications/adverse events (especially for mesh) must be explicitly and completely reported in any research. HIGH

- Long term outcomes (> 2 years) of intervention studies are needed. HIGH

### IV. RECOMMENDATIONS FOR ETHICS IN RESEARCH

Continuity in clinical direction from design through authorship is mandatory. Investigators should be involved in the planning stage and a publications committee should be named at the beginning of the clinical trial. The Uniform Requirements for Manuscripts Submitted to Biomedical Journals, from the International Committee of Medical Journal Editors should be followed. Authorship requires:

- Substantial contributions to conception and design or acquisition of data or analysis and interpretation of data,
  - Drafting the article or revising it critically for important intellectual content,
  - Final approval of the version to be published

- Authors should provide a description of what each contributed and editors should publish that information.

- Authors should have access to all raw data from clinical trials, not simply selected tables

Clinical trial results should be published regardless of outcome. The sponsor should have the right to review manuscripts for a limited period of time prior to publication but the manuscript is the intellectual property of its authors, not the sponsor.

- All authors should be able to accept responsibility for the published work and all potential conflicts of interest should be fully disclosed.
The scientific committee which met at the end of the 1st ICI in 1998 supported the idea that a universally applicable questionnaire should be developed, that could be widely applied both in clinical practice and research.

The hope was expressed that such a questionnaire would be used in different settings and studies and would allow cross-comparisons, for example, between a drug and an operation used for the same condition, in the same way that the IPSS (International Prostate Symptoms Score) has been used.

An ICIQ Advisory Board was formed to steer the development of the ICIQ, and met for the first time in 1999. The project’s early progress was discussed with the Board and a decision made to extend the concept further and to develop the ICIQ Modular Questionnaire to include assessment of urinary, bowel and vaginal symptoms. The first module to be developed was the ICIQ Short Form Questionnaire for urinary incontinence: the ICIQ-UI Short Form. The ICIQ-UI Short Form has now been fully validated and published [2].

Given the intention to produce an internationally applicable questionnaire, requests were made for translations of the ICIQ-UI Short Form at an early stage, for which the Advisory Board developed a protocol for the production of translations of its modules. The ICIQ-UI Short Form has been translated into 30 languages to date. Two further, newly developed and fully validated, modules have been finalised since the third consultation and are now being incorporated into clinical practice and research, and translated accordingly for international use. The ICIQ-VS[7] provides evaluation of vaginal symptoms and the ICIQ-B [3] can be used to assess bowel symptoms including incontinence. Both questionnaires also provide assessment of the impact of these symptoms on quality of life (Table 1).

Where high quality questionnaires already existed within the published literature, permission was sought to include these within the ICIQ in order to recommend them for use. Eleven high quality modules have been adopted into the ICIQ which are direct (unchanged) derivations of published questionnaires (Table 1).

www.ICIQ.net provides details of the validation status of the modules under development for urinary symptoms, bowel symptoms and vaginal symptoms and provides information regarding the content of existing modules. Information regarding production of translations and the ICIQ development protocol is also available for those interested in potential collaborations to continue development of the project.
Many people leak urine some of the time. We are trying to find out how many people leak urine, and how much this bothers them. We would be grateful if you could answer the following questions, thinking about how you have been, on average, over the PAST FOUR WEEKS.

1 Please write in your date of birth:  

2 Are you (tick one):  

Female  
Male  

3 How often do you leak urine? (Tick one box)  

never  
about once a week or less often  
two or three times a week  
about once a day  
several times a day  
all the time  

4 We would like to know how much urine you think leaks. How much urine do you usually leak (whether you wear protection or not)? (Tick one box)  

none  
a small amount  
a moderate amount  
a large amount  

5 Overall, how much does leaking urine interfere with your everyday life? Please ring a number between 0 (not at all) and 10 (a great deal)  

not at all  
a great deal  

ICIQ score: sum scores 3+4+5  

6 When does urine leak? (Please tick all that apply to you)  

never – urine does not leak  
leaks before you can get to the toilet  
leaks when you cough or sneeze  
leaks when you are asleep  
leaks when you are physically active/exercising  
leaks when you have finished urinating and are dressed  
leaks for no obvious reason  
leaks all the time  

Thank you very much for answering these questions.

### REFERENCES

The ICS defines three types of Bladder Charts and Diaries which can be used to collect data:

**Micturition Time Chart**
- times of voiding and
- incontinence episodes

**Frequency Volume Chart**
- times of voiding with voided volumes measured,
- incontinence episodes and number of changes of incontinence pads or clothing.

**Bladder Diaries**
- the information above, but also
- assessments of urgency,
- degree of leakage (slight, moderate or large) and descriptions of factors leading to symptoms such as stress leakage, eg. running to catch a bus

It is important to assess the individual’s fluid intake, remembering that fluid intake includes fluids drunk plus the water content of foods eaten. It is often necessary to explain to a patient with LUTS that it may be important to change the timing of a meal and the type of food eaten, particularly in the evenings, in order to avoid troublesome nocturia.

The micturition time and frequency volumes charts can be collected on a single sheet of paper (Fig. 1). In each chart/diary, the time the individual got out of bed in the morning and the time they went to bed at night should be clearly indicated.

Each chart/diary must be accompanied by clear instructions for the individual who will complete the chart/diary: the language used must be simple as in the suggestions given for patient instructions. There are a variety of designs of charts and diaries and examples of a detailed bladder diary are given. The number of days will vary from a single day up to one week.

**INSTRUCTIONS FOR COMPLETING THE MICTURITION TIME CHART**

This chart helps you and us to understand why you get trouble with your bladder. The diary is a very important part of the tests we do, so that we can try to improve your symptoms. On the chart you need to record:
1. When you get out of bed in the morning, show this on the diary by writing ‘GOT OUT OF BED’.
2. The time, eg. 7.30am when you pass your urine. Do this every time you pass urine throughout the day and also at night if you have to get up to pass urine.
3. Each time you pass urine, collect the urine in a measuring jug and record the amount (in mls or fluid ozs) next to the time you passed the urine, eg. 1.30pm - 320 mls.
4. If you leak urine, show this by writing ‘W’ (wet) on the diary at the time.
5. If you have a leak, please add ‘P’ if you have to change a pad and ‘C’ if you have to change your underclothes or even outer clothes. So, if you leak and need to change a pad, please write ‘WP’ at the time you leaked.
6. At the end of each day please write in the column on the right the number of pads you have used, or the number of times you have changed clothes.

When you go to bed at the end of the day show it on the diary - write ‘Went to Bed’

**INSTRUCTIONS FOR USING THE BLADDER DIARY**

This diary helps you and us to understand why you get trouble with your bladder. The diary is a very important part of the tests we do, so that we can try to improve your symptoms. On the chart you need to record:

1. When you get out of bed in the morning, show this on the diary by writing ‘GOT OUT OF BED’.
2. During the day please enter at the correct time the drinks you have during the day, eg. 8.00am - two cups of coffee (total 400 ml).
3. The time you pass your urine, eg. 7.30am. Do this every time you pass urine throughout the day and night.
4. Each time you pass urine, collect the urine in a measuring jug and record the amount (in mls or fluid ozs) next to the time you passed the urine, eg. 1.30pm/320ml.
5. Each time you pass your urine, please write down how urgent was the need to pass urine: ‘O’ means it was not urgent.
+ means I had to go within 10 minutes.
++ means I had to stop what I was doing and go to the toilet.
6. If you leak urine, show this by writing an ‘W’ on the diary at the time you leaked.
7. If you have a leak, please add ‘P’ if you have to change a pad and ‘C’ if you have to change your underclothes or even outer clothes. So if you leak and need to change a pad, please write ‘WP’ at the time you leaked.
8. If you have a leakage please write in the column called ‘Comments’ whether you leaked a small amount or a large amount and what you were doing when you leaked, eg. ‘leaked small amount when I sneezed three times’.
9. Each time you change a pad or change clothes, please write in the ‘Comments’ column.
10. When you go to bed at the end of the day show it on the diary - write ‘Went to Bed’.
**Frequency - Volume chart - Standard Version - 7 days**

Urodynamic Testing
I. INTRODUCTION 431
A. URODYNAMICS 431
I. WHAT IS URODYNAMICS? 431
II. WHAT SHOULD BE THE ROLE OF URODYNAMICS IN CLINICAL PRACTICE? 432
III. THE TESTS OF CONVENTIONAL URODYNAMICS 433
1. UROFLOWMETRY 433
2. FILLING CYTOMETRY 433
3. PRESSURE-FLOW STUDIES (VOIDING CYTOMETRY) 433
4. URETHRAL PRESSURE PROFILOMETRY 434
**IV. TECHNOLOGICAL INNOVATIONS IN URODYNAMICS**

1. **AIR-CHANGED CATHETERS FOR PRESSURE MEASUREMENT**
   - Objective assessment of bladder sensation
   - Non-invasive pressure (flow) measurements
   - Urethral retro-resistance pressure
   - Urethral pressure reflectometry
   - Ultrasound imaging
   - Urodynamics: normal values, reliability and diagnostic performance

**I. REPRODUCIBILITY OF FILLING CYSTOMETRY AND AMBULATORY URODYNAMICS**

1. **INTER-OBSERVER, TEST-RETEST AND PRACTICE VARIATION**
2. **SHORT-TERM (WITHIN-SESSION) REPRODUCIBILITY**
3. **INTERMEDIATE-TERM REPRODUCIBILITY**
4. **LONG-TERM REPRODUCIBILITY**
5. **REPRODUCIBILITY OF AMBULATORY URODYNAMICS**

**II. CYSTOMETRY: NORMAL VALUES**

1. **NORMAL VALUES: FILLING CYSTOMETRY AND AMBULATORY URODYNAMICS**
2. **COMPLIANCE**
3. **NORMAL SENSATIONS AND BLADDER CAPACITY**
4. **DETRUSOR (OVER-) ACTIVITY IN NORMAL SUBJECTS**
5. **INFLUENCE OF CATHETER ON VOIDING**

**III. REPRODUCIBILITY, RELIABILITY AND NORMAL VALUES OF URETHRAL PRESSURE MEASUREMENTS**

1. **NORMATIVE AND COMPARATIVE DATA FOR MAXIMUM URETHRAL CLOSURE PRESSURE**
2. **RELIABILITY OF URETHRAL PRESSURE VARIABLES**
3. **AGING**
4. **OTHER PARAMETERS AFFECTING THE MEASUREMENT OF URETHRAL CLOSURE PRESSURE**

**IV. LEAK POINT PRESSURE**

1. **INTRODUCTION**
2. **RELIABILITY OF LEAK POINT PRESSURE MEASUREMENTS**
   - Diagnosis
   - Treatment
   - Within-patient variability

**V. DIAGNOSTIC PERFORMANCE OF FILLING CYSTOMETRY AND AMBULATORY MONITORING**

1. **SENSITIVITY AND SPECIFICITY OF FILLING CYSTOMETRY IN OVERACTIVE BLADDER SYNDROME**
   - Detrusor overactivity incontinence
   - Detrusor overactivity alone
   - Overactive bladder syndrome and detrusor overactivity
   - Distinguishing or defining characteristics of detrusor overactivity
   - Provocative manoeuvres
2. **AMBULATORY URODYNAMICS: SENSITIVITY AND SPECIFICITY**

G. PSYCHOLOGICAL ASPECTS OF URINARY INCONTINENCE, ENURESIS AND FAECAL INCONTINENCE 790
I. INTRODUCTION 791
II. CLINICAL BEHAVIOURAL DISORDERS 791
III. CLINICAL BEHAVIORAL DISORDERS IN CHILDREN WITH ENURESIS AND URINARY INCONTINENCE 792
1. EPIDEMIOLOGICAL STUDIES 792
a) Nocturnal Enuresis 792
b) Urinary Incontinence (Daytime Wetting) 794
2. CLINICAL STUDIES 794
a) Nocturnal Enuresis 794
b) Urinary Incontinence (Daytime Wetting) 795
IV. CLINICAL BEHAVIORAL DISORDERS IN CHILDREN WITH FAECAL INCONTINENCE 796
1. EPIDEMIOLOGICAL STUDIES 796
2. CLINICAL STUDIES 796
V. SUBCLINICAL SIGNS AND SYMPTOMS OF WETTING CHILDREN 798
1. IMPACT ON CHILDREN 798
2. IMPACT ON PARENTS 798
VI. GENERAL PRINCIPLES 799
1. ASSESSMENT 799
   a) Screening Questionnaires 799
   b) Child Psychiatric Assessment 799
2. OF PSYCHOLOGICAL DISORDER 801
3. UROTHERAPY 801
4. NON-SPECIFIC APPROACHES 802
5. COUNSELLING 802
6. COGNITIVE-BEHAVIOURAL THERAPY 802
7. BASELINE AND OBSERVATION 802
8. BIOFEEDBACK 802
9. ALARM TREATMENT 803
VII. CONCLUSION AND SUMMARY 804

Neurologic Urinary and Faecal Incontinence

A. Introduction 829
B. Pathophysiology 831
   I. SUPRAPONTINE LESIONS 831
   II. PONTINE LESIONS 831
III. SUPRASACRAL SPINAL CORD LESIONS 831
IV. SACRAL (CONUS MEDULLARIS) LESIONS 832
V. SUBSACRAL LESIONS (CAUDA EQUNIA OR PERIPHERAL NERVES) 832
C. Neurological urinary incontinence 832
   I. EPIDEMIOLOGY 832
      1. NEUROLOGICAL LESION BY DISEASE LOCATION 832
         a) Diseases Affecting Brain/Brainstem 832
         b) Diseases of the spinal cord 833
         c) Peripheral nerve problems 834
         d) Other 835
   II. SPECIFIC DIAGNOSTICS 835
      1. HISTORY 835
      2. PHYSICAL EXAMINATION 836
      3. URODYNAMIC TESTS 836
         a) Electromyography (EMG) during cystogram 836
         b) Filling parameters 837
         c) Filling technique 838
         d) The outlet during voiding 838
         e) Bladder sensation 838
         f) Complications of urodynamic testing 838
      4. SPECIAL TESTS 839
         a) Bladder-cooling reflex; the ice water test (IWT) 839
         b) Bethanechol supersensitivity test (BST) 840
         c) Electrodiagnostic tests 840
   III. CONSERVATIVE TREATMENT 843
      1. OVERVIEW ACCORDING TO TYPE OF LESION 843
         a) Supraspinal lesions 843
         b) Suprasacral lesions 843
         c) Lower motor neuron lesions 843
      2. SPECIFIC INTERVENTIONS 844
         a) Behavioral therapy 844
         b) Catheters and appliances 846
   IV. PHARMACOTHERAPY 849
      1. DRUGS FOR NEUROGENIC STORAGE DYSFUNCTION 849
         a) Bladder relaxants 849
         b) Intravesical bladder relaxants 850
         c) Drugs for sphincter deficiency 854
      2. DRUGS FOR TREATING VOIDING DYSFUNCTION 854
         a) Alpha-adrenergic antagonists 854
         b) Botulinum toxin 854
         c) Cholinomimetics 855
V. ELECTROSTIMULATION 855
   1. ELECTRICAL NEUROMODULATION 855
      a) Anogenital Stimulation 856
      b) Pubendal Nerve Stimulation 856
      c) Dorsal Genital Nerve (DGN) stimulation 856
      d) Posterior tibial nerve stimulation 857
      e) Repetitive transcranial magnetic stimulation 857
      f) Deep brain stimulation 857
   2. ELECTRICAL STIMULATION OF THE PELVIC FLOOR MUSCULATURE 858
      3. INTRAVESICAL ELECTRICAL STIMULATION (IVES) 858
VI. SURGICAL TREATMENT OF URINARY INCONTINENCE 859
   1. SACRAL NEUROMODULATION 859
      a) Hypotheses on the modes of action of neuromodulation 859
      b) Treatment of neurogenic detrusor overactivity incontinence 859
      c) Sacral neuromodulation for urinary retention in neurological bladder dysfunction 859
   2. DENERVATION PROCEDURES FOR TREATING REFLEX URINARY INCONTINENCE DUE TO DETRUSOR OVERACTIVITY 862
      a) Peripheral bladder denervation 862
      b) Isolated rhizotomy of ventral and/or dorsal sacral roots 862
      c) Rhizotomy of posterior sacral roots and stimulation of the anterior sacral roots 863
   3. SURGERY FOR INCONTINENCE ASSOCIATED WITH POOR BLADDER EMPTYING DUE TO DETRUSOR UNDERACTIVITY 865
      a) Surgical treatment of detrusor external sphincter dyssynergia 865
      b) Bladder neck incision (BNI) for detrusor-bladder neck dyssynergia (DBND) 871
   4. SURGERY TO INCREASE DETRUSOR STRENGTH 872
   5. STRESS URINARY INCONTINENCE (SUI) DUE TO SPHINCTERIC INCOMPETENCE 872
      a) Bulking agents 873
      b) Autologous Sling Procedures 874
      c) Suburethral tapes 875
      d) Artificial urinary sphincter (AUS) 875
      e) Surgery of the bladder neck 876
      f) Complete bladder neck or urethral closure 878
   6. SURGICAL ALTERNATIVES EXCLUDING DENERVATION PROCEDURES TO TREAT REFLEX INCONTINENCE DUE TO NEUROGENIC DETRUSOR OVERACTIVITY 878
      a) Bladder augmentation using intestinal segments 878
      b) Autoaugmentation by detrusor myotomy 883
      c) Bladder augmentation using biomaterials 884
      d) Cutaneous continent urinary diversion 885
      e) Non-continent cutaneous urinary diversion 889
D. Neurological faecal incontinence 894
   I. EPIDEMIOLOGY 894
   II. NEUROPHYSIOLOGY OF BOWEL DYSFUNCTION 894
   III. ASSESSMENT 895
   IV. CONSERVATIVE TREATMENT 895
      1. BOWEL PROGRAM /BOWEL CARE 895
      2. SPECIFIC TECHNIQUES 896
         a) Diet 896
         b) Toileting 896
         c) Digital rectal stimulation 896
         d) Manual stool extraction 896
      3. CHEMICAL STIMULANTS 896
      4. ASSISTIVE TECHNIQUES FOR DEFECTION 897
V. SURGICAL TREATMENT 898
1. SACRAL NERVE STIMULATION 899
2. ANTEGRADE CONTINENCE ENEMA (ACE) 901
3. DYNAMIC GRACILOPLASTY 903
4. ARTIFICIAL ANAL SPHINCTER 903
5. COLOSTOMY 907
6. POSTANAL REPAIR 907
E. Specific neurological diseases 907
I. DEMENTIAS 907
1. DEMENTIA AND URINARY INCONTINENCE 907
2. ALZHEIMER’S DISEASE 907
a) Epidemiology and prevalence 907
b) Pathology and disease-specific urinary tract problems 908
c) Diagnosis and treatment 908
d) Guidance for further research 909
3. VASCULAR DEMENTIA 909
a) Epidemiology and prevalence 909
b) Diagnosis 909
c) Pathology and disease-specific urinary tract problems 910
d) Disease specific diagnosis and treatment 910
e) Recommendations for further research 911
4. DEMENTIA WITH LEWY BODIES 911
a) Epidemiology and prevalence 911
b) Pathology and disease-specific urinary tract problems 911
c) Disease specific diagnosis and treatment 912
5. FRONTOTEMPORAL DEMENTIA (FTD) 912
a) Epidemiology and prevalence 912
b) Pathology and disease-specific urinary tract problems 912
c) Diagnosis and treatment 912
6. CONSTIPATION AND FECAL INCONTINENCE IN DEMENTIA 912
7. NORMAL PRESSURE HYDROCEPHALUS 913
a) Epidemiology and prevalence 913
b) Pathology and disease-specific urinary tract problems 913
c) Diagnosis and treatment 913
II. MULTIPLE SYSTEM ATROPHY 914
1. EPIDEMIOLOGY AND PREVALENCE 914
2. PATHOLOGY AND DISEASE-SPECIFIC URINARY TRACT PROBLEMS 914
3. DIAGNOSIS AND TREATMENT 915
4. FAECAL INCONTINENCE 916
III. PARKINSON’S DISEASE 917
1. URINARY INCONTINENCE 921
a) Pathology and disease-specific urinary tract problems 917
b) Specific diagnosis and treatment 918
2. CONSTIPATION AND FAecal INCONTINENCE 919
a) Pathology and disease-specific problems 919
b) Disease-specific diagnosis and treatment 920
IV. CEREBRAL LESIONS AND CEREBRAL VASCULAR ACCIDENTS 921
1. URINARY INCONTINENCE 921
a) Pathology and disease specific LUT problems 921
b) Disease-specific diagnosis and management 922
V. MENINGITIS-RETENTION SYNDROME 923
VI. ACUTE DISSEMINATED ENCEPHALOMYELITIS (ADEM) 925
VII. SPINAL CANAL STENOSIS 926
1. CAUDA EQUINA SYNDROME 927
2. LUMBAR DISC PROLAPSE 927
VIII. NEUROPATHIES AND MUSCLE DISORDERS 928
1. GILLUAIN BARRE SYNDROME 928
a) Urinary dysfunction 929
b) Bowel dysfunction 929
2. FAMILIAL AMYLOID POLYNEUROPATHY 930
3. FAMILIAL DYSAUTONOMIA 930
4. CHARCOT-MARIE-TOOTH DISEASE 930
5. AUTONOMIC NEUROPATHIES 930
a) Acute Idiopathic Autonomic Neuropathy 930
b) Autoimmune Autonomic Ganglionopathy 930
c) Pure Autonomic Failure 931
6. DISORDERS OF THE NEUROMUSCULAR JUNCTION 931
7. MUSCLE DISORDERS 931
a) Muscular Dystrophies 931
b) Mitochondrial cytopathy 931
8. PERIPHERAL NEUROPATHY DUE TO IATROGENIC LESIONS (FOCAL NEUROPATHY) 931
a) Hysterectomy (simple and radical) 932
b) Abdominoperineal resection and total mesorectal excision 932
IX. MULTIPLE SCLEROSIS 934
1. EPIDEMIOLOGY 934
2. URINARY DYSFUNCTION IN MS 934
a) Infectious complications 935
b) Alterations of the bladder 935
c) Bladder cancer 935
d) Complications of the upper urinary tract 936
e) Risk factors in urological complications 936
f) The role of urodynamics in multiple sclerosis 936
3. COLORECTAL DYSFUNCTION IN MS 937
a) Epidemiology 937
b) Pathophysiology of MS-related digestive disorders 938
X. SPINAL CORD LESIONS 938
1. URINARY INCONTINENCE 938
a) Epidemiology and prevalence 938
b) Pathology and disease-specific LUT problems 938
c) Disease specific management 942
d) Guidance for further research 944
2. FAECAL INCONTINENCE 945
a) Epidemiology and prevalence 945
b) Pathology and disease specific lower gastrointestinal (LGIT) problems 946
c) Conservative bowel management 946
d) Guidance for further research 947
XI. MYELOMENINGOCOELE 947
1. URINARY INCONTINENCE 947
2. BOWEL PROBLEMS 949
XII. SYSTEMIC AND OTHER CONDITIONS 950
1. SYSTEMIC LUPUS ERYTHEMATOSIS 950
a) Urinary incontinence 950
b) Faecal incontinence 952
2. HERPES ZOSTER 951
3. HIV 952
a) Urinary incontinence 952
b) Faecal incontinence 952
4. NEUROSYPHILIS 953
5. DIABETES MELLITUS 953
a) Urinary incontinence 953
b) Faecal Incontinence 954

Incontinence in the Frail Elderly
A. General considerations 1003
I. INTRODUCTION 1003
II. SEARCH STRATEGIES 1004
III. DEFINING THE FRAIL OLDER POPULATION 1004
1. FRAILTY 1004
2. IMPACT OF UI ON MORBIDITY AND INSTITUTIONALISATION 1005

B. Urinary Incontinence in frail older people 1005

I. AETIOLOGY AND ASSESSMENT 1005

1. BACKGROUND 1005
2. QUALITY OF THE DATA 1005
3. UI AS A GERIATRIC SYNDROME 1005
4. AGE-RELATED CHANGES RELEVANT TO UI IN THE FRAIL ELDERLY 1006
   a) Bladder 1006
   b) Urethra 1008
   c) Pelvic floor 1009
   d) Vagina 1010
   e) Prostate 1010
   f) Other changes 1011

5. FACTORS OUTSIDE THE LOWER URINARY TRACT CAUSING OR CONTRIBUTING TO UI 1011
   a) Medications 1011
   b) Co-morbid conditions and functional impairment 1011
   c) Neurological and psychiatric disorders 1014
   d) Depression 1014
   e) Falls 1015
   f) Stroke 1015
   g) Recommendations for research 1015
   h) Recommendations for practice 1015

6. ENVIRONMENTAL FACTORS 1015
   a) The physical environment 1016
   b) Processes and quality of care 1016
   c) Assessment 1017
   d) Knowledge 1017
   e) Processes of care that reduce functional status 1017
   f) Lack of toileting assistance 1017
   g) Staffing levels and skill mix 1019
   h) Use and misuse of continence aids 1019
   i) Recommendations for research 1021
   j) Recommendations for practice 1021

II. ASSESSMENT OF THE FRAIL OLDER PERSON WITH UI 1021

1. COMPONENTS 1021
   a) Identification of frail older persons 1021
   b) Primary care assessment 1022
   c) Cough stress test 1022
   d) Postvoid residual measurement 1022
   e) Urodynamic testing 1022
   f) Ultrasound estimation of bladder weight 1022

2. SUMMARY OF EVIDENCE 1023

3. RECOMMENDATIONS FOR EVALUATION (SEE ALGORITHM) 1023

III. FACTORS IN MANAGEMENT 1023

1. BACKGROUND 1023

2. ROLE OF COMORBIDITY IN MANAGEMENT DECISIONS 1023

3. DEFINING OUTCOMES FOR TREATMENT 1023

4. ROLE OF REMAINING LIFE EXPECTANCY IN TREATMENT DECISIONS 1024

5. PREFERENCES FOR CARE 1024

6. COSTS AND BENEFITS OF UI TREATMENT IN THE FRAIL ELDERLY 1025
   a) Estimating Costs 1025
   b) Benefit and effectiveness of treatment 1026

7. ISSUES IN DRUG TREATMENT 1027
   a) Age-related changes in pharmacology 1027
   b) Availability of low dose agents 1027
   c) Inappropriate polypharmacy 1027
   d) Adverse drug effects 1027
   e) Drug interactions 1029
   f) Potentially inappropriate drugs for older persons 1029

8. SPECIAL ISSUES UNIQUE TO FRAIL OLDER MEN 1030

9. SUMMARY OF THE EVIDENCE 1031

IV. TREATMENT OF URINARY INCONTINENCE IN THE FRAIL ELDERLY 1031

1. LIFESTYLE INTERVENTIONS 1031
   a) Quality of data and results 1031
   b) Summary of the evidence 1031

2. BEHAVIOURAL INTERVENTIONS 1031
   a) Quality of data 1032
   b) Efficacy 1032
   c) Summary of evidence 1035
   d) Interventions with caregivers and long term care staff 1035

3. INTERVENTIONS WITH LONG TERM CARE STAFF AND CAREGIVERS 1035
   a) Quality of data 1036
   b) Results 1036
   c) Recommendations for practice 1039

4. PHARMACOLOGICAL TREATMENT 1040
   a) Background 1040
   b) Quality of data 1040
   c) Results 1041
   d) Summary of the evidence 1046
   e) Recommendations for practice 1047

5. SURGICAL TREATMENT IN THE FRAIL ELDERLY 1047
   a) Background 1047
   b) Incontinence surgery in frail elderly women 1048
   c) Incontinence surgery in frail elderly men 1049
   d) General issues in surgical care of the frail elderly 1049
   e) Summary of evidence 1049
   f) Recommendations for management 1050
   g) Recommendations for research 1050

6. CATHETERS 1050
   a) Background 1050
   b) Quality of the data 1050
   c) Rates of IDC use in frail older adults 1051
   d) IDC for end of life care 1052
   e) Management recommendations 1052
   f) Intermittent catheterisation as an alternative to IDC in frail older adults 1053
   g) Research recommendations 1053

V. NOCTURIA IN THE OLDER ADULT 1053

1. BACKGROUND 1053

2. QUALITY OF THE DATA 1053

3. PREVALENCE, INCIDENCE, AND IMPACT 1054

4. PATHOPHYSIOLOGY 1055

5. DIAGNOSTIC ASSESSMENT 1055

6. TREATMENT 1056
   a) Behavioural approaches and treatment of comorbidity 1056
   b) Pharmacotherapy 1057
   c) Surgical and procedural treatments 1059

7. SUMMARY OF EVIDENCE 1060

8. RECOMMENDATIONS FOR MANAGEMENT 1060

9. RECOMMENDATIONS FOR RESEARCH FOR NOCTURIA IN THE ELDERLY [636] 1060

VI. MODELS OF CARE FOR THE FRAIL ELDERLY WITH UI 1060

1. BACKGROUND 1060

2. HOME CARE 1060

3. CONTINENCE NURSE ADVISORS AND NURSLED MODELS 1061

4. COLLABORATIVE PRACTICES BETWEEN NURSE PRACTICE NURSES AND PHYSICIANS 1061

5. INSTITUTIONAL LONG TERM CARE 1062

6. OTHER INSTITUTIONAL SETTINGS 1063

7. RESEARCH RECOMMENDATIONS 1064

C. FAECAL INCONTINENCE 1065

I. BACKGROUND 1065

II. PREVALENCE AND RISK FACTORS FOR FAECAL INCONTINENCE 1065

1. PREVALENCE ESTIMATES FOR FAECAL INCONTINENCE 1065

2. PREVALENCE AND INCIDENCE ESTIMATES OF FI IN COMMUNITY-DWELLING OLDER ADULTS 1065

3. PREVALENCE ESTIMATES OF FI IN HOSPITALIZED OLDER ADULTS 1067
4. PREVALENCE AND INCIDENCE ESTIMATES OF FI IN LONG-TERM CARE RESIDENTS 1067
5. FAECAL INCONTINENCE IN OLDER ADULTS — THE “HIDDEN” PROBLEM 1067
6. RISK FACTORS ASSOCIATED WITH FI IN OLDER ADULTS 1068
III. THE AGEING LOWER BOWEL AND PATHOPHYSIOLOGY IN OLDER ADULTS WITH FAECAL INCONTINENCE 1068
1. QUALITY OF DATA 1068
2. ANORECTAL FUNCTION IN HEALTHY OLDER ADULTS 1068
3. CAUSES OF FAECAL INCONTINENCE IN OLDER ADULTS 1070
4. EVALUATION OF FAECAL INCONTINENCE IN OLDER ADULTS 1072
5. TREATMENT OF FI IN OLDER ADULTS 1073
   a) Quality of data 1073
   b) Multi-component treatments for FI 1073
   c) Treatment of FI in nursing home settings 1074
   d) Treatment of FI in stroke survivors 1074
   e) Sacral Neuromodulation/Percutaneous tibial nerve stimulation for FI in older adults 1074
6. SUMMARY OF EVIDENCE ON THE TREATMENT OF FI IN FRAIL OLDER PEOPLE 1074
7. RECOMMENDATIONS - TREATMENT OF FI IN FRAIL OLDER PEOPLE (ALL GRADE C) 1075
8. AREAS FOR FURTHER RESEARCH ON FI IN FRAIL OLDER PEOPLE 1075
REFERENCES 1076

Committee 12

Adult Conservative Management

I. INTRODUCTION 1103
A. UI IN WOMEN 1103
   I. LIFESTYLE INTERVENTIONS 1103
   1. PREVENTION 1103
   2. TREATMENT 1103
      a) Weight loss 1103
      b) Physical activity 1104
      c) Physical Forces (exercise and work) 1105
      d) Smoking 1106
      e) Dietary factors 1106
      f) Constipation 1107
      g) Other 1108
   3. OTHER LUTS 1108
   4. FACTORS AFFECTING OUTCOME 1108
   II. PELVIC FLOOR MUSCLE TRAINING (PFMT) 1108
      1. RATIONALE AND PRINCIPLES 1108
         a) Biological rationale for PFMT for SUI 1108
         b) Biological rationale for UUI 1109
         c) Principles of skeletal muscle strengthening 1109
         d) Principles of behaviour change 1110
      2. PREVENTION AND TREATMENT (PREGNANT AND POSTNATAL WOMEN ONLY) 1110
         a) Is PFMT effective in the prevention of UI in childbearing women? 1111
         b) Is PFMT effective in the treatment of UI in childbearing women? 1113
         c) Is PFMT effective in the mixed prevention and treatment of UI in childbearing women? 1114
      3. PREVENTION (OTHER WOMEN) 1116
         a) Is PFMT effective in the prevention of UI? 1116
      4. TREATMENT (WOMEN) 1116
         a) Is PFMT better than no treatment, a placebo or a control group treatment? 1116
         b) Is one type of PFMT programme better than another? 1120
         c) Is PFMT better than other treatments? 1129
         d) Does the addition of PFMT to other treatments add benefit? 1134
      5. OTHER LUTS 1135
6. FACTORS AFFECTING OUTCOME 1136
   a) Age 1136
   b) Other 1136
III. WEIGHTED VAGINAL CONES (VCS) 1137
   1. PREVENTION 1137
   2. TREATMENT 1138
      a) Are VCs better than no treatment, placebo or control treatments? 1138
      b) Are VCs as effective as other treatments? 1138
      c) Are VCs combined with PFMT better than PFMT alone? 1144
   3. OTHER LOWER URINARY TRACT SYMPTOMS (LUTS) 1144
   4. FACTORS AFFECTING OUTCOME 1144
IV. ELECTRICAL STIMULATION (ESTIM) 1144
   1. PREVENTION 1152
   2. TREATMENT 1152
      a) Is EStim better than no active treatment (placebo, sham, control or no treatment) for treatment of UI? 1152
      b) Is one type of EStim better than another in the treatment of UI? 1154
      c) Is EStim better than other treatments for UI? 1154
      d) Does the addition of EStim to other treatments add any benefit in the treatment of UI? 1156
   3. OTHER LUTS 1158
   4. FACTORS AFFECTING OUTCOME 1158
V. MAGNETIC STIMULATION (MStim) 1158
   1. PREVENTION 1160
   2. TREATMENT 1160
      a) Is MStim better than no active treatment (placebo, control or no treatment)? 1160
      b) Is one approach to MStim better than another? 1163
      c) Is MStim better than other treatments? 1163
      d) Does the addition of MStim to other treatments add any benefit in the treatment of UI? 1163
VI. SCHEDULED VOIDING REGIMENS 1164
   1. PREVENTION 1165
   2. TREATMENT 1165
      a) What is the most appropriate bladder training (BT) protocol? 1166
      b) Is BT better than no treatment, placebo or control treatments? 1167
      c) Is BT better than other treatments? 1168
      d) Can any other treatment be added to BT to add benefit? 1169
      e) Does the addition of BT to any other treatment add benefit? 1170
      f) Timed voiding 1171
   3. OTHER LUTS 1171
   4. FACTORS AFFECTING OUTCOME 1172
      a) Age 1172
      b) Other 1172
VII. COMPLEMENTARY AND ALTERNATIVE MEDICINES 1172
VIII. SUMMARY AND RECOMMENDATIONS 1173
   1. SUMMARY 1173
   2. RECOMMENDATIONS FOR PRACTICE 1173
      a) Lifestyle Intervention 1173
      b) PFMT (principal recommendation) 1173
      c) PFMT (other recommendation) 1173
IX. FUTURE RESEARCH DIRECTIONS 1174
   a) Lifestyle Intervention 1174
   b) Pelvic floor muscle training (PFMT) 1175
   c) Vaginal cones (VC) 1175
   d) Electrical stimulation (ESTim) and magnetic stimulation (MStim) 1175
   e) Scheduled voiding regimes, especially bladder training (BT) 1175
B. PELVIC ORGAN PROLAPSE (POP) 1175
I. LIFESTYLE INTERVENTIONS 1176
1. PREVENTION
a) Quality of data
b) Results
c) Summary

2. TREATMENT

II. PHYSICAL THERAPIES
1. PREVENTION
a) Quality of data
b) Results
c) Summary

2. TREATMENT
a) Quality of data
b) Results
c) Summary
d) Recommendations

III. PESSIONS
1. QUALITY OF DATA
2. OUTCOME
a) Patient reported outcomes

IV. IV. RECOMMENDATIONS AND RECOMMENDATIONS
1. RECOMMENDATIONS FOR PRACTICE
2. FUTURE RESEARCH DIRECTIONS
a) Lifestyle interventions
b) Pelvic floor muscle training (PFMT)
c) Pessaries

C. URINARY INCONTINENCE IN MEN
1. LIFESTYLE INTERVENTIONS
2. PHYSICAL THERAPIES
1. PREVENTION
a) Quality of data
b) Results
c) Summary

3. OTHER LUTS
a) Age
b) Other

4. FACTORS AFFECTING OUTCOME

5. POSTOPERATIVE TURP PFMT

6. POSTOPERATIVE TURP PFMT FOR INCONTINENT MEN
a) PFMT with digital rectal feedback (DRE) after radical prostatectomy
b) PFMT with BF after radical prostatectomy
c) PFMT plus or minus BF with EStim or MStim after radical prostatectomy
d) PFMT compared to other interventions after radical prostatectomy

4. PREOPERATIVE TURP PFMT

5. PREOPERATIVE AND/OR POSTOPERATIVE TURP PFMT

6. POSTOPERATIVE TURP PFMT FOR INCONTINENT MEN

7. PFMT FOR OTHER LUTS
a) PFMT for post micturition dribble (PMD)

8. FACTORS AFFECTING OUTCOME

III. ELECTRICAL STIMULATION (ESTIM)
1. PREVENTION OF UI
2. TREATMENT OF UI
a) Is EStim better than no treatment, placebo or control treatment?
b) Is one approach to EStim better than another?
c) Is EStim better than other treatments?

3. OTHER LUTS
4. FACTORS AFFECTING OUTCOME
a) Age
b) Other

IV. MAGNETIC STIMULATION (MSTIM)
1. PREVENTION OF UI
2. TREATMENT OF UI
a) Is MStim better than no treatment, placebo or control treatment?
b) Is one approach to MStim better than another?
c) Is MStim better than other treatments?

V. SCHEDULED VOIDING REGIMENS
1. PREVENTION OF UI
2. TREATMENT OF UI
a) Bladder training
b) Timed voiding

3. OTHER LUTS
4. FACTORS AFFECTING OUTCOME
a) Age
b) Other

VI. COMPLEMENTARY AND ALTERNATIVE MEDICINES

VII. SUMMARY

APPENDIX 1

APPENDIX 2

REFERENCE
VI. INCONTINENCE AFTER OTHER TREATMENT FOR PROSTATE CANCER AND NEOBLADDER FOR BLADDER CANCER 1251
1. BRACHYTHERAPY 1251
2. CRYOSURGICAL ABLATION OF THE PROSTATE 1251
3. HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) 1251
4. INCONTINENCE AFTER NEOBLADDER CONSTRUCTION 1253

VII. TRAUMATIC INJURIES OF THE URETHRA AND PELVIC FLOOR 1253

VIII. CONTINUING PEDIATRIC PROBLEMS INTO ADULTHOOD: THE EXSTROPHY-EPISPADIAS COMPLEX AND OTHER CONGENITAL ANOMALIES 1254

1. EARLY MANAGEMENT OF EXSTROPHY AND EPISPADIAS 1254
2. LATE BLADDER FUNCTION 1255
3. MANAGEMENT OF INCONTINENCE 1256
   a) Investigation 1256
   b) Medical Management 1256
   c) Bulking Agents For The Bladder Outflow 1256
   d) Surgical Management 1257
   e) Diversion 1257

**Recommendations for research**

3. **Physiological testing**
   - Endoanal ultrasonography includes cases of faecal incontinence.
   - Anal sphincter atrophy at MRI is recommended.
   - Anal sphincter defects on MRI are recommended.

**Surgical incision**

1. **Vagal nerve stimulation**
   - Recto-anal inhibitory reflex is recommended.

**Equipment and testing**

2. **General**
   - Equipment and testing is recommended.

**Magnetic resonance imaging**

3. **Surgical incision**
   - Normal anal sphincter anatomy at MRI is recommended.
   - Anal sphincter defects on MRI are recommended.
   - Anal sphincter atrophy at MRI is recommended.

**Endoanal ultrasound imaging**

4. **Physiological testing**
   - Normal anal sphincter anatomy at MRI is recommended.
   - Anal sphincter defects on MRI are recommended.
   - Anal sphincter atrophy at MRI is recommended.

**Vagal nerve stimulation**

5. **Physiological testing**
   - Recto-anal inhibitory reflex is recommended.

**Equipment and testing**

6. **General**
   - Equipment and testing is recommended.

**Magnetic resonance imaging**

7. **Surgical incision**
   - Normal anal sphincter anatomy at MRI is recommended.
   - Anal sphincter defects on MRI are recommended.
   - Anal sphincter atrophy at MRI is recommended.

**Endoanal ultrasound imaging**

8. **Physiological testing**
   - Recto-anal inhibitory reflex is recommended.

**Equipment and testing**

9. **General**
   - Equipment and testing is recommended.

**Magnetic resonance imaging**

10. **Surgical incision**
    - Normal anal sphincter anatomy at MRI is recommended.
    - Anal sphincter defects on MRI are recommended.
    - Anal sphincter atrophy at MRI is recommended.

**Endoanal ultrasound imaging**

11. **Physiological testing**
    - Recto-anal inhibitory reflex is recommended.

**Equipment and testing**

12. **General**
    - Equipment and testing is recommended.

**Magnetic resonance imaging**

13. **Surgical incision**
    - Normal anal sphincter anatomy at MRI is recommended.
    - Anal sphincter defects on MRI are recommended.
    - Anal sphincter atrophy at MRI is recommended.

**Endoanal ultrasound imaging**

14. **Physiological testing**
    - Recto-anal inhibitory reflex is recommended.

**Equipment and testing**

15. **General**
    - Equipment and testing is recommended.

**Magnetic resonance imaging**

16. **Surgical incision**
    - Normal anal sphincter anatomy at MRI is recommended.
    - Anal sphincter defects on MRI are recommended.
    - Anal sphincter atrophy at MRI is recommended.

**Endoanal ultrasound imaging**

17. **Physiological testing**
    - Recto-anal inhibitory reflex is recommended.

**Equipment and testing**

18. **General**
    - Equipment and testing is recommended.

**Magnetic resonance imaging**

19. **Surgical incision**
    - Normal anal sphincter anatomy at MRI is recommended.
    - Anal sphincter defects on MRI are recommended.
    - Anal sphincter atrophy at MRI is recommended.

**Endoanal ultrasound imaging**

20. **Physiological testing**
    - Recto-anal inhibitory reflex is recommended.

c) Sexuality 1748
d) Catheter-related Pain 1748
e) Adjustment to a Catheter 1749
 f) Self-management 1749
g) Summary 1749
4. OVERALL RECOMMENDATIONS RELATING TO CATHETERS 1750
 a) Intermittent catheters 1750
 b) Indwelling catheters 1750
c) Catheter valves 1751
5. PRIORITIES FOR RESEARCH 1751
 a) General 1751
 b) Intermittent catheters 1751
 c) Indwelling catheters 1751
d) Catheter valves 1752
e) Quality of life 1752

XIII. PRODUCTS FOR PREVENTING OR CONTAINING FAECAL INCONTINENCE 1752
1. PRODUCTS TO PREVENT OR CONTAIN LEAKED STOOL 1752
2. QUALITY OF DATA 1754
3. RESULTS 1755
 a) Anal Plugs 1755
 b) Rectal Trumpet 1756
c) Rectal Catheter Systems 1756
d) Anal Pouch 1757
4. SUMMARY 1758
5. RECOMMENDATIONS 1758
6. PRIORITIES FOR RESEARCH 1758

XIV. SKIN HEALTH AND CONTINENCE PRODUCTS 1758
1. BACKGROUND 1758
 a) The role of urine and faeces in skin irritation 1759
 b) Prevalence of incontinence-associated dermatitis / perineal dermatitis 1760
c) Pressure ulcers and incontinence 1761
2. CLINICAL STUDIES OF THE IMPACT OF PRODUCTS AND PRODUCT MATERIALS ON SKIN HEALTH 1762
 a) Quality of data 1762
 b) Results 1763
3. CLINICAL STUDIES OF SKIN-CARE PRODUCTS AND NURSING PRACTICES TO MAINTAIN OR IMPROVE SKIN HEALTH 1764
 a) Quality of data 1765
 b) Results 1765
4. SUMMARY 1767
5. RECOMMENDATIONS 1767
6. PRIORITIES FOR RESEARCH 1767

XV. ODOUR CONTROL PRODUCTS 1768
Committee 21  
Continence Promotion, Education & Primary Prevention

I. LITERATURE SEARCH 1789
II. INTRODUCTION 1789
III. CONTINENCE PROMOTION AND AWARENESS 1790
1. BACKGROUND 1790
2. RAISING AWARENESS AND UNDERSTANDING 1790
3. HELP-SEEKING (CARE-SEEKING) BEHAVIOR 1791
   a) Barriers to seeking care 1792
   b) Gender-specific disparity 1793
   c) Symptom impact and bother 1794
4. CONTINENCE PROMOTION PROGRAMS 1794
   a) Creating public awareness 1795
   b) Program evaluation 1796
5. RECOMMENDATIONS FOR CONTINENCE PROMOTION AND AWARENESS (GRADE D) 1797
IV. CONTINENCE ADVOCACY 1797
1. BACKGROUND 1797
2. CONTINENCE ADVOCACY WORLDWIDE 1798
   a) Funding 1798
   b) Collaboration 1798
3. RECOMMENDATION FOR CONTINENCE ADVOCACY (LEVEL OF EVIDENCE-3, GRADE D) 1799
V. SERVICE DELIVERY, MODELS AND ACCESSING CARE 1799
1. BACKGROUND 1799
2. NEED FOR SERVICES 1800
3. MODELS OF CARE 1800
   a) Single specialist 1801
   b) Nurse specialist or advisor 1801
   c) Multidisciplinary resource and referral centre 1802
   d) Primary care 1803
   e) Other service models 1804
4. RECOMMENDATIONS FOR SERVICE DELIVERY, MODELS AND ACCESSING CARE 1807
VI. PROFESSIONAL EDUCATION 1807
1. BACKGROUND 1807
2. MEDICAL EDUCATION 1808
   a) Generalists (family physicians/general practitioners/primary care physicians) 1808
   b) Specialist physicians 1809
3. NURSING PROFESSIONALS 1809
   a) Generalist nurses 1809
   b) Specialist nurses 1810
   c) Nursing assistants 1811
4. PHYSIOTHERAPY AND OTHER ALLIED HEALTH PROFESSIONALS 1811
5. IMPACT OF CLINICAL GUIDELINES 1812
   a) Audits and assessments of guidelines 1814
6. RECOMMENDATIONS FOR PROFESSIONAL EDUCATION (GRADE D) 1815
VII. PRIMARY PREVENTION 1815
1. BACKGROUND 1815
2. POPULATION-BASED PREVENTION 1815
3. PREVENTION OF UI IN OLDER ADULTS 1816
4. PREVENTION OF FAECAL INCONTINENCE 1817
5. RECOMMENDATIONS FOR PRIMARY PREVENTION (GRADE C) 1817

Economics of Urinary & Faecal Incontinence, and Prolapse

I. INTRODUCTION 1831
II. BACKGROUND 1831
1. PERSPECTIVE 1831
2. COUNTRY SPECIFIC ECONOMIC ISSUES 1833
3. COSTS AND TIME 1833
III. TYPES OF ECONOMIC ANALYSIS 1834
1. OVERVIEW 1834
   a) Cost of illness (COI) 1834
   b) Cost minimization analysis (CMA) 1834
   c) Cost consequence analysis (CCA) 1834
   d) Cost-effectiveness analysis (CEA) 1834
   e) Cost-utility analysis (CUA) 1834
   f) Cost benefit analysis (CBA) 1834
   g) Summary 1834
2. DETAILS OF DECISION ANALYSIS 1835
   a) Steps in a decision analysis 1836
   b) Decision Tree 1837
   c) Markov Model 1838
3. STATISTICAL ANALYSIS 1838
4. BUDGET IMPACT ANALYSIS 1838
IV. PRACTICAL ASPECTS OF ECONOMIC ANALYSIS IN THE CONTINENCE FIELD 1839
1. HEALTH OUTCOME MEASURES SUITABLE FOR USE IN ECONOMIC ANALYSES 1839
   a) Incontinence specific outcomes 1839
   b) Health Status and Quality of Life Measures 1839
   c) Health value 1839
2. “DO IT YOURSELF” - HOW TO CONDUCT A COST-UTILITY ANALYSIS: THE COMMITTEE’S RECOMMENDATIONS 1840

Research Methodology

I. INTRODUCTION 1865
1. LEVELS OF EVIDENCE 1865
2. PRIMARY GUIDING ETHICAL PRINCIPLES 1865

24
3. INFORMED CONSENT IS AN ETHICAL CORNERSTONE OF HUMAN SUBJECT RESEARCH 1866

4. SPECIFIC INFORMED CONSENT IS REQUIRED FOR RESEARCH PARTICIPATION. 1866

5. THE INVESTIGATOR HAS AN ETHICAL RESPONSIBILITY TO TAKE RESPONSIBILITY FOR ALL ASPECTS OF THE RESEARCH 1866

6. ENSURING PARTICIPANT SAFETY IS PARAMOUNT 1866

7. HIGH QUALITY DATA MANAGEMENT IS KEY TO PROVIDING VALID AND ETHICAL RESEARCH RESULTS [41] 1867

8. USEFUL WEBSITES 1867

9. FINANCIAL CONFLICTS OF INTEREST 1867

II. DEFINING THE RESEARCH QUESTIONS 1867

III. EXPERIMENTAL STUDIES 1867

1. RANDOMIZED CONTROLLED TRIALS 1867
   a) Simple randomization 1868
   b) Block randomization 1868
   c) Stratified randomization 1868
   d) Parallel Group Trials 1868
   e) Crossover Trials 1868
   f) Non-inferiority trials 1869
   g) Equivalence trials 1869
   h) Superiority trials 1869

2. NON-RANDOMIZED CONTROLLED CLINICAL TRIAL(S) 1869

3. PRAGMATIC AND EXPLANATORY TRIALS 1869

4. DRUG TRIALS ARE CATEGORIZED ACCORDING TO THE FOLLOWING DEFINITIONS [30, 50] 1870
   a) Phase I studies 1870
   b) Phase II studies 1870
   c) Phase III studies 1870
   d) Phase IV studies 1870

5. BIAS, BLINDING AND EFFECTS ON VALIDITY 1870
   a) Blinding 1870
   b) Unblinded trials 1870
   c) Single blind trial 1870
   d) Double blind trials 1871

IV. ELIGIBILITY CRITERIA 1871

V. SAMPLING STRATEGIES 1871

VI. DATA COLLECTION 1872
   a) Baseline data 1872
   b) Observations 1872
   c) Tests 1872
   d) Follow-up 1872
   e) Quality of life measures 1872
   f) Socioeconomics 1872

VII. OUTCOME MEASURES 1872

1. PRIMARY OUTCOMES 1872

2. SECONDARY OUTCOME 1873

3. TYPES OF OUTCOME MEASURES 1873

VIII. STATISTICAL CONCERNS 1874

1. SAMPLE SIZE CONSIDERATIONS 1874

2. SAMPLE SIZE CALCULATION 1874

3. THE TARGET DIFFERENCE 1875

IX. ANALYSIS 1875

X. REPORTING RESEARCH RESULTS 1877

XI. SPECIAL CONCERNS FOR SPECIFIC STUDIES 1878

1. BEHAVIORAL AND PHYSIOTHERAPY TRIALS 1878
   a) Terminology 1878
   b) Behavioral interventions 1878
   c) Lifestyle interventions 1878
   d) Physiotherapy 1878
