- Cleaning and maintenance requirements, responsible person and the burden that cleaning could represent.
- Personal preferences and aesthetics, particularly where equipment is to be used at home, and especially in ‘public’ areas of the home such as a lounge room.

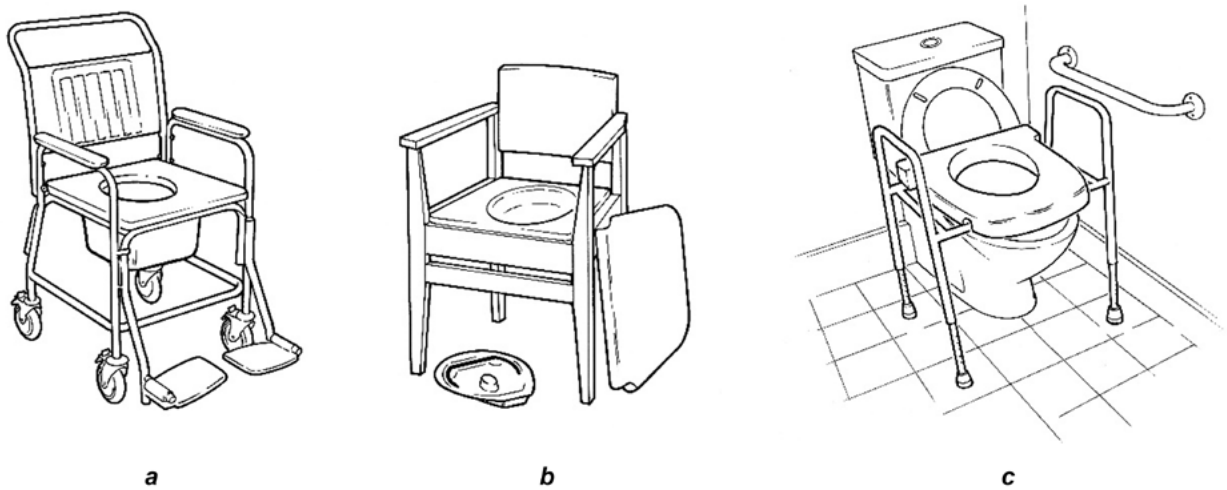

Fig E-1: Commode chair with wheels (a), chair with commode (b) and toilet frame with integral raiser and grab bar (c).

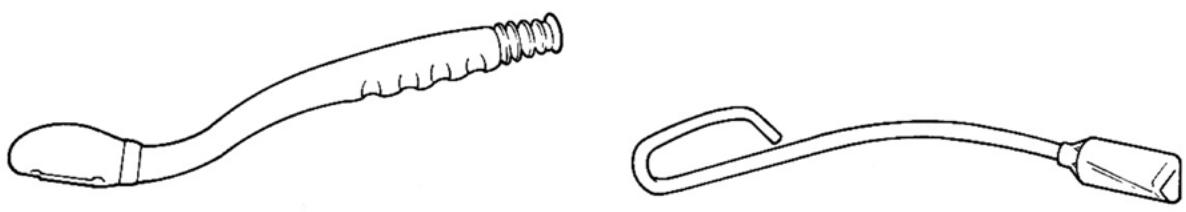

Fig E-2: Example bottom wipers.

(rounded, triangular-shaped with a flatter seat and rolled edges to provide handgrips) and shovel or 'fracture' pans (rectangular or wedge-shaped with a flattened end that is positioned beneath the individual, and with a handle at the opposite end).

Alongside issues around privacy and dignity, bedpans have other disadvantages. They do not readily permit the user to assume positions that facilitate urination or defaecation and are uncomfortable or even painful to sit on (59). Users fear missing the pan while urinating and can wait a long time for care staff to remove the pan after elimination is completed (59). Without lids, care must be taken to avoid spillage of contents when removing a bedpan from under an individual and transporting contents for disposal can be malodourous. The design of some female handheld urinals may also make them suitable (for men or women) for collecting faeces (41).

Table E-2 lists the main factors influencing the appropriateness of a commode, shower-chair or bedpan as a solution for individual needs, and Fig E-1 and Fig E-2 show examples of products in this category.

1. EVIDENCE

This review identified four studies about the design of grab bars to assist toileting (60) (61) (62) (63), one study about the design of an iToilet (64), and one study about signs used to identify the location of public toilets (65). Kennedy *et al.* (60) compared different designs and positions of grab bars installed near toilets. Using two vertical grab bars, compared to one vertical bar, a horizontal bar, a diagonal bar, or no bars, was preferred and more effective for persons who toilet independently. Vertical bars also had the lowest centre of pressure displacement during toilet transfers, decreasing the risk of falls. For those in nursing homes needing toileting assistance, grab bars that fold-down/swing-away on both sides of a toilet were preferred and required less limb muscle effort than standard grab bar configurations (61) (62).

A device named "Safe Embrace", consisting of a hinged U-shaped stainless-steel bar, has been developed to prevent falling off a toilet (63). The device is mounted behind the toilet and is pulled down over an individual's head to rest around the front of their trunk and on which they can rest their arms.

Panek (64) described a prototype design of an iToilet. The iToilet project, funded by the European Union, aims to develop an information and communication technology (ICT) enhanced modular toilet system to support the autonomy, dignity and safety of older persons living at home. The iToilet will be a motorised chair with bilateral arms/attached grab bars and adjustable height and tilt, which fits over a toilet. The iToilet controls will be available on a remote control integrated into the grab bars or by voice command (in English, German and Hungarian languages). The iToilet will contain a 3D sensor aimed at recognising and alerting falls. The iToilet's components will be modular and can be selected according to individual needs and preferences.

Signage is an important factor for identifying the location of public toilet facilities. Knowing the location of public toilets is a common self-management strategy of individuals with incontinence (66). In many cases, signs of these facilities contain graphics (icon of a man or woman) and text. An analysis of how factors such as graphics, text, and colours of the background, graphics or text of toilet signs affect recognition resulted in the hypothesis that when a sign is designed in accordance with a population's stereotypes and familiarity, reaction time to identify the sign will be shorter. (65)

Recognition of a men's or women's toilet was measured by the reaction time of Taiwanese university students and staff (50 men and 50 women) to press a key on a computer keyboard. Six levels of sign-presentation styles were randomly shown on a screen: graphics for men's and women's toilets, men's and women's toilets in Chinese text (characters), and men's and women's toilets in English letters. The sign-presentation styles had three colour levels: blue, red, or black graphics or text on a white background or white text and graphics on a coloured background.

Results showed that participants had faster reaction times for toilet signs using Chinese text rather than graphics and English text. Using non-stereotypical colours, i.e., red for men and blue for women's toilet signs, prolonged reaction times. However, when the same colours were used as the background of the sign, the reaction times remained unaffected. There were some differences by sex; for example, men required more time for identifying women's toilet signs. Using red for women's toilet signs resulted in shorter reaction times for women than when using blue.

2. SUMMARY

- A conventional or suitably adapted flush toilet is preferable to using a commode or bedpan wherever it is safely possible to do so (67) (68) (69) **(Level of Evidence 3).**
- Commodes or shower chairs (where an individual can safely use them) are preferable to bedpans. Bedpans may position users poorly to urinate or defaecate and may cause pain (59) **(Level of Evidence 3).**
- Commode (and shower chair) designs offer limited trunk support, which, combined with long periods of unsupervised use, may increase the risk of falls (68) **(Level of Evidence 3).**
- Shower chairs may be preferable to static commodes in terms of facilitating access to a toilet, preserving privacy, dignity and the management of noise and odour (67) (68) (**Level of Evidence 3)**.
- A shower-chair or commode stability must be assessed to ensure it is safe and appropriate for individual needs (34) (52) (50) (51) (48) (54) **(Level of Evidence 3).**
- Grab bars installed near toilets are used to reduce the risk of falls and facilitate transfer onto the toilet seat. Those who can toilet independently prefer bilateral vertical grab bars while those who need toileting assistance prefer bilateral fold-down grab bars compared to one grab bar or other positions (60) (61) (62) **(Level of Evidence 3).**
- A U-shaped stainless-steel bar that can be positioned in front of a person on the toilet is available to decrease the risk of falling off a toilet (63) **(Level of Evidence 4).**
- Assessment for toileting assistive devices for those with SCI should include a review of functional capacity to undertake toileting and bowel care, postural stability and transfers to and from the shower chairs/commodes, risk for pressure injuries, skin integrity, and interface pressure mapping (54) **(Level of Evidence 3).**
- Signs identifying the location of toilets using graphics, text, and colours that are familiar and normative to local users promote recognition (65) **(Level of Evidence 3).**

Table E-3: Recommendations relating to com-modes, mobile shower-chairs and bedpans.

- Privacy and dignity should be considered during toileting, including the management of associated noise and odours **(Grade of Recommendation C)**.
- Wherever safely possible, access to a conventional or adapted toilet should be considered to preserve the user's safety and modesty during transportation **(Grade of Recommendation C).**
- The use of bedpans should be minimised to the greatest extent possible without unnecessarily resorting to invasive options such as catheterisation **(Grade of Recommendation C).**
- Full and careful assessment of individual needs, including mobility, transfers, postural stability, skin integrity, access to the perianal area, and safety must be undertaken before equipment is prescribed or used, and should be followed by regular reviews to assess ongoing suitability **(Grade of Recommendation C).**
- Regardless of the equipment employed, users must have ready access to toilet paper and/or moist wipes and hand washing or sanitising supplies, and/or appropriate adaptive devices or assistance to help them when toileting **(Grade of Recommendation C)**.
- People should have safe and easy access to a direct method of calling for assistance when left alone on a toilet on any type of toileting equipment. People should be transferred off a toilet, commode, shower chair or bedpan in a timely manner after completion of elimination to reduce skin injuries and fall risk **(Grade of Recommendation C)**.
- Regular evaluation and ongoing maintenance of toileting equipment should be ensured in any environment **(Grade of Recommendation C).**

3. RECOMMENDATIONS

Recommendations relating to commodes, mobile shower-chairs and bedpans are summarised in Table E-3.

4. PRIORITIES FOR RESEARCH

- Evaluative studies of toilet seat raisers, toilet frames/surrounds, padded toilet seats, grab and support rails, bidets or personal cleansing/drying systems, bottom wipers, etc., for ease of use, the effectiveness of promoting continence, and safety.

.• Validated and standardised clinical assessment tools and outcome measures to guide the selection and determine the success of shower chairs/commodes for those with long-term needs, particularly adults with SCI (54).
- Development and testing of ICT-enhanced toileting assistive devices (64).
- Signs identifying the location of toilets should use graphics, text, and colours that are familiar and normal to local users and those following international standards to promote timely recognition (65).

F. ABSORBENT PRODUCTS

There is little new work on absorbent products to add to that discussed in the 6th consultation (36). There have been three new studies on the effective use of disposable bodyworn absorbent products for moderate-heavy incontinence (70) (71) (72) and an attempt to develop a new international standard to measure their leakage performance (73). A further study (74) compared washable pull-on pads with disposable pads for managing mild to moderate UI. Also published have been a new patient-reported outcome measure for absorbent product users (75), a new ICS standard providing recommended nomenclature for disposable bodyworn absorbent products (76), a novel method designed to measure the usability of absorbent products from caregiver's perspectives (77) and a study on the environmental impact of disposable absorbent incontinence products (78). Most significantly, Gray *et al.* (79) have published the outcomes of a project in which the US Wound, Ostomy and Continence Nurses (WOCN) Society charged a task force with creating evidence-based recommendations for assessing, selecting, using, and evaluating body-worn absorbent products for adults with urinary and/or faecal incontinence. The task force completed a scoping literature review to identify recommendations supported by adequate research to qualify as evidence-based, and then convened a panel of experts to develop consensus statements. Finally, these consensus-based statements underwent a second round of content validation using a modified Delphi technique using a different panel of clinicians with relevant expertise. The conclusions for this project have been folded into the following text.

General guidelines on patient assessment for product selection are discussed in Section B. Aspects of assessment that are particularly important regarding absorbent products are frequency / severity and time of day (day and/or night) of leakage; user's sex / gender (some products work better for some than others); ability to change products independently / need for carer assistance; product changing position (standing / lying); laundry / drying facilities available; individual priorities (e.g. need for discreetness); personal preference for design / materials (e.g. disposable versus washable designs); and lifestyle / living environment (at home / travel / work etc.). There is an international standard (ISO 15621:2017) which provides useful guidelines for evaluating absorbent incontinence products, covering these factors.

The key aspects of absorbent product performance have been identified and prioritised by interviewing men and women taking part in a series of clinical trials (25). There was notable consistency across patient groups (light / heavy incontinence, men / women), with all indicating that their top priority was - unsurprisingly -the ability of a

product to hold urine without leakage. Other important factors were: discreetness, containment of odour, the ability of a product to stay in place, comfort when wet and the ability to keep skin dry.

Since the 6th consultation (36), Yearwood-Martin et al. have developed a patient-reported outcome measure (PadPROM) to help with user evaluations of absorbent products (75), but it has yet to be used in any published studies. A novel method designed to discriminate between the usability of products from a carer perspective, evaluating product fit, workload and satisfaction has been developed in a simulated environment and requires real-world testing (77).

Incidental findings from product evaluations indicate that, although it is almost always an important factor, absorption capacity alone does not determine whether a user will choose to use a product. Some users may have frequent, small volume, low flow-rate losses of urine ("dribble"), whilst others may be dry for days but then have a higher volume, higher flow-rate incident ("gush" or "flooding"). Both may prefer to use products intended for light incontinence. Mobile and independent community-dwelling women with all levels of incontinence are reported to generally prefer small products, and they are often willing to change them frequently rather than use larger products and change them less often (80). Conversely, dependent, immobile individuals may prefer the security of larger products despite relatively low volumes of urine loss due to their dependence on others for product changing.

The mass of urine in an individual wearer's products can vary enormously, and studies that have collected and weighed used products have found overlap between the quantities recorded for different sub-groups of users. For example, in a study of absorbent products for moderate-heavy incontinence used by older people in residential care, around 15% of weighed products had less than 100g of urine in them, even though it was usually much more (81) while, in a study of older women with light incontinence living in the community, about 10% of used products had more than 100g of urine in them, even though it was usually much less (82).

Although the number of products used per day might be a good measure of the degree of urinary incontinence, this has not been found to be the case in nursing home residents in Norway (28). Absorbent products (of unspecified design) used by residents in six homes were collected and weighed, and a poor correlation was found between the number of products used over 48 hours and the total mass of urine in them. Caregivers tending to change products at routine times was the likely explanation.

Some studies have focused on the use of absorbent products by men. Teunnissen and Lagro-Jansson (83) interviewed 56 men with UI of which only nine used absorbent products. They concluded that men use them less frequently than women, have little knowledge about purpose-built products, are more likely to construct their products out of absorbent materials such as towels, and are less satisfied with absorbent products than women. Furthermore, men may prefer other available devices such as urinary sheaths (84) (Section G).

However, the findings of these studies about male and female product use and preferences may not be generalisable to all countries and cultures. In some countries, only limited ranges of absorbent products are available (predominantly all-in-ones), with products for light incontinence less frequently available. Since the sixth consultation (36), Teerawattananon et al. have reported a significant improvement in health-related quality of life and independence in activities of daily living when patients with chronic UI or FI in two Thai rehabilitation centres were provided with an adequate supply of disposable all-in-ones, having previously used not more than two per week (72).

All-in-ones are widely sold in supermarkets, prominently displayed, and may be viewed with less embarrassment than in countries supplied primarily through healthcare systems or pharmacies. In comparison, sheath systems may be harder to access and relatively more expensive. Climate (and consequently customary mode of dress) can affect the acceptability of sheaths and their attendant drainage bags.

1. ABSORBENT PRODUCT CATEGORIES

Most absorbent products are bodyworn but some (underpads) are designed to be placed beneath the user, and products in either category may be disposable (discarded after a single use) or washable (laundered and reused multiple times). Although each category encompasses many brands, all products fall into one of just a small number of generic designs (Table F-1), which further divide into those intended for men, women (or both) or children. However, the names used to describe these generic designs can vary considerably among - and even within – countries and cultures, and there is a confusing plethora of synonyms in use in the clinical and academic literature and in the information provided by product suppliers. This makes it difficult to review the literature and draw on it for advice on selecting products and using them effectively.

Since the 6th consultation (36), the International Continence Society has begun addressing this problem by publishing consensus-based recommendations for nomenclature relating to disposable bodyworn absorbent products (76), and its recommendations have been used in the classification that follows. Similar guidance is not yet available for underpads or for washable products of any design, but the nomenclature used below has been chosen for consistency with the ICS guidelines for disposable bodyworns where possible. The International Standards Organisation is also working on nomenclature for absorbent products, but its findings are not yet available.

Bodyworn absorbent products for UI fall into the seven design groups shown in Table F-1 and Figs F-1 to F-11, each having the defining and main variant features described in Tables F-2 to F-8. Products come in a wide range of absorbencies for managing light through to very heavy UI, but it is useful to divide them into two main sub-groups: those intended for light UI (usually smaller products) and those for moderate-heavy losses (usually larger products). Furthermore, designs relying on a close fit around the wearer's body are often supplied in a range of sizes to fit, for example, small, medium or large users. It does not necessarily follow, however, that a product designed to fit a large body has a higher absorbency than one intended for a small person.

Table F-1: Classification of absorbent products for incontinence. Terms in brackets are acceptable alter-natives to the preferred (unbracketed) terms. (76).

Design categories:	Bodyworns	Underpads
Design groups	Pads Unbacked pads Male pads Male pouches Pull-on pads (Protective underwear) All-in-ones (Wrap-around pads, Adult briefs) Belted pads (Belted products)	Bed pads Chair pads

Table F-2: The defining features and main variant features of pads (See Figs F-1 to F-4)

Defining features	A waterproof-backed absorbent product that is held in place using separate, close-fitting (regular or specially designed) underwear.
Main variant features	• Products may be disposable or reusable. • Products may be used by either sex, but some are intended (by their colour, style, shape, or the placing of absorbent material, for example) just for men or just for women. Some variants are intended for children. • Products come with different absorption capacities. • Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit, comfort and prevent leakage. • Disposable variants may have an adhesive strip on the back or adhesive wings to the sides to help secure them in underwear; Washable variants may have hook-and-loop patches or other means of securing. • Disposable variants may have a wetness indicator. • Products may or may not be suitable for containing FI as well as UI.

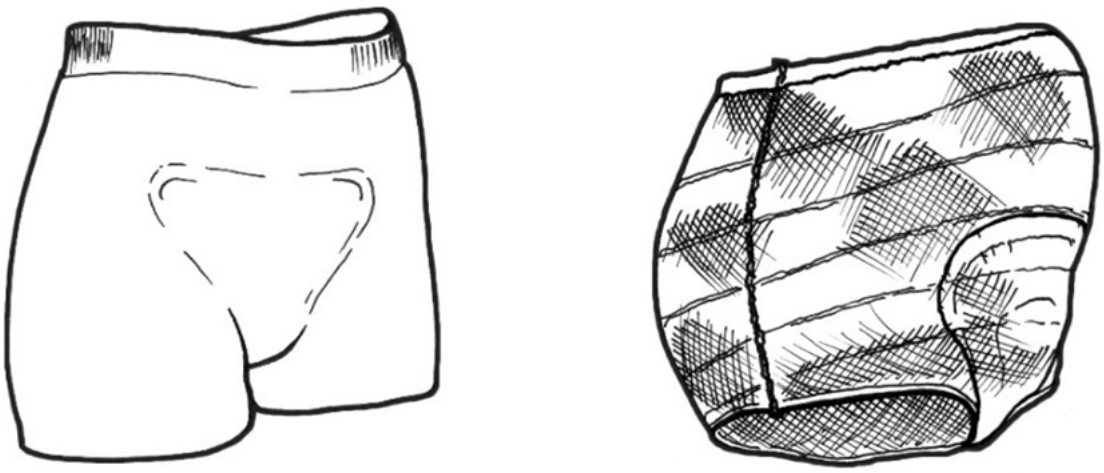

Fig F-1: Mesh briefs with (a) and without (b) legs for supporting disposable bodyworn pads.

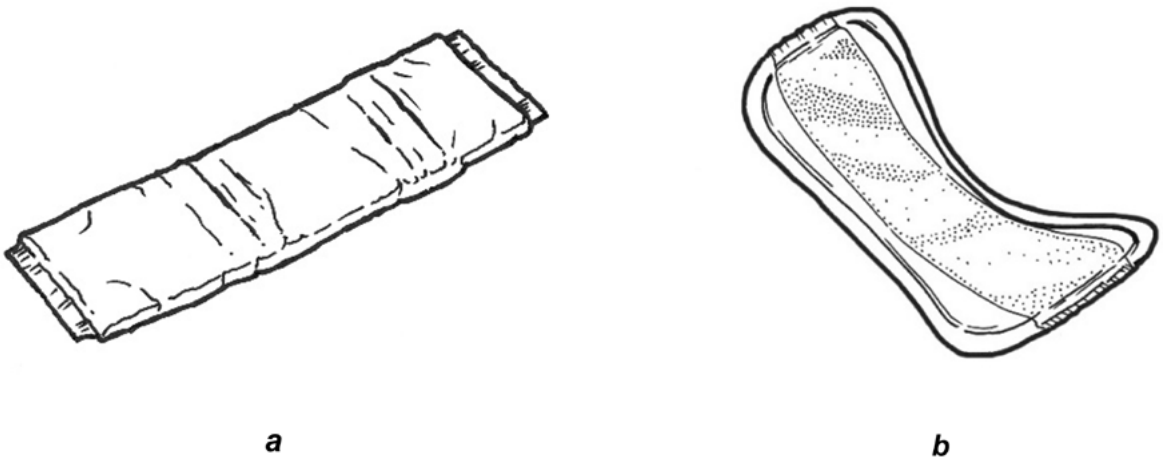

Fig F-2: Small, disposable, unshaped (a) and shaped (b) insert pads for light incontinence.

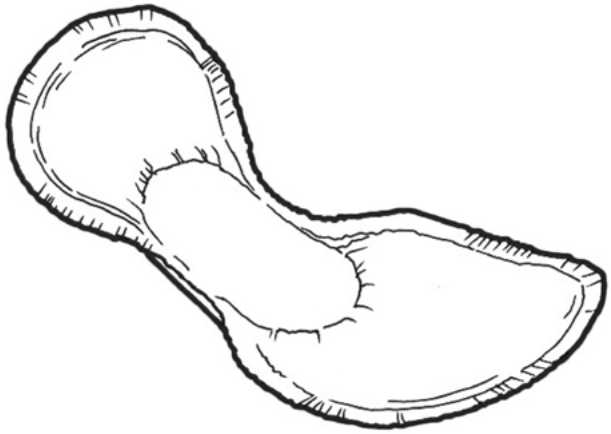

Fig F-3: Large, disposable, shaped insert pads for moderate / heavy incontinence.

Table F-3: The defining features and main variant features of unbacked pads. (Unbacked pads are simi-lar in appearance to those shown in Fig F-2, but without the waterproof backing.)

Defining features	An absorbent product without a waterproof backing used either (i) inside another product such as a category 6 product to supplement its absorption capacity or to reduce the frequency with which it needs to be changed (the unbacked pad may be changed with relative ease, without necessarily needing to also change the outer product), or (ii) on its own, secured using separate, close-fitting, underwear which itself includes waterproofing in the pad area.
Main variant features	• Products may be used by either sex. • Products may be rectangular or contoured to better fit the wearer. • Products come with different absorption capacities. • Products may or may not be suitable for containing FI as well as UI.

Table F-4: The defining features and main variant features of male pads. (See Fig F-6b)

Defining features	A waterproof-backed absorbent product for men that is designed to cover the penis and scrotum and is held in place using separate, close-fitting (regular or specially designed) underwear.
Main variant features	• Products come with different absorption capacities. • Longitudinal elastic side barriers and leg cuffs at the sides may be included to im-prove fit and comfort and prevent leakage. • Products may have an adhesive strip on the back to help secure them in underwear

Table F-5: The defining features and main variant features of male pouches. (See Fig F-6a)

Defining features	A waterproof-backed absorbent product for men, fashioned into a pocket into which the penis, and sometimes the scro-tumis placed. They are held in place using separate, close-fitting (regular or specially designed) underwear.
Main variant features	• Products come with different absorption capacities. • Products may have an adhesive strip on the back to help secure them in underwear. • Products may have a hook and loop fastening system or adhesive tape to secure the product around the penis

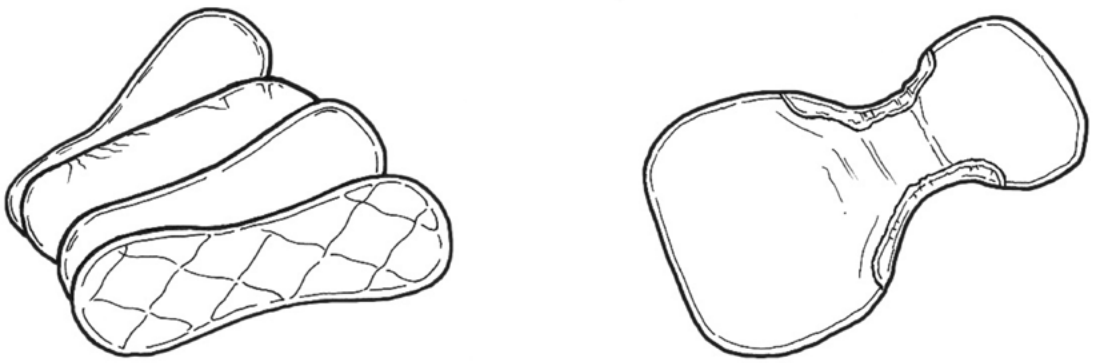

Fig F-4: Washable, shaped insert pads for light (a) and moderate / heavy (b) incontinence.

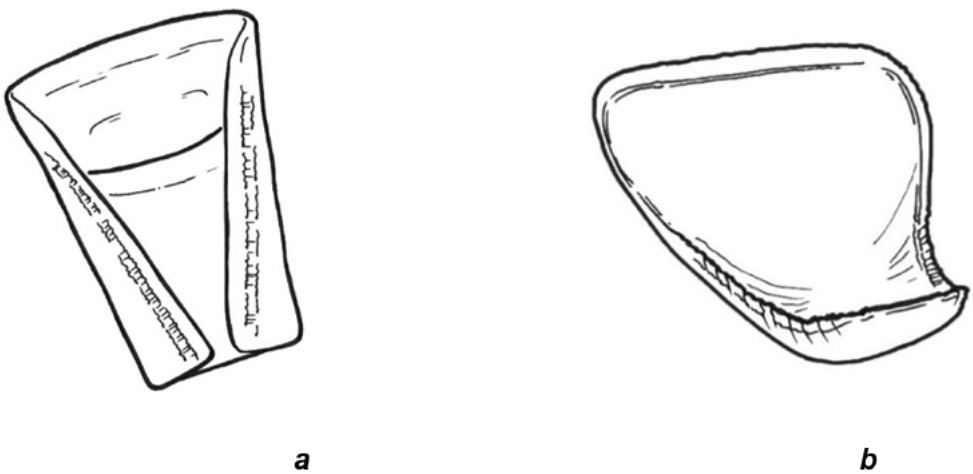

Fig F-5: (a) A male pouch and (b) and a male pad. Both come in disposable and washable variants.

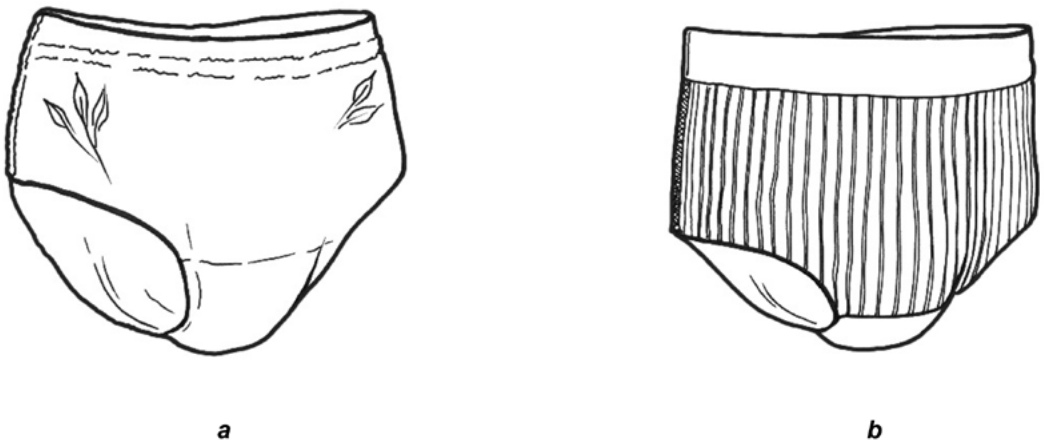
Table F-6: The defining features and main variant features of pull-on pads (protective underwear).

Defining features	A product in which the absorbent core, waterproof backing and the means to hold it in place are combined in a single design resembling regular underwear. Elastic linings around the waist and hips help give a close fit.
Main variant features	• Products may be used by either sex, but some are intended (by their colour, style or the placing of absorbent material, for example) just for men or just for women. • Products come with different absorption capacities and to fit different body sizes. • Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be in-cluded to improve fit and comfort and prevent leakage. • In some designs, side seams can be torn away for easy removal. • Products may have wetness indicators. • Products may or may not be suitable for containing FI as well as UI.



a *b*

Fig F-6: Disposable pull-on pads for moderate / heavy incontinence for women (a), and for men (b).

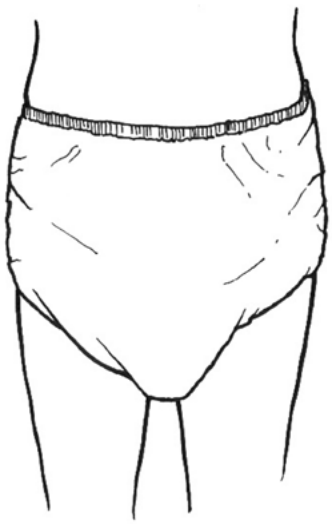


Fig F-7: Washable pull-on pads for moderate / heavy incontinence (unisex).

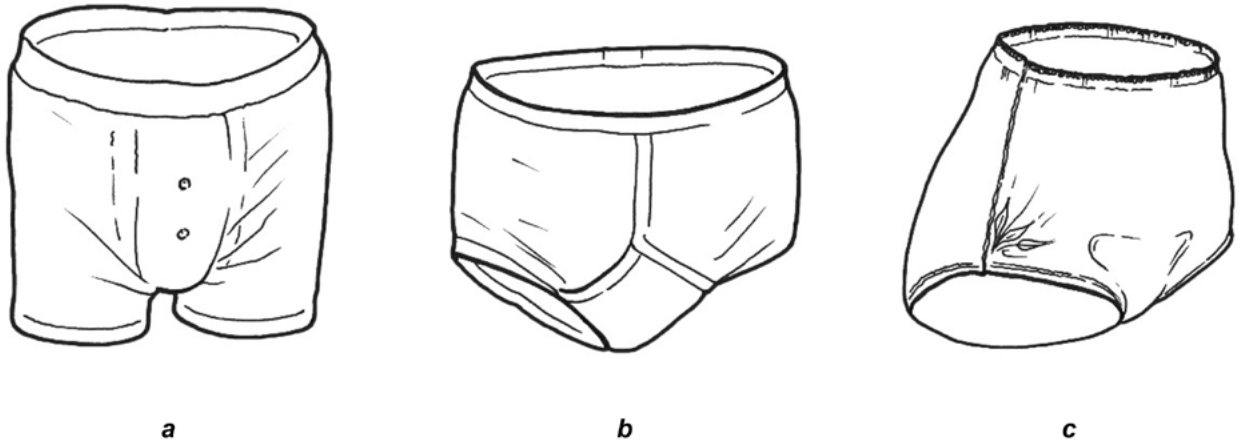

Fig F-8: Washable pull-on pads for light incontinence: boxer style for men (a), y-front style for men (b), and for women (c).

Table F-7: The defining features and main variant features of all-in-ones (wrap-around pads, adult briefs).

Defining features	A one-piece product in which the absorbent core and the means to hold it in place are combined in a single design, secured using adjustable adhesive tabs or a hook and loop fastening system at the sides.
Main variant features	• Products may be used by either sex, but some are intended (by their colour, style, or the placing of absorbent material, for example) just for men or just for women. • Products come with different absorption capacities and to fit different body sizes. • Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be in-cluded to improve fit and comfort and prevent leakage. • Products may have wetness indicators. • Products may or may not be suitable for containing FI as well as UI.

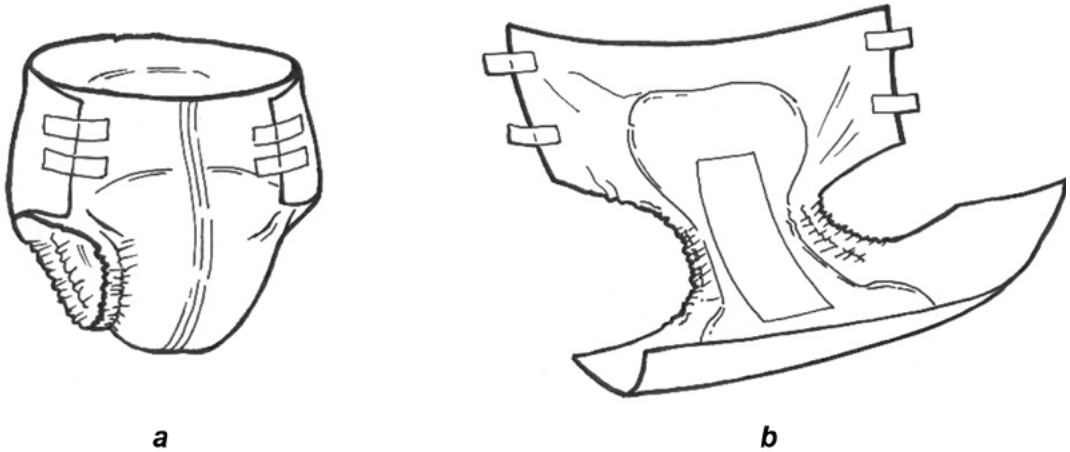

Fig F-9: Disposable all-in-ones, closed (a) and open (b).

Fig F-10: Washable all-in-ones.

Table F-8: The defining features and main variant features of belted pads (belted products).

Defining features	A one-piece product in which the absorbent core, waterproof backing, and the means to hold it in place are combined in a single design, secured by means of an adjustable belt with adhesive tabs or a hook and loop fastening system.
Main variant features	• Products may be used by either sex, but some are intended (by their colour, style or the placing of absorbent material, for example) just for men or just for women. • Products come with different absorption capacities and to fit different body sizes. • Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be in-cluded to improve fit and comfort and prevent leakage. • Products may have wetness indicators. • Products may or may not be suitable for containing FI as well as UI.

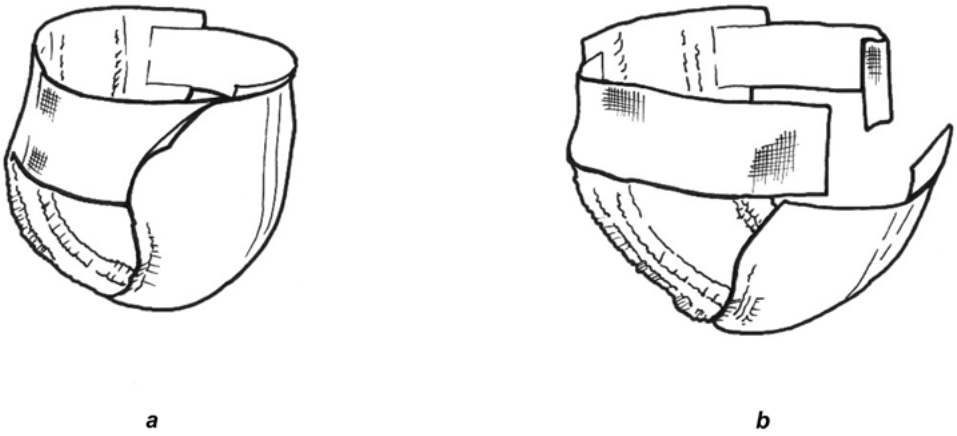

Fig F-11: Disposable belted, closed (a) and open b)

Very few products are designed specifically to contain faeces, but those intended (primarily) for UI are commonly used to manage FI, too.

Sometimes people make their own products, typically folding terry-towelling squares into briefs, fastening with pins and using plastic pants as a waterproof barrier. Such pants may also be worn over more conventional designs in an attempt to reduce leakage and / or odour.

“Body” garments (like vests which have a crotch section that opens and closes with snap fasteners, much like those manufactured for babies) may be useful to help hold products in place and may reduce any rustling noise from the plastic backing material on absorbent products.

Underpads are usually simple rectangles of different sizes to be used on the bed (bed pads) or chair (chair pads). Washable underpads may have a high friction backing or – with bed pads - have ‘wings’ for tucking beneath the mattress to help keep them in place. Underpads vary widely in absorbency, with less absorbent products being used as ‘back-up’ along with bodyworn products and more absorbent bed pad variants being used as sole protection on the bed at night.

Availability of products will necessarily affect choice. However, even where only a single product type (e.g. all-in-ones) is readily available, within that product type, particular brands and / or absorbencies may work better for some users or circumstances than others. Clinicians and users are likely to manage incontinence more successfully if they familiarise themselves with the advantages and limitations of different designs and brands. For example, cheaper products may be less reliable but adequate for use at home when more frequent changing is possible. Conversely, the high priority of achieving reliable protection when away from home may justify using more expensive products then. Similarly, more absorbent products intended for night-time use may provide extra valued security during the day when travelling.

2. ABSORBENT PRODUCT MATERIALS

Absorbent products – disposable or washable – usually comprise three main layers: an absorbent core sandwiched between a waterproof backsheet beneath and a water-permeable topsheet next to the wearer’s skin.

The main component in disposable absorbent cores is invariably fluffed wood pulp, but most also contain powdered superabsorbent polymer, usually concentrated in the crotch region where it is most likely to get wet. Superabsorbent polymers hold much more urine – weight for weight – than fluffed wood pulp and retain it far more tenaciously under pressure. They are usually based on cross-linked salts of polyacrylic acid whose chemistry can be varied according to the balance of properties such as absorption capacity and absorption speed desired. It is increasingly common for absorbent cores to comprise two or more layers, each designed to perform a different function. For example, an upper layer might comprise low absorbency fibres engineered to receive and distribute urine efficiently and maintain a dry layer next to the skin, while lower layers provide absorption capacity. Some disposable products have ‘breathable’ plastic backings designed to reduce skin occlusion.

The absorbent core of washable bodyworn products is usually made from cotton terry-towelling or from a needlefelt or knitted fabric comprising rayon and / or polyester fibres. A variety of polymers are used for waterproofing. In general, the thicker, stiffer materials are more durable (the durability of the plastic backing often determines the lifetime of the product) but less comfortable. Topsheets are usually made from either cotton – which is hydrophilic and intended to have good dry comfort – or polyester – which is hydrophobic and intended to have good wet comfort. Traditional, washable fabric squares – folded into shape and secured using waterproof pants – are usually made from cotton terry-towelling.

Concern for the environment and for controlling costs has led to an increase in the number of washable products available on the market. An important consideration in the comparison of washable and disposable designs is their relative environmental impacts. Since the 6th consultation (36), Willskytt & Tillman (78) have published a useful case study on the environmental costs associated with absorbent incontinence products. They identified a number of ways to reduce environmental impact through more efficient use of resource materials, reuse of some product components, and effective recycling and quantified the potential gains.

3. ABSORBENT PRODUCT CAPACITY AND USER REQUIREMENTS

Absorbent products come in a range of absorbencies for different levels of incontinence, and understandably purchasers wish to know how much urine they will hold. However, there is no simple answer: no product has a simple absorption capacity; that is, a volume of urine below which it is guaranteed not to leak. Rather, the probability of a product not leaking decreases as the urine volume increases. The mark of a more absorbent product is that – for a given urine volume – it is less likely to leak than a less absorbent alternative.

This is a complex concept to communicate in sales literature and product packaging and so companies commonly quote a simple absorption capacity figure, even though it is based on a misconception. Some use the volume of fluid a product will hold in a laboratory test - usually international standard ISO 11948-1 (78) - but this figure can be very misleading. Although it correlates well with leakage performance for some groups of users), the volume of urine that a product will hold when tested with ISO 11948-1 is enormous compared with how much it will hold in real use. For this reason, some companies prefer to quote a “working capacity”, which might be calculated as some proportion of its capacity under laboratory test. However, this is still misleading as it implies that the product will not leak until the working capacity is exceeded. A simple, valid and widely accepted solution to this problem has yet to be devised.

It is equally difficult to determine user needs concerning the volume of urine their products need to hold. Not only can different users leak widely differing volumes from each other, but an individual user may also leak widely differing volumes on different occasions. This means that, like product performance, users’ needs cannot be easily quantified. For the purposes of this review, the evidence is divided into that relating to light UI and that relating to moderate-heavy UI. Published data describing users as ‘lightly incontinent’ place the median and 90th percentile urine volumes in their used products at around 15ml and 100ml, respectively (85). Similarly, those with

Table F-9 Bodyworn absorbent products for women with light urinary incontinence

	Disposable	Washable
Design groups	Inserts (Fig F-2)	Inserts (Fig F-4a)
	Pull-ups i.e., pants with integral pad	Pull-ups i.e., pants with integral pad (Fig F-8c)
	Menstrual pads	

moderate-heavy UI have yielded corresponding figures of about 250ml and 600ml (85).

4. BODYWORN ABSORBENT PRODUCTS FOR WOMEN WITH LIGHT URINARY INCONTINENCE

There are four main product designs for women with light incontinence (Table F-9). In addition, menstrual pads are known to be frequently used for light urinary incontinence. The disposable pull-ups are relatively expensive, single-use items and seldom-used for light incontinence except as 'emergency' items. Underpads are not commonly used for light incontinence.

4.1. Evidence

A small number of robust comparative evaluations and one Cochrane review of absorbent products for women with light incontinence have been published, (86). Most studies are now rather old (2004 or earlier) and relate to products no longer available (22) (24) (87) (88). There has been one published study of pads for women with light incontinence since the 6th consultation (36) and that compared a disposable pad with a washable pull-on pad (74).

In the most recent substantial study (2008), Fader *et al.* (85) used a crossover randomised design to compare the most common product designs: disposable pads, menstrual pads, washable pull-on pads, and washable pads for women with light UI. Three product brands were selected to represent each design, and each brand was tested for one week (three weeks for each design block, a total of 12 weeks). Product performance was characterised using a validated questionnaire to evaluate product performance (leakage, discreetness etc.) with a five-point scale (very good – very poor) at the end of each week of product testing. A product change and leakage diary were used to record the severity of leakage from products (three-point scale: a lot, a little, or no leakage), and numbers of laundry items and products used were recorded to estimate costs. Skin health changes were recorded weekly. At a final interview, preferences were ranked (with and without costs), acceptability of the design recorded (highly acceptable – totally unacceptable) and overall opinion marked on a visual analogue scale (VAS) of 0-100 points (worst design – best design). The VAS score was used to estimate cost-effectiveness.

Eighty-five women (mean age 60) completed the study and 8691 used pads were weighed. The disposable pad was significantly better than the other designs on most variables except for discreetness. For leakage prevention, overall acceptability and preference, disposable pads were significantly better than menstrual pads, which were better than washable pull-on pads, which were better than washable pads. There was no clear benefit for skin health using either washable or disposable designs. Most women preferred the disposable pads but some preferred the other cheaper designs (6/85 preferred menstrual pads; 13/85 preferred washable pull-on pads, both of which were >50% cheaper to use than disposable pads). Washable pads were significantly worse than the other designs (72/85 found them unacceptable). Overall, there were generally more practical problems with washables, particularly when away from home (Level of Evidence 1).

The authors concluded that allowing women to choose their preferred product design (or different designs for different circumstances) would be more cost-effective and provide better patient satisfaction than the provision of disposable pads (the most expensive product) alone.

More recently, in a controlled cross over trial, Alam and colleagues (74) asked 70 women with mild to moderate urinary incontinence (defined as a response of "small" or "moderate" amount to the ICIQ-SF question "How much do you leak?" (89) to compare a disposable pad with a washable pull-on pad. Each woman used each of the products for a period of two days. Outcome measures were responses to the I-QOL Incontinence Quality of Life Instrument (90) and a product performance questionnaire for each product. Fifty-two women completed the study. There was no significant difference between the two products for I-QOL total scores or I-QOL sub scores concerning avoidance and limiting behaviours, psychosocial impacts or social embarrassment. However, the washable product scored significantly better on the product performance questionnaire regarding the overall impression, discreteness, comfort when dry, comfort when wet, ability to keep skin dry, and kindness to skin. There was no difference between the products in their ability to hold urine without leaking.

4.2. Summary

- Disposable pads are generally more effective in terms of leakage and more acceptable than menstrual pads, washable pull-on pads, and washable pads **(Level of Evidence 1)**.
- Menstrual pads are cheaper and washable pull-on pads cheaper still (on a per-use basis) than disposable pads and they are acceptable to many, particularly those with lighter incontinence and particularly when used at home. They may also be more readily available in some regions than disposable pads designed specifically for incontinence. **(Level of Evidence 1).**
- Washable pads are not acceptable to most women with light urinary incontinence. (**Level of Evidence 1)**.

4.3. Recommendations

Recommendations relating to bodyworn absorbent products for women with light urinary incontinence are listed in Table F-10, while Table F-11 describes the user characteristics, priorities and contexts which favour or discourage the use of the different product designs.

Table F-10: Recommendations relating to body-worn absorbent products for women with light urinary incontinence.

- Disposable pads should be recommended as the most effective and preferred absorbent product for women with light UI **(Grade of Recommendation B).**
- Menstrual pads or washable pull-on pads may be considered sufficient for some patients with very light urinary in-continence and are cheaper **(Grade of Recommendation B).**
- Washable pads are not recommended for women with light UI **(Grade of Rec-ommendation B).**
- Combinations / mixes of designs for different situations (e.g. disposable pads for going out, washable pull-on pads for staying at home) are likely to provide optimum management in terms of patient needs and cost-effectiveness, and product advice and provision (where purchased by institutions / services) should reflect this **(Grade of Recom-mendation B).**

See also the general recommendations relating to absorbent product selection in Table F-20 and to washable products in Table F-21.

4.4. Priorities for research

- Because the performance of washables is generally poor (particularly for leakage) compared to disposables, the development of better washable products for women with light urinary incontinence is a priority.
- The strategy of women using different designs for different situations (e.g., when at home, away, at work) needs to be evaluated.

5. BODYWORN ABSORBENT PRODUCTS FOR MEN WITH LIGHT URINARY INCONTINENCE

There are five main bodyworn absorbent product designs for men with light UI (Table F-12). However, disposable and washable pads are often unappealing to men as they are frequently marketed as specifically for women and bear a strong resemblance to menstrual pads. Anatomical differences are also likely to mean that they are less effective for men. Male pouches and male pads (Fig F-5) are designed to be more suitable for men by containing or covering the penis.

5.1. Evidence

Only one randomised trial evaluating absorbent products for men with light UI has been published (91). Six male pouches (all disposable), six male pads (5 disposable, 1 washable), one unisex disposable pad, and one washable pull-on pad were chosen to represent the four main designs available in the UK in 2003 and evaluated. Seventy men with light UI completed the study, evaluating each product for a week in turn and recording their views with product performance questionnaires, both after testing each product and having tested all the products in a given design category. They also filled out product leakage diaries and saved used

Table F-11: User characteristics, priorities and contexts which favour or discourage the use of the dif-ferent bodyworn absorbent product designs for females with light UI.

Product Type	More likely to suit you if...	Less likely to suit you if...
Disposable pads	• You are most concerned about reliably containing.	• Low cost is a priority for you. • Discretion is a priority for you.
Menstrual pads	• Low cost is a priority for you.	• Your leakage is at the heavier end of light leakage.
Washable pull-on pads	• Low cost is a priority for you • Your leakage is very light.	• You do not have adequate laundry facilities. • You are unwilling to use washable products. • You are not prepared to carry used products when out. • Your leakage is at the heavier end of light leakage.
Washable pads	• Low cost is a priority for you. • Your leakage is very light.	• You do not have adequate laundry facilities. • You are unwilling to use washable products. • You are not prepared to carry used products when out. • Your leakage is at the heavier end of light leakage.
NB The content of this table is based on the referenced evidence cited in the chapter, but the unrefer-enced version provided for the lay public on the accompanying website (www.continenceproductadvisor.org) is reproduced here.		

products for weighing. 'Overall opinion' was used as the primary outcome variable.

Results showed:

- The performance of male pouch designs was significantly worse than that of the male pad and unisex pad designs. The most common problems with male pouches were staying in place and difficulties re-inserting the penis in it once it was wet.
- The unisex disposable pad was effective at containing leakage and was substantially cheaper than the male pad designs.
- Male pads had the best leakage scores, but one product was significantly better than the others. It was leaf-shaped (approximately triangular and slightly elasticated along two edges to give shaping / cupping).
- The washable male pad was less successful than the five disposable male pads.
- The washable pull-on pad attracted polarised overall opinion scores (loved or hated). It scored well for staying place but poorly for leakage.

In a later trial (92) the performance of three continence devices (sheath drainage system, body-worn urinal (BWU), penile clamp) and disposable absorbent products was assessed by 56 men with persistent UI (>1 year) post radical prostatectomy. Each product was tested for three weeks. The results for the non-absorbent products are reported in other sections (G, I and K). Absorbent products were judged to be good for everyday activities and best for night-time use, most easy to use, comfortable when dry but most likely to leak and most uncomfortable when wet. However, there was a preference for having a mixture of products to meet daytime needs; around two-thirds of the men elected to use different products in different contexts. They reported that absorbent products and other

Table F-12: Bodyworn absorbent products for men with light urinary incontinence

	Disposable	**Washable**

	Male pouches (Fig F-5a)	Male pouch (Fig 5a)
		Pull-up pads (Fig F-8a & F-8b)

Table F-13: Recommendations relating to bodyworn absorbent products for men with light UI.

- **Disposable male pads (especially leaf-shaped) are recommended as the most acceptable and effective design for men with light incontinence, but some men prefer other designs which should be considered as alternatives (Grade of Recommendation B).**
- **Simple unisex pads are cheaper and may be acceptable to some men with light UI (Grade of Recommendation B).**
- **Washable pull-on pads are likely to be most suitable for men with very light incontinence who have difficulties keeping a (male) pad or male pouch in place (Grade of Recommendation B).**
- **Disposable absorbent products- as opposed to male devices - are recommended for night-time users with post-prostatectomy incontinence (Grade of Recommendation B).**

See also the general recommendations relating to absorbent product selection in Table F-20 and to washable absorbent products in Table F-21.

Table F-14: User characteristics, priorities and contexts which favour or discourage the use of the dif-ferent absorbent product designs for males with light UI.

Product Type	**More likely to suit you if...**	**Less likely to suit you if...**
Disposable male pouches	• Discretion is a priority for you • Using a specifically male product is important to you.	• You have penile retraction. • Your leakage is at the heavier end of light leakage.
Disposable male pads	• Actually, they suit most men.	
Unisex disposable pads	• Low cost is a priority for you. • You are happy to use a unisex product.	
Washable pull-on pads	• Your leakage is very light. • Low cost is a priority for you. • You are mobile and active.	• You do not have adequate laundry facilities. • You are unwilling to use washable products. • You are not prepared to carry used products when out. • Your leakage is at the heavier end of light leakage.
NB The content of this table is based on the referenced evidence cited in the chapter, but the unreferenced version provided for the lay public on the accompanying website (www.continenceproductadvisor.org) is reproduced here.		

devices have different strengths and limitations which suit them to different circumstances and activities.

5.2. Recommendations

Recommendations relating to bodyworn absorbent products for men with light UI are listed in Table F-13, while Table F-14 describes the user characteristics, priorities and contexts that favour or discourage the use of the different product designs.

5.3. Priorities for research

Although the performance of washable products was generally poor (particularly for leakage) compared to disposables, some men would like to use washables. The development of better washable products is, therefore, a priority for men with light UI.

6. BODYWORN ABSORBENT PRODUCTS FOR MEN AND WOMEN WITH MODERATE-HEAVY URINARY INCONTINENCE

There are at least 12 absorbent product designs for men and women with moderate-heavy UI (Table F-15). Most bodyworn products are disposable but washable variants of most designs are available, too.

Disposable and washable bed pads and chair pads may be used as sole protection or as “back up” to a bodyworn product (See Sections F7 and F8).

6.1. Evidence

Although reported in the 5th International Consultation (92) two clinical studies of absorbent products for moderate-heavy incontinence conducted by Fader *et al.* (85) - one community based, the other in nursing homes - remain the most recent studies of reasonable size. In the community-based trial, 85 moderate / heavily incontinent adults (urinary or urinary / faecal) living in their own homes (49 men and 36 women) were enrolled and tested three (or two) products from each of five design categories (total of 14 test products): disposable pads (with mesh pants); disposable all-in-ones; disposable pull-on pads; disposable belted pads; and washable products (variety of bodyworn designs). All products were provided in a daytime and a (mostly more absorbent) night-time variant. Products were selected based on having similar scores for absorbency across the designs (Rothwell scores (93), see section F6) and performance data from pilot studies. In the nursing-home-based trial, 100 moderate / heavily incontinent adults (UI or UI and FI) living in a total of 10 nursing homes (27 men and 73 women) evaluated one product from each of the four disposable design categories above. Products were selected on the basis of their performance in the community-based trial and again, day and night-time variants were provided.

Product performance was characterised using validated questionnaires that asked the participants or carers to evaluate product performance (leakage, ease of putting on, discreetness etc.) using a five-point scale (very good – very poor) at the end of each test period. Used products were individually weighed and the perceived severity of leakage from them was recorded on a three-point scale (none, a little, a lot). The numbers of laundry items and products used were recorded to estimate costs, and skin health changes were recorded by the participant or by the researchers. At the end of testing, participants (or their carers) were interviewed and asked to rank their preferences (with and without costs), state the acceptability of each design (highly acceptable – totally unacceptable) and record their overall opinion on a visual analogue scale (VAS) of 0-100 points (worst – best design). A product changing experiment was conducted with 12 women from the nursing home based trial to determine any differences between product designs. Under idealised conditions, products of the different designs were applied (by the same carers) in random order for each patient, and product change times were recorded with a stopwatch.

Results (Community):

- Disposable pads had worse leakage performance than the other disposable designs for day and night use.
- Disposable pull-on pads were preferred over disposable pads for the daytime.
- Disposable belted pads were not better overall than traditional all-in-ones.
- Performance and preference findings differed between men and women, probably due - in part – to the larger leakage volumes experienced by the men.
- Disposable pull-on pads (the most expensive design) were better overall than the other designs for women during the day or night
- Disposable all-in-ones were better for leakage than disposable pads (the cheapest), but women did not prefer them; for men, disposable all-in-one pads were better, both overall and for leakage and were the most cost-effective design.
- A washable product with a felt absorbent core and an integral plastic backing fixed by poppers performed significantly worse for leakage than the other two washables and was not included with them in the analysis comparing designs.
- Washable cotton terry-toweling (2 designs): one, a simple square, folded and pinned in an all-in-one shape and, the other, an all-in-one-like design (both worn with plastic pants) were better for leakage at night than the disposable designs but were less popular overall for daytime use. Only 25% of women found them acceptable, but over 60% of men found them highly acceptable at night.

Table F-15: Absorbent products for adults with moderate-heavy UI

	Disposable (single use)		**Washable (reusable)**	
Type	Bodyworns	Underpads	Bodyworns	Underpads
Design groups	Pads (Figs F-1 and F-3) All-in-ones (Fig F-9) Belted pads (Fig F-11) Pull-on pads (Fig F-9)	Bed pads Chair pads	Pads (Figs F-1 and F-4a) All-in-ones (Fig F-10) Belted pads Pull-on pads (Fig F-7)	Bed pads Chair pads

- There were many practical problems dealing with washable products, particularly when out of the house. But they were more acceptable at home.
- No firm conclusions could be drawn about the performance of designs for faecal incontinence, and there was no firm evidence that there were differences in skin health problems between designs **(Level of Evidence 1).**

Results (Nursing home):
- Disposable belted pads were not easier or quicker to change than disposable all-in-ones.
- Carers found disposable pull-on pads and disposable pads significantly easier and quicker to apply than the other designs (in the standing position).
- The ability to stand was associated with the carer preference for disposable pull-on pads or disposable pads.
- Various older studies (2004 or older) have involved user trials of washable bodyworn products alone (94); disposable bodyworn products alone (95) (96); comparisons between disposable and washable bodyworn products (97) (98) (99) (100) (101) (102) (103) (104) (105); or between disposable and washable bed pads and bodyworns (27) (106) (107). The results from these studies are of limited value because of the many new products that have superseded them, but they do yield useful insights that apply to generic designs.

In 2014 Fader *et al.* published a study that used a "shopping experiment" to investigate the preferences of community-dwelling UK women and men with moderate-to-heavy urinary incontinence for four different designs of disposable absorbent products (pads, all-in-ones, belted pads and pull-on pads) and towelling washable / reusable products, day and night (108). Participants tested each design and selected products they would prefer, given a range of different budgets. Disposable pads (the design most frequently supplied by the UK National Health Service) were ranked second to disposable pull-on pads by women and lowest by men. When faced with budget constraints, up to 40% of participants opted for 'mix-and-match designs. Over 15 different combinations of products were selected by participants in this shopping experiment. Most (91%) stated a willingness to 'top-up' assigned budgets from their own income to secure preferred designs. Participants displayed diverse preferences, and Fader *et al.* concluded that enabling user choice of absorbent product design through individual budgets could improve the satisfaction of consumers and efficiency of allocation of limited resources.

In new studies since the 6th consultation (36), Bitencourt and colleagues (70) and Fernando and Wagg (109) investigated the use of disposable absorbent products by hospitalised adults. In a study aimed at discovering the reasons why patients were using absorbent incontinence products at all (disposable all-in-ones), Bitencourt *et al.* (70) recruited 105 adults (61% female, 39% male; 52% aged 20-60, 48% over 60) from surgical wards in a Brazilian hospital. They found that only 15% of patients had UI or diarrhoea. For a further 38%, there was no recorded reason for wearing absorbent products, while mobility impairment and / or cognitive impairment were the declared reasons for the balance. The authors proposed the adoption of an "Evaluation Scale for Diapers Use in Adults" to assist care staff in determining when the use of absorbent products was appropriate, and to monitor their use.

Fernando and Wagg (109) set out to establish the views of wearers and carers on acceptable wait times before soiled absorbent products for incontinence (of unspecified design) are changed. They recruited 50 patients (84% female, 16% male; mean age 79 years, all over 65) from a tertiary acute care hospital in Canada. They found statistically significant differences in patients versus care providers for daytime UI, with patients mostly intolerant of wait times more than 1 hour after an episode of UI, while carers considered longer wait times acceptable. Both patients and care providers reported that products soiled by FI required changing within 15 minutes both during the day and at night. The actual wait times experienced by patients were longer than the times deemed acceptable by patients or care providers. The study highlighted the importance of appreciating patient perspectives in promoting person-centred care.

6.1.1. Disposable, bodyworn absorbent products for urinary incontinence: development of international standards.

Because clinical evaluations are expensive and time-consuming, laboratory evaluation of absorbent products – particularly in support of purchasing decisions and marketing – is widespread. Few laboratory methods have been clinically validated, but there is a clinically-validated International Standard (ISO 11948-1) relating to the leakage performance of disposable bodyworn pads and all-in-ones for adults with moderate-heavy UI in institutions (93). It describes a simple method for measuring the absorption capacity of products in the laboratory that was shown to correlate well with the leakage performance of 18 different products evaluated in an international multi-centre clinical study involving 112 heavily incontinent adults (110). The strength of the correlation between technical and clinical data depended on the exact parameters being compared, but typically r = 0.9 **(Level of Evidence 2)**. This laboratory test (the Rothwell method) is now in common use in the UK, Sweden and other countries and provides a basis for selecting similar products with which to make direct comparisons (for cost purposes) or to select promising products for inclusion in clinical trials.

The ability of ISO 11948-1 to predict the leakage performance of more recent products (138 all-in-one and pad designs) for heavy UI was investigated by Cottenden *et al.* (111). Correlations were poorer than in the original 1993 study but still strong enough to make the method useful.

The Rothwell method merely measures the absorption capacity of the material in a product and would be blind to any enhancement to leakage performance that might be achieved by distributing the material optimally or by such product features as elastication. Since the 6th consultation (36), a study has been published (73) that compared the Rothwell method with a manikin method thought to hold potential as a new international standard. It achieved slightly higher correlations with user test data than the Rothwell method and, unlike Rothwell, was able to detect the benefits of elastication. However, its poor reproducibility (between laboratories) subsequently led to its abandonment as a candidate for a new international standard, although it has been published as a national standard in some countries. The need for a validated and widely accepted replacement for Rothwell persists.

Although leakage performance is a very important measure of product effectiveness, other factors are of course important too. Accordingly, it is helpful for users to systematically evaluate several products with similar leakage performance, as they may differ in other important variables such as fit and comfort.

Table F-16: Recommendations relating to bodyworn absorbent products for men and women with moderate-heavy UI.

- Sex (and gender) should be considered when products are prescribed / purchased for users. As men often have substantially higher incontinent urine volumes than women, men may require more products and / or more absorbent products than women (Grade of Recommendation B).
- Sex (and gender) should also be considered when products are prescribed / purchased for users because men and women are likely to prefer different designs. Men generally prefer disposable all-in-ones to pads (Grade of Recommendation B).
- Recommend disposable pads to women as an acceptable cost-effective alternative to pull on pads (Grade of Recommendation B).
- Caution is recommended if washable designs are being considered. Heavy bulk confines their use mainly to the night-time (where they may be particularly useful for users who lie on their side). They are unacceptable for most people during the daytime and for most women at any time. For this reason, a blanket policy of health services providing washables alone is not recommended. If washables are being considered, refer to Table F-21 (Grades of Recommendation B).
- Freedom from leakage: Where possible, international standard laboratory tests should be used to rank the likely leakage performance of disposable pads and disposable all-in-ones for moderate-heavy UI (Grade of Recommendation B). In general, all-in-ones should be selected in preference to pads to minimise leakage (Grade of Recommendation B).
- Carer application: When products are applied by a carer to a patient who can stand for product changing, disposable pads or pull-on pads should be used as they are easier and quicker to change than all-in-ones or belted pads. If the patient is lying down (e.g. at night), pull-on pads should be avoided (Grade of Recommendation B).
- Combinations of designs for different situations (e.g. disposable pads for staying in, disposable pull-on pads for going out, washable all-in-ones at night) are recommended to provide optimum management in terms of patient needs and cost-effectiveness (Grade of Recommendation B).

See also the general recommendations relating to product selection in Table F-20 and to washable products in Table F-21.

Table F-17: User characteristics, priorities and contexts which favour or discourage the use of the dif-ferent pad designs for adults with moderate-heavy UI.

Product Type	More likely to suit you if...	Less likely to suit you if...
Disposable pads	• You are female. • Discretion is a priority for you. • You want a product that is easy to put on. • You can stand up (with assistance if necessary) but can't change your own product.	• Your leakage is very heavy. • You are mobile and active.
Disposable pull-on pads	• You are female. • Discretion is a priority for you. • You want a product that is easy to put on. • You can stand up (with assistance if necessary) but can't change your own product. • You are most concerned about reliably containing leakage.	• You find the removal of clothing for changing the product difficult. • Low cost is a priority for you. • You need a product for use at night and need help with product changing.
All-in-ones	• You are male. • Your leakage is very heavy. • You are unable to stand to change the product.	• Discretion is a priority for you.
Belted pads	• You are male. • You are most concerned about reliably containing leakage.	
Washable pads	• You are male. • Your leakage is very heavy, particularly at night.	• You do not have adequate laundry facilities. • You are unwilling to use washable products. • You are not prepared to carry used products when out • Discreetness and appearance are priorities for you.
NB The content of this table is based on the referenced evidence cited in the chapter, but the unreferenced version provided for the lay public on the accompanying website (www.continenceproductadvisor.org) is reproduced here.		

6.2. Summary

- There is no single best product design (i.e., one design that is significantly better than all other designs for all users) **(Level of Evidence 1).**
- Different designs are better for men and women. In particular, men generally leak substantially higher volumes of urine than women **(Level of Evidence 1)**.
- For men, disposable pull-on pads or disposable belted pad designs are not better overall than the cheaper disposable all-in-ones, indicating that the latter is the most cost-effective design for men. For women, pull-on pads are better overall than the other designs (except for night-use for those living in nursing homes) **(Level of Evidence 1)**.
- Unlike men, women in the community do not favour disposable all-in-ones over disposable pads, and of these cheaper designs, pads may be preferred by women **(Level of Evidence 1)**.
- The leakage performance of disposable pads and disposable all-in-ones for heavy incontinence can be predicted with reasonable precision using an ISO laboratory test **(Level of evidence 2)**.
- Washable products are vof variable design, materials, and performance. Terry-towelling products (used with plastic pants) have good leakage performance but limited acceptability - confined mainly to some men at night **(Level of Evidence 2).**
- The leakage performance of disposable pads is worse than other disposable designs, but they leak significantly less if they are held in place by mesh rather than ordinary pants **(Level of Evidence 3)**.
- There is no firm evidence regarding the performance of different designs for faecal incontinence and no firm evidence that any design or type of material (washable or disposable) is better or worse for skin health **(Level of Evidence 4)**.

6.3. Recommendations

Recommendations relating to bodyworn absorbent products for men and women with moderate-heavy urinary incontinence are summarised in Table F-16, while Table F-17 describes the user characteristics, priorities and contexts that favour or discourage the use of the different product designs.

6.4. Priorities for research

- Comparison of absorbent products (disposable and washable) when used by caregiver-dependent users in the community.
- Development of more effective and acceptable disposable designs specifically for men.
- Development of more effective and aesthetically acceptable washable products, particularly for night-time use and for women.
- Development of a new international standard to replace or complement ISO 11948-1 (Rothwell method), which can detect any benefits of such features as elastication.

7. DISPOSABLE UNDERPADS

The most recent publications on the use of bed pads were in 1994 (27) (106), which probably reflects their diminished and limited role in the long-term management of incontinence. The presence of a disposable underpad on a chair discloses the fact that the user is incontinent. The use of bed pads for sole protection requires clothes to be pulled up (or absent), which poses a threat to a person's dignity. Disposable bed pads easily become displaced, folded and creased inhibiting both performance and comfort, and possibly threatening skin health. Large disposable bed pads with wings to tuck under the mattress may have a role as bed protection 'back-up' to bodyworn absorbent products. The main use of disposable underpads should be confined to temporary bed or chair protection such as during clinical procedures (e.g. enemata) or when using a urinal.

Trials comparing different disposable bed pads are few (27) (112) (113), and it is not possible to draw firm conclusions from them on the effectiveness of different product design features and materials.

Bed pads are generally supplied as non-sterile items, and some case reports published between 1985 and 1997 suggest that recycled paper in bed pads could be a potential source of infection (114) (115) (116) (117). However, there are no recent studies and risk to patients appears to be minimal when products are used as directed.

7.1. Summary

No robust data are available on the effectiveness of current disposable chair pads or bed pads or of their various design features or constituent materials. There is a possible risk of infection from bed pads made from recycled paper for immunocompromised users **(Level of evidence 4).**

7.2. Recommendations

Recommendations relating to disposable underpads are summarised in Table F-18.

Table F-18: Recommendations relating to disposable underpads.

- Disposable underpads should not be used for long-term management of UI or FI but have a useful role as temporary protection for chairs and beds during clinical procedures (Grade of Recommendation C).
- Immunocompromised people should not use bed pads made from recycled paper because of the risk of infection (Grade of Recommendation B).

7.3. Priorities for research

Disposable underpads have a limited role in continence management but are known to be widely used. An exploration of patient views regarding their use may help demonstrate their limitations, particularly regarding skin health.

8. WASHABLE UNDERPADS

Aspects of assessment that are important regarding washable underpads are patient acceptability and preference, particularly with regard to willingness to be naked below the waist (if the product is to be the primary means of protection, rather than acting as back up to a bodyworn product) and availability of laundry and drying facilities.

Some evaluations have found significant differences between products relating to leakage performance, and skin health but none of the products evaluated are now available (118) (119). Compared products always differed from one another in too many respects for it to be possible to extract reliable generic conclusions that can be related to current products. However, the choice of topsheet material and the presence or absence of features like tuck-in flaps and

integral water-proofing appear to be, primarily, matters of personal preference.

In institutional settings, washable bed pads are commonly used by multiple patients and questions are often asked about the risk of cross-infection. Cottenden *et al.* (120) assessed the risk by determining the microbial content of 145 bed pads of five different designs after a night's use by incontinent adults, followed by laundering using a standard foul wash procedure which included heat disinfection at 71°C for three minutes. Laundering destroyed all known pathogenic organisms, although some commensal flora were isolated in small numbers. It was concluded that foul wash laundry left bed pads safe for multiple patient reuse with no demonstrable risk of cross-infection.

8.1. Summary

The literature contains insufficient robust data on which to base guidelines for choosing between washable bed pads. Choice of topsheet material and the presence / absence of design features like tuck-in flaps and integral/separate water-proof backing appear to be, primarily, matters of personal preference **(Level of evidence 3).** Provided an approved foul wash procedure is used, the risk of cross-infection between different users of a bed pads is very low **(Level of Evidence 2).**

8.2. Recommendations

Recommendations relating to washable underpads are summarised in Table F-19.

Table F-19: Recommendations relating to washable underpads.

- If considering using washable under-pads for sole use (i.e. without a body-worn product), the patient will need to be naked below the waist. This needs patient consultation and approval (Grade of Recommendation C).
- Personal preferences of users with regard to topsheet material, tuck-in flaps and integral waterproof backing should be considered in making product selections (Grade of Recommendation C).
- An adequate foul laundry wash cycle should be used, so the risk of cross-infection between successive users of washable bed pads is low and not a contraindication for their use (Grade of Recommendation B).

8.3. Priorities for research

Research on these products is not seen as a high priority.

9. ABSORBENT PRODUCTS FOR CHILDREN WITH URINARY AND / OR FAECAL INCONTINENCE

Most children are expected to achieve daytime dryness by the age of three (121). However, some boys take longer to become dry and some (e.g. children with learning and physical disabilities) may never do so. These children usually require absorbent products to contain leakage.

Aspects of assessment that are particularly important regarding bodyworn products for children are the presence of faecal incontinence, day / night incontinence, level of independence with toileting, and use of aids such as callipers.

No studies of absorbent products have been published since the 5th consultation (92). The existing study was a comparison of all-in-one and pull-on pad designs (26).

Findings indicated that, generally, the all-in-one and pull-on pad products performed similarly. Overall, all-in-ones were preferred for night-time use by the majority of parents. By contrast, 40% of parents preferred pull-on pads for daytime use, and these were found to be particularly appropriate for older children and those who were attempting independent toileting, provided they did not have faecal incontinence. All-in-ones were more suitable for children who were dependent on carers and / or had faecal incontinence and wore callipers or adapted footwear. The authors recommended that both all-in-ones and pull-on pads should be supplied for children, with pull-on pads (which are about 50% more expensive than all-in-ones) being provided for selected children during the daytime.

9.1. Summary and recommendations

All-in-ones and pull-on pads meet different needs, and both should be made available to children with disabilities, dependent on assessment **(Level of Evidence 3 / Grade of Recommendation C)**.

9.2. Priorities for research

- Comparison of washable and disposable bodyworn absorbent products.
- What are the problems faced by parents / caregivers and children in managing continence with different product designs and materials?

10. ABSORBENT PRODUCTS FOR FAECAL INCONTINENCE

Very few absorbent products specifically designed to contain FI are available and no studies comparing different products were found. Most absorbent products used by people with FI were designed primarily to address UI.

Bliss *et al.* (122) have reported preliminary findings of a survey of the use, evaluation and suggested modifications of absorbent products for faecal incontinence, based on a study with 188 community-living persons with the problem. Forty-five per cent of persons used an absorbent product for FI. Ninety-eight percent of those with UI and FI used the same type of product for both. Suggested improvements in product designs included having better odour control, fit, and ability to stay in place; a clearer distinction between the front and back of a pantiliner or pad; adding wings for greater absorbency, and making them flushable, cooler feeling, wider and longer in the rear and more absorbent but less bulky. For mild faecal incontinence, especially when faeces remain between the buttocks without soiling underwear, persons have used a small disposable gauze surgical dressing placed between the buttocks (Fig F-12). This product was more acceptable than a pantyliner or pad to some men (122) **(Level of Evidence 2)**.

Recent work on odour relating to absorbent product usage for FI is described in Section P, while management of FI using products other than absorbent ones is described in Section N.

10.1. Recommendations

- A disposable gauze dressing that can be placed between the buttocks should be considered and may be acceptable for men with light faecal incontinence **(Level of Recommendation C).**

10.2. Research priorities

- Better designs of absorbent products are needed for light and moderate FI (with and without UI).

11. BROADER RECOMMENDATIONS

General recommendations on absorbent product selection and recommendations relating to washable products, in particular, are summarised in Tables F-20 and F-21, respectively.

Table F-20: General recommendations on pad selection

- **Individuality:** No one product works best for all users: needs and priorities vary. Accordingly, users should be advised to try a variety of products when possible **(Grade of Recommendation B).**
- **Brand differences: People should be advised that** individual product brands within a design group often exhibit a wide range of performance and acceptability for individuals, and it cannot, therefore, be assumed that products of different brands but the broadly similar design will be equally acceptable or effective **(Grade of Recommendation B).**
- **Combinations of designs:** Absorbent products vary greatly in price and performance, and suitability for individual needs. Users should be advised that they may find combinations of designs preferable and cost-effective. For example, women might use disposable pull-on pads (expensive but discreet and good for leakage) for going out and disposable pads (cheap, less good for leakage) for staying at home. Men might use disposable all-in-ones for daytime and washable terry-towelling products for nighttime **(Grade of Recommendation B).**
- **Freedom from leakage:** Nobody wants their product to leak, but compromises have to be made. If it is a priority for a product to successfully contain a person's most severe accident, it may need to be substantially more bulky and expensive than is needed most of the time. Advise users that they may choose to tolerate a higher risk of product leakage in exchange for being able to use cheaper, smaller, more discrete products. Priorities for a given user should be investigated in making product selections **(Grade of Recommendation C).**
- **Comfort and skin health:** In general, products containing superabsorber should be selected in preference to those without (Grade of Recommendation B). Shaped pads should usually be selected in preference to unshaped **(Grade of Recommendation C).**
- **Staying in place:** No product is effective if it slips from the position. Pads should be used with stretch (e.g. cotton / lycra) underwear or mesh pants **(Grade of Recommendation B)**. Shaped pads should be used in preference to rectangular pads **(Grade of Recommendation C).**
- **Ease of putting on and taking off:** The ease of putting products on and taking them off should be considered, especially for caregivers and for incontinent users with reduced mobility or dexterity **(Grade of Recommendation C).**
- **Aesthetics and discretion:** A possible preference for small, more discrete products (even if they are more likely to leak) should be considered, especially for those wishing to wear close-fitting clothing **(Grade of Recommendation C).** The possibility of plastic backing materials rustling noisily should be taken into account in selection**(Grade of Recommendation C).**
- **Independence and lifestyle:** The ability of a user to change his / her own product should be considered **(Grade of Recommendation C):** those able to change their own product can often manage with a smaller (less absorbent) one than those reliant on a caregiver. Users who travel should consider in their choice of product(s) the practicalities of carrying a supply, disposing of used ones, and dealing with laundry **(Grade of Recommendation C)**.
- **Costs:** Cost issues should be approached with caution **(Grade of Recommendation C)**. Expensive products do not necessarily work better than cheaper ones. Cheaper products do not necessarily save money. If they leak more, they may have to be changed more frequently and / or lead to higher laundry costs. More product changes will mean increased caregiver workload. However, more absorbent products will not necessarily reduce product consumption rates: products are often changed according to the nursing unit or personal routine.

Table F-21: Recommendations relating to washable pads.

- **Laundry issues:** Access to good, reliable washing and drying facilities should be checked before washable products are introduced **(Grade of Recommendation B).** Laundry – especially of bed pads – can be heavy work, beyond the capability of frail incontinent people or their caregivers. The number of washable products needed per user depends on laundry turn-around times. Drying times for washables can be long and expensive, especially for bodyworns for heavy incontinence and for bed pads.
- **Personal preferences:** Personal preferences (of both users and caregivers) with regard to choosing between washable and disposable products should be carefully taken into account **(Grade of Recommendation C).** Some users prefer the chore of laundering washables to anxiety over when their next consignment of disposables will be delivered. Washables generally require less storage space than disposables. Discreet disposal of disposables can be a challenge. The possibility of using a mix of disposable and washable products should be considered **(Grade of Recommendation C)**. Some users who choose disposables when at home prefer washables when travelling because of the space that disposables occupy in luggage and the possible inconvenience of disposal. Others use washables at home and disposables when away as they see the balance of disadvantages and advantages differently.
- **Personalisation of products:** In institutions, the chore of personalizing washable products and sorting them after each laundry cycle should be considered before they are introduced **(Grade of Recommendation C).** Washable bodyworns are often personalised to particular users. In institutions, this means marking products with users' names and sorting them after laundry, an extra task for caregivers. Washable bed pads are not usually personalised.
- **Staining:** Washable products should not usually be used by those with faecal incontinence – beyond occasional light smearing – because of staining **(Grade of Recommendation C)**. Skin sprays and ointments may also stain washables.
- **Costs:** Cost comparisons between washable and disposable products should be made with caution **(Grade of Recommendation C).** Key factors are local arrangements (mostly laundry and transport costs), the durability of the products (which depends on how carefully they are used and the criteria for deciding when they should be replaced); the costs of ordering, transporting and disposing of disposables; and product purchase costs. Much of the cost of washables is encountered with the initial capital outlay for stock. This also represents a commitment to use the products for an extended period, and so expensive mistakes can be made if it transpires that a better product was / has become available. It will usually be wise to experiment with samples of a variety of alternative products before committing to major purchases.

G. EXTERNAL URINE COLLECTION DEVICES

External urine collection devices are primarily available for men.

Close-fitting penile sheaths (sometimes called condom catheters, uridomes, Texas catheters or external catheters) are male incontinence devices (no practical equivalent is currently available for women). The sheath fits over the penis much like a contraceptive condom and collects urine as it leaves the body. The sheath is normally connected at its outer end to a tube that leads to a urine drainage bag. Urine drains into the bag, which is usually worn on the thigh or calf and is collected there until emptying is convenient. Sheaths come with a variety of design features and the main ones are listed in Table G-1 and illustrated in Fig G-1.

The main factors that make sheaths (un)suitable for men are summarised in Table G-2.

An effective urinary sheath is one that stays securely in place for an acceptable period, is leak-free, comfortable to wear, easy to apply and remove, avoids skin damage and channels the urine effectively into a urine drainage bag. Correct sizing and fastening are critical to product success. Users indicate that the foremost important quality of a penile sheath is security from leakage, followed by comfort and ease of application and removal.

Table G-2: The main factors that make sheaths (un)suitable for men.

Sheaths are suitable for men with:
• Moderate to heavy urine loss.
• Urinary frequency and / or urgency.
• Limited Mobility
(Sheaths can be used in combination with intermittent catheterisation.)
Sheaths are not advised for men with:
• Confusion or psychological vulnerability. Sensation through spinal cord injury or neuropathy (111) (112) (113).
• A retracted or very small penis (alternative products are available).

Table G-1: The main design features of sheaths.

- **Materials:** latex, silicone rubber or other synthetic polymers.
- **Size:** range of diameters (about 20-40 mm, in 5-10 mm increments) and lengths; most companies supply a measuring tool to ensure the best fit; guide is placed at the widest point of the penis, typically about 20 mm from the base **(110).**
- **Adhesive:** may be integral to the sheath (one-piece systems) or be a separate strip or spray (two-piece systems).
- **Applicator:** some sheaths are provided with an applicator with the aim of making application easier or reducing manual contact with the penis.
- **Anti-kinking / twisting features:** these are intended to improve drainage by aiming to prevent the sheath from kinking or twisting at the distal end near the connection to the drainage bag tube.
- **Anti-blow-off:** some designs aim to reduce the likelihood of the sheath blowing off at high urine flow rates, as at the beginning of a void; for example, the distal end of the sheath may be thickened and bulbous to stop the internal walls from sticking to one another between voids.
- **Connections to the drainage bag:** some designs aim to increase the ease and security of drainage bag connection, for example, a push ring or ridge at the end of the outlet tubing.
- **Retracted penis:** some sheaths are designed with or without specific features in order to accommodate a retracted penis, for example, a shorter sheath or a wider adhesive seal.
- **Durability:** varies according to the manufacturer. 24 hours is a common recommendation, but some are intended for extended wear.
- **Transparency:** some sheaths are made from transparent materials (e.g. silicone), which can allow for observation of penile skin condition along the shaft and glans.

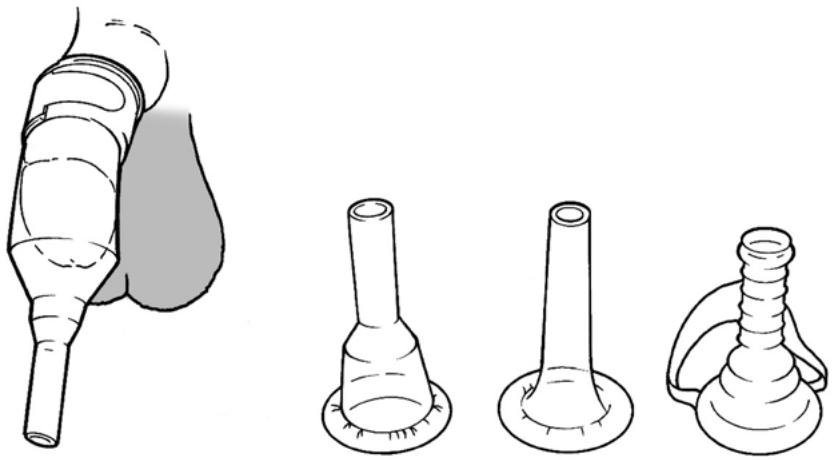

Fig G-1: Sheath without integral adhesive, secured with external fixation (a), and a variety of sheaths showing anti-blow-off features and applicator (b).

1. EVIDENCE

The 6th International Consultation (36) identified trials in which a sheath system was compared to alternative continence products: indwelling catheters (123), pads (84) or one sheath versus another (124) (125) (126) and the results from these studies are included in the summary section, below.

Since the last consultation, two studies have been published (18) (127). Saint and colleagues compared UTIs, pain, discomfort and other complications between two otherwise similar groups of men who received either a sheath or an indwelling catheter for short-term urinary management during hospitalisation (n=80) (127). The two device types were similar in terms of the proportions of men experiencing UTIs and other non-infectious complications. Pain, discomfort, bleeding, or other trauma were experienced by signif-

Table G-3: Reported complications associated with sheath use.

Complication	Prevention/Treatment
Contact dermatitis or allergy; balanitis, oedema (131) skin maceration from wet exposure (132)	Allergy to latex can develop over time; change the product to silicone base; routinely check skin; ensure skin is dry before application of sheath and skin barrier; ensure sheath is the correct size.
Compression, tourniquet effect; (133) (134) (135).	Use sheaths with caution in individuals with no penile sensation; avoid adhesive straps or use straps with stretch to allow for penis expansion/ contraction; correct size is critical.
Skin irritation (136).	Ensure sheath does not become twisted near the distal end to avoid stagnation of urine and extended urine contact with penile skin; good genital hygiene.
Glans irritation/pressure ulcer	Ensure adequate space at the end of the sheath to prevent pressure on the glans.
UTI – range 40-63% (137) (138).	Ensure consistent drainage – if sheath twists, it will block urine flow; at-risk individuals – those with poor hygiene, cognitively impairment who may tug/twist sheath drainage tubing.
Hydronephrosis (139) (140).	Detrusor over activity risk factor for vesicoureteral reflux; may require antimuscarinics & intermittent catheterisation in addition to sheath drainage; warn users of the risks of acute urinary retention (AUR) when consuming large amounts of alcohol in a short time – individuals should be taught signs of AUR & teaching of intermittent catheterisation if engaged in high fluid intake or recreational drugs.
Fibro-epithelial penile polyps (141) (142) (143).	Close skin observation by user or caregiver; good user education to aid in proactive skin health
Isolated gangrene (144).	Immunocompromised individuals are at high risk for infection related to condom use.

icantly fewer men being fitted with a sheath than with an indwelling catheter. However, the two devices were comparable on removal.

Da Silva and colleagues reported that amongst thirty hospitalised men using sheaths, poor fitting of the devices by nurses was common, skin damage occurred in one third, and that the majority of patients received no guidance on sheath use (128).

There is a need for greater education of health professionals, lay-carers and users about sheaths. An expert panel noted resistance to the introduction of external collection devices, including sheaths, in hospital settings and the need for education on their application, effectiveness and possible complications. The importance of education of patients and lay-carers in ambulatory care about safe and effective device application was also noted (129). Half of the men included in one trial comparing sheaths with pads, bodyworn urinals and penile clamps had previously tried a penile sheath system but only one of these had received assistance from a healthcare professional for fitting and follow-up (18).

A sheath product which is secured to the glans is available. Manufacturer information suggests that the product is useful for men with a short or retracted penis for whom a standard sheath system is unsatisfactory. Apart from testimonials, there are as yet no published data evaluating the product and only one paper (130) that suggested the product could be a useful alternative to a conventional sheath.

Although many men use sheaths successfully, several case studies attest to the potential problems (Table G-3). It is of note that most such problems are preventable with proper sizing, continuous drainage, routine changing and appropriate skin care.

A review of findings relating to odour associated with sheath use is given in Section P.I.4.

2. SUMMARY

- Sheaths are more comfortable than indwelling catheters, and UTI incidence is similar (84) or somewhat lower in sheath users without dementia (123) **(Level of Evidence 2)**.
- Men with moderate incontinence using a sheath rank QOL better with a sheath than when using an absorbent product (84) **(Level of Evidence 2)**.
- Sheaths with integrated adhesive are preferred over those with an adhesive strip or applicator (124) (126) **(Level of Evidence 2).**
- Silicone sheaths are preferred over latex (124) **(Level of Evidence 2).**
- Men prefer a choice of continence products (pads, sheath, clamp) depending on activities and lifestyle (18) **(Level of Evidence 2).**

3. RECOMMENDATIONS

Recommendations regarding urinary sheaths are summarised in Table G-4.

Table G-4: Recommendations relating to urinary sheaths.

- Product differences mean that men should try different products before making a final selection **(Grade of Recommendation B)**.
- Offer men access to a combination of continence products (sheath, pads, clamps), depending on activity **(Grade of Recommendation B)**
- Advice men that key performance characteristics are security (i.e. ability to keep a leak-proof seal and channel urine to the drainage bag without leakage) and ease of application and removal of the sheath **(Grade of Recommendation B).**
- Advise men that sheath applicators may not make sheath application easier **(Grade of Recommendation B).**
- Sheaths with integral adhesive (one-piece systems) \should be offered over (two-piece systems) **(Grade of Recommendation C).**
- Sheath users should be monitored for latex or adhesive allergies, skin health, tissue damage and UTI **(Grade of Recommendation C).**
- Advise men then when possible, the external sheath rather than the indwelling urethral catheter should be the urinary collection device of choice. **(Grade of recommendation B).**

4. PRIORITIES FOR RESEARCH

- Evaluation of leg bag and sheath design features claimed to reduce twisting and kinking at the drainage bag connection site.
- Evaluation of products advertised as suitable for men with a retracted penis.
- Studies to generate and validate procedures to help identify the type of sheath most likely to suit an individual.

H. URINE DRAINAGE BAGS AND ACCESSORIES

Urine drainage bags fall into two main categories. Bodyworn bags generally have a lower capacity (less than 500 ml) and are designed to be worn under clothing on the leg (often called leg-bags) or around the waist. They aim to provide discreet storage of urine and can be attached to either a catheter or a sheath. They are mainly used during the day and are secured to the leg or waist in a convenient position using a range of straps or other support devices. The popularity (or otherwise) of many features is generally a matter of personal preference.

Second, there are large capacity bags - commonly called night bags – which are designed to provide additional drainage capacity overnight or for people who are permanently in bed. They are usually held in a position away from the body on either a floor-stand or a hanger that hooks onto the bed or chair frame. They may also be connected to a bodyworn bag to form a link system for overnight use.

Expert opinion found in best practice guidelines recommends positioning drainage bags so that they are off the floor, but data are insufficient to establish whether this practice reduces the incidence of bacteriuria. (145) (146) (147)

To prevent cross contamination, a closed drainage system is standard and, in the home, it is common to use vinegar, household detergent or diluted bleach (148) (149) (150) (151) (152) to clean drainage bags.

The main design features and variants of urine drainage bags are described in Table H-1 and illustrated in Fig H-1, and Fig H-2 shows a variety of tap designs

Urine drainage bags are suitable for those with:

Table H-1: Drainage bag features

	Leg bag	Night bag
Capacity	350-900 (usual 500 ml)	2000-4000 ml
Material	Transparent PVC (polyvinyl chloride), PVDF (polyvinylidene fluoride (less noise from rustling)), or polyethylene or rubber / latex.	As with leg bags.
Wear position	On thigh or calf; on the abdomen.	Situated below bladder with tubing distributed to prevent low hanging/dependent loops.
Attachment	Latex or cloth elastic straps.	Separate frame/stand or hooked on bed or wheelchair.
Connecting tube	Various lengths; can be cut to meet individual needs.	One length only; intended to maintain a closed link system.
Drainage tap	Flip valve, separate cap, screw cap.	As per leg bags.
Sampling port	If present, located in drainage tubing.	Located in drainage tubing.
Comfort	Cloth backed prevents skin irritation.	No specific comfort features.
Discretion	Internal welds reduce bulging and the sound of urine on movement.	None are discreet; may be covered with a cloth bag to disguise bag.
Anti-kinking	Connecting the tube reduces kinking and twisting, so that urine drainage is not obstructed.	Sturdy plastic tubing does not allow twisting at the catheter site but may kink along drainage tubing.
Anti-reflux valve	Non-return flap valve to prevent urine reflux if the bag is raised above bladder; may reduce risk of CAUTI.	As with leg bags.
Linkage system	Allows attachment of leg bag to night bag so maintain a closed system; may reduce risk of cross-infection.	

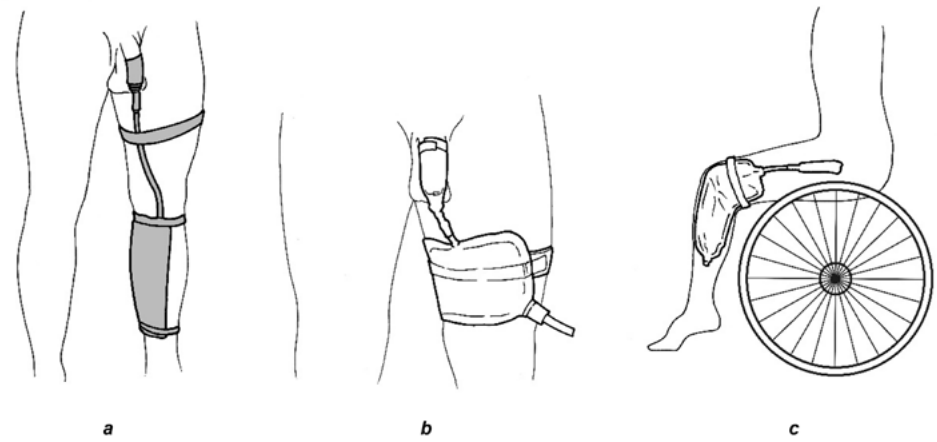

Fig H-1: A urine drainage bag shown worn on the calf (a), a discreet thigh urine drainage bag (b) and a shaped urine drainage bag for wheelchair use (c).

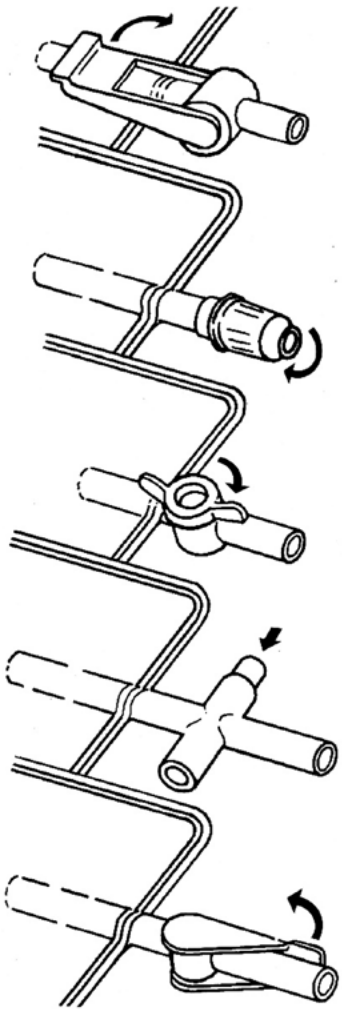

Fig H-2: A variety of urine drainage bag tap designs. The arrows indicate the action needed to open and close each valve.

- The visual acuity to see the tap / spigot and the manual dexterity to open and shut it (153) (154).
- The ability to assess skin condition where straps and drainage bag contact the leg.

1. EVIDENCE

The last consultation (36) identified three new trials addressing dependent drainage tubing loops (or airlocks) (155), specimen collection technique (156) and catheter securement (157), two dependent loop prevalence studies (158) (156) and two best practice surveys (159) (157).

Since the last consultation (36), there have been no clinical trials addressing this topic. However, one study used computational models to examine the influence of tubing design on urodynamics and explored its potential to influence biofilm formation and encrustation. Results indicated that tubing diameters could be reduced by 40%-50% and still meet flow rate standards for leg bags. The authors proposed that this might also reduce tube kinking (160).

2. SUMMARY

- Taps are sometimes difficult to open and may leak onto the fingers when the bag is emptied (161) (162) **(Level of Evidence 2)**.
- Chafing between bag and skin is often reported (161) (162) **(Level of Evidence 2).**
- Bags with tubing that is flexible and can be cut to length to suit the individual are appreciated (161) **(Level of Evidence 2).**
- Discreet bags (that are not readily visible beneath clothing) are appreciated (161) **(Level of Evidence 2)**.
- Designs in which the tap and outlet spouts are widely separated are most effective at preventing contamination of the hands with urine (163) (164) **(Level of Evidence 2).**
- There is insufficient evidence that pre-connected products reduce the incidence of bacteriuria (147) (Level of Evidence 2).
- There is no evidence that the addition of antiseptic agents to drainage bags prevents the onset of bacteriuria (165) **(Level of Evidence 2)**.

- Comfort and ease of applying straps to the leg is key to successful wear (154) (166) (167) **(Level of Evidence 2)**.
- If there are dependent loops in the drainage tube, airlocks can compromise efficient bladder emptying (155) (156) **(Level of Evidence 3)**.
- Most drainage bags (bodyworn and night bags) have an integrated anti-reflux valve, but it is unclear whether they reduce the incidence of CAUTI (147) (168) **(Level of Evidence 3)**.
- There is inadequate evidence to state that single-use (147) or daily change of leg bags or drainage bags reduces bacteriuria or CAUTI. In practice, drainage bag changes ranged from every 3 days to more than 20 days (169) (170) (171) **(Level of Evidence 3)**.
- An abdominal 'belly bag' drainage system may be more convenient, comfortable and less likely to cause discomfort than leg and night bags (172) **(Level of Evidence 3)**.

Table H-2: Recommendations relating to urine drainage bags and accessories.

- Practitioners should recommend taps which are easy to open and should not leak onto the fingers when the bag is emptied **(Grade of Recommendation B).**
- Care should be taken to avoid chafing between bag and skin **(Grade of Recommendation B).**
- Individual needs and personal preferPences should determine the use of leg / suspension / attachments and position of where the bag is worn (166) **(Grade of Recommendation C).**
- An abdominal drainage bag ('Belly Bag') may be considered as a convenient, comfortable option to a leg secured bag (172) **(Grade of Recommendation C).**
- A closed urinary drainage bag system where the system is only broken to change the sterile bag according to the manufacturer's directions should be consider. This may reduce the onset of bacteriuria **(Grade of Recommendation A).**
- Drainage systems for night bags should be positioned off the floor to reduce the risk of cross-infection (145) (146) (173) **(Grade of Recommendation C).**
- All facilities should enforce regular monitoring of practice to ensure adherence to evidence-based guidelines on catheter/drainage bag management **(Grade of Recommendation C)**.
- Catheter securement devices should be in place on the thigh or abdomen for all indwelling catheters **(Grade of Recommendation C).**
- Dependent catheter loops should be minimised to allow optimum urine drainage **(Grade of Recommendation C).**

3. RECOMMENDATIONS

Recommendations relating to urine drainage bags and accessories are summarised in Table H-2.

4. PRIORITIES FOR RESEARCH

- Evaluation of a linked system with night bag/leg bag and the onset of bacteriuria compared to changing from day to night bag.
- Reviewing practice in home settings: is a closed catheter drainage system more effective at preventing symptomatic UTI than reusable non-sterile urinary drainage?
- Most effective and acceptable cleaning methods for non-sterile urinary drainage systems.
- Development of catheter tubing that prevents the formation of dependent loops.

I. MALE BODYWORN URINALS AND DRIBBLE CONTAINERS

Products such as bodyworn urinals (BWU) and dribble containers (penile pouches) are an alternative to a sheath system (Fig I-1). They usually comprise a ring-shaped opening or cone-shaped component which is worn around the penis (and held firmly against the pubis by means of a belt and straps) and channels urine to an integral collection bag. There are two main designs: one-piece with the cone and flange as a single combined unit, or two-piece, where the cone and flange are separate and connect when in use. BWUs are more substantial collection devices than sheaths. They are designed to be washed and reused multiple times and to be worn over extended periods. They are less frequently used than sheaths but may be a good option for those with a retracted penis or who do not wish to wear a sheath. Dribble containers (penile pouches) involve holding a drainage bag or other container over the penis using a much lighter structure than the flanges used in bodyworn urinals. They are often disposable.

The more substantial designs should be fitted by a specialist: a good fit is crucial for comfort and to avoid leakage. It is also important that the wearer / carer understands how to use the device and the importance of skin care. The wearer / caregiver will need good manual dexterity to manage the device. Several urinals will be needed to use in rotation, allowing each to be properly washed and dried between periods of use.

The main factors that make bodyworn urinals (un)suitable for men, and the challenges to be addressed in using them effectively are summarised in Table I-1.

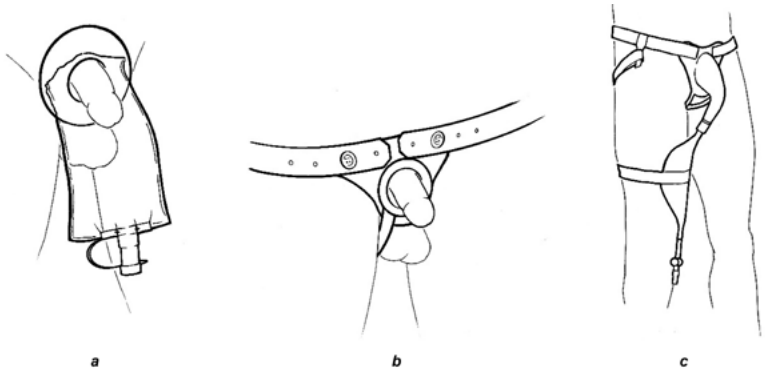

Fig I-1: A disposable penile pouch (a), a pubic pressure flange (with the cone removed) (b), and a bod-yworn urinal with leg bag (c).

Table I-1: The main factors that make bodyworn urinals (un)suitable for men, and the challenges to be addressed in using them effectively.

BWUs are suitable for men with: • A small or retracted penis that will fit into and stay in the flange. • Moderate to heavy urine loss. • Urinary frequency and / or urgency. • A preference to use a bodyworn urinal rather than absorbent products during the day. • The ability to walk but chair / bed-bound during the day.
BWUs are not suitable for men with: • Confusion. • Poor manual dexterity and who are unable to connect the straps. • Impaired mobility who spend large amounts of time lying most of the day (device tends to slip out of position). • Confusion or psychological vulnerability. • Decreased sensation through spinal cord injury or neuropathy (153) (174) (175). • A retracted or very small penis (alternative products are available).
Particular challenges related to BWU use are: • Maintaining a secure fit to prevent the penis from slipping out of the cone resulting in leakage. • Kinking or twisting of the tubing at the junction of the cone. • Risk of skin damage or allergy from the chafing of the leg straps or from the flange against the pubis.
To be effective, the user / carer must: • Understand how to use the device and the importance of skin care. • Have good manual dexterity to manage the device. • Have fitting done by a specialist to ensure the best leak-proof fit. • Moderate to heavy urine loss. • Urinary frequency and / or urgency. • Limited mobility.

1. EVIDENCE

At the time of the 6th International Consultation (36), only one trial evaluated bodyworn urinals or dribble containers. Macaulay *et al.* (18) conducted a randomised controlled trial that included BWUs. Fifty-six men compared (day and night, and for three weeks each): a BWU, sheath drainage, a penile clamp (daytime only), and the absorbent product they had regularly used before the trial. Outcome measures were *overall opinion* (rated on a 10-point visual analogue scale) for day or night use; *product acceptability* (not acceptable / poor / acceptable / good); *advantages and disadvantages* of the test products; *revealed preferences* (which products men used three months after the test).

The BWU was rated as "acceptable" by 48% of participants for daytime use at home, more comfortable when wet than pads, but worse than pads, sheaths or clamp in all other aspects, including self-image. It was also described as leaking in certain postures, particularly when sitting, as the penis can slip out of the flange. No significant differences in quality of life (measured by the King's Health Questionnaire) were noted at the three months follow up. At the conclusion of the study, men were more informed on product choices and, although most (58%) were using a mix of products at the three-month follow-up, few (22%) included a BWU in their mix.

2. RECOMMENDATION

Expert fitting and careful user selection should be ensured to ensure the effective and appropriate use of bodyworn urinals **(Grade of Recommendation B).**

3. PRIORITIES FOR RESEARCH

- Development and evaluation of leak-free, comfortable, and aesthetically acceptable BWUs for men.
- Development and validation of a reliable instrument to measure the performance of different BWU designs and the impact on the quality of life of users.

J. MECHANICAL DEVICES FOR WOMEN WITH UI

Mechanical devices for women are designed (primarily or in part) to prevent urinary leakage. There are three main categories:

External urethral devices: products that are applied over the urethra at the opening.

Internal urethral devices: products that are placed inside the urethra.

Internal vaginal devices: products that are inserted into the vagina.

The main factors that make mechanical devices (un)suitable for women are summarised in Table J-1

Table J-1: The main factors that make mechanical devices (un)suitable for women.

Mechanical devices may be suitable for women with:
• Stress urinary incontinence.
• Good hand control.
• Good memory and cognitive function.
• The ability to understand how to use them.
• A preference for preventing leakage over containing it.
They may be used in combination with other con-servative management approaches such as PFMT.
Mechanical devices may not be suitable for women with:
• Urinary urgency, frequency syndrome / OAB.
• Urinary tract infections.

1. EVIDENCE FROM THE 6TH INTERNATIONAL CONSULTATION (2016)

The published evidence on mechanical devices for women with UI is best introduced by reviewing each device category in turn.

1.1. External urethral devices

There are two different urethral inserts currently on the market.

The Femsoft (Fig J 1A) is a urethral insert made up of a short silicon tube encapsulated by a fluid-filled silicone sheath with a tip designed to conform to and seal the bladder beck and proximal urethra. It is intended for daytime use during physical exercise and is self-inserted (using a separate insertion probe) and removed at user discretion. It is available in two lengths (3.5 cm and 4.5 cm). Before insertion, the proximal end of the cylinder is distended relative to the distal end but, as the user pushes the device (guided by the insertion probe) into the urethra, fluid transfers temporarily to the distal end, returning once the device is in place, so securing it. One study found that device use led to a significant decrease in overall daily incontinence episodes and a higher quality of life. Women with severe SUI had a greater reduction of incontinence episodes per day than those with mild or moderate SUI (176). Positive results have also been reported with women who have a complex medical history having undergone surgical repair of obstetric vesicovaginal fistula. A retrospective study found 76% of women reported being dry, although no significant results were able to be made given a lack of evaluable data recorded. Further evaluation is required to test the acceptability and safety of the device in this population (177). Side effects can include bacteriuria (38.7%), UTI (41.3%), device migration into the bladder (1.3-3.3%) and device rupture (1.1%) (176) (177). A small study found that the device significantly decreased SUI during supervised and unsupervised exercises compared to not using the device. Out of six women participating, there were two cases of dysuria and one case of haematuria, although the haematuria and one case of dysuria resolved despite further device use (178).

The InFlow is an intraurethral valve pump intended for women with a chronic acontractile bladder who would otherwise use intermittent or indwelling catheterisation. The device consists of a short silicone urethral available in various lengths for specific fitting under local anaesthetic. It is maintained in position by distal proximal flanges. When the bladder is full, an inner turbine-like valve is activated by a handheld magnetic device and allows bladder emptying. When the handheld device is removed, the valve closes, maintaining continence. For selected women dissatisfied with catheterisation, the device may provide an alternative to self or indwelling cathe-

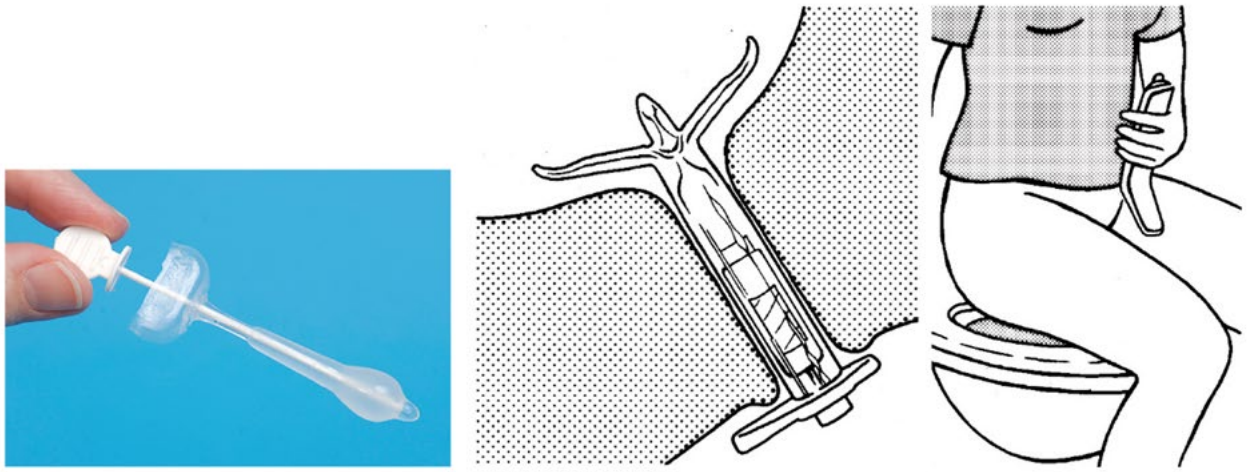

Fig J-1: Intra-urethral devices for women: the Femsoft, with separate insertion probe (white) in place (a); and the InFlow Intraurethral Valve-Pump, in position (b) and with the handheld magnetic activation device in position (c).

terisation and improve quality of life (179). Chen and colleagues found that patients who were successfully able to use the device in a trial period to assess tolerance and regular support were more likely to benefit from device use. High levels of device-related adverse events include UTI (10-50%), device expulsion (5-43%) and asymptomatic bacteriuria (56%) (133-135). Discontinuation rates were also high in two studies (50-62%) with key reasons being discomfort (27-30%), unexpected leakage (7-21%) and spontaneous expulsion (5%) (134-135). To date, no long-term research is available on the adherence to the device nor the effects that it may have on bladder / urethral mucosa (180).

1.2. Internal vaginal devices

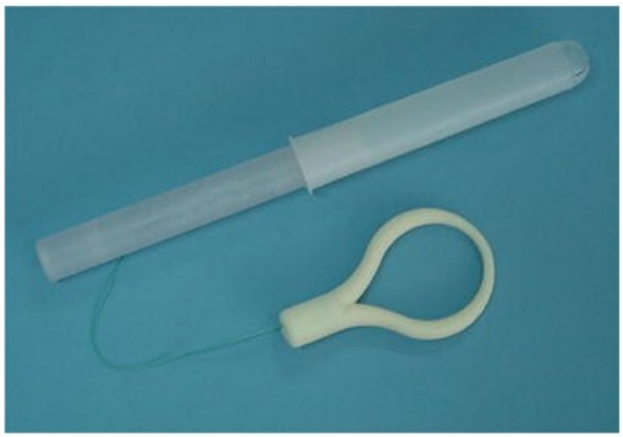

Fig J-2: Vaginal device to support the bladder neck: the Diveen, with applicator.

Intra-vaginal devices aim to correct urinary stress incontinence and have achieved varying success utilising traditional tampons, pessaries, contraceptive diaphragms, and intravaginal devices. Follow up and patient teaching are important. Side effects of vaginal devices can include UTI, discomfort (during insertion, removal or wearing of the device, device being too large or discomfort of genital tract) and vaginal symptoms include spotting and irritation. One study found there was no consensus on the frequency of pessary changes. However, a health professional survey found that the majority of replacements, washings and reinsertions of vaginal pessaries occur every 6 months after the initial insertion (181). Several designs of intravaginal devices are available and those with associated evidence are listed below.

1) Tampon compared to pessaries

Both tampon and pessary may provide protection against activity-induced incontinence (171)

1) Diaphragm / pessaries

Diaphragms (177) and pessaries (182) (183) (184) (185) have all been used with some success and may be an alternative to surgery or whilst awaiting surgery for some women **(Level of Evidence 1).** One study on pessary use has found mixed results with improvements in urgency incontinence, SUI and voiding difficulty in more than half of patients but six (14.3%) developed new-onset urinary incontinence (186). Another study found that pessary use was associated with decreased pelvic organ prolapse symptoms, frequency of urination but resulted in higher levels of new-onset SUI than SUI improvement (187).

Pessaries and behavioural therapy

Kenton *et al.* (188) Schaffer *et al.* (189) both performed a planned secondary analysis of a multi-centre randomised trial from the original ATLAS trial (190). Schaffer *et al.* (189) found the level of education, incontinence severity and post-menopausal status were predictors of success regardless of whether participants were in the continence pessary, behavioural therapy or combination therapy group. Kenton *et al.* (188) observed no changes in pelvic floor symptom bother and HRQOL between pessary and behavioural therapy groups. Therefore, individual preferences should be considered in the approach to the non-surgical treatment of SUI.

1) Vaginal devices designed specifically to support the bladder neck

One device which aims to specifically support the bladder neck (marketed as Diveen; Fig J-2) may be effective in improving incontinence symptoms (191, 192).

The 75NC007 device is designed to automatically situate itself beneath the urethra and bladder to support the former and the bladder neck. It has been found to be effective in decreasing the number of stress urinary incontinence episodes with minimal adverse events: one case of UTI and one case of metrorrhagia among 46 women who used the device. The authors concluded that despite the small sample size, the device is a safe and effective non-invasive treatment for women with SUI (193).

1) Reusable vaginal hollow tampon

A hollow tampon-like device has been made to sit behind the pubic bone, support the urethra during episodes of increased intra-abdominal pressure. One study of 59 women with SUI found a significant reduction (72% median) in urine loss in women with moderate and severe incontinence (>30g/day) on a 24-hour pad weight test but no significant benefit for women with mild symptoms (<30g/day) after three weeks of device use (194). Another study of 52 women of similar age showed significant reductions in a 24-hour pad weight test from a median 6.6g urine loss pre-insertion to 2.2g after four weeks of device use (195). Five percent of participants experienced acute bacterial cystitis, 7% had difficulty inserting and/or removing the device and 7% required out of hours attendance due to difficulty removing the device (194) (195).

1) Disposable vaginal devices

A single-use, disposable intravaginal device (Poise Impressa) Fig J-3 has a resin core with support ‘poles’ covered with a soft nylon mesh that stretches between the arms of the poles to act as a sub urethral sling. Based on two short-term studies, the use of the device has resulted in significant decreases in SUI episodes compared to baseline. 92% of women reported feeling dry and significant improvements in self-reported quality of life (196) (197). In one study, 28% of women experienced spotting and 8% asymptomatic bacteriuria as adverse events (185), but the percentage of specific types of adverse events were undefined in the second study (196) (197).

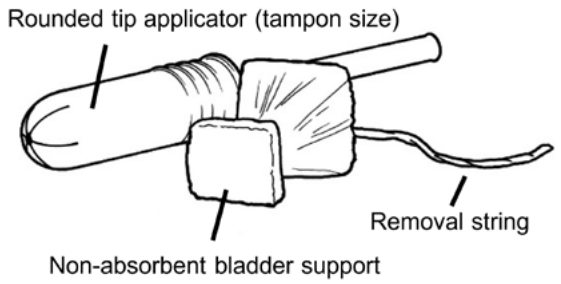

Fig J-3: The Poise) / Impressa (Kimberly Clark, USA) intravaginal device.

Systematic reviews

Lipp *et al.*'s Cochrane review for mechanical devices (198) currently confirms that there is little evidence from randomised controlled trials to judge device effectiveness against no treatment, and large well-conducted trials are required for clarification. There was also insufficient evidence to favour one device over another and little evidence to compare mechanical devices with other forms of treatment.

The European Association of Urology (EAU) summarises evidence from its full guidelines on assessment, diagnosis and nonsurgical treatment of urinary incontinence. It presents limited evidence for the use of mechanical devices for urinary incontinence. It recommends that physicians should not routinely offer intravaginal devices as a treatment for incontinence *(Grade Brecommendation)* (199).

Intravesical devices

- An intravesical attenuation device was evaluated in a randomised controlled trial for the treatment of SUI. The device involves having a balloon inserted into the bladder, inflated then sealing the device. It then acts as a sponge that focuses on reducing the spikes in intravesical pressure due to higher levels of abdominal pressure. Participants were randomised to treatment or sham procedure (no balloon insertion). Key issues were device malfunction, patient discomfort and invasive procedures resulting in a high withdrawal rate (200). Further studies have taken place on this device and are outlined in the next section.

2. NEW EVIDENCE FOR THE CURRENT CONSULTATION

New research studies conducted since the last consultation have enhanced our knowledge of mechanical devices for female urinary incontinence. Five new randomised controlled trials and one systematic review have been reported since the last consultation (36). Scarabelot and Colleagues (2018) conducted a systematic review that assessed the use of a pessary in the treatment of pelvic floor dysfunctions including urinary incontinence (201). Three trials follow up on the Rovner *et al.* (200) study on the effectiveness of the novel intravesical attenuation device on stress urinary incontinence (202, 203) (204). Four further studies, including one randomised controlled trial and three prospective single cohort studies, assess the efficacy of pessaries on women living with pelvic organ prolapse and stress urinary incontinence (205-208). Finally, one study assesses a new, single-use, one-size-fits-all device and its capacity to reduce stress urinary incontinence during a pad weight test (209).

McCammon *et al.* (202), Wyndaele *et al.* (204) and Winkler *et al.* (203) all studied the treatment effects of the intravesical attenuation device product on women with stress urinary incontinence. All three studies followed a prospective, randomised, single-blind, sham-controlled multi-centre design. All three share the same two primary outcome : at least a 50% reduction in a provocative pad weight test and at least a 10-point increase in their Incontinence Quality of Life (I-QOL) questionnaire survey after three months from baseline. Only Wyndaele *et al*. were able to achieve this dual primary measure after 3 months while McCammon *et al.* only achieved the outcome measure related to pad weight, although similar results between both groups were attained for the I-QOL survey. All three intravesical attenuation device trials highlight significant issues with the device and procedural tolerability. The rates of study withdrawal were 25.5%, 17.4% and 40.7% in the McCammon *et al*., Wyndaele *et al.* & Winkler *et al.* studies respectively. The main reasons for the high withdrawal rates were device and procedure intolerability, bladder irritation, and device-related adverse events. Adverse events were also high in each study, with 85.9%, 67% and 43.9% of participants experiencing them during the Winkler *et al.*, McCammon *et al.* and Wyndaele *et al.* studies respectively. The most commonly occurring adverse events were dysuria, urinary urgency, and gross haematuria. All adverse events in each of the McCammon *et al.* and Winkler *et al.* trials and all tolerability issues in the Wyndaele *et al.* study resolved fully after device removal. These three studies point to existing issues with device tolerability and a high level of adverse events as a result. The tested intravesical device is not currently commercially available.

Dueñas & Miceli (205) examined the efficacy of a ring pessary in 94 postmenopausal women with advanced pelvic organ prolapse (stages III and IV). The pessaries were not removed or replaced periodically unless there were adverse events associated with them and were kept in place until the end of the study (minimum 18 months follow up). At baseline, 55% of patients reported voiding difficulty, 37% reported stress urinary incontinence and 47% reported urge urinary incontinence. After one month of pessary use, 92% of participants with voiding difficulties found improved symptoms, as did 77% with stress urinary incontinence and 75% with urge urinary incontinence. A more recent study utilised a similar research method evaluating pessary use on another cohort of 123 women with advanced pelvic organ prolapse found it reduced voiding difficulty, stress urinary incontinence and urge urinary incontinence symptoms in 94%, 69% and 74% of participants respectively after 1 month of pessary use as compared to baseline (207). Both studies also showed 11-12% developed new onset stress urinary incontinence after 1 month. Overall, the results showed that participants with advanced stage pelvic organ prolapse could continue pessary use to address urinary incontinence without having to self-manage it. This practice could have financial implications by reducing the economic costs associated with regular pessary change.

Ring pessaries have also been shown to increase the quality of life of women with pelvic organ prolapse experiencing incontinence. Mendes and Colleagues have found that pessary use showed a significant improvement in quality-of-life domains, including perceived health status, UI impact, daily limitation, social limitation and severity measures (208).

Lovatsis *et al.* (206) examined the effectiveness of a bell-shaped pessary. It has a bell-shaped lower end which allows it to be seated just above the introitus at the level of the urethra providing support at the time of stress. Women with SUI were divided equally into treatment and placebo groups, with the latter receiving a silastic ring in place of the pessary. Participants did not self-insert the de-

vice, and a drape was placed so that participants were unaware of which device had been inserted. Upon placement of the device, two-thirds of the treatment group achieved a significant result of at least a 50% reduction in a provocative pad weight test (held pre- and post-placement) compared to 22.2% in the placebo group. No adverse events were documented, nor was there any significant discomfort with device placement. Despite the success, long-term trials will be required to test overall efficacy and real-world effectiveness.

A new intravaginal device has been evaluated for its effectiveness in reducing stress urinary incontinence in 26 women as part of a prospective, single cohort study. The device is single-use, one size fits all and utilises increased intra-abdominal pressure to apply pressure on the urethra only when there is a risk of urine leak. A modified 1-hour pad weight gain test was conducted pre-insertion, with participants drinking 250-500ml of water before inserting the device. With the device, pad weight gain was 79.4% lower on average than without the device, with a range of 0-23.6g pad weight increase. No adverse events were reported during the study. However, the length of assessment (1 hour) and tasks completed do not lend themselves to real-life applicability and long-term studies need to be conducted to validate device efficacy (209).

Scarabelot *et al*. (201) conducted a systematic review on the use of pessaries on pelvic floor dysfunction including treatment of urinary incontinence. Five trials were included in the review, of which two evaluated pessary use on UI and recruited women with SUI and overactive bladder. The reviewed articles demonstrate that the use of vaginal pessaries can be effective in the treatment of both urinary incontinence and pelvic organ prolapse. The authors noted that there is still a lack of long-term studies assessing pessary use, and the outcomes have often been narrowed to quality of life and satisfaction with device usage.

3. SUMMARY

Some mechanical devices may be effective and relatively non-invasive (with the exception of intraurethral or intravesical devices); however, there is a lack of randomised controlled trials and long term follow up for most products. The choice and use of mechanical devices should be made in consultation with experienced clinicians who can monitor product use regularly for adverse events and provide information and education to women who have been assessed as appropriate for the device. Specifically:

- Pessaries may be effective in SUI management and represent an alternative or complementary non-surgical approach although long term evidence is lacking. **(Level of Evidence 1).**
- Improved continence is possible for women with SUI with intravaginal devices. However, product evaluation has been limited and varies across a range of products **(Level of Evidence 3).**
- There is not enough evidence to compare the efficacy between products and severity and improvement in SUI. Comparison between device efficacy and severity of incontinence was only reflected in two studies **(Level of Evidence 3).** Relatively high drop-out rates in monitored studies may contribute to limitations in product efficacy, difficulties in the application or other factors such as discomfort **(Level of Evidence 3)**.
- Device efficacy and individual needs can be used as a guide to determine acceptability and choice of product. **(Level of Evidence 3)**.

4. RECOMMENDATIONS

Recommendations relating to mechanical devices for women with UI are summarised in Table J-2.

Table J-2: Recommendations relating to mechanical devices for women with UI.

- Internal vaginal support devices may be option when treating women with SUI, dependent upon the availability of the product, ease of insertion / removal, acceptance and cost **(Grade of Recommendation C).**
- Internal urethral devices are invasive, costly and have had a limited evaluation. However, they may be considered for intermittent and occasional use (such as during vigorous exercise) **(Grade of Recommendation C).**

No recommendations can be made on internal bladder devices pending ongoing trials. Studies have shown a significant level of adverse events for participants when they use the device (which mostly resolve after device removal). There is a high level of withdrawal rates for study participants and studies have not been conducted by researchers independent of the manufacturer.

5. PRIORITIES FOR RESEARCH

New devices - particularly invasive products– must be evaluated by randomised controlled trials, including long-term follow-up.

Evaluate the long-term effects of existing mechanical devices for urinary incontinence on the urethra and / or bladder to determine their real value and safety.

Comparison studies to other forms or like-forms of mechanical devices, conservative therapy, surgery and / or containment options are required.

Health economic assessment including cost-effectiveness and effects on quality of life be included when evaluating mechanical device use.

K. MECHANICAL DEVICES FOR MEN WITH UI

Male mechanical devices (also called penile clamps or penile compression devices) are designed to prevent urine leakage by compressing the penile urethra using a clamp design or a peri-penile strap (Fig K-1).

For some men, mechanical devices offer a cost-effective and convenient option for continence compared with a sheath and drainage bag or absorbent pads or for those who do not wish to undergo invasive incontinence surgery. However, there is potential for tissue damage and penile ischaemia, and these devices should be used with caution. The clinical opinion is that the device should be released at least every two hours and is unsuitable for use overnight or when sleeping (18). Careful assessment is necessary and they should be fitted by a trained health professional and re-evaluated on a regular basis. The availability of online products means that men can purchase devices without assessment -- healthcare pro-

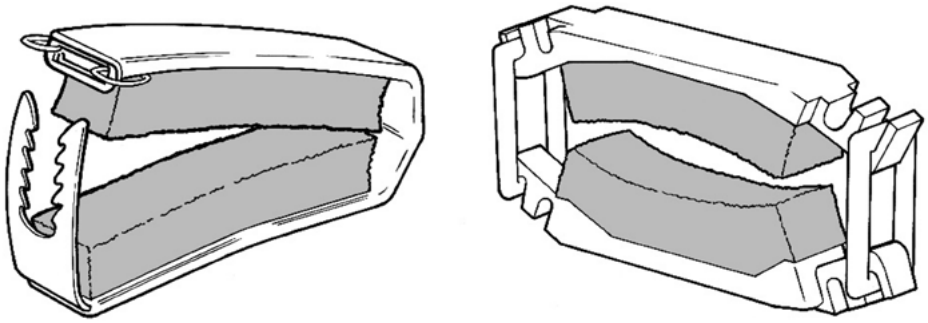

Fig K-1: Mechanical devices for men

fessionals should be alert to the need for education of men on the safe use of these mechanical devices.

A penile compression device should be comfortable, easy to apply and remove and cause no untoward effects on skin or penile vessels. It should not be used for urgency incontinence. The main factors that may make mechanical devices (un)suitable for men are summarised in Table K-1.

Table K-1: The main factors that make mechanical devices (un)suitable for men.

Mechanical devices may be suitable for men with:
• Sufficient bladder capacity to allow about 2 h wear before needing to release the device.
• Mainly stress urinary incontinence.
• Cognitive ability to remember to release the device at regular intervals.
• Adequate hand function that the device can easily be opened and closed.
• Penile length to allow comfortable placement of the device on the shaft and not the glans.
Mechanical devices are not be suitable for men with:
• Poor memory or impaired cognitive function.
• Overactive bladder / urgency inconti-nence.
• Penile skin irritation/dermatitis.
• No penile sensation or sensation of bladder fullness.

1. EVIDENCE

Although a range of devices is available, there has been little research on their safety and efficacy.

Three trials (18, 210, 211) were identified for the last consultation (36). The first evaluated the effect of three penile compression devices on mean urine loss, subjective opinion and cavernosal artery blood flow (210). The Cunningham clamp was the most successful device in terms of continence, ease of application and comfort but was also associated with the highest reduction of penile blood flow, indicating a potential for ischaemia if the device was placed too tightly. When the clamp was placed in a comfortable position and tightness, it controlled leakage well but did not eliminate it so that participants still wore a small continence pad.

The second was a randomised, controlled trial (18) of 56 men with persistent incontinence post prostate cancer treatment. Men tested, for 3 weeks each, the Cunningham penile clamp, penile sheath and bodyworn urinal (BWU) and compared these to their usual product of continence pads. Significant differences in acceptability, comfort, effectiveness ease of use were found between products: the Cunningham clamp was good for short, vigorous activities that increased abdominal pressure such as golf or swimming and was the least likely to leak. However, nearly all mean found the clamp uncomfortable or painful. Other products – sheath, pads, and bodyworn urinal – were also rated. Participants rated the sheath as effective for dryness and 'good' for extended use such as travel; the bodyworn urinal received the least positive reviews and did not stay in place well, particularly when the user was seated. Pads were positively rated for most activities and best for night-time use. Overall, participants indicated a preference for having a mixture of products to meet daytime needs. This is an important trial as it is the first to systematically compare several different continence products for men.

A third trial with 16 men measured IIQ-7 scores pre and post use of the penile compression device (Dribblestop™) as well as subjective impressions of ease of use, comfort, activity levels and overall satisfaction (211). There was a significant improvement in the IIQ-7 score; 14/16 participants found the device easy to use, allowing them to be more active and more confident and would recommend the device to others.

Since the 6th consultation, there have been two relevant studieswere found. A computational model identified design characteristics that provide the safest mechanical conditions in the penis to minimise tissue damage with the purpose of designing a safer clamp; these were envelopment, adaptability and durability (212). Another evaluated tissue response to applied loading with four different designs of clamp, all of which indicated tissue and blood flow compromise during device application but recovery within 40 minutes of removal indicating that the application of a clamp for one hour is likely to be safe (213).

2. SUMMARY

- Penile compression devices may be a valuable continence option for some men, particularly where activity may not only exacerbate incontinence but also preclude the use of bulky and / or absorbent products. **(Level of Evidence 1).**
- Men who used a compression device ranked them as easy to use and effective. **(Level of Evidence 1).**
- Some men found the Cunningham clamp uncomfortable or painful. **(Level of Evidence 1)**.
- Male mechanical devices can partially control urinary leakage, but they may not eliminate it at comfortable levels of compression. However, they are likely to lead to reduced cavernosal artery blood flow and therefore, care must be taken to ensure regular removal or release **(Level of Evidence 2).**

3. RECOMMENDATIONS TABLE

Recommendations relating to mechanical devices for men with UI are summarised in Table K-2.

Table K-2: Recommendations relating to mechanical devices for men with UI.

- Male mechanical devices should be be considered for men with stress urinary incontinence who are cognitively intact and aware of bladder filling, have normal genital sensation, intact penile skin and sufficient manual dexterity to open and close the device **(Grade of Rec-ommendation B)**
- Devices should be fitted by a trained health professional and reviewed regularly **(Grade of Recommendation C)**.
- Mechanical devices should be consid-ered as an option for short-term use when undertaking sport or other activities and as an adjunct to management with other continence products **(Grade of Recommendation C).**

4. PRIORITIES FOR RESEARCH

Further research is necessary on the length of time a device can remain in place, the amount of compression that is safe for penile vessels, and the effect on skin health and comfort when using the device. It is possible that one penile compression device will not meet the needs of all men, and further design considerations may be warranted.

L. INDWELLING CATHETERS

Indwelling urinary catheters (Fig L-1a) are inserted into the bladder urethrally (UC) (Fig L-1b) or suprapubically (SPC). Table L-1 lists the contexts in which long-term catheterisation (> 30 days) is most commonly used.

Table L-1: The contexts in which long-term in-dwelling catheterisation (> 30 days) is most com-monly used.

- Bladder outlet obstruction (BOO) where patients are unsuitable for - or waiting for - surgical or medical relief.
- Chronic retention that is causing incon-tinence, infection, renal dysfunction or substantial patient discomfort and when intermittent catheterisation is not feasi-ble.
- Continence care for comatose patients.
- Pressure ulcers at risk of urine contami-nation or non-healing incontinence as-sociated dermatitis where non-invasive methods (e.g., urinary sheath) are not feasible or have been unsuccessful.
- Intractable urinary incontinence where catheterisation enhances the patient's quality of life when alternative non-invasive approaches are unsatisfactory or unsuccessful.

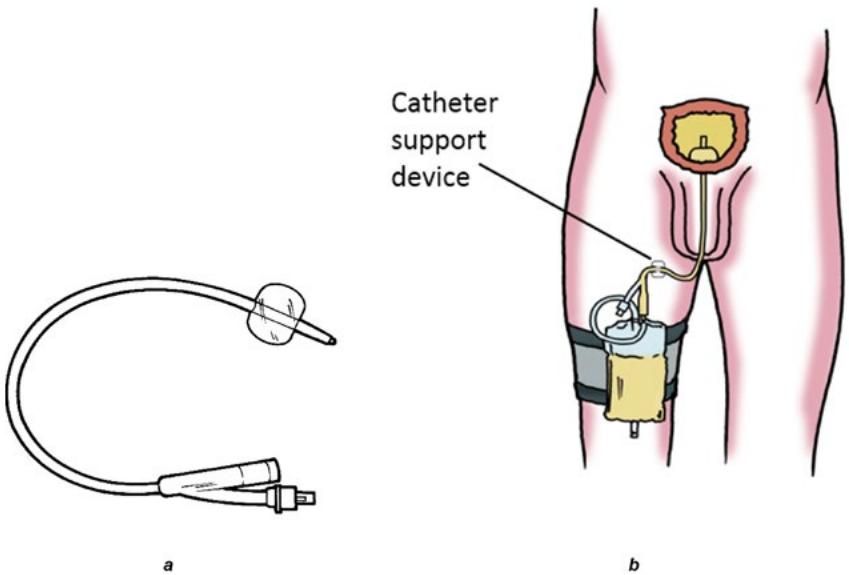

Fig L-1: An indwelling catheter with balloon inflated (a) and in position in the urethra / bladder.

The older hospitalised person is at particular risk of having an unnecessary catheter or one remaining in situ for a prolonged period and/or being discharged without instruction for catheter care or date for removal (197, 198). Common risk factors for catheters unnecessarily remaining in situ are listed in Table L-2.

Table L-2: Common risk factors for indwelling catheters unnecessarily remaining in situ.

- Absent or poor documentation on the reason for catheter insertion.
- Extended hospital stays.
- Transfer from one clinical setting to another **(214)**.
- No documented care plan for catheter removal **(214) (215)**.
- Immobility, confusion / decline in function **(216)**

Several prevalence studies have indicated that about 9% of nursing home residents have a long-term indwelling catheter (range 7%-38%) (217) (218) (219) (220) (221) (222) (216). Duration of use can be for many years - in one US-based study, mean use was 11.7 years (ranging in months from 1-589; median 8.8 years) (170) (223) (224).

Catheters should not be inserted as a continence measure until all other reasonable continence management/treatment strategies have been ruled out such as toileting, containment products and/or medication (213). In the evidence reviewed below, the primary focus is on the research related to long-term indwelling catheters (remaining in situ > 30 days).

The characteristics of the ideal catheter and ideal catheter material – according to expert opinion – are summarised in Table L-3, while Table L-4 outlines suitable materials, balloon size, catheter gauge and catheter length for different situations.

Table L-3 Characteristics of the ideal catheter and catheter material.

An effective indwelling catheter should have the following design characteristics:

- Be retained in the bladder effectively yet easily removable without trauma to the tissue.
- Have a soft 'tip' within the bladder to avoid pressure damage to the mucosa.
- Achieve effective drainage while minimising the risk of bladder mucosa being 'sucked' into the drainage channel.
- Conform to the shape of the urethra.

The ideal catheter material should:

- Be soft / flexible for comfort.
- Cause minimal tissue reaction or friction.
- Be sufficiently firm for easy insertion and maintenance of lumen patency in situ.
- Have elastic recoil so that an inflated balloon can deflate to almost its original size.
- Be resistant to colonisation by micro-organisms and to encrustation by mineral deposits.

Table L-4: Suitable catheter materials, balloon size, catheter gauge and catheter length for different situations.

	Short term	Long term	Comments
Material	Latex or plastic PTFE-coated latex.	Silicone elastomer-coated latex. Hydrophilic polymer-coated latex. All silicone.	Latex catheters: avoid where possible -- urethral discomfort due to high surface friction, risk of rapid encrustation by mineral deposits; risk of latex allergic reactions (225) (226) (227) (228) (229) (230) or anaphylaxis (231). Coated catheters cause the least friction and tissue reaction (232). Silicone catheters are stiffer & have thinner walls and slightly larger lumen compared to same size non-silicone-coated catheter; less likely to kink/bend (233); not affected by topical creams used for skin excoriation compared with coated latex catheters (234).
Balloon size	10 ml; larger balloon (30ml) only for post-op haemorrhage control.	10 ml	Large balloon contraindicated unless surgically required because of the risk of irreparable bladder neck erosion. Silicone catheter balloons may have water loss over time, with the catheter falling out (235) (236); fill the balloon with sterile water and replace fluid periodically, knowing that 1/4 to 1/2 could be lost over time (235).
Gauge	Adult 14-16 Fr; post-op procedures with haematuria/clots larger lumen 18-24 Fr.	Adult 14-16 Fr; smallest size to maintain good drainage (237) (238) (239).	Large diameter: Potential blockage of para-urethral glands and urethral injury.
Length	Male/female 41-45 cm	Male 41-145 cm; female option 25 cm.	

1. EVIDENCE

Few randomised controlled trials have been conducted on either long or short term catheterisation since the last consultation (36). The trials that have been undertaken are typically small, with sample heterogeneity, imprecise outcomes and short term follow up. Most data are of **Level of Evidence 4**, based on clinical experience and expert opinion. Two new Cochrane reviews relating to long-term catheter use add to existing reviews to attest to the lack of evidence which precludes drawing robust conclusions (See Appendix 2 for a listing).

Studies can be usefully reviewed under the following headings:
- Catheter characteristics and materials.
- Catheter coatings and CAUTI.
- Meatal cleansing.
- Catheter encrustation.
- Bladder calculi.
- Catheter-related pain.
- CAUTI.
- Bladder cancer.
- Management strategies.
- Education of health care professionals.
- Quality of life.
- Cost.
- Urinary catheters versus other strategies.

Catheter characteristics and materials

Feneley and colleagues wrote in 2012 “in an era that has witnessed outstanding technological advances in medical practice, it is difficult to understand why we are still unable to perform the relatively simple task of draining urine from the bladder without producing infection and a range of associated complications” (240). Efforts to improve the traditional Foley design include a novel balloon shape (241), drainage tubing designed to optimise flow (160) and additional eyeholes (242). Clinical testing is still awaited.

Catheter coatings and CAUTI

Considerable work has been committed to finding a catheter coating that will prevent CAUTI or delay the onset in both acute and long-term care. To date, and despite dedicated attempts to find options, there are no coated/impregnated catheters that will delay the onset of CAUTI in the long-term user. There may be a modest benefit for those catheterised seven days or fewer.
- **Silver:** Two new trials comparing CAUTI with silver alloy versus standard catheter were found. One RCT compared silver SPCs and standard SPCs with 288 urogynaecology patients and found no clinically meaningful difference in rates of UTI at six weeks (243). The other RCT compared silver alloy-coated UCs with standard among 489 spinal cord injury patients for a minimum of seven days and found no difference in UTI rates (244). Other randomised trials conclude that silver alloy catheters do not significantly reduce the incidence of CAUTI in acute care (245) (246) (247).
- **Antibiotic/antiseptic impregnated catheters:** Earlier catheter studies on the effect of nitrofurazone (248-251); minocycline and rifampicin (252); chlorhexidine, silver sulfadiazine, triclosan (253-257) have suggested benefit, but outcome measures of bacteriuria vs CAUTI, heterogeneous patient populations and small samples have limited the clinical impact of these findings. The largest randomised trial to date comparing nitrofural silicone, silver alloy-coated latex or a PTFE standard catheter (n=7102 acute care, short term catheter subjects) found that the nitrofural catheters had a small and not clinically meaningful decrease in CAUTI and were more uncomfortable than silver alloy or PTFE catheters. No significant decreases in symptomatic CAUTI occurred with silver alloy catheters compared to control (235). One large pilot RCT compared nitrofurazone coated catheters with non-impregnated with 214 subjects and found no improvement in the incidence of UTIs (250). Laboratory work continues to show promise in antibiotic and antimicrobial catheters (258) (259-264) but clinical testing is required.
- Other coatings or treatment undergoing laboratory testing: Zwitterionic molecules (in an anti-fouling coating) decreased biofilm development by 80% over seven days as compared with untreated catheters (265) (266). Laboratory testing also includes nanoparticle coatings on catheters (267) (268) coating with antimicrobial enzymes (269) (270), polydopamine peptide coating (271), the addition of plant extracts (272), the release of salicylic acid (273), interference with bacterial signalling (274) (275), the use of bacteriophages to control colonising mixed-species biofilms (276) (277) (278) and the application of low electrical currents to dislodge mature biofilms (279). Future opportunities for CAUTI control are promising based on the sophisticated laboratory work underway.

Meatal cleansing

Since the last consultation, one large (n=1642 catheter users) multi-centre stepped wedge RCT reported that the use of chlorhexidine solution for meatal cleansing prior to catheter insertion decreased CAUTI compared with normal saline (4 CAUTI in 2338 catheter days for chlorhexidine and 13 CAUTI in 2889 catheter days for normal saline) for short-term users (280). A recent systematic review and meta-analysis of the effectiveness of antiseptic cleansing of the meatal area concluded that there is some evidence that some antiseptic solutions might be more effective than sterile water in preventing the onset of bacteriuria, but the evidence base is challenged by the diverse range of antiseptics used in trials (281). Effective handwashing by healthcare professionals, caregivers and patients, before and after handling catheters and drainage equipment, is generally accepted to be the most important component of any infection control strategy. Healthcare professionals and formal caregivers should also wear gloves.

Catheter encrustation

Catheter encrustation affects the quality of life, nursing time and healthcare costs (282). Several approaches have been tested to reduce the problem including catheter maintenance solutions (283) (284), fluid intake (285) (286) and catheter valves. Preventative strategies have largely failed, but recent laboratory research, using advanced imaging techniques, has improved the understanding of crystalline biofilm formation which may aid in the development of anti-microbial materials resistant to colonisation (287).

Catheter encrustation (Fig L-2) occurs in up to 50% of LTC users, with resultant increased costs to services and patients (221) (288) (289) (290) (291). Mineral deposits - calcium phosphates and magnesium ammonium phosphate (struvite) - precipitate from the urine under alkaline conditions and cause blockage. In one trial prevalence of catheter blockage in a two month period was 11.08 per 1000 catheter-days’ use (282). During the 12 months of another trial (292), both treatment and control groups had a reduction in blockage (4.76 and 6.04 per 1000 catheter-days, respectively) but there were no statistically significant differences between groups.

Fig L-2: Section of a catheter showing encrusta-tion and blockage.

Precipitation of different ionic species (i.e. Ca++, Mg++, and phosphates) is influenced by their ionic concentrations in the urine and by the presence of urea-splitting micro-organisms such as *Proteus mirabilis* (293) (294) (295) (296). The pH at which ions precipitate from the urine varies, not only for different ions but also between individuals and at different times (297) (298). These factors contribute, at least in part, to individual susceptibility to catheter encrustation and time to blockage. 'Blockers' experience recurrent catheter blockage within a few days to a few weeks (288), and urine from recurrent blockers tends to have a very narrow 'safety margin' between 'voided' urinary pH and the pH at which crystallisation

Table L-5: Catheter maintenance solutions.

Suby G or Solution G[1]	3.23% citric acid solution, pH 4, containing magnesium oxide to minimise tissue irritation, aimed at reducing encrustation. Used where routine catheter maintenance is required to reduce the build-up of encrustations.
Solution R[1]	6% citric acid solution, pH 2, containing magnesium carbonate, aimed at dissolving encrustations. A stronger acid than Suby G and therefore not recommended for frequent, regular use.
RenacidinR[2]	A citric acid solution, pH 3.5-4.2, containing glucono-delta-lactone to minimise tissue irritation and magnesium carbonate, aimed at reducing encrustation.
Mandelic acid 1%[1]	An acidic solution, pH 2, aimed at inhibiting the growth of urease-producers. A stronger acid which is not commonly used to reduce catheter encrustations
Saline 0.9%[1,3]	A neutral solution, pH 7, is recommended for the flushing of debris and small blood clots. Neutral pH solutions will not dissolve catheter encrustations.
Chlorhexidine 0.02%[1]	An antiseptic solution aimed at preventing or reducing bacterial growth, in particular, E. coli and Klebsiella species (but will not prevent biofilm formation on long-term catheters)

[1] Available in the UK pre-packed in a sterile delivery device designed for instillation into a urinary catheter.
[2] RenacidinR is approved in the USA for kidney stone disintegration only. Although it may be effective in certain situations for persistent catheter blockers, there are no supporting studies. [3] Saline is widely available

Table L-6: Catheter encrustations - theory and evidence

	Theory	Results	Level of Evidence
Catheter materials.	Intent to reduce/stop biofilm adherence.	To date, *no evidence* that any material (silver coated latex; hydrogel or silicone-coated latex, 100% silicone; nitrofurazone coated silicone.	1
Citrate Washout solutions (Catheter maintenance solutions): Suby G, Solution R, renacidin).	Reduction of pH; mobilisation of crystalline collections; eradicate P Mirabilis.	Citrate solutions clinical studies: *no evidence* to date.	1
		Renacidin laboratory results show promise; no clinical studies.	4
Washouts: saline, sterile catheter.	Mobilise catheter debris.	*No evidence of benefit.*	1
Urease inhibitors: Acetohydroxamic acid 1.0 mg/ml & fluorofamide 1.0 microg/ml.	Lower pH in the presence of P. mirabilis.	Laboratory studies: Reduce pH in the laboratory; in clinical studies, side effects were unacceptable.	2
Fluid Intake: Water (279); acidic fluids (lemon 60 ml/L water/lime juice), potassium citrate 6g/L	pH increases when urine concentration decreases + citrate. Citrate (orange, lemon, lime juice) concentration may change pH & mineral crystallisation.	*Weak evidence* of reduced blockage (438). No evidence that cranberry juice decreases pH in catheterised people.	2
Electron Donating surfaces or electrical current through silver electrodes attached to the catheter.	Proteus mirabilis suppression.	Laboratory results only – may inhibit growth; need clinical studies.	4
Triclosan catheter balloon fluid.	Triclosan suppresses biofilm formation.	Laboratory results only – need clinical application.	4
Proteus targeting.	P mirabilis has four adhesins that help make it stick to the bladder and catheter, a protective capsule, several secretions that promote extraction of host nutrients, quick migration capacity, and a powerful urease.	Laboratory studies of strong electron-donating surfaces; triclosan in the catheter balloon need clinical testing.	4

(or nucleation) occurs (294) (299). This margin is much wider in non-blockers (296).

Catheter maintenance solutions

Pursuit of a solution to managing catheter blockage is ongoing and several catheter maintenance solutions are marketed (Table L-5). However, there is no evidence that any are effective in preventing encrustation or blockage in the clinical setting:

- Washout / maintenance solutions (284) (300) (301).
- Catheter coating or material (291) (302) (303) (304) (305) (306) (307) (308) (309) (310) (311).
- Oral medication (312) (313).
- Balloon instillation (314) (315) (316).

Several solutions are marketed to decrease encrustations/increase catheter time in situ (Table L-5). However, to date, there is no clinical evidence that catheter maintenance solutions are effective in improving catheter drainage (317). For patients who have blocking or encrusted catheters, the key nursing procedure is to review the catheter integrity, observe for reduced flow or obvious encrustation and change the catheter before it blocks. A characteristic pattern of 'catheter life' can usually be identified with record-keeping of three or more catheter episodes (294) (299) (318). This may allow proactive strategies of care designed to change the catheter before likely blockage.

Concerns have also been raised about a potential negative effect of washouts on the urothelium (283) (294) (299) (319) (320) (321) (322) (323). There is weak evidence that citric solutions (orange, lemon or lime juice) and / or water intake may change pH and mineral crystallisation (285) (324) (325). Table L-6 summarises the theory and evidence of research efforts on encrustation.

Bladder calculi

Indwelling catheters (UC and SPC) are a known risk factor for bladder calculi formation compared to intermittent catheterisation (326) (327) (328) (329). This increased risk is independent of age, sex, level and degree of injury, and the risk increases with the duration of catheterisation so that by 5 to 10 years of continuous urethral or SP catheter use, 33% to 46%, respectively, will have been treated for a bladder calculus (330). Any foreign object, like a retained piece of fluff from gauze or pubic hair can cause a stone. Careful attention to hygiene and catheterisation techniques could prevent this complication (331).

In a prospective cohort study of 66 SCI patients in Nigeria, encrustations and P. mirabilis were predictive of bladder stones; thus, ultrasound was recommended for persons with these risks to identify and treat bladder calculi (332).

Symptoms of bladder calculi vary from unresponsive CAUTI to catheter bypassing, spasms and haematuria. Individuals who do not respond to the appropriate treatment of CAUTI should have a urological referral.

Catheter-related pain

Catheterised individuals report discomfort, pain and restricted activities because of catheter-related painful bladder spasms, the position of the catheter/tubing or catheter changes (170) (333). In a prospective observational study of 116 patients post urological surgery, the type of surgery and catheterisation history predicted moderate to severe catheter-related bladder discomfort (263). In a sample of 202 long-term indwelling catheter users, 23% reported catheter-related pain (other than during the catheterisation procedure) over the previous two months (282). Women complained about the pain because of sitting on the catheter or sores in the vaginal area. Bladder spasms, CAUTIs, blockage, and dislodgement can all contribute to catheter-associated pain, as well as insertion and removal procedures (334) (335) (336) **(Level of Evidence 3).**

If bladder spasm is the cause of pain, a low dose of an anticholinergic medication may help (337). Attention to the catheter position and tubing is needed to prevent kinks or twists, to ensure that the catheter straps are not blocking urine flow and that the individual is not sitting on the tubing (338). Other approaches include treating constipation if present, ensuring that the catheter is the smallest size to provide adequate drainage, and ensuring that the catheter is secured and the drainage bag is well supported to prevent dragging on the catheter.

Catheter-associated urinary tract infections (CAUTI).

The most common infecting organisms are Escherichia coli, Enterococcus spp, Candida, and other Gram-negative and Gram-positive isolates (339). Up to 40% of cultured specimens from long term catheters will show *Proteus mirabilis* as a key organism in biofilm production, catheter blockage and pH alteration because of urease production. Table L-7 highlights the progression of initial colonisation to adherent biofilm.

Table L-7: Biofilm production from initial coloni-sation to adherent biofilm.

Biofilms **(340) (341) (342) (343) (344) (345) (346)**.
• Rapid colonisation of micro-organisms forms a strongly adherent biofilm on catheter and drainage equipment sur-faces.
• Biofilm formation begins by deposition of a conditioning layer of proteins, electrolytes and other organic mole-cules from the urine
• Micro-organisms attach to catheter sur-faces & divide to form micro-colonies, ultimately developing a complex three-dimensional structure, including fluid-filled channels through which the bio-film members receive nutrients, diffuse away wastes and send chemical sig-nals to each other
• Microorganisms growing as a biofilm are less susceptible to antimicrobial therapies than free-living organisms and are a major source of resistant, nosocomial pathogens
• *Proteus mirabilis* is a common biofilm isolate that secretes urease causing hydrolysis of urea to free ammonia, raises urine pH and promotes precipita-tion of calcium phosphate and magne-sium ammonium phosphate (struvite) and catheter blockage.

Onset of CAUTI

- All individuals with indwelling urinary catheters will develop colonisation (asymptomatic bacteriuria) at 5-8% per day to 100% by day 30 (347) (348) (349) (237) **(Level of Evidence 1)**.
- Even short term antibiotic use in a catheterised patient may place them at risk of CAUTI (340) (350) **(Level of Evidence 2)**.
- Most catheter users developing bacteriuria will remain asymptomatic and not require treatment **(Level of Evidence 1)**.
- 24% of those developing bacteriuria will develop a symptomatic UTI without bacteraemia (351) **(Level of Evidence 1)**.

- 4% with bacteriuria will develop bacteraemia, a serious health care problem (351) **(Level of Evidence 1).**

Aetiology of CAUTI

Biofilm formation on the catheter surfaces begins as early as 24 hours after insertion. Microorganisms derive from the patient's own colonic and perineal flora or from the hands of healthcare personnel during catheter insertion or management (340) and gain access in two ways:

- Extraluminally during catheter insertion or via the periurethral space.
- Intraluminally following breaks in the closed system or contamination of urine in the drainage bag or break in a closed system (within 32-48 hours v 72-168 hours respectively) (352).

Diagnosis of CAUTI

The generally accepted CAUTI definition is outlined in the U.S. National Healthcare Safety Network (NHSN) document (225). The criteria are guidelines for practice – individual patient presentation may differ. Further work is required on the most appropriate outcome measures and the corresponding patient-reported symptoms of CAUTI, particularly in long term users.

Treatment of CAUTI

- Prophylactic antibiotics prior to re-catheterisation are not recommended (139) (347) **(Level of Evidence 1)**.
- Routine use of prophylactic antibiotics or antiseptics in LTC patients is not supported and may favour the emergence of resistant organisms (139) (242) (348) (349) **(Level of Evidence 1)**.
- Cranberry juice does not affect the incidence of CAUTI (350) **(Level of Evidence 1)**.
- Urine cultures should be obtained before initiating treatment to permit selection of specific therapy for the infecting organism; extensive use of broad-spectrum therapy should be avoided (351) **(Level of Evidence 2)**.
- The catheter should be replaced prior to collecting a urine sample for culture and sensitivity or prior to starting antibiotics in symptomatic patients (139) (352) (353) (354) **(Level of Evidence 2)**.

Reducing the risk of CAUTI

Current evidence is weak regarding all aspects of CAUTI prevention in long term catheter users. Based on the existing research, none of the following factors have been shown to reduce the incidence of CAUTI:

- Pre-connected urine drainage bags (353).
- Perineal cleansing (353).
- Suprapubic versus urethral insertion (354) (355) **(Level of Evidence 2)**.
- Silver alloy antimicrobial surfaces (356) (357).
- Catheter coatings to reduce protein absorption (358).
- Inflation of the balloon with a biocide solution, such as Triclosan (305) (314).
- Disruption of matrix or glycocalyx components with agents such as heparin (359).
- Numerous trials of oral antibiotics, antimicrobial bladder washes, drainage bag solutions and topical disinfectants all lead to the conclusion that bacteriuria and UTI may be suppressed temporarily at best, but resistant organisms are highly likely to emerge (341).

Bladder cancer

The reported incidence of bladder cancer associated with chronic indwelling catheterisation varies across studies (360, 361) (362). In a US-based study of 3,670 SCI subjects with indwelling catheters, the incidence of bladder cancer was 77/100,000 population vs 17/100,000 for the US general population (363) **(Level of Evidence 3).** Even SCI patients without an indwelling catheter may have a higher risk of bladder cancer 15 times that of the general population, and it is postulated that the neurogenic bladder may itself be a risk factor (364). The potential relationship between the duration of catheterisation and cancer development could be studied further, particularly because patients change their form of bladder drainage, which confounds the subgroup analysis in retrospective studies. Squamous cell cancer also was reported in two cases in persons with suprapubic catheters, which is believed to be uncommon and needs to be differentiated from granulomatous conditions which are common (365). Bladder calculi have been identified as an independent risk factor for bladder cancer by some authors (361).

Carcinoma within the cystostomy tract with SPC has also been reported (366) (367) (368). However, Hamid *et al*. (369) raise concerns over the interpretation of screening cystoscopy and biopsy in this population and note the importance of distinguishing between histological changes and confirmed cancers when interpreting study results. Guidelines on catheter management include a recommendation that patients with urethral catheters in place for 10 years or more should be screened annually for bladder cancer (370) **(Grade of Recommendation C)**.

Catheter management strategies

In addition to CAUTI and encrustation, catheterisation is associated with several other complications: trauma due to malposition, leakage, calculi, false passage, haematuria, dislodgement, urethral strictures, hypersensitivity or anaphylaxis related to the catheter material (371) (372) (373). In a prospective surveillance project in a U.S. Veteran's Administration hospital, genitourinary trauma was as common as CAUTI (374). In one group of 202 community-dwelling adults with long-term catheters, the authors described catheter-related problems: 31% with CAUTI, 24% blockage of the catheter, 12% accidental dislodgement, pain (23%), sediment (63%), bladder spasms (36%), or urine leakage (43%) (282). Many case reports describe catheter-related complications such as urethral injury (375) (376) (377), intraperitoneal rupture of the bladder (378) (379), fistula (380), and iatrogenic hypospadias (381). These complications consume nursing time, compromise quality of life, and are costly to the healthcare system.

Overall, complications can be reduced if systematic approaches are taken to catheter care. Guidelines and protocols for catheter-care practices have been developed by clinical experts and should be part of an institution's care mandate. Research findings on topics such as meatal cleaning, lubrication, catheter securement, pain, and encrustations are discussed below.

Suprapubic versus urethral catheter insertion: Incidence of complications such as CAUTI, bladder calculi and encrustations do not differ between urethral or SP routes, but SPCs do offer easier access to catheter site, easier recatheterisation, and may be more comfortable for individuals. Table L-8 compares the two insertion approaches.

Table L-8: Comparison of long term urethral and suprapubic catheters.

Comparisons	Urethral	Suprapubic
Insertion	Insertion by a qualified healthcare professional	The initial placement must be by urologist/expert; may require anaesthetic
Upper urinary tract complications: vesicoureteral reflux; renal dysfunction, hydronephrosis; pyelonephritis renal calculi	No difference	
Urothelial Cancer	No difference	
Lower urinary tract complications: bladder calculi	No difference (384) (385).	
Lower urinary tract complications: ASB; symptomatic UTI	No difference (327) (356) (386).	
Lower urinary tract complications: urethral	Risk of urethral stricture, urethritis, scrotal abscess	Rare; SPC protects the anterior urethra (387).
Urinary incontinence/skincare	By-passing occasionally causing perineal dermatitis; can usually be treated by medical/ nursing management	Urethral leak, especially if prior urethral/bladder neck trauma from UC; can only be treated surgically. Risk of over-granulation of stoma tract causing pain/bleeding on removal (388) (389) (390). Stoma site can be prone to IAD from urine leak or irritation from the catheter.
Access for catheter insertion	It can be difficult in patients with leg spasms, who are obese, men with retracted penis	Straightforward when track established; tract can close within hours if catheter falls out.
Not suitable if	Urethral deformity/stricture	Haematuria of unknown origin, Bladder tumour Small contracted or fibrotic bladders Obesity if pannus covers SPC site; obesity makes catheter insertion more difficult or impossible because of the trocar length. Abdominal scarring from surgery or radiation

When changing a SPC, the new catheter should be inserted as quickly as possible as a delay of only a few minutes can result in partial obliteration of the tract (382)(383) and the tract will close completely within 24 hours. It is also possible to insert the new catheter too far into the bladder, so it enters the ureter with resultant trauma with balloon inflation. Careful observation of the length of the catheter external to the abdomen and the angle of protrusion prior to catheter change can help to ensure the correct positioning of the new catheter (384). However, this is not always enough evidence to show correct positioning. A case presentation of a catheter that had “doubled-back” and showed the correct length suggests that imaging may occasionally be required to ensure correct placement. Dressings around the stoma site are not normally required unless there is excessive discharge, causing staining and / or sticking to clothing

Maintaining effective catheter drainage

The use of urinary catheters is rarely completely trouble-free. Catheter drainage can be compromised by a variety of factors from simple causes such as kinked tubing or the position of the drainage bag, to bladder spasm, the pressure of a constipated bowel on the adjacent urethra, suction of bladder mucosa into the catheter eye, or blockage by blood clots, mucus or encrustations. The algorithms in Fig L-2, Fig L-3 and Fig L-4 combine current evidence-based knowledge and expert opinion to provide some guidance on troubleshooting common problems. Further research is required to determine if dependent loops, which allow urine stasis, could contribute to CAUTI (158).

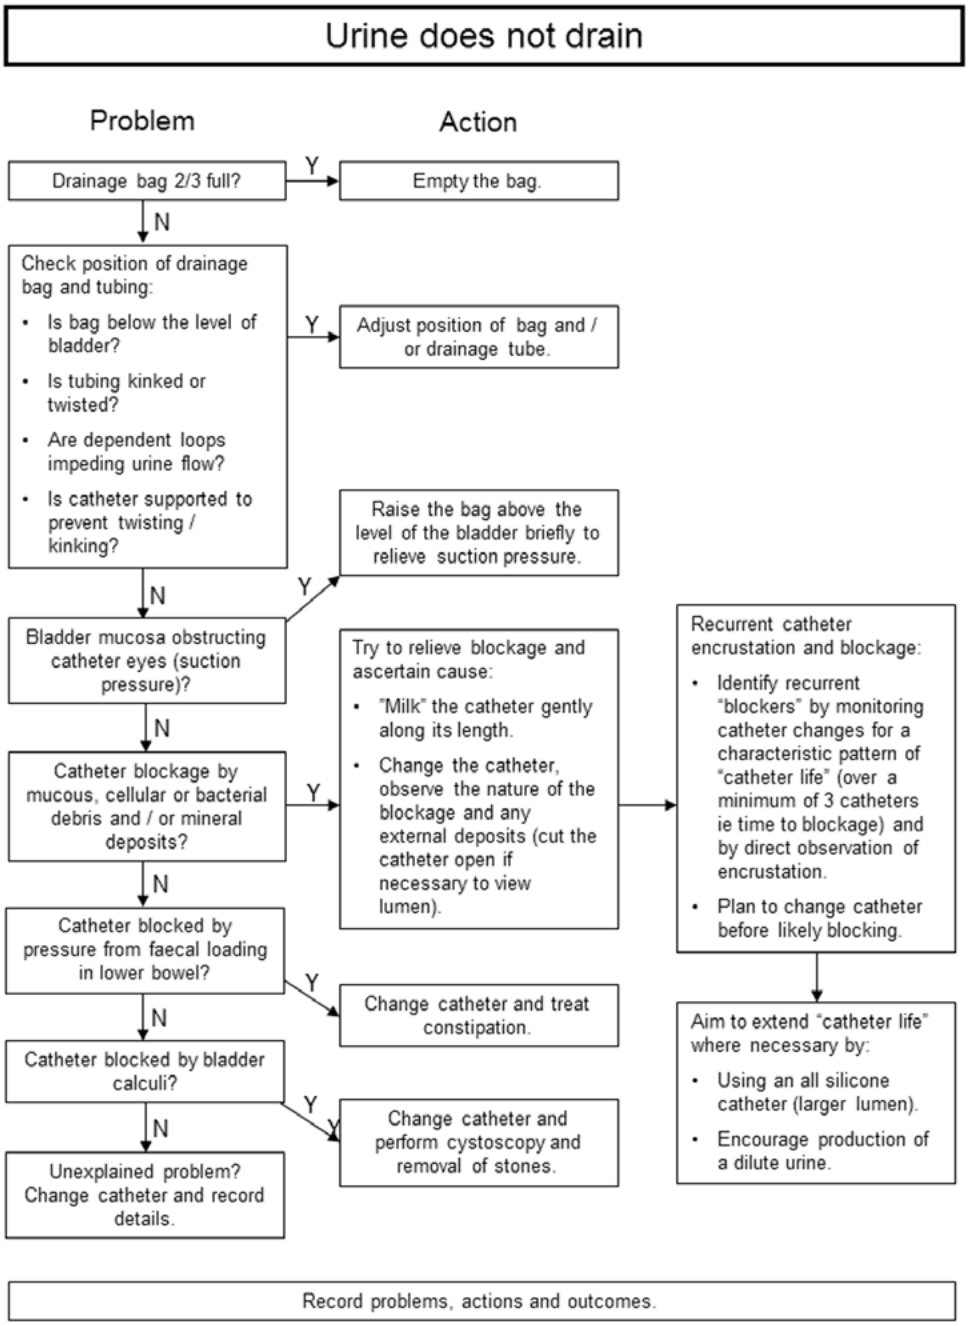

Fig L-3: Troubleshooting long-term indwelling catheter problems: urine does not drain. (N = No; Y = Yes). (Always have a spare catheter available).

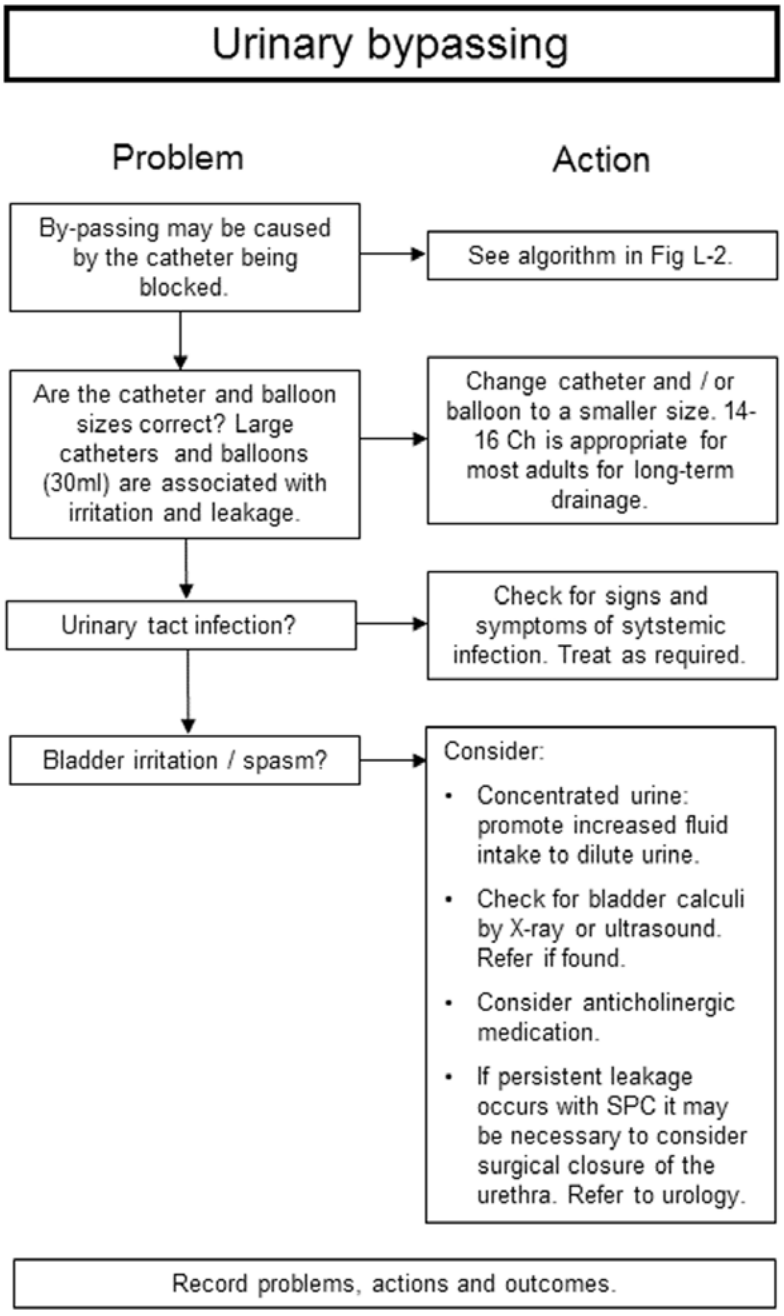

Fig L-4: Troubleshooting long-term indwelling catheter problems: urinary bypassing.

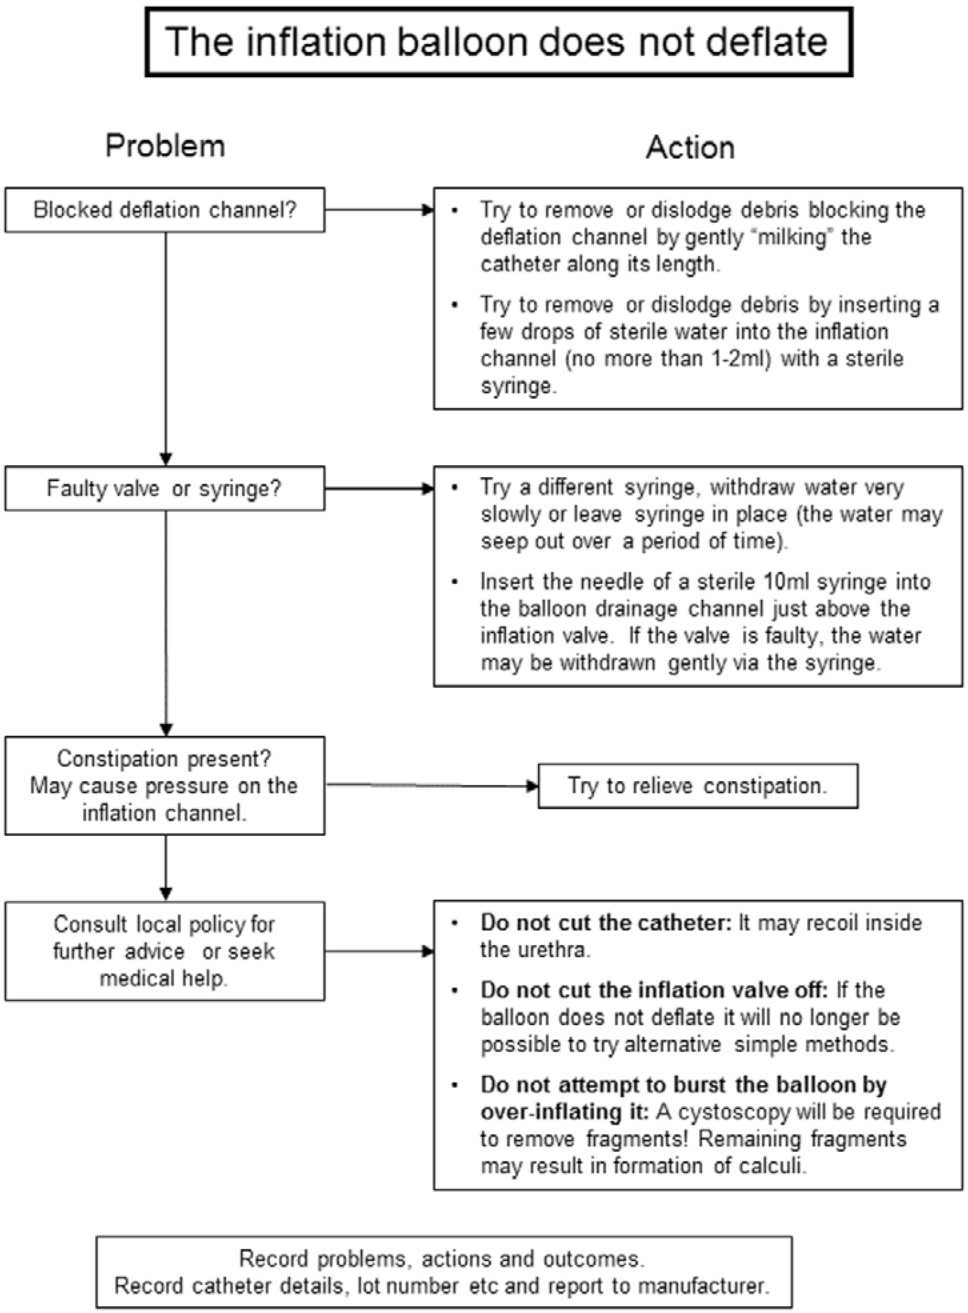

Fig L-5: Troubleshooting long-term indwelling catheter problems: the inflation balloon does not de-flate.

Catheter valves

A catheter valve is a compact device used to control urine flow and is connected to the catheter outlet in place of a bag to allow a discreet alternative to conventional urine drainage bags. Valves are available in a variety of designs (Fig L-6) ranging from simple devices used for up to a week to more complex forms which last longer, and which may permit one-handed action. Most valve designs can be attached to a drainage bag at night to allow free drainage while the patient sleeps.

- Suitable for: those who can manipulate the valve mechanism and empty the bladder regularly to avoid bladder distention and accompanying risks of reflux on the upper urinary tract.
- Not suitable for: people with poor manual dexterity, low bladder capacity, detrusor overactivity, vesicoureteric reflux, renal impairment, lack of bladder fullness sensation or cognitive impairment.

Evidence supporting the beneficial effects of catheter valves is derived from expert opinion and there is a paucity of research in this area. A lack of knowledge on valves may interfere with appropriate use; therefore, a full assessment is required to determine whether the person is a good candidate for a catheter valve using a systematic process, such as an algorithm (385).

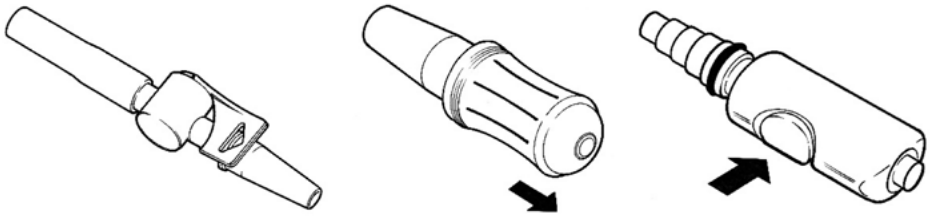

Fig L-6: A variety of catheter valves with different closure mechanisms.

There is little new research on catheter valves. Findings from studies indicate (386) (387) (388) (389) (390):

- Catheter valves provide a well-accepted system of bladder emptying for those who can manipulate the valve mechanism and empty the bladder regularly to avoid overfilling **(Level of Evidence 2)**.
- There is no evidence of increased risk of CAUTI, bladder spasms or discomfort compared to conventional drainage systems, although there may be a higher incidence of nocturnal frequency and episodes of bypassing with valves. **(Level of Evidence 2)**.
- Valves may promote maintenance of bladder tone and capacity **(Level of Evidence 4)**.
- Preferred valve design should be easy to manipulate, leak-free, and inconspicuous (399). **(Level of Evidence 3)**.
- An automatic valve system for LTC patients (400) may be helpful for patients who lack sufficient dexterity to manage a manual valve.

A catheter valve may facilitate periodic flushing, but clinical evidence is currently lacking on reduction of encrustations and prolonging catheter life. Only one controlled laboratory study has explored the question (401), indicating that time to blockage with valves was extended by over 50% compared to controls. There is an opportunity for clinical research in this area.

Catheter-change frequency

There is no research evidence to support specific change intervals for IUC or SPC (391). Thus protocols vary widely between facilities from monthly to several months if the catheter is trouble-free.

Lubrication

Guidelines and clinical reports suggest that injury or discomfort may be minimised by using a sterile lubricant or anaesthetic gel (392) (393) for male catheterisation; few have considered the procedure for women or for supra-pubic catheterisation (394). Results are mixed on the benefit of lignocaine versus water-based lubricant for female catheterisation: one trial demonstrated lignocaine gel group had a significantly lower median procedural pain score compared to the group receiving a water-based lubricating gel (395), whilst another trial found no difference between lubricants (396). In a small trial with infants, intraurethral lidocaine resulted in less catheterisation distress than topical or topical and intraurethral water based lubricants (397).

The United Kingdom National Institute for Health and Care Excellence (NICE) guidelines on infection control (398) recommend: 'an appropriate lubricant from a single-use container should be used during catheterisation to minimise trauma and infection'. Anaesthetic gels may be contraindicated in patients with damaged or bleeding urethral membranes and should be used with caution in those with cardiac conditions, hepatic insufficiency and epilepsy (399). Lubricants that contain chlorhexidine have been reported to trigger anaphylaxis in a small number of patients during catheter insertion, and consequently, a careful history is required to screen for sensitivities (400).

Fluid intake

Apart from catheter maintenance solutions, laboratory studies suggest that dilute urine or increased urinary citrate concentration from orange juice or other fruit juices could be beneficial (324), but randomised clinical studies are needed to assess the benefit of fluid adjustments.

Catheter Securement

Catheter securement may prevent movement of - and tension on - the catheter and potentially reduce the incidence of urethral erosion, trauma and pain, prevent accidental dislodgement from traction (401), and possibly reduce the incidence of bacteriuria (402). Of note is that whilst securement is intuitively better care, it is not necessarily put into practice. Two studies highlight this: of 82 nurses (8 continence specialists), 98% recommended securement, but only 4% were documented using it (403); in a one-day point prevalence study in acute care, only 18% (8 of 44) of the catheters were secured (157).

Several securement devices are available, ranging from:

- Adhesive devices (potential for skin irritation).
- Non-adhesive straps covered in fabric (can slip down with full urine bag).
- Holster styles (404).
- Adhesive tape such as silicone tape can be gentler than paper tape, based on a single trial with children (405). One case report in paediatrics demonstrated efficacy in using an adult leg bag to hold the catheter in place (406).

The choice will depend on the individual's usual activity, clothing, size of the thighs and the weight of the bag it would support. All need to be comfortable, easy to use, and gentle to the skin (407).

Self-management

Self-monitoring, a component of self-management, involves awareness of what to notice and related measurements or observations (408). Self-monitoring urine flow was found to be helpful in preventing or minimising catheter-related problems in a pilot study with 11 community-based individuals over a six months' time period (224). In the follow up randomised trial (N=202), a self-management programme for long-term indwelling urinary catheter users was tested in an experimental design. The intervention consisted of a 3-day intake and urinary output diary, educational booklet, and three home visits by a study nurse (404). The outcomes of CAUTI, blockage and accidental dislodgement were evaluated over the 12 months' participation, measured in bi-monthly phone call interviews, using a general estimating equation and rates calculations. In the first six months of the study, blockage reports of occurrence (yes / no), but not frequencies of the event, were significantly lower in the experimental group than in the control group. No group differences were found for the full 12 months of the study or for other outcomes;

however, examination of rates indicated that both groups improved over the 12 months' study for all outcomes. Researchers believe that the self-monitoring through the use of repeated interviews and of a catheter calendar for data collection in both groups contributed to overall self-care management improvements (292).

Education of healthcare providers

Despite the development of quality guidelines and the attention on CAUTI, knowledge and understanding of appropriate catheter care and risks of prolonged use remains suboptimal in many centres (409) (410) (411) (412) (413) (414). Educational approaches to research-based recommendations for catheter selection and minimising problems are welcomed by healthcare professionals and need to be made available in a variety of ways as part of ongoing staff updates (415) (416) and as part of quality improvement/patient safety strategies. It is widely accepted that catheters should be avoided where possible, and dwell time should be minimised where a catheter is required. Numerous quality improvement and pre-post design studies report on interventions to reduce the use of catheters, often hospital-based with a focus on multifaceted catheter care bundles (417) (418) (419) (420) (421) (422).

Quality of life and catheterisation

Indwelling catheters can have both positive and negative effects on life quality. Users report reduced activities (423), embarrassment (333) (336), shame or stigma (223). Other concerns are loss of privacy (223) (335) (424) (425), end to sexual activity (426) (425) (427) (428), loss of manhood (429) and fear of odour and leakage (223) (428) (430) (431). Some indicate that care providers often dismiss their anxiety and concerns or do not provide enough information about sexuality or catheter care (425) (432) (Level of Evidence 3).

Positive benefits of catheterisation are also noted. In one qualitative study with 27 community-dwelling adults, perspectives differed (433). Some who were no longer wet regarded the catheter positively, and several developed more self-reliance as they dealt with catheter problems. Others described the challenge of finding bathrooms and adjusted or limited their outings accordingly **(Level of Evidence 2).** Similar results were found in another qualitative study of 36 persons; changes in sexuality, behaviour, and self-esteem varied among individuals. Some said the catheter had no impact and others indicated it had profound effects on body image and sexuality. A suprapubic catheter was of benefit to some, and the catheter position was importantly related to comfort, aesthetics, and body image (432).

The Consortium of Multiple Sclerosis Centres (434) oversaw a postal survey asking general questions about bladder and bowel management. Of the 9397 respondents, 12.8% used either intermittent or indwelling catheterisation. Fifty-three percent reported catheterisation having a positive impact. While the majority used intermittent catheterisation (64.7%), neither indwelling nor intermittent catheterisation appeared to affect QOL (435).

It is known that adherence to recommended bladder management post-SCI is not always optimum for a variety of reasons (436). People sometimes switch from IC to an indwelling catheter -- despite the inherent problems with an indwelling catheter -- because of QOL issues (436). Many use different bladder drainage methods over time (224) (437). In one chart review of people with SCI, 52% who were discharged using IC chose urethral catheterisation by 6 months, citing discontinuation because of: the need to depend on caregivers, poor hand functioning, spasticity, incontinence (despite anticholinergic drugs) and toileting inconvenience **(Level of Evidence 3).** Problem-solving by users for best catheter care is an area open for research. As part of a randomised clinical trial teaching self-management in 202 long-term indwelling catheter users, there were no group differences for QOL, though QOL improved somewhat during the 12 months of participation in each group (292).

Practical aspects of living with the catheter, such as managing the drainage bag, can be significant (see Section H). In a small pilot study based on a postal questionnaire to LTC catheter users (n=59) (525) almost 25% of respondents stated that wearing a bag had a major negative effect on everyday living. Concealment was a key concern (89%), and visibility of the bag can be considered demeaning and declares a loss of bladder control (223) (335), and the fear of the bag leaking contributes to vulnerability. Even a short-term catheter can assault one's dignity. In a study on post-operative short-term catheter use, people complained about feeling "on display" and objectified (424) **(Level of Evidence 3).**

Until recently, formal measurement of QOL has been limited because no validated instruments have been available. There are now two instruments measuring the quality of life in people with indwelling urinary catheters, an earlier version (438) validated in two small samples and a robust measure recently available (31). The latter measure is recommended for use**(Level of Evidence 3)**.

Cost-benefit of different catheters

Few studies have been published on the cost benefits of different catheters. The focus of economic studies has been in acute care using models to predict a proportion of patients with bacteriuria who will develop symptomatic UTI or bacteraemia. One UK based decision- analytic cost-effectiveness study was found in relation to a randomised trial over six weeks for short term catheterisation. The conclusion was that nitrofurazone coated catheters but not silver coated ones were more cost-effective (439). In a companion study of costs associated with long-term catheters in Swedish nursing homes, catheter care costs were associated more with basic care than acute interventions; 90% of the cost was for personnel (291).

Urinary catheters versus other care strategies

Few studies have compared indwelling catheterisation with other strategies to manage urinary incontinence, not least because of the difficulties in recruiting to and conducting robust trials. Sheath systems are associated with fewer incidences of bacteriuria, symptomatic UTI or death than indwelling catheters (123). Participants reported that sheaths were more comfortable and less painful than indwelling catheters.

Preferences for different urinary incontinence treatments have been studied in long-term care (440). Most respondents preferred non-invasive strategies (containment products and prompted voiding) to invasive strategies such as indwelling catheterisation (441). Older adults stated they would choose a treatment based, in part, on feeling dry, being natural, not causing embarrassment, being easy, and not resulting in dependence.

2. SUMMARY

- Asymptomatic bacteriuria should NOT be treated with antibiotics; routine urine culture is unnecessary (unless urological instrumentation is planned) **(Level of Evidence 1)**.
- Meatal cleansing of a catheterised individual by simple washing with soap and water (i.e., not with antimicrobial agents) during routine bathing or showering is recommended (Level of Evidence 1). The use of chlorhexidine for meatal cleansing before

catheterization rduced UTI for short term users in one study **(Level of Evidence 2)**.
- A closed drainage system reduces the risk of catheter-associated infection **(Level of Evidence 2)**.
- Midnight versus morning removal of catheters (see table) results in longer time to first void and larger first void and no difference in recatheterisation rate **(Level of Evidence 2)**.
- Use of alpha-blockers pre catheter removal after AUR results in fewer re-catheterisations and improved voiding **(Level of Evidence 2)**.
- Silver alloy coated catheters do not reduce the onset of CAUTI **(Level of Evidence 1)**. Antimicrobial catheters can prevent bacteriuria during short-term catheterisation (<14days) **(Level of Evidence 1)**.
- Nitrofurazone coated catheters reduce CAUTI risk but are associated with discomfort. Potential toxicity and / or antimicrobial resistance is unknown **(Level of Evidence 2)**.
- All currently available catheter materials are subject to bacterial biofilm formation **(Level of Evidence 1).**
- Recurrent urinary catheter blockage occurs in as many as 50% (range 24-50%) of all long-term catheterised patients **(Level of Evidence 2)**.
- Recurrent urinary catheter blockage caused by encrustation occurs in 40-50% of all long-term catheterised patients **(Level of Evidence 2)**.
- In most individuals with a long-term indwelling catheter, a characteristic pattern of 'catheter life' can be identified **(Level of Evidence 3)**.
- Evidence from *in vitro* models of the catheterised bladder indicates that: i) dilute urine; ii) high urine citrate content (> 1.5mg/mL) reduces the risk of blockage **(Level of Evidence 2)**.
- There is insufficient evidence from RCTs to assign an in vivo level of evidence for catheter washouts.
- Suprapubic catheterisation (SPC) is an appropriate alternative to urethral catheterisation **(Level of Evidence 1)**.
- There is some evidence for a reduction in catheter-associated infection in SPC use during short-term catheterisation **(Level of Evidence 2)** compared to urethral catheter insertion. However, there is no corresponding evidence for long-term suprapubic catheterisation **(Level of Evidence 2)**.
- Patient comfort, quality of life and satisfaction with SPC is generally good compared to urethral catheters **(Level of Evidence 1)**.
- Catheter valves provide a well-accepted system of bladder emptying for suitable patients who can manipulate the valve mechanism and empty the bladder regularly to avoid overfilling **(Level of Evidence 2)**.
- There is no evidence of increased risk of urinary tract infection with valves compared to conventional drainage systems **(Level of Evidence 2)**.

3. RECOMMENDATIONS

Recommendations relating to indwelling catheters are summarised in Table L-9

Table L-9: Recommendations relating to indwelling catheters.

- Indwelling catheters should only be used after alternative management strategies have been considered and rejected as unsatisfactory **(Grade of Recommendation A).**
- Duration of catheterisation should be minimal **(Grade of Recommendation A).**
- A closed drainage system should be maintained to reduce the risk of catheter-associated infection (Grade of Recommendation A). Meatal cleansing with plain soap and water (not with antimicrobial agents) is recommended for everyday washing **(Grade of Recommendation A).**
- Addition of disinfectants to drainage bags, bladder irrigation and antibiotic prophylaxis is NOT recommended as a routine infection-control measure **(Grade of Recommendation A).**
- Silver-alloy catheters are not recommended for use in acute or long-term care as they do not significantly reduce the incidence of CAUTI **(Grade of Recommendation A).**
- Routine urine culture in an asymptomatic patient is not recommended **(Grade of Recommendation B).**
- Catheter materials designed for long-term use (all-silicone, silicone or hydrogel-coating) should be used where a catheter is expected to be used long-term (i.e. >14days) **(Grade of Recommendation B).**
- If a long-term use is being considered, both SPC and UC should be offered, following appropriate risk assessment **(Grade of Recommendation B).**
- Routine washout solutions to reduce encrustation or debris are NOT recommended **(Grade of Recommendation B).**
- Preconnected urine drainage bags and catheters as a means to prevent CAUTI are NOT recommended **(Grade of Recommendation C).**
- UC and SPC catheters and drainage bags should be adequately supported to maintain patient comfort and prevent meatal or cystostomy tract damage from traction or abrasion **(Grade of Recommendation C).**
- UC and SPC insertion should be carried out only by appropriately trained and skilled practitioners, using an aseptic technique **(Grade of Recommendation C).**
- Effective handwashing before and after handling catheters and drainage equipment should be performed to reduce the incidence of CAUTI **(Grade of Recommendation C).**
- In patients with recurrent catheter encrustation and blockage, systematic monitoring should be undertaken to identify a characteristic pattern of 'catheter life' and instigate pre-emptive catheter changes prior to likely blockage **(Grade of Recommendation C).**

4. PRIORITIES FOR RESEARCH

1) General

- Agreement on key outcome measures to permit comparisons between studies:
  - Standardised definition of UTI for catheterised individuals.
  - Asymptomatic bacteriuria in a catheterised patient and its clinical / research implications.
  - Standardised time frames for following patients.
  - Documentation of the use of antibiotics prior to and during a study, e.g., preoperatively in surgery or commencement of antibiotics for other conditions during the study,
- Mixing study outcomes of asymptomatic bacteriuria and symptomatic urinary tract infection (CAUTI) limits meaningful comparisons and contributes to a lack of knowledge of effective ways to treat symptomatic CAUTI (442).
- Comparative studies of different patient groups, e.g., males and females, different age groups, patients at home and those in institutional care, including patients' comfort, satisfaction, and quality of life measures.

Indwelling catheters

- Address the barriers healthcare professionals face regarding optimum catheter management.
- Compare catheterisation techniques, e.g., CIC, suprapubic and urethral catheters, on CAUTI and other risks or potential benefits.
- Review any detrimental effects on bladder tissue from persistent asymptomatic bacteriuria in long-term catheterised patients.
- Studies demonstrating the efficacy of new designs of the catheter on reducing CAUTI, blockage and other catheter-associated harms and improving cost-effectiveness or quality of life for users.
- Conduct laboratory and clinically based research of strategies to reduce recurrent catheter encrustation and blockage, including maintaining dilute urine, increased level and acceptance of urinary citrate, the role of acidic 'catheter maintenance' solutions.
- Further development of catheter materials resistant to microbial biofilm formation, new approaches to disruption of the biofilm, or alternatives to catheterisation.
- Development of further self-management research focusing on decreasing blockage and CAUTI.
- Explore the role of caregivers in providing care to people with long-term catheters.

a) Catheter valves

- Clinical investigation of the effect of catheter valves on incidence and frequency of catheter encrustation and blockage.
- Cost-effectiveness studies of disposable versus re-useable valves.
- Studies designed to demonstrate if catheter valves promote maintenance of bladder tone and capacity.
- Further examination of combination management strategies such as valve during the day and free drainage overnight.
- Studies demonstrating the value of new designs in catheter valves, e.g., those operated by magnets for people lacking in hand dexterity.

M. INTERMITTENT CATHETERS

Intermittent catheterisation (IC) is the act of passing a catheter into the bladder to drain urine or maintain stricture patency via the urethra or a catheterisable channel such as a Mitrofanoff diversion. Urine is drained and the catheter removed until the next indicated time. IC avoids many problems associated with indwelling catheters, but urinary tract infections (UTI) remain an issue for many IC users and most research until recently has focused on UTI as an outcome. Intermittent catheterisation is a sterile technique in care settings and a clean procedure for community-based individuals who self-catheterise or have a single caregiver providing bladder care. Policy on sterile single-use catheters varies by country or re-use of catheters for IC. To date, there is an absence of evidence to support sterile single-use catheters for community-dwelling individuals with respect to prevention of UTI, although users may report improved quality of life with a single use catheter. In this section, we provide an overview of the current literature on IC related UTI, quality of life and cost-effectiveness.

The main factors that make intermittent catheterisation (un)suitable for people are listed in Table M-1.

Table M-1: The main factors that make intermittent catheterisation (un)suitable for people.

Intermittent catheterisation may be suitable for those with:
• Neurological disorders resulting in urinary retention or incomplete emptying.
• Detrusor sphincter dyssynergia.
• Incomplete emptying post-operatively, e.g. following Botox incontinence surgery.
• Acute urinary retention (most commonly in men).
• Urethral stricture requiring ongoing management.
• Continent urinary diversions such as a Mitrofanoff diversion.
Intermittent catheterisation is not suitable for those with:
• Poor hand dexterity or visual problems or no caregiver to assist.
• Insufficient cognition to understand the process.
• Reluctance or inability to perform the technique themselves, and unwillingness to accept the procedure from a caregiver.

1. EVIDENCE

At the time of the 6th International Consultation (36), there were 30 published randomised controlled trials on some aspect of IC and 7 Cochrane reviews including the topic. Findings from the last (6th) consultation are included in the summary below.

Since the last (6th) consultation (63), there have been three IC-related RCTs (443) (444, 445), one Cochrane review (446), five systematic reviews (447-450) (451, 452), five qualitative (or meta-synthesis) studies (453-457) and one laboratory-based study on catheter cleaning (458). Five cost analysis/effectiveness papers were found (459-463).

Most research on IC continues to relate to catheter-associated urinary tract infection (CAUTI), quality of life and cost-effectiveness.

1) Short-term bladder management

Under 14 days: Zhang *et al.* (464) conducted a systematic review and meta-analysis to compare the rates of UTI and postoperative urinary retention (POUR) in individuals who had undergone total joint arthroplasty, randomised to either an indwelling urethral catheter or IC. Nine RCTs involving 1771 patients were included. All indwelling catheters were removed within 24-48 hours postoperatively. Rates of UTI were similar between groups, and it was concluded that for patients at risk for POUR, indwelling catheterisation removed 24-48 hours postoperatively was the preferred option. For those low-risk patients, either indwelling catheterisation or IC could be appropriate or catheterisation following the surgery could be on a needed basis.

Choice of catheter
Comparison of short-term (<14 days) urethral indwelling or urethral intermittent or suprapubic catheterisation in adults hospitalised for a wide range of reasons, from urogynaecology surgery to medical management was presented in a Cochrane review (465). The authors concluded that suprapubic catheters reduced both asymptomatic bacteriuria, recatheterisation and pain compared with indwelling urethral catheters but that the evidence for symptomatic UTI and asymptomatic bacteriuria for indwelling urethral or IC was inconclusive. The evidence was also inconclusive for advantages of suprapubic versus IC.

In a cost comparison analysis (Markov Model) between three short-term catheter management pathways (indwelling catheter removed at a care facility, indwelling catheter removed by the patient at home or intermittent self-catheterisation), IC was found to be the most cost-saving option (472).

Long-term / continuing chronic bladder management

UTI prevention:
With respect to the incidence of UTI and long-term IC, a recent Cochrane review compared one type of catheter design versus another, aseptic versus clean technique, single-use versus multiple-use catheters, in both adults and children. Twenty-three trials met the inclusion criteria. The authors concluded that there is still no convincing evidence that the incidence of UTI is affected by any technique, coated or uncoated catheter or single or multiple-use 'clean' catheters. The authors noted that current evidence is weak, and trial design issues remain a significant issue (446). Four other reviews reported on either hydrophilic versus uncoated catheter or single-use versus reuse of catheter, and overall for both comparisons, it was found that evidence is generally weak, and further well-designed trials are needed to address whether there is any impact on the incidence of UTI (447-450).

Four papers reported on the use of Markov decision models to compare the cost-effectiveness of hydrophilic catheters with uncoated (459-462). All four reported that hydrophilic coated catheters were cost-effective but given the lack of clarity regarding the clinical effectiveness of hydrophilic coated catheters cost-effectiveness remains uncertain.

One review sought to establish whether the use of antiseptics for meatal cleansing was effective at reducing the incidence of UTI but found that the answer remains unclear (281).

A large scale RCT of 404 adults using IC compared the use of low dose antibiotic prophylaxis with no prophylaxis and found it to be effective in reducing UTI, but authors expressed concern about increased antimicrobial resistance with this strategy (443).

One RCT of 75 adults with neurogenic bladder compared single-use and reuse of PVC catheters and found no difference between the groups (444). One RCT 78 children with neurogenic bladder compared hydrophilic coated catheters with uncoated catheters and found that hydrophilic catheters might decrease the risk of UTI, but noted some participants had problems handling the coated catheters (445). One small scale study recruited people who reused catheters and provided single-use hydrophilic catheters and reported that the novel single-use hydrophilic catheters were preferred by most users (466).

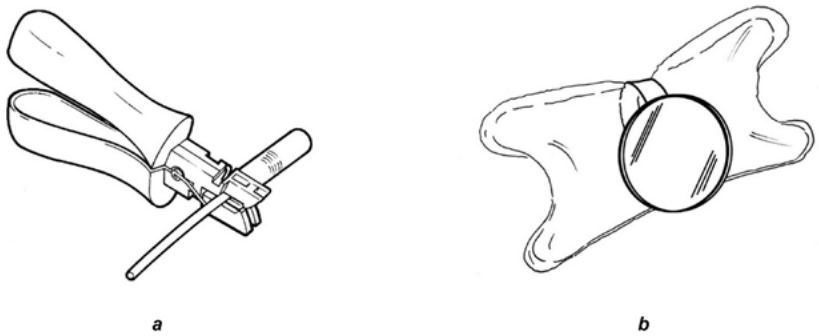
Quality of life / patient preferences
Moving away from UTI, recent research also focuses on IC users' quality of life and preferences. Research in this area predominately explores catheter designs (e.g. different lengths, 'ready to use' presentation) with different materials such as PVC-free and catheters with coatings, such as hydrophilic. Unsurprisingly, these studies are often industry-sponsored. Another trend in the literature is the focus on user groups with neurogenic bladder disorders and how IC can improve their quality of life. IC continues to be seen as the most commonly used procedure for those with incomplete bladder emptying and offers the ability to be self-caring, maintain independence and the opportunity to decide when and where to empty the bladder.

Other aspects that are evident in the literature are how long-term IC impacts an individual's daily life. Apart from obstacles such as insufficient hand movement or being unable to sit, which can restrict some patients access to IC, worries, embarrassment (467) and psychological coping mechanisms (468), studies also report that patients find intermittent catheters unwieldy, difficult to use or to carry discreetly (469). As one study reports moreover, the efficacy of CIC is often measured by the individual's quality of life. A randomised, crossover, multicentre study evaluated discreet design compact catheters compared to standard catheters, which were used by those with neurogenic bladder dysfunction. Results found that 63% preferred the discreet, compact hydrophilic coated intermittent catheter design as it contributed to a significant improvement in patient quality of life (469). Choice of product which offers discretion, ease of use and eliminates social anxiety is current user preference (468) (470).

IC users' views of UTIs have been explored, concluding that users are uncertain about signs and symptoms and when to seek help (453).

Perceptions of cleaning and re-using catheters have been reported from both the users and healthcare professionals' points of view, with a range of opinions found from both groups (454, 456).

Although there are several devices available to enable catheterisation by the individual - mirrors, catheter holders, and clothing retractors - it is of note that no published studies have explored IC users' impressions of these devices. Fig M-1 shows a catheterisation aid.



a *b*

Fig M-1: A catheter holder / insertion aid (a) and an inflatable cushion with mirror, to be held between the knees and provide a better view of the urethral meatus when self-catheterising (b).

Self-management research

a) One small trial has tested the feasibility and usability of a web-based intervention in a sample of people with spinal cord injury (N=34) using intermittent catheters (IC). Prior to the pilot with 30 individuals, the three-month intervention was pre-tested (N=4), and suggestions were given to refine the application, including modifying the web-based interactive urinary diary for mobile phone use. The single group pre-post study involved: a 23-page online educational booklet links to ICI's Catheter Products website and other related products, two phone calls with a study nurse in the first month and a follow-up phone call at three months to revise goals and approaches. In addition, discussion fora were provided, moderated by the study team and 2 peer advisors chosen from the pretesting group (471) (472). Measures about self-efficacy and self-management of IC were developed and tested. The web-based application was well received, with the forum being used the least often yet well liked. Catheter-related self-management was significantly improved with most comments about positive changes in fluid intake. Catheter self-efficacy and quality of life increased slightly, and UTI decreased from the three months prior to the study (42% to 30%), but these changes were not statistically significant.

2. SUMMARY

- There remains insufficient evidence to state that one catheter product or catheterisation technique is better than another in the prevention of UTI in IC users **(Level of Evidence 1)**.
- Soap and water combined with a 15-minute Milton soak (Milton method) renders catheters free of pathogenic organisms **(Level of Evidence 1)**.
- Quality of life might be improved with the use of compact portable IC catheters compared to standard length catheters or through single-use catheters (particularly hydrophilic coated catheters. **(Level of Evidence 2)**.
- Antibiotic prophylaxis may be beneficial for select individuals but must be weighed against the potential of antibiotic resistance **(Level of Evidence 2)**.
- There are several catheter products on the market: uncoated PVC requiring added lubricant; gel-coated; hydrophilic gel coated. Personal preference may determine use **(Level of Evidence 4).**
- Aids such as clothing holders, mirrors or catheter holders may facilitate catheterisation **(Level of Evidence 4).**

3. RECOMMENDATIONS

Recommendations relating to intermittent catheters are summarised in Table M-2.

Table M-2: Recommendations relating to intermittent catheters.

- Intermittent catheterisation (IC) should be routinely offered for those with ongoing bladder emptying problems and re-sidual urine > 100ml who are able to manage the technique **(Grade of Recommendation A).**
- IC technique can be taught to all ages of people with appropriate motivation and manual dexterity (or to a carer where this is acceptable to both parties). Appropriate education and ongoing support should be offered for optimum IC use and maintenance **(Grade of Recommendation C/D).**
- Offer advice on frequency of catheterisation. Ths should be based on individual needs to prevent over-filling of the bladder **(Grade of Recommendation C).**
- An external lubricant or lubricant-coated catheter should be offered to minimise urethral trauma **(Grade of Recommendation C).**
- IC users should be offered access to different catheters or catheter-packs for different purposes (e.g. ease of use may be particularly important when at work or in public) **(Grade of Recommendation C).**

4. PRIORITIES FOR RESEARCH

- Testing of catheter cleaning methods by large groups to assess safe multi-use of catheters.
- Ensure trials adhere to a consistent definition of symptomatic urinary tract infection.
- Cost-effectiveness studies should include patient acceptability/ satisfaction with the procedure and or product.
- Health utility in various situations needs to be considered, e.g., at home vs away.
- Further development of self-management research in IC users in various populations in multiple sites.
- Large, well-designed trials are needed to determine whether re-use of catheters is equivalent to single-use.

N. PRODUCTS AND DEVICES FOR PREVENTING OR MANAGING FAECAL INCONTINENCE AND ITS SEQUELAE

1. INTRODUCTION

Various products and devices may be used to manage faecal incontinence (FI) and its complications of skin damage and odour. Anal plugs, anal inserts, and vaginal inserts aim to prevent faecal leakage and are suitable for use by community-living, physically mobile individuals. Rectal catheters, long and short rectal tubes, and a non-balloon-based intra-rectal sheath redirect faeces from the rectum, collecting it in an external drainage bag in patients confined to bed in hospital or long-term care settings due to illness or functional disability (480-483). Peri-anal pouches and various types of absorbent pads collect or absorb faecal leakage for containment. Absorbent pads for managing faecal incontinence are covered in Section F . Incontinence-related skin and odour problems are addressed in Sections O and P, respectively. Other devices and products are reviewed for their ability to manage faecal incontinence here. Approaches to conservative management of faecal incontinence that are often concurrent with the use of products or devices are addressed comprehensively in chapters 16, 17 and 11.

1.1. Anal Plugs

Anal plugs were among the earliest product designs for preventing faecal leakage. An anal plug (Fig N-1) consists of a removable, small cup-shaped piece of foam that is held in a collapsed position by a film for insertion. When the film comes in contact with the moist rectal mucosa, the plug opens to block the passage of faeces (473) (474). An anal plug is inserted like a suppository using a lubricant gel and can be removed by pulling on an attached string or expelled by raising intra-abdominal pressure and pushing as during normal defaecation.

Fig N-1: An anal plug (from www.continenceproductadvisor.org)

Table N-1: Main factors that make anal plugs suitable or unsuitable for people with faecal incontinence

Anal plugs are suitable for individuals who:
• Wish to prevent leakage for a specific period (during exercise or after an enema or rectal irrigation).
• Who have leakage associated with spina bifida, anorectal malformation, rectal sphincter injury.
Anal plugs are not suitable for individuals:
• With active disease of the bowel or rectum.
• Who have a SCI and are at risk of autonomic dysreflexia.
• For whom a device might disrupt an established bowel routine.

An anal plug can successfully prevent FI in individuals with a variety of aetiologies, more so in adults than children (475) (476). The most recent Cochrane review of the effectiveness of anal plugs in preventing faecal incontinence published in 2015 (477) reached conclusions similar to those for the last International Continence Consultation, that anal plugs are useful as a treatment or adjuvant treatment of faecal incontinence in select individuals but that tolerance is limited (36). Individual studies have shown that the self-reported effectiveness of the plug in adults ranged from 83% (564) to 38% (478). In one study of children, 32% were completely continent using an anal plug, and 13% reported “total failure” (476).

The most common concerns and problems associated with wearing an anal plug include discomfort and failure to retain the plug (478). Children seemed to experience less discomfort than adults (476). The studies evaluating anal plugs had relatively small sample sizes unsupported by power analysis, and most had non-experimental designs. Table N-1 lists the main factors that make anal plugs suitable or suitable.

Another type of anal plug consists of an inflatable cuff or balloon at the end of a short pliable silicone catheter inserted into the rectum and connected to an external notification device (479). The cuff is inflated by the patient with approximately 30 cm^3 air using a syringe. When faeces enter the rectum, a signal from a photosensor on the catheter is sent to a pager which then notifies the person to inflate the balloon by pressing a button on the pager. Before a voluntary bowel movement, the balloon is deflated using a syringe and the catheter is withdrawn and can be reinserted. The catheter can be cleaned and reused for up to 28 days of actual time in the body. Replacing the fastener cap each day is recommended.

The latest design of this anal plug resulted in a significant decrease in FI after 14 days compared to baseline in 11 of 17 patients (64.7%) in a multi-centre trial according to two FI severity scores device (479). The Cleveland Clinic incontinence score decreased with the use of the device from a mean of 15.3 (range, 13–20) to 7.2 (range, 2–12) ($p<0.001$), and the American Medical Systems incontinence score decreased from a mean of 107 (range, 100–119) to 60 (range, 7–102) ($p<0.001$). There was a significant improvement in quality of life for all four domains of the FIQOL scale. Limitations of this plug are that some patients think it is too complicated to use, lack the dexterity to operate it and may be alerted when there were only small amounts of faeces in the rectum.

1.2. Anal Insert

An anal insert (Fig N-2) is made from supple silicone with two discs. The top or proximal disc sits inside the rectum beyond the anal sphincters and is available in two diameters and is intended to form a seal at the top of the anal canal. The bottom or distal disk remains outside the anus to avoid displacement into the rectum and ease manual removal (490). A removable applicator with

Fig N-2: An anal insert.
(from www.continenceproductadvisor.org)

a finger covering like a thimble and a spindle within the insert is used to introduce the device into the rectum and is then withdrawn after the device is in its final position. The anal insert is single-use and expelled during defaecation or can be removed manually by pulling on the bottom outer disc.

Use of an anal plug (Fig N-1) reduced the median daily frequency of faecal incontinence from 0.9 (mean 1.1 ± 0.9) episodes/d at baseline to 0.2 (mean 0.3 ± 0.4) episodes/d at 12 weeks ($p < 0.001$) in 73 adults who completed a non-randomised, single-group study (480). After the 4 weeks when the insert was no longer used, the median faecal incontinence frequency increased to 0.5 episodes/d (mean 0.7 ± 0.7), but this frequency was also significantly lower than baseline ($p < 0.0001$). Use of the anal insert resulted in a ≤50% reduction in FI frequency in 77% of the completers.

No serious adverse events and three moderate adverse events (faecal urgency, soreness, and bleeding haemorrhoids) in two subjects were reported using an intent to treat (ITT) analysis. Unpleasant symptoms were a sense of faecal urgency (26% of 91 subjects), irritation (13%), pain (7%), and soreness in the anal area (6%). Displacement of the insert into the anal canal occurred in 24% of subjects, which resolved with the expulsion of the device during bowel movements.

1.3. Vaginal Insert for Faecal Incontinence

A vaginal insert offers an alternative approach to preventing FI in women (481). The vaginal insert consists of an inflatable balloon on a silicone-coated stainless-steel base that is situated posteriorly in the vagina and ventrally to the rectum and a pressure-regulated pump. The wearer inflates the balloon insert to one of five preset pressures with the pump, which then occludes the distal rectum preventing leakage of faeces.

In a month-long study of 61 women who had FI at least four times in two weeks using a treatment group only design, the intent-to-treat analysis showed that 78.7% of the women could be fitted with the device and had their FI reduced by at least 50%. Using the device significantly improved QOL associated with FI. Nearly all users (96%) reported the device was comfortable or unnoticeable. Seventy-two percent of the original subjects used the vaginal bowel-control system for an additional two months with continued benefit.

There were 18 device-related adverse events (e.g., vaginal abrasions, erythema, irritation, ecchymosis, bruising) experienced by 23% of subjects. Adverse symptoms included discomfort of having the device in the vagina, cramping, pelvic pain, and UI, frequency, and urgency occurred in 3-10% of women, which were all more common during the fitting period. Limitations of the vaginal insert are the inability to be fitted with the device or adverse effects.

1.4. Rectal catheters and long and short rectal tubes

Rectal catheters (sometimes referred to as bowel catheters or faecal or bowel management systems) and rectal tubes of different sizes drain liquid faeces through openings at their proximal end into an external collection bag (Fig N-3). Rectal catheters and their collection bags are a closed system designed for extended use (US FDA approved for 29 days). Typically a balloon near the proximal tip is inflated to prevent faecal leakage around the catheter and to retard inadvertent expulsion of the tube during defaecation (482). Bowel management programs using these catheters often include daily or more frequent saline irrigations through the rectal catheter to maintain liquid consistency of stool and catheter patency (483).

Few studies of rectal catheters measure their effectiveness in preventing faecal incontinence or seepage; most focus on preventing or healing skin/wound problems. However, seepage around the catheter does occur (476, 484). In a study of 29 paediatric patients, the mean number of daily FI episodes decreased approximately 30-50% (486). In a study of 29 adult patients, varying degrees of leakage around the rectal catheter were reported in 71% of 198 assessments; 35% of these leakages extended to pads on the bed or beyond (484).

Non-blinded and non-independent endoscopic observations suggest the rectal catheter does not cause rectal mucosal damage during the recommended length of use (29 d in the US) (484) (475) (485). However, as the rectal catheter is used more in practice, there are reports of serious adverse events, including gastrointestinal haemorrhage and rectal bleeding requiring blood replacement, recto-urethral fistula, and mucosal pressure necrosis or ulceration, and unwanted expulsion (486) (487), (488), (489).

Use of a long rectal tube with or without inflating its balloon or off-label use of a short nasal-pharyngeal airway in the rectum (referred to as a rectal trumpet) can also redirect faeces to an external collection bag (490). A possible advantage of the rectal trumpet over longer rectal tubes is that it is easier for nurses to manage, and its shorter length has less contact with the rectal mucosa, reducing

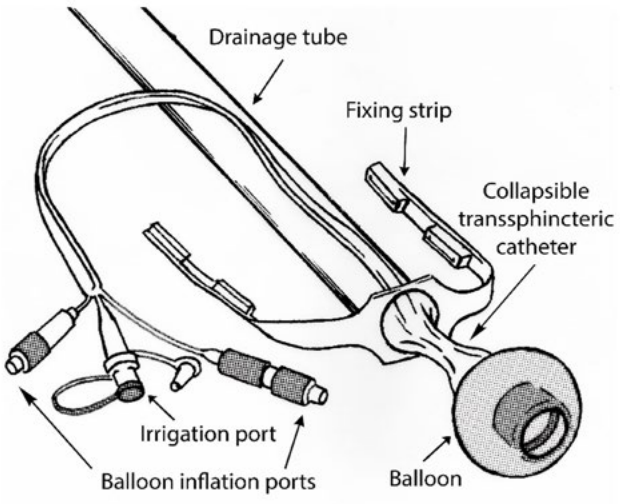


Fig N-3: A rectal catheter and drainage bag.

the area of possible damage. Limitations of the smaller rectal tube are similar to those for the rectal catheter including possible damage to the lower rectal mucosa and risk of expulsion from forceful Valsalva movements and dislodgement during repositioning of the patient and linen changes or from tugging on the collection bag (490). The use of these tubes is controversial because their safety has not been established and concerns of rectal bleeding, ulcerating or perforating the rectum, damaging the anal sphincter, or stimulating intestinal secretion worsening incontinence (482) (491-493)

Table N-2 lists the main factors that make rectal catheters / trumpets unsuitable for people with FI.

Table N-2: The main factors that make rectal cath-eters / tubes unsuitable for people with FI.

Rectal catheters / trumpets are not suitable for those with:
• Intestinal mucosal disease.
• Immunosuppression.
• Gastrointestinal bleeding or bleeding tendencies.
• Recent myocardial infarction or prostate surgery (492) (501).

Use of a rectal catheter with or without inflating the balloon is controversial because of concerns of ulcerating or perforating the rectum, damaging the anal sphincter, stimulating intestinal secretion worsening incontinence (482, 492, 493).

1.5. Perianal Pouch

An external perianal pouch consists of an external collection bag connected to a pliable wafer, which has an opening at its centre and an adhesive on the body side. The wafer adheres to the perianal skin (Fig N-4). The bag has a resealable port at its distal end through which faeces can be drained or connected to a larger, gravity drainage bag without the need to remove the wafer from the skin. Some pouches have a small, folded flap that allows flatus to escape so that it doesn't inflate and rupture the bag.

An external perianal pouch (491, 494) can collect leaked stool. The pouch avoids the risks of rectal mucosal or sphincter damage associated with rectal catheters or small tubes. Disadvantages of the anal pouch are difficulty in applying it and maintaining its seal and potential skin damage from removing the wafer or from the contact of faeces in the pouch with skin (490, 495).

There are few studies of rectal catheters, small rectal tubes, and anal pouches, and they often do not compare these products/devices or directly evaluate the ability to divert FI as an outcome. One study compared the effectiveness of a bowel catheter, rectal trumpet, or usual care in preventing or healing skin damage associated with FI , can be considered an indirect measure of FI management (496). Usual care included a perianal pouch. Critically ill patients (n=59) who were incontinent of liquid faeces were randomly assigned to one of the treatments. Results showed that the usual care group had significantly lower (better) scores for dermatitis-like skin after treatment compared to baseline, and there were no significant differences in the incidence or healing of pressure ulcers among groups. A validated and reliable instrument for assessing incontinence associated skin damage (IASD), (the IASD instrument (497) was used.

Fig N-4: An anal pouch.
(from www.continenceproductadvisor.org)

The pouch avoids the risks of rectal mucosal or sphincter damage associated with rectal catheters or small tubes. Disadvantages of the anal pouch are difficulty in applying it and maintaining its seal and potential skin damage from removing the wafer or from the contact of faeces in the pouch with skin (495) (490).

2. NEW EVIDENCE FOR THE CURRENT CONSULTATION

No recent studies of the effectiveness or tolerance of anal plugs were identified for this review. Regarding anal and vaginal inserts for FI six new studies and one systematic review (498) informed the current consultation. There are two studies about the anal insert (499) (500) and four about the vaginal insert. One of the four studies about the vaginal insert reports its effectiveness in preventing FI (501). Two studies, which are secondary analyses of the primary study reported by Richter *et al.*, examined other factors such as patient characteristics influencing fitting of the device and effects of the device on defecation and stool characteristics and (502, 503). In the fourth study, comfort, acceptability, and extent of rectal occlusion by the device were investigated (504). Regarding rectal catheters and peri-anal pouches, there are two new studies investigating a novel non-balloon, non-tube based intra-rectal device (505, 506) and one case report each of complications of a rectal catheter (507) and short rectal tube (508). One study evaluated the ability of a one-piece drainable pouch for preventing the development of incontinence associated skin damage in bedbound patients with FI (509), and a case report described the use of an ostomy pouch adapted to be a peri-anal pouch for a patient with FI to promote healing of gluteal abscess wound complicated by necrotising fasciitis (510).

Anal Insert

In a prospective pilot study investigating the effectiveness of the anal insert in decreasing FI , 15 patients (10 men, 5 women, median age 57 years (range (24-74)) who underwent restorative proctocolectomy for ulcerative colitis were asked to use the vaginal insert for 14 days, at least once during the day and once at night and to increase as tolerated (499). Six patients continued to take the same baseline dose of loperamide while using the insert and one continued cholestyramine. Patients completed the ICIQ-B instrument as a measure of anal incontinence at baseline and after 14 d. In an intent to treat analysis, ICIQ-B scores for night-time faecal leakage were significantly less at 14 days (0.93 (0-3)) (median (range)) compared

to baseline (1.8 (1-5)) (p=.03). Scores for faecal leakage during the day and other measures of the ICIQ-B were not significantly different. Regarding adverse effects, one patient reported bleeding and another pain when the device was inserted.

Regarding patient satisfaction, the same number of patients, six of 14 (43%), were satisfied or dissatisfied with the effectiveness of the device and 2 (14%) were neither satisfied nor dissatisfied (499). Eight of 14 patients (57%) were satisfied with the acceptability of the device, four (29%) were dissatisfied, and two (14%) were neither satisfied nor dissatisfied. Limitations of the study include the absence of a randomly assigned control group, lack of reporting the frequency of using the vaginal insert, small sample size, and an outcome measure for anal incontinence, which includes flatus versus FI

A retrospective review of the health records of 30 patients who were prescribed use of an anal insert after restorative proctocolectomy showed that there was a significant decrease in anal incontinence at follow-up (500). St. Mark's Incontinence score was calculated by patient interview at the time the device was prescribed (5(7-18)) (median (range)) and at the first follow-up clinic visit (10(2-18) (p<.001). The median follow-up time to the first clinic visit was 11 weeks (range = 8-14 weeks). Anal incontinence symptoms improved in 20 (67%) of patients, worsened in three (10%) and showed no difference in seven patients (23%). Approximately one-third (11, 37%) of patients used the regular sized insert, while the remainder (19, 63%) used the larger insert.

Adverse effects of the anal insert were rectal bleeding in one patient and pain/discomfort in four patients who discontinued use before the follow-up clinic visit (500). Eleven patients (37%) reported the anal insert fell out easily, three (10%) patients had difficulty inserting the device, and four (13%) stated it did not work as expected. Regarding user satisfaction, 20% of users disliked the device, and 80% liked it; 56.6% of users said they would like to continue using it. Limitations of the study are the lack of a randomly assigned control group, variability in the time to prescribing the anal insert after restorative proctocolectomy (which was not reported) and of the follow-up period, an outcome measure for anal vs faecal incontinence, reliance on patient recall vs a daily bowel diary for obtaining anal incontinence data in an unspecified number of patients, and other potentially missing data in the health record.

Vaginal Insert

In a prospective, multi-site, open-label one-group study, the clinical effectiveness and safety of the vaginal insert in 73 women with FI mean (SD) age 61.3 (11.5), number of vaginal births 2.2 (1.1), who had shown a decrease of 50% in FI episodes during a two-week trial period was studied (501). The median number of FI episodes over the two-week trial period was 10 (range 4-83). The primary outcome of effectiveness was having a 50% or greater reduction in FI episodes at 3 months compared to baseline as reported on a bowel diary during the 12-week study. At 3 months, 53 patients (73% (95% CI, 61-82%)) in the intent to treat (ITT) analysis had a successful outcome. In the per-protocol analysis, the success rate was 84% (52/83, (95% CI, 73-92%)). In the ITT group, the effectiveness of the vaginal insert at 6 and 12 months was 71% of 73 patients (95% CI, 59-81) and 70% (58-80), respectively. In the per protocol group, 54 patients were followed for 12 mos., and 94% of 54 patients (95% CI, 85-93%) met the primary outcome. There were no serious adverse events reported. Overall, 62 (85%) of subjects had a moderate or mild adverse event, and 28 (38%) of subjects had one related to the device, such as vaginal or pelvic discomfort/irritation, vaginal wall injury, lower urinary tract symptoms, vaginal infections, and constipation. Other adverse events occurred during fitting the device and were similar in type.

Satisfaction (using the Patient Global Impression of Improvement (PGI-I) scale and quality of life (using the FIQL tool) were measured in the per protocol group (501). Satisfaction was high (>89%) at three, six, and 12 mos. and all FIQL subscales improved. The strengths of the study were its inclusion of patients from multiple sites and follow-up period. The main outcome was measured at 3 months, but preliminary information about longer-term effectiveness up to one year was reported. Limitations were the lack of a control group and the severity of FI, limiting generalizability.

Matthews *et al.* (2016) (502), in a secondary analysis of the baseline diary data from the above study (501) compared characteristics of women who were successfully fitted with the vaginal insert and those who were not. Of the 10 women in whom fitting of the device was attempted, 61 (55.5%) were successfully fitted within four visits. Unsuccessful fitting was associated with previous prolapse surgery (p=.007) and shorted vaginal length, which was subjectively estimated using two fingers (p=.041). Limitations of the study are subjective estimations of vaginal length and widths and potential variations and small sample size.

In another secondary analysis of the reported by Richter *et al.* (501) the impact of the vaginal insert on bowel function, including frequency of bowel movements, urgency associated with a bowel movement, stool consistency, and degree of stool evacuation was examined (503). Data were reported by 52 women with FI (19-75 years old) on a two-week bowel diary during the baseline period and again at one month after using the vaginal insert. The total number of bowel movements per patient over a two-week period decreased from 20.9 at baseline to 15.3 at the follow-up at one month (p=.0002). Urgency was associated with an average of 54% of bowel movements at baseline to 26% at the follow-up p<.0001). The percentage of liquid stools (6-7 on the Bristol stool form scale) decreased from 36% at baseline to 21% at follow-up (p<.0001). Incomplete evacuation decreased from 39% of bowel movements during the baseline period to 26% at follow-up (p<.0034). Limitations of the study are lack of a randomised control group, a sample with severe levels ofFI , longer-term results based on a *per protocol* analysis, and the inability of women who could not be fit with the device to participate.

A study of 13 women with FI (mean age 70.7 years (range 40-90 years)) who were fitted with the vaginal insert reported on its comfort, acceptability, and degree of occlusion of the rectum when inflated (510). Comfort was reported by 12 patients after device insertion, during inflation, post inflation, and while walking using a 10-point scale from 1=no discomfort to 10=extremely uncomfortable. There was more discomfort (higher scores (mean (sd)) during inflation (3.3 (2.6)) and post inflation (3.5 (2.9) than during insertion (2.1 (2.0) orwalking (2.6 (2.0)). Five patients (45%) reported no discomfort for deflated and inflated states of the device. As many as 82% of the women indicated a willingness to use the vaginal insert after the study. Occlusion of the rectum was estimated by a physician during a digital rectal exam. When inflated, the device occluded ≥75% of the rectum in 54% (7/13) of patients and ≥50% of the rectum in 77% (10/13) of patients. Limitations of the study are non-validated measures of outcome variables, short time of assessment and subjective estimation of rectal occlusion.

Buono and Dave-Heliker (498) conducted a systematic review of studies about mechanical inserts (anal plugs, anal inserts, and vaginal inserts) published through July 2018. The review includ-

ed eight studies, some of which were addressed in previous ICI reviews.. The authors concluded that limited evidence indicates that these devices are effective, safe and can be recommended as a therapy for patients with FI.

Rectal Catheters and Tubes

Conventional rectal catheters are tube-shaped with an inflatable balloon surrounding the proximal end of the tube to anchor it within the rectum and reduce seepage around the tube. A new indwelling stool diversion closed system has a pliable diverter with a lattice design (resembling the shape of a badminton shuttlecock) that sits above the anorectal junction and is connected to a thin plastic sheath which in turn is connected to an external collection bag (505). The non-balloon-based diverter is folded into a disposable applicator used to insert it into the rectum, and the diverter self-expands after the applicator is removed. There is a withdrawal mechanism that collapses the internal diverter for removal. The collection bag has a one-way valve at its connection with the sheath and ports to obtain samples. Like other rectal catheters, this stool collection kit is approved for use for 29 days by the US FDA.

In a pilot study of 20 patients in an intensive care unit in the US, the non-balloon-based diverter was used for a mean of 3.54 (2.90) days (mean (sd)) (505). Patients were 60% male, 40% female, and (mean (sd) age 74 (12.3) years. Minor leakage from the diverter occurred in 86% patients and major leakage in 86% of patients. Spontaneous expulsion occurred in 10% of patients and no adverse events were observed. Limitations of the study are lack of a randomized control group, unknown measure of major and minor stool leakage, and short duration of device use and evaluation.

In a second study, the non-balloon-based diverter was used in 20 bedbound adults (16 male, 4 female, age = 56.7 (13.6)) (mean (sd))) with FI within the past 24 hours in a neurological unit in India (506). Ten patients had the device *in situ* for up to 24 hours in Phase 1, and 10 patients had the device in situ for up to 120 hours (5 days) in Phase 2. Perianal anal skin was examined for leakage every 4-6 hours. Of the 186 assessments of 20 patients, 174 assessments (93.5%) showed no leakage and 12 (6.4%) showed minor leakage. The device was dislodged or removed in five patients (25%). Sigmoidoscopy was performed in 16 of the 20 patients and two had minor mucosal erythema. Study limitations are similar to those in the study by (505).

There was a published case report about the development of a rectovaginal fistula in a patient treated with a rectal catheter/faecal management system (507). The patient was an 18-year-old female with leukaemia who developed multisystem complications including liquid FI after a matched unrelated donor stem cell transplant and preconditioning with chemotherapy and radiation and eventually died. The rectovaginal fistula was discovered by examination after 31 days of having the rectal catheter (which was beyond the recommended 29 days due to the severity of her illness).

In a quality improvement project, a retrospective chart review of 400 patients in a transitional care unit who received two types of short rectal tubes (a Mallinckrodt 32 Fr catheter or Robertazzi style 36 Fr rubber nasopharyngeal airway) for stool diversion and containment showed 9 probable and 3 possible cases of tube-associated rectal haemorrhage (508). The short rectal tubes were in place for a mean of 8.7 days. Of the 12 patients with the haemorrhages, 67% had cirrhosis, 58% were coagulopathic, and 91% required a transfusion of packed red blood cells after the haemorrhage. The hospital subsequently discontinued the use of the short rectal tubes. Study limitations are potential bias and incompleteness due to the indirect methods used to identify patients who received a short rectal tube and who experienced a rectal haemorrhage.

3. SUMMARY

An anal plug, anal insert, and vaginal insert can be useful as a treatment or adjuvant treatment of FI **(Level of Evidence 2).** These devices have been evaluated primarily in ambulatory, community-living individuals who need little to no assistance in managing FI and toileting. Both adults and children have used anal plugs.

An anal insert has been used by some patients up to 14 weeks. Many users liked the device, and more than half of users were interested in continuing use longer term. Symptoms of defecation urgency, irritation, pain, and expulsion may reduce tolerability. **(Level of Evidence 2)**

A vaginal insert can prevent FI and improve quality of life. Many users were satisfied with the device and were willing to use it long term. Some users may experience vaginal irritation, urgency, bleeding, or abrasions. **(Level of evidence 2)**. Some women may have difficulty being fitted with a vaginal insert; a history of prolapse surgery and short vaginal length reduces the likelihood of being successfully fitted **(Level of evidence 2).**

Rectal catheters and shorter rectal tubes successfully divert faeces to an external collection bag. Rectal catheters are primarily used in acutely and critically ill patients. Rectal catheters and shorter rectal tubes are often used to facilitate the healing of perineal wounds, but leakage around the catheters may result in perianal skin damage. **(Level of Evidence 3).**

The use of rectal catheters and shorter rectal tubes are associated with adverse events such as haemorrhage and rectal bleeding, especially in patients with bleeding tendencies or fistulae **(Level of Evidence 3)**.

A non-balloon-based stool diverter with a pliable lattice can be a useful option for diverting and containingFI. It has been evaluated mainly in bedbound patients. Minor rectal leakage and expulsion are limitations of its use. **(Level of Evidence 3)**.

An external perianal pouch can collect stool that would leak from the rectum. Difficulty in the application and long-term adherence of the pouch are limitations. **(Level of Evidence 3)**.

4. RECOMMENDATIONS

Recommendations relating to products for FI prevention and management are listed in Table N-3.

5. PRIORITIES FOR RESEARCH

- Additional evaluation of the anal plug, anal insert, and vaginal insert using experimental, well-controlled controlled designs, larger and adequately powered samples, and valid and reliable objective measures over longer periods of use
- Development of alternative devices to prevent FI , perhaps utilising wireless technology, intra-rectal plugs, or pouches that inflate and deflate as needed, which have fewer safety risks, come in a variety of sizes for adults and children, and are comfortable, tolerable, and effective.

Table N-3: Recommendations relating to products for FI prevention and management.

- Anal plugs may offered to reduce FI, but some patients are likely to use them on a limited basis or reject them due to discomfort **(Grade of Recommendation B)**
- An anal insert should be considered for decreasing FI. Its tolerability to adults seems to be better than the anal plug, but it is also associated with unpleasant symptoms such as minor irritation, defecation urgency, and expulsion may occur. **(Grade of Recommendation B)**
- A vaginal insert that compresses/occludes the rectum should be considered be a treatment option for women to prevent faecal incontinence. Discomfort, minor vaginal bleeding, and urinary urgency may occur. **(Grade of Recommendation B)**
- A non-balloon based faecal diverter with a lattice design maybe considered as an alternative option to a rectal catheter or short or long rectal tube in bedbound patients when more widely available. This device has been tested in patients in ICUs and neurological units. Minor rectal irritation, faecal seepage and unwanted expulsion in some patients have been identified as side effects to date. **(Grade of Recommendation C)**
- A rectal catheter should be considered for diverting faeces in acutely and critically ill patients unable to control bowel movements and at risk for skin damage or needing to heal wounds. Close monitoring for faecal seepage and integrity of perianal skin is recommended. **(Grade of Recommendation C)**
- The use of a short rectal tube (e.g., a naso-pharyngeal tube inserted into the rectum) may be offered to preserve perianal skin integrity or facilitate wound healing in patients with loose/liquid faecal incontinence. The safety of these types of tubes has not been fully evaluated. **(Grade of Recommendation C)**
- Thesetubes are not recommended for critically ill patients with high bleeding tendencies due to the risk of haemorrhage requiring treatment. **(Grade of Recommen-dation C)**
- A standard rectal tube with and without an inflatable balloon for faecal diversion is recommended primarily for non-ambulatory patients with liquid stool. The safety of these types of tubes has not been fully evaluated. **(Grade of Recommendation C)**
- Caution and close monitoring for complications and for appropriate balloon inflation is recommended when bowel catheters with balloons are used . **(Grade of Recommendation C)**
- An anal pouch attached to a drainage catheter can be considered to contain/divert liquid stool. Because there is a risk of skin damage when removing the wafer adhering the pouch it is not recommended where the skin is already damaged, or where need for faecal diversion is less acute (e.g., where stool is more formed) **(Grade of Recommendation C).**

- Development and evaluation of an external anal pouch that is easy to apply and remove, better adheres to skin, and perhaps, even promotes healing of damaged skin to which it would be applied.
- More rigorous evaluation of the non-balloon-based, faecal diverter with lattice design as well as rectal catheters with balloons and small tubes using experimental designs, larger and adequately powered samples, and valid and reliable measures

O. SKIN HEALTH

Skin repeatedly exposed to urine and/or stool is at high risk to develop incontinence-associated dermatitis (IAD). This concept was first introduced in the late 1980s (511), was later propagated by an expert group in the US (512) and is widely used today (513). It is included in the latest WHO ICD-11 classification under the label 'Irritant contact dermatitis due to incontinence' (EK02.22) and described as 'irritant contact dermatitis from prolonged contact with urine or faeces as a result of incontinence.' (514). IAD is characterised by cutaneous inflammation, often accompanied by secondary infection (512, 515). Early clinical signs include erythema, oedema and pain. Later stages are associated with maceration, erosions and excoriations (516, 517).

Depending on the care setting and the ways of measurement and reporting, published IAD prevalence estimates vary between 3% up to 60% (518-523). The exposure of the skin to urine and/or stool is a prerequisite to making the diagnosis of IAD, but not every incontinent patient develops IAD. Available evidence suggests that the following factors seem to increase the risk for IAD development: stool incontinence compared to UI alone (519, 521), dual incontinence (519, 524), high frequency of bowel movements (525), diarrhoea (525, 526), overall high care dependency including limited mobility (519, 524, 525, 527), diabetes mellitus (521, 526), and overweight (521, 528, 529).

IAD prevention and treatment includes promotion of continence (see chapter 20), the use of absorbent, diversionary and containment products, and topical skin-care procedures and products (513).

1. EVIDENCE

Since the 1940s, the design of absorbent hygiene products has constantly been improving in terms of absorptive capacity and breathability of materials (530). Since the 6th consultation (36), three RCTs (531-533) and one non-randomized study (534) were published comparing different absorbent products regarding the effects on preventing and treating IAD. In addition, one systematic and meta-analysis was published investigating the effects of faecal collection devices on IAD in critically ill patients (535).

Trowbridge *et al.* (531) compared two absorbent underwear products in 122 females (mean age 56 years) with UI during a 14 day wear period in the USA. There was very mild erythema in skin areas exposed to both products with minor differences between groups that were not clinically relevant. Both products were well tolerated, and two product-related adverse events occurred (erythema) that resolved during the study **(Level of Evidence 2).**

Francis *et al.* reported a cluster RCT on four medical-surgical wards in a US hospital (532). They compared superabsorbent disposable absorbent underpads with a breathable backsheet (n = 210, intervention group) with moderately absorbent reusable incontinence pads with a polyvinyl chloride backing (n = 252, control group) in patients with urinary and/or faecal incontinence (mean age 79 years). Hospital-acquired IAD was 17% in the control and 13% in

the intervention group, which was not statistically significantly different **(Level of Evidence 2)**.

Clarke-O'Neill *et al.* performed a cluster RCT in UK nursing homes (533). Four different pad designs (insert pads, all-in-one-diaper, pull-up pants, belt-shape diapers) were worn for two weeks by each of n = 78 nursing home residents (mean age 83 years) in a cross-over design. Skin problems occurred in nearly every nursing home resident in each pad design group, and there was no statistically significant difference between groups **(Level of Evidence 2)**.

The non-randomized study by Motta *et al.* was conducted in US nursing homes (534). Single-use disposable briefs and nonvapour, permeable moderately absorptive underpads were replaced by disposable high-fluid capacity underpads in nursing home residents with IAD or at risk for IAD. Forty residents (mean age 83 years) were followed up for four weeks. At baseline, n = 25 residents had IAD, n = 15 residents had intact skin. There was a statistically significant decline in residents with IAD over the study period, and the skin of the n = 15 residents remained intact **(Level of Evidence 3).**

IAD was considered in 16 RCTs and three quasi-experimental studies. The results of 12 studies were used in a meta-analysis (535). Review results suggest that anal pouch and anal catheter/tube collection devices reduce the occurrence of IAD in critically ill patients with faecal incontinence (535) **(Level of Evidence 1).**

Overall study results indicate that absorbent, diversionary and containment products prevent IAD development and/or promote IAD healing. There seem to be minor differences in terms of skin health when comparing similar absorbent products categories and designs (531, 533). Results also indicate that products with a higher absorptive capacity seem to decrease IAD development (532) and promote IAD healing (534).

Clinical studies on the effectiveness of skincare procedures for preventing and treating incontinence-associated dermatitis in adults

Skincare procedures to prevent and treat IAD include skin protection, cleansing and restoration. However, there are overlaps because many skincare activities have several effects on the skin (513, 536).

Since the last consultation (36), two systematic reviews have been published summarizing the evidence about the effects and the effectiveness of skincare products and procedures to prevent and treat IAD in adults (18+ years) (536, 537). A Cochrane review by Beeckman *et al.* (536) included 13 RCTs and quasi-RCTs, and a Joanna Briggs Institute review by Pather *et al.* (537) included 10 RCTs and quasi-RCTs. Both systematic reviews covered a search period until 2016 (536, 537). In 2020, a systematic review examined evidence to prevent and/or to treat IAD in older (65+ years) adults. The search period was between 1990 and 2018, and 13 RCTs and/or quasi-RCTs were included (538). Overall, these three systematic reviews summarized the evidence of 23 studies addressing IAD prevention or treatment using topical applications (536-538). All review authors concluded that there was a lack of high-quality evidence. Disregarding methodological limitations and risk of bias of the individual studies, the review results suggest that using any skin protection strategy and product is beneficial in preventing and treating IAD compared to 'standard care' or 'doing nothing'. Cleansers and washcloths containing low-irritating surfactants, dimethicone and/or emollients are more effective in protecting the skin compared to using water and traditional soap **(Level of Evidence 2).** When comparing low-irritating cleansers and cleansing strategies directly with each other, no differences in product performance were observed **(Level of Evidence 2).** The use of topical skin protectants such as barrier films or lipophilic barrier products ('barrier creams') reduced the IAD incidence compared to using no product **(Level of Evidence 2).** The superiority of one skin-protecting product against another could not be shown **(Level of Evidence 3).**

In addition to the studies included in the three systematic reviews (536-538), results of two RCTs (539, 540) and four non-randomized studies (541-544) and one case-series (545) have been published. One RCT compared a cyanoacrylate film-forming skin protectant (intervention group, n = 24) with a zinc oxide containing lipophilic barrier product (control group, n = 21) in n = 6 children and n = 39 adults (mean age 65 years) with IAD in the US (539). In the intervention group, there was a reduction of 11% and in the control group of 34% of an IAD severity score. Complete reepithelialisation was achieved in n = 6 patients in the intervention and n = 5 patients in the control group **(Level of Evidence 2).** No product-related adverse events occurred (539).

The other RCT compared the effects of the same cyanoacrylate film-forming skin protectant (intervention group, n = 10) with a standard IAD care approach (control group, n = 10) in hospital patients with IAD in two European hospitals (540). IAD severity improved in two patients in both groups each and one IAD lesion healed completely in the control group **(Level of Evidence 2)**.

Coyer *et al.* implemented a 'bundle' of IAD prevention measures, including the use of washcloths with 1% dimethicone and a barrier film based on acrylate terpolymer formulation in a general ICU in an Australian hospital (542). After the implementation, the IAD incidence was lower (15%) compared to baseline (32%). The implementation also reduced the IAD severity (542) **(Level of Evidence 3).**

Brennan *et al.* conducted a non-randomized IAD treatment study in an ICU in the US (541). Patients with IAD (n = 16, mean age 71 years) received twice-weekly an acrylate-based skin protectant by painting a thin layer on the affected areas. There was an IAD severity improvement in 13 patients **(Level of evidence 3).**

Avşar et al. implemented a complex skin care regimen in an ICU in Turkey, including the use of soft disposable cleaning wipes and the application of a barrier cream on healthy skin but also on IAD lesions to promote healing (543). The proportion of patients with IAD was lower after the intervention (10%) compared to baseline (3%) **(Level of Evidence 3).**

Takahashi *et al.* (544) followed 21 older patients (mean age 84 years, 8 male, 13 female) for four weeks who were incontinent, had confirmed genital candidiasis and wore diapers. At every washing at the time of diaper change, a 0.75% miconazole nitrate-containing soap was used. Over the four weeks of treatment, the IAD severity and the number of candida infections reduced substantially **(Level of Evidence 3).**

Woodward described three cases of adult patients with severe IAD (545). After treatment with a Medihoney containing leave-on product, IAD healing occurred **(Level of Evidence 4)**.

Taken together, the results of these additional studies support the conclusions of the three systematic reviews: The implementation of a structured IAD prevention and treatment strategy including mild skin cleansing and skin and/or IAD lesion protection using films

or barrier products prevents IAD and promotes healing (541-543, 545). Direct head-to-head comparisons seem to indicate little differences in IAD prevention and treatment products (539, 540). The use of an antifungal soap for skin cleansing also seems to support IAD healing (544).

There is an ongoing discussion as to whether and how topical products affect the absorbency of absorbent products, but so far, there are only four studies using artificial testing scenarios on the volar forearm skin (79). There are no studies investigating possible 'clogging' of briefs or pads and possible effects on skin health in incontinent patients.

2. SUMMARY

Skin exposed to urine and/or stool is at high risk of developing IAD. The best strategy to prevent IAD is to limit and/or to prevent prolonged and repeated exposure. Absorbent hygiene products (e.g. pads, diapers, pants) absorb moisture from incontinence (urine or liquid stool) and lock the liquid inside the absorbent core material and therefore reduce the moisture load on the skin surface (79, 530). The evidence summaries of the previous consultation (36) and this update indicates that products with high absorptive capacity (superabsorbent polymer core) and breathable material promote skin health compared to less absorptive and more occlusive products. This finding also corresponds to a Canadian guideline, recommending high absorbency pads in patients who are unable to toilet, and the use of external collection devices is not possible (546). The use of faecal collection devices also helps to prevent and/or to promote IAD healing. The skin should be cleaned with mild non-irritating cleansers using soft material (e.g. wipes). Evidence indicates that topical leave-on products (such as lipophilic or film-forming products) creating a barrier on the skin surface decrease IAD incidence and promote healing. A clear superiority of one skin protecting product against another could not be shown.

3. RECOMMENDATIONS

- Use absorbent products with high absorptive capacity and breathable material in subjects at risk for IAD or with IAD **(Grade of Recommendation B)**
- Use faecal containment devices in critically ill patients with faecal incontinence **(Grade of Recommendation B)**
- Use non-irritating skin cleansing products/procedures to remove stool and/or urine after incontinence episodes **(Grade of Recommendation B)**
- Use skin-protecting topical products at skin areas exposed to stool and/or urine (**Grade of Recommendation B)**
- Use topical products (e.g., barrier products, film-forming products) to protect IAD lesions and promote healing **(Grade of Recommendation B)**

4. PRIORITIES FOR RESEARCH

A major challenge in the field of IAD research is the wide range of different devices and products used in clinical studies to prevent and/or treat IAD (536). Even if particular products have been investigated in a trial, there is no guarantee that these products are still available because manufacturers constantly modify existing and develop new products (533). A solution could be the development of a device and product classification system based on main ingredients and/or performance characteristics using standardized terminology. This may enhance scientific communication and comparisons in the future.

Another main limitation is the use of many non-comparable outcomes and outcome measurement instruments in existing clinical trials (536-538). This impedes the comparison of prevention and treatment effects between studies and possible meta-analyses. Five core outcomes have been recently identified for clinical IAD trials: erythema, erosion, maceration, IAD-related pain and patient satisfaction (547), and the first attempts of how to measure these outcomes have been made (548). Research must further investigate how to best measure these five core outcomes, and they need to be implemented in a standardized fashion in future clinical trials.

P. ODOUR CONTROL PRODUCTS

Fear of odour from leaked urine, stool or flatus is a major concern that preoccupies many people suffering from incontinence. Worry about odour and the stigma associated with "smelling bad" is an issue consistently raised in studies that have explored experiences and opinions of patients with incontinence over time (36). The fear of odour plays a role in people's affective and behavioural responses to incontinence. Concern about odour can interfere with social relationships, cause people to isolate themselves within their home, or serve as a trigger to seek clinical care (549) (550) (551).

Additionally, caregivers are bothered by odour. Nurses caring for patients with diarrhoea during tube feeding rated odour as one of the most unpleasant aspects of caregiving (539). Malodours, trigger negative emotional reactions and avoidance. (552).

The odour associated with urine leakage is mainly due to the production of ammonia from urea by bacterial ureases, whereas factors that contribute to the odour of faeces and flatus include differing states of health and gastrointestinal function, diet composition, the profile of colonic microbes, relative concentrations of volatile sulphur and hydrogen-containing gases, and, possibly, short-chain fatty acids or ammonia (553) (554) (555) (556) (557). For example, dietary protein that escapes small intestinal digestion and absorption and reaches the colon provides a substrate for bacterial fermentation resulting in increased malodorous flatus (557). Using the frequency of searches on Google for information about unpleasant body odours as a surrogate of the presence of these symptoms, Korownyk (2018) (558) concluded that there is a seasonal variation in odours. The greatest number of searches about flatulence occurred in January, and the lowest was in July, and seasonality explained 88% of the variability in search frequency. A limitation of this study is that unlike the other body odours studied, the search about flatulence did not specify its odour component, but rather flatulence in general.

Odours associated with human faeces and urine are distinctive and recognizable to humans and can be detected at very low concentrations (552). Individual sensitivity to odours is affected by a variety of factors including genetics, age (with perception declining after age 60 years), sex (with women having greater perception than men), psychological state (anxiety is associated with greater odour sensitivity), and previous experience and exposure to a smell (increasing sensitivity in some persons). Furthermore, belief or expectation about the presence of body odour can result in a person misinterpreting an environmental odour as their own or perceiving an odour when none is present; thus, some individuals with incontinence mistrust their ability to detect bodily malodours (552).

Understandably, there is a demand for products that will mask or contain odour or, preferably, prevent it.

Odour control products play a key role in helping people with incontinence retain their sense of adulthood, identity, independence, and engagement in social life and in supporting their caregivers. Some patients with incontinence place a high value on products that mask, control, reduce, or eliminate odour (559). According to evaluations of different types of absorbent products for urinary (25) or faecal incontinence (560), the ability of absorbent products to reduce or contain odour is one of the top factors related to the selection or positive evaluation of a product. Women with light urinary incontinence rated 'the ability of absorbent products to contain smell' as the second most important factor when choosing a product, after the 'ability to hold urine' (25). Odour control had the lowest percentage of "good" ratings across various types of bodyworn incontinence absorbent products evaluated by community-living adults with faecal incontinence (n=189) (560).

Environmental odour is another concern when portable toileting devices are used. Where commodes were used for defecation in a home setting, carers identified the problem of odour lingering even after a commode had been emptied (53). Most bedpans do not have lids, resulting in odour spread when transporting their contentsfor disposal. There remains little research about cleaning frequency or products for commodes, bedpans, or urinals and their effectiveness in reducing any residual odour. Toilet bowl cleaning products are suitable for cleaning a commode or bedpan; many contain bleach or antibacterial ingredients, but their effect on reducing odour has not been studied. Gel formulations are advertised by manufacturers as being better able to cling to hard-to-reach surfaces than liquid agents. Use of a deodorizer in a room or near a commode can be considered.

There have been several innovative approaches to products for reducing odour associated with incontinence with varying levels of evidence and effectiveness. Current odour control products for faecal incontinence can be categorised as orally ingestible products that aim to reduce the production of malodorous gas or those that aim to contain or absorb expelled flatus odour.

Oral ingestible products that aim to reduce the production of malodorous gas include probiotics, the enzyme α-galactosidase, and oral charcoal mixtures.

a) Probiotics

In a randomised controlled trial, administration of *Lactobacillus plantarum* (5 x 107 CFU/ml) to patients with irritable bowel disease (n=60) was associated with a significant reduction in flatulence and pain (561) **(Level of Evidence 1).**

b) Enzymes (α-galactosidase)

In a randomised crossover trial, administration of 240 GalU alpha-galactosidase to healthy adults (n=19) was associated with less frequent flatulence events five hours after the test meal, but there was no difference in bloating or pain (562) **(Level of Evidence 1).**

In a randomised controlled trial, there was a significant reduction in the production of intestinal gas and the severity of flatulence after administration of 1200 GalU of alpha-galactosidase but not after administration of 300 GalU to healthy adults (n=8) following a test meal of beans (563) **(Level of Evidence 1).**

c) Oral charcoal mixtures

A randomised double-blind study comparing 194 mg of activated charcoal or placebo administered in a double-blind manner to healthy adults (n=13) immediately after a 'bean meal' and at 30-minute intervals for two hours after the meal showed a significant reduction in the mean number of flatus events in those given the activated charcoal (564). **(Level of Evidence 2)**

In a randomised controlled trial using 8 adult dogs, the production of hydrogen sulphide was significantly reduced following the administration of activated charcoal, *Yucca schidigera*, and zinc by 71, 38, and 58% respectively, and by 86% by the combination of all three agents (565).

In an *in vitro* study, flatus was collected from healthy adults (n=15) who had been given 15 g lactulose and had eaten a meal supplemented with beans and treated with activated charcoal and then with zinc acetate (554). Treating the collected flatus with zinc acetate reduced sulphur gas content but did not totally eliminate odour, while activated charcoal removed virtually all odour. **Level of evidence 3**

Products for trapping expelled odour comprise clothing, pads, and cushions containing activated charcoal (555), bedding fabrics and absorbent pads treated with antimicrobials (566) (567), a re-usable garment (568), lavender scent applied on body worn absorbent pads (24), and penile sheaths.

a) Products containing activated charcoal

The extent to which the odour associated with flatus was reduced by the use of different types of continence products containing activated charcoal was evaluated (555). The devices included four different types of charcoal-activated pads worn inside conventional underwear, two types of charcoal-activated wearable briefs, and five types of charcoal-activated cushions upon which to sit (555). The products that were reported as being the most effective were the briefs (95-99% absorbency), followed by the pads (55-77%), usual clothing (22%), and cushions (20%) **(Level of Evidence 3).** The briefs seem to provide the greatest surface area for contact with malodorous rectal gas. The limited absorption of malodorous gas by clothing suggests that washing the outer clothing, as well as underwear, is important to reduce odour.

b) Microbial treated fabrics and pads

In vitro experiments showed that cloth treated with acrylonitrile copper sulphide inhibited the growth of most bacteria causing urinary tract infection and that cloth treated with iron-phthalocyanine effectively eliminated bad-smelling gases (566).

In another *in vitro* study, suspensions of a range of bacterial, viral, fungal and yeast micro-organisms were applied to the cloth. N-halamine siloxane coatings were found to inactivate most antimicrobials and prevent odour caused by the bacterial generation of ammonia on urine-soaked fabrics (567).

c) Re-Usable Garments

The ability of a reusable under-garment called 'HealthDri' to control odour associated with UI was rated as adequate or excellent by 80% of men (n=84) and women (n=42) who used the product for one month (568).

d) Scents on disposable pads

In a multicentre evaluation of different disposable bodyworn absorbent pads for light UI, pads on which lavender scent was applied did not control odour significantly better than other pads (24).

Penile Sheaths

Penile sheaths are reported to reduce the odour associated with UI. In one study of 61 men, Conveen Optima urosheaths had higher ratings for odour management, feelings of security and freedom, self-image, discretion and skin integrity, but not for ease of use, compared to absorbent pads (60). In another study, nursing home staff rated the odour in the room of residents with UI and FI as being lower after urosheaths were used for 1 week (550).

A broader review of findings on the use of penile sheaths is given in Section G.

1. NEW EVIDENCE FOR THE CURRENT CONSULTATION

14 new peer-reviewed papers were identified to inform the current consultation about odour associated with incontinence and continence products:

- A theoretical paper about the role odour plays in human affective and behavioural responses to incontinence (552)
- Four qualitative studies about the impact of odour (569-571) (572)
- A descriptive in vitro study about a new technique to identify bacterially formed odorants and reduce the odour of UI in absorbent incontinence products - reported in four papers (573) (574) (575) (576).
- Two further papers about odour neutralising technology (ONT), including a randomised single-bind parallel study (531) and a descriptive study about the effects of using ONT in disposable incontinence products on skin health (577)
- A feasibility study about an odour detecting device (578).
- A publication about the development and validation of an instrument that includes an item to measure product users' concerns about the smell (29)
- Two randomized trials investigating the effects of ingestion of probiotics versus digestive enzymes (579) or bismuth subgallate (580) on flatus odour.

Probiotics or Digestive Enzymes

In a double-blind, randomized study (579), adult patients who underwent gastric bypass surgery for severe obesity and had adverse postoperative symptoms were randomly assigned to 1 of 3 groups: Probiotics group A (1g *Clostridium butyricum MIYAIRI* (5 billion colony-forming units (CFUs))), Probiotics group B (300 mg *Bifidobacterium longum BB536* (8 billion CFUs)), or Digestive enzymes group (Aczym containing 100 mg takadiastase N, 20 mg cellulose AP, 50 mg lipase MY, and 100 mg pancreatin). Products were taken twice daily for 2 weeks. Outcomes were measured by self-report using the Gastrointestinal Quality of Life Index that was modified to include 2 new items for foul-smelling flatus and oil flatus; possible scores range from 0 to 4 (0= the worst and 4=the best option).

Of the 60 participants, 53 completed the study (19 in Probiotics group A, 18 in Probiotics group B and 16 in Digestive enzymes group). The score for the foul smell of flatulence of all groups together improved from 1.02 before the intervention to 2.4 after, $p<.05$. Scores for an excessive amount of flatus also improved from 1.3 before to 2.5 after the intervention ($p<.05$). Study limitations include the absence of a control group and intent to treat analysis, modification of a validated tool, and inclusion of subjects with an altered gastrointestinal tract.

Bismuth Subgallate

In a prospective, randomized, double-blinded, placebo-controlled, crossover study (580), adults who reported flatus and/or stool odour changes at least 6 months after loop duodenal switch surgery for morbid obesity participated in two treatment periods, each lasting for 1 week, separated by a 1-week washout. Patients received 200 mg bismuth subgallate, 2 capsules per meal, or a placebo. Outcomes were measured by self-report using the Gastrointestinal Quality of Life Index that was modified to include 4 new items, including those for smelly gas and stool; possible scores range from 0 to 4 (0= the worst and 4=the best option). Of the 36 participants, 29 completed the study. The mean (sd) score for smelly gas improved from 0.4 (0.5) before the intervention to 1.8 (1.3) afterwards, $p=.001$. The mean (sd) score for smelly stool improved from 0.5 ± 0.6 before the intervention to 1.9 ± 1.3 afterwards, $p=.001$. Study limitations include potential carryover effects between periods, absence of an intent to treat analysis, modification of a validated tool, and inclusion of subjects with an altered gastrointestinal tract.

Odour Sensor and Alarm

Ortiz Perez *et al.* (578) describe the design and development of a prototype of a portable "smart" device for detection, discrimination, and notification of odours associated with urine and faeces. The device is an accessory to a mobile phone and uses Bluetooth to transfer raw data from the odour sensing unit to the smart device, which performs the data analysis and notification tasks. The gas detection is based on semiconducting metal oxide technology and was capable of detecting relevant trace gases in urine or faeces such as ammonia, methyl mercaptan, and dimethyl sulphide. Further development and performance testing is needed before the device will be available.

The impact of odour

Fear of odour associated with incontinence continues to emerge as a salient finding. Animut *et al.* (569) used a phenomenological approach to explore the experience of living with obstetric fistula and the experience of becoming an obstetric fistula patient in a small sample of women (average age 33.8yrs) in Ethiopia. Concern about smelling bad caused the women to experience psychological health and social problems. Changole *et al.* (570) also conducted qualitative interviews with women with obstetric fistula and their family members in Malawi. They reported the women and their families had very little prior awareness and knowledge about the condition or its causes. A qualitative study involving interviews with women with obstetric fistula in Nigeria reinforces the impact of the stigma associated with the odour of uncontrollable leakage of urine and faeces in some communities. Mohamed *et al.* (571) reported the women described socially removing themselves from community gatherings and having to frequently wash their clothes and use perfumes to cover the offensive odour and always carry extra clothes and water in order to control the urine incontinence and bad odour. Finally, according to the findings of a qualitative study of 22 community-dwelling women (65 years and older) with UI from South Korea, deodorising the smell was one of several self-management strategies the women adopted in order to preserve their self-respect in the sociocultural environment (572).

Drawing on research about the physiology of the olfactory system, Dalton & Maute (552) published a theoretical paper about odour

and malodour perception as it relates to the odours of urine and faeces. The authors discussed the biological and psychological bases underlying odour perception and ‘‘odour worry’’ among people with incontinence. They claimed odours, and malodours in particular, can trigger immediate, reflexive emotional, and behavioural responses. This is because, whilst olfactory signals are transmitted to the thalamus and neocortex, where they are translated into conscious awareness, they are also transmitted to the non-cognitive limbic area and are translated into emotional information. Malodours, such as the odour of urine and faeces, are by their very nature, perceived as negative and are associated with decay or contamination and risks for health and wellbeing. Moreover, malodour induces feelings of discomfort that can impede cognitive performance and elicit negative emotional responses such as disgust and behavioural responses such as social distancing. ‘If an odour is produced, a host of concerns arise around the social meaning of being a malodour source with the corresponding emotional anticipations and responses’ (p 129).

The authors also discussed the concept of hypervigilance about the potential for malodour from urine or faeces. Hypervigilance can lead a person with incontinence to smell odours that are not physically present, i.e., ‘a phantom odour.’ These findings suggest clinicians could play a role in allaying peoples’ concerns about real or perceived odour associated with incontinence.

Despite emerging research about the central role odour plays in peoples’ affective and behavioural responses to incontinence, it is rarely evaluated. However, a new self-reported quality of life questionnaire developed by *Yearwood-Martin et al.,* (29) could be used for this purpose. The ICIQ-PadPROM was designed to assess the treatment effect of absorbent continence products. It contains one item about ‘odour-worry’.

Products that aim to prevent, absorb, or control odour associated with UI

A new development in the science associated with odour, continence products and incontinence is a technique to identify bacterially formed odorants and reduce the odour of UI in absorbent incontinence products. Sponsored by industry, Forsgren-Brusk *et al.*, (573), Hall *et al.*, (574), Ryttsen *et al.,* (575) and Widen *et al.*, (576) described an *in vitro* study in which adjusting the pH of the superabsorbent from 6.0 to pH 4.5 and pH 4.9 significantly ($P < 0.05$) inhibited the bacterial growth rates, in most cases, both at 6 and 12 hours. The effect was greatest at pH 4.5.

In addition, two new studies were found that described the effects of adding an odour neutralising agent to absorbent disposable incontinence products. Sponsored by industry, Gutshall *et al.*, (577) evaluated the effect of odour neutralising technology (ONT) on skin health in a series of tests including the cumulative irritation test, the behind-the-knee study for trans epidermal loss and the Human Repeat Insult Patch Test for contact sensitisation. The ONT was a proprietary mixture of functional fragrance components that aimed to neutralize amines. The researchers reported ‘the ONT products produced minimal skin reactions that were like the non-irritant controls or in-market control products without ONT’. Sponsored by the same company, Trowbridge et al., study (531)conducted a single-blind randomised parallel study to compare the effect of a disposable incontinence product with ONT with non ONT products in a sample of 122 people (60 ONT product/52 non-ONT product). The outcomes of interest were skin health and overall comfort. The researchers reported ‘In-use 14-day testing demonstrated few statistical differences between an experimental product with unique ONT and currently marketed product for skin assessments and comfort. Both products were comfortable and well tolerated.

Products that aim to prevent, absorb, or control odour associated with FI

No new studies were identified.

2. SUMMARY

- Odour control products have a key role in helping people with incontinence retain their sense of personhood, identity, independence, and engagement in social life and supporting their caregivers **(Level of Evidence 3)**.
- The clinical effectiveness of treating fabric-based continence products with antimicrobial agents to reduce the odour associated with urine is unclear (548) (549) **(Level of Evidence 4)**.
- Compared with continence pads, penile sheaths may have a greater ability to reduce the odour associated with urine leakage 60) (550) **(Level of Evidence 2).**
- Users of a particular type of reusable undergarment reported being satisfied with their ability to control the odour associated with UI (551) **(Level of Evidence 3).**
- Users of disposable absorbent products reported being dissatisfied with products’ ability to control the odour associated with FI (552**) (Level of Evidence 3).**
- Oral intake of certain probiotics *(Lactobacillus plantarum*, 1 g *Clostridium butyricum MIYAIRI*, or 300 mg *Bifidobacterium longum* BB536), enzymes (α-galactosidase or Aczym), oral charcoal mixtures, or bismuth subgallate may reduce production of malodorous gas (541) (543) (544) (545) (546) (579), (580) **(Level of Evidence 1).**
- Products or devices that are activated with charcoal can absorb odour associated with flatus; charcoal activated wearable briefs are more effective than charcoal activated cushions or pads (542) **(Level of Evidence 3).**
- Applying scent to disposable body worn pads does little to reduce the odour associated with urine (20) **(Level of Evidence 3).**
- A portable sensor connected to a mobile phone can detect odours of urine and faeces and may have potential to notify patients of their presence (578) **(Level of Evidence 3)**.
- Evidence for cleaning the collection container of commodes or shower chairs or bedpans to reduce odour is scarce and relies on expert advice; anti-microbial cleaning solutions destroy bacteria responsible for the breakdown of urea in urine or producing flatus in faeces and may be used to wash these products **(Level of Evidence 4)**.

3. RECOMMENDATIONS

Recommendations relating to products for odour associated with incontinence are listed in Table P-1.

4. PRIORITIES FOR RESEARCH

- Development of an absorbent product that can eliminate, reduce, or mask the odour of leaked urine, faeces, and flatus while protecting the skin.
- Development of bodyworn undergarments and textile products (soft furnishings and bedding) for eliminating, reducing, or masking odour associated with urine, faeces, and flatus.

Table P-1: Recommendations relating to incontinence and odour.

- Inform patients with FI about the limited ability of disposable bodyworn incontinence products to reduce the odour associated with FI **(Grade of Recommendation C).**
- Inform patients that odoriferous rectal gas may be better absorbed with bodyworn briefs containing activated charcoal rather than with separate pads or cushions **(Grade of Recommendation C).**
- Since some pads absorb up to 75% of gas, offer patients who have smaller amounts of gas the opportunity to compare pads and briefs for themselves. **(Grade of Recommendation C).**
- Patients with irritable bowel syndrome should consider a trial of the probiotic **Lactobacillus plantarum** to reduce flatulence **(Grade of Recommendation C)**
- For those persons experiencing stool leakage due to flatus, over-the-counter α-galactosidase containing products, which reduce the production of malodorous gas can be tried **(Grade of Recommendation B).**
- Patients with malodorous flatus after bariatric surgery may be offered a trial of probiotics (1 g **Clostridium butyricum MIYAIRI** or 300 mg **Bifidobacterium longum BB536**) or digestive enzymes (Aczym) **(Grade of Recommendation B).**
- Washing of outer as well as underclothing after flatus should be performed to reduce odour due to absorption of gas by clothing **(Grade of Recommendation C).**
- Equipment used for toileting should be cleaned after each use following local infection control policies in institutional environments to reduce odour and maintain hygiene and aesthetics. **(Grade of Recommendation D).**
- Use of a deodorizer in a room or near a commode should be considered **(Grade of Recommendation D).**
- Investigation of whether probiotics or changes in dietary intake can eliminate or reduce the odour of flatulence or leaked faeces.
- Evidence-based guidelines to inform the cleaning and maintenance of commodes, shower chairs and bedpans in home and institutional environments.

APPENDIX 1

The literature search to identify material for this chapter - additional to that reviewed for the last (6th) consultation (63) - was conducted as follows. MEDLINE and CINAHL databases were searched from 2016 – 2020 for English language publications. Detailed search strategies were developed for each electronic database searched. Consideration was given to variations in terms used and spellings of terms in different countries so that studies were not missed. Relevant abstracts were examined, and then pertinent articles were retrieved and reviewed, and the reference lists were searched for further studies. For product categories associated with little or no research literature, the analysis relied on expert opinion from clinical practice papers.

The following main search terms were used: incon-tinence AND device*, toilet* AND facilities, female, male, urinal*, commode*, bedpan*, urin* AND sheath, condom AND catheter*, *, intermittent catheterisation, indwelling catheterisation, catheterisation, catheters, incontinence OR absorbent pad*, urinary AND catheter* (in title), urinary AND leg bag* OR legbag* OR drainage bag, faecal OR faecal AND incontinence AND plug OR pouch OR bag OR device, OR manage* system, incontinence OR perineal AND dermatitis OR in-flammation OR skin damage, incontinence OR perineal OR diaper AND dermatitis OR inflammation OR skin damage OR skin lesion OR erythema OR rash OR erosion.

APPENDIX 2

Details of Cochrane reviews relating to long-term and short-term catheter use are described in Table Ap21.

Table Ap2-1: Cochrane reviews on long term and short term catheterisation.

Date	Authors	Research Q	Comparisons	No. of Trials	Conclusions
Cochrane Reviews on LONG TERM Catheterisation					
2010	Hagen et al (576)	Long term: Are bladder washouts effective in maintaining catheter patency.	No washout vs saline or acidic solution; saline vs acidic solution vs antibiotic solution.	5	Insufficient evidence to state whether blockage, UTI or time to first catheter change is affected by washout.
2012	Niël-Weise et al (577)	Long term: Urinary catheter policies for LT catheter drainage.	IUC vs SPC/IC; prophylaxis vs sx treatment; vs AB P vs microbiology.	1 on IUC.	A possible benefit of ABP in LT IDC but resistance is a serious concern.
2012	Jahn et al (578)	Long term: Types of catheters for long term use.	Antiseptic vs standard catheters; standard vs standard catheter.	3	Evidence insufficient to effect of silver alloy catheter on CAUTI; hydrogel catheter may be better tolerated than silicone catheter.
2013	Jamison et al (579)	Long term: Catheter policies for LT voiding problems in neurogenic bladder.	IC vs IUD. IUD vs SPC Sheaths vs IUC or SPC. IC vs timed voiding.	0	No trials were found.
2016	Cooper et al (402)	Policies for replacing long-term indwelling urinary catheters in adults	different policies for replacing long□term indwelling urinary catheters in adults	3	Insufficient evidence to assess the value of different policies for replacing long□term urinary catheters on patient outcomes
2017	Shepherd et al (293)	Washout policies in long-term indwelling urinary catheterization in adults	catheter washout policies (e.g., washout versus no washout, different washout solutions, frequency, duration, volume, concentration, method of administration)	7	Evidence was not adequate to conclude if washouts were beneficial or harmful
Cochrane Reviews on SHORT TERM Catheterisation					
2006	Phipps et al (580)	ST urinary catheter policies following urogenital surgery.	UC vs no catheter; UC vs SPC; duration. Clamping prior to removal.	36	Recatheterisation higher in non-UC group or UC vs SPC; early removal reduces the risk of UTI; clamping may increase the risk of UTI and delay normal voiding.
2005	Griffiths and Fernandez (581)	Short term: Policies for urethral catheter removal (midnight vs morning).	Midnight vs other times (morning).	18	Possible benefit from midnight removal -larger 1st void/longer time to 1st void, shorter stay; no difference in recatheterisation rate.
2013	Lusardi (582)	Short term: Antibiotic prophylaxis in short term catheterisation.	Prophylaxis (vs none).	6	Weak evidence that ASB, pyuria and fever are reduced.
2014	Fisher (583)	Short term: Alpha blocker pre catheter removal in AUR.	Alpha-blocker vs placebo or no treatment.	9	Improved voiding with AB vs placebo and reduced incidence of repeated AUR.
2014	Lam et al (584)	Short term: types of catheters.	Silver alloy/oxide; Nitrofurazone; Minocycline + rifampicin all vs standard catheter.	26	Reduction of CAUTI: no difference with silver alloy; weak evidence that nitrofurazone reduced risk of CAUTI/ bacteriuria; may cause more discomfort than standard catheters.
2015	Kidd et al (474)	Short term use of SPC vs IUC.	IUC vs SPC; IUC vs IC.	25	SPC vs IUC: ASB, recatheterisation and pain reduced in SPC group; IUC vs IC: inconclusive re: UTI, ASB, pain.

ASB = asymptomatic bacteriuria. SPC = suprapubic catheter. IUC = indwelling urethral catheter. IC = intermittent catheterisation. AUR = acute urinary retention. CAUTI = catheter associated urinary tract infection. sx = signs and symptoms

I. INTRODUCTION

This chapter reports advances in knowledge on primary prevention, continence promotion, models of care, and education. It continues to reflect the shift in paradigms from a singular focus on secondary and tertiary treatment, and management to the inclusion of primary prevention and health promotion, i.e., promotion of bladder and bowel continence. The interest in primary prevention has led to the development of new theories and conceptual models about bladder health, especially continence, across the life-course[1] and new definitions for bladder and pelvic health[2, 3].

Traditionally urinary incontinence (UI) and faecal incontinence (FI) were topics not freely discussed or shared by the public, public health providers, or healthcare professionals interested in the promotion and maintenance of health. Many people with these conditions feel shame and stigmatized and do not seek help[4]. Despite this barrier however, empirical and evidence-based resources are becoming available to promote continence and prevent incontinence.

Research and public health initiatives funded by national governments have increased and practice guidelines have been developed and put into use in recent years. Inclusion of the public in research through community engagement and community-based participatory research practices has also increased[5]. Innovative approaches to research and individual and population-level interventions are being used to advance knowledge, change behaviour, and ultimately improve health outcomes. Social media use has increased to conduct research, disseminate knowledge, as a research recruitment means, a venue to provide updates on research advances, and obtain timely feedback about policy and research recommendations[6]. Many countries carry out national or local public awareness campaigns, often spearheaded by a national continence organisation, and the internet is increasingly being viewed as a convenient source of health information for the public[7].

This chapter updates the 2017 International Consultation on Incontinence (ICI) chapter in these areas: primary prevention, continence promotion, models of care, and education and provides recommendations in each area. Most information contained in this chapter primarily relates to UI and FI. These conditions are prevalent but continue to be under-investigated in many populations. As the evidence mounts for non-biologic determinants of urinary and faecal incontinence and for the sheer numbers of people at risk for developing these conditions, the focus in the first chapter section is on population-based primary prevention research. Emerging evidence supports strategies to promote continence in specific populations, yet more research is needed to quantify the benefits of primary preventative strategies, especially across the life-course.

It will review recent continence promotion literature and includes health promotion and help-seeking (care-seeking) behaviours (HSB) for faecal and urinary incontinence. Progress for continence promotion activities globally has been made, yet rapid adoption of existing primary prevention practices appears limited on an individual or population-level.

Information is provided about continence promotion programmes and advocacy through worldwide organisations. There remains inadequate information about the impact of these efforts on changing public and healthcare policies, public and health professional attitudes, beliefs, and knowledge about bowel and bladder continence.

The chapter discusses models of continence care and service delivery. It will consider variations in service delivery worldwide and recommended proven models of care. The final chapter topic addresses education of healthcare professionals about bowel and bladder continence, including the development and use of public health and medical guidelines and care pathways. Although the committee found information about recent practice and research initiatives, little evidence-based research to support widespread dissemination and translation exists.

II. PRIMARY PREVENTION OF UI AND FI

Literature search is found in Appendix 1.

1. BACKGROUND

Primary prevention aims to, "prevent a disease from ever occurring", and "refers to actions aimed at avoiding the manifestation of a disease". [8] These actions include interventions to improve health by: 1) changing the impact of social and economic determinants of health, 2) providing information about how to reduce risks of disease and clinical preventive services to people, and 3) delivering community and individual-level interventions to reduce risks. Although UI is not considered a disease, primary prevention of UI in adults is important because of its prevalence across the life-course, financial and societal costs, and impact on the quality of life (QoL) of affected individuals and caregivers. A report from the Global Coalition on Aging published in 2018 noted the importance of bladder health and that overactive bladder affected employee productivity and healthy active aging[9]. This document supported conclusions from an earlier consensus statement that healthcare professionals and policymakers and funding bodies need to address UI primary prevention efforts[10].

One driving force for developing primary prevention interventions for UI is epidemiological evidence of population aging. The United Nations reported there were 703 million people aged 65 years and over in 2019 and projected that the number will double to 1.5 billion people aged 65 years and over by 2050, representing 16% of the world's population. Forty-seven countries considered least developed (for statistical purposes) by the United Nations are projected to have the fastest increase of the older population, i.e., 37 million in 2019 to 120 million in 2050[11] These global aging estimates have significant implications for the number of people expected to develop UI + FI and other chronic non-communicable diseases associated with UI + FI (i.e., diabetes, arthritis, and neurological disorders). In addition to population aging another factor that has implications to UI + FI prevalence and incidence is obstetric fistula. The World Health Organization estimates 50,000 to 100,000 women annually experience obstetric fistula during childbirth and 2 million women in Asia and sub-Saharan Africa are living with untreated fistulas[12]. These fistulas are considered preventable and, left untreated, lead to untold suffering as a result of UI and FI[13]. Population aging and obstetric fistulas serve as exemplars for prioritizing primary prevention. The science of primary prevention of UI + FI incorporates an urgent need to reduce and eliminate existing inequities in healthcare access and utilization, reduce healthcare and societal costs from UI + FI and its causes across the human lifespan, and increase the workforce of educated and clinically competent healthcare and public health providers.

Two additional driving forces to develop primary prevention interventions are the accumulation of evidence that multiple factors extrinsic to the individual person influence the health and function of the lower urinary tract and increased scientific and professional interest in developing a prevention science agenda[14]. Since the Sixth ICI, multiple advances in primary prevention of UI science in women have occurred. For example, a research definition of bladder health in women and girls was developed by a transdisciplinary group of researchers in the United States. Bladder health was defined as, "A complete state of physical, mental, and social well-being related to bladder function and not merely the absence of lower urinary tract symptoms (LUTS). Healthy bladder function permits daily activities, adapts to short-term physical or environmental stressors, and allows optimal well-being (e.g., travel, exercise, social, occupational, or other activities)"[15]. Knowledge about women's perceptions of bladder health and associated function has deepened through qualitative research[16].

Research terminology was also developed to assess bladder health across the life-course of women[17]. In addition to a bladder health definition, pelvic floor health was defined as, "the physical and functional integrity of the pelvic floor unit through the life stages of an individual (male or female), permitting an optimal quality of life through its multifunctional role, where the individual possesses or has access to knowledge, which empowers the ability to prevent or manage dysfunction"[18].

To facilitate the development and organization of research questions and priorities, a conceptual framework that, "encompasses all facets of social ecology, integrates biology with social ecology, and emphasizes a life course perspective described the multi-level domains across the human life-course" was published[19] . This framework was adapted from Glass-McAtee Society-Behavior-Biology[20] and the World Health Organization framework of social determinants of health[21]. The resultant framework creates a foundation for researchers to use in developing interventions to prevent UI in women across their life-course. To differentiate the individual from population level outcomes, a model was proposed to illustrate the multi-stage approach to education, detection, intervention, embedded change, and outcomes (see Figure 1). At the intersection of individual and environment, evidence has emerged that potentially modifiable toileting behaviors in women are associated with UI[22]. The physical environment has been implicated in influencing women's toileting behaviors[23]. There are no systematic reviews of population-based primary prevention interventions.

Professional organisations sponsor activities and events to heighten the public's awareness of the importance of bladder health and continence. These include but are not limited to: The World Federation for Incontinence and Pelvic Problems (WFIPP) sponsorship of World Continence Week since 2013 (www.wfipp.org); the United Nations observes May 23rd to heighten the awareness of urgency to end obstetric fistula (www.un.org/en/observances/end-fistula-day); the Continence Foundation of Australia (www.continence.org.au), and Canadian Continence Foundation disseminates information to healthcare provider and public. The Continence Foundation of the American Urological Association (AUA) has designated November bladder health awareness month (www.auanet.org) in the United States. A listing of continence societies is located at Worldwide In-

continence Organizations – Managing Life with Incontinence. In the UK, the Urology Foundation runs a urology awareness month in September. Evaluation of the effectiveness of these programmes are not available.

2. PREVENTION OF UI IN SPECIFIC POPULATIONS

2.1. Hospitalised adults

UI is prevalent (26%) in hospitalized adults 65 to 74 years old, and more so in those 85 years and over (35.2%)[24]. There is little evidence for effects of intervention designed to prevent UI in hospitalized adults. Hospital based programs to detect and manage UI have been reported, and nursing education and standardized assessment improves nursing compliance to the clinical protocols[25,26]. Authors of a Cochrane review however noted there is insufficient evidence to guide UI care after stroke[27], and qualitative research revealed that nurses working in orthopaedic units often do not view UI as a priority in care, have inadequate knowledge and do not attempt to prevent UI[28]. Measures to facilitate knowledge implementation have been recommended[29], as has screening women annually for urinary incontinence as a preventative measure[30].

2.2. Women during pregnancy and postpartum

Interventions to prevent UI in prenatal women from twenty-four studies including 15982 women were evaluated in a systematic review and meta-analysis with the authors concluding that low to moderate evidence existed that pelvic floor muscle exercises (PFME) reduced the odds of UI during pregnancy and postpartum. The authors further noted that these women had been continent prior to starting PFME, but PFME did not treat the UI for those who had UI prenatally[31]. Authors of another systematic review concluded that PFME performed by continent women in early pregnancy may reduce risk of UI in late pregnancy[32]. There was insufficient information about the effects of antenatal PFME in the late postpartum period, i.e., 6 to 12 months post childbirth. Further the authors stated, “A population-based approach for delivering postnatal PFME is not likely to reduce UI.”

Interventions to prevent UI in postpartum women were evaluated in a systematic review[33]. The common intervention in the six studies included in the systematic review was pelvic floor muscle training (PFMT) although other behavioural interventions were used in some of the included studies, i.e., lifestyle modification, bladder training, programmed urination. The authors concluded that training of the pelvic floor in the immediate and late postpartum stages is effective in preventing UI. They further noted that barriers to exercise protocol adherence can be overcome with specific interventions.

In a qualitative study women identified barriers to performing PFMT including not having adequate information and training to sustain practice. The participants suggested that using an app with information and reminders about PFMT would be beneficial[34]. A continence app for the purpose of enhancing PFME adherence has been validated for clinical practice use[35].

The results from an implementation project for promoting PFME in women who were in the antenatal and postnatal periods at one hospital were reported. The authors found that both nurses and women had inadequate information and education about PFME prior to the project and nursing skills improved after implementation of the project as did women’s knowledge[36]. A narrative review that provided a summary of quantitative and qualitative evidence for PFME during pregnancy and the postpartum period concluded that PFME is effective in preventing UI. The authors noted that provider behavioral support is as important as the prescription for PFME[37]. In addition, authors of a systematic review concluded that group-based PFME during pregnancy was found to be more cost-effective effective than providing individualized PFME to postnatal women who are incontinent[38].

Urinary and fecal incontinence can be a preventable complication of childbirth in young women, especially those living in developing countries. A population-based study in India aiming to identify risk factors for and prevalence of obstetric fistulas found that inadequate pre-natal services, childbirth at home, and poorly equipped emergency obstetric services in health centers increased risk of fistulas. Overall prevalence of obstetric fistulas was 0.3% [39]. The authors recommended a community-level plan to increase emergency obstetric resources, address socio-economic determinants associated with obstetric fistulas, and training for community workers and healthcare providers to recognize women at risk of obstetric fistula during childbirth.

2.3. Older people

An international (i.e., Canada, France and UK) pragmatic cluster randomized trial was conducted with community-living women aged 65 to 98 years old who reported they had at least two UI episodes weekly. These women had not sought professional help for UI in the past year nor were they currently taking medications to treat UI. They were recruited from community organizations who participated in continence promotion workshops. There was sustainable one-year improvement in incontinence in the group that received a continence promotion workshop, i.e., an interactive discussion on myths, self-management techniques, and lifestyle interventions, compared to the group that received a healthy aging workshop[40]. A continence questionnaire, the Continence Index, was developed to predict future UI in older women. Factors that emerged as the strongest predictors of UI included body mass index, sneezing, belief of developing future UI, difficulty in stopping the urine stream, and problems with memory specifically with regard to remembering names[41].

A multisite randomized controlled trial, Translating Unique Learning for Incontinence Prevention, (TULIP), was conducted in the United States with community-living women 55 years and over (N= 647) in which women were followed 3, 12, and 24 months after the intervention. The intervention consisted of bladder health information by either 2-hour face to face instruction or a 20-minute DVD with the same information. Investigators found both methods equally effective. There was no difference in UI (measured by the International Consultation on Incontinence Short Form) between the groups at 3, 12, and 24 months[42]. Wu et al., noted that although PFME was effective in mid-life women who have UI, its effect on preventing UI is not clear[43].

A multi-site randomized controlled trial to prevent UI was conducted with older adults who had hip fracture. Adults who had UI prior to the fracture or cognitive impairment that did not allow individuals to participate or understand the educational intervention were excluded. Researchers used the urinary habit training intervention within the Nursing Intervention Classification. The goal of this intervention was to establish a predictable pattern of bladder emptying to prevent UI. The intervention was provided by one of the researchers during hospitalization in 30 minute sessions the second to fourth

day post- operation[44]. Incidence of UI at 3- and 6- months post hospital discharge was significantly lower in the education group (25.5%) compared to the control group (49%) relative risk 0.52, 95% confidence interval [0.3, 0.9].

2.4. Men postprostatectomy

Since the Sixth ICI[45], a systematic review with meta-analysis was published on the efficacy of PFME for post-prostatectomy incontinence. Twenty-two studies were included in the review and 15 studies were used for meta-analysis. The authors were interested in determining if variation in the content and delivery of the PFME protocol explained differences in outcomes among clinical trials. Meta-analysis revealed the PFME group had better outcomes compared to the control group when specific conditions were met including but not limited to where pre-operative PFME were performed, where instructions to contract urethra were given, and when continence was defined as no leakage[46] Recommendations were made to target exercises to UI pathophysiology and principles of motor learning as well as principles of exercise physiology[47].

2.5. Healthy men

No evidence for primary prevention was located for men across their life-course.

3. PREVENTION OF FI IN SPECIFIC POPULATIONS

3.1. Women in pregnancy and postpartum

A systematic review of literature to investigate the effectiveness of physiotherapy to prevent and treat FI in women was conducted. Twenty-two studies were included and the authors concluded that physiotherapy improves muscle strength, endurance, anal sensation and that biofeedback was beneficial in preventing FI[48]. Little evidence exists for the effects of PFME on FI in the postnatal period[49].

A systematic review was performed to determine if cesarean delivery could prevent postpartum FI[50]. However, from the 24 studies included FI was not found to be reliably prevented by cesarean delivery.

3.2. Other adult populations, e.g. older people and men

There remains a lack of research and understanding of the role of primary prevention for FI in comparison to UI. Most of the available evidence focuses on the risk factors for development and management of FI but does not consider the role of primary prevention. Research is needed to assess the role and effectiveness of population-based interventions as seen in UI such as improving education and understanding of bowel health and teaching self-management / conservative management techniques for FI.

4. PREVENTION OF UI + FI IN CHILDHOOD

Although research on primary prevention of UI and FI in children is limited, there is some evidence to suggest that early toilet training may help to prevent day and nighttime wetting later in childhood[51], [52], [53], [54]. Furthermore, there is some evidence that leaving bladder and bowel issues untreated may result in them continuing into adolescence and adulthood, or precipitate issues earlier in adulthood than would otherwise have been expected[55],[56] , [57].

The limited evidence focuses on identifying potential risk factors from childhood that increase the risk of development of UI and FI in later life. However, many of the primary prevention models in adults focus on early intervention of education and conservative therapies to prevent UI and FI. The challenge in children is that the benefit of these interventions is undetermined. A recent Cochrane review assessing the effects of conservative interventions (e.g., lifestyle behavioural advice, PFMT, biofeedback, urotherapy, etc.) for treating daytime UI in children found little reliable evidence that can help affected children, their carers and the clinicians working with them to make evidence-based treatment decisions[58]. Well-designed research investigations, with defined interventions and consistent outcome measurement are needed.

Summary

Primary prevention of urinary and fecal incontinence remains in its nascent stage, but population aging, preventable obstetric incontinence outcomes, and significant advances in understanding bladder health and UI primary prevention are driving the need to develop effective primary prevention interventions across the human life-course. Foundational evidence has demonstrated that modifiable risk factors exist across multiple levels: intrapersonal, environmental, and societal. High quality RCTs are needed in men, women and children at different life stages and across the life-course to develop evidence for the effectiveness of population and individual-level primary prevention intervention for UI and FI.

Levels of Evidence/Recommendations

- Pelvic floor muscle exercises can prevent UI and FI in pregnant and postpartum women. (Level of Evidence: 1)
- Education designed for community-dwelling older women can prevent UI. (Level of Evidence: 1)
- Pelvic floor muscle exercises should be provided to pregnant women. (Grade of Recommendations: A)
- Education to prevent UI for older women should be provided. (Grade of Recommendations: A

RESEARCH PRIORITIES

- We are unable to make recommendations on the role of primary prevention for UI in men, for FI for all populations and in Childhood. Further research is urgently required in these groups.

III. CONTINENCE AWARENESS AND PROMOTION

Literature Search is found in Appendix 1.

1. BACKGROUND

According to the World Health Organisation (WHO), health promotion is, "the process of enabling people to increase control over, and to improve, their health. It moves beyond a focus on individual behaviour towards a wide range of social and environmental interventions"[59]

Efforts to promote awareness about incontinence and its treatment can be enhanced by adopting evidence-based theories and methods from the field of health promotion and by heightening awareness of the World Health Organisation social determinants of health[60]. Health promotion frameworks can be used to plan and evaluate the effectiveness of strategies and programmes used to promote continence.

2. RAISING AWARENESS AND UNDERSTANDING

Consumer education is a critical component of effective continence promotion. Education of individuals with, or at risk of, UI and/or FI, their family members or informal caregivers, and healthcare professionals increases awareness about incontinence and the benefits of prevention and management. The goals of consumer education are elimination of stigma, promotion of help-seeking, and reduction of suffering[61].

A meta-ethnographic study by Toye and Barker (2020), analysed 41 studies of the experience of living with UI, including 1046 people from 13 countries[62]. All the studies included women and eleven included men. The concepts that emerged centered on whether UI was normal or an illness; the impact on the individuals' perceptions of self; the stigma, shame and guilt; the difficulties and benefits of talking; maintaining control of the incontinence and reaching the point of requiring help.

Toye and Barker found that UI was described as 'part and parcel of my life' and physical history and therefore not an illness. It was considered normal for older women and mothers to have UI: 'Leaking is associated with being decrepit and incompetent, which makes its secrecy imperative if I am to be seen as normal'. It 'symbolises infancy and extreme old age'. Help seeking was restricted when individuals felt that UI was personal, minor or low priority. Asking for intervention occurred when the impact of the UI on life and work was greater than the embarrassment of disclosure, or when there was anxiety about a possible serious medical condition. A 'culture of secrecy' and incontinence as 'taboo' was described with UI experienced as 'anomalous… it defies social categorization: I am ill and also not ill; urination is normal and also not normal; I am an adult and also not like an adult.'

Using a quantitative descriptive design, Day et al [63] surveyed 50 community-dwelling women's knowledge about UI. Findings revealed that the women had poor knowledge, principally in relation to UI risk factors (38.8%), prevention (40.5%), treatment (39.4%) and management (49.4%), suggesting that women have unmet

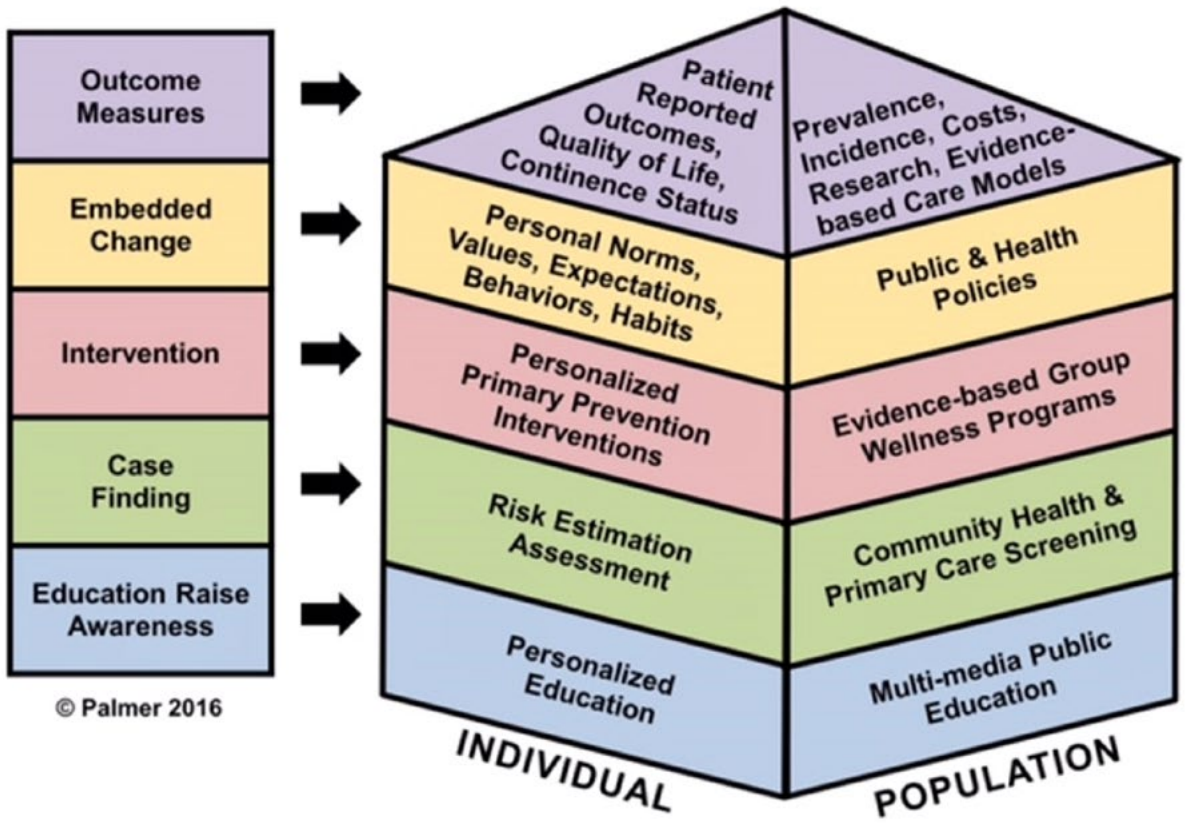

Figure 1: Primary prevention model

educational needs related to UI and indicating an area for improved consumer education. According to a qualitative analysis of open-ended questions from a survey of 1,458 women with UI in Washington State, women had a range of different interpretations and understanding about the causes of UI, with many believing it was a normal part of being female[64]. A systematic review of nineteen studies, including 11,512 women found that most women had poor knowledge of pelvic floor muscle dysfunction, (PFD) including risk factors and treatment options[65]. However, Siddiqqui et al (2016) in a study of 113 White, black and Latina women found that awareness of UI varied across ethnic groups, with Latina women least aware and awareness was influenced by how easily they could access information and through which media[66].

A cross-sectional study of 1092 college women aged 19 -24 and 25-30 years old found that the older age group had more awareness and understanding of UI and FI than the younger age group, with those who were majoring in science having the greatest awareness[67].

In a study of three hundred and forty-six women Chen et al (2019) found that the knowledge of women attending geriatric, community and primary care hospital clinics was similar[68]. However, knowledge of pelvic organ prolapse (POP) (78.2%) was higher than knowledge of UI (37.6%) in those with awareness of these conditions. They also found that lower educational attainment and being unaware that UI and POP are medical conditions was more strongly associated with low knowledge of PFD. Furthermore, the authors argue that promotion of awareness may increase presentation for early intervention and, therefore, for conservative treatment options.

There was a similar lack of awareness of FI with only 29.8% of 601 adults in Korea aware of the term. Knowing the term was 'significantly associated' with seeking help[69].

An important aspect of continence promotion involves dispelling the pervasive myth that incontinence is normal, temporary, not a medical issue or inevitable due to aging childbirth[70]. The lack of clear description of UI as a disease may also hinder continence promotion[71].

Spencer[72] described a pre and post evaluation of an education programme for women with UI and found education alone was insufficient to alter women's beliefs. The researcher emphasized the need for more engagement about the topic, and to consider individualized learning needs.

Mendes et al (2017) propose that knowledge is limited by lack of discussion about UI [71]. Clinicians play an important role in encouraging discussion and providing information about UI[73] and can empower an individual to make changes and set goals for UI self-management[74].

In a convenience sample survey of 360 women in Israel, researchers found that women who suffered from UI and those who were older generally had more knowledge about UI including causes and treatments[75]. Another small focus group study with African American and Latina women in the U.S. demonstrated general misconceptions about causes of pelvic floor disorders, symptoms, and treatments[76]. Participants were eager to gain more information, particularly to share with their daughters, and identified placing family demands before their own health needs as a barrier to seeking care. An online survey study of 1,092 adolescent and young women aged 19-30 years enrolled at a university in the U. S. revealed that those in the 25-30 years age cohort were more likely to have received information about UI, FI, and POP [67].

Some countries governments provide support for continence promotion but much of the health promotion effort related to continence issues is undertaken by professional bodies, non-governmental continence organisations, advocacy groups and industry. The ICS provides information about peak bodies and advocacy organisations that are active in the area of health promotion, advocacy and represent the interests of people with, or at risk of, incontinence (http://www.ics.org/SiteLinks.aspx). Through the activities of these organisations and with the engagement of external stakeholders such as educational, healthcare, and community service providers, these organisations aim to increase community awareness and understanding about incontinence, reduce social stigma, and raise public awareness about risk factors and options for managing incontinence.

Consumer knowledge about FI is also generally limited. Patel et al[77] conducted a content analysis of comments from 89 community-dwelling adults with FI to examine their continence literacy. The findings indicated that while many consumers had a significant emotional component to their experience of FI, their knowledge about terms to use to describe their condition was often limited[78], [79], [80].

As part of a larger study that used a postal and internet survey conducted with members of a National Crohn's and Colitis Support Group, Norton and Dibley[81] investigated factors that influenced help-seeking in people with inflammatory bowel disease (IBD) related FI, and their needs or desire for continence services. The most commonly cited reasons for not seeking help were: a lack of knowledge about from whom to seek help, how to seek help, and where to seek help.

3. USE OF THE INTERNET AND SOCIAL MEDIA

The internet is frequently searched for health information, and coverage of relevant health topics is growing. The benefits of acquiring health information via the internet include its wide accessibility, anonymity, and informality with eight in ten internet users in the U.S. looking online for health information[82]. The use of Social Media (SoMe) is popular internationally (4.14bn people worldwide); although the use of SoMe platforms varies with age, gender and educational attainment. Statistically, older adults still use significantly fewer digital applications and spend less time online, probably because it seems time consuming, or they might fear that they will get things wrong[83].

Amante et al[84] (63) investigated access to care and use of the internet to search for health information using data from the 2011 National Health Interview Study (NHIS). Of 32,139 adult respondents, 43.55% (13,997) reported searching the internet for health information. These authors suggested that a main reason for the widespread use of the internet to obtain health information was users did not consider their questions severe enough to warrant the effort or time to obtain routine, urgent, or emergent clinical attention.

Evaluations of internet-based information about incontinence suggest the internet may prove to be a useful tool for consumer education and public health outreach particularly in light of the reluctance of those affected by stigmatized illnesses such as incontinence to

seek treatment or to ask health care professionals for information[85]. For example, in a study of 208 people attending GP appointments in the UK conducted by Al-Shammary et al [86],the majority of people who used the internet felt able to discuss UI with their GPs or with the practice nurse, suggesting that information gleaned from the internet helped consumers make decisions about seeking help. Forty-five percent of respondents used the internet before consultation for the purpose of self-diagnosis. Mazloomdoost et al [87] evaluated the use of social networking and internet use as a source of information about pelvic floor disorders among women who presented to a clinical practice for female pelvic medicine and reconstructive surgery. The majority (75%) reported high internet use, with 53% using the internet or social networking to learn more about their pelvic floor condition, although only 4.9% primarily searched for information prior to seeking face to face help of their gynaecologists. Gonzales et al conducted a large-scale analysis of online social media posts to capture the experience, knowledge and perceptions among women with stress urinary incontinence (SUI). Extraction of 985 online posts by 762 unique users from 98 websites, demonstrated that SoME posts influence decision making when seeking care for stress urinary incontinence and choosing a treatment. Analysis of SoMe interactions can accordingly provide insight into patient behaviours, improve patient centred care and decision making in the future.

Several researchers have questioned the quality of continence information on the internet and social media, and all agree that there is a growing need for validation. Diering et al[88] evaluated the content, credibility, and function of 15 websites with UI content that had been developed by professional health care organisations for use by healthcare providers. The researchers concluded the internet served as a useful resource for 'state-of-the-art' knowledge about UI that health professionals can use to update their knowledge but also cautioned users to critically evaluate content. Using the World Health Organisation 'Health on the Net' (HON) principles, Saraswat et al[89] evaluated 150 websites using 17 commonly used terms for 'female UI' in English, French, German and Spanish, and compared website sponsors. The total number of websites for each term was variable, however 'female sling surgery', had the most websites (18 million), followed by 'incontinence surgery' (9.8 million). The most commonly encountered sponsors were physicians/surgeons (37%), followed by commercial sites (30%), government organisations or educational institutions (20%), and non-profit organisations (5%). The findings highlight the importance of assessing the quality and validity of internet health information, particularly as many websites also act as a platform for advertising. An evaluation by Dueñas-Garcia et al[90] of 13 patient-focused websites addressing treatment options for POP and stress UI also raised concern about the quality of information available to consumers. Using the DISCERN instrument, a validated instrument to assess the quality of written consumers health information relating to treatment options, the researchers reported available English-language professional websites written to inform patients about management choices for SUI and POP omit key components of quality patient information.

Clancy et al[91] reviewed 35 websites: their study aimed to evaluate the quality and readability of highly visible websites on overactive bladder (OAB). They concluded that popular websites on OAB are of low quality, written for a high school to college-level readership, and often lack adequate information to assess the potential for commercial bias. Patients should be cautioned that incomplete and potentially biased information on OAB is prevalent online. Leo et al,[92] aimed to investigate the utility of social media and search engines to disseminate FI information. They looked at Facebook, Twitter and search engines such as Google/Yahoo/Bing and agree that the internet appears to have potential to be a useful platform for patients to learn about FI and share information; however, given the lack of focus of available data, patients may struggle to identify valid and useful information.

Burton et al[93] agreed with the precautionary advice. They found that prevention and treatment strategies are common in online discussions of PFD, but at least one third of these recommendations have no evidential support. They suggest that there is a role for further online education and social media engagement by health care specialists to promote evidence-based practices, especially in the prevention of PFD. In addition, Alsyouf et al[94] looked further than primary prevention and focused on 'Fake News' on social media in genitourinary malignancies. They evaluated the accuracy of the articles shared most on popular social media platforms (Facebook, Twitter, Pinterest, and Reddit) and concluded that misleading or inaccurate information on genitourinary malignancies is commonly shared and they highlight the importance of directing patients to appropriate resources.

Qin et al[95] aimed to identify the prevalence, authorship, and type of information pertaining to topics in urogynecology on social media (Instagram) via hashtag and content analysis. More than 500,000 posts related to urogynecology were identified. The five most popular hashtags were pelvic floor, interstitial cystitis, pelvic pain, incontinence, and prolapse. Most were authored by patients (34.6%), allied health professionals (29.2%) and physicians (13.4%). Further authorship and content analysis revealed that allied health professionals authored the most informational posts, while patients authored more unrelated, patient experience, community building, and humorous posts. Qin et al hypothesized that greater physician participation may increase the quantity of educational posts and offer a low-cost platform for networking and connecting with patients and other providers.

Borgmann et al[96], published recommendations on the appropriate use of social media to improve online professionalism, as an initiative of the European Association of Urology.

Sajadi and Goldman's[97] study to assess the quality of incontinence resources available among social networks, also showed that most websites providing UI information were not certified by an accrediting body. Using the term 'incontinence', the researchers searched for information on Facebook, Twitter, and YouTube, to evaluate its usefulness. Their conclusion was that while social networks have great potential for consumers with incontinence to connect with each other and find medically informative resources, there was insufficient useful UI content, especially from healthcare professionals and incontinence organisations. Social network sites are a key future source of information for consumers about incontinence, and medical professionals and societies should target these avenues to reach and educate consumers. Healthcare professionals, continence organisations, and recognised advocacy organisations have a key role to play in assisting consumers to find reliable information about UI / FI by providing details of reputable web sites and by playing a role in interpreting findings from high quality research and reframing them for consumption by the general public.

Saiki and Cloyes [98]conducted a content analysis of publicly archived blog texts from 19 women living with UI. The findings revealed a focus on securing social connection and a place in the human community. Thus, blogging may offer women with UI a means by which they can safely disclose their condition and socially connect. Another recent evolution in digital communication is the growth of online communities and discussion groups. Frederiksen et al[99],

recognized the popularity of web-based discussion forums among pregnant women. Their findings suggested that online conversations and discussions significantly influence the health literacy in this population. Recognizing and supporting these new sources of information, may be useful for health professionals in consultations with pregnant women. Similar suggestions are confirmed by Grant et al[100]. They recruited postnatal women, using Facebook communities and explored women's barriers to access adequate information and education on how to do a PFMT contraction. Their respondents concluded that adding online education and apps about PFMT would be the most useful for their needs and circumstances.

Internet and mobile applications (apps) might target a specific barrier: several researchers tried to study the implementation of mobile resources to raise awareness. Sudol et al[101], reviewed patient-centered apps in female pelvic medicine and reconstructive surgery. They found that patients are likely to obtain information that is irrelevant or inaccurate, even if the appropriate search term is used. But after carefully excluding inaccurate apps, they were confident that 23 remaining apps scored well and could be shared with patients. Goode et al[102] performed a study providing physiotherapy education to postnatal women in an attempt to meet consumer needs in a changing hospital environment. Their quality assurance project demonstrated the advantage of digital health resources or apps but strategies to improve awareness of the resources should be investigated further.

Hofman et al[103], aimed to increase self-management of SUI via a mobile app and investigated the long-term effects of using a mobile app, in a RCT. Li et al[104], investigated a mobile application in postpartum pelvic floor dysfunction with a large cross-sectional study. Saboia et al[105], published their manuscript about the construction of an educational app for prevention of postnatal UI. Also, Asklund et al[106] performed a RCT using a mobile app for treatment of stress urinary incontinence. All these well-designed studies, found promising results on increasing compliance and adherence to treatment strategies, by using apps. Self-management might really be boosted by these digital strategies. Although it needs to be emphasized that there seems to be a striking lack of evidence about the added value of mobile applications to raise awareness. Applications rather tend to assist in treatment strategies. Once persons are offered them, they seem beneficial, but currently they are not the most common way to raise awareness, increase continence promotion or help seeking behaviour.

Meppelink et al[107], aimed to study the added value of social media for people with low health literacy in the Netherlands. Their conclusions are that for communication, professionals should make better use of digital messaging features. Videos, narration, and interactivity are scarcely used but can be valuable for people with low health literacy.

Although the internet has changed how many people access health information, internet access is far from universal, especially in developing nations, among older and poorer sections of society in developed nations, and among people with low levels of education and lower socioeconomic status[108].

In both developing nations and in countries with limited health systems and dispersed populations, innovative methods are needed to disseminate information about incontinence, such as through community nursing infrastructures and lay health workers.

4. RAISING AWARENESS IN CHILDHOOD

4.1. Children

Clinical experience often demonstrates a lack of awareness of the prevalence and impact of continence problems on children and their families. Healthcare professionals often have little or no education about bladder and bowel issues and may erroneously believe that in childhood they are self-limiting or the result of psychological issues[109], despite evidence that lower urinary tract symptoms in childhood increase the likelihood of adult nocturia and symptoms of overactive bladder.

Awareness raising among parents, childcare, education and healthcare professionals about the impact of delayed toilet learning beyond a child's second birthday, or suboptimal enactment of toilet learning on urinary continence is required[110].

4.2. Adolescents

Hebert-Beirne et al[111] identified that girls need appropriate education about pelvic health. 103 girls aged 13-17 participated in an educational intervention and 65 were the control group. Knowledge of anatomy, function and healthy hygiene practice was low prior to the intervention. They also found a high prevalence of at least occasional UI (46.7%) and that six one-hour sessions of education improved knowledge and awareness of pelvic health.

A cross-sectional study of 740 fourteen- to eighteen-year-old girls found that 37% had SUI, with 6% having symptoms more than once weekly; 54% had urgency UI (11% more than once weekly); 5% had enuresis, with 1.6% wet every night. While 56% found symptoms bothersome and it affected daily activities in 39% only 7% had visited a healthcare professional (HCP). Embarrassment and not knowing who to see were listed as reasons for this. The study suggests that UI is prevalent in adolescents and suggests that clinicians should be proactive in raising this when assessing and treating them[112].

Dix[113] reports that HCPs lack of awareness of continence conditions in young people, while Whale[114] advises that clinicians have a responsibility for ensuring that young people understand their bladder or bowel condition to be able to build trust, ensure appropriate psychological support and self-management. In a separate study Whale [115] also found that young people felt that school staff were unaware that continence problems could affect their age group but were motivated to address their lack of knowledge. Guidance is now available for them in the UK[116].

5. ENVIRONMENTAL FACTORS

Zhang[117] (2018) argues that UI is 'an environmental, social and cultural construct', in that society decides acceptable venues for urination and that perceptions of UI affects its culture and hence management. As an example, if UI is considered part of aging, then this belief will affect desire to treat. However, Zhang recognises that the immediate environment, such as access to the toilet is also influential.

Environmental barriers to seeking treatment for incontinence include the reactions of partners, families and colleagues[118]. Environmental factors that inhibit maintenance of continence include

availability of public toilets[119] , [120]. Poor quality, limited availability or employers restricting use of toilets in the workplace[121] and issues with cleanliness, availability, and privacy in public toilets[122] were all associated with increased likelihood of lower urinary tract conditions in women. Lack of aids and adaptations were also found to be barriers to continence in the home[119].

Inhibitory factors for continence within the hospital setting include the overuse of containment products and urinary catheters, delay in care, unfamiliar environments, lack of continence promotion, and deficits in HCP knowledge[123]. Within the community, the perception that incontinence is inevitable in patients with dementia and containment is the only response alongside family carers desire to protect privacy or avoid institutionalisation may present barriers to optimal continence[119]. A meta-ethnographic study found that the secrecy and shame associated with urinary incontinence had a significant impact on ability to seek help and that HCPs recognition of patient desire for concealment, but proactivity in questioning about UI would reduce taboos and promote continence[62].

For children and young people, barriers to continence include prolonged use of continence products[104, 110], restricted access to and poor condition of school toilets[115].

6. CONTINENCE ADVOCACY

Advocacy is defined as the act or process of defending or maintaining a cause or proposal. Advocacy, as it pertains to incontinence, involves assisting individuals to find necessary health care and treatment. Organisations composed of professional and public members promote continence advocacy as a core mission.

A central goal of most continence advocacy organisations is raising public awareness and understanding about the types of incontinence, risk factors for incontinence, and available treatments, services, and management products. These organisations provide a public voice for an unheard consumer population in political and health-care governance, development, and planning processes. In recent years, consumers and clinicians have been involved in identifying and prioritizing important areas of research relating to incontinence in order to inform research development and funding decisions[124], [125]. In addition, through advocacy organisations, consumers of health care have become more closely involved and influential in the activities of clinical professional organisations.

Another major role adopted by many continence organisations is the direct provision of information support to those affected by incontinence and their caregivers. The types of information provided include information and support about symptoms, risk factors and associated conditions, treatments and management strategies, and availability of, and access to, health and social services. Such information is provided through a variety of sources, including consumer-oriented magazines and electronic newsletters, internet-based information resources, telephone support lines (often staffed by qualified nursing or counseling staff), and printed media such as leaflets and booklets on a wide variety of topics. Other innovative strategies have included outreach work through travelling information roadshows and events[126]. Organisations also provided emotional supports to people with incontinence by putting them in touch with others similarly affected either through direct contact at meetings or through internet discussion forums, as well as providing specialist training and education to healthcare professionals.

Continence organisations reviewed varied in scale and in nature, from small consumer or clinician groups that focus on quite specific bladder symptoms or conditions, to large and well-funded national organisations that address bladder problems as a peak body. Often the founding and development of such organisations resulted from the dedication of a small group of consumers, clinicians, or both, that worked to promote awareness and understanding of incontinence among the public and healthcare providers and to provide optimal services and support to those affected. These organisations represented a wide diversity of models, including consumer-led, company-sponsored, consumer-only, professionals-only, and organisations which have deliberately set about trying to bring together all relevant stakeholders in a relatively democratic model. Globally, these organisations played a dynamic role in building both public and professional awareness and reducing the taboos associated with this under-served and under-reported condition.

6.1. Funding

The degree of funding available inevitably affects the level and scope of work. In some countries, such as Australia and to a lesser degree New Zealand, continence promotion organisations have government support for their work. In other countries such as the U.S. and UK, financial support generally came from charitable donations from individuals and foundations, or through the support of the pharmaceutical industry and continence products manufacturers. Most continence organisations believe that more funding from any source will improve advocacy work but there is no evidence to support this.

6.2. Research priorities

The James Lind Alliance, is a non-profit making initiative that allows clinicians, patients and carers to form Priority Setting Partnerships to agree on the ten most important evidence uncertainties, so that health researchers are aware of the issues that are most important for those affected by specific conditions.

6.3. Effectiveness

While the work of the voluntary and continence advocacy sector is extensive and appears appreciated by professionals and consumers, no quantitative or qualitative evidence of their effectiveness could be found, with this remaining an area for future research.

Summary

Based on survey and qualitative data regarding consumers' understandings and knowledge of incontinence, the general public has limited knowledge about incontinence. The effectiveness of strategies to promote awareness about incontinence and its treatment can be enhanced by adopting evidence-based theories and methods from the field of health promotion and should be underpinned by awareness of the social determinants of health. Consumers increasingly access the internet for health information but the quality of information about incontinence is variable.

Clinicians and continence promotional bodies play an important role in helping consumers find high quality reliable information. The majority of publications on Continence Promotion and Programmes are qualitative or mixed methods designs which the Oxford Level of Evidence does not recognize.

Advocacy is necessary for people who have continence issues and many organisations have advocacy as their mission. A wide

range of models of continence advocacy, including collaborative models that bring consumers and different groups of health professionals together, do exist. Recent research regarding formalized evaluation on the effectiveness of these organizations was not located.

Levels of Evidence/Recommendations

- Continence promotion is required to address broad gaps in knowledge about incontinence. This includes effective communication to and education of both HCPs and the public, through a variety of mediums, with regard to UI and FI potentially affecting all age groups (Level of Evidence 3).
- Strategies to promote awareness about incontinence and its treatment can be strengthened by the use of evidence-based theories and methods from the field of health promotion, including the social determinants of health (Level of Evidence 4)
- The internet represents an important source of information about incontinence, however the quality of information is variable (Level of Evidence 3)
- Evidence for the impact of continence advocacy worldwide was based on opinion (Level of Evidence: 4) (Grade of Recommendation: None)

Research priorities

How effective are Continence Advocacy Organisations? Does their effectiveness vary for different populations (eg the elderly, children and young people, males post prostatectomy, women post-partum etc.)?

How can awareness and accessibility to information for all ages and for different cultural groups be improved at a local / national / international level?

How effective are new methods of communication at raising awareness and is their impact different for varying client groups?

What can be done to improve awareness of new methods of communication to promote appropriate self-management and help seeking behaviours for UI and FI?

To improve the quality of the information on the internet / digital media

IV. HELP-SEEKING (CARE-SEEKING) BEHAVIOUR

Literature Search is found in Appendix 1.

1. BACKGROUND

UI, FI and other PFDs, such POP, are health issues not discussed as openly as other health issues. Help-seeking or care-seeking, for UI and in particular, FI remains poorly understood, likely due to the lack of rigorous exploration of this behaviour. Despite increased awareness among healthcare providers and consumers of healthcare over the last decade, health seeking behavior for these issues remains low, despite the high level of efficacy of conservative care strategies[127].

As described in the 6th ICI edition, a Model of Pathways to Treatment offers a framework to explore the existing literature on the barriers and facilitators to seeking care and sex-differences in help-seeking. This model proposes four sequential time intervals in the process of receiving treatment: 1) appraisal, 2) help-seeking, 3) diagnostic, and 4) pre-treatment, during the first time interval the person detects bodily changes. These changes may be appraised as a normal change or abnormal, such as a symptom of an underlying condition. If the person determines the bodily change is abnormal, s/he is motivated to seek help from a healthcare provider for one of two reasons: 1) concern that the change is from a serious underlying condition; or 2) due to the consequences of the change. During this time interval, the person considers seeking help from a healthcare provider based on the outcomes of their appraisal of the symptoms and their self-management. Situational, contextual, and social factors can play a role during this phase in creating facilitators and barriers to seeking help. Once the person makes the first consultation with a healthcare provider, the diagnostic process begins, and afterwards, treatment is initiated. In order for a consumer to be able to appraise their current health status with respect to continence, awareness and associated knowledge related to pelvic floor function and dysfunction is needed[128].

Four items related to help-seeking behavior are the focus of this section. 1) detection and appraisal of bodily changes related to PFDs; 2) self-reported reasons to discuss symptoms with a healthcare provider; 3) effective strategies to promote accurate appraisal of bodily changes as well as seeking guidance from a care provider and 4) how knowledge, attitudes and beliefs (KAB) impact help-seeking behavior. Using non-health professional and indirect resources (such as blogs, chat groups, and website) was considered to be self-management or self-care, not help-seeking behaviour.

The research questions are:

a) What factors act as barriers/facilitators to help-seeking for UI and FI?

b) How do knowledge, attitudes and beliefs impact help-seeking behaviour for UI, FI and PFDs?

c) Do sex differences exist for help-seeking for UI and FI?

d) What extrinsic factors influence help-seeking behaviour?

e) What strategies are effective to promote awareness and/or help-seeking for UI and FI?

2. FACTORS THAT ACT AS BARRIERS / FACILITATORS TO HELP-SEEKING

Since the publication of the 6th ICI edition[128], multiple descriptive studies, including quantitative and qualitative systematic reviews

were located noting that intrinsic and extrinsic factors can act as barriers/facilitators to help-seeking for PFDs. In addition, two RCTs were retrieved. The vast majority of this literature pertains to UI. Additionally, substantially more information about help-seeking behaviours in women across the adult lifespan than for men was retrieved.

It is well established that although prevalence estimates differ across studies, the available evidence indicates that UI and overactive bladder (OAB), in particular are highly prevalent conditions among women and that these conditions have a negative effect on quality of life[128]. A recent large population-based study (n=26,466 women) determined over 70% of women with UI and associated symptoms did not seek help [129].

2.1. Intrinsic factors associated with barriers/facilitators:

Studies capturing a global perspective, triangulate to affirm that help-seeking is facilitated by severity of symptoms, dealing with symptoms for a longer period of time and having a high degree of social support[130, 131]. In fact, discussing UI symptoms with a relative made the individual 3-5 times more likely to seek help in a large population- based study[129]. With respect to severity, a recent study determined that women with UI who sought care had higher median Pelvic Floor Dysfunction Index (PFDI-20) and Urogenital Distress Inventory (UDI-6) scores compared to non-care seekers (73.96 vs. 16.67, P < 0.0001, and 41.67 vs. 8.33, P < 0.0001). Specifically, a PFDI-20 score of 33.33 (83.33% sensitivity and 79.30% specificity) had very good discriminatory accuracy in distinguishing care and non-care seekers[132]. The same study determined a UDI-6 score of 25.00 (83.33% sensitivity and 83.59% specificity) had excellent discriminatory accuracy in distinguishing care and non-care seekers. In fact, the multivariable predictive model used in this study accurately identified 82.4% of care and non-care seekers[132]. Another psychometrically sound self-report questionnaire that has been found to best assess the knowledge, attitudes and associated practice regarding UI is the Barriers to Incontinence Care Seeking Questionnaire (BICS-Q)[133].

Reasons women who were postpartum gave for not seeking help were: low priority, belief it was normal part of childbirth, and feeling ashamed[134]. Among women with gynaecological cancers who experienced concomitant LUTS, the failure to seek help was attributed to a perception that the LUTS were not perceived by the women as serious enough symptoms to warrant attention and to their lack of awareness of treatment options[135].

Bothersomeness, the degree to which the symptoms interfere with an individuals' life, is another key factor that consistently correlates with help-seeking[128, 130, 136, 137]. Since the publication of the ICI 6, the degree of bother has been determined as the mediator between UI severity and help-seeking[138]. Furthermore the International Consultation on Incontinence Questionnaire-UI Short Form (ICIQ-SF) has been determined as a discriminative measure to delineate bothersome UI[138].

A recent large qualitative synthesis, conducted by Mendes and colleagues[71] extracted 189 findings from 28 studies, grouped them into 25 categories and synthesized them into eight themes shedding further light on the issue of help-seeking behaviour. The eight synthesized findings were: (i) cultural and religious backgrounds and personal reluctance contribute to delays in seeking UI treatment; (ii) the inevitable and regrettable problem of UI endured silently and alone affects women's daily activities and their social roles; (iii) poor knowledge and the vague nature of the symptoms mask the fact that UI is a disease; (iv) the experiences provoked by UI and the sense of shame regarding the condition have contributed to impair women's lives; (v) UI has provoked negative effects on women's intimacy and sexual satisfaction and provoked changes in the ways they experience their sexuality and sexual function; (vi) UI is considered a consequence of pregnancy and childbirth, inherent to aging or a religious punishment; (vii) the women affected by UI adopt several strategies to improve their health status; and (viii) women have personal preferences toward care providers and treatments; they confront difficulties through UI treatment and some care needs are not met[71]. Related, but different themes were determined by another research group who conducted a meta-ethnography to better understand the experience of living with UI[62]. Their analysis determined: i) not perceiving disease, ii) shame, iii) lack of support from important others, and iv) non-optimal health care system to be inhibitors of help-seeking behaviours. Facilitators were found to be reduced quality of life and positive support from important others. These finding corroborate the broad literature base and point to the facts that knowledge and beliefs regarding UI and associated care options and efficacy of treatment remain important gaps to be addressed.

Many women view UI as a societal taboo and fear stigmatization[139] and embarrassment in talking about PFDs[140], particularly UI and FI, as reasons identified as contributing to low rates of seeking care. A survey in Korea noted that women were embarrassed by being incontinent and did not seek help, but women who did not have UI said they would consult with a healthcare provider should they develop it[141]. In another study[142], women (61.9%) reported one reason for not seeking help for UI was that they hoped UI would spontaneously disappear (similar to findings by Buurman and Lagro-Janssen[135]) but interference with prayer, sexual, physical, and social activities were reasons to seek help. Using the Theory of Planned Change, researchers found that help-seeking intention can be predicted. They also found that high perceived self-efficacy in managing symptoms could act as a barrier to seeking help. They postulated that women viewed themselves as managing well and not needing help from others[143].

As far as FI is concerned, one study was located comparing help-seeking for UI to FI. While knowledge scores pertaining to participants understanding of UI and FI were low across the board, they were lower for FI[144].

3. KNOWLEDGE, ATTITUDES AND BELIEFS ABOUT UI & FI

Women's knowledge, attitudes, and beliefs (KAB) about PFD including UI, FI and POP have been long thought of as both barriers and facilitators to help-seeking behaviours. Research about KAB in women with PFDs is increasing, primarily in the U.S. A systematic review of 3,152 studies investigating whether women have adequate knowledge about PFDs found that knowledge was limited and was influenced by low socioeconomic status, African-American ethnicity, low educational level, and low access to information[65]. Many women believe PFDs, especially UI, are a normal part of aging[141, 145, 146] and thus do not seek help for what they perceive as a non-problem. A secondary analysis of the Canadian Institutes of Health Research-funded Continence Across Continents to Upend Stigma and Dependency (CACTUS-D) study of adult women (n=4446, mean age 78.2 years), found that of the 2022 with UI, 48.3% held the belief that UI is normal for ageing. This belief was held by women who had a more impaired quality of life but more

age, perception of overall health, severe incontinence and greater quantities of pad use did not make women less likely to hold this belief[147]. These women were also less likely to have performed previous PFME.

Lack of knowledge and attitude of neglect about UI combined with certain cultural and social systems can affect help-seeking behavior. This was demonstrated in a community-based qualitative study conducted in four villages in rural Western India to explore the attitude of women with UI[148]. Fourteen women (mean age 42.9 years) were interviewed and six themes emerged; i) attitude toward the problem and seeking help; ii) caste discrimination; iii) individual support system; iv) priorities and lack of time; v) lack of privacy; and vi) social taboo and personal belief. Women were unaware of this condition being abnormal and as they did not consider UI to be a health problem, they were ignorant about the remedy.

An Australian cross-sectional survey[149] was conducted to evaluate pregnant women's awareness, knowledge and beliefs about PFMs and the need to exercise these muscles. Seventy-six percent of respondents (n=633) knew that PFMs can prevent UI, but only 27% knew that they prevented FI, and 41% thought it was normal to leak urine when pregnant.

Women who believe that the cause of their UI is out of their control (e.g., part of being female, due to childbirth) believe that nothing can be done to treat it and so do not seek-treatment. Women report being too embarrassed to discuss their symptoms with anyone, including healthcare providers[150 151 152 153 154 155 156]. Several studies have shown a strong association between lack of UI knowledge proficiency and sociodemographic factors (e.g., lower levels of education and racial disparities)[157 158 159 160].

However, assessing someone's knowledge of a given subject is complex and requires the development of validated instruments[161]. Fante et al[65] conducted a systematic review of women's knowledge about the pelvic floor structures (muscles, ligaments, organs), its functions, dysfunctions, and possible conservative treatments for each disorder through surveys, questionnaires, or any other available instrument within the literature. Validated questionnaires and designed pilot-tested forms were the most frequently used ways of assessing knowledge with the prolapse incontinence knowledge 24-item questionnaire (12-item PIKQ-UI and 12-item PIKQ-POP) used most frequently. Using the PIKQ, Chen and colleagues[8] surveyed a population of adult women seeking primary care in the U.S. finding a considerable dearth of PFD knowledge; 72% of respondents were UI knowledge non-proficient and 54% were POP knowledge non-proficient. Several demographic factors (i.e. 40–49 and ≥ 80 years age groups, African-American race, income <$30,000/yr., lower educational attainment) were significantly associated with both UI and POP knowledge non-proficiency.

Overall, POP-related knowledge is low in women[159, 162] and understanding of the term, pelvic floor prolapse is low. Good and colleagues[163] conducted a cross-sectional study of English-speaking women (N=217) with POP symptoms who completed a self-administered questionnaire, that included 5 prolapse-related knowledge items modified from a previously PIKQ-POP validated questionnaire[161]. Only 44% of items were correctly answered. Although higher education increased knowledge, even college–educated women on average answered less than 50% of the questions correctly[164]

A study of women (age range 42-94 years) who had high literacy levels indicated significant knowledge deficits and a poor understanding of PFDs, including UI. Although this study had a small sample (N=36), the authors drew implications about women's ability to give informed consent because of the complexity of PFDs and the difficulty in understanding them[165]. In another study, knowledge deficits about UI were found to exist in women across all ages, income levels, and races[157]. A study of high-school and college age athletes in the U.S. found that more than 25% of the young women surveyed experienced UI during strenuous physical activity, but 90% had never reported their symptoms to anyone. Further, 91% had never heard of PFME, indicating a lack of knowledge about UI and pelvic floor functioning[166]. A study of adolescents (14-21 years) by Arbuckle and colleagues[167] found that only 19.5% had heard about POP and only 5.1% had heard about FI. However, this study and others[67] have shown that adolescent women have similar interest in learning more about PFD.

Beliefs play a role in help-seeking behavior. Telephone surveys of racially diverse women (i.e., African American and Caucasian) in the US reported that they did not seek help for UI because of their belief there were no available treatments[168]. Another study with an ethnically diverse group of women (median age 34 years) found that the women held similar attitudes about UI, although no differences were found among the women based on ethnicity in agreeing that good treatments for UI existed (OR, 0.91; 95% CI, 0.33–2.6)[169]. Authors of a systematic review on perceptions about female UI concluded that similarities existed among women from different racial and ethnic groups in terms of managing UI but their perceptions about UI differed[67].

From the literature reviewed, knowledge deficits along with varying attitudes and beliefs that normalize UI or created emotional responses of embarrassment about UI acted as barriers to help-seeking[66, 170 171 172]. Most of the research on KAB about PFD is on UI and in community-dwelling women, but the level of knowledge of UI has been studied in sub-populations such as minorities and in institutions[173].

Joh and colleagues (2018) conducted a cross-sectional survey to assess FI knowledge, attitudes and help-seeking behaviours among community-dwelling adults undergoing national health screening in Korea. Only 29.8% (n=601) were aware of the term FI and knowledge levels were low. As to attitudes, 24.6% considered FI to be very rare and 22.3% considered it to be moderately distressing. Knowing the term FI was significantly associated with overall help-seeking behaviour (OR:9.23;95%CI:2.09-40.77). Based on these studies, it would appear that a larger knowledge gap exists related to FI.

3.1. Level of severity and bothersomeness of UI symptoms and consequences of symptoms

UI severity in women between 58-70 years was the main reason for reporting UI to a healthcare provider[174]. Women had greater odds of getting treatment for UI when their symptoms had become more frequent (adjusted OR, 3.16, 95% CI, 1.15–8.67) and bothersome (adjusted OR, 1.09, 95% CI, 1.01–1.18) in the prior year[175]. Another study found however, that bother from UI mediated the relationship between UI severity and help seeking behaviour. Thus, women who perceived bother sought help for UI regardless of the level of severity[138]. Bother, as well as concern about a serious underlying condition, was also a reason to seek help for women between 45 -65 years living in Iran while neglect, embarrassment, an assumption that UI was caused by aging, and economic issues acted as barriers to seeking help[176] . The literature revealed that more severe UI and bother from UI can act as facilitators to help-seeking.

It is difficult however to generalize findings among studies because different definitions for help-seeking and various instruments were used, although it appears there are common findings including age, type and severity of UI, and feelings of embarrassment are significantly related to barriers to seeking care[177].

In a study conducted with men (N=1240), with a mean age 63.3+12.7 years, who sought help for LUTS at a urology clinic, subjects were asked by a physician before evaluation to select the most bothersome symptom. Nocturia accounted for 32.9% of initial complaints and it persisted in approximately 50% of men over time[178].

Men over 50 years old (n=18) who had visited their GPs were asked to participate in semi-structured interviews about reasons they sought help with LUTS. The researchers found that men could be grouped into 3 categories: those who were concerned about cancer, those who found the symptoms a nuisance, and those who were prompted to seek help after seeing public information about LUTS[179].

4. EXTRINSIC FACTORS THAT ACT AS BARRIERS/ FACILITATORS TO HELP-SEEKING FOR UI

Health care system factors constitute a number of issues cited across the international literature for help seeking. Women with low incomes (i.e., $30,000 USD annually) were less likely to discuss UI with a healthcare provider, even though they had health insurance, as compared to women at higher income levels[128]. Costs of care and inconvenience have been found to create barriers, highlighting the fact that social factors play a role in a woman's decision and ability to seek care as described in the ICI 6th edition[128].

Recent qualitative research has further developed the understanding of extrinsic influences. For example, of the eight themes established by Mendes and colleagues (2017), the majority incorporated social factors[71]. Moreover, a 'non-optimal healthcare system" was a found as a primary inhibitor of help seeking behavior in a recent meta-ethnography study[62]. The current health care system-related barriers that inhibit women from discussing their symptoms with healthcare professionals represent an important gap to address given that discovering treatment was available for UI was the trigger for 30% of women studied to seek help[180]. Additionally, Biyik and colleagues (2019) determined that an important trigger for seeking help for incontinence was healthcare providers' confirmation of continence problems. Thus, the role of healthcare professionals acting as facilitators to help-seeking care is effective and important[181].

A complex interaction between the use of adaptive or self-care behaviours, help-seeking and ultimately successful self-management of UI exists[182]. The literature clearly indicates a number of common adaptive behaviors in the process of coping with UI. These commonly include: convenience/defensive voiding (urinating often), restricting fluid intake, avoiding certain activities, using absorbent padding and wearing dark coloured clothing[183] [184]. An analysis of 1059 women with overactive bladder (OAB), determined the most common adaptive behavior to be convenience/defensive voiding[184]. Similarly, another recent study, which implemented a factor analysis that informed the validation of the Adaptive Behaviour Index, determined behaviours most often associated with both UI and FI, fall into the domains of hygiene and avoidance[185]. Bathroom mapping, and using absorbent pads were two key established adaptive behaviours under the hygiene domain. Urinating often (convenience/ defensive voiding) and wearing easy to remove clothing represent two key established factors in the avoidance domain. The analysis conducted by Wei and colleagues resulted in a 17-item index (Adaptive Behaviour Index) providing empiric evidence that women reporting greater pelvic floor symptom severity are more likely to use adaptive behaviors[185]. The Adaptive Behaviour Index quantifies adaptive behaviors and has potential to enhance understanding how individuals cope with UI and FI, what facilitates, or limits help seeking and associated successful self-management.

Appropriate self-management of UI and FI, demands active engagement and responsibility from the affected individuals . When people hide their PFDs and do not seek help, they are more likely to use poor coping strategies and adaptive behaviours. Understanding the distinction between self-management and similar concepts, such as coping, is necessary for conceptual clarity in the FI and UI literature. A recent concept analysis provides clarity on this issue, as specific to UI[182]. Through an analysis of 17 papers, Klein and colleagues determined that outcomes of UI self-management are directly influenced by an individuals ability to engage in self-management tasks and the provision of social support. Thus, sufficient knowledge seeking is essential for successful self-management of UI. It is certainly feasible for women to achieve acceptable self-management of UI without seeking health care, but people should feel empowered to broach the subject with a provider to avoid engaging in practices, such as restricting fluid intake or engaging in defensive voiding, that negatively impact health[182].

Social and cultural attitudes were previously cited[127] as barriers to help-seeking and this issue appeared to cross many cultures[128]. Likewise, additional research affirms "cultural and religious backgrounds and personal reluctance contribute to delays in seeking UI treatment" as represented as the first of one of 8 themes determined from a qualitative synthesis of 28 studies exploring health seeking for UI[71].

5. SEX DIFFERENCES FOR HELP-SEEKING BEHAVIOURS FOR UI

Very few studies have explored the differences in help-seeking behavior in women vs. men, and no studies that directly compared sex differences in help-seeking behaviours for UI were located. Nonetheless, women have been found to prefer not to seek medical advice for UI, while men tend to go to doctors more often than women[186]. Across multiple studies, women demonstrated a preference for discussing UI with other women, rather than an HCP[187]. Except for treatment seeking behaviours, both men and women are found to practice self-management coping methods for the management of UI such as going to the toilet more frequently[186].

Unique to women, the perinatal care period represents a time when several authors have noted the initiation of pelvic floor symptoms which is not surprising given the well-known relevant risk factors associated with PFD. This is also a time when women are interfacing more regularly with HCPs. A recent study conducted by Moossdorff-Steinhauser and colleagues (2021) is the first to report on women seeking help for UI when they are pregnant. Importantly, only 13% of the women in this study sought help for their symptoms. The majority of those who did seek help were already under the care of a specialized physiotherapist for other pregnancy-related complaints, typically pelvic girdle pain[188]. The authors discussed

reasons for pregnant women not seeking help including 40% believing symptoms would spontaneously recover in the post-partum period. This highlights women's lack of awareness of the UI during pregnancy being a risk factor (two- to six-fold risk) for the presence of UI postpartum[189]. Bothersomeness was also correlated with help seeking in this study and a high proportion of pregnant women reported low bother or few symptoms[188]. These findings indicate that non-help-seeking pregnant women experience little bother, just like women in the general population[190]. They also highlight an opportunity for improved care and knowledge translation for women through this time period to facilitate immediate and later help-seeking. However, current health care provider knowledge gaps need to be overcome[188].

These findings corroborate with those of a previous study that determined counselling about UI in pregnancy and during postpartum physical exercise, predicted 47.8% of the variance in treatment-seeking behaviour and that counselling during pregnancy can contribute substantially to increasing the number of women treated for postpartum UI[191].

Sex-differences in help-seeking behaviour can exist and research to determine the barriers and facilitators that are shared and that differ between the sexes are needed to develop effective strategies to encourage early help-seeking for UI.

Awareness and knowledge of UI and FI, satisfaction with the information strategy and self-efficacy appear to be important factors related to help-seeking behaviour. To date there is limited data related to the effectiveness of community-based population health approaches to promote knowledge of UI and FI and associated help seeking. It has been recommended that women interfacing with care in the perinatal care period be offered more tailored care regarding UI and FI [188 191]. Additionally, a small RCT examining help seeking among women concluded that all women in the general population over the age of 55 years should undergo screening and treatment if appropriate[192]. Public information campaigns have been suggested to enhance consultation rates providing that passively receiving and actively seeking information have the same effects on help-seeking behaviour[131]. However, only one small RCT (n = 168) determined clinically important improvement in pelvic health anatomy knowledge following a six-week educational intervention among girls 13-17 years of age when compared to a control group[111]. The quality of this RCT is too low to base any recommendation, although evidence is certainly indicating the benefits of structured education-based interventions before and throughout the perinatal care period for women. No studies have specifically explored effective strategies to improve help seeking for men.

Summary

The lack of an accurate denominator to determine the rate of adults who have UI undermines efforts to determine the proportion of adults with UI who seek help from healthcare providers for it. UI affects health-related quality of life (HRQoL) and is associated with activity impairments when compared to continent adults. Therefore, eliminating and minimizing barriers and reinforcing factors that facilitate help-seeking across the lifespan, across cultures and that are sex-specific should be a priority in research.

The literature reviewed supported the Model of Pathways to Treatment in that adults reported that bothersome or severe UI led them to seek help from a healthcare provider for UI symptoms and their consequences. Respondents to surveys also reported that extrinsic factors created significant barriers to seeking help.

Help-seeking is a complex behaviour influenced by multiple factors including social and cultural ones. Increased knowledge of PFDs can improve self-reporting of symptoms and reduce disease burden. Inclusion of qualitative methods to better understand how men and women think about and make meaning of bodily changes, symptoms and consequences of UI is needed to create foundational research that will lead to help-seeking interventional research. Common terminology and validated instruments are essential to advance knowledge. Analyses that examine sex-differences in factors that act as barriers and facilitators to help-seeking are also needed.

Levels of Evidence/Recommendations

- Only 2 small RCTs for help-seeking behaviour were located (Level of Evidence 1b)
- Knowledge, attitudes and beliefs about UI, FI and pelvic organ prolapse affect help-seeking behavior.
- Recommendation: No recommendation regarding help seeking behavior was possible based on the low quality of the RCTs focus and the low level of majority of the evidence provided by the available research.

V. MODELS OF CARE, DELIVERY AND ACCESSING CARE

Literature search in found in Appendix 1.

1. BACKGROUND

Global demographic trends suggest that with an aging population, the incidence of urinary incontinence will rise in the coming years, bringing significant health and economic implications for both patients and payers[193]. However, there is limited organizational evidence to guide payers and providers about appropriate service configurations which will deliver efficient guideline-compliant, high-quality patient care[174]. Internationally continence care is based on various care models that reflect the respective national health systems[194]. This global diversity of care challenges comparisons of different care models and hampers setting up of quality enhancement systems enabling iterative improvements in care provision, that are replicable worldwide. Also, even in the developed world, provision of appropriate patient-centric care is difficult due to the lack of appropriately skilled health care professionals, at all levels of care, embedded within an efficient and stratified care pathway. Low levels of integration of continence services result in duplication of provision, concentration of services in specialist centres and relatively low provision of community-based care[195], [196]. Additionally, provision of care may be dictated by imbalances in the level of reimbursement versus the true cost of providing treatment[193]. This has resulted in a bias towards surgical intervention over more conservative treatment strategies[197], [198]. In low- and middle-income countries, continence care is also hampered by the low cultural priority accorded to it and patriarchal morals that ensure women remain second class citizens[199].

Given the complexity of this landscape, this section attempts to evaluate different care models for provision of continence care and to understand the challenges and benefits of each model, especially when implemented in real world settings.

2. FACTORS UNDERLYING ACCESS TO SERVICES

2.1. Patient knowledge, attitudes, and preferences

A key factor underlying access to, and provision of services is how the patient navigates through the system. Therefore, discerning how the patient understands and seeks healthcare warrants attention. Knowledge and attitudes about UI and care may influence patient choice regarding services, suggesting that as QoL worsens, care-seeking increases[200]. UI may be perceived as a family issue rather than a disorder affecting only one family member in some cultures, particularly those where living with extended family is more typical[201]. Family support was often seen as an important component when dealing with UI[202]. This has been discussed in more depth earlier in the chapter.

Many women may prefer to take an active role in their own care. For example, in a survey of 265 Norwegian women with UI, O'Donnell and Hunskaar[203] found that 60% of women wanted to be actively involved in their care decisions about hormonal health, compared to only 38% for their general health care needs[204]. This finding may also have been influenced by the context of care and educational level of the woman[183] or associated with the desire for adequate clinical information rather than for active treatment decision-making[205]. Furthermore, a large cross-sectional community mail survey of women with UI in France, Germany, Spain, and the UK found that many women preferred to be treated for UI by their primary care providers, despite easy access to specialized services[206]. Appropriately trained continence nurses and physical therapists appeared able to provide quality UI care for women and patients women were satisfied with care provided by continence nurses[207 208 209].

More recently a systematic review that considered a worldwide perspective on how women experience UI portrayed significant difficulty for women to access healthcare influenced by reluctance, lack of knowledge and stigma[71] Lack of knowledge may be influenced by misinformation. Vasconcelos et al reviewed 19 papers focused on knowledge and attitude in women, which identified that misconceptions about UI continue to exist despite improved access to information[210]. Therefore, healthcare provider attention on how information is interpreted and understood is a fundamental first step.

2.2. Clinician's preferences

A UK cohort study investigating what determines clinicians' referring of women with UI onto secondary care identified that older women and those from ethnic backgrounds were less likely to be referred[211]. Therefore, a combination of patient and clinician beliefs possibly challenge care delivery. Incontinence and its consequences receive little respect[212]. Consequently the complexity of human nature and its fear of bodily functions have to be considered when striving for the best models of care.

3. MODELS OF CARE

A report on continence care services worldwide noted that services were scattered, inconsistent and that considerable discrepancies exist in their funding[213]. The report concluded that accessible (and affordable) continence care and multidisciplinary teamwork were necessary. Funding and reimbursement are key challenges regardless of the model of care employed in any country. Although vital, it is not a top priority for governments and payers around the world[214].

However, implementation of integrated services can be challenging due to infrastructure limitations and other barriers. Kirst et al (2017) identified measures of success for integrating care in their literature review of 65 international papers[215]. One of the key measures is the confidence with multidisciplinary working relationships. An example of integrating care is a study that aimed to provide an evidence-based specification for the procurement and organisation of continence care. Evidence was gathered through a systematic literature review and semi-structured interviews, resulting in the Optimal Continence Service Specification (OCSS) which provides useful guidance for service delivery[193]. Furthermore, a scoping review along with an international expert panel identified key performance indicators (KPIs) which offer measures for defining what continence care should look like[216].

A key challenge in the spread and adoption of the KPIs is the requirement of robust clinical leadership and convincing methods of implementation. Therefore, the development of improved strategic models, such as the OCSS[193] and KPIs [195] have the potential to support the development and strengthening of services.

The OCSS modules include: 1) case detection, 2) specialist assessment and treatment, 3) case coordination, 4) caregiver support, 5) community-based support, 6) use of containment products, and 7) use of technology (Figure-2). The key recommendations are detailed in Table-1.

There are many factors that can highlight the importance of adequate investment in community continence services to health care planners. For instance, a UK national policy document proposes a framework for commissioners and health care providers to develop continence services that reduce health related harm and costs[217]. The pursuit of dignity in care yet ensuring value for money may be challenging to reconcile in some cases, but outcome measures are critical for evidencing what works and informs further improvements. Despite the widespread launch of UK national policy, the potential of frontline continence services is yet to be fully realized.

The provision of continence care and services in each country depends on the organization and infrastructure of its health services. Because UI is prevalent and affects men and women of all ages who receive medical care from a variety of health care providers (e.g., PCP, family physician, geriatrician, gynaecologist, nurse practitioners), there will seldom be one point of entry to continence care.

A major barrier to facilitating continence services models is the lack of studies that compare effectiveness of specific continence care delivery systems. There is paucity of data on the effectiveness of services outlined by the OCSS. No published studies have directly compared the effectiveness of specific delivery systems for continence care. However, a cost-effectiveness study which implemented the OCSS strategy, identified that nurse-led specialist service improved care delivery for community-dwelling elderly[218]. Also, despite evidence for active intervention, emphasis often remains on urine containment and passive UI management rather than on

Table 1: Optimal Continence Services Specification Recommendations.

1. Ensure ease of access by the establishment of robust referral pathways from detection of incontinence through to appropriate assessment and treatment.
2. Shift the responsibility of basic continence care away from Primary Care Physicians (PCPs) to continence nurse specialists (CNSs) in primary care where available, where CNSs are unavailable, train existing healthcare professionals such as primary care-based nurse practitioners, community nurses, physician's assistants or, in developing countries, local community healthcare workers, to provide evidence-based continence care.
3. Where possible, use a case coordinator to ensure collaborative working, especially to help delay or prevent admission of patients to permanent care settings; given the general trend to more integrated clinical pathways, in particular concerning patients with multiple co-morbidities, it is necessary to strike a balance between specialization and holistic case management approaches.
4. Promote use of self-management tools and techniques, as well as the provision of information on the use of containment products.
5. Emphasize shared decision making between healthcare provider and patient/caregiver, and educational campaigns on the nature of the illness and treatment strategies.
6. Integrate specialists with other parts of the care pathway and ensure they play a key role in quality governance, training and the dissemination of best practice.
7. Use a comprehensive assessment of user, product, and usage related factors to assess the needs of patients and caregivers with regards to containment products. This process should be standardized, valid and easily reproducible. The final decision regarding choice of product should remain with the end-user: the patient and/or their informal or professional caregiver.
8. Use of technology should be integral to the delivery of continence care. Technology should enable self-care and connect patients, caregivers and enable providers to monitor progress and troubleshoot problems.
9. For payers: to provide the highest quality continence care, ensure care standards are incentivized. This can be achieved through stipulating the achievement of targets on certain outcome and operational measures, careful use of quality-related financial incentives, emphasis on clinical governance and optimal pricing that is most strongly correlated to the true cost of providing a service.
10. Establish accredited programmes of training for nurses who want to become CNSs and other health or social care professionals such as social workers wishing to improve their competence in delivering continence care.

active therapy. Evidence also points towards scarcity of product supplies. An audit of the continence services in the UK revealed that rationing of pads and absorbent products was widespread, with most patients limited to four pads per day[219]. In addition, 59% of the continence services surveyed provided pads for children under the age of four, which was outside of the published national guidelines. These findings indicated the need for improved implementation of continence services.

A range of existing service delivery models were found in the literature and described below.

3.1. Single Specialist

The single specialist model, offering both medical and surgical treatment, is most common in developed countries and is usually led by a specialist physician (i.e., urologist, gynaecologist or urogynaecologist). A nurse continence advisor or continence nurse specialist may be included as an integral part of the services.

According to international clinical guidelines, specialists in continence care should be part of the referral chain focused on those with severe symptoms or the patients who are unresponsive to conservative treatment strategies, complex patients and those with a clear indication for more invasive treatments[128]. Also, while providers of specialist assessment and treatment should probably be separate from those providing initial assessment and treatment, it is important that there is operational integration with other components of service[193]. In the real world however, single specialists, especially in private practice, often work in their own silos offering all services within their own practices. A greater focus on surgical management could be a concern.

Specialists have an important role in facilitating the sharing of best practice and training as well as in quality governance[193]. However, the integration of an academic centre with a community-based services has proven to be challenging in the past with barriers to overcome regarding funding sources and existing healthcare infrastructure[220]. Training of general gynaecologists in continence care is also a challenge. Amongst specialist physicians, such as gynaecologists and urologists, relatively few specialize in continence compared to the prevalence of the condition[193]. Also, in the era of the superspecialist (urogynecologist), gynaecologists may not be motivated to enquire about and manage UI: in a retrospective review, resident physicians documented any type of bladder symptom (incontinence, urgency, frequency, dysuria, nocturia) in only 16.3% of 196 charts[221]. The residents may think of prolapse and incontinence as the domain of the urogynaecologist and are still uncertain if they will perform these procedures in their future practice [221]. When the authors prospectively randomized patient charts (n = 88) to carry a chart-alert sticker (e.g., "Do you leak urine?") that reminded the residents to ask about UI in their general gynaecology clinics, the inquiry rate increased from 4% to 34%.

3.2. Nurse Specialist

Nurse-directed models of incontinence care have been popular and subject to several studies. Farrell and colleagues studied a stepwise care delivery model that included continence advisor and nurses[222]. The model concluded a positive effect compared with the traditional medical model. In Australia, New Zealand and the UK, a national network of Continence Nurse Advisors (CNAs) or Continence Nurses provides an example where they integrate services, and guide patients through the referral route most appropriate to meet their needs. The efficacy of Continence Nurse Practitioners (CNPs) in the UK was reported by Matharu et al who studied 450 women over 40 years of age who underwent urodynamic studies in the UK after seeing a trained CNP[223]. In women diagnosed with bladder overactivity, the CNP prescribed medications to 79% of patients and PFMT to 64.8% of the women. In those with urodynamic SUI, 88% had appropriately been prescribed PFMT. Nurses assessed and assigned women to appropriate conservative treatments, resulting in shortening waiting times for urodynamics and specialist assessment.

There is a long history of the efficacy of the nurse specialist in the delivery of community continence care [224] [225] [226] [227]. In the U.S.,

urology nurses have been trained as "teachers" to successfully implement behaviour modification programmes to groups[228]. Nurses played an important role in the evaluation and management of POP, a condition which is often associated with concomitant UI[229].

When compared to primary care providers, nurse specialists can offer effective care. For instance, Choi et al performed a case-controlled intervention study with primary care patients (male and female) who had LUTS in China[141]. The intervention group (N=360) received a nurse-led continence care programme and a control group (N=360) received usual care by their PCPs. Outcome measures included symptom severity, HRQOL, self-efficacy, global health, and self-reported health service utilization at 12-months. The intervention group had significant improvements in LUTS severity and HRQOL, although improvements in the amount of urine leakage were not significantly different between the two groups. A higher proportion of intervention group (as compared to control group) reported increased self-efficacy (43.48% vs. 66.83%), improved global health condition (17.74% vs. 41.5%), having doctor consultation (18.5% vs. 8.06%), having medication due to LUTS (26.50% vs.11.29%) and having non-drug therapy due to LUTS (59.5% vs.9.68%).

Holtzer-Goor conducted a study investigating cost-effectiveness of inclusion of a nurse specialist in the treatment of UI in primary care in the Netherlands[230]. A decision analytic model was developed comparing the current care pathway for UI in the Netherlands with the pathway as described in the OCSS[193]. The new care strategy was operationalised as the appointment of a continence nurse specialist (NS) located with the GP. With the new care strategy, a QALY gain of 0.005 per patient was achieved while saving €402 per patient over a 3-year period. Although no health gains were achieved in both groups, the authors concluded that a NS in the GP practice would likely reduce UI, improve QoL, and reduce costs.

The emergence of the nurse consultant role has also contributed to an alternative provision of care. Lee reported findings from a study investigating the introduction of nurse consultants (NC) in Hong Kong[231]. The study focused on a range of patient outcomes including UI. A total of 280 patients, 140 in each cohort under NC or non-NC care, participated in the study. The study showed that patients under NC care had favourable patient health and service outcomes compared with those under non-NC care. The NC cohort also reported a high level of patient satisfaction.

These studies offer confidence in the value of nurse specialists and nurse consultants for the delivery of continence care. However, consistency in role definitions isn't always clear. Despite this, the community nurse, NS and NCs all have a role to play in early identification, assessment and treatment of bladder and bowel dysfunction. A systematic review identified a dearth of available research to understand the community nurse role in continence care[232]. The review reveals the lack of educational preparation and recommends that UI is positioned as a priority area of care. Models of care should consider the role of the generalist and their place in first line interventions and robust signposting. Furthermore, optimum delivery can be influenced by organizational, contextual factors and educational preparation[233 234].

3.3. Multidisciplinary Resource and Referral Centre

As we develop an expanding knowledge base of effective investigation and management protocols for women with pelvic floor symptoms, there will be an increased emphasis on multi-agency management of PFD[235]. Urological, gynaecological and colorectal dysfunction do not exist in silos; a blinkered focus specified by the confines of a single specialty and perceived limited options for treatment is unlikely to address the multiple causations and consequences of PFD[235]. Hence a multidisciplinary team is imperative to provide comprehensive care, especially at the tertiary level.

The multidisciplinary approach is a means of synchronizing treatment between various specialties and streamlining the patient pathway[235]. A system of cross-referral of patients is enhanced by regular face-to-face meetings between specialists in the core areas of colorectal surgery, urogynaecology, urology, pain, psychology and functional gastroenterology[235]. It is vital to extend membership beyond doctors alone to include continence nurse specialists, pelvic floor physiotherapists, biofeedback nurses and physiologists, as they all have distinct skills central to the assessment and management of these patients with often multiple deficits.

The clinical experience and medical evidence of this diverse group inform the details of management of these patients. The multidisciplinary team approach should not be thought of as being restricted only to a tertiary setting. While some of the specialist expertise may not be widely available, it is still a valuable way of managing people with difficult symptom combinations / multiple comorbidities etc as well as streamlining management at the local community level, depending on the expertise available[235].

A multidisciplinary clinic dedicated to a specific cohort of patients (65 years or older) in Canada demonstrated its success in improving continence care, via a retrospective chart review, in older patients with complex medical issues, thereby promoting successful aging[236]. The collaboration of a nurse, physiotherapist and physician to assess and treat bladder and bowel symptoms, while tackling co-morbidities that underpinned many of the symptoms, illustrates an exciting yet uncommon approach. Condition-specific multidisciplinary clinics have the potential to significantly improve quality of life. A qualitative study highlighted the distress and psychological impact of living with UI for people with cognitive impairment leading to the incorporation of a urology service within a cognitive impairment clinic as a pilot[237]. Fundamental to the success of such a clinic will be the integration with nursing and therapy staff and effective clinical pathways.

3.4. Primary Care

Primary care providers hold a strategic position in the early detection and management of UI[238]. Most women, particularly those aged 60 or older, use a family practitioner or internist to provide ongoing medical care and persons aged 75 and older average 6.5 physician visits per year[239] Also, for those involved in some managed care plans, a primary care physician may be the only feasible pathway to specialized treatment, when this is deemed necessary[240]. Thus, involving primary care physicians in the care pathway for UI and setting up an efficient triage system whereby patients with the most complicated symptoms are referred to specialist providers would enable provision of cost-effective care to the largest number of patients[240]. In the UK[241] and Sweden[242 243], continence services usually fall under the remit of primary care providers through individual health improvement programmes[194].

However, in a 2002 survey amongst Canadian family physicians, almost two-thirds of the respondents reported that differentiating types of incontinence was difficult and over 60% of them considered managing UI to be a difficult task[244]. Only 37% indicated that they had an organized plan for continence issues. In the US, Cohen et. al. found that, among primary care providers, only 25% initiated

a discussion of incontinence with their patients[245]. In their cohort, older patients were less likely to be asked about incontinence compared with younger patients. To address these needs, the Agency for Health Care Policy and Research (AHCPR), now called Agency for Healthcare Research and Quality, put together structured recommendations for management of UI with a multifaceted approach for primary care providers including physician and office staff education, logistical support, frequent interaction and feedback, patient screening forms, and patient education materials[246]. However, a group randomized trial in the US in which 21 of the included 41 primary care practices were trained in the guidelines, showed that rates of assessment and management of existing UI were low in both the control and intervention groups[240].

Surveys of primary care providers regarding UI management have shown contrasting results. A descriptive survey of 158 family physicians in Alberta[246] revealed that while 53.8% reported that they proactively discussed UI with their patients and 70% felt fairly confident in managing UI, 24% of them had received no training in UI management since graduation. Most family physicians referred patients for specialist care, with few referrals to community services. Respondents thought that continence services were scarce, with long waiting times, and that such services were generally overstretched. Also, they believed that although high-quality continence care was a personal priority, it was not a priority focus for their practice partnerships or networks. On the other hand, a cross-sectional electronic survey of primary care providers in the US showed that they were twice as likely to screen for (75%) and felt better informed to manage UI versus FI (35%). High reported interest in educational materials, coupled with high reported rates of perceived importance of screening for UI and FI suggests that PCPs welcome informative interventions to streamline diagnosis and treatment[247].

While there is increasing demand for primary care services due to an ageing population and reforms that shift care from hospitals to the community, the supply of physicians is limited and there are cost constraints[207]. Shifting care from physicians to nurses in primary care can potentially reduce costs and physician workload and maintain quality of care[206]. Nurse-led continence services for patients with UI have been integrated into the health care system in many countries[144], such as the UK, the Netherlands, the US, Canada[248] and Sweden[242].

A multicentre RCT in the Netherlands (PromoCon Study) comparing a 1-year intervention by trained NS's with care-as-usual after initial diagnosis and assessment by general practitioners revealed better continence rates, after three months in the patients seen in nurse-led clinics after correction for known effect modifiers (UI type and BMI), however, no differences were found between the groups in the 1-year linear trend[249 250]. A focus group study of six nurse specialists involved in the RCT later revealed that they felt competent to offer the needed services and were appreciated by the patients[251]. They were confident that they added value to the practice, particularly since many of the GPs were seen as lacking interest in UI. However personal contact with the GPs, availability of enough time, adequate equipment and financial resources are important preconditions for effective nurse specialist care[251]. An RCT in the UK which evaluated the impact of an 8-week primary intervention package delivered by a continence nurse practitioner showed that the percentage of individuals who improved and were cured after 3 months was significantly higher in the study group, when compared with care provided by GPs and continence advisory services in the area[241]. The results were maintained at the 6 months point.

3.5. Group intervention models

Group intervention models for delivering first-line treatment for UI has long been found feasible[40 252 253 254] and these models may be an equally effective and potentially cost-saving approach[255]. Haque et al investigated group exercises classes for women aged 60-75 years across Bangladeshi villages delivered by a paramedic (who provide front-line health care in the area)[256]. The rate of UI reduced for those women who participated. As identified by the study, sustainability of health gain requires continuity of classes. However, implementation of group intervention models, such as the classes, draws on a variety of factors. For instance, Schmuhl et al highlights factors for effective implementation, such as adequate funding, staffing, good facilitation, and recruitment of participants whilst being sensitive to underpinning stigma that may inhibit attendance[257].

Using a group approach to improving awareness, empowerment, knowledge, and health seeking behaviours for those suffering with incontinence is gaining credibility. As identified by Cera in their single-group efficacy trial of a continence education programme delivered by a Nurse Practitioner, there is a strategic opportunity to embed such models into integrated models[258].

3.6. Models using lay instructors

A study has shown that non-medical lay instructors can be taught how to instruct patients in proper PFM exercises[259]. This train-the-trainer model may be useful to help disseminate behavioural therapy on a more widespread basis. Literature is scanty when searching for models using lay instructors specific to continence care. However, drawing on exercise for community dwelling elders, Kim et al provides a useful insight into using peer-community trained residents[260]. In their quasi-experimental study, the intervention and control groups (30 elders in each group) received either an experience programme over eight weeks, or two training sessions on aging and arthritis. Six lay people received 16 hours of training from a nurse educator. The findings didn't reveal any significant difference between the two groups for outcomes in pain, shoulder flexibility, depression, or life satisfaction. However, self-esteem increased for the intervention group. As the authors highlight, lack of experience may sit at the heart of the disappointing results.

3.7. Telemedicine

Telemedicine, which provides safe, equitable, patient-centred care, has gained significant momentum in recent years[261]. The use of telemedicine is at the heart of a virtual clinic, to support the assessment, monitoring and management of patients at a distance, away from traditional face to face clinic consultation[262]. Potential benefits include improved satisfaction, reduced carbon footprint and reduction in unnecessary appointments and journeys to a hospital[263]. It could also fill the gaps where resources and manpower are lacking[193]. The format and delivery of a virtual clinic varies widely depending on the technology deployed[264] including telephone[244], online web sessions[265] and Skype[266] .

There is a growing body of evidence in support of tech-based initiatives. Providers should use clinical judgement and existing data to guide them on which clinical conditions are appropriate for virtual care[261]. Telemedicine is unlikely to be appropriate in clinical situations where a physical examination or diagnostic test is required. However, an individualised approach encompassing a combination of virtual and face to face appointments may be an option[267].

A Swedish randomized controlled trial on pelvic floor muscle training for women with SUI had 3 months of either an internet-based treatment program (124 women), including email support and cognitive behavioural therapy assignments, or a treatment program sent by post, though the intention-to-treat analysis showed highly significant improvements ($p < 0.001$) with large effect sizes (>0.8) with both interventions, there were no significant differences between the two groups in the ICIQ-UI SF and ICIQ-LUTSQoL symptom scores[268]. However, more participants in the internet group perceived that they were much or very much improved, reported reduced usage of incontinence aids and were satisfied with the treatment program. Furthermore, health specific QoL improved in the internet group, but not in the postal group. A supportive patient-provider relationship was developed in the internet-based program, despite the lack of face-to-face contact. The researchers concluded that internet-based treatment programs can increase access to care and empower women.

However, in a randomized controlled trial in which 195 women with UI were randomized to either a standard clinic or a virtual clinic, the virtual arm had no impact on the short-term dimension of the Patient Experience Questionnaire and overall was not as cost-effective as standard care, due to greater clinic re-attendances[264]. The consultation times were, however, briefer, communication experience was enhanced, and personal costs were lower in the virtual clinic group. The authors conclude that for medical conditions of a sensitive or intimate nature, a virtual clinic has potential to support patients to communicate with health professionals about their condition.

Mobile health technologies including electronic application (app)-based treatment that delivers advice, training, and motivation for managing UI by oneself could offer advantages over usual care, removing the barriers to treatment access and improving adherence to training[269]. More than 100 apps for UI management are already available, yet evidence for their effectiveness is scarce. Furthermore, these apps tend to focus on SUI alone and to have diverse content[270]. In a Swedish study, app treatment improved UI symptoms and quality of life after 3 months compared with postponed treatment and was cost-effective at 12 months[271]. A recent small Brazilian study also showed increased adherence to pelvic floor muscle exercises and an improvement in UI symptoms after 3 months of app-based treatment compared with written instructions alone[267].

In the URinControl randomized controlled trial in Dutch primary care involved 262 women (randomized to UrinControl app or usual care). While both groups showed improvements, the change in symptom severity with app-based treatment was non-inferior to that with usual care[269]. App-based treatments, with their potential advantages of privacy, accessibility, and lower cost, may provide women with a good alternative to consultation[269].

3.8. Continence care during COVID 19 epidemic

Patients face unique challenges during the pandemic owing to inherent vulnerabilities of these populations[272]. A cross-sectional study in Austria found that women's QOL remained significantly impaired by their pelvic floor disorders, with associated symptoms maintained and psychological strain experienced during the lockdown imposed due to the pandemic[273]. All 99 interviewed women were strongly willing to continue their treatment.

Medical providers worldwide, especially those practicing continence care for elderly and vulnerable patients, have been required to adapt and streamline services to provide continued care while minimizing unwarranted, multiple healthcare facility attendances and patient contact where possible, by conducting remote consultations, delaying non-urgent visits, and optimizing provision of one-stop services[272]. To enable patients to retain access to healthcare, many countries have revised regulations to allow health care providers to use telemedicine and receive appropriate reimbursement[274]. For example, the Centers for Medicare and Medicaid Services in the US have broadened access to, and reimbursement for, telemedicine services[275].

Various international societies and organizations have published guidance for management mainly based on consensus and expert advice, given that the evidence base to support recommendations is still scarce[276] [277] [278] [279]. A rapid review that synthesized current recommendations on urogynaecological care during the pandemic revealed the following: Virtual clinics were recommended for new and follow-up patients, to assess and initiate treatment, as well as to triage patients who require face-to-face appointments[272]. Behavioural and medical therapies, initiated by virtual or remote clinics, were recommended as first line options. Deferment of outpatient investigations such as urodynamics and cystoscopy for benign indications and suspension of prolapse and continence surgery, was considered prudent, except in specific circumstances such as gross haematuria, procidentia with upper tract complications, failed pessaries, when stage I sacral neuromodulation was in place or in cases of neurogenic bladder with a high risk of upper tract complications.

Expanding the availability and accessibility of technology is increasingly required. However, the longer-term effects of deferment of majority of outpatient and inpatient procedures are as yet unclear. When seeing patients face-to-face, appropriate screening, use of adequate personal protective equipment (PPE), appropriate physical distancing and sanitation are needed.

Regional or local anaesthesia was recommended during surgery where possible, to reduce aerosol generation associated with general anaesthesia. Screening for COVID-19 symptoms and testing preoperatively is advised, as evidence has shown poorer surgical outcomes for asymptomatic COVID-19 patients, therefore surgery may worsen or accelerate progression.

The Brazilian Association of Physiotherapy in Women's Health put together a set of recommendations for physiotherapy management of urogynaecological disorders during the pandemic[280]. These included emphasis on telephysiotherapy care including the use of apps, phone calls, etc; physiotherapeutic assessment of PFD symptoms and PFM function using telehealth and provision of appropriate health education materials to patients, especially those who are able to contract their PFMs. Women who are not able to contract their PFMs need to be informed about the limitations of using all physiotherapeutic resources when receiving telephysiotherapy.

The pandemic has led to a new paradigm in patient care that may well sustain even after the pandemic has abated. While telemedicine has opened a new door for many medical specialties, allowing continued safe evidence-based care, the pandemic has tipped the balance away from surgery and towards nonsurgical treatments while attempting not to sacrifice outcomes or quality of care[271]. Research is needed to understand both the positive and negative impact these changes have had on patients and future service delivery models.

4. GLOBAL SERVICE DELIVERY MODELS (INCLUDING CARE IN THE DEVELOPING WORLD)

There are wide variations in continence care service delivery across the world. Factors that affect the delivery of a continence care service include population demographics and patient characteristics; cultural differences in healthcare seeking and disease recognition; geographical healthcare access; financial healthcare access; maturity and development of existing continence care provision; extent to which services are integrated; economic and regulatory levers available to influence healthcare provision and application of technology in the delivery of care[193].

In many countries, but particularly low-income ones, incontinence is not a priority with only basic levels of care provided by community health providers, if at all[281]. Continence services are a relative luxury, to which countries with a low per capita income are unlikely to devote scarce resources, especially while other population health issues have precedence. The potential demand for UI services in developing nations far outstrips the resources that are available. Many of the problems in continence care in these countries are related to the immaturity of the wider healthcare system[10]. Addressing continence care needs while these countries develop their healthcare infrastructure will likely require innovative solutions to make the most of limited resources[193].

Female continence care is an emerging field even in urban parts of developing countries such as India; a few specialists offer care in private practice with no integration into referral care pathways or linkages with the community leaving vast swathes of underserved populations in urban slums and rural parts of the country. The provision of services will depend on the commitment of dedicated HCPs who, with support of government, industry and local continence organizations, can educate a new generation of service providers who will carry the services to remote communities. Increased use of advanced communication technologies can help to disseminate continence promotion materials among nurses and other health professionals worldwide[261].

Where there is a paucity of continence nurse specialists and physicians, it will be necessary to train existing professionals, especially those who currently see people with incontinence, and those who are well placed to deliver continence care[193]. Healthcare professionals are capable of learning a variety of skills, often outside of their usual domain [193]. For example, in the Netherlands, primary care-based nurse practitioners (called Praktijk Ondersteuners, or POHs) have taken on an increasing role in the management of UI in some regions[282]. In the United States, advanced practice providers (nurse practitioners, physician assistants) have acquired additional education and training in providing continence services[283]. In rural Bangladesh, research is currently being undertaken to investigate the role of village “paramedics” or other trained healthcare workers to carry out basic continence care (unpublished data).

In communities largely outside the reach of pharmaceutical or surgical interventions, group exercise-based programs for UI, that include PFMT, mobility exercises, and bladder education, appear to be promising low-cost interventions[284]. Community-based education via a train-the trainer programme has shown promise, as described by Saiki and Morales[285]. Their qualitative investigation of 25 self-identified community workers in southern New Mexico identified a lack of knowledge on how best to help the women living with incontinence in rural communities. However, the enthusiasm for learning was apparent and findings revealed several themes for programme development, but education programmes such as this will require continuing cultural sensitivity to ensure effective initiation and sustainability. Additionally, in a cluster randomized trial in Bangladesh in which 625 women aged 60-75 years from 16 pairs of villages were randomized to receive either the group intervention or bladder health education alone[284], the change in the number of leakage episodes between baseline and 24 weeks was -6.64 in a random effects model accounting for cluster randomization. Post-trial, a further 6-month exercise intervention comprising of 48 exercise sessions led by village paramedics was initiated in 20 villages[256]. 130 women from nine villages in the exercise arm of the trial were followed up 12 months after the intervention concluded. Those exercising at follow-up had an odds ratio (OR) of 3.49 (95% confidence interval [CI], 1.86-6.58) of being continent at follow-up. At roll-out, 38.6% achieved continence, comparable to 43.0% in the trial using physiotherapy preceptors. Thus, group exercise classes led by paramedics resulted in a marked improvement in continence but maintenance requires exercise postintervention.

Global variation and diversity with continence care delivery will continue to be a challenge. That said, a fundamental shift to better care needs a powerful clinical voice that transcends politics and ego. The World Health Organisation (WHO) encourages integrated health care but advocates for political commitment[286]. Furthermore, WHO has included UI within one of their 10 proposed priorities ‘*aligning health systems to the needs of older people’* as part of their Decade of Healthy Ageing (2020–2030)[287].

5. CONTINENCE CARE IN OTHER CLINICAL SETTINGS

Continence promotion, education, and treatment can occur in a variety of clinical settings, particularly in relation to other associated clinical conditions. However, global diversity presents a real-world challenge on how best to do this. In higher income countries, opportunities present themselves and are ripe for improving continence care whatever the setting. For example, UI commonly occurs after acute stroke. Rehabilitation nurses who work with post-stroke patients could play an important role in continence care. Research shows this may not happen regularly[288]. Heart failure is another common clinical condition, particularly among older adults, associated with UI. A study of 182 heart failure patients with at least monthly UI revealed that 83% had not asked for help with their incontinence symptoms and 64% were interested in learning more[289]. Many patients, particularly those with concomitant diabetes, were contemplating changing their behaviours and seeking care for UI. These findings indicate that this group may be receptive to education and interventions that improve urinary symptoms.

A multinational qualitative study examined data from focus groups of rehabilitation nurses in the UK, Sweden, and China[290]. They found that only limited assessment of continence was routinely performed by most nurses in this setting with a particular focus on containment. Edwards concurs with these findings, having investigated patients aged 65 years and older with a fragility fracture because of a fall[291]. Of 3184 patients, 63% (2009) were assessed for urinary continence following a hip fracture and a problem was identified in 41% (817) of these. Twenty-one percent (1187) of 5642 patients with non-hip fragility fractures were assessed and a problem was found in 27% (316). Hip fracture patients were more likely ($p<0.0001$) to receive a continence assessment and have problems detected. Only about half of those with problems were offered inter-

vention or a referral to a continence service. Admission to hospital for non-hip fracture patients was a strong predictor of being assessed (p<0.0001). Edwards concluded rates of assessment and action for those who fall and have continence problems are low despite current national guidelines.

Older people can be the majority of those admitted to acute care[292]. This setting provides care to manage short-term, but urgent, health problems and UI was prevalent. For example, a prospective cohort study of 577 patients (mean age 82 +/- 6.9 years) admitted to general medical wards of three acute care hospitals in Brisbane, Australia, found UI rates of 43.8% (243/555) premorbid, 36.7% (176/479) during admission, and 35.3% (187/530) at discharge[293]. Moreover, of 438 patients at the time of discharge, 38 (12.8%) had new onset UI.

One group of patients with a high risk for developing UI in hospital are female hip fracture patients. In a previous study, secondary analyses of data from 6,516 hospitalised women with a fractured hip revealed 21% became incontinent during hospitalisation[294]. Similar findings were reported for elderly patients admitted to hospitals in Israel[295], Switzerland[296], and Italy[297]. Zisberg and colleagues conducted a prospective cohort study of 352 patients aged 70 and older who were continent prior to admission to an acute care hospital[295]. They found, 17.1% developed UI during their hospitalization, and in a multivariate analysis, the use of a urinary catheter or diaper were associated with the development of UI (4.26 95%CI 1.53-11.83 and 2.62 95%CI 1.17-5.87 respectively). Zurcher and colleagues surveyed 78 elderly inpatients in a Swiss hospital and found 41 (51%) screened positive for UI, yet only 10 (24%) of nursing records documented the presence of UI[296]. Moreover, the use of absorbent pads was the only intervention documented. The number of patients who declined to be asked about their continence status was minimal (n=5).

Other research on UI in acute care continues to draw attention to an over reliance on containment, and inadequate attention to identifying and addressing potentially contributing factors. For example, Ostaszkiewicz and colleagues conducted a point-prevalence survey of 447 hospitalised older adults in acute and subacute care settings in Australia and found 60% with a continence product or device, however, 50 (41%) patients with an absorbent pad denied having experienced UI or FI in the preceding 24 hours[298]. By contrast, 113 patients (16%) who reported UI or FI in the same period had no continence product or device.

The lack of awareness of UI and how it is interrelated with illness and disease continues to be a significant problem. Hälleberg Nyman highlighted the importance of leadership as a bedrock of improving evidence-based UI care[299]. For instance, their process evaluation involving two orthopaedic wards in Sweden identified that leadership quality influences facilitation and implementation of guidelines. Even though containment of UI appears to persist as the most common approach to continence care[300], efforts are being made to support decision making for non-specialised clinicians[301]. Facilitating good decisions at the right time and in the right context has the potential to improve continence care.

6. ELDER SERVICES (LONG TERM CARE OR NURSING HOMES)

Long term care for frail elderly persons is provided in a variety of types of institutional settings throughout the world. Continence care in these settings is dependent upon many factors (Box 1)

Despite UI being a quality indicator in U.S. nursing homes (NH), significant barriers exist with translating research on toileting assistance programmes, such as prompted voiding and other interventions into practice[302]. This issue is especially concerning given the current and future growth in the frail elderly population. Available evidence indicated that the focus was too often on containment and use of pads or absorbent products compared to active continence promotion or treatment. A Cochrane review supported this finding and noted that none of the studies reviewed focused on attempts to maintain continence in facility residents[303]. A systematic review of systematic reviews on the most frequently used behavioural interventions used in long-term care indicated limited evidence for short-term effectiveness[304].

Barriers for improving continence care were considered multi-level and included: lack of knowledge about UI, beliefs about UI, high workload, low commitment from co-workers, and lack of institutional support[305]. Multiple strategies were seen as necessary for quality improvement in continence care to occur. These included creating a sense of urgency about the problem and a sense of solidarity among co-workers and facility administration. Managerial oversight and communication about the evidence of performance before and after the quality improvement program and use of evidence to make decisions about how to modify the programme were considered essential to programmatic success[302]. Little evidence was available to determine how older adults who received the interventions perceive and respond to them[306]. Higher registered nurse to patient ratio was identified as a facilitator of better continence care[307].

Tools to assist care givers with treating and managing UI have been tried. For instance, the development of individualized continence profiles for use with NH residents that could identify residents who may benefit from various forms of assessment and interventions[308]. Likewise, another tool previously worked to involve NH residents more actively in their fluid intake and continence care. After a 12-week intervention, overall hydration status improved, and time spent in saturated incontinence absorbent products decreased significantly in a cohort of 153 NH residents who participated in the intervention[309]. Distance learning techniques have been successfully used to teach and implement programmes and strategies for management of UI in NH[310].

Ostaszkiewicz et al identified in a qualitative investigation of 19 nursing home staff that the underpinning ethos was one of low expectation for improvement[311]. Thus, their care centred on continence management only, as in cleaning and containing. As the authors encourage, educational preparation should challenge beliefs and increase understanding of bladder and bowel dysfunction. The use of technology within the nursing home setting has been gathering pace, such a smart incontinence wear. (Cho et al 2021) However, as Strauven et al informs us, embedding technology into this setting is complex and needs to address the human factors (for example, teamwork, tasks, equipment, workspace, culture, and organization)[312].

Box 1: Factors influencing continence care.

- Type of resident care need (those requiring long-term skilled and personal care, short-term rehabilitation, post-hospitalization care)
- Physical environment
- Organisational culture and leadership commitment to providing high quality care
- Number, education, and motivation of direct care staff
- Access to physicians with interest in and understanding of continence care
- Financial and regulatory incentives to provide appropriate continence care

7. CARE AT HOME

Optimum continence care at home can help prevent early admission to a long-term care setting. Drennan and colleagues[313] interviewed thirty-two caregivers about their strategies for managing older adults with UI and dementia at home. They recommended that professionals, especially those in primary care, should be more proactive in questioning patients about UI and toileting habits to identify counter-productive and harmful strategies. A more recent insight via a critical review of 57 papers into caregiving at home for those suffering with dementia identifies the under-development of evidence to inform best care[314]. There is a continued need for deliberation of specialist roles, responsibilities, and protocols to guide and encourage appropriate referrals and ensure good collaboration, such as the integrated service model.

Summary

This section has attempted to assess several continence care models and understand the problems and benefits of each, particularly when implemented in real-world settings. Complexity and diversity exist despite efforts to improve continence care.

A range of service delivery models have been considered; single specialist, nurse specialist, multidisciplinary resource and referral centre, primary care, and other models (group intervention, lay instructors, eldercare services, tech-based clinics and models in developing countries). Within this spectrum the evidence supports nurse-led community services leading to higher health-related QoL and in some instances higher cure rates. Multidisciplinary referral settings are also reporting favourable outcomes. There remains discrepancy between availability of guidelines for different healthcare delivery settings, leadership quality and educational preparation. The Optimum Continence Service Specification is an example of an integrated model, which has shown that within a 3-year period, cost-effectiveness can be achieved, especially when societal costs are considered. Further research on cost-effectiveness and patient-level effectiveness of continence care models in a variety of healthcare delivery settings is urgently needed.

Evidence Levels And Recommendations

- Service delivery models for Continence Care can be effective. (Level of Evidence: 4)
- A care delivery model should be based on the principles as described in the Optimum Continence Service Specification. (Grade of Recommendation: C)
- Increased emphasis is needed on non-physician models of care (nursing, nurse practitioner, continence advisor, physiotherapy, physician assistants, etc.). (Grade of Recommendation: C)
- Despite the proliferation of guidelines, there is increasing evidence that practicing clinicians and nurses (in the community, acute care, and in long term care) are not consistently following them. Implementation models should be developed on how to translate guidelines into practice. (Grade of Recommendation: C)

VI. EDUCATION AND CLINICAL GUIDELINES

Literature Search for Medical Literature is found in Appendix 1.

1. BACKGROUND

Professional education regarding continence occurs in a wide variety of settings ranging from undergraduate education in medicine, nursing, physiotherapy and other related disciplines, through the full continuum of graduate education, post-graduate training (e.g. Fellowship) and ongoing professional education. This includes both formal education incorporated into established curricula or clinical experiences, and informal types of education such as on-the-job training and point-of-care instruction. Education may be directed toward generalists or specialists and will differ based on the topic of interest and the target learners. The focus of educational topics can range from evaluation and care of individual patients or clinical conditions, to population health and health policy. Examples of clinical education could include surgical skills training for surgical residents and fellows, community and ambulatory care, bedside, or operating room care for nurses, or biofeedback training for physical therapists.

Education of the lay public and patients is a crucial part of overall efforts in education and continence promotion as discussed earlier in this chapter. In the creation and discussion about this section, the committee recognized that a number of different terms are often used interchangeably when referring to this population. These terms include public education, layperson education, patient education, client education, consumer education, etc. These terms can have important distinctions depending on the perspective of those involved. For example, ‘patients’ may indicate those receiving care or suffering from a particular condition such as UI. The term ‘clients’ implies that people are receiving some type of services from a professional provider. And the term ‘consumer’ implies that the person is using either goods or services related to their UI. For simplicity, the term patient education will be used when reviewing the evidence for those suffering from a particular condition and public education will be used to summarize the information generally available.

The term carer and care giver can represent many different populations. It can suggest qualified health care professionals, paid support workers who should have received some basic formal education (also termed professional care givers) or informal carers who may include spouses, family and friends of the dependent individual who have no training / education in continence care. Many individuals may be cared for by a combination of different care givers in a variety of settings including long term care facilities, the community, schools etc.

This section reviews professional education on continence from a broad perspective across disciplines and specialties alongside the available evidence regarding patient, public and caregiver education. It will also discuss the clinical guidelines that have been introduced or updated since the last ICI and the impact that these may have on patients and services.

2. PROFESSIONAL EDUCATION

Professional education forms a critical foundation for all aspects of continence care. This includes the full gamut of professions and disciplines involved in care in this field. While it is agreed that education across areas is vital, most of the published work in this field has been focused on nursing, physiotherapy, and medical education. This is not to diminish the importance of education in other areas including occupational therapy, pharmacy, social work, and others. The role of multi- and inter-disciplinary education is also important but has not been a strong focus in recent publications on continence education.

The COVID-19 pandemic has had an interesting effect on professional nursing and medical education, particularly in relation to live versus virtual educational delivery methods. It has also influenced clinical care delivery. A variety of platforms are available that can be used for both educational and clinical purposes[315]. There has been an increased emphasis on development and dissemination of virtual education platforms.

An intriguing aspect of virtual education is the opportunity to provide training in a more multidisciplinary setting, and across multiple sites. This has the potential to increase the reach of global and multinational educational efforts. It has several important implications including possible increased education in places where this has been limited or absent. Examples would include rural areas or developing countries where dedicated continence care is limited and where there are few trained professionals on this topic.

2.1. Nursing Education

Education related to continence is typically included as a part of overall nursing training. However, the amount and specifics of training can vary widely among programmes. Qualitative research with focus groups of nursing students and registered nurses in practice found that most received education on continence through self-learning, some classroom education, skills labs or on clinical wards[316]. However, although considered important, many respondents thought sessions were either too short or did not go into enough educational detail. E-learning has been successfully designed to teach nurses about the associations between continence and mobility[317]. Online educational courses on urinary incontinence have been successfully developed and disseminated to nurses practicing in isolated rural communities[318]. This type of educational programming could be expanded and used more widely to reach nurses living and training in a diverse variety of communities and areas.

Since the last ICI, the bulk of published work in the area of professional nursing education has focused on evaluation of baseline knowledge and attitudes of nurses, nursing assistants, and other related health care workers[319]. It was noted that some but not all research on the topic has examined subsequent clinical patient outcomes.

In a study in Korea, attitudes, facility bed capacity and continuing education on urinary incontinence were statistically associated with better practice scores for registered nurses[320]. However, improved scores for practice aides were only associated with knowledge and attitudes about urinary incontinence.

A recent study showed that targeted education on continence improved knowledge for licensed nurses following the intervention[321]. However, health care aides persisted with the incorrect belief that incontinence is a normal part of the aging process. This demonstrates that additional work is needed in this area to influence and shift knowledge for some providers. A meta-analysis has shown that in other published studies, many nurses incorrectly believe that incontinence is inevitable in elderly patients[222]. Particularly in studies examining attitudes and knowledge among community-based nurses. This is an important area for future exploration because underlying attitudes and knowledge play an essential role in translating information into actual clinical practice. These gaps in knowledge should be key targets for future educational efforts.

Detailed technical training related to catheter placement, maintenance and care still appears to be lacking in many programmes. Many nurses and physicians who do not routinely deal with urologic issues often defer or are unable to address clinical needs related to catheters. This frequently leads to urologic consultations for basic questions or concerns. Dedicated education on catheters could be useful to help minimize delays of care and allow for more rapid and direct patient management. This also applies to intermittent catheterization (IC). Gray et al surveyed 343 nurses and found wide variability in methods and use of resources used by nurses to teach IC[322]. Seventy percent of respondents were registered nurses (RNs), and 15.6% were advanced practice nurses. Surprisingly, when presented with four clinical scenarios, 9.0 – 20.9% of respondents selected the wrong type of urinary catheter for a given case. Less than half (48.1%) engaged lay caregivers or family members when trying to teach their patients IC. These results highlight the need for improved nursing education on this topic. Education on catheter use also influences attitudes and perceptions of technical issues such as single-use versus reusable catheters[323]. There has been technical information released that is designed to teach proper catheter care and removal methods[324]. Ongoing maintenance measures for patients living with chronic urinary catheters is also important, and nurses play a key role in this care[325 326].

Cobb et al conducted a needs assessment study of 985 nurses who specialized in wound, ostomy and continence care regarding colostomy irrigation practice[327]. Overall, 59% identified ostomy irrigation as an evidence-based practice, but half of nurses indicate they do not routinely teach this to patients. Dahlke et al recently examined educational needs for nursing staff taking care of geriatric patients in an acute care setting[328]. This identified a mismatch between self-reported knowledge gaps and higher actual quiz scores on knowledge assessment. Specific areas identified as needing additional education included managing behaviors in older adults with cognitive impairment, use of chemical and physical restraints, and the associations between mobility and continence. Additionally, a critical literature review has been published which summarizes recent work on nurse perception and management issues[329].

Several publications examined ostomy nursing training needs, and collated resources on nursing care for patients with ostomies to help improve self-care[330 331]. Simulation education tools using high-tech mannequins have been developed to improve nursing instruction for patients to irrigate continent catheterisable urinary reconstructions and orthotopic neobladders[332]. This teaching method improved knowledge and confidence for nurses instructing their patients about these procedures.

Implementation of technology is an important methodology in nursing education. For example, use of ultrasound scanners to measure bladder and post void residual volumes is common in acute care hospitals, but can also have important applications in long-term care facilities and other settings[333]. Nurse-led and evidence-based interventions often prove quite successful and are beneficial in a variety of areas. For example, rehabilitation nurses often function as team leaders in rehabilitation clinical settings, with a role that includes teaching of other team members[334]. Targeted continence education has also been shown to improve nurse compliance with formal assessment pathways and management methods for both urinary and fecal incontinence in the tertiary acute care setting[335].

Several current studies are investigating nursing attitudes and care related to specific conditions. A qualitative study examining neurogenic lower urinary tract dysfunction in people with multiple sclerosis (MS) that includes both patients and nursing professionals is being conducted in Ireland[336]. A prospective, multifaceted, randomized controlled educational trial addressing FI targeted to care givers in nursing homes is ongoing in Norway[337]. It is hypothesized that improved education will enhance attitudes and knowledge which in turn could translate into improved diagnosis and management. Another qualitative study examined an intervention for nursing staff caring for people with continence issues in clinical stroke care wards[338]. Communication was seen to be a challenge from the patient perspective. Nurses described improved knowledge and a shift from containment to rehabilitative approaches for continence care.

The concept of dignity has emerged as a core element of continence care, particularly within nursing[311]. This is a multidimensional concept that has important implications for patients and practitioners. It is inherently linked to both general and health-related quality of life. Additional research on this topic will help expand our understanding of how this critical issue influences not only nursing but other forms of care. It may also uncover other as yet unidentified aspects of the continence spectrum and lived experience that can enhance future understanding in this field.

Future educational research work should examine how to best sustain educational programs, and specific educational outcomes as even highly successful educational programmes have problems with funding and staffing. Many published studies only examine the effects of a specific educational effort in the short-term, with little research looking at continuing and ongoing educational efforts. Future research should include the long-term satisfaction of learners and educators, as recommendations for new and innovative training methods could not be made based on current evidence.

2.2. Physiotherapy Education

In terms of physiotherapy education, the majority of published work since the last ICI has focused on influences on patient outcomes. In contrast, there has been little published work on educational methods or results of educational programming for physical therapists.

Clinician beliefs are important in the perception of physiotherapists and can influence various aspects of education. A study using structured focus groups found three main themes associated with excellence in physiotherapy related to continence[339]. These included high levels of skill and experience; strong research capabilities and partnerships with other researchers; and the role of mentorship for new practitioners. Consumer-focused care was identified as a core skill for physiotherapists at all levels of practice.

The International Continence Society (ICS) has recently published a guideline on education for physiotherapists related to pelvic floor and continence care[340]. This outlines a progressive, three level set of knowledge, clinical skills and education fundamentals for physiotherapists working in the broad areas of continence.

As in all areas of health education, competency-based training has become an important aspect of development of educational curricula and educational evaluation for physiotherapists[341]. It is noted that pelvic floor physiotherapy is not included as part of the core curricula in many programs, but it should be a goal for future educational programming. This is substantiated by work that demonstrates that many trainees across disciplines lack baseline knowledge about the risk factors for urinary incontinence in women[342]. Among the groups studied, physiotherapy students had the lowest baseline knowledge about risk factors. All students were interested in receiving more education in this area.

Application of physiotherapy for continence in nursing homes is an intriguing and perhaps underutilized resource[343]. These clinicians provide a variety of care services targeted at improving mobility and functional status, which could include pelvic floor therapy and continence promotion. Additional work and development of a more uniform application, role specifics and dissemination are needed.

2.3. Medical Education

Medical education on continence and elimination typically forms a very small part of overall medical education. At the undergraduate level, there are so many aspects of basic and clinical science that need to be addressed that often just a cursory introduction to this field is provided. Most of the detailed professional education on continence within various fields of medicine tend to occur at the graduate medical education (GME) level. These include residency training programmes in urology, and obstetrics and gynecology. Some education on this topic may be included in other fields such as neurology, neurosurgery, physical medicine and rehabilitation, gastroenterology and colorectal surgery. Education in primary care fields such as internal medicine and family medicine is much more variable. Some programs may include specific training in this area while others may not include any training as part of their curriculum.

With training, it is noted that all levels of medical providers can effectively teach pelvic floor muscle strength assessment as part of the pelvic examination[344]. This is important for subsequent patient education in clinical practice.

Simulation education methods have continued to gain popularity, particularly in undergraduate and residency training[345]. This may become even more important as educational delivery has changed during the recent COVID-19 pandemic.

Most of the published work in professional medical education since the last ICI has focused on specific surgical techniques. These include methods to treat urinary incontinence such as various forms of slings for management of stress incontinence and pelvic organ

prolapse repair options. Resident training in graduate medical education has been shown to be safe and effective for this type of surgery[346].

There has been increased emphasis on laparoscopic and particularly robotic methods of surgery in the past five years. One study compared surgeon experience and bony anatomy of the pelvis to clinical outcomes for patients undergoing robot-assisted radical prostatectomy for prostate cancer[347]. This demonstrated that surgeon experience (considered a form of ongoing advanced education) and anatomy both influenced clinical outcomes.

Formal modular training has been successful in developing robotic skills to perform radical prostatectomy, a surgery that can be difficult to learn initially[348]. Training on the robot requires time and dedicated effort. Use of dual console technology, where both the trainee and the more experienced surgeon educator are operating together, can enhance education and improve clinical outcomes for patients[349].

Other published studies have looked at continence results of procedures where incontinence may be an adverse outcome. This includes radical prostatectomy in men, and other forms of prostate treatment for bladder outlet obstruction and benign prostatic hyperplasia. Prospective training has been shown to be effective for laser enucleation of the prostate, which is a newer technique that can be difficult to master[350]. The number of cases performed by each surgeon and case density over time were found to be important educational factors. This experiential learning is an important educational component for this type of surgery. Increased surgeon experience has been shown to reduce both surgical time and adverse events whilst improving outcomes for this type of procedure[351]. Dedicated resident education has also been shown to be effective[352].

Feedback to surgeons in the form of a 'report card' has also been studied. This provides direct information on clinical outcomes with the goal of improving outcomes and minimizing adverse events. A prospective study was designed and implemented for surgeons performing radical prostatectomy for prostate cancer[353]. Although this did provide immediate feedback which surgeons found useful, it ultimately did not appear to alter clinical outcomes for patients[354].

Further research is needed to understand the optimal methods of training for surgical procedures and to determine how competency is achieved and maintained.

3. PATIENT / PUBLIC EDUCATION

3.1. Patient Education

Patient education consists of healthcare professionals teaching patients about their disease and offering therapeutic instruction, particularly information about self-management strategies, drugs, adaptation of their dosage and side-effects[355]. Patient education regarding normal and abnormal bladder function has been found to be helpful in the establishment of healthy bladder habits[356].

However, there was very little evidence to highlight the benefit of patient education for people with bladder and bowel conditions and the difference it may make to their outcomes. Most patient education studies found did not meet the quality criteria for inclusion. There are also inherent issues with generalisability of data as there are no standardised methods, techniques, or delivery for patient education or even any agreement on the content required for education.

For example, Bladder training (BT) is a well established therapy for patients with OAB. However, there is no clarity about the techniques and methods used to deliver it. An international survey performed by Elnagger et al reported that there was no consistency from respondents in how BT programmes were implemented in different clinical settings and environments nor was there consistency on how and what the patients were educated to do[357]. As there are no clinical trials comparing different approaches, it makes it difficult to determine the most appropriate and effective BT protocol[358].

To try to overcome this, a consensus statement for adults has been developed by a virtual consultation subgroup of the ICS Nursing committee and an expert panel using a modified Delphi Approach[359]. No universal definition of bladder training or bowel training was found, therefore a consensus definition was developed and agreed for each. Limited high-quality studies of bladder training were identified but no studies investigating the use or effectiveness of bowel training for urgency faecal incontinence in adults were found. It is hoped that the consensus statements will support healthcare practitioners to design and develop consistent bladder and bowel training and enable future research. The International Children's Continence Society (ICCS) have also developed a standardization document for the definitions, indications and practice of urotherapy in children and adolescents[360].

Halpert et al performed a literature review on patient provider interactions and patient education in those with irritable bowel syndrome (IBS)[361]. Several IBS educational approaches have been studied ranging from self-help interventions such as guidebooks to cognitive behaviour-based self-management, and one versus multiple sessions of IBS education, alone or as part of a multicomponent intervention. They reported that even a brief one-time psycho-educational group intervention in the form of an IBS class, consisting of information on diet, a healthy lifestyle, and general information regarding pathophysiology and IBS symptoms, is efficacious in changing cognitions and fears about IBS and in improving disease-related quality of life. According to findings from a focus group study, obtaining information from people who have UI and their carers may be useful in helping these individuals to develop self management tools that women could use on their own in the future[67].

Not all studies had positive results from patient education. Landbrotndtner et al found that that in a real world clinical setting, the development of pathways which included a patient education programme for those with IBS was less effective than expected[362].

Another study showed that intensive education about UI related to radical prostatectomy for cancer did not lead to better continence outcomes following surgery[363]. Therefore, educational efforts alone may not be sufficient to yield successful outcomes. Further research to establish whether there are any measures alongside education for patients that will promote the best outcomes is required. Investigation into how, when and where education is being delivered to patients and the role of the family involvement in education may also be enlightening.

3.2. Public Education

Recently there has been a substantial increase in publications related to public education for incontinence. These have broadly focused on several areas including knowledge and perceptions about incontinence and associated conditions, development and dissemination of public education or programmes related to continence, and the availability and quality of social media and elec-

tronic applications for public education on continence and related topics. Many of these have already been discussed earlier in the chapter under continence promotion and help seeking behaviour, alongside a review of the challenges in the validity of the content of this information.

A challenge for all public education is in the terminology used in the content. In a review by Williams et al, 44 focus groups were conducted across seven US states with adolescent and adult women to explore lay language and discourse related to bladder health and function[364]. They reported a definitional discordance between medical and lay views of bladder problems, suggesting a need to clarify the meaning of medical terms for lay persons.

Du et al undertook a review of patient education materials on female pelvic floor disorders available online from a variety of National / International Organisations[365]. They found that most of the materials evaluated were written at a minimum of high school level and were above the target readability recommended by the National Institutes for Health and Joint Commission. Providing information in a format and at a level that enhances comprehension of the material is essential to promote continence and improve patient care.

Innovations in public education treatment programmes for UI and associated conditions incorporated technology applications[366]. Delivery of a PFM programme via the internet was found to be more effective at one year among those with initial short-term improvement in symptoms, increasing age, and among those who continued regular PFME[367]. Other researchers have shown a mobile app was effective in helping train women with SUI about PFME and could be useful to enhance education about the condition[368]. Another study of 41 women demonstrated that an avatar based online educational programme was effective in improving health related quality.

4. CARER / CAREGIVER EDUCATION

4.1. Professional caregiver education

Very little evidence is available regarding carer or caregiver education. In a recent ICS white paper on ethical considerations in older adults with UI, it is acknowledged that in intimate continence care for older adults with cognitive impairment, caregivers require advanced knowledge and skills to manage the care interaction in ways than minimize the risk of harm to both the carer and to the care recipient, while also protecting the person's dignity and providing good continence care[369].

The 'Dignity in Continence Care Framework' is a theoretical framework developed by Ostaszkiewicz, which suggests strategies for the future education of nurses and formal care workers supporting care dependent individuals about continence care[370]. It suggests an educational program based on seven learning outcomes:-

1. To develop an empathic understanding about the range of human emotional responses to incontinence and care-dependence, and to recognize the effect of these responses on behaviours
2. To discuss practices that dignify a care dependent person with continence care needs
3. To describe a person-centred approach to continence care for cognitively impaired care dependent individuals
4. To demonstrate therapeutic communication strategies that build a care dependent person's resilience, and promotes their physiological and psychological wellbeing
5. To describe strategies that promote a partnership-centred approach to continence care that affirms the relationship between a care dependent person and their family
6. To conduct a foundational continence assessment
7. To describe practices that represent targeted and individualized partnership-centred continence care.

This education program is currently being developed and trialled, but results were not available at the time of publication.

4.2. Informal caregiver education

These is a paucity of data in the understanding of the educational needs of informal care givers. It has been reported that informal caregivers under reported their care recipient's UI and needed substantially more support from HCPs to manage the condition[371]. Yet it has also been reported that a third of professional care givers do not know how to teach family members about incontinence and this may represent a significant barrier to the continence care that the family can provide[372].

For many family members continence education is provided by national charities / advocacy organisations. An example of this are the parent/carer workshops that are run by ERIC, The Children's Bowel and Bladder charity[373].

5. CLINICAL GUIDELINES

An extensive array of clinical guidelines related to the evaluation and management of urinary and fecal incontinence have been published. These have been developed and disseminated by a wide variety of professional and public health groups, with each guideline tending to focus on specifics unique to the given field connected with the development group. In many ways, guidelines serve as a form of enduring professional education. They are essentially a collection of mostly evidence-based information that is used to create standardized methods of assessment and treatment for a given condition or set of clinical problems.

Since the last ICI, none of the previously published clinical guidelines have been formally retired or discontinued. However, some guidelines have been updated or expanded, and several other new guidelines have been published.

Drake et al published an update summarizing the International Continence Society fundamentals of good urodynamic practice[374]. This is the standard to which urodynamic studies should be conducted and includes information on both study technique and reporting methods. Another guideline has made recommendations for urodynamics in patients with spinal cord injury[375]. The International Children's Continence Society also published a recommendation on standardization of urodynamic studies in pediatric patients[376].

The UK Continence Society (UKCS) published a guideline summarizing the minimum standards for continence care in the UK in adults[377] and in paediatrics[378]. This took a multidisciplinary and multiprofessional approach to continence care and management. The document includes recommendations for standardization of education and training, clinical care, and a framework for service delivery.

It is broad and extensive in scope and covers both urinary and fecal continence topics.

The prior AUA/SUFU guideline on non-neurogenic overactive bladder in adults was updated in 2019[379 380]. The main change was that pharmacological therapies were changed from second line to an optional part of first line therapy in combination with behavioral measures. This reflects modern practice as many practitioners and patients chose this option at the time of initial treatment. The AUA/SUFU guideline on surgical management of female stress urinary incontinence was also updated[381]. This evidence-based review incorporated new surgical techniques and methods and removed some that are now considered outdated. Finally, the AUA and SUFU jointly developed a new guideline related to incontinence after prostate treatment including the full spectrum of prostate care[382]. This includes information on risk factors, patient assessment prior to and after prostate interventions, and a stepwise approach to therapies. Several algorithms are included related to patient evaluation, surgical management and device failure for artificial urinary sphincters and other devices.

The Japanese clinical guideline regarding female lower urinary tract symptoms was also updated in the interim[383]. This incorporated new evidence-based data that was developed since the prior publication in 2013.

Although use of mesh and other implanted materials remains controversial in some aspects of surgical treatment for female incontinence and pelvic organ prolapse, there continues to be ongoing research. Two consensus statements have been published on the topic since the last ICI[384 385].

One of the new condition-specific guidelines examines management of bladder dysfunction in patients with Parkinson's disease and with other forms of gait pathology[386]. Voiding dysfunction and other continence issues are common in this condition, and this provides recommendations for management. It also includes information that helps differentiate Parkinson's disease from other conditions such as multisystem atrophy (MSA). Collaboration between neurologists and urologists is highlighted.

The Wound Ostomy Continence Nursing Society (WOCN) published a clinical guideline focused on the management of adults with fecal and/or urinary ostomies[387]. This comprehensive guideline includes recommendations on pre- and postoperative patient education, stoma site marking, selection and use of appliances and pouching systems and other aspects of stoma care and quality of life. A similar guideline was also published in Italy[388].

Several guidelines have examined issues related to fecal incontinence. This includes a European consensus statement on the use of sacral neuromodulation for this condition[389]. A two-part Japanese guideline examines definitions, risk factors, epidemiology, quality of life questionnaires, methods of evaluation and conservative measures for therapy[390 391]. Fecal incontinence in children was also addressed by the International Children's Continence Society[392].

A summary article examining published guidelines for urinary incontinence in women was recently published[393]. This was a structured literature review which identified guidelines on the topic and synthesized information in a single document. This provides a succinct resource for researchers and clinicians seeking more information on the diversity and range of published guidelines for female urinary incontinence.

Several guidelines on pediatric continence issues have been published or updated since the last ICI. This includes the guideline from the ICCS on nocturnal enuresis, one on treatment of daytime incontinence and one in neuropdevelopmental disorders and incontinence in children and adolescents[394 395 396]. NICE guidelines on urinary tract infection and constipation have also been published[397 398]. There is also a new two part guideline from the European Association of Urology (EAU) and the European Society of Pediatric Urology (ESPU) on both the conservative and surgical management of neurogenic bladder in children and adolescents[399 400] Overall, this advocates a proactive approach to care and supports surgical management in select patients but notes a relatively high revision rate of 50% overall.

The Canadian Agency for Drugs and Technologies in Health published a review of available guidelines on long-term indwelling urinary catheters[401]. This included several scenarios which highlighted both accurate indications for use, and examples of misuse.

Vaginal hormone replacement therapy and other non-hormonal treatments are frequently prescribed for treatment of atrophic vaginitis, vulvovaginal atrophy, and prevention of recurrent UTIs. A new clinical guide on this topic was recently published by the European Menopause Andropause Society (EMAS)[402]. They note that this can be useful in select patients with mild urinary incontinence symptoms. This group also recently published an evidence-based guideline that summarizes treatment options for urinary incontinence in postmenopausal women[403] which includes the full spectrum of options including behavioral measures, diet modification, pelvic floor exercise, pharmacologic treatments, neuromodulation and chemodenervation of the bladder, and various surgeries.

Unfortunately, there has been little substantive research in the interim since the last ICI examining how guidelines are used, and the degree to which clinicians tend to follow guidelines in actual care settings. This would be important and could provide valuable insight into how practical guidelines really are in daily practice, and if they ultimately make a demonstrable difference in patient care outcomes.

Summary

Professional continence education across disciplines and specialties remains variable. Many health care providers do not receive formal education on UI, FI, or other continence-related topics as part of their general education and for those who do, many feel that it is insufficient. There is an ongoing need to continue to expand and evaluate educational offerings on topics related to continence and bladder and bowel health across all levels of training and for both generalist and specialist professionals. Virtual platforms and simulation training may prove to be valuable tools in times where classroom-based learning is challenging, but also as a way to reach a wider audience and provide an 'on-demand' education that allows flexible learning around individual schedules.

Public education directed toward patients, clients and consumers is an important part of the overall spectrum of information and dissemination of continence promotion. This can take many forms ranging from the provision of health information between health care providers and individual patients to public service announcements and other mass media communications. Although there has been a recent increase in public education efforts, research in this area is still in its relative infancy.

Methods of guideline dissemination are variable, and clinician awareness of guidelines can be a challenge. It can also be difficult to make clinical choices in cases where different guidelines may provide conflicting recommendations. Future work is needed to continue to assess existing and new guidelines, methods of guideline dissemination, ways to improve awareness of guidelines, and techniques to continually improve practice, along with a need understand the impact of clinical guidelines on patient outcomes.

Levels of Evidence/Recommendations

- Professional and public education of UI, FI and POP is not evidence based on the materials reviewed (Levels of Evidence: 3-4)
- There is a need for research on both educational content and methodology across all disciplines, particularly as the emphasis on primary care education increases and the opportunities for exposure to targeted content decreases (Recommendation Grade C)
- There is a need for additional research on interdisciplinary and team education, virtual education methods, and hands-on and simulation training related broadly to continence care (Recommendation Grade C)
- There is a need for additional focused research on methods to enhance patient and public education about UI, FI and POP, both at an individual and broader public level (Recommendation Grade C)
- Research is needed to examine methods to improve efficiency of public education including group training, mass marketing, and other techniques (Recommendation Grade C)
- The role of technology in public education for continence promotion should be examined in more depth (Recommendation Grade C)
- Future research methodologies should incorporate the standardised methods and definitions as set out in new consensus and standardisation documents (Recommendation Grade C)
- Guidelines for various aspects of continence evaluation and management have been established (Levels of Evidence: 3 to 4)
- There is a need to continue to evaluate the quality and relevance of existing clinical guidelines, particularly in the context of updating these materials or creating new guidelines based on emerging evidence (Recommendation Grade B)
- There is a need to continue to evaluate the quality and relevance of existing clinical guidelines, particularly in the context of updating these materials or creating new guidelines based on emerging evidence (Recommendation Grade B)
- There is a need for additional research on guideline dissemination, awareness and adoption among clinicians, and the impact on a wide range of outcomes including incidence and prevalence of disease, treatment efficacy, prevention efforts, costs, and health care policies (Recommendation Grade C)

VII. CONCLUSIONS

Continence promotion involves many different components including primary prevention strategies, health care advocacy, and methods of encouraging help-seeking behaviours. It also includes development of models to enhance provision of and access to health care in a wide variety of settings ranging from community programmes, to facility-based and institutional programmes, to widespread governmental initiatives. Education, of both health care providers and the public remains a cornerstone of successful continence promotion. Although there has been an increase in attention to these topics in recent years, additional work will be needed to actively advance our knowledge and to foster future progress.

APPENDIX 1

Primary Prevention
Online databases Pub Med, Cinahl, Pychinfo, and Medline were searched, with focus on literature published in and after 2010. Search terms used (aware* OR educat* OR promot* OR instruct* OR interven* OR teach* OR learn* OR lifestyle OR behav* OR change*) AND prevent* AND (incontinen* OR continent* OR continence*) NOT continental Sort by: Relevance Filters: Publication date from 2011/01/01; Adult: 19+ years

Continence Awareness, Promotion and Advocacy:
Online databases Pub Med, Cinahl, Pychinfo, and Medline were searched, with focus on literature published in and after 2016. Search terms used: 'awareness', 'consumer', 'education', 'urinary incontinence', 'faecal incontinence', 'incontinence', 'continence', 'continence awareness', 'continence promotion', 'health education', 'public education', 'public awareness', 'pelvic organ prolapse', health literacy, health promotion', 'outcome measures'

Continence Promotion Programmes: Online databases Pub Med, Cinahl, Pychinfo, and Medline were searched, with focus on literature published in and after 2016. Search terms used: 'awareness', 'consumer', 'education', 'urinary incontinence', 'faecal incontinence', 'incontinence', 'continence', 'continence awareness', 'continence promotion', 'promotion programme', 'health education', 'public education', 'public awareness', 'health literacy', 'health promotion'

Continence Advocacy: Online databases Pub Med, Cinahl, Pychinfo, and Medline were searched, with focus on literature published in and after 2016. Search terms used: 'awareness', 'consumer', 'urinary incontinence', 'faecal incontinence', 'incontinence', 'continence', 'continence promotion', 'promotion programme', 'public awareness', 'advocacy', 'consumer awareness', 'continence advocacy'

Patient advisory groups: Online databases Pub Med, Cinahl, Pychinfo, and Medline were searched, with focus on literature published in and after 2016. Search terms used: 'patient advisory groups', 'patient advisory groups' AND 'bladder' OR 'bowel' OR 'continence' OR 'incontinence' OR public floor

Awareness in Children: Online databases Pub Med, Cinahl, Pychinfo, and Medline were searched, with focus on literature published in and after 2016. Search terms used: 'children' AND 'continence' AND 'awareness'

Help-seeking (care-seeking) behaviour:
Search of pubmed /embase /cinahl/psyc /psychlit/eric/biosis /Scopus/Cochrane /WOS/JBI was conducted for the years 2011 to 2016. The search terms for each search were: PUBMED: (((health*[tw] OR care[tw] OR help[tw]) AND (acceptance[tw] OR accepting[tw] OR accept[tw] OR seek[tw] OR seeks[tw] OR seeker[tw] OR seeking[tw])) OR "Patient Acceptance of Health Care" [Mesh] OR "help-seeking"[tw] OR "care-seeking"[tw]) AND ((incontinen*[tw] OR continen*[tw]) NOT continental) AND ((Adult[Mesh]) OR adult*) CINAHL/PSYC/ERIC: ((TX (health* OR care OR help) N5 (acceptance OR accepting OR accept OR seek OR seeks OR seeker OR seeking)) OR (MH "Help Seeking Behaviour") OR (TX "help-seeking" OR "care-seeking")) AND (TX (incontinen* OR continen*) NOT continental) AND (MH "Adult+" OR TX adult*) FROM 2011 EMBASE: health*:ab,ti OR care:ab,ti OR help:ab,ti AND (acceptance:ab,ti OR accepting:ab,ti OR accept:ab,ti OR seek:ab,ti OR seeks:ab,ti OR seeker:ab,ti OR seeking:ab,ti) OR 'help-seeking':ab,ti OR 'care-seeking':ab,ti OR 'help seeking behaviour'/exp OR 'patient acceptance of health care'/exp incontinent OR incontinence OR continence NOT continental 'adult'/exp OR adult*#9 AND #10 AND #12 AND [2011-2016]/py WOS: ((health* OR care OR help) AND (acceptance OR accepting OR accept OR seek OR seeks OR seeker OR seeking)) OR TOPIC: ("help-seeking" OR "care-seeking") Refined by: TOPIC: (incontinence OR incontinent OR continence OR continent) AND TOPIC: (adult* OR man OR woman OR men OR women) Timespan: 2011-2016. REFERENCES **2102**

I. INTRODUCTION

Urinary and faecal incontinence and prolapse are problems that affect many people in society. Not only do they cause considerable distress to those affected and their families but there are significant impacts on both quality and quantity of life. In addition to the impacts on health and wellbeing, these conditions impose a considerable cost to individuals and families, health services and society in general. The magnitude of these costs is not precisely known but cost of illness studies (see section on types of economic studies below) have estimated that in 1995 the annual costs of urinary incontinence in both men and women was over USD 26.2 billion(1) Roughly, 50% of this cost was related to stress urinary incontinence and 35% fell directly on those with stress urinary incontinence (mainly from the purchase of containment products and cleaning)(1,2).

Since then, this cost would have increased substantially due to an ageing population and price inflation. These financial costs do not fully reflect the health impact. Villoro (2016)(3) estimated that in Spain alone over 350,000 quality-adjusted life-years (QALYs) were lost due to UI amongst women 60 years of age and older. Assuming that each QALY is valued at USD 50,000 then the cost to Spanish society would be USD17.5 billion (in 2019 USD). With respect to overactive bladder associated with urinary incontinence a recent cost analysis of estimated a total annual direct of health care cost in 2007 of $65.9 billion with projected cost of $76.2 billion in 2015 and $82.6 billion in 2020 for overactive bladder associated with urinary incontinence(4) .

For faecal incontinence the prevalence in the general population is 2-3% but for people aged over 65 years and living in a care home it is 40%. It has significant social, psychological, and economic ramifications(5-8). Incontinence can compromise quality of life for patients with concomitant significant impact on patient's families, caregivers, friends, and the healthcare team. As the general population grows, the prevalence of faecal incontinence is expected to grow(8,9) which will result in a substantial increase in economic burden both on patients and society. The full economic cost of faecal incontinence is not clear with few new data available in the last twenty years) (10). A 1995 estimate of community-based healthcare cost for faecal incontinence exceeded $11 billion annually in the United States(5). If adjusted for the rate of inflation, the comparative 2021 annual rate of healthcare cost for faecal incontinence would exceed $19.1 billion per year.

With respect to pelvic organ prolapse it has been estimated that in the US roughly 9.2 million women will be affected by pelvic organ prolapse by 2050(9), with approximately 300,000 undergoing surgery each year at a cost over US$1bn. Similar estimates for a European context were provided by Subramanian (2009)(11) who estimated that the annual cost of managing pelvic organ prolapse in 2005 Euros was €144m, €83m and €81m in Germany, France and England, respectively.

These costs illustrate that as societies we devote considerable resources to the management of these conditions. The question that arises is could we use these resources in a better way? We need to ask this question because regardless of which country we live in, the resources available to provide health care are not sufficient to meet all the many different needs that exist. This means that we need to make choices about what we do and what we do not do. One criterion which might be used to inform a judgement is the economic concept of efficiency. An efficient allocation of resources occurs when we allocate the resources we have available to maximise the benefits. This situation occurs when the benefits we obtain from using the resources one way are greater than those we would have obtained in the next best alternative use of these resources. This gets us to the economic definition of cost, where the cost of using resources in one way is that we give up the opportunity to use the resources in other desirable ways.

This chapter starts with a summary of the findings from the preceding consultation. It provides key background material to help the reader understand the methods used in economic evaluation (Section III) before summarising the finding of economic evaluations published since the preceding consultation (Section IV). Finally, it concludes with a summary and future research priorities (Section V).

II. SUMMARY OF THE MAJOR FINDINGS FROM THE PRECEDING CONSULTATION

The last edition of this chapter found that very few studies estimated lifetime costs and benefits. When comparing treatments that had very different initial treatment costs, this could create a bias towards treatments that have lower initial costs (behavioural or pharmacological treatment), as opposed to treatments that are initially expensive (surgical). When considering the results of all identified studies this needs to be borne in mind.

The following sub-sections summarise the evidence from the last edition.

1. STRESS INCONTINENCE AND OAB

1.1. Behavioural therapies

There were seven articles identified that evaluated economic aspects of behavioural techniques. The evidence suggested that behavioural programs were more costly than usual care. However, it remained unclear if they provided value in part because there was heterogeneous adherence to these treatments between studies. Some studies reported improved continence (measured using pad tests, pads used per week, post void residual, functional impairment measure, and the ICIQ(12) . However, these impacts were not reflected in measures of health-related quality of life measured using generic tools, such as the EQ-5D. This raised questions whether these generic instruments were sufficiently sensitive to small but important changes or whether these changes were actually important to patients. Consideration is also needed as to whether initial treatment with less costly (and less intensive) care followed by more intensive options for non-responders is worthwhile economically. The use of incentives to encourage adherence to, and maintenance of these behavioural therapies may also have value.

1.2. Surgery for stress incontinence

Thirty-five new papers were identified in the prior search related to the economics of surgery for stress incontinence. Most studies lacked end point data beyond 12 months on costs or effectiveness. Many studies also only compared different surgical treatments to each other. Thus, in general, given the follow-up time frame and the restricted set of treatment comparisons, it made it very difficult to make statements about the cost-effectiveness of surgical treatments compared to non-surgical treatments.

Studies were quite heterogeneous in terms of the type of comparison made. For example, one study(13) looked at the use of pre-operative urodynamic testing for sling surgery and concluded that there are times when it is overused and other times when it is underused both of which could affect the cost and effectiveness of care. Other studies considered issues of surgical timing and were not excluded from the last consultation.

Included studies were both trial and model based (see Section III.5) comparing surgical treatment such as mid-urethral sling (MUS), single incision mini slings to non-surgical interventions such as surgery to PFMT. The focus of many of the papers identified from the consultation was the comparison of similar surgical techniques utilizing a substitute material (e.g., a commercial sling versus a handmade sling).

Unfortunately, many of the identified studies presented weak evidence, made unwarranted conclusions, were unclear in presentation, or made errors in calculations. One notable error identified in more than one study was in the calculation of the incremental cost-effectiveness ratio; which is critical when assessing relative efficiency (see Section III).

1.3. Surgery for urge incontinence and refractory OAB

Two primary treatments for urge urinary incontinence and refractory OAB were identified: sacral nerve stimulation (SNS) and Botulinum Toxin A. The studies compared cost-effectiveness of SNS to Botulinum Toxin injection, and to oral medical treatment (14,15). In addition, two publications looked at economic aspects of different SNS test phases(16,17). The results of the different mid- to long-term cost-effectiveness analyses supported a therapeutic pathway starting with SNS compared to Botulinum Toxin injection(18,19). Reducing need for hospitalisation (e.g., local instead of general anaesthesia) and optimal lead placement (e.g., less need for revision, lower amplitude for stimulation) appeared to be important influencing factors. The Committee reiterated the need to collect primary data for quality adjusted life year (QALY) outcomes in future studies of SNS.

1.4. Pharmacotherapy of stress incontinence

No pharmacotherapy cost-effectiveness analyses for stress urinary incontinence (SUI) were identified as in the last report. This was consistent with the lack of available approved pharmacological therapies for stress incontinence.

1.5. Pharmacotherapy Urge Incontinence and OAB

A few cost-effectiveness (CEA) and cost-utility (CUA) analyses (see Section III for explanation of these types of analysis) on commonly used pharmacological treatments for overactive bladder and urgency urinary incontinence were identified. Treatments considered included oxybutynin (Ditropan®) as a tablet or as a patch (Oxytrol®); tolterodine (Detrol®), darifenacin (Enablex®), trospium (Sanctura®), solifenacin (Vesicare®), fesoterodine (Toviaz®), and mirabegron (Myrbetriq®). Most of the studies were funded or performed by individual pharmaceutical manufacturer creating a strong possibility of potential conflicts of interest. Other common limitations included the use of incontinence-specific utility measures, limited time frame and limited comparison to alternative treatments. The previous consultation highlighted the fact that while industry funded studies often include experts in performing CEA and can use, on first sight, sound methods, they must be interpreted carefully for the possibility of bias. For example, the selection of assumptions included in the models like the values used for the probability of events (e.g., drug response, likelihood of transitioning to a different treatment strategy, probability of side effects or adverse events), timeframe, costs and perspective can all be chosen to have subtle (or not so subtle) but cumulatively important impacts on estimates of cost, effects and cost-effectiveness.

2. PROLAPSE TREATMENTS, COST IMPLICATIONS

Newer surgical approaches for POP identified in the last report included laparoscopic sacrocolpopexy, robotic sacrocolpopexy, and vaginal mesh. It was assumed that these new modalities may include very costly capital investments in equipment (such as robotic systems), use expensive disposable instruments, use costly mesh kit products, take longer (or shorter) operative time, and/or be associated with (more or less) adverse events and future procedures. They might also be associated with shorter hospital stay and more rapid recovery. Therefore, cost-effectiveness was well suited for these modalities and several economic analysis studies were identified.

The identified studies included a retrospective cross sectional longitudinal study(20) whose findings could not be elucidated, two cost minimisation studies(21,22) that compared robot-assisted with open sacrocolpopexy and laparoscopic sacral colpopexy (LSC) with total vaginal mesh, a systematic review(23)that included only randomized controlled trials (2 trials, n = 156) comparing laparoscopic and robot-assisted sacrocolpopexy (heterogeneity between the two studies precluded a meta-analysis)(24) among other studies.

The meta-analysis studies showed that robot-assisted sacrocolpopexy was costlier than laparoscopic sacrocolpopexy with similar clinical outcomes. The results of the systematic review that had small, randomized studies, suggested that robotic surgery significantly increased cost compared to the conventional laparoscopic sacrocolpopexy with no improvement in outcome. A decision-analytic model was developed to assess the cost-effectiveness of abdominal sacral colpopexy (ASC) vs. sacrospinous ligament fixation (SSLF) to determine if the improved outcomes of ASC justify the increased expense(25). In this study, abdominal sacrocolpopexy was a cost-effective alternative compared with sacrospinous ligament fixation.

The committee concluded that by standard thresholds, abdominal sacrocolpopexy (ASC) may be cost-effective compared to sacrospinous ligament fixation (SSLF) and performing a mid-urethral sling with ASC may be cost-effective compared to ASC alone. Mesh-augmented anterior vaginal wall repair was not cost-effective compared with a non-mesh fascial plication repair and pre-operative screening for endometrial cancer before prolapse surgery is likely not cost effective in asymptomatic, postmenopausal women. They also highlighted the fact that in the field of prolapse, it was not yet known whether any currently available health status measures were sensitive to treatment benefit, so that CEA may still not be feasible in this area.

3. ECONOMIC CONSEQUENCES OF FAECAL INCONTINENCE

3.1. Prevention

Two costing studies(26,27) were identified but there was only one cost-effectiveness analysis(28) that compared cost-effectiveness of primary sphincter repair versus delayed sphincter repair for anal

Society. This is potentially the widest approach. It would include productivity effects and health effects as well as costs and effects that fall both in and outside the health care sector. It can be difficult to identify, measure and value all costs and benefits, so it is more common to see costs that fall on the health care sector, patients and productivity effects (this perspective is recommended by several health care regulatory organisations internationally)
Health and care systems (common in studies conducted in several European countries). Here the focus is on costs to the health care system and health outcomes measure in clinical units (e.g., numbers cured) or QALYs. This is the recommended perspective by the National institute of Health and Care Excellence in the UK
Patient. Here the focus might on costs and outcomes most relevant to the individual patient so it might include out of pocket expenses (directly purchased health care and co-payments), insurance premiums. It may also include costs to the individual of time away from work or reduced ability to carry out normal activities – so lost in wages and incomes and lost leisure time
Health service payer. This shares similarities with the health care system perspective but where in the health system perspective we consider all costs that fall on the health system here we would only include costs that fall on an individual payer. For example, if the payer is an insurance company, then this perspective would exclude costs falling on others (like patients). The costs considered would not be the cost of producing health care but the cost of purchasing it (i.e.), the charge that may be much higher. Outcomes may be measured in a variety of different ways (see types of economic study below)
Health Care provider. If it is only a single provider, the focus is on the production cost of care to that provider. It excludes costs falling on other groups (other care providers, patients, etc). Outcomes can be measured in a variety of different ways (see types of economic study below).

Box 1: Common perspectives taken in Economic Evaluation

sphincter injury in the prevention of faecal incontinence. The study concluded that primary sphincter repair was the most cost-effective strategy being associated with 5.72 QALYs for a cost of £2750 compared with delayed sphincter repair, which yielded 3.73 QALYs for a cost of £2667 over ten years.

3.2. Treatment

Cost-effectiveness analyses on the treatment of faecal incontinence primarily focused on sacral nerve stimulation (SNS) as a first-line surgical treatment for patients with faecal incontinence. The studies that were identified for SNS compared to conservative treatments had mixed reviews. Three studies assessed the cost-effectiveness of sacral nerve stimulation in comparison with other surgical treatments. The strength and weakness of these studies were noted, and the committee acknowledged that it was encouraging to see economic analyses of Sacral Nerve stimulation for faecal incontinence. However, more data about long-term cost-effectiveness in faecal incontinence were urgently needed.

4. SUMMARY AND FUTURE RESEARCH PRIORITIES

The committee noted that some high-quality economic analyses had been published. They attributed this to the requirement for cost-effectiveness data from NICE and other similar bodies. This along with standardization of methods in trial-based analyses had led to higher overall quality. As regards methodology, they noted that researchers needed to consider carefully how they construct the model-based analyses so that that “real life” assumptions are made. Finally, the committee encouraged researchers to provide information on the uncertainty around an incremental cost-effectiveness ratio (see Section III.6 on sensitivity analysis).

III. IMPORTANCE OF ECONOMIC EVALUATION

1. INTRODUCTION

As the previous section illustrates, economic evaluation has the capacity to inform judgements about the opportunity costs of using health care resources in a given way. Economic evaluation has been defined as the “comparative analysis of alternative courses of action in terms of their benefits (e.g., health effects) and costs (e.g., the resource use)(29).” The types of economic evaluation are described in more detail in the next section, but all involve the same three steps:

- Identify
- Measure
- Value

Critical to this process is once the interventions to be compared have been clearly defined, is to define which costs and benefits are important to the decision-maker. There is no single right answer about which costs and benefits are important rather this is dictated by who the decision-maker is. Therefore, in any economic evaluation it is important to define the perspective. Different studies may adopt different perspectives, and this can affect the conclusions that are drawn. Typical perspectives are set out in Box 1.

2. TYPES OF ECONOMIC ANALYSIS

There are several types of economic analyses that can be conducted for health and medicine. The analyses apart from cost of illness studies, aim to provide information about a choice (or set of choices). The methods to assess costs for the different types of economic analyses are the same but what differs is how outcomes are measured and valued.

2.1. Cost minimisation analysis

Cost minimisation analysis (CMA) compares the costs of alternative interventions which are known to have equivalent clinical outcomes. Outcome equivalence should be supported by clinical evidence. This analysis aims to establish which intervention has the lowest cost. A common problem with many published cost minimisation analyses is that outcome equivalence is assumed or based on the erroneous assumption that failure to detect a statistically significant difference is evidence that there is no difference between interventions compared.

2.2. Cost-effectiveness analysis

Cost-effectiveness analysis (CEA) compares the costs and outcomes of alternative health interventions where outcomes are measured in terms of a single natural, or clinical measures. For example, one such outcome could be episodes of incontinence avoided. In a cost-effectiveness analysis, the effectiveness of treatments is reported relative to their costs. To do this the difference in (often called the incremental) cost and incremental effect are combined into a single metric known as the incremental cost-effectiveness ratio (ICER). The ICER is:

$$ICER = \frac{Average\ Cost_{\ 1} - Average\ Cost_{\ 2}}{Average\ Effect_1 - Average\ Effect_2}$$

Where, $_1$ and $_2$ refer to intervention 1 and Intervention 2 respectively. Whilst still being a very common form of economic analysis, over time the number of CEAs reported has decreased due to the previously published guidelines on the conduct of economic analyses produced by the Washington panel(30) or due to guidelines set by agencies that oversee reimbursement decisions.

2.3. Cost consequence analysis

A cost-consequence analysis (CCA) can be thought of lying in between a CEA and a cost utility analysis (CUA). In a CCA costs are equated against multiple consequences (for example episodes of incontinence, adverse events, need for further treatment, etc). There is no attempt to aggregate these effects into a single measure as there is in CUA and no ICER is calculated. Rather the goal is to present the trade-off between costs and the different outcomes.

2.4. Cost utility analysis

CUA compares the costs and outcomes of alternative interventions and measures health outcomes in terms of both quantity (life years) and quality of life. This analysis is a variation of cost-effectiveness analysis. Effects are commonly reported in terms of outcomes such as quality-adjusted life years (QALYs) or disability adjusted life years (DALYs)(31). The former is more commonly used in high income countries, with the latter more commonly used in low and middle income country settings. The advantage of the QALY is that it combines gains from reduced morbidity (quality gains) and reduced mortality (quantity gains) into a single measure. The value of a given health state is measured in utilities (see Section 5.2 below) which represent the preference for a given health state relative to other health states

CUA shows how an intervention extends people's lives (life year gains) and improves the quality of life compared to alternative options. The use of QALY as a measure of health outcome enables comparisons to be made across disease areas, and thus are particularly useful for broad-based resource allocation decision-making.

2.5. Cost benefit analysis

CBA measures both costs and effects of interventions in the same units, normally monetary. With this type of analysis, health (and potentially other benefits of health care) has a monetary value placed on them. This monetary value might be based upon someone's productive worth or by estimating willingness to pay for the specific health care or intervention. There are challenges in valuing benefits in this way. For example, great care would be needed when valuing benefits based on someone's productive worth as such an approach can systematically bias against those on lower wages and salaries. In general researchers and policy makers can be averse to placing a monetary value to life. Furthermore, many published studies that purport to be a cost benefit analysis do not attempt to measure the benefit of care but rather equate costs with monetary savings – this makes them cost analyses only.

3. MEASURING AND VALUING COST

3.1. Which costs to include?

Economic evaluations need to identify all the important and relevant costs of alternative interventions(29,32). A common pitfall in economic evaluation is losing sight on what costs should be measured. The key is understanding the opportunity costs. As described in Box 1, the perspective of a study should inform what specific costs are appropriate to include in the analysis. Which perspective should be adopted depends upon where differences are expected to be incurred and what costs are relevant to the decision-maker. In CMA, CEA, CUA and CBA identical costs can be excluded as they would not contribute to the difference in costs.

3.2. Correcting for the effects of inflation

When estimating costs, we often measure the direct costs that are closely related to healthcare and any type of care because of illness. The easiest way to present costs is relative to a specific year (e.g., 2020). However, as costs change over time, this needs to be accounted for in the analysis. Costs incurred in previous years should be inflated using published inflation indices such as the US Consumer Price Index (www.stats.bls.gov) or the UK Health services cost index or the Retail Price Index (www.statistics.uk.gov).

3.3. Discounting future costs

When costs occur is also important to consider in an economic analysis. People tend to prefer to receive income now but to defer costs until the future. What this means is that costs (and savings) that occur in the future are given less weight in an economic analysis as compared to costs that occur in the present.

People have time preference for money and futures costs should be discounted to represent present value. Investment in preventative healthcare reduces the possibility of costlier problems in the future. Economic analyses use discount rates to estimate the net present value of future costs. There is some debate about the appropriate discount rate(33-35) but many international studies use a discount rate of 3-5% per annum.

4. MEASURING AND VALUING HEALTH BENEFITS

As described in Section 3 above, the nature of assessing benefits between the different types of economic evaluation varies consid-

erably. This section focuses on how health benefits are measured. This is because there is an increasing interest in the use of patient reported outcome measures more generally in health research but also that these measures can be used in CUAs.

4.1. Health status and quality of life measures

There are several validated health status measures that are frequently used which describe an individual's current health state. These instruments are referred to as heath related quality of life (HRQoL) measures and they can be either condition specific or generic. Condition specific measures, as the name implies are designed to focus on a specific condition and as such have limited or no applicability to other conditions. Generic measures in contrast are designed to measure impact of health across many conditions and as such can be used draw comparisons between treatments for different conditions.

With respect to incontinence there are numerous clinical measures used e.g., 24-hour pad test, voiding diary or urodynamics. These clinical measures can be useful, but they may reflect the impact of the condition or changes in the severity of that condition on an individual. It is for this reason a variety of validated condition specific HRQoL instruments for OAB, prolapse or incontinence are used (e.g., Incontinence quality of life (I-QOL)(36). Generic measures, for example EQ-5D(37) and SF-12(38), often consider a broad range of dimensions of quality of life using phrasing that make them relevant to multiple conditions. Although generic quality of life measures have broader applications, comparisons of treatments will usually require an algorithm to generate a summary score and not all measures have an algorithm.

Both condition specific and generic measures of HRQoL can be used in CEA (with results presented as the incremental cost per unit change in HRQoL or incremental cost per additional person achieving a minimally important difference), however, they can be of limited value for economic evaluation if their scoring algorithm is not based upon the preferences of patients or the public for health.

4.2. Utility measurement

A feature of CUA is the health effect considered including change in quantity and quality of life, with valuation of quality of life based on formal consideration of preferences for the health states(29). The

Instrument	Description
ED-5D	The most commonly used MAU instrument is the EQ-5D(37). The EQ-5D is made up of 5 attributes mobility, self-care, anxiety/depression, usual activities and pain/discomfort. In the original instrument (the EQ-5D-3L) each attribute has 3 severity levels: no problem, some problems and major problems. More recently, a new version, EQ-5D-5L, which has increased the number of severity levels for each attribute to 5 has been developed. Value sets can be identified from the tool developers' website (www.healthfoundationb.org) as can country versions of the questionnaires. It is also possible to convert questionnaire responses from the EQ-5D-5L into the older 3L value set using the results of validated mapping studies(40).
Short Form 6D (SF-6D)	This instrument is based on the popular Short form 36 (SF-36) and it can also be derived from the SF-12. The SF-6D consists of a multi attribute clarification system with six attributes: physical functioning, role limitations, social functioning, pain a, mental health and vitality, developed from information collected from the SF-36(41) questionnaire and a scoring table. The initial scoring model was developed using standard gamble methods on a random sample of the general population in the UK(42).
Health Utilities Index (HUI)	The HUI(43) consists of HUI2 and HUI3. The HUI2 classification system includes 7 attributes: Sensation, Mobility, Emotion, Cognition, Self-Care, Pain and Fertility – each with 3 to 5 levels. The HUI3 classification system comprised of 8 attributes – Vision, Hearing, Speech, Ambulation, Dexterity, Emotion, Cognition and Pain – each with 5 or 6 levels of ability/disability. Each has a health status classification system and a scoring formula based on standard gamble utilities measured from the general population. The scores are on the conventional dead (0) to health (1). HUI3 should be used as the primary analysis as it has the more detailed descriptive system, full structural independence and population norms. Whilst the HUI may be more sensitive for some conditions it is worth noting that the value set was derived from a Canadian population only.
15D	The 15D is a less commonly used generic, comprehensive, 15-dimensional, standardized, self-administered measure of health-related quality of life (HRQoL) that can be used both as a profile and single index score measure(44). The dimensions include breathing, mental function, speech (communication), vision, mobility, usual activities, vitality, hearing, eating, elimination, sleeping, distress, discomfort and symptoms, sexual activity, and depression. Each dimension is divided into 5 levels. The single index score (15D score) on a 0-1 scale, representing the overall HRQoL, is calculated from the health state descriptive system by using a set of population-based preference or utility weights.
Assessment of Quality of Life (AQoL)	The AQoL(45) is a multi-attribute utility measure for use in economic evaluation, measuring health-related quality of life. The AQoL measures 5 dimensions: illness, independent living, social relationships, physical senses and psychological wellbeing. Each has three items. The lower bound of the utility score is -0.04 and the upper bound is 1.
King's health questionnaire (KHQ)	There is also a mapping of the King's Health Questionnaire to utility weights, and the OAB-q questionnaire (46,47) (Brazier J et 2008, Yang Y. et al 2009). These mapped algorithms have shown responsiveness but, as with all tools, a significant difference does not imply a meaningful difference. For example, a 10 point increase from base-line has been suggested to represent a minimally important difference on the OAB-q(48).

Box 2: Summary of the more common HRQoL tools used as the basis for estimating health state utilities

measures of these preferences are typically described as health state utilities. To understand utilities, consider the following: most people would prefer to be healthy over a given period of time rather than suffer constant urinary or faecal incontinence. Utility measurement refers to valuing these preferences on a scale where the best state of health (normally taken to be perfect health) is score 1 with death scored as 0. For example, if the measured utility for urinary incontinence is 0.60 and treatment improves this to 0.70, then the value of the treatment is 0.70 – 0.60 = 0.10. If this utility gain is maintained over time, say for 10 years, then the gain is 0.10 x 10 = 1.00 QALY.

Utilities can be based upon condition specific or generic measures of HRQoL. The use of a condition specific measure allows a single metric combining quantity and quality of life to be estimated but is not best suited to compare across conditions e.g., compare treatments for faecal incontinence to with those to prolapse, if they have impacts on different dimensions of health. Generic measures however are routinely used compare the effect of interventions in different health fields, or different interventions within the same field. For example, the QALYs gained from treatment for incontinence could be compared with those gained from treatment for depression.

Direct and indirect methods have been used to elicit utilities(39). The most common direct elicitation methods for valuation include time trade off (TTO), standard gamble (SG), the visual analogue scale (VAS). For a description of these methods, see the previous chapter in this ICI series.

Indirect utility elicitation is frequently used in clinical research because it is low cost and easier for participants than direct elicitation. Most indirect measures are based on multi-attribute utility (MAU) instruments, which split HRQoL into health domains (e.g., mobility and emotions). Respondents provide estimates for each attribute, which are then 'valued' based on pre-defined weights and summarized into a single utility score. Table 1 summarises key aspects of commonly used instruments in incontinence and prolapse research.

5. TRIAL AND MODEL BASED ECONOMIC EVALUATIONS

The assembly of the data that is required for an economic evaluation can take the one of two stylised forms(29). First it can be collected as part of a single empirical study like a randomised trial. This is often called a within trial economic evaluation(49). The alternative approach is to take data from multiple sources and to integrate them into a mathematical model(50). These two approaches are best thought as being complementary and indeed some economic evaluations will include an element of modelling.

5.1. Within trial analysis

The International Society for Pharmacoeconomics and Outcomes Research (ISPOR) has issued guidance on within trial analysis(51). Trials themselves are designed to determine the relative effects (i.e., efficacy, effectiveness and safety) of interventions (i.e., new drugs, devices or ways) in delivering care. As estimates of costs, and cost-effectiveness can be thought of as just other measures of relative effect, it may be possible to integrate an economic evaluation into a study. This can have numerous benefits. First, a well-designed RCT can estimate marginal difference in costs and outcomes in an empirically unbiased manner. Second, the additional research cost and burden of collecting the economic data can be modest. Third, the data collected as part of a trial can be used to explore statistical imprecision surrounding costs, effects and cost-effectiveness. As cost-effectiveness is a ratio of two correlated measures, standard statistical tests like t-tests should not be used to do this. More frequently bootstrapping is used to estimate statistical imprecision.

However, not all RCTs are ideal candidates for incorporation of an economic evaluation. One reason for this is that the external validity of a trial (its generalisability) can be limited due to restrictive inclusion criteria. Exclusion criteria are often used to increase safety and improve statistical power; however, the results may not generalize to broader populations. There are pressures to balance a trial's internal validity and its external validity, and the Precis 2(52) provides tools for understanding factors that affect the internal and external validity (https://www.precis-2.org/). A second reason that may restrict a trial's usefulness is that the trial may not compare the most relevant alternatives, or the alternatives compared may not reflect current practice. A final issue is that the follow-up period of many trials is too short to capture all relevant costs and effects.

5.2. Model based economic evaluations

An economic evaluation model can be based upon a single empirical study, or a synthesis of multiple studies. Common arguments advanced for the adoption of model based economic evaluations include:

- Structure the economic question and compare all relevant alternatives
- Extrapolate beyond observed data
- Link intermediate and final endpoints (e.g., death)
- Non-availability of parameter estimates
- Generalise results to other settings/patient groups
- Use synthesised evidence and facilitate head-to-head comparisons where RCTs do not exist
- Enables all variability and uncertainty to be explored
- Indicate the need for further research

Reflecting on these bullet points are the 5 steps involved in building an economic evaluation model. The first step involves identifying the structure of the problem and this requires the listing of all decision alternatives, all clinical outcomes, the possible sequence of events, and the time over which the model will measure. Step two involves assigning probabilities to all chance events (e.g., death). Step three involves quantifying the benefits (e.g., QALYs) for all outcomes. The fourth step involves the mathematical calculation of expected value for each strategy in order to identify the preferred strategy. The final step involves conducting sensitivity analysis to check that the model is robust across a range of clinically meaningful possibilities. As an extension of this final step, it also identifies key areas for further research.

Every economic evaluation model involves some assumptions. Frequently, assumptions are needed to incorporate trial data in the model. For example, a common assumption is that the effect shown in a randomised trial is generalizable to the modelled population. Published economic evaluation models should include a table of assumptions along with other data inputs; frequently this is the first table in the study report.

The structure of the problem (step 1) often points to a specific type of economic evaluation model. A taxonomy of model types is provided by Brennan and colleagues(53) and has recently been updated(54). Common modelling approaches are: Decision trees; Markov models; Individual patient simulation models and discrete event simulations.

5.2.1. Decision tree analysis

Decision trees are so named because they look like a tree with a trunk, branches and leaves. They are best suited to addressing questions where there is no interaction between patients (e.g., the treatment of one patient does not affect the treatment of another) and for when events that might occur are not recurrent. In a decision tree, there is a distinction between a decision node and a chance node. A decision node is a point where a choice is made by the decision maker (typically a physician or patient). For example, for a woman with stress incontinence, the choice to operate (yes or no) would be represented with a decision node. A choice must have at least 2 mutually exclusive options; though a choice involving more than 2 options are possible. This means that a woman could not choose both an operation and no operation. A chance node is a point where chance determines what happens next. For example, if surgery is chosen, then there is a chance that the surgery will not be successful and a chance that it will be successful. The point where these two alternatives might occur is represented by a chance node. As can be seen from this case the two alternative changes must be mutually exclusive, and collectively be exhaustive (the surgery will either work or it will not). Collectively the probability of these two events happening must sum to 1).

In addition to chance and decision nodes, a decision tree also includes terminal nodes. These nodes are the final outcomes (the payoffs) for the pathway taken (e.g., cured/not cured, cost). What outcome is chosen will depend upon the type of economic evaluation conducted (see Section IV).

Once the structure of the decision tree has been defined then the next step involves identifying probabilities at each chance node. These data could come from a single empirical study or they might come from the published literature. In both cases consideration needs to be given as to whether these data are appropriate. Where data are obtained from the literature this should be systematically identified with clear inclusion and exclusion criteria applied so that problems of distorted assembly are avoided. In addition, where possible, the probabilities data on the distribution around these probabilities should be sought. For example, for surgery the probability of success might be 58% with a 95% CI 51-68%. If surgery were being compared to medical management, then the probability of success might be similarly estimated or if data from a trial or meta-analysis were available then a relative effect could be taken from there so that the probability of success for medical management is the probability of success for surgery multiplied by the relative effect size.

Once probabilities are assigned then values for both costs and outcomes must be assigned. These are measures of cost and effects must be assigned to the nodes. The effect measures used can be ones consistent with any of the forms of economic evaluation set out in Section III. With costs, effects and probabilities assigned, one can then "run" the decision tree. Running the model involves starting at each terminal node and working left or backwards. In the example below, the expected value for the surgical survival node is 3.8 QALYs (see Figure 1). A similar approach is used to work out the expected values for each of options that are decided between at the decision node.

5.2.2. Markov models

A decision tree can get very complicated if we need to consider costs and effects over time for a complex and changing condition. A person, for example, could get surgery for stress incontinence, but over time, we need to include the potential for surgical failure. One common approach to capture this is to use a Markov model. In

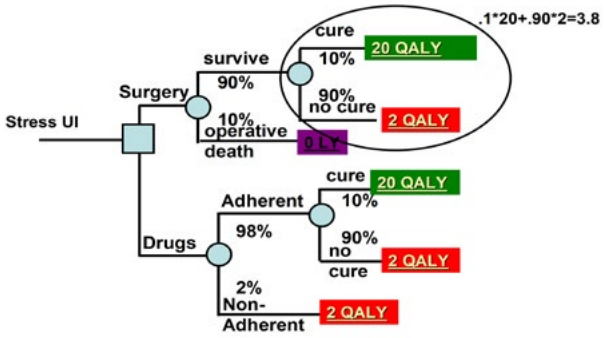

Figure 1: Example of a decision tree for the comparison of surgery with drug therapy for stress urinary incontinence

a Markov model, the pathways of care and changes in health over time for a cohort of patients is described as a set of mutually exclusive health states that the individual can move over time. The duration of time considered by the model is called the time horizon and it should be as long as necessary to capture all impacts on costs and effects. For this reason, a lifetime time horizon is often adopted. At least one of the states is what is called an absorbing state – that is a state the individual can enter but cannot leave. Commonly in Markov models, death is represented as an absorbing state.

Some aspects of the Markov model construction are similar to a decision tree. Setting up the model is quite similar. One must identify the health states and the transition probabilities. What is quite different is that one must determine the cycle length—the rate at which you allow people to change states. The cycle length should be a clinically meaningful period of time and this choice is also frequently affected by the availability of data. There may be publications showing annual failure rates for surgery and so one could choose an annual cycle. Given that the cycle length might be lengthy, it is sometimes quite appropriate for states to have decision trees embedded within them to capture the impact of transitory events e.g., infections, or to determine what future events are possible.

For each state within the model both costs and effect measures are assigned. Costs reflect the care given during time spent in that state and effect measure may reflect events that occur in that state or may be represented by a health state utility. The model works by

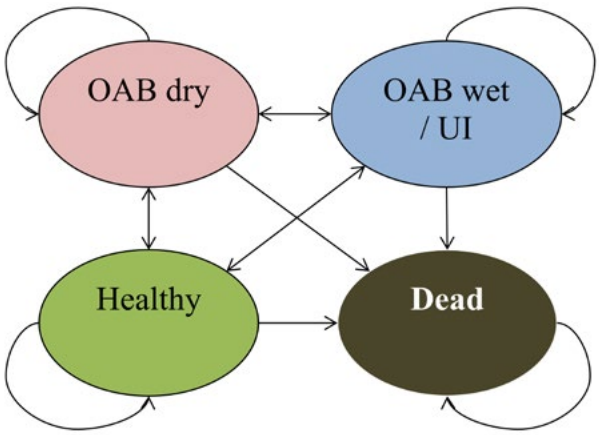

Figure 2: Example of a Markov model for use when evaluating treatments for overactive bladder

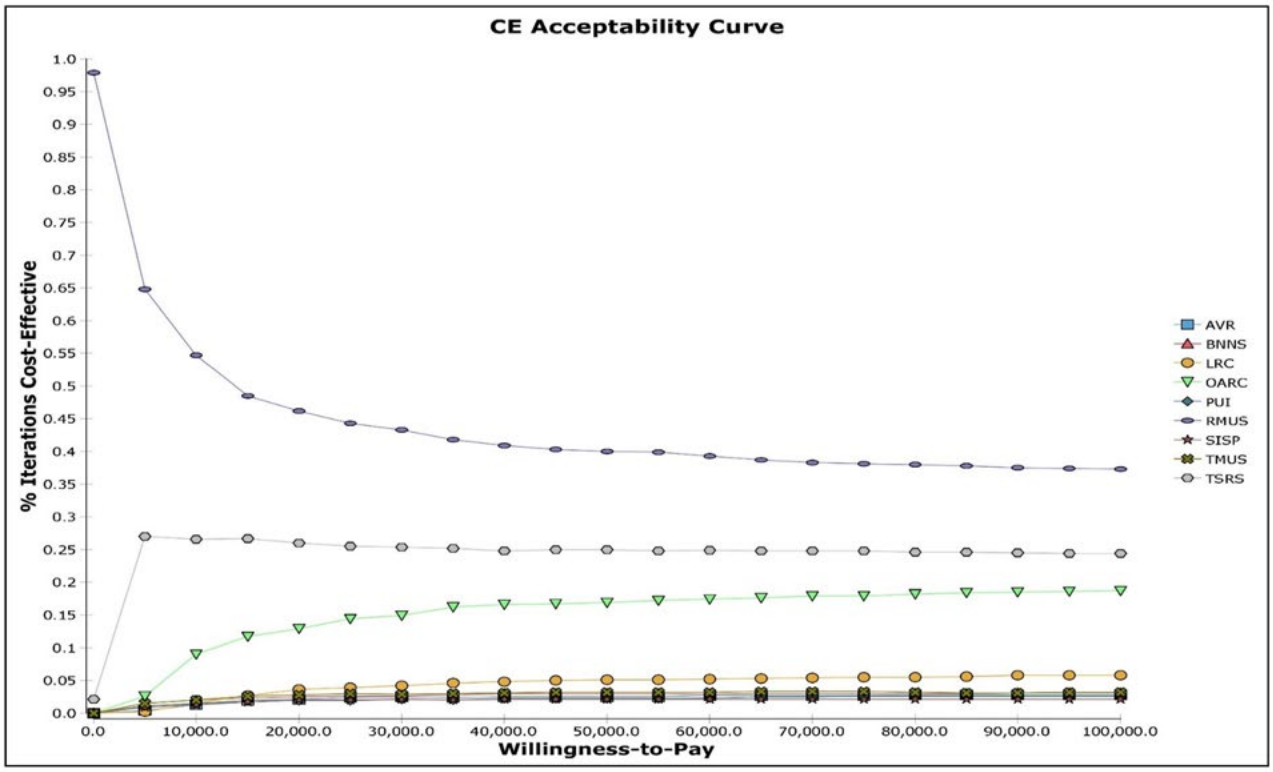

Figure 3: Cost-effectiveness acceptability curves for the nine strategies: lifetime time horizon

making calculations for each cost and effect measures for each cycle and summing these together to produce a cumulate estimate of cost and effects over the time horizon modelled. Figure 2 shows a very basic four-state Markov model for people with overactive bladder. At each time point, a person has to be in one (and only one) of the states. But at the end of each cycle, the individual can move to another state, shown with arrows, depending on the possible states and a probability. If the person dies, they enter and cannot leave this health state.

5.2.3. Microsimulation models

In a Markov model one important assumption is that the models are memoryless. That is prior treatment and events do not influence the success or otherwise of future treatments. One way around this is for the model to include sequences of events in what are called tunnel states. For example, if after surgery a person could have repeat surgery the costs and outcomes for that second (or third, etc) surgery can be modelled as a separate set of states. This can quite quickly become very complicated. In such circumstances an alternative is to model a set of individuals. Each individual moves through the model one at a time and accumulates their own unique history (an example of this form of model is that by Javanbahkt and colleagues modelling surgical treatments for SUI described in Section 4.3.2 below).

5.2.4. Discrete Event Simulations

Discrete event simulations address some of the challenges that face Markov models and microsimulations. They allow for nested, interdependent events and can be especially useful when considering situations where an individual is asked to queue or wait for treatment or where the use of care by one person may restrict the access (or perhaps outcomes of care) of others. Discrete event simulations have not been widely used to study pelvic floor and bladder issues.

6. SENSITIVITY ANALYSIS

Regardless of whether the type of economic evaluation is a CMA, CEA, CUA, etc. or a within trial or model-based analysis all economic evaluations should include sensitivity analysis. Sensitivity analysis can be used to vary one or more parameters at a time to assess the effect of these changes on the output. One and two-way sensitivity analyses are useful for identifying the relative leverage across the parameters.

For the decision model to include uncertainty, a probabilistic sensitivity analysis is required. This involves running Monte Carlo micro-simulations where transition probabilities are chosen at random from a distribution. These Monte Carlo simulations run cohorts of patients through the model many times. The results yield information on the expected values as well as the uncertainty around that expected value. These complex models can be built in Excel, but some people prefer specialized software such as TreeAge. Over the past decade, there has been considerable discussion on how to best present results from decision models. Readers will probably encounter cost-effectiveness acceptability curves (CEACs), which present CEA results with uncertainty (Fenwick & Byford, 2005). An example of a CEAC is shown in Figure 3.

7. ELEMENTS OF A SOUND ECONOMIC ANALYSIS

Economic evaluation readers need to know that the methods employed in the study are appropriate and that the results are valid to establish that the results are useful in their decision-making context. This section draws on a list of the elements of a sound economic evaluation described in Drummond et al (29) and the BMJ guidelines(55) for submitting and reviewing economic papers. For those preparing economic evaluations we refer readers to the CHEERS checklist for the reporting of economic evaluations(56). It may not be possible for every study to satisfy all the points, but the systematic application of these points enables readers to identify the strengths and weaknesses of an economic evaluation (Box 3).

8. IMPLEMENTATION SCIENCE

Implementation scientists are focused on reducing gaps in the delivery of evidence-based care. They test strategies to reduce these gaps. Some tweaks, such as shortening the time horizon and changing the perspective from societal to payer, helped, as was noted in the 2016 CEA Panel(58). The International Society for Pharmacoeconomics and Outcomes Research (ISPOR) developed a budget impact analysis (BIA) that is designed to examines the costs for the decision maker. Increasingly BIA and other economic tools are being used in implementation science, but these analyses differ from the traditional CEA.

BIA was developed to inform a decision maker, often a hospital director, on the budgetary ramifications for a decision(59,60). A BIA will often focus on the decision maker's costs over a short time frame (e.g., 1-3 years). Other parameters in the model, such as patient characteristics or input costs, can also be tailored specifically for the decision maker. Making decisions based solely on a BIA can lead to suboptimal societal results(61) but it may lead to an optimal decision for the hospital director.

Economic evaluation in implementation science is a rapidly evolving area as researchers test alternative strategies to improve the quality of care. These strategies include creating educational material, obtaining leadership support, finding additional funding, and using an internal facilitator (62). They are also highly heterogenous in their resource intensity. One of the challenges is being able to differentiate the cost of using different implementation strategies from the cost of evidence-based treatment. In general, the decision maker needs information on costs because they can identify how these costs change over time with the phase of deployment (e.g., initial adoption versus sustained use)(63,64). Economic evalua-

1. Research question
It is important that the study has a well-defined question, posed in an answerable form. The question should clearly identify the alternatives being compared and the perspective (see Box 1) from which the comparison is to be made.

2. Clear description of competing alternatives
A comprehensive description of the competing alternatives is essential for the readers to judge the applicability to their own setting. This can help assess whether any costs or outcomes have been omitted from the analysis (see also point 4 below).

3. Establish the effectiveness of alternatives
How has the effectiveness of the alternatives compared been assessed? Evidence on effectiveness may come from a single study such as a randomised trial or from a systematic review of several clinical studies and used in an economic model (see Section III.5).

4. Identify all important and relevant costs and outcomes
The study should also ensure that all the important and relevant costs and outcomes for each alternative have been identified.

5. Measure cost and outcomes in appropriate units prior to valuation
Once the important costs and outcomes have been identified they must be measured in appropriate physical and natural unit e.g., number of pads used.

6. Value cost and outcomes appropriately
The sources and methods of valuation of costs and outcomes should be clearly stated to ensure that they are credibly valued (see Section III.3.1). The approach used to estimate costs and outcomes has to be clearly described. This includes all sources of costs and utilities.

7. Adjust cost and outcomes for differential timing
The costs and outcomes need to be adjusted for differential timing as they might not all occur at one time point (see Section III.3.3).

8. Perform incremental analysis of costs and outcomes (see Section III.2.2)
If one intervention is more effective and more costly than another then an ICER should be calculated. Interpretation of the ICER is based on what is the maximum acceptable value for a unit of effectiveness, such as a QALY, this value varies from country to country.

9. Perform sensitivity analysis (see Section III.6)
Every evaluation will have some degree of imprecision or other form of uncertainty. Briggs et al (2000)(57) identified several types of uncertainty. To explore the impact of this uncertainty sensitivity analysis is performed.

10. Presentation and discussion of study results
Presentation of the economic evaluation should include all the issues of concern to users.

Box 3: Key features to consider when reading an economic evaluation

tions are increasingly common in implementation science and there is a growing literature to guide researchers interested in implementation issues (65-67) (Wagner, 2020; Wagner, Dopp, et al., 2020; Wagner, Yoon, et al., 2020).

IV. SUMMARY OF RECENT ECONOMIC EVALUATIONS

1. URINARY INCONTINENCE

1.1. Non-surgical interventions for urinary incontinence

1.1.1. Behavioural therapies

Women may prefer conservative/behavioural therapy, at least as a first-line treatment, because it is non-invasive with few adverse side effects. Conservative/behavioural therapy, (hereafter referred to as behavioural therapy) covers a class of techniques for preventing incontinent episodes through behaviour change. The most common behavioural treatment is pelvic floor muscle training (with or without biofeedback) (68)(10).

There is considerable variation in behavioural techniques and their adjuvant use of professional staff. Some modalities use intensive, one-on-one clinician-led training with direct verbal feedback often involving physical examination of the pelvic floor, while other options are more focused on group training or self-care techniques. The self-made techniques are the most useable options for the incontinent women. The level of intensity is important as it not only affects the effectiveness, but it also affects the cost of the intervention, with more intensive interventions generally being more effective and more expensive than less intensive options.

Since the last edition three economic evaluations in the use of PFMT were identified. Hagen et al (2020) (69) compared basic versus biofeedback-mediated intensive pelvic floor muscle training (biofeedback pelvic floor muscle training) for women with urinary incontinence. The results indicated that at 24 months, biofeedback pelvic floor muscle training was not significantly more expensive than basic pelvic floor muscle training, but neither was it associated with significantly more quality-adjusted life-years. The probability that biofeedback pelvic floor muscle training would be cost-effective was 48% at a £20,000 willingness to pay for a quality-adjusted life-year threshold.

In the second study Sjostrom et al (2017)(70) performed a cost-utility analysis of SUI treatment with the app, Tät (pelvic flow exercises for women), compared with no treatment. They estimated that the extra cost per QALY for the app treatment was €7615.5, and the sensitivity analyses indicated a potential range of −€2425.7 to €14,870.6 and they concluded that self-management of SUI with an app for PFMT is a cost-effective first-line treatment alternative. In a third study Simpson et al (2019)(71) performed a cost-utility analysis of nonsurgical treatments; pelvic floor muscle therapy (PFMT), a disposable tampon-like device (Impressa), a self-fitting intravaginal incontinence device (Uresta), and a traditional incontinence pessary for stress urinary incontinence (SUI) in healthy adult women with a health system perspective over a 1-year time horizon. They concluded that their findings favoured PFMT as the most cost-effective nonsurgical treatment option for SUI.

A brief economic commentary was presented in an update of the Cochrane Review on this topic(68) based on the data available (31 trials involving 1817 women from 14 countries. Trials were of small-to-moderate size, with follow-ups generally less than 12 months and many were at moderate risk of bias). The review of effects showed that PFMT can cure or improve symptoms of SUI and all other types of UI. It may reduce the number of leakage episodes, the quantity of leakage on the short pad tests in the clinic and symptoms on UI-specific symptom questionnaires. The brief economic commentary summarised the existing economic evaluations and it suggested that in terms of cost-effectiveness PFMT looks promising.

1.1.2. Pharmacotherapy for incontinence

Although pharmaceutical companies must show that a new drug is safe and efficacious prior to approval and marketing, the requirement for evidence of cost-effectiveness (i.e., whether the new drug is cost-effective compared to another treatment), varies from country to country. For example, the U.S. Food and Drug Administration does not require economic data in its review of a new drug but leaves economic questions to the purchasers (e.g., insurance companies, government purchasers or individuals). Similarly, in other countries the European Medicines Agency in the European Union and the Medicines and Healthcare products Regulatory Agency in the UK also do not require evidence of cost-effectiveness. However, in many of these countries an extra 'national' agency does make judgements about cost-effectiveness. An example of this is the National Institute for Health and Care Excellence (NICE). NICE require all drugs (and other therapies) to be evaluated using a standard reference case methodology. With this methodology a therapy is not recommended if the incremental cost per QALY is above £20,000 unless there are other reasons e.g., fairness or end of life of care arguments. This threshold has not changed for several years and hence in real terms it is reducing (because of the effects of inflation). There is also some pressure to reduce this threshold because it appears higher than the value placed on a QALY in real world decisions(72). In Australia, manufacturers likewise must prove cost-effectiveness, but there is no explicit threshold to be listed on the Pharmaceutical Benefit Scheme (whereby patients pay a subsidized cost for the drug). However, only therapeutic efficacy and safety must be shown for it to be available in Australia as a non-subsidized "private" prescription. Many purchasers (as in Australia) have formularies or lists of medications that they are willing to pay for, and the economic evaluation is frequently part of the request to place the new drug on the formulary. The same situation exists, for example in the Czech Republic. In the next sections, we review the literature since the prior Committee publication in 2016 on the economics of drugs for incontinence and overactive bladder.

We identified no cost-effectiveness articles related to pharmacotherapy for stress urinary incontinence (SUI) in the past 3 years since the prior ICI report in 2016. This is consistent with the lack of available pharmacological therapies for stress incontinence. (NOTE: Duloxetine is approved only by the European Medicines Agency, an Agency of the European Union, for depression, anxiety and diabetic peripheral neuropathy.)

For urge urinary incontinence/over-active bladder evaluations please see Section IV.2.1.

1.2. Containment products

Data on the overall cost of incontinence/containment products such as pads utilized in the US is over 1 billion US dollars. There is no precise indication of the real place for absorbent products in the management of urinary incontinence, regardless of the aetiology of the incontinence or the clinical context (73). Nevertheless, sometimes, it is not possible or appropriate to promote continence, and

the focus shifts to managing incontinence to enable the person to maintain dignity and avoid the complications of poorly managed urinary incontinence(74).

For the current update no economic evaluations were identified in this area. Given the many different designs that are available, their different suitability's for the type of incontinence and the characteristics of the person using them, this represents a significant evidence gap. This gap is compounded when it is noted that given the numbers that suffer from incontinence the use of pads and other continence products is substantial. From a cost perspective in many countries these are available over the counter without prescription and without reimbursement(73). This means that the costs fall on individuals and their families, many of whom may already be suffering significant financial hardship. Prescription for incontinence products is available in some countries such as the UK and the Czech Republic although, access to this prescribed care may be limited.

1.3. Surgical interventions for stress urinary incontinence

The review of economic evaluations of surgical interventions for stress urinary incontinence from across the world is hampered by the variability in health care delivery systems and variability in costs(75)**.** A recent systematic review of economic evaluations focusing on the cost estimates illustrated the hetrogeneity in costs that existed between studies conducted in 13 countries(76). A second systematic review (77) reviewed 26 economic evaluations, of which 13 were model-based analyses. This review found that MUS and colposuspension (open/laparoscopic) were the most frequently assessed procedures over one and five years. The identified studies suggested that MUS and single-incision slings are among the most cost-effective. However, caution needs to be exercised when interpreting reviews of economic evidence. It is for this reason that the guidance from Cochrane on the synthesis of economic evaluations emphasises that the focus of the review is to understand the causes of heterogeneity rather than come to a single precise estimate of cost (or cost-effectiveness) that is not applicable to anyone(76).

In terms of new economic evaluations there have been four evaluations which have been published. Of these, 3 related to surgical treatments of SUI in women and one related to surgical treatments of incontinence post-prostatectomy. With respect to surgical treatment of SUI, the first of these was by Lier et al. (2017)(78) who compared TOT with TVT as a surgical treatment of SUI in 195 women for 5 years, in Canada**.** TOT saved an average of $2368 and gained 0.04 QALYs when compared against TVT which suggested that TOT is potentially more cost-effective than TVT.

In the UK the cost-effectiveness of nine common surgeries for SUI was evaluated as part of a comprehensive health technology assessment (77). The surgeries considered were: Retropubic mid-urethral slings (MUS)/ TVT against; transobturator MUS (TOT), traditional sling, single incision sling, open retropubic colposuspension, bladder neck needle suspensions laparoscopic colposuspension, anterior vaginal repair, and urethral bulking agents. They utilized a Markov microsimulation model from the UK NHS perspective over 10 years and lifetime time horizons(79). Evidence on effects came from over 120 trials combined using network meta-analyses. Other data came from existing economic evaluations(80), other focused searches. The study suggested that retropubic mid-urethral slings would be the most cost-effective option for SUI treatment. Sensitivity analysis showed that complication rates and relative treatment effectiveness appeared to have the largest effects. They suggested that further long-term research of initially appearing cost-effective procedure (e.g., retropubic-MUS) and complications management might confirm the safety, effectiveness and cost-effectiveness of such interventions.

In the third study Electrical Muscle Stimulation (EMS) was evaluated for the treatment of SUI amongst women in the UK (81). Over the lifetime of women, EMS results in reduction of costs by £250 and £327, and an increase in 0.03 and 0.13 QALYs in the "cure" and "improvement" analyses, respectively. In a probabilistic sensitivity analysis EMS cost-effectiveness is greater than 74% at a cost per QALY threshold of £20,000, the threshold level adopted by NICE in the England.

With respect to surgery for incontinence post prostatectomy, a Canadian-based group(82) utilized a Markov model to evaluate the surgical options. Artificial urinary sphincter was concluded to be more cost-effective than male slings over one year. Similar conclusions were drawn when the analyses were replicated for five- and ten-year' horizons.

2. URGE URINARY INCONTINENCE/OAB

2.1. Pharmacotherapies

In contrast to stress urinary incontinence some economic evaluations were identified in the treatment of overactive bladder (OAB). OAB is a symptom-driven condition and in identified studies the costs of physician visits and incontinence pads were included in nearly all analyses. However, the wider impacts such as OAB associated depression and nursing home costs were rarely included, despite being large cost drivers in cost of illness studies.

Since the last consultation two studies have compared mirabegron versus antimuscarinics drugs(18,83). Arlandis-Guzmán(18) and colleagues modelled the two treatments over a 5-year time horizon, for the Spanish Health Service. The incremental cost per patient with mirabegron 50 mg compared with tolterodine was €196. Taking a wider societal perspective gave an incremental cost of €157. The gain in QALYs with mirabegron compared with tolterodine was 0.0127 QALY. Consequently, the incremental cost per QALY with mirabegron versus tolterodine was €15,432 and €12,425 for health service and societal perspectives respectively. The probability that mirabegron would be cost-effective at a willingness to pay threshold of €30,000 was: 70% (health service) and 71% (societal) versus tolterodine. Other drugs were also compared with mirabegron. For these comparisons mirabegron had the following probabilities of being cost-effective; 94% (health service and society) versus solifenacin 5 mg; 84% (NHS) and 85% (society) versus solifenacin 10 mg; 96% (health service and society) versus fesoterodine 4 mg; 98% (health service) and 99% (society) versus fesoterodine 8 mg.

The second study was conducted in Japan. In this study, mirabegron 50 mg was reported to be cost-effective compared to treatment with antimuscarinics(83). Over a 5-year time horizon mean QALYs were 3.860 for first line mirabegron and 3.839 for first line tolterodine. Costs per patient were ¥526,191 and ¥472,390 for first line mirabegron and tolterodine respectively. This resulted in an incremental per QALY of ¥2,565,927 for first line mirabegron compared with first line tolterodine. This value is below the willingness-to-pay threshold of ¥5 million per QALY used in Japan. In more severe states, the incremental cost per QALY however exceeded ¥5 million.

A further three studies did not compare specific treatments rather they compared treatment by pharmacotherapy with non-treatment. To do this they used a range of different study designs. None of these studies were explicitly described as economic evaluations but for each the results could be reinterpreted as cost-consequence analyses. These studies all used non-randomised designs which may be prone to selection biases. Therefore, care has to be taken not to over interpret their results.

A cross-sectional study using data from an internet-based questionnaire of a nationwide sample of 75,000 adults (US National Health and Wellness Survey) evaluated the impact of treating urge and mixed UI. It was used to look at OAB treatment users compared with non-treatment users (i.e., those who self-reported that they never used treatment and whose condition reportedly interfered with life activities or was difficult to manage) (84). Outcome measures included healthcare utilization and work productivity and activity impairment questionnaire-based scores. Direct and indirect costs were estimated using labour and medical expenditure data sources ($2008). Treatment (vs. non-treatment) users were more likely to be female (81% vs. 70%), older (mean = 63 vs. 53) and reporting more moderate-to-severe OAB (71% vs. 53%; all $p < 0.05$). Adjusting for covariates, treatment users had significantly lower activity impairment, more provider visits and higher total direct costs ($27,291 vs. $21,493) per year. Though this is a non-randomised design and as such prone to selection biases, it is suggestive that treatment for UUI/MUI may help with symptom management and lessen activity impairment but at higher costs compared to never users.

A study, performed by a pharmaceutical company, concluded that OAB treatment resulted in cost savings from the US payer perspective compared to no OAB pharmacotherapy for vulnerable elderly OAB patients(85). Costs of treating OAB with fesoterodine compared to no OAB pharmacotherapy were assessed using a decision analytic cost model. Implicit in this model were estimates of effectiveness. Vulnerable elderly OAB patients were defined as age ≥65 years with 2-15 UUI episodes/day and at risk of deteriorating health by a score of ≥3 on the Vulnerable Elders Survey (VES)-13. Fesoterodine treatment response was defined as no UUI episodes after 12 weeks of treatment and assumed that was maintained up to one year. OAB-related costs included OAB drug costs, healthcare resource use (inpatient hospitalization, outpatient visits, and physician office visits), and OAB-related co-morbidities (falls/fractures, urinary tract infections, depression, and nursing home admissions; $2013). It was reported that treating OAB patients could save $1616 per patient vs. no OAB pharmacotherapy. Costs were most sensitive to changes in fesoterodine efficacy followed by the annual costs of inpatient hospitalization. This analysis did not include cognitive impairment, assumed a low prevalence of UUI (13.5%), used a high probability treatment response (51% no UI episodes at week 12).

A further Spanish retrospective study looked at the cost-effectiveness of treatments for 3094 actively working patients initiating first treatment with antimuscarinics (fesoterodine, solifenacin or tolterodine) from 31 primary care centres (86). The study compared fesoterodine versus solifenacin and tolterodine. Adherence (medication possession ratio) was 90%, 87% and 86%, respectively). Treatment persistence was 40% vs. 35% and 34%) and days of sick leave were 5, 10 and 9 days. Cost per patient after correcting for covariates were €371, €703 and €683 in €2014; all $p < 0.05$). While it is not clear how sick leave and productivity were assessed, the results suggest that initiating treatment with fesoterodine to treat OAB (compared with solifenacin or tolterodine) had fewer days of sick leave, lower loss of productivity and was lower in cost.

2.2. Surgical interventions

Since the last consultation four economic evaluations have been published that have considered surgical interventions for OAB. One compared OnabotulinumtoxinA (Botox) 100 U with best supportive care from a UK context (87). Two compared Botox with anticholinergics from a US perspective(88,89)and one compared Botox with sacral neuromodulation using data from nine U.S. centres(90). For the comparison of Botox and best supported care, a Markov model with a 10 year time horizon was adopted. It was reported that Botox lowered total costs and resulted in better quality of life than best supportive care alone. The incremental cost per QALY was less than £20,000 90% of the time in the probabilistic sensitivity analysis conducted(87).

The first of the two studies that compared Botox against anticholinergics found that over a two year follow-up that Botox as a first line of treatment had the highest quality-adjusted life year (QALY) but was more costly that than non-selective anticholinergics(89) but selective anticholinergics were more costly than Botox. Botox was also found to be cost-effective when the costs of any further treatments when initial treatment has failed were included or excluded. The second multicentre considered costs and QALYs for 231 women over a one year follow up(88). The study reported no evidence of a difference in QALYs and costs (i.e., the study was underpowered to detect differences).

The last economic evaluation compared Botox with sacral neuromodulation using data from nine U.S. centres(90). QALYs were reported as comparable but sacral neuromodulation procedures was more costly than Botox, $35K vs $7,460 over a two-year analysis, and $36K vs $12K over a five-year analysis. Based upon these data sacral neuromodulation was highly unlikely to be considered cost-effective compared with Botox.

3. PELVIC ORGAN PROLAPSE

With regard to studies that assessed different management strategies for pelvic organ prolapse (POP) six studies were identified. Two were based on comparison of pelvic floor exercises with other non-surgical treatments and three of the identified studies were economic evaluations of surgical interventions for POP. Three of the identified studies were carried out alongside clinical trials, three studies utilised an economic decision model and one used a within trial approach and a decision model to consider the outcomes at different time horizons.

3.1. Non-surgical interventions for pelvic prolapse

Two studies were identified that considered non-surgical interventions for pelvic prolapse and both of these were within trial economic evaluations and both reported results for a CEA and CUA. Panman et al 2016 (91) compared the use of PMFT with pessaries in woman over a two-year period. Cost-effectiveness was reported as the incremental cost per point improvement on the PFDI-20. The cost-utility analysis reported the incremental cost per QALY, though the sources of the utility values were unclear. The additional cost to improve one point on the PFDI-20 in the pessary group compared with the PFMT group was $77 (USD 2014). The authors inappropriately reported a negative ICER for both the CEA and CUA (which is not readily interpretable). On average however the use of pessaries was more costly but no more effective. A second study by Panman et al (2017) (92) compared PFMT management with watchful wait-

ing. The same cost-effective and cost-utility outcomes as Panman et al (2016)(91) were reported. In the CEA, the incremental cost per unit improvement in PFDI-20 for PFMT compared with watchful waiting was €43 (Euros 2013). For the CUA, the incremental cost per QALY for PFMT compared with watchful waiting was €31,983. Statistical imprecision was explored using bootstrapping. These data suggested that there was a 55% probability that PFMT would be considered cost effective (this form of analysis requires that the probability be estimated relative to a threshold value for the decision-makers willingness to pay for a QALY. However, the threshold value was not stated.

Due to the nature of reporting or the findings themselves the evidence supporting PFMT vs either pessaries or watchful waiting is far from compelling. For example, for the comparison with watchful waiting drawing a firm conclusion based upon the data would be like basing a conclusion on the toss of a coin.

3.2. Surgical interventions for pelvic prolapse

Five economic evaluations comparing surgical interventions were identified. Of these Glazener et al (2017)(93) compared mesh inlay interventions for the treatment of primary and recurrent prolapse in two concurrently conducted randomised trials. A within trial cost utility analysis was undertaken. This analysis took a UK NHS (health service) perspective with participant costs included in a sensitivity analysis. Follow-up was over two years. For those with primary prolapse, standard repair which involved fascia being separated from the vaginal wall and the fascial defect plicated (sutured or buttressed) was compared with standard repair including a biological graft inlay and standard repair with a non-absorbable or combined mesh inlay. When the analysis sought to make the best use of available data and missing data were imputed using appropriate techniques it was found that at a cost per QALY threshold of £30,000 standard repair had a 52% probability of being cost-effective. Synthetic mesh and biological repair had probabilities of 29% and 20% respectively. There were significant patient costs incurred. These included: time spent travelling to and from appointments, time on sick leave and private treatments. However, the inclusion of these costs did not affect the overall conclusions. The results of the primary surgery were extrapolated beyond the trial time horizon to 5 years using a Markov model. In this model, a woman could move between various states of prolapse repair or complications. Standard repair was estimated to be less costly and marginally more effective than either the synthetic or biological mesh. When the decision-maker was willing to pay a maximum of £30,000 per QALY the probability each treatment would be considered cost-effective was 22%, 57% and 21% for standard repair, synthetic mesh and biological graft, respectively.

For recurrent prolapse standard repair was compared to standard repair with a non-absorbable or combined mesh inlay and standard repair with a mesh kit procedure. The probabilities that each treatment was cost-effective at a £30,000 per QALY threshold was: standard repair (32%); mesh inlay (19%) and mesh kit (49%). As for repair of primary prolapse there were significant patient costs, but these were evenly distributed across the groups. The authors conclude that there was no compelling evidence for the use of mesh for recurrent prolapse repair, unless there is significant failure of standard repair over a longer term follow up than the 2 year period reported in the study.

Hemming et al (2020)(94) compared two surgical interventions in the management of both uterine and vault prolapse. Two within trial cost-effectiveness analyses were carried out with a surgical intervention for vaginal hysterectomy in both groups. The uterine group compared uterine preservation with hysterectomy and the vault group compared transvaginal vault surgery and abdominal vault surgery (colposuspension). With respect to the uterine trial, the result of the within trial evaluation, showed additional costs for the uterine preservation group with no significant difference in the amount of QALYs gained at 12 months. The inclusion of costs borne by the trial participants did not impact these conclusions. Extrapolating these results over the patient's lifetime using a Markov model gave similar results to the within trial analysis. The results of the vault surgery trial concluded that abdominal vault repair incurred significant costs but with no evidence of additional QALYs when compared with transvaginal vault repair. Conclusions remained consistent across the sensitivity analyses conducted.

Ohno et al 2016(25) also compared surgical treatments for prolapse in a model-based cost utility analysis from a societal perspective. Despite the authors taking the societal perspective, costs which were reported were only health care costs. This model compared abdominal sacral colpopexy (ASC) against sacrospinous ligament fixation (SSLF). The form of decision model was not described but health service costs were derived from Medicare data. QALYs were derived using utilities based on the HUI3 data taken from the National Population Health Survey (95). The model considered post-operative SUI, recurrent pelvic organ prolapse, and post-operative dyspareunia. All participants in the model were assumed to have a baseline utility of 0.93 (i.e., almost full health prior to surgery). ASC was estimated to be both more costly and more effective than SSLF with an incremental cost per QALY gained of $24,574 (USD 2013), lower than the proposed threshold of $50,000 per QALY. In sensitivity analysis, the conclusions were found to be sensitive to cost of the surgery and the post-operative rate of SUI. No probabilistic sensitivity analysis was performed which means it is uncertain how imprecise the conclusions are.

A further model based CUA was conducted by Slade et al (2020) (96). This model made use of data from a network meta-analysis in a Markov model from a UK NHS perspective. The utilities used were taken from Glazener et al. (2017). Anterior colporrhaphy (AC) was the dominant strategy being the least costly and the most effective. Although the results of the meta-analysis found that there was greater effectiveness with biological and synthetic mesh, this is offset by an increased likelihood of complications. The authors note that complications were often poorly reported and more studies about the longitudinal effects of both biological and synthetic mesh are warranted.

Whilst a number of different studies compared the different surgical approaches to the management of prolapse, Wyman et al (2020) (97) investigated the cost and benefits of the use of preoperative pelvic magnetic resonance imaging (MRI) to identify women with a high risk of surgical failure. A CEA based upon a decision tree model was carried out from a third-party payer perspective. It was estimated that imaging increased cost by $400 (USD 2014) compared with no use of routine MRI-based screening but also led to a 17% higher likelihood of success after the initial surgery. This results in an incremental cost per surgical failure of $2298. The results of the probabilistic sensitivity analysis conducted showed that the probability that imaging would be cost-effective would be 50% at threshold of $7100 or more. The reason this threshold was chosen was not clear.

Summary and Conclusions:

With regard to PMFT interventions there is limited evidence with some methodological and reporting limitations in the identified studies. Further evaluations which explore a longer time horizon and full

exploration of uncertainty would fortify these conclusions. The evidence for surgical management of prolapse is limited with several economic evaluations falling short of generally accepted reporting of methods. Nevertheless, two robust and well-designed studies, Glazener (2016)(93) and Slade et al (2020)(96), found that mesh interventions were not likely to be cost effective. Future research of both longitudinal clinical outcomes and economic evaluations with full probabilistic sensitivity analysis will be beneficial in the understanding of the best surgical techniques to manage pelvic organ prolapse. There is early evidence in relation to the effectiveness of preoperative imaging, but this also requires further high-quality economic evaluations to draw firm conclusions.

4. FAECAL INCONTINENCE

4.1. Evaluation and testing

Faecal incontinence is a diagnosis that can be made on clinical history alone, however, patient reported symptoms are a poor indicator of underlying pathophysiology. Diagnosis is best made by a focused and appropriate evaluation. Costs incurred for evaluation may range from transportation to the healthcare facility to that of conservative or surgical treatments. While the costs of evaluation have been assessed no economic evaluations were identified that compared alternative modes of clinical evaluations and testing.

4.2. Conservative therapies

While it may be feasible to provide the relative costs of conservative treatments (e.g., behavioural modification, scheduled toileting and dietary fibre supplementation), cost-effectiveness still needs to be evaluated. Unfortunately, no economic evaluations were identified since the last consultation.

4.3. Medications

Pharmacoeconomics remains a constant challenge and of increased interest. With advent of newer medications, there may be cost savings in the newer drug versus the older drug, reduction of hospitalizations, or reduction in costs associated with managing adverse side effects of older drugs(98). Again, no economic evaluations were identified since the last consultation.

4.4. Advanced therapies

Patients may fail to respond to conservative therapy and require more advanced or surgical therapy such as vaginal bowel devices, stem cell therapies, anal slings, neurostimulation, bulking agents, radiofrequency, sphincter repair, sphincter replacement, or faecal diversion. These newer therapies are beginning to surface. Only one economic evaluation was identified since the last consultation. Hounsome et al (2018) (99) compared sacral nerve stimulation and percutaneous tibial nerve stimulation for faecal incontinence using a decision analytic model. The analysis was run over a 5 year time frame. Percutaneous tibial nerve stimulation prior to sacral nerve stimulation compared with delivering sacral nerve stimulation straight away was both more effective and less costly in all scenarios. The probability of this strategy being cost-effective was around 80% at £20,000–£30,000 per quality-adjusted life-year (QALY).

V. SUMMARY AND FUTURE RESEARCH PRIORITIES

Since the last ICI several high-quality economic analyses have been published. This chapter has focused on what are called full economics evaluations. The chapter has not considered so called partial economic evaluations – these studies consider costs alone or effectiveness alone. The reason for this is that full economic evaluations are the only studies that provide information about efficiency.

Despite extensive searching there were several areas where no new published studies were identified. One of these was pharmacotherapy treatments for stress urinary incontinence and this is consistent with the lack of pharmacological therapies for stress incontinence. There were economic evaluations identified in other areas. Three studies were found in the use of PFMT in the treatment of urinary incontinence. A brief economic commentary was included as part of an updated dated Cochrane review on this topic. This brief economic commentary suggested that in terms of cost-effectiveness, PFMT looked promising. This commentary did not subject any of the identified economic evaluations to critical appraisal. However, a study conducted alongside a large RCT reported that that biofeedback mediated PMFT was unlikely to be cost effective in a UK setting.

The majority of studies identified related to surgical or pharmacotherapy for urge incontinence/OAB interventions. For surgical intervention for stress urinary incontinence 4 studies were identified. Of these, 3 related to surgical treatments of SUI in women and one to surgical treatments of incontinence post-prostatectomy. One economic evaluation was conducted alongside a randomised controlled trial and the others were model based. A robust model-based study reported that results suggest that retropubic mid-urethral sling (retro-MUS) is the most cost-effective surgical intervention over a 10-year and lifetime time horizon and highlighted the need for further long-term research. There was only one study that looked at the cost-effectiveness of slings in the treatment of male incontinence and evidence suggests that the AUS was more cost effective however, these results need to be interpreted taking into account that although the study was based on the best available evidence, there is a lack of long-term data on the clinical effectiveness of slings in the treatment of male incontinence.

Several studies were published that compared pharmacotherapies for OAB. The type of analysis conducted varied considerably, but the reporting of the type did really correspond to the type of analysis conducted. For example, three studies did not compare specific treatments rather they compared treatment by pharmacotherapy with non-treatment. None of these studies were explicitly described as economic evaluations but for each the results could be reinterpreted as cost-consequence analyses. This goes against previous recommendations of the committee that researchers correctly label their studies to avoid confusion.

Since the last consultation four economic evaluations have been published comparing onabotulinumtoxinA (Botox) compared with best supportive care or anticholinergics or sacral neuromodulation. The results suggest that Botox is a cost-effective treatment for urge urinary incontinence compared to these treatments. varied depending on comparator even though there was some evidence that there did not appear to be in the differences in QALYs therefore the results were mainly driven by the costs of Botox.

Several studies were identified in the management strategies for the Pelvic organ prolapse (POP); Two of these studies looked at non-surgical interventions and four considered surgical interventions. The reporting of the non-surgical studies meant that the evidence was not compelling. Likewise, some of the economic evaluation evidence for surgical management of prolapse fell short of generally accepted reporting of methods. However, two robust and

well-designed studies found that mesh interventions were not likely to be cost effective. Only one economic evaluation was identified for management of faecal incontinence, and it was model based.

As noted in earlier consultations the requirements of reimbursement agencies and guidelines for economic evaluation publications have been the drivers for the improvement of the quality of the identified studies. With respect to the economic evaluations identified there have been some very high-quality studies reported. It was however disappointing to see some examples of poor practice still being published and there is still room for improvement in conduct and reporting of economic evaluations. Overall, in most of the areas considered in this chapter there is need for more primary collection of quality of life as well as long term follow up data.

Most studies included quality of life measures and incremental cost-effectiveness ratios (ICER) and reported the willingness to pay threshold. For all areas future research should seek to capture the full impact of the interventions considered over time and more fully address both statistical and other forms of uncertainty using sensitivity analyses. Many studies identified were piecemeal in that they did not consider all relevant alternatives. This indicates that there is a need for more and better large-scale modelling studies based upon best available evidence.

A further limitation relates to the application of economic evaluation methods. The studies identified estimated cost-effectiveness for the average patient. This is common practice, but such studies are not sufficient to inform decisions about adoption of interventions. Economic evaluation in implementation science is a rapidly evolving area as researchers test alternative strategies to improve the quality of care. One of the challenges identified in implementation science is the ability to differentiate the cost of using different implementation strategies from the cost of evidence-based treatment. There is a growing literature to guide researchers interested in implementation issues.

VII. CONCLUSIONS 2132

REFERENCES 2132

I. INTRODUCTION

This chapter summarizes important new aspects of research arising from data and discussion as a product of this consultation. This chapter includes issues inclusive of recommendations for ongoing and future research focus related to prevention, improved elucidation of mechanisms of causation of disease, personalised medicine, and topical areas of research focus related to specific pelvic floor conditions.

This report stresses the need for clear and consistent use of definitions with approved terminology, as well as published guidelines arising from International Continence Society (ICS) and other major professional societies and consensus groups. Previously the Oxford Centre for Evidence-based Medicine Levels of Evidence and Grades of Recommendation (http://www.cebm.net/levels_of_evidence.asp) have been used for this purpose however the addition of clear and consistent methods of evidence classification as defined by the GRADE system will be highlighted and strongly recommended for inclusion.

1. SCIENTIFIC INTEGRITY, RIGOR, REPRODUCIBILITY IN BIOMEDICAL RESEARCH

Good research practice mandates the determination and definition of the experimental or research topic.

(1-18) Increasingly, meta-analytic reviews provide a background and foundation to potential subsequent clinical research projects. The Cochrane Incontinence Group (http://healthsci.otago.ac.nzldsm/wch/obstetrics/cure) provides a summative review of pelvic floor topics. The prospective formulation of the rationale, objectives and hypotheses for a proposed study may be constructed on this basis. Critical to study design is a consideration of the power of the study and subsequent termination of sample size necessary to answer statistically driven conclusions. (19) The study design should provide the highest quality of evidence to test the given hypothesis in the most thorough and robust manner. Clinical practice and clinical research often overlap. Recommendations as to optimal integration of the two are extant and lucid. (20 -24) There should be clear understanding on both parts of the clinical researcher and the patient/subject as to the differentiation of standard and routine clinical care as opposed to formal clinical research systematic investigation leading to generalizable knowledge. (25)

The U.S National Institutes of Health (NIH) convened a joint workshop in 2014 in collaboration with the Nature Publishing Group and Science, and produced detailed guidelines pertinent to research integrity and data reporting inclusive of: statistical analysis, transparency in reporting, data and material sharing, and consideration of refutations. Also included was a consideration of image-based data (i.e. immunohistochemistry or western blots) and biological materials which must be detailed in order to ensure reproducibility of design and interpretation (i.e. antibodies, cell lines, and animals).

The incorporation of new technologies in benign urologic research including artificial intelligence (AI), social media, and genetic engineering all pose important ethical questions. Regarding AI, researchers must be willing to provide full disclosure regarding any algorithmic code that underlies research decisions (26). For social media research, privacy concerns and unintentional biases are important to consider as highlighted by a recent, retracted article entitled, “Prevalence of unprofessional social media content among young vascular surgeons.” (27) The study was highly criticized for its bias against young women surgeons and for targeting private social media accounts in the name of research. (28) In terms of genetic engineering, the use of Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) technology, and new abilities to alter the human genetic code either in embryos or adult humans must be applied with extreme care and consideration of underlying ethical issues. (29)

2. RESEARCH ETHICS

Medical research is founded on the highest ethical basis. This ethical foundation arises from experiences that have arisen from prior endeavors with both positive and negative implications for the current and future status of basic and clinical research endeavors.

The Belmont Report entitled „Ethical Principles and Guidelines for Protection of Human Subjects of Research“ outlines critical aspects of research and was summarized in the prior edition of this chapter. (30) These principles include Respect for Persons, Beneficence, and Justice and are critical aspects of ethical research. Studies must be free of coercion, undue investigator interference, and risks otherwise unintended including physical, emotional or psychologic trauma.

Criteria defining ethically based research include: clearly defined study aims, prospective planning, data base registration, and feasibility, and there should be a reasonable assumption that new knowledge will be provided at the end of the study; as well as reasonable and achievable study goals which will advance knowledge. (20,30-32)

Ethical approval is a critical procedural aspect of research and requires Institutional Review Board (IRB) approval for human subject research protocols. Additionally, informed consent is an absolute ethical requirement for human subject research and must contain three elements: 1) it must be voluntary, 2) it must provide a full disclosure of relevant information including risks, benefits, and alternatives, and 3) it must be presented to an individual or surrogate who has clear decision-making capability. Autonomy is a critical aspect of informed consent and should be easily understandable and meaningful to potential participants. (32 -34)

Informed consent should include the type of study, associated randomization, and inherent risks of the trial. The document should include a statement allowing the subject to decline participation with no attendant consequence to any ongoing medical care and whether or not remuneration is provided. If an adverse event occurs during the study and is related to the study, a statement as to risk mitigation should be included. (32,33)

An obligation to disclose relationships with industry and financial disclosures related to supplemental personal income exists as part of the informed consent process. (32-36) Institutional contracts and oversight are critical for study integrity. The U.S. National Institutes of Health (NIH) provides clear guidance as to this process. (37,38)

II. EVIDENCE

1. BACKGROUND

To many currently practicing clinicians, evidence-based medicine (EBM) may seem to be well established in undergraduate and postgraduate teaching, and in the methods that guideline bodies use to reach recommendations, but it remains a young and dynamic field. The concept of clinical epidemiology was only introduced in the 1930's; formal teaching of critical appraisal of medical literature began in the 1960's; and even the term "evidence-based medicine" was coined as late as 1991, by Gordon Guyatt at McMaster University. (39) The core concept of EBM has been to use the current best evidence from clinical research to improve the care of individual patient. (40) The foundations of EBM were built on an understanding that there was a hierarchy of clinical evidence, with some study designs, and some individual studies producing more credible evidence than other. (41)

Evidence-based clinical practice guidelines play a critical role in guiding decision-making at the point of care and should therefore be developed to the highest standards. (42) The earliest editions of the ICUD's books, including this work on urinary incontinence, used essentially narrative summaries of a body of evidence, to reach four strengths of recommendation for each intervention or test: "highly recommended, recommended, optional and not recommended." From around 2002 onwards, corresponding with the 2nd through 6th editions of this text, it was recognised that these different strengths of recommendation should be backed by a systematic rating of the quality of evidence. The ICUD adopted, with minor modifications, the widely used Oxford Centre for Evidence Based Medicine system, (43)incorporating both a hierarchy of levels of evidence, and a subsequent grade of evidence. These grades (A to D) were based on a narrative assessment of the highest level of evidence reported, and the consistency of evidence at that level.

Subsequent to the publication of the 6th edition of this work, a worldwide consensus has emerged for a shift to a more transparent system for evaluating evidence and reaching recommendations about that evidence. This system, known as Grading of Recommendations Assessment, Development and Evaluation (GRADE) (44) has been found to be reproducible (45) and been widely adopted including by specialty guideline bodies including the American Urological Association (AUA), European Association of Urology (EAU) and international and national general guideline bodies including Cochrane, the WHO, and NICE. The consistent use of the same framework across different guideline developers is a positive development that should facilitate collaboration and resource sharing. (46)

In this summary of current methods for EBM in incontinence, we first give an overview of general considerations when evaluating a body of evidence focusing on the different domains by which GRADE judges the certainty of evidence; we then conclude with a brief overview of how the GRADE system moves from assessment of evidence to make guideline recommendations. For further reading, one of the best resources for understanding how to apply the principles of evidence-based medicine is the JAMA's Users' Guide series, in particular the articles on therapy and prevention. (47,48) There are also many EBM resources specifically for urologists. These include the Users' Guide to the Urological Literature series, (49) as well the Evidence-based Urology In Practice series, (48) that explains these principles using urology-relevant examples.

2. RATING THE CERTAINTY OF EVIDENCE

GRADE stands in contrast to some prior systems such as that by the CEBM in Oxford that it does not appraise individual studies, (44) but a body of evidence as summarized in a high quality systematic review.(50) Critical aspects of a high-quality systematic review should be governed by the A MeaSurement Tool to Assess systematic Reviews Assessment (AMSTAR)-2 criteria. (51) These include an a priori protocol, ideally registered in advance, a comprehensive search strategy, performance of key steps independently and in duplicate by two or more investigators as well as the use of a system like GRADE to rate the certainty of evidence. Unfortunately, many systematic reviews published in the urological literature are of low methodological quality. (52)

2.1. The importance of a clear question

Guideline panels seek to develop actionable, evidence-based recommendations to support clinical decision making at the point of care. To do so, it is important that the panel has clearly articulated what clinical question the recommendation is meaning to address. (43,52) Any question addressing clinical management should follow the following format and include four components: Patients (P), the intervention (I), a comparator (C) and the relevant outcomes (O) of interest. For example, a guideline panel on prostate cancer seeking to address the role of Retzius-sparing for the surgical management of clinically localized prostate cancer, may formulate the following question: In patients with clinically localized prostate cancer, how does a Retzius sparing approach compared to a non-Retzius-sparing approach with regards to urinary continence as well as the risk of serious surgical complications, recurrence free survival and disease specific survival. Components of this question in the so-called PICO question will then also guide an information specialist in developing a comprehensive search strategy to identify all relevant studies. (53)

2.2. Addressing the importance of outcomes

An important aspect of GRADE is its focus on outcomes that are of direct importance to the patient. (52) This is relevant, since clinical research studies oftentimes focus on endpoints that are easy to measure but are not of direct interest to patients. Examples include PSA levels suggesting biochemical recurrence after treatment for clinically localized prostate cancer and DEXA bone density scores; these are surrogates for disease specific survival and fractures, respectively. GRADE emphasizes that guideline recommendations should be based on outcomes that are of direct patient importance, rather than on surrogates. In settings where no evidence is available to inform these patient important outcomes, information on surrogate outcomes can be used to indirectly inform how these outcomes may be impacted. We will discuss this later under the domain of indirectness.

To identify which outcomes are most patient important, the guideline panel thus should assemble a comprehensive list of outcomes that are potentially impacted. (52) Importantly, they should include both outcomes that reflect a potentially desirable effect but also those that reflect a potentially undesirable effect, for example drug-related adverse events. Based on this comprehensive list, the panel should go through a prioritization process during which outcomes are rated on a scale from 1-9. On the scale, scores from 7-9 characterize outcomes of critical importance for decision making. Ratings of 4-6 are outcomes that are important, but not critical. Ratings of 1-3 items that are considered not critical and not important and therefore are of limited importance. Ultimately, outcomes that fall into the latter

category are omitted from the evidence summary that is compiled as the basis for the panel deliberations. The overall certainty of evidence rating that characterizes a recommendation is ultimately determined by those outcomes that are deemed as critical; this will be discussed further in this text.

2.3. Judging the certainty of evidence in the context of guideline development

GRADE makes a distinction between how the certainty of evidence is established in the context of a systematic review versus in the context of a clinical practice guideline. (54,55) For the latter, the certainty of evidence reflects the extent to which confidence in an estimate of effect is adequate to support recommendations. Therefore, it is context specific. It also requires some judgment as to what effect size represents a clinically meaningful effect.

2.4. Domains that impact the certainty of evidence of randomized control trials

Historically, rating systems have placed an undue emphasis on study designs alone. Whereas GRADE also begins with study design, with randomized control trials starting off as high certainty evidence and observational studies as providing lower certainty evidence it recognizes that under certain circumstances, well-done observational studies may provide stronger evidence then evidence drawn from the body of randomized control trials. (54) It has clearly defined five criteria that may lower the certainty of evidence from randomized control trials (as well as three criteria that may increase the certainty of evidence from observational studies reviewed below).

2.5. Study limitations

This domain of study limitations captures the major limitations that have historically been referred to as risk of bias. (56) GRADE recognizes that the confidence that we can place on recommendations decrease if the underlying studies lack important methodological safeguards against bias. These include appropriately randomized patients with allocation concealment to guard against selection bias, blinding of patients and personnel to guard against performance bias, and blinding of the outcome assessments to guard against detection bias. In addition, large losses to follow up present the risk of attrition bias and failure to report outcomes (typically those for which no effect was observed) may amount to selective reporting bias. In addition, the analysis of superiority studies should be performed as intention to treat. Shortcomings in the methodological quality of randomized controlled trials are very common and therefore frequently prompt downgrading the certainty of evidence.

2.6. Inconsistency

In a systematic review, the authors will seek out in aggregate the results of studies that all address the same PICO. Therefore, one would expect the results of all the studies to be similar. However, it is not uncommon for there to be considerable heterogeneity or variability in the results as reflected in differing estimates of treatment effect. Potential explanations for this variability include clinical differences in populations (for example, different disease stages), in interventions (for example drug dosages), comparators (for example usual care or placebo) and/or in different ways of assessing the same outcome (for example, some studies using validated and others non-validated instruments to assess quality of life). In addition, studies may differ in the methodological rigor with which they were conducted (for example, some studies blinded outcome assessors and others did not). Lastly, some degree of variation can be explained due to chance variation. Whenever there is considerable variability that cannot be explained due to chance, systematic review authors should seek to explain this variability. Ideally any hypothesis they explore, should be defined a priori. Ultimately, if no good explanation is identified for the observed inconsistency between studies that contributed to a pool effect, GRADE recommends rating down for inconsistency. (57)

2.7. Indirectness of evidence

The domain of indirectness can be categorized into two different types. (58) First, there may be no direct head-to-head comparisons between two types of interventions but each of these interventions may have been compared to placebo or to sham surgery. Whereas the findings of such studies, may still allow for important inferences about the relative effectiveness of these two interventions, we would be less certain of these results if they had been compared in the setting of one trial. Secondly, there may be important differences between the intended population, intervention, comparator, or outcome of interest as defined in the PICO, versus that of the available body of evidence. For example, in the absence of clinical trial evidence in children, it may be reasonable to apply study results from adolescents; however, the underlying degree of confidence that we can place in the treatment effects would be lower.

2.8. Imprecision

This GRADE domain relates to the issue of small sample sizes, low event rates and wide confidence intervals. (59) If the confidence interval of the pooled effect size includes values that would lead to a different interpretation of the evidence, GRADE would recommend that you rate down the certainty of evidence. A related concept in this context is also the optimal information size (OIT), which relates to the required sample size that a single adequately powered randomized control trial would require.

2.9. Publication bias

It is a well-established phenomenon that positive studies that demonstrate that a new intervention performs better than an established intervention (or placebo) are met with greater interest by the urological community then negative studies that failed to do so. This often results in publication in higher impact journals, more rapid acceptance, increased dissemination in the form of secondary publications, as well as editorials and exposure in social media. Meanwhile, negative studies may only be presented as abstracts at meetings, or not at all made public. Therefore, when reporting bias is strongly suspected, either from a funnel plot, or for example when published evidence is limited to a small number of trials which are all published by industry, GRADE would recommend to rate down for this reason. (60)

2.10. Domains that impact the certainty of evidence of observational studies

For many important questions in urology, the available evidence is limited to (comparative) observational studies. In most cases, the resulting evidence will be of low or very low certainty. However, in unusual circumstances, they may produce moderate or even high-quality evidence. The most practically relevant scenario is when methodologically strong observational studies that are not compromised by risk of bias yield large or very large and consistent estimates of the magnitude of the treatment effect. In those situations, although the observational studies are likely to overestimate the true effect, the weak study design is unlikely to explain all the apparent effect. (61) One example, may be the effect of androgen ablation in patients with newly diagnosed metastatic prostate cancer with neurological symptoms due to cord compression. Although the impact of immediate castration has never been studied in the setting of a randomized control trials, the dramatic effect of treating patients would allow us to be confident that it is indeed effective. The two other criteria that will at times allow us to be more confi-

dent in the results of observational studies relate to the existence of a dose response gradient, or the situation in which all plausible biases would decrease the magnitude of an effect.

2.11. Evidence profiles and summary of findings tables

GRADE evidence profiles and summary of findings tables represent two structured approaches to present a summary of evidence to a guideline panel. (62) They differ in the degree of detail that they provide. An evidence profile includes detailed information about the certainty of evidence assessment; specifically, it will inform the user which specific domain contributed to the rating down (or up) of the certainty of evidence, if applicable. The summary of findings table omits that information. Both representations share many characteristics. These include explicit information about the number of included studies, participants, relative and absolute effect size estimates as well as the rating of the certainty of evidence with foot notes that explain how the authors arrived at a given rating. These types of evidence summaries, typically a summary of findings table, are foundational for the deliberations of a guideline panel.

3. USING EVIDENCE TO MAKING RECOMMENDATIONS.

One important prerequisite for the process of making recommendations is to establish an overall certainty of evidence. This is necessary because any given recommendation is expected to impact all outcomes simultaneously. As per GRADE, the overall certainty of evidence will usually be based on the lowest certainty of evidence for any outcome that was deemed to be critical. For example, if there is moderate certainty of evidence for a certain desirable effect of an intervention yet the certainty of evidence describing an undesirable effect of that same intervention is not well established, then the resulting overall certainty of evidence should be low.

3.1. Strength of recommendation

The strength of a recommendation reflects the extent to which we can be confident that the desirable effect of an intervention outweighs the undesirable effects; in other words, that the patient is likely to experience a net benefit. (63) Importantly, GRADE only has two categories of recommendation which are strong or weak (which may also be called conditional). Strong recommendations are appropriate when the panel members, based on the available evidence and a series of structured judgements they have made, are confident that the desirable effects of adherence to a recommendation outweigh the undesirable effects. Weak recommendations are appropriate when the desirable effects of adherence to a recommendation probably outweigh the undesirable effects, but the panel is less confident. GRADE also recognizes that there is a subset of recommendations, so-called good practice statements, that panel may perceive to be important to communicate but that should not be graded. (64,65) Lastly, there is no category of "expert opinion" in GRADE, since this usually refers to indirect, oftentimes poorly documented observational or even anecdotal evidence that has not been well reported (66); however there are strategies in how guideline developers can nevertheless move forward in making evidence-based recommendations. (67)

GRADE operationalizes what a given recommendation of a certain strength should mean to patients, clinicians, and policy makers. The implications of a strong recommendation are:

- For patients: Most affected individuals in the same setting would want the recommended course of action and only a small proportion would not. A discussion of the intervention should be offered.
- For clinicians: Most people should receive the recommended course of action.
- For policy makers: The recommendation may be adopted as a policy (or performance measure) in most situations.

Meanwhile, the implications of a weak recommendation are:

- For patients: Most affected individuals in the same setting would want the recommended course of action but many would not.
- For clinicians: Although we expect a net benefit if a patient follows a weak recommendation, different choices may be appropriate for different patients. Shared decision-making will be important to help each patient arrive at a management decision consistent with his or her values and preferences.
- For policy makers: These recommendations are usually not suitable as policy of performance measures. It may require considerable debate and involvement of stakeholders.

3.2. Factors that determine the strength of a recommendation

GRADE has defined four major determinants of the strength of recommendation as well as three additional considerations. (67)

Balance between desirable and undesirable consequences

This represents a judgment on part of the panel members to what extent the aggregate of potential benefits of an intervention weigh up against the potential downsides of an intervention, based on the best estimates of those consequences as summarized on the summary of findings table. For example, a new chemotherapy regimen for metastatic renal cell carcinoma may extend overall survival but come at the price of reduced quality of life. Panel member deliberations would likely center around the relative weighting of these outcomes and the magnitude of the resulting net benefit (or harm). These considerations become even more complex when several outcomes contribute to both desirable and undesirable effects. When advantages and disadvantages are closely balanced, a weak or conditional recommendation would be appropriate.

Certainty of evidence

The overall certainty of evidence is the second determinant of the strength of recommendation. The more uncertainty there is about the magnitude of the benefits and harms of an intervention the less appropriate it would be to make a strong recommendation for or against the particular course of action. Therefore, outside of five paradigmatic circumstances that GRADE has described, an overall low or very low certainty of evidence calls for the resulting recommendation to be a weak or conditional recommendation.

Patients' values and preferences

The third factor that impacts the strength of recommendation is the uncertainty about or variability in patients' values and preferences. (68) Ideally, a systematic review of high-quality studies that a been performed to elicit these values and preferences would help inform this domain. However, such high-quality studies often do not exist and therefore the panel members' perception of these values and preferences and the variability stands in. To the extent that we are uncertain about the values and preferences of the target audience of a given guideline, or there is considerable variability of these values and preferences, a weak or conditional recommendation will be appropriate. (69,70)

Resource utilization

Although many guideline developers may choose not to perform a formal cost effectiveness analysis, general considerations about

costs, both direct and indirect and the total budget impact of a given recommendation are important.

The greater the incremental cost from a given intervention, the less appropriate a strong recommendation will be made.(71)

Importantly, costs of drugs and surgical procedures will often vary widely across the marketplace making it important for guideline developers to define the setting.

Equity, acceptability and feasibility.
These are additional considerations that may be relevant for the panel deliberations. If a given intervention would reduce equity, this may be reason to formulate a weak or conditional, rather than strong recommendation. The same goes for concerns about acceptability of an intervention among stakeholders, and the feasibility of implementing a recommendation in a given jurisdiction.

3.3. The GRADE evidence to decision framework
Historically, panel deliberations supporting many guidelines have not been transparent and reproducible. To address this issue, GRADE has developed an evidence to decision framework that facilitates a structured decision-making process to support and document the final recommendation that a panel arrives that. Doing so, increases confidence in the final product and should also improve recommendation uptake. The evidence to decision framework includes all the above domains and takes the panel through a process of deliberation and judgments to ultimately reach a strong or weak/conditional recommendation. (64,72) Of note, GRADE discourages the potential option of "no recommendation can be made" since patients, clinicians and policy makers ultimately do need to make a decision. One approach is to specify under which circumstances a given recommendation may be appropriate. For example, for patients with a renal stone who are candidates for both ureteroscopy and shockwave lithotripsy, the panel may make a weak/conditional recommendation for shockwave lithotripsy in patients wishing to minimize the perioperative risk (but it willing to accept a higher retreatment rate).

3.4. Wording of recommendations
Once a recommendation has been made, it should be clearly articulated. Therefore, GRADE recommends for panel members to use standardized terminology to express a given type of recommendation. (63,73) For strong recommendations, the suggested wording is "the panel recommends"; for weak recommendations, the suggested wording is "the panel suggests". Organizations using GRADE to develop guidelines may deviate from the suggestions, but consistency in signaling a given strength of recommendation will be important. In addition, GRADE recommends that recommendations that are intended to express that something should not be done use the wording "the panel recommends against" or the "the panel suggests against", rather than stating "the panel does not recommend" or "the panel does not suggest", since this wording is less direct and explicit. (74)

3.5. Conclusion
GRADE provides a methodologically rigorous and transparent framework for summarizing and rating the certainty of evidence and for arriving at guideline recommendations based on this evidence. Moving from evidence to recommendations requires several judgments on part of the panel members. Although GRADE cannot assure that these judgments are appropriate, it makes these judgments both explicit and transparent, and thereby the ultimate recommendation reproducible.

III. FOCUS AREAS

1. PREVENTION AND INTERVENTION RESEARCH

Research in prevention of urinary incontinence continues to evolve. Modifiable risk factors of pelvic floor disorders, inclusive of transitional age issues, aging related disorders and the lack of understanding of what represents a healthy bladder and the individual behavioral, interpersonal and environmental factors that contribute to bladder health all need further investigation. (75)

In 2015, the NIH launched the Prevention of Lower Urinary Tract Symptoms (PLUS) research consortium to provide the foundational evidence to support future prevention intervention studies. This group has subsequently produced seminal papers related to a variety of impacts on voiding status and pelvic health issues. This network has produced numerous well-conceived trials which have advanced knowledge of lower urinary tract conditions inclusive of: the design of the Prevention of Lower Urinary Tract Symptoms Bladder Health Instrument (PLUS-BHI) (76), the transdisciplinary approach to promoting bladder health across the stages of life as standardized by the consortium (77), and progress in reporting for consortium creation and shared mission with mutual decision-making. (78)

2. GENOMICS, PROTEONOMICS, TRANSCRIPTOMICS, METABOLOMICS – PERTAINING TO INCONTINENCE AND ASSOCIATED INTERVENTIONS.

"Omics" studies have the potential for comprehensive assessment of a biological system, and the integration of "omics" technologies is known as systems biology. Genomics, the measurement of all common genetic variation, and proteomics, the measurement of expression of all proteins are the two most developed aspects of this family of therapeutics and diagnostics. The use of the "omics" suffix has now been expanded to include all kinds of biological molecules and subtypes of molecules, but the most common additional applications include transcriptomics, the measurement of total gene expression, and metabolomics, the measurement of all metabolites. The potential of these technologies to impact personalized medicine and also to understand individual variation is vast.

2.1. Genomics
Genome wide association study (GWAS) has revolutionized the study of the genetics of common diseases. GWAS identifies genetic regions or loci associated with a trait, with the first identified gene being that for macular degeneration. GWAS is a cornerstone of the Wellcome Trust Case Control Consortium study. This includes studying type 1 diabetes, type 2 diabetes, coronary heart disease, hypertension, bipolar disorder, rheumatoid arthritis, and Crohn's disease. All of these diseases are common, with genetic, environmental, and lifestyle risk factors impacting presentation and natural history. (79,80,81,82)

For most common diseases, there may be hundreds of gene variants, each with inducible and suppressive effects, for which conventional GWAS is not sensitive enough to detect differences. Two

significant limitations of GWAS exist. One major limitation is that GWAS cannot fully explain the observed heritability of complex conditions. (82,83,84) Even with large sample sizes ,GWAS is currently not able to uncover the full genetic architecture of a condition. The second major limitation is that GWAS is inconsistent for identifying causal variants.(84)

Many single nucleotide polymorphisms (SNPs) identified in GWAS are intergenic, but even identification of genie SNPs may not directly help to uncover the underlying biology. GWAS, when used to assess genetic loci for incontinence, has not identified any specific risk loci.(85,86) This situation is likely to change as the size of the incontinence GWAS consortia grows.

2.2. Transcriptomics

Total gene expression has been performed using cDNA microarrays, which provide for simultaneous measurement of active mRNA expression for all known and putative genes and transcripts in a cell or tissue at any given moment.

This technique has been used extensively for the study of bladder carcinomas. (87) A number of studies have been limited by whole genome expression in cultured human detrusor smooth muscle cells (88, 89) or in cultured human urothelial cells, (90,91) rather than in vivo. Using urinary sediment as the source of material may over-represent senescent or apoptotic cells. (92) Transcriptome data from healthy portions of the bladder for patients undergoing cystectomy has also been measured either using microarrays (93) or more recently RNA sequencing (94), with the latter experiment now publicly available. (95) RNA sequencing has numerous advantages over microarray, including that it can capture expression of unknown mRNAs, and their variants, whereas microarrays are limited to detection of known sequences. To our knowledge, RNA sequencing has not been used in functional urology.

Only two studies have applied whole genome arrays to benign bladder biopsies. Both evaluated interstitial cystitis. (96,97) Both studies attempted to differentiate expression associated with ulcerated and non-ulcerated areas of the bladder in interstitial cystitis.

2.3. Proteomics and Metabolomics

The expressed proteins in a cell or tissue is considered the proteome, whereas the metabolome encompasses only the smaller molecules less than 1 kDa in size as identified with spectroscopy. Biomarker discovery is dependent on these two fields, specifically in urine. Many existing biomarkers in both urology and gynecology are themselves proteins (e.g. PSA and CA125). The numeric amount of human proteins is thought to be more than 250,000 human proteins and there are believed to be around 5,000 small metabolites. Research using these tools in pelvic floor disorders remains limited. Understanding of the urinary tract microbiome has substantially evolved due to advancements in these areas. (98,99,100)

2.4. Limitations of "omics" Research

Incontinence is an archetypical example of a common complex disease, with multiple subtypes and an array of complex potential causes. It has a wide range of environmental and lifestyle risk factors, that might obscure attempts to identify meaningful biological differences. Stress and urgency incontinence overlap much more commonly than expected by chance, suggesting that they might have common environmental or genetic risk factors (101), but it is not a trivial problem to correctly assign women as having stress, urgency, or mixed incontinence either on the basis of symptoms (102) or laboratory testing.(103) Thus any "omics" study of incontinence faces substantial problems with case ascertainment, and potential problems with misclassification bias, which might further obscure biological signals. Although these technologies can be applied to any common trait, they been most successful for conditions with tightly defined pathology. Incontinence, as a symptomatic condition, certainly does not have a single clear pathogenesis, and the subtypes of incontinence have multiple potential causes. (104)

The common pitfalls of clinical research described above tend to be magnified in "omics" research. Two particular problems need to be planned for in the design of all "omics" studies, both relating to the lack of specific hypothesis. "Omics" research seeks to define differences in any of a large number of molecules between cases and controls, or between different experimental conditions. For some "omics" technologies, formal consensus has been reached regarding adjustment of significance to account for the huge number of simultaneous measurements. For all "omics" studies very careful consideration of sample size is needed at the planning stage to account for loss of power from multiple comparisons.

The ability to replicate "omics" results is another concern. A risk of false positive results confounding issues compounded by effect size errors exists in "omics" studies.{ (105,106) However, the potential for "omics' investigative methods to elucidate complex disorders of aging or condition specific disorders such a fibrosis associated with external toxins has recently been demonstrated to be robust and reproducible. (107,108,109)

IV. BASIC SCIENCE RESEARCH

Drawing from the human ethical oversight construct, the development and implementation of a similar process to ensure animal welfare is now common practice and required at all research institutions conducting research with animals. In 1986, the term IACUC (Institutional Animal Care and Use Committee) was coined in the Animal Welfare Act where the composition of each institution's IACUC committee was delineated. Each IACUC must ensure the use of animals for research is performed in a humane manner compliant with federal guidelines and regulations.

1. LABORATORY ANIMALS AND RESEARCH

Advancement of modern medicine, including Functional Urology, is greatly accelerated by the judicious use of laboratory animals, acting as an essential tool for testing scientific hypotheses, deepening our understanding of the mechanisms of disease and eventually leading to the development of novel therapies. Scientists are directly responsible for the welfare of the animals used in experiments and are guided in their activities by the national and international laws and regulations, protecting the animals and ensuring the implementation of 3R principles of animal research (Replace, Reduce, Refine). 3R Principles represent a responsible approach to animal experimentation. The goal is to replace animal experiments whenever possible, while keeping the number of animal experiments as low as possible and only use the necessary number of animals. Refinement of laboratory practices and procedures is vital to ensure that the distress inflicted upon the animals is as low as possible. In addition, the newest changes in the EU regulation (EU Directive 2010/63) emphasize the intrinsic value of animals and introduce Animal Welfare Bodies for assessment of all animal license applications prior to submission to the governmental organs. The concept of transparency of animal research is very important, as most

science is funded by the public and is accountable to the society. The US Animal Welfare Act requires that all research is approved by the duly appointed Institutional Animal Care and Use Committee (IACUC). India also has elaborated the regulations, including Prevention of Cruelty to Animals Act 1960 and The Breeding of and Experiments on Animals Rules 1998 with newest amendments up to the Bill 2017. China, which uses approximately 20 million animals per year, follows its own nation-wide animal protection law, however, lack of harmonization with existing international regulations singles out animal research in this country, and hinders effective international collaboration in experiments involving lab animals.

Publication of results involving animal research is another area undergoing continuous change, after a survey of 271 publications carried out in 2009 revealed lack of consistency and identified a number of issues that need to be addressed in order to improve experimental design and reporting in publications describing research using animals (110). This led to publication of the original ARRIVE (Animal Research: Reporting of In Vivo Experiments) guidelines in 2010, and the current updated version ARRIVE 2.0 appeared in 2020 (111). These guidelines are a checklist of information to be included in publications describing animal research. Reporting animal research in adherence with the ARRIVE guidelines 2.0 ensures transparent and thorough reporting. This enables readers and reviewers to scrutinize the research adequately, evaluate its methodological rigor, and reproduce the methods or findings. Most journals require the authors and reviewers alike to ensure implementation of the ARRIVE checklist, which includes reporting the study design, sample size, inclusion and exclusion criteria, randomization and blinding, outcome measures, statistical methods, the detailed information on the used experimental animals and experimental procedures, and reporting the results.

2. LOWER URINARY TRACT DYSFUNCTION (LUTD)

Using animal models in Functional Urology has a long history. Laboratory animals helped to elucidate the mechanisms of bladder dysfunction, attributed to different diseases, and to establish new approaches to therapy, which can be subsequently translated to humans. These studies and the rationale for the use of laboratory animals have been thoroughly reviewed in several excellent recent publications (112 – 116).

Several rodent models of bladder dysfunction have been developed using rats, mice, and guinea pigs to study voiding and storage function in normal conditions and in various disease models using cystometry. While rodents are cheap, and offer other advantages including possibility of genetic manipulation, it should not be forgotten that the mechanisms of micturition are different between mice and humans: rat micturition requires a pulsatile activity dubbed “milking action’’ of the urethra; rat, mouse and guinea pig bladder contraction is mediated primarily via ATP, not acetylcholine as in humans. Nevertheless, cystometry in rodents continues to be used and improved, transitioning from anesthetized to awake animals for both UDI (urodynamic) and EUS-EMG (117) to achieve the results comparable to human urodynamic investigation. Micturition in free moving animals was traditionally monitored by the spot assay, which has recently been improved by using Micturition Video Thermography (MVT) – a fully digitalized non-invasive void spot assay reported in 2019 (118). Imaging technology is being continuously applied to control voiding events in combination with catheter implantation followed by UDI, and recently, a closed-loop wireless system with an implantable device wrapped around the bladder and measuring changes in resistance during bladder filling and emptying was used in freely moving rats (119). Similarly, high frequency ultrasound proved to be an effective method for assessing bladder and urethral measurements during urinary function in mice (120).

Rodent models of bladder dysfunction employ either direct changes (injury, stimulation, etc.) to the bladder, its blood supply or peripheral innervation, or injuries to the spinal cord, or brainstem, leading to changes of lower urinary tract function. Neurogenic bladder dysfunction was studied in models of Parkinson’s disease, stroke and Multiple Sclerosis in experimental autoimmune encephalomyelitis mice. Additionally, many transgenic mouse disease models can develop LUTD, and be used to delineate or validate the involvement of particular molecules and signaling pathways in disease development (121,122).

Bladder function in rodents can be investigated with optogenetic methods, which are increasingly applied to elucidate the role of selected structures (smooth muscle cells, peripheral nerves, defined areas of CNS) in bladder contractility and responses to stimuli. Optogenetics uses light-responsive proteins (opsins) to activate defined cell populations. Using transgenic mice or viral expression vectors to deliver activating and inhibitory opsins, membrane potential of the bladder smooth muscle cells was modulated to regulate the contractile behavior of the bladder (123). Optogenetic silencing of nociceptive primary afferents was shown to reduce evoked and ongoing bladder pain (124), or to activate the sciatic nerve similar to neuromodulation (125). This approach was instrumental in studying the subtypes of neurons from Barrington’s nucleus which control the bladder and sphincter function (119). A further advancement of this approach was the development of a fully implantable, soft optoelectronic system for wireless, closed loop optogenetic modulation of bladder function to control inhibitory opsins expressed virally and by bladder sensory afferents (120). Although such systems are still a long way from the translational applications in human trials, being able to reduce neural activity and facilitate bladder storage function by delivering a corrective signal opens an exciting new field in Functional Urology.

Non-rodents are also being used to study bladder dysfunction, including feline spontaneous (interstitial) cystitis, which was previously extensively studied. Recently, however, several transgenic mouse models have been developed as an alternative, including URO-OVA/OT-I mice, a transgenic autoimmune cystitis model that spontaneously develops bladder inflammation (126). More transgenic mouse models are being evaluated for bladder function, and new genes regulating voiding are being discovered, such as the recently described acyloxyacyl hydrolase (AOAH) (127). Therefore, it is likely that the use of large animals will further decrease. The notable exception are pigs: micturition volume and frequency of Göttingen minipigs are comparable with that of humans, making them the better choice for translational research in fields such as urology, neurology and nephrology (128). Minipigs are big enough to allow telemetric monitoring following implantation of transmitters (telecystoscopic monitoring) and can be used for testing devices suitable for human application, such as the recently reported Bladder Pill, a wireless intravesical device for real-time bladder pressure measurement (129). Minipigs are also used for drug testing, and toxicological evaluation, both relevant for urological application. High costs of maintenance and generally low number of used animals are the disadvantages of this species compared to mice, however, the advent of transgenic pigs (130) might offer new possibilities for their use in Functional Urology.

3. PELVIC FLOOR DYSFUNCTION

Animals models to study pelvic floor disorders (131,132) and their treatment (133) are advantageous as they allow for a focused evaluation of specific factors without involvement of interfering co-factors. On the other hand, most animals are quadrupeds with a different pelvic floor muscle construction including a tail, a different load distribution on the pelvic floor and a different birth process and hormonal changes.

3.1. Pelvic floor anatomy

In quadrupeds, the bulk of weight is perpendicular to the spine so that the pelvic organs are supported mainly by bony structures, whereas in bipeds the pelvic floor supports the pelvic organs. In addition, in quadrupeds the tail movements are dependent on the levator ani. Rodents have a similar pelvic floor structure and function of the vaginal connective tissue to humans, making them a preferred model for evaluating connective tissue support. Rats seem to have a more histologically comparable pelvic floor to humans than mice and rabbits. Rabbits due to the large surface of the abdominal wall are a good model to test the biomechanical behavior of implants (134). Sheep are a large animal option with a similar anatomy of the pelvic organs and a three-level support similar to what has been described by DeLancey in humans. The main difference being a lack of obturator internus muscle, sacrospinous ligaments and a different shape and orientation of the pelvis (135). Pigs, like sheep have a similar anatomy to humans, but both need space to be boarded. Non-human primates (NHP), of which squirrel monkeys are the best studied, are most similar to humans but have the obvious limitations such as long-life cycle, expertise needed to handle them, and ethical constraints.

3.2. Estrous cycle and length of gestation

Rodents have a regular and short estrous cycle and length of gestation. Rabbits do not have an oestrus cycle, ovulation is induced by coital vaginal stimulation. Sheep have an oestrus cycle of 17 days and 147-day gestation period. Ewes can have prolonged labor and relatively large fetuses. NHPs again are very similar to humans. Squirrel monkeys, besides similar anatomy and estrous cycles also have large fetuses relative to the maternal pelvic outlet and long labor (136). None of these animal models develop menopause.

There are various models of pelvic floor dysfunction. Denervation by pudendal nerve crush has been used to stimulate urinary and fecal incontinence in rats and to evaluate therapeutic approaches and neuroregeneration (137). Unlike humans where the pudendal nerve innervates the M. pubocaudalis and iliocaudalis, atrophy of these muscles could only be induced by damage to the LA nerve in squirrel monkeys (138). Vaginal delivery can be simulated by distending a balloon in the vagina with different volumes and for different durations causing mechanical stretch and hypoxia (138). Iatrogenic menopause is generally induced by ovariectomy as most animals used for research purposes do not develop menopause (139). Findings are inconsistent most likely due to the difference in age at the time of ovariectomy and the interval to measurement. Aging itself however, natural or accelerated, leads to a drop in oestradiol underscoring the interaction between age and hormonal changes in animals (140). Various genetically manipulated mouse models have been developed to study the effect of changes in pelvic floor connective tissues on pelvic floor function (141-145).

Research in human tissue for pelvic floor dysfunction is hampered by the prolonged natural history of disease and the difficulties associated with obtaining human tissue. Various animal models in different animals and using different techniques have been developed, each with unique advantages and disadvantages. Careful selection, well designed and powered studies and consistent reporting are imperative to minimize the number of animals used and optimize outcome and forward our knowledge on pelvic floor dysfunction.

V. TRANSLATIONAL CONCEPTS

Translational research involves results and findings obtained from multiple sources including the basic science laboratory, clinic and community environments and developing these datasets into interventions benefiting the health of individuals and the public. Translational developments may span diagnostics, therapeutic, behavioral , and psychologic interventions. (146)

Translational research is a critically important link between the bench and the bedside. Unfortunately, only about 2 percent of the current US federal funding goes to translational research. The translation of basic biological discoveries into clinical applications that improve human health is an intricate process that involves a series of complex steps: the discovery of basic information about the pathogenesis of a disease; an assessment of whether that information has the potential to lead to a clinical advance; development of candidate diagnostics, devices or therapeutics; optimisation of the candidates in preclinical settings; regulatory assessment of the data to determine use for human use; testing in human clinical trials; application for approval for widespread clinical use; and ultimately, the assessment of approved diagnostics, devices, and therapeutics during widespread use in real-world settings. (147) Initiatives to integrate the public and private sectors led to the formation of the National Center for Advancing Translational Sciences (NCATS) at the US National Institutes of Health in 2012. NCATS research projects and initiatives focus on addressing scientific and technical challenges to reduce and remove obstructions in the development of new treatments and tests that will ultimately improve human health. The aim of NCATS is to catalyse the scientific community to propose implementation projects including therapeutic target validation, chemistry, virtual drug design, preclinical toxicology, biomarkers, efficacy testing, phase zero clinical trials, drug rescue and repurposing, novel clinical trial design and post-marketing research. With translational research, the focus is on the result, not the process. However, the impact of experimental methods differences, species response variances, or aging related dysfunction must be considered in the intrepretation of the results derived from translational analyses. (148)

VI. CLINICAL RESEARCH

1. STATISTICAL METHODS AND STUDY CONDUCT

Many definitions for „clinical research“ have been proposed. The National Institutes of Health (NIH) currently defines clinical research as research with human subjects that is:

Research conducted with human subjects (or on material of human origin such as tissues, specimens, and cognitive phenomena) for which an investigator (or colleague) directly interacts with human subjects.

Excluded from this definition are in vitro studies that utilize human tissues that cannot be linked to a living individual. It includes: (a) mechanisms of human disease, (b) therapeutic interventions, (c) clinical trials, or (d) development of new technologies.

1.1. Outcomes Research and Health Services Research

Patient-oriented research encompasses many study designs, from cross-sectional questionnaire studies to large-scale clinical trials. The NIH defines a clinical trial as, „A research study in which one or more human subjects are prospectively assigned to one or more interventions (which may include placebo or other control) to evaluate the effects of those interventions on health-related biomedical or behavioral outcomes.“ Clinical trials of an experimental intervention may be done in a small group of people to determine a safe dosage range and identify side effects (Phase I), in a larger population to determine efficacy and further evaluate safety (Phase II), in a very large population to compare effectiveness with other standard or experimental interventions and to collect information that will allow the interventions to be used safely (Phase III), and to monitor the effectiveness and safety of the approved intervention in the general population after it has been marketed (Phase IV)

Conducting clinical research is challenging. An Institute of Medicine workshop identified several key challenges as follows (149):

1. Prioritising of clinical research questions
2. The divide between clinical research and clinical practice
3. Globalisation of clinical trials
4. The cost of clinical trials
5. Narrow incentives for physician participation in clinical research
6. Shrinking clinical research workforce
7. Need to navigate administrative and regulatory requirements
8. Recruitment and retention of patients

The next section focuses on some challenges that are of particular relevance to studies of urinary incontinence and pelvic organ prolapse.

1.2. Inclusion and Exclusion Criteria

Inclusion criteria are often narrow; while results derived from a homogenous pool of participants is more likely to demonstrate a difference from an experimental intervention, the results also may be biased and applicable only in this homogeneous population (150), causing translation to generalized practice to be problematic. Narrow-inclusion criteria also may hamper the ability to meet recruitment goals. But, while broad inclusion criteria yield more generalizable results, these may also make it harder to attribute statistical significance to the intervention under study.

Inclusion criteria which focus on the condition for which the trial is providing intervention must be considered in concert with the consideration of the primary outcome measure. If an inclusion measure defines “disease,” it is essential that the outcome measure does not include this same measure or cut-point as “success.” It is also important to note that a given condition, such as stress urinary incontinence, will be present or absent depending on which outcome measure is used to define it. Investigators should avoid using one outcome measure to exclude women from a study and then a different outcome measure defining the same condition as the primary outcome measure.

Exclusion should emphasize criteria to reduce risk to potential participants, and, especially in longer-term studies, to reduce those factors that could hamper the potential for follow-up. It is important to include individuals in whom the treatment would likely be used once widespread. For example, in testing a new drug for urgency incontinence, that is excreted by the kidneys, it is important to exclude people with high serum creatinine levels, but equally important to include older individuals with multiple comorbidities in specific studies, as these are also likely to benefit from a drug for urgency incontinence once released. However, certain exclusion criteria may purposefully exclude certain common conditions (such as poor glycemic control) to potentiate safety associated with clinical trial interventions.

1.3. Blinding (Masking)

Controlled clinical trials require blinding of both investigator and site personnel and the subject (participant). Participant blinding is feasible in many types of trials (pharmaceutical trials) but may not be possible in trials of some surgical procedures, behavioral or physical therapies, or health care delivery methods. In these studies, the only possible blinded person is often the assessor. Thus, a third-party independent assessor may be required to optimize site blinding. It may be advantageous for the clinical staff to be aware of the assignment to allow them to monitor the health and safety of individuals, since the potential effects of the treatment (side effects) will often be known in advance. Single blinding ameliorates biased reporting of symptoms and/or side effects by participants. However, clinical staff can influence data collection and change other aspects of participants’ care when they know which study treatment subjects are receiving. It should be noted that blinding is not impossible in all surgical trials and should be considered when possible

1.4. Randomization

Stratified randomisation ensures equal distribution of subjects with a particular characteristic in each group when blocking is employed within strata. This is particularly important if certain participant characteristics are likely to influence the outcome. For example, in incontinence research, variables such as prior failure of therapy, degree of pelvic organ prolapse or severity of incontinence might be considered important enough to stratify at randomisation, because unequal distribution of variables important to the outcome may create headaches during the data analysis. Increasingly, demographics are being considered as critical elements in stratifaction of study populations.

The gold standard in analysing randomised trials is by intention-to-treat, according to the group to which subjects were randomised, regardless of the extent of compliance with the intended treatment. Appreciable loss to follow-up in a trial (which is not the same as adherence with intended treatment, lack of efficacy, or the observation of adverse events) may present serious problems both in terms of generalizability of the findings to the wider population and, in the case of differential loss to follow-up across treatment groups, to the validity of the comparisons. Results should always be accompanied by a full and clear description of how the analysis handled deviations from intended treatment and missing outcome measures. Missing outcome data may also affect study conclusions. (151) Sensitivity analyses can be used to test the exclusion of, or assumptions about, missing values; practical examples of such analyses are becoming more common. (152) Also, the use of last observation carried forward (LOCF) may be used in certain circumstances when subject withdrawal is problematic, however in regulatory approval trials, this technique is not optimal.

2. PROTECTION OF SUBJECTS AND INFORMED CONSENT

Ensuring participant safety is paramount. An independent data safety monitor (DSM) or data safety monitoring board (DSMB) is important to evaluate the study on an ongoing basis to determine early evidence of significant harm or benefit. (153,154) Depending on the size, complexity, and risks of a trial, the DSMB is comprised of experts needed to monitor interim data to ensure the safety of the participants. The DSMB should be established prior to initiation of the trial. In addition to reviewing results of the study for safety monitoring they may evaluate interim analyses to ensure that a treatment is not producing unacceptable levels of side effects and/or efficacyc . (153) Clinical events committees (CEC) may also be used in clinical trials as another oversite group to assist in unbiased, third party assessment of adverse events and other clinical reports arising from trials, especially those evaluating device interventions.

2.1. Analysis

High quality data management is key to providing valid and ethical research results. (155) The analytical plan should be consistent with study aims and the a priori analytical plan should be included at the time of the protocol entry into a clinical trials registration system. (156) Stopping rules or boundaries are established to assess-if the study should continue or be terminated due to futility (that is, no conclusion will be drawn due to low enrollment, few outcome events, or high drop out rates etc.), reaching an endpoint, or identifying increased risks. Guidelines for stopping the study should be agreed upon, prior to the start of the trial. Interim analyses (in particular those based on efficacy) will have implications for the study power. Specialist statistical advice and support will be essential to address these issues, (157) Investigators must not be aware of the results of interim analyses, however, since this may cause bias by influencing how vigorously any given patient is recruited into or followed up in the study, and most importantly, runs the risk of a type 11 error (i.e. mistakenly concluding benefit when there is none). Nevertheless, emergency procedures for unblinding a patient‘s allocation are required in case of a severe side effect or concomitant serious illness where knowledge of treatment assignment is essential for patient management and safety. (157)

3. CHALLENGES IN CONDUCTING TRIALS IN DEVELOPING COUNTRIES

Conduct of clinical trials in developing countries presents ethical, organizational, cultural and infrastructural challenges to researchers, pharmaceutical companies, sponsors and regulatory bodies.(A balance between managing these challenges while yet conducting the trials is important so that research can be encouraged and supported in order to bring maximum public health benefits to these communities, often underrepresented in research. Difficulties, as outlined by authors of an investigator-initiated trial, include “obtaining valid informed consent, ethical compensation mechanisms for extremely poor populations, poor health infrastructure and considerable socio-economic and cultural divide_s (158). Other challenges include appropriate linguistic translations of forms and support documents, access to care at the conclusion of the trial, administrative bottlenecks, equitable investigator (as well as participant) compensation, difficulty in obtaining skilled researchers, and regulatory bodies with different standards from those of developed countries.

3.1. Trial Registration and Data Sharing

The International Committee of Medical Journal Editors (ICMJE) initiated a policy in 2005 requiring investigators to enter information about trial design into an accepted clinical trials registry at or before the time of first patient enrollment. (159) This requirement, adapted by many journals, aims to restrict the practices of selective publication and selective reporting of research outcomes, as well as to prevent unnecessary duplication of research effort. The ICMJE accepts registration in any registry that is a primary register of the WHO International Clinical Trials Registry Platform (ICTRP) or in ClinicalTrials.gov. The ICMJE encourages registration of research with non-trial designs, such as observational studies, but does not require it at this time. The ICMJE also encourages posting of clinical trial results in clinical trial registries but does not require it; such posting is not considered a prior publication if the results are limited to a brief abstract or tables.

Standards recommended by ICMJE are frequently adapted by medical journals and therefore play a major role in guiding research conduct. Thus, it is of interest to note that at the time of this writing, the ICMJE posted proposed requirements for sharing clinical trial data and is inviting public feedback. In an editorial, the Committee notes that “there is an ethical obligation to responsibly share data generated by interventional clinical trials because participants have put themselves at risk” (160).The ICMJE recommendation continues: “As a condition of consideration for publication of a clinical trial report in our member journals, the ICMJE proposes to require authors to share with others the de-identified individual-patient data (IPD) underlying the results presented in the article (including tables, figures, and appendices or supplementary material) no later than 6 months after publication.” The proposal also requires that authors outline a detailed plan for data sharing at the time of clinical trial registration. Nuances of data sharing should be considered in planning clinical trials (for example, in the consent process, participants must be asked to provide consent to have de-identified data shared publicly). Investigators should stay abreast of changes in this rapidly evolving area.

Many funding agencies around the world require publications resulting from such funding to be deposited in an open repository, so that they are freely available to all. In general, authors submit the post-print (the manuscript after peer review and acceptance but before copy editing, formatting or other journal-specific tasks) to a repository accessible online without charge. A large number of journals now assist the author by automatically depositing the published content into a repository such as PubMed Central.

3.2. Reporting Research Results

The investigator has an ethical responsibility to take responsibility for all aspects of the research, ensuring that the work is done rigorously and to maintain the integrity of the research. Investigators should adhere to published standards in reporting their research results, in order to maximise quality and transparency. Further, most journals require this. Adherence to these guidelines and the use of flow diagrams in particular is associated with improved quality in reporting of RCTs. (161) The “Enhancing the QUAlity and Transparency of health Research” (EQUATOR) Network project (www.equator-network.org) provides a continuously updated platform of the many different guidelines now available for reporting the design, methods and results of different study types. The most commonly used guidelines for clinical research are listed below:

- Consolidated Standards of Reporting Trials for randomized clinical trials (162)
- Strengthen the Reporting of Observational Studies in Epidemiology (163) Of note, these guidelines do not pertain only to

prospective cohort studies, as sometimes assumed, but also to cross-sectional, case-control and retrospective studies.
- Standards for Reporting of Diagnostic Accuracy (164) : for studies about the accuracy of diagnostic tests.
- Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (165): for systematic reviews
- Standards for Quality Improvement Reporting (166)

3.3. Study Conduct and Statistical Methods

The role of quality RCTs as providing the strongest level of evidence in incontinence research should be fully acknowledged by researchers, for studies about quality improvement in health care the following guidelines and consensus statements are informative:
- Excellence (SQUIRE) (166)
- Standard protocol items for clinical trials (SPIRIT) - this is an excellent resource in planning a clinical trial. (167)

To improve guidelines adherence, a checklist accompanies each guideline. It is crucial that the reporting guidelines be considered during the planning phase of the study in order to ensure that all key elements are collected as required.

Most of the guidelines contain additional separate items for certain types of studies. In this section, we use the CONSORT guidelines as an example. CONSORT includes additional guidelines for reporting parallel group randomised trials, pragmatic trials, non-inferiority and equivalence trials, and cluster randomized designs. (168) The statement includes a checklist of items that covers a comprehensive set of characteristics of a clinical trial. These include clear statements about the objectives of the trial, intended study population, planned comparisons and justification for any subgroup or covariate analyses. The method and unit of randomisation should be stated. For all trials, specifications for the sample size calculation (primary outcomes, target differences, etc.) should be stated and justified. In addition, the precision actually obtained in a study must be presented. This requires confidence intervals as well as the observed p-values, at least for primary outcomes but preferably for all outcomes. The principal confidence intervals should be for comparisons between the groups, rather than for differences in the outcomes within the trial groups. (157,169,170) Results should include a trial flow diagram, with numbers and reasons for the exclusion of eligible subjects, the number randomized and subsequent losses to follow-up. (171) Protocol deviations should be described and explained. (172)

Harms of the trial should be described for each treatment group. Finally, the discussion should include a brief summary of the trial‘s findings, possible explanations for the results, interpretation of the findings in light of the literature, limitations of the trial including internal and external validity, and the clinical and re search implications of the study. (173) Some guidelines also include specific information that must be included in publication abstracts. These are particularly important to follow, given that many readers rely solely on the abstract for their interpretation of a study.

4. SPECIAL CONCERNS FOR SPECIFIC STUDIES

4.1. Systematic Reviews

Systematic review remains perhaps the most formalised part of epidemiology, with a wealth of available guidance for the correct conduct and reporting of reviews (164, 174-178) , and the creation of recommendations based on the evidence. (176) Without transparent reporting of systematic reviews, it is difficult for editors and readers to judge the quality of a review. One fundamental step that is frequently overlooked is prospective registration of the review protocol in a database such as PROSPERO. The types of studies included should be pre-specified, along with all planned outcomes and analyses.

Searches should encompass a range of sources, perhaps including Medline, EMBASE and CINAHL. Importantly, as many studies never reach publication, efforts should be made to search the grey literature. It is almost always helpful to directly contact primary study authors for clarifications, additional information about methodology, and even additional data or analyses where necessary.

The screening and data extraction process should be planned in advance, and all reviewers should be trained to use the data forms, to achieve a high level of consensus. All screening and data extraction should be performed independently and in duplicate. Reference lists should be hand searched for all included articles, applying the same standardised screening process, as this can pick up additional relevant studies.

Statistical methods are equally formalized for metaanalysis. Fixed effects models (Mantel-Haenszel weighting) (179) should be used for meta-analyses with only two studies, or for three or more studies and low heterogeneity, but otherwise random effects models (Dersimonian and Laird) weighting should be used. (175)Assessments of risk of bias in primary studies, and for the meta-analysis as a whole (177), are important particularly when formalising recommendations based on the pooled evidence, and should follow the most relevant scheme for the types of studies included. (178)

4.2. Quality Improvement Studies

The SQUIRE (2.0) guidelines facilitate performance, analysis, and publication of quality improvement. (166) SQUIRE 2.0 is the inclusion of a glossary of key terms to help standardise definitions and clarify the use/misuses of commonly employed phrases in the quality improvement literature. Terms such as „intervention,“ „opportunity costs,“ „process,“ and „systems“ are clearly defined. The guidelines also present information about context (interpreting the work within its own unique environment), and studying the intervention (evaluating the generalisability of the intervention as opposed to simply performing or doing it). The guidelines are presented in a printable 18-item table that takes potential quality improvement investigators through a step-by-step process for performing and publishing their work from abstract to conclusion.

4.3. Observational Studies Using Routinely Collected Health Data

Observational studies using routinely collected health data obtained for clinical and administrative purposes (often referred to as „database studies“) are increasingly common, given the increased availability of health administrative data, disease registries, electronic health record data repositories, public health reporting data, etc. The major advantage of these studies, that the data are already collected often on millions of people, is also the major drawback: Because the data were collected without a specific a priori research goal in mind, the database may lack key information needed. Further, the information collected, especially in administrative data collected for billing purposes, may not be accurate; validation is often required. However, the potential of such databases to enable efficient and cost-effective research is substantial.

The REporting of studies Conducted using Observational Routinely-collected health Data (RECORD) Statement is an excellent resource for investigators planning and reporting such studies. (180) Below we summarize, based on this statement, some of the key recommendations for investigators planning studies using routinely collected health data. Further detail is available in the full report.

- Clarify whether the analyses were exploratory or confirmatory, and indicate whether the hypotheses were generated before or after data analysis.
- For studies that involve linkage of databases, display in detail the data linkage process.
- Explicitly state the methods used to identify study subjects, including whether identification is based on single codes, algorithms (combinations of records or codes), linkage between databases, or free-text fields.
- Provide a complete list of codes and algorithms used to classify exposures, outcomes, confounders, and effect modifiers.
- Describe data cleaning methods at different stages of the study (for example, how were missing data and repeated measures handled?)
- Clearly define how the final study population was derived.
- Consider potential sources of bias: „(1) codes or algorithms to identify study populations, outcomes, confounders, or effect modifiers (misclassification bias); (2) missing variables (unmeasured confounding); (3) missing data; and changes in eligibility over time“. (180)

Unmeasured confounding is particularly problematic in these types of studies. The fact that an outcome was assessed in a very large population cannot make up for the absence of an important potential confounder in the database. The investigator is better off looking elsewhere to answer the research question at hand. Another problem frequently arising in studies using large databases are changes in composition of the database population or coding practices over time. Such changes challenge the integrity of temporal comparisons using the dataset. Finally, some journals require that the author attest to the reliability and validity of key variables used in a database before they will consider publication of these studies.

5. EXPERIMENTAL DEVICES AND MATERIALS

Surgical research presents unique challenges to efforts at optimizing patient care. It is important to create a pathway for real advances while simultaneously protecting patient safety. When new procedures are substantially different from prior operations there should be a broad-based preliminary exploration leading to a comparative trial if warranted. At the same time, many minor modifications of surgical procedures are inappropriate for randomized trials and if required, surgical progress would be slowed. (181)

It has been argued that the first patient in whom a procedure is performed should be randomized. (183,183) Alternatively, it has been suggested that case series for new procedures are allowed until the procedure finds its intended use and to avoid doing studies while those performing the procedures are on the „learning curve“. Typically, new surgical procedures for incontinence have been reported as case series. (184,185) Pilot and feasibility studies are necessary, providing sufficient methodological evidence for the further randomized trials. They can also provide the lowest level of evidence for treatment effects and justify for the trials. However, in some situations, case series may be „harmful“. An accumulation of „positive“ case series may present a premature certainty about benefits of a procedure and make it even more difficult to perform randomized trials. (186,187) Influential members of the surgical community may endorse a new procedure and if the procedure is considered better it may be difficult to get surgeons and patients to randomize or a trial may appear to be unethical with a „proven“ procedure. (182)

Therefore, devices often are widely adopted by clinicians based on anecdotal data, marketing, or small case series. This raises a unique problem for trials in this area: 1) Surgeon buy-in can be difficult to obtain as some surgeons („early adopters“) may perceive that the newest therapy is best and thus be unwilling to randomize patients to receive the traditional therapy, 2) Other surgeons („late adopters“) may perceive that the data available do not support use of the newest therapy and thus be unwilling to randomize patients, 3) Patients may be unwilling to be randomized to traditional therapy because they are influenced by marketing forces propelling the newest devices to the forefront, and 4) Device companies frequently modify their materials or technique recommendations; therefore, by the end of the 3-5 years it typically takes to complete the earliest outcome assessment for a surgical randomized trial, the device tested is no longer the same as the device used in the trial. Thus, the results may be discounted as being no longer applicable.

An important area of concern in surgical and device studies is patient recruitment procedures. The protocol should detail the procedure for selection of consecutive patients who meet the inclusion criteria. All situations in which a patient meets the inclusion/exclusion criteria but is not offered enrolment by the investigator should be documented. The number of patients who decline enrollment should be stated, along with the reasons. It is vital that clinician researchers do not „cherry pick“ from their patients, that is, that they do not limit recruitment to those patients considered to have the greatest chance of cure or lowest chance of risk. The study population should be as generalizable as possible. There should be a complete accounting of all participants in the study including the reasons for subject withdrawal. Participants must be well informed about what is known and not known about devices or procedures being tested. They should not be led to assume that because a device is on the market, it is „safe and effective“, as gaining knowledge about this is the purpose of the trial.

Randomized controlled trials (RCTs) have long been recognized as the gold standard for assessing the efficacy of clinical interventions, valued for their statistical rigor and mechanisms to avoid bias (188) . However, clinicians increasingly recognized the limitations: each patient had unique pathological findings, each surgeon had different skills, and each operation involved countless choices about anesthesia, premedication, surgical approach, instrumentation, and postoperative care, all of which defied the standardization that clinical trials required. In recent years, the significance of real-world study (RWS) in clinical research has gradually been realized (189). Real world evidence (RWE) in medicine means evidence obtained from real world data (RWD), which are observational data obtained outside the context of RCTs and generated during routine clinical practice (189). It is derived from a number of sources that are associated with outcomes in a heterogeneous patient population in real-world settings, such as patient surveys, clinical trials, and observational cohort studies. RWS that can sustain follow-up observation after the completed RCT research holds important significance. However, it should be emphasized that RWS must be fit for purpose, and it cannot replace RCT (190).

6. SURGICAL INTERVENTIONS

Cross-sectional studies of surgical procedures by type can provide estimates of prevalence, variation by age, race, and region as well as morbidity and mortality. (191,192) This type of information raises important health policy questions regarding physician practices, patient preferences for incontinence treatment, and differential access to, and the utilization of care. Observational studies can provide important information about effectiveness and complications of surgical procedures, and also are very helpful in designing and selecting potential randomized clinical trials.

The randomized controlled trial is the accepted „gold standard“ for research of treatment effects. In all surgical specialties, there has been growing concern regarding the limited number of randomized controlled trials for surgical procedures, poor methodological standards in those that have been performed, and a perception that surgeons are reluctant to rigorously test new surgical interventions. (182,186, 193,194)

The body of literature of surgical randomized trials in pelvic floor disorders is increasing. Modern trials are beginning to overcome historical limitations including insufficient sample sizes, lack of blinding of the participants and/or individuals assessing the outcomes, short follow-up, inclusion of limited number of surgeons only, poor description of the technique, and lack of standardized outcome measures. Multicenter treatment networks appear effective in overcoming some of these limitations. Differential drop out after randomization (or for cohort studies, after the intervention} can introduce bias. Randomization can occur in the operating room after the patient was anaesthetized, reducing this risk. (195,196)

For studies of specific surgical procedures, the technique should be described in such detail that it could easily be reproduced in another study. Standardization of the procedure may vary depending on the research question. (197) Surgical trials using a small number of highly skilled surgeons are analogous to medical trials where only compliant patients are randomized, reflecting efficacy of the procedure in an ideal setting. It may be more generalizable to a mixture of skill level among surgeons in the community, and so reflect effectiveness of the procedure in usual practice. (187)

Masking (blinding) of participants as to their assigned intervention and those assessing the outcome is particularly important for surgical trials for incontinence because there may be enthusiasm by the patient or surgeon for a new procedure, many outcomes are based on the patient‘s own assessments such as symptom and quality of life scores, and the intervention is primarily for improvement of symptoms. (181)

Organizations and treatment networks have been established to address many issues related to surgical interventions. Examples include the UK National Institute of Clinical Excellence (NICE www.nice.org.uk), the Australian Safety and Efficacy Register of New interventional Procedures- Surgical (ASERNIP-S www.surgeons.org/asernip-s}. The NICE and ASERNIP-S provide systematic reviews of new operations, assessment of effectiveness, and recommendations that the technique has sufficient data for widespread use, or that the techniques appear unsafe, or that further research are required before its widespread usage.

The need for more surgical randomized trials is well recognized, and in recent years, the number of surgical trials has grown. When it comes to surgical treatment, most RCTs have a high or ambiguous risk of bias, especially selection bias. Due to the nature of the operation, it is not feasible to blind participants and staff (198). Recently, RWS has gradually become a hot research method by strictly standardizing the design, measurement and analysis of clinical big data (199). It allows for surgeons to evaluate the surgical procedures in a larger population and provided high-quality evidence in the true clinical situation.

7. RESEARCH PRIORTIES FOR SURGICAL AND DEVICE TRIALS

An agreed and standardized technique for the surgical procedure or device application should be clearly defined

The safety and serious side effects of new operations or devices, especially implantable devices and biologic materials, must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicenter cohort studies when RCTs are not practical.

Valid informed research consent is required in all trials of research surgical interventions; this research consent is separate from the main surgical consent.

Whenever possible, randomization for surgical trials should occur at the time of surgery to minimize dropouts and switch of procedure

Reports of successful treatment should be limited to subjects with a minimum (not mean) of one-year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated.

Long-term follow-up of RCT cohorts in an observational cohort is recommended

8. RESEARCH PRIORTIES FOR PHARMACOTHERAPY TRIALS

Although many randomized clinical trials (RCTs) of pharmacotherapy for urinary incontinence have been published in recent years, a great deal more remains to be learned (200). In addition to conventional clinical trials of oral drug therapy for urinary incontinence, novel clinical trials of botulinum toxin injection to bladder wall (201,202) and autologous stem cell transplantation to urethral submucosa (203) have emerged in recent years.

The trials have been mostly limited to 8-12 weeks of treatment giving little information about long-term safety and efficacy of therapies. Inclusion criteria are often stringent, such that the study population of healthy middle-aged people bears little resemblance to the patients for whom providers wish to prescribe medication. There is less than adequate information about special patient groups-men, children, neurogenic patients, and especially the frail elderly. Because incontinence induces such an impact on the older population, well-designed studies to define the utility and safety of drug therapy are greatly needed in this group.

Anticholinergics are commonly used for the treatment of overactive bladder (OAB). In the elderly population, this can add to an individual’s anticholinergic load. There are increasing data suggesting that a high anticholinergic load increases the risk of cognitive adverse

events and the development of dementia in the elderly (204). The further studies focused on the anticholinergic load in frail elderly with OAB are needed (205).

Another issue of special relevance in trials of pharmaceutical agents is the controversy regarding placebos in clinical trials. Regardless of whether a drug is effective or not, simply giving a drug to a patient may produce a beneficial response. To assess if a drug has an effect over and above the placebo response, it is usually tested against an inactive substance (placebo). In incontinence studies, the placebo effect may be quite large, anywhere from 30-50% in recent published studies (206). In order to account for this, investigators and regulators have generally demanded a placebo arm in most clinical trials of medication. While this may be acceptable to participants for short trials, it is neither ethical nor feasible to withhold treatment for longer periods of time. Recently, a clinical trial using stem cells where a conventional treatment set as a control group has been enrolled, but these trials are still few. Further, clinicians and patients generally want to know how a new drug compares with established treatment. Masking, while desired in all types of trials, is especially important in pharmacological trials. Further, it is feasible to do in such trials (as opposed to surgical or conservative interventions, in which masking may not always be possible) and thus should be prioritized. However, the identical appearance of two pills does not guarantee that participants will be unaware of group assignment. Side effects common with anticholinergic therapy, such as dry mouth, may unmask participants. Studies should assess the degree to which masking was successfully maintained.

New clinical trials have emerged, including stem cell transplantation and intravesical injection of botulinum toxin, which are different from the conventional oral drug therapy. Little is known about the safety, efficacy and tolerability of drug therapy beyond 12-week trials. High anticholinergic load may induce cognitive adverse events in frail elderly with OAB. Placebo has a role in the improvement of urinary incontinence, supporting the need for placebo control in RCTs.

Research Priorities

As effective drug therapy is available for most forms of incontinence, active drug comparator arms are recommended for most trials.

Long-term follow-up of RCT cohorts in an observational cohort is recommended. -

Further studies focused on the anticholinergic load in frail elderly with OAB are recommended. -

9. COST ANALYSIS

Economic and health policy outcomes are gaining increasing importance, as policy makers deliberate the values of different therapies. The financial burden on the health care system, the patient and patient's family of various treatment options makes cost an important outcome to measure. We recommend that cost analyses be planned with clinical studies whenever possible. Costs may be influenced by economic and political factors that are subject to change at any time; however, when basic units of work, time, and resources are carefully defined, models of costs remain useful even if market forces change in an unforeseen manner.

In health and medicine, economic analyses are descriptive and/or comparative. Descriptive data include the socioeconomic cost caused by the disease and its current treatment, whereas comparative data provide an economic evaluation of different treatment strategies and interventions where costs are compared to health outcomes.

There are several relevant types of cost analysis, some of which require a high level of expertise to conduct:

- Cost of illness analysis (COi) typically quantifies the burden of medical expenses (direct costs) and the resulting value of lost productivity (indirect costs) attributable to a specific condition such as an illness or injury (207,208).
- Cost effectiveness analysis (CEA) measures the costs and consequences of two or more diagnostic or treatment pathways related to a single common effect or health outcome. It then summarizes the results in ratios that demonstrate the cost of achieving a unit of health effect for different types of patients and for variations of the intervention. (209,210)
- Cost utility analysis (CUA) is a form of cost effectiveness analysis in which particular attention is paid to the quality of health outcome related to treatment. In CUA, health effects are expressed in terms of quality-adjusted life years.
- (QALYs). (211) A QALY is a measure of health outcome that assigns to a given period of time a weighting that corresponds to the health-related quality of life during that period, and then aggregates these weights across time periods. The QALY is important because it considers both quantity and quality of life.

Cost benefit analysis estimates the net social benefit of an intervention by comparing the benefit of the intervention with the cost, with all benefits and costs measured in dollars. Health outcomes are converted into monetary values using „willingness to pay" (the value an individual would pay for reduction in illness severity) or „risk of death" or „human capital" methods (an individual's value to society based on productivity or future wages). (197,207)

For a further discussion of these concepts please see Chapter 21 (Economics of Urinary and Faecal Incontinence, and Prolapse).

Research Priorties

Cost analysis should be incorporated into clinical studies whenever possible. (210)

10. BEHAVIORAL AND PHYSIOTHERAPY TRIALS

The lack of consistent terminology severely hampers the ability to build a body of literature about conservative interventions. The terms „behavioral therapy," „lifestyle intervention," „conservative treatment," „non-surgical treatment," „physiotherapy," „biofeedback and pelvic floor muscle exercise" are often used interchangeably and incorrectly to describe both the same, and different interventions. While such therapies are discussed elsewhere in this consultation, we here advance this committee's opinion about appropriate terminology, consistent with the most recently updated terminology manuscript. (212)

According to the Oxford Advanced American Dictionary the term behavioural is „the way someone behaves, especially towards other people", and behavioural science is the study of human behav-

iour. We recommend that behavioural science be limited to studies that evaluate how people do or do not behave as desired.

Lifestyle modification interventions for UI are discussed elsewhere in this consultation and have traditionally included diet modification, intake of caffeine and carbonated soft drinks, fluid restriction, weight loss, smoking cessation and advice of increasing general physical activity level. Behavioural science can be used to understand how and why people change lifestyle to, for example, adhere to exercise and weight loss programs, but it should not be used as term to replace specific therapies such as physiotherapy or pelvic floor muscle training.

Physiotherapy refers to assessment, prevention and treatment given by an authorised physiotherapist (ICS physiotherapy committee www.icsoffice.org). It involves "using knowledge and skills unique to physiotherapists" and "is the service only provided by, or under the direction and supervision of a physiotherapist" (WCPT 1999). This implies that the term physiotherapy should only be used in trials where the professional providing the intervention is a physiotherapist. We recommend describing the actual intervention instead of using the term physiotherapy: e.g. pelvic floor muscle training with or without biofeedback, electrical stimulation, pelvic floor muscle training with vaginal cones or resistance device etc. This accurately describes the intervention and is neutral towards the administering professional. Publications should report the actual profession of the interventionist (e.g., physiotherapist, general practitioner, urogynaecologist, urologist, midwife, nurse, fitness instructor), rather than using the vague term, "therapist."

Biofeedback: Biofeedback encompasses "a group of experimental procedures where an external sensor is used to give an indication on bodily processes, usually in the purpose of changing the measured quality". (212,213) Biofeedback equipment was developed within the area of psychology, mainly for measurement of sweating, heart rate and blood pressure under different forms of stress. Today, a variety of biofeedback apparatuses are commonly used in clinical practice to assist with PFMT, and the biofeedback can be either visual, auditory or both. In many textbooks the term "biofeedback" has been used to classify a method as different from PFMT. However, bio feedback is not a treatment on its own. It is an adjunct to training. For example, it may measure the response from a single PFM contraction or provide visual feedback during attempts to relax the muscles. Hence, a more precise terminology is PFM training or relaxation with or without biofeedback.

Many different assessment methods can be used to provide biofeedback. These include: manometry measuring urethral, vaginal and anal squeeze pressure, dynamometry, surface, wire and concentric needle EMG, ultrasonography and MRI. (214,215) In addition to traditional biofeedback apparatuses, other instruments can offer valuable feedback. Vaginal and anal surface EMG, urethral, vaginal or anal squeeze pressure measurements, ultrasound and MRI can all be used to make the patients more aware of muscle function, and to enhance and motivate patients' effort during training. (216)

Conservative interventions/treatments: Conservative interventions include all of the above, and this term includes everything except medication and surgery. (214,215) As several studies have found that more than 30% of women with pelvic floor dysfunction are not able to perform a correct PFM contraction at the first consultatiocn. (217-220) It is mandatory to report how ability to perform a correct contraction was assessed before commencing an exercise trial. Also, in electrical stimulation research one should report in which way response to the stimulation was assessed.

Although there is level A, grade 1 evidence for some of the conservative interventions such as PFMT for SUI and POP, a variety of new conservative methods to treat the condition are frequently suggested in clinical practice and in the literature. These new methods are often presented as being effective but are usually only based on a hypothesis based on theories, data from small experimental laboratory studies/small clinical series, or associations found in large epidemiological studies. If the clinicians like the approach, it soon enters clinical practice and textbooks without any further critical testing. (221) A model for how new therapies ideally should enter clinical practice has been proposed((222). In this model, the new idea should go through at least several stages before they enter practice:

- Clinical observation and laboratory studies
- Clinical exploration
- Pilot studies
- Randomised controlled trials
- Refinement, e.g. dose-response issues
- Active dissemination of the method if it has proven to be effective

It is important that the patients participating in the 3 first stages before the RCT are given full information that they are participating in an experimental treatment, and that the clinician does not know if this new approach is effective. The patients also need to be informed if there are other proven effective treatments available.

10.1. Reporting of Trial Characteristics

In addition to reporting the specific type of intervention (e.g. PFMT with biofeedback compared to PFMT alone or electrical stimulation) and the profession administering the intervention, the intervention needs to be described in such detail that other investigators can reproduce the intervention. This includes:

- Ability to perform a correct PFM contraction.
- Frequency: number of home training sessions and supervised training sessions (e.g. every day, 3 times/week)
- Number of repetitions and sets (e.g. 12 sets x 3 times/ day)
- Duration: length of each training session (e.g. 20 minutes), and duration of the total training period (e.g., 3 months, 6 months)
- Intensity: In exercise science, this is usually reported as % of one repetition maximum for strength training. In pelvic floor muscle training it is often described as attempts to reach maximum contractions or utilizing submaximal contractions. Another description of intensity is the holding time in seconds, e.g.: 6-8 sec
- Adherence: the degree to which participants follow the prescribed protocol, usually reported as a percentage of the total possible.
- Educational material provided, such as apps, DVDs, brochures and booklets should be described. (223)
- Assessment: All devices used for assessments (e.g. manometers, dynamometers, ultrasound and EMG) must be described in detail, and their responsiveness (ability to detect small changes), reliability and validity should be reported{. (225)

10.2. Adherence vs. Effectiveness

It is important to note that adherence is not the same as the effectiveness of a program, as it is possible to have high adherence, but still little effect of training. (225) Hence, when reporting the effect of conservative interventions, it is ideal to also measure the exposure variable that the treatment is expected to change (e.g. muscle strength, ability to relax etc.). This variable should not be

confused with the primary or secondary outcomes of the intervention (e.g leakage measured with pad testing, number of leakage episodes or Qol).

In many areas of conservative interventions there are high quality RCTs, systematic reviews and meta analysis showing statistically significant and clinically relevant differences between the intervention and the untreated control group or other interventions. Of conservative therapies, PFMT for SUI/MUI has the strongest evidence to support its use; further, the more intensive the program (more supervision, higher dosage of training) the better the effect. In addition, there is also 1A evidence/recommendation for PFMT to be first line treatment for POP (see chapter ICI Conservative Treatments in Adults). Therefore, when comparing new methods and innovations with established PFMT, it is important to compare the new intervention with the current best evidence, meaning the effective arm of the reported RCTs. Unfortunately, it is common to compare new methods with an ineffective training protocol, thereby overestimating the effect of the new method and claiming that it is equal to or better than "the old method". When comparing different methods, the dosage also needs to be the same in both treatment arms (e.g. when comparing PFMT with and without biofeedback, the number of supervised sessions, length of the sessions, frequency of home treatment and duration of the intervention must be the same). In a multicenter RCT comparing the exact amount of exercise dosage and attention by the therapist between PFMT with and without biofeedback, there was no additional effect of adding biofeedback on long-term continence outcomes. (226)

10.3. Adverse Events and Cost

There are few adverse effects or complications reported after conservative interventions, but they do exist, (e.g. in electrostimulation),(227) and adverse effects or lack of adverse effect, and inconvenience to the patients should be reported. Although seldom harmful, conservative treatments are time-consuming and can be costly for participants and paying parties because of the need for close follow up during the interventions. Cost effectiveness studies are crucial to fully understand where conservative therapies fit in the treatment armamentarium. (228)

10.4. Outcome Measures

The need for use of responsive, reliable and valid outcome measures in research is covered elsewhere in this chapter. The RCTs published in conservative treatment have applied a plethora of outcome measures, making systematic reviews and metaanalysis difficult or impossible to conduct. Therefore, in future research it is important to use established and recommended outcome measures. In addition to description and use of responsive, reliable and valid primary and secondary outcome measures, future studies should include description and assessment of adherence to the intervention protocol, measurement of the independent variable (the intervention; e.g. strength training, relaxation training) and measurement of the possible underlining mechanisms of how the treatment works. It is usually not possible to blind the participants or those providing the intervention, but the assessors of outcome should always be blinded to group allocation.

10.5. Specific and Non-Specific Effects

There have been some concerns that the effect of conservative treatments can be attributed to non-specific effects such as the extra attention of the therapist. The role of the therapist is to educate, motivate and empower the patient to be able to perform the actual program, secure high adherence, and minimize participant drop out. In patient-reported outcomes and reports on quality of life, it may be difficult to separate the effect of the attention and the actual effect. However, the effect of the attention is less likely to affect outcomes such as muscle strength, urodynamic assessments, pad testing and morphological changes measured by ultrasound and MRI. Investigators blinded to treatment allocation should conduct all assessments in order to minimize bias. The logistics of this should be addressed during the planning phase of the study. In a high quality RCT, Dumoulin et al address the problem of attention in physiotherapy research. (228) Women with persistent SUI, three months after childbirth were randomized to either two different training regimens or a control group receiving relaxation massage for the back and limbs for the same amount of time as the supervised pelvic floor muscle training groups. 70% were cured on pad-testing in both treatment groups while there was no effect on urine loss in the relaxation massage group. Participants in the massage control group had improvement in disease specific quality of life.

10.6. Power Calculations and Number of Participants

Some of the RCTs on conservative treatments are flawed by small sample sizes, this being especially evident in electrostimulation studies and may account for negative effects caused by type II errors. It is important that future studies use results of previous published studies to make appropriate power calculations that incorporate estimates of dropouts and loss to follow-up to decide the optima! number of participants needed. Recruiting large numbers of participants may come at the expense of the rigor of the intervention. (229) Weak interventions (e.g. non-optimal training dosages or suboptimal electrostimulation parameters) are unlikely to be effective and do not yield the true effect of an intervention. In meta-analyses, adding RCTs with large sample sizes but weak and ineffective interventions can dilute the effect of smaller RCTs with higher methodological and interventional quality (229)

10.7. Long-Term Studies

Challenges in long-term follow-up studies include cross over to the more effective treatment after cessation of the original RCT, co-interventions during the follow-up period, recurrent events (e.g. new pregnancy}, competing events (other diseases leading to incontinence) and loss to follow up. For conservative interventions it is expected that any training effect will diminish over time if no maintenance training is conducted or the pre- or co-contraction of the pelvic floor muscles has not resulted in morphological changes to the pelvic floor during the original trial. [230] Nevertheless, of the 19 long term follow-up studies reported by Bø & Hilde five studies reported sustained success rates (ie, percentage remaining

free of UI at long-term follow-up), which were between 41% and 85%. Surgery rates in the long term varied between 5% and 58%. (231) In order to control for as many of the above-mentioned factors as possible, it is recommended that the long term follow up study should be planned together with the original RCT. (232) Loss to follow-up and adherence to the protocol during the follow-up period must be reported. (221,222,224,226-229,233)

Research Priorties For Conservative Treatment Trials

- Use correct terminology to describe the intervention.
- Report details of ability to perform correct contraction, dose-response issues and adherence.
- Use recommended outcome measures with high responsiveness, reliability and validity.
- Compare new methods with the best available intervention.

- Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions.
- For long-term follow-up studies report cross over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up

11. RESEARCH PRIORTIES FOR SPECIAL PATIENT GROUPS

11.1. Men with LUTS

When considering men with LUTS, one must consider some unique factors that may influence urinary tract symptoms independently of any intervention, and so confound any data. These are the presence of the prostate gland that can cause bladder outlet obstruction (BOO), and the rarity of sphincter incompetence except in men who have undergone surgery for benign or malignant prostatic disease. For short term outcomes after intervention studies, these factors are unlikely to be relevant, but longer term follow up, and large observational or epidemiological studies· may need to take these factors and changes over time into account when analyzing data. The prostate gland may complicate research outcomes as a result of outflow obstruction (either at baseline, or development of a new problem during follow up studies). Also, for patients with prostate cancer (either at the time of enrollment, or during follow up of longer studies), it is likely that both the disease, and the treatment given (surgery or radiotherapy) may alter urinary tract function and symptoms independently of any intervention in the study and thus confound the outcomes. , Overall, about 2/3 of men with LUTS have urethral obstruction and over 50 % have detrusor over-activity, although a much smaller number have urinary incontinence due to detrusor overactivity. (234) If prostate size is considered to be a variable that could affect outcomes, measurement of prostate volume should be made before and after treatment. The method used to measure volume and its reliability and validity should be provided if available or their absence indicated. Any associations between outcomes and change in prostate size should be tested for using appropriate methods and reported. Consideration should be given to stratifying participants by prostate volume when there is suspicion that response to therapy may be size dependent.

Insofar as about 2/3 of men with LUTS have bladder outlet obstruction (BOO), any research protocol in men should consider inclusion of a method to screen for it. At the least, maximum free urinary flow rates and measurement of post-void residual urine should be recorded before and after treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. Synchronous pressure-flow studies are generally desirable and should be included whenever feasible. Several pressure-flow nomograms have been proposed to diagnose obstruction in men. It is important to specify which if any nomogram is being used; the ICS nomogram is recommended. (235)

Research Priorties In Men

- Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a potentially important variable, or to change during the intervention and follow up.
- Maximum free flow rate and measurement of post-void residual urine should be recorded pretreatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables.
- Participants should be stratified by prostate size at randomisation when size is considered to be a potentially important determinant of treatment outcome.
- Clinical evaluations of different male UI products, including strengths, limitations and efficacy in clinically relevant subgroups.

11.2. Women with LUTS

11.2.1. Hormonal effects:

Our knowledge of hormonal influences on the lower tract remains limited. Randomised clinical trials and prospective cohort studies have demonstrated that hormone replacement therapy (HRT) does not improve or may worsen incontinence. (236-238) It therefore seems appropriate that information about menstrual and hormonal status should be an integral part of the baseline history. New studies designed to examine the influence of hormones on incontinence (if considered ethical by an appropriate review board) should include details of hormonal status (premenopausal, postmenopausal without HRT, post-menopausal with HRT), the route and type of HRT (oestrogen only, combined sequential, combined continuous), and whether or not oophorectomy has been performed.

11.2.2. Obstetric History:

The influence of vaginal childbirth on the structure and function of the female pelvis is the focus of much recent and ongoing research but the complex interactions remain incompletely understood. While it is clear that childbirth, and particularly vaginal childbirth increases the risk of incontinence and pelvic organ prolapse, the potential effect of further childbirth on previous or current treatments of incontinence (especially surgery) has yet to be determined.

Potentially confounding variables include: number and route of deliveries (vaginal/Cesarean), use of forceps or vacuum, infant birthweight and head circumference, duration of second stage of labor, use of episiotomy and any vaginal or perineal trauma, and epidural anesthesia. The importance of these variables will depend upon the specific study design; for randomized studies the allocation process should balance these between groups, but consideration should be given to stratifying or minimizing the randomization against one or more of these important factors, depending on the exact intervention. For epidemiological or observational research each of these factors should be collected and included in univariate and multivariate analyses.

Research Priorties in Women

- Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol.
- High quality, symptom and bother scores (e.g.,ICIQ-FLUTS, KHO, PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes
- Standardised assessment of pelvic organ prolapse (by POP-Q) should be performed before treatment and at the time of oth-

er outcome assessments in alL research where prolapse and continence outcomes are being assessed.

- Criteria for cure/improvemen/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests.

- Assessment of the impact of treatment on sexual function should be performed with other outcome assessments when appropriate.

11.3. Frail older and Disabled Men and Women

There are a number of unique and pertinent research issues for this population. In the frail elderly, important variables include:

- Demographic information: Advancing age, white race, and women (238-240) are associated with an increase risk of incontinence and each of these variables should be adjusted for in most analyses.
- Medical Conditions: Medical conditions related and unrelated to the lower urinary tract have been shown to increase the risk of incontinence in older women and are especially important to assess in the frail older population. (240-244)
- Prior hysterectomy has also been suggested as a potential risk factor for incontinence in older women. (244,245)
- Medication Inventory: Certain medications may exacerbate incontinence and therefore a complete medication inventory is essential. (244,246 – 249)
- Physical function: Mobility is often impaired in the frail elderly and impacts urinary control (250), therefore mobility should be assessed using validated instruments such as the Bartel Orcats or AOL scales. (250,251) Data on walking aids or wheelchairs, gait speed, and manual dexterity may also be collected.
- Cognitive function: Cognitive function impairment and/or dementia increase the risk of incontinence. (252) The Mini-Mental Status Scale Examination (253) assesses global cognitive function, and the Confusion Assessment Method (CAM) is a standardized assessment for delirium. (241) A battery of neuropsychological tests to measure subtle impairments in cognitive function include the Buschke Selective Reminding Test (verbal learning and memory) (254) the Digit Symbol (incidental memory, visual scanning and motor speed)., (255) and the Trails A (attention and visual).

Outcome measures should be selected for applicability to the frail elderly. Commonly used self-reported measures of frequency of urinary symptoms, severity, or level of bother may not be possible in the cognitively impaired frail elderly patient. Similarly, voiding diaries that have been shown to be valid and reliable in assessing urinary frequency, nocturia, and incontinence episodes by type may not be feasible or reliable (256-258). Motivated and trained staff, caregivers, or family members may be able to adequately collect diary data; however, this has not been validated.

In nursing home or inpatient settings, wet checks by staff at set intervals have been used in a number of studies. There are limitations to the measurement including visually determining what is “wet” because of new absorbent materials and staff reports not always being reliable or valid, due to under-reporting(.(259,260)

To overcome the limitation of defining magnitude of incontinence and under reporting, 24-hour pad weight tests may be used. (261,262) Pad weighing tests and wet checks are feasible and can provide important outcome data if staff is well trained and checks are often. I (262) New outcome measures specific to the frail older population such as increased socialization or decreased caregiver burden need to be developed.

12. RESEARCH PRIORTIES FOR STUDIES OF NEUROGENIC POPULATIONS

Neurogenic lower urinary tract dysfunction (NLUTD) is defined as a bladder disorder secondary to a known neurological lesion, disease or condition. This broad definition includes a very heterogeneous constellation of neurological disorders and syndromes making the clinical diagnosis of neurogenic bladder (NGB) difficult in many cases. Classification of NLUTD has three primary aims – to aid in discriminating or identifying an unknown underlying neurological disease process, to characterise the nature of the dysfunction so as to develop a treatment plan, and to assess the risk of secondary effects (e.g. on the upper tract) which may influence the necessity and aggressiveness of treatment. The latter two are clearly relevant to research in neurogenic incontinence and must be reflected in study design and patient description.

It is difficult to find a classification system for NLUTD that serves both clinical and research demands that is satisfactory for each of the three aims. The published NLUTD classification systems have been reviewed in detail in textbooks. Both the disease process and the site of the neurological lesion(s) are relevant in the study of NLUTD, yet even this informationis inadequate to predict the functional lower urinary tract deficits for an individual patient. There is no one method that meets the broad needs of classification in this group. Typical or classic cases are often well described but it is especially difficult to describe mixed and incomplete lesions. Historically, classification systems oversimplify or become extremely complex to apply in routine clinical practice.

A new classification system has been proposed by Powell to better define the neurogenic lesion or condition affecting lower urinary tract function and thereby help direct treatment. (261)The SALE (Stratify by Anatomic Location and Etiology) classification system for NLUTD is based on seven categories (six anatomical/aetiological and one future biomarker), each having a neurological defect (upholds basic definition) in a distinct anatomic location. The system incorporates the presence or absence of bowel dysfunction and autonomic dysreflexia. The proposed classification divisions would benefit research stratification including supra-pontine, pontine, supra sacral, sacral, lower motor neuron/neuropathy, and syndromes with no definitive neurological lesion detected thus far.

According to the European Association of Urology guidelines for managing the neurogenic bladder, primary aims for treatment (also research) include protection of the upper urinary tracts, improve urinary continence, restore function and improve quality of life when possible.. (264) Despite proper classification and guideline adherence, it must be acknowledged that the complexity of neurological diseases and variations in individual behaviour almost always call for a customised approach to therapy, further complicating research in the neurogenic patient. All of these factors may complicate study design as it becomes difficult to create workable inclusion and exclusion criteria that apply to other than a narrow segment of the neurogenic population. Ideally a broad population of potentially relevant participants would be enrolled in research studies with full characterisation of both the neurological condition and the nature of the lower urinary tract dysfunction so as to allow for subgroup

analysis. The new SALE system may provide a better classification scheme for NLUTD.

Study planning is being undertaken with the cooperation of urologists, neurologists, and other clinicians, who have a specific interest and special training in the neurogenic patient. Baseline data collected by history in subjects with neurogenic lower urinary tract disorders should include:

- bladder volumes by diary or examination (maximum voided or catheterised volume, post voiding residual urine, total capacity);
- mechanism of bladder evacuation: normal (volitional), spontaneous involuntarily („reflex“), Crede, sterile intermittent catheter (SIC), clean intermittent catheter (CIC), intermittent catheter by second person, or suprapubic or urethral catheter;
- use of external appliances (e.g., diaper or pad use, condom catheter, urethral catheter, suprapubic tube);
- the typical time span of continence (continence interval) following last bladder evacuation and maximal continent bladder volume.
- bowel function, sexual function, and specific neurologic deficits
- the evolution of the condition of (changes in) the upper tract should be included in the outcomes evaluation of treatment for NLUTD.

Where possible these factors should be controlled for in analyses and stratified for in randomisation for interventional studies, or patients with certain factors should be excluded. The details will depend on the research question to be asked.

12.1. Outcome Measures for NLUTD

Follow-up recommendations for patients with NLUTD are based on long-standing evidence suggesting increased risk of bladder cancer as well as upper tract deterioration in this patient population. A study of cancer-specific mortality in a population of U.S. Veterans with Spinal Cord Injury demonstrated up to 70% greater bladder cancer specific mortality in patients with SCI as compared to those without the condition. In a study by El Masri regarding the issue of cystoscopic surveillance, the author stated, „Since the second world war, integration of urological surveillance and timely intervention in the management of patients with SCI has reduced morbidity and mortality prolonging survival.“ (265) However, despite this observational data, strong evidence regarding the type and timing of surveillance in patients with NLUTD is lacking.

Several organizations have set out to improve outcomes by creating evidence-based guidelines for follow-up and surveillance. Some of the more publicized of these include:

- European Association of Urology (EAU): „Guidelines on Neurogenic Lower Urinary Tract Dysfunction“. (266)
- United Kingdom: National Institute for Health and Clinical Excellence (NICE) „Urinary Incontinence in Neurological Disease: management of lower urinary tract dysfunction in neurological disease“. (267)
- U.S. Veteran‘s Health Administration Handbook on Spinal Cord Injury and Disorders (SCI/D) Systems of Care. (268)
- American Urological Association (AUA) and Society for Urodynamics Female Pelvic Medicine and Urogenital Reconstructiuon (SUFU): Guidelines for Urodynamics (269)
- The AUA/SUFU Guideline on Adult Neurogenic Lower Urinary Tract Dysfunction: Diagnosis and Evaluation (270)
- The Consortium for Spinal Cord Medicine „Bladder Management in Adults with Spinal Cord Injury“. (271)

A comprehensive review of these guidelines is beyond the scope for this chapter; however, key areas included renal function testing, imaging, cystoscopy, and urodynamics. The most aggressive surveillance protocol came from the EAU guidelines that recommended yearly renal function testing, imaging every 6 months, and urodynamics at least every 1-2 years. The NICE guidelines recommended ultrasound surveillance every 1-2 years, consideration of urodynamics for high-risk patients, and that surveillance cystoscopy should not be performed. The newest AUA/SUFU guidelines recommend against surveillance cystoscopy in patients with NLUTD and chronic indwelling catheters based on two recent meta-analyses (272,273). The variability in these guidelines, which are derived mainly from poorly done observational studies and are consensus based, speaks to a pressing research need for the ICI to encourage long-term evidence-based studies on outcomes in patients with NLUTD and how these are affected by different forms of surveillance and management.

Measuring quality of life outcomes in the NLUTD population has often lagged behind other lower urinary tract disorders due to the heterogeneity of the neurological conditions that are often grouped together (i.e. spinal cord injury with multiple sclerosis). Several patient-reported outcome measures (PROMs) have been specifically designed for measuring the quality of life in patients with neurogenic bladder. Costa and associates described the Qualiveen in 2001 to measure the quality of life in patients with spinal cord injury and it has been validated and is available in English, French, Dutch, Spanish and Italian. Clark and Welk contributed an excellent review of 16 PROMs for assessment of quality of life and symptoms in neurogenic bladder patients. (274,275). Selection of the appropriate PROM for measuring quality of life outcomes is essential for clinicians and researchers working with the NLUTD population.

The following summary highlights recommendations for research in the key areas of this Consultation.

13. RESEARCH PRIORITIES

13.1. Pathophysiology of NLUTD

- An area of priority for research is the development of a more directly informative classification system which would include anatomical location and aetiology in association with corresponding urinary, faecal and neurological symptoms, information from clinical neurophysiological testing and urodynamic abnormalities as well as prognostic biomarkers. As such, the classification would describe a patient suffering from NLUTD and simultaneously inform about the most appropriate treatment, follow-up regimen, and long-term prognosis
- The thalamus may be a promising target for the development of new therapies for lower urinary tract dysfunction. Further investigation on this matter is needed before its potential role can be elaborated.

13.2. Diagnostics

- Additional studies are needed to establish neurological populations and absolute indications for the use of invasive urodynamics in NLUTD as a primary assessment tool and as specialized assessment tool as well as establish its best application for follow-up of treatment modalities
- Research to establish what is ‚urodynamic safety‘ in NLUTD, preferably by population studied
- Identify clinical predictors of urodynamic findings in NLUTD
- Further development of patient reported outcome measures needed in NLUTD

- Further research into neuroimaging and its association with clinical neurourological practice
- Further development and standardisation are needed for the use of electrosensation tests to assess their role as a clinical test
- Research to produce high level evidence to define UTI's in neurological patients
- Need more evidence for the use of prophylactic antibiotics to reduce symptomatic urinary tract infections after invasive UDS

13.3. Management of NLUTD

- Research into mechanisms and prognosis of the development of bladder cancer in patients with NLUTD
- It is currently not possible to state whether any IC method or catheter type is advantageous due to the poor quality of available studies. Further research on the topic is strongly recommended

13.4. Pharmacotherapy for NLUTD

- Further research is needed to establish the efficacy and safety of the newer antimuscarinics in NLUTD, long-term outcomes and safety, the efficacy and safety of mirabegron in NLUTD, as well as combination treatments
- Oral and intravesical cannabinoid agonists have shown promising results either in clinical or preclinical studies, and should be further investigated for optimal balance between efficacy and safety in NLUTD
- Further research needed on pharmacotherapy for detrusor-sphincter dyssynergia, sphincter deficiency and detrusor underactivity

13.5. Minimally Invasive Treatments Botulinum Toxin A

- Further research is needed on long-term outcomes and safety, administration techniques, the bio-equivalence of the various preparations, the concomitant use of anticholinergic drugs or 3-agonists, mechanisms of action, and wider effects
- Future research should also focus on PROs and patient satisfaction, tolerability issues, alternative techniques of application, ways to minimise posttreatment voiding dysfunction in patients who void freely
- Larger studies in select patient populations are also recommended

13.6. Electrical Neuromodulation

- Further studies on chronic pudenda[nerve stimulation must be carried out to identify the best stimulation parameters and to verify the long-term results in patients with inadequate bladder emptying due to DBND, either as a first-line procedure or as a complementary approach to DBND recognised following permanent urethral stenting. Further studies are needed
- Bladder augmentation using biomaterials or tissue engineering is promising, but the preliminary results need to be confirmed by larger studies
- IVES is a viable option to induce/improve bladder sensation and to enhance the micturition reflex in patients with incomplete central or peripheral nerve damage, but corroborating controlled evidence is needed
- Research to establish indications for sacral neuro-modulation in the care of DSD in neurological urinary dysfunction.
- Effectiveness of tibial nerve stimulation (transcutaneous, percutaneous, and implantable)

13.7. Specific Neurological Conditions

There is a need for robust epidemiological research, insight into mechanisms, studies on utility of diagnostic tests, assessment of urinary tract risk factors, and randomized trials to assess benefits and harms of therapy for specific neurological diseases. Urinary and faecal incontinence both suffer from limited high-quality research, and fecal incontinence in particular.

Priority Research Topics include investigations into:

- Systematic cataloguing of the specific brain centres pertinent to lower urinary tract control, and how they are at risk in given neurological diseases
- How medications for LUTS may influence specific neurological diseases or associated dysfunctions (e.g. blood pressure control)
- The clinical relevance of functional brain imaging to clinical management
- Indicators of neurological presentation or progression that may be first evident in urological clinics
- Outcomes for interventions for smooth sphincter dyssynergia

VI.I Research Priorties in Faecal Incontinence

- Develop and test interventions for promoting care seeking and self-management of fecal incontinence (and associated odour and urgency)
- Develop and test interventions for increasing coping skills and health literacy related to faecal incontinence for patients and family caregivers
- Evaluate tailoring the management of faecal incontinence based on patients' goals, peer support, and the use of current technologies such as mobile devices for delivering management and support interventions to patients and family caregivers
- Collect data on faecal incontinence whenever practical as part of research on urinary incontinence
- Develop techniques for diagnosing faecal incontinence and its aetiologies using new and available diagnostic technologies
- Develop user-friendly measures and instruments for quantifying the severity of faecal incontinence and other components of anal incontinence separately and in total
- Investigate the epidemiology of the different types and subtypes of bowel and anal incontinence
- Well-designed and adequately-powered studies are needed to evaluate fecal incontinence treatment modalities currently available including:
- Effectiveness of lifestyle modifications including weight loss, exercise, diet and eating pattern modifications, and supplementing dietary fibre as an adjuvant or combined strategy
- Comparative effectiveness trials of instrumented biofeedback training versus neuromodulation

14. RESEARCH PRIORTIES IN POPULATIONS AFFECTED BY BLADDER PAIN (INCLUDING INTERSTITIAL CYSTITIS)

The pathogenesis and pathophysiology of IC / BPS remains unknown. Diagnosis should be obtained by excluding diseases that can be confused with symptoms and no curative treatment exists (276-281). Recent studies suggest that the pathophysiology of Hunner type IC (HIC) and non-Hunner-type IC (NHIC)/BPS is significantly different (282) and the former is characterized by pancystitis,

frequent clonal B-cell expansion and epithelial denudation. Therefore, IC/BPS may be categorized by the presence or absence of Hunner lesions, rather than by clinical phenotyping based on symptomatology (281,282). Basic research and clinical trials should be conducted separately for each. Research recommendations are:

- Research that focuses identify bladder-specific pathology, a bladder pain syndrome-specific biomarker
- Develop a simple, non-invasive diagnostic tools for HIC and BPS.
- Research that focuses identifying specific pathology (the pathogenesis of a B-cell population abnormality in Hunner lesions) and biomarkers for HIC and NHIC/BPS.
- Standardize the manners of hydrodistension.
- Research to develop a curative treatment for HIC and BPS.
- Establish patient databases in different region and conduct longitudinal follow-up to understand the natural history of the disease and to examine the differences in disease natural history among regions.
- Develop a simple, non-invasive diagnostic test for BPS
- Research that focuses identify bladder-specific pathology, a bladder pain syndrome-specific biomarker
- Broaden the research scope to improve symptom-based classification to identify the degree of bladder and non-bladder symptoms.
- Establish patient databases in different regions and conduct longitudinal follow-up to understand the natural history of the disease and to examine the differences in disease natural history among regions
- Develop a practical multi-disciplinary care model and test it in various settings.
- Develop an easy-to-use tool for non-specialists to readily identify co-morbid conditions that may impact on the need for additional consultation and suggest specific treatment pathways.

15. RESEARCH PRIORTIES IN PELVIC ORGAN PROLAPSE

The effect of pelvic organ prolapse on lower urinary tract function remains poorly understood. Pelvic organ prolapse may potentially affect lower urinary tract function by obstruction of the urethral outflow, and thereby mask sphincter weakness (so called “occult” stress incontinence). Emerging evidence suggests that prolapse may contribute to the symptoms of OAB and correction of the prolapse may modulate these symptoms. Thus, it is important to include assessment of pelvic organ prolapse in incontinence research on women. A validated assessment method for prolapse should be used to identify the stage of prolapse; the Pelvic Organ Prolapse Quantification System (POP-Q)(9) is recommended. Research protocols should be developed, either excluding women with prolapse severity beyond a specified stage, or the analysis plan should include stratification for stage of prolapse in randomisation, and adjustment for prolapse stage in any analysis. For larger studies where regression analyses are planned, stage of prolapse should be considered a mandatory factor for inclusion. Prolapse should be graded at the same time as the outcome assessment for incontinence and LUTS is performed.

POP may induce a various type of lower urinary tract symptoms (LUTs); not only storage symptoms but voiding symptoms, according to the types and severity of POP (276,277). Although POP surgery generally improves LUTs, overactive bladder (OAB) may persist and/or de-novo stress urinary incontinence (SUI) may occur after surgery (276, 278, 279). Also, there is a risk of voiding dysfunction after POP surgery and its incidence varies depending on types of surgical procedure and baseline patient characteristics. (276, 280-29

Further research is required in areas of the management of LUTS in patients with POP and the assessment of LUTs before/after various types of POP surgery (including transvaginal mesh surgery and laparoscopic/robot-assisted sacrocolpopexy) as below. Especially, long-term follow-up of LUTs and other adverse events (including chronic pain and mesh extrusions) in cases treated with transvaginal mesh surgery is required.

Significant further research is required in most areas of the surgical management of prolapse including but not limited to:

- Uterine prolapse and its various treatment options
- Surgery for recurrent prolapse
- Identifying risk factors for recurrent prolapse
- Re-evaluation of prolapse quality of life questionnaires to ensure they are sensitive to change
- The utilization and incorporation of tissue engineering in pelvic organ prolapse surgery
- Impact of POP surgery on bladder overactivity.
- Impact of POP surgery on urinary voiding dysfunction
- Impact of rectocele repair on symptoms of obstructed defaecation and fecal incontinence
- Impact of various types of POP surgery on OAB.
- Impact of various types of POP surgery on SUI.
- Impact of various types of POP surgery on urinary voiding dysfunction.
- Impact of rectocele repair on obstructed defecation and fecal incontinence.
- Long-term follow-up of LUTs and other adverse events (including chronic pain and mesh extrusions) in cases treated with transvaginal mesh surgery.
- Re-evaluate prolapse quality of life (P-QOL) questionnaires to ensure they are sensitive to changes after treatment.
- Identifying risk factors and predictors for persistent/de-novo incontinence after POP surgery.

16. RESEARCH PRIORTIES IN MINORS (CHILDREN, ADOLESCENTS AND TRANSITIONAL SUBJECTS)

The conduct of clinical research in children is no more difficult than in adults, as parents and caregivers are often motivated and eager to participate. Four overriding issues separate pediatric research from the general recommendations. First, developmental physiology and psychology varies widely within the group referred to as children who undergo many different stages: newborns, infants, toddlers, preschoolers, school age children, adolescents and young adults. They not only differ from older adults, but also undergo rapid developmental changes within a short time. Because children are growing, any treatment, especially pharmacological and surgical therapy, may affect them profoundly in the long term. On the other hand, treatment in children can be more effective than in adults precisely due to this developmental flexibility. A specific aspect is the close interaction between the developing central nervous system and peripheral organs such as the bladder. In addition, the interaction between the urinary and gastrointestinal system plays a special

role in this age group. Second, compliance with therapy requires the inclusion of parents, as children and even adolescents depend on caregivers to administer treatment in most studies. Third, reporting of symptoms and outcomes requires the assessment by both parents (proxy) and children. Symptoms reported by a caregiver may not be interpreted in the same way as the child, which is important to consider. Finally, the issue of informed consent is complex with children, but this has been settled by legal requirements in most countries.

Urinary incontinence in children falls into four main categories: organic, i.e. neurogenic (myelomeningocele and other less common neurogenic etiologies) or structural; nocturnal enuresis, which can be either mono-symptomatic or polysymptomatic; non-organic daytime urinary incontinence, including detrusor overactivity, voiding postponement and dysfunctional voiding without neurological disease. This issue of age groups is most crucial in children with myelomeningocele. These children are often on medication beginning at a very young age and continuing for many years; the long-term safety of medications in children must be established in all age groups. We recommend that clinical studies have long-term (five years or more), open label extension arms to monitor safety, particularly focusing on normal growth and development and the effects on treatment of liver and central nervous system function. Therapy for other causes of incontinence in children tends to start at a later age, i.e. the definitional age of incontinence (5 years).

Assessment of compliance with therapy is always difficult and can also be so with children. Compliance with voiding diaries, a significant issue in the adult population, has to be monitored to achieve reliable results. The social and family interactions between the child and parent or caregiver, as well as own behavioral issues and disorders, can influence the accuracy of data collection and treatment compliance, both positively and negatively.

Outcome measures have been developed in children as in adults. Validated, age-specific symptom and disease-specific quality of life instruments are available for most chronic disease for the pediatric population, as well as generic instruments. Early efforts in this area have been reported for dysfunctional voiding and daytime incontinence. Invasive urodynamics can be used when deemed appropriate (specifically in the neurogenic population). but is usually not required in non-organic incontinence.

- Long-term follow-up is of critical importance in the paediatric population in order to ascertain the effect of a treatment on normal growth and development.

Broadened the research scope to improve symptom-based classification to identify the degree of bladder and non-bladder symptoms.

- Establish patient databases in different regions and conduct longitudinal follow-up to understand the natural history of the disease and to examine the differences in disease natural history among regions
- Research is needed to develop standardized outcome measures including validated, age specific symptom and disease-specific quality of life outcome measures.
- Research of problems specific to different age groups is needed. Especially, incontinence in preschool children and in adolescents is needed.
- The transition and transfer from pediatric to adult care should be studied and evidencebased recommendations should be formulated.
- Develop a practical multi-disciplinary care model and test it in various settings.
- Develop an easy-to-use tool for non-specialists to readily identify co-morbid conditions that may impact on the need for additional consultation and suggest specific treatment pathways.
- The specific incontinence problems of young adults aged 18-21 years need more attention in research.
- Incontinence in children and adults with special needs is a neglected part of research and clinical care. These include individuals with intellectual disability, specific syndromes, autism spectrum and other disorders.
- The interaction between brain and bladder and/or gut needs to be studied with new functional and structural imaging techniques of the CNS.
- Treatment studies of daytime urinary inconti nence, including pharmacotherapy and urotherapy, are needed.
- The correlates of sleep in children with nocturnal enuresis needs to be elucidated in more detail.
- Life span, longitudinal epidemiological studies from childhood to adulthood in a prospective design are required to procure representative data.

17. RESEARCH PRIORTIES IN BASIC SCIENTIFIC RESEARCH

- Integrate data from reductionist experiments to inform the formulation of better systems-based approaches in the investigation of the pathology of the lower urinary tract (LUT), the genital tract (GT) and the lower gastrointestinal tract (LGIT) through:
  - the development of animal models that accurately describe human pathological conditions, including the greater use of large-animal models
  - the better use of reverse translational approaches for linking animal models to the human disease.
- Encourage greater emphasis on basic research to characterise tissues receiving relatively little attention: ie the lower gastrointestinal tract; the bladder neck and urethra; the ureter, pelvic floor musculature
- Generate research programmes for foetal and neonatal research in LUT and LGIT function.
- Use genome-wide bioinformatics and population health surveys to generate testable hypotheses regarding the physiological and pathophysiological functions of the LUT, GT and LGIT.
- Generate improved experimental approaches to investigate the pathophysiology of the LUT and LGIT by:
  - the use of human tissue from well-characterised patient groups.
  - the development of emerging areas such as: tissue engineering; proteomics and metabolomics
  - increased collaborations between biological, physical and mathematical sciences.
- Develop centers of excellence or consortia of excellence in LUT, GT and GIT research
- Integrate expertise from university departments, academic medical units and industry
- Encourage translational approaches to research.
  - develop inter-institutional research-training programs to allow new researchers the opportunity to better interact and exchange ideas.

- Additional emphasis on the importance of research to medical trainees and science graduates through:
  - establishing research training as a corecomponent of post-graduate clinical development
  - increased access to support funds, especially scholarships and personal awards
  - organisation of focused multidisciplinary research meetings, either stand-alone or as dedicated sessions during national and international conferences
  - greater interaction between medical centres and Higher Education Institutions (HEIs).
  - allowing researchers-in-training better access to international meetings through reduced registration charges and improved travel grants.
  - inclusion in clinical meetings of point-counterpoint session(s) with both basic science and clinical viewpoints.
  - development of research fora for exchange of ideas between active researchers and industry.
  - lobbying research funding organisations about the medical and social importance of LUT and LGIT disorders.
- Increase emphasis on research into LUT and LGIT in HEIs through greater representation on grant-funding agencies

VII. CONCLUSIONS

The 2021 Consultation expanded and focused on specific areas which were summarized by the 2016 committee and working document. This committee places significant emphasis on the needs for standardization of data aggregation, interpretation, analysis, reporting and summary presentation with grading of evidence. The meaningful advancement of research in the focus areas of this consultation, should be promoted with lucid research question and hypothesis. Once the research focus is identified, careful design, conduct and analysis of the research study is paramount. Prompt dissemination with appropriate data sharing is strongly recommended to benefit affected individuals and the broader research community. Data registries and multi-institutional collaboratives will improve the potential ability for the acquisition of large and generalizable data sets which can be used for basic, translational, and clinical trials which will help to address population-based conditions and diseases.

7TH INTERNATIONAL CONSULTATION ON INCONTINENCE

RECOMMENDATIONS OF THE INTERNATIONAL SCIENTIFIC COMMITTEE

EVALUATION AND TREATMENT OF URINARY INCONTINENCE, PELVIC ORGAN PROLAPSE AND FAECAL INCONTINENCE

A. Wagg, P. Abrams, K-E. Andersson, M. A. Averbeck, L. Birder, D. Bliss, L. Cardozo, D. Castro-Diaz, F. Cruz, D. de Ridder, S. de Wachter, R. Dmochowski, C. Dumoulin, M. Fader, E. Finazzi Agrò, C. Fry, H. Goldman, P. Hanno, V. Khullar, T. Kessler, M. Kilonzon, C. Knowles, E. van Laeke, C. Maher, I. Milsom, K. Moore, C. Murphy, A. Rantell, E. Rovner, D. Robinson, S. Salvatore, A. Wein
and the members of the committees

INTRODUCTION
The 7th International Consultation on Incontinence took place online in November 2021 and was organ-ised by the International Consultation on Urological Diseases and the International Continence Society (ICS), to develop consensus statements and recommendations for the diagnosis, evaluation and treatment of urinary incontinence, faecal incontinence, pelvic organ prolapse and bladder pain syndrome. Oppor-tunity for discussion was offered both in real time and asynchronously, by the use of question and answer fora, enabling attendees to comment upon presentations and pose direct questions to the committees, resulting in refinement and modifications where necessary

The consensus statements are evidence based following a thorough review of the available literature and the global subjective opinion of recognised experts serving on focused committees. The individual com-mittee reports were developed, and peer reviewed by open presentation and comment. The Scientific Committee, consisting of the Chairs of all the committees then refined the final consensus statements. These consensus statements will be periodically re-evaluated in the light of clinical experience, techno-logical progress and research

Co-sponsored by
International Consultation on Urological Diseases (ICUD)
International Continence Society (ICS)

In collaboration with
Major international associations of urology, gynaecology and urodynamics
and other medical associations

RECOMMENDATIONS OF THE INTERNATIONAL SCIENTIFIC COMMITTEE

6. RECOMMENDATIONS FOR PRIORITIES IN RESEARCH 2201

1. DEFINITIONS

The consultation agreed to use the current Interna-tional Continence Society definitions (ICS) for lower urinary tract dysfunction (LUTD) including incontinence, except where stated. These definitions were published in the journal Neurourology and Urodynamics (2002; 21:167-178 and 2006; 25: and can be viewed on the ICS website: www.ics.org

The following ICS definitions are relevant:

LOWER URINARY TRACT SYMPTOMS (LUTS)

LUTS are divided into storage, voiding and post micturition symptoms.

Urinary incontinence is a storage symptom and defined as the complaint of any involuntary loss of urine. This definition is suitable for epidemiological studies, but when the prevalence of bothersome incontinence is sought, the previous ICS definition of an "involuntary loss of urine that is a social or hygienic problem "can be useful.

Urinary incontinence may be further defined according to the patient's symptoms

a) **Stress (urinary) incontinence:** Complaint of involuntary loss of urine on effort or physical exertion e.g., sporting activities), or on sneezing or coughing. (Sporting activities)

b) **Urgency (urinary) incontinence:** Complaint of involuntary loss of urine associated with urgency.

c) **Postural (urinary) incontinence:** Complaint of involuntary loss of urine associated with change of body position, for example, rising from a seated or lying position.

d) **Mixed (urinary) incontinence:** Complaint of involuntary loss of urine associated with urgency and with effort or physical exertion or on sneezing or coughing.

e) **Incontinence associated with chronic retention of urine:** Complaint of involuntary loss of urine which occurs in conditions where the bladder does not empty completely as indicated by a significantly high residual urine volume and/or a non-painful bladder which remains palpable after the individual has passed urine. (Note: The ICS no longer recommends the term overflow incontinence. A significant residual urine volume denotes a minimum volume of 300 ml, although this figure has not been well established.)

f) **Nocturnal enuresis:** Complaint of involuntary loss of urine which occurs during sleep.

g) **Continuous (urinary) incontinence:** Complaint of continuous involuntary loss of urine.

h) **Insensible (urinary) incontinence:** Complaint of urinary incontinence where the individual is unaware of how it occurred

i) **Coital incontinence (for women only):** Complaint of involuntary loss of urine with coitus. This symptom can be further divided into that occurring with penetration and that occurring at orgasm.

j) **Functional (disability associated) incontinence:** Complaint of involuntary loss of urine that results from an inability to reach the toilet due to cognitive, functional or mobility impairments in the presence of an intact lower urinary tract system.

k) **Multifactorial incontinence:** Complaint of involuntary loss of urine related to multiple interacting risk factors, including factors both within and outside the lower urinary tract such as comorbidity, medication, age-related physiological changes and environmental factors.

Urinary incontinence can exist in isolation or may be associated with other lower urinary tract symptoms. The ICS classifies lower urinary tract symptoms (LUTS) into bladder storage, voiding and post-micturition, and pelvic organ prolapse symptoms. The following section summarises the definitions of LUTS described by the ICS-SSC.

Overactive bladder is characterised by the storage symptoms of urinary urgency, usually accompanied by increased urinary frequency and nocturia, with or without urgency urinary incontinence, in the absence of urinary tract infection or other obvious pathology.

Urodynamic Diagnosis

- **Detrusor Overactivity** is a urodynamic observation characterised by involuntary detrusor contractions during the filling phase, which may be spontaneous or provoked.

Detrusor overactivity is divided into:

  - **Idiopathic Detrusor Overactivity**, defined as overactivity when there is no clear cause
  - **Neurogenic Detrusor Overactivity** is defined as overactivity due to a relevant neurological condition.

- **Urodynamic stress incontinence** is noted during filling cystometry and is defined as the involuntary leakage of urine during increased abdominal pressure, in the absence of a detrusor contraction.

INTERSTITIAL CYSTITIS/BLADDER PAIN SYNDROME (IC/BPS) AND HUNNER LESION DISEASE (HLD)*

- **IC/BPS** is defined as chronic pelvic pain, pressure, or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary

symptom such as persistent desire to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.

- **Hunner Lesion Disease** refers to patients who meet the IC/BPS definition with cystoscopic findings of discrete inflammatory areas in the bladder consistent with the histologic criteria for Hunner lesion.

PELVIC ORGAN PROLAPSE

- **Urogenital prolapse** is defined as the symptomatic descent of one or more of: the anterior vaginal wall, the posterior vaginal wall, and the apex of the vagina (cervix/uterus) or vault (cuff) after hysterectomy. Urogenital prolapse is measured using the POP-Q system.

- **Rectal prolapse** is defined as circumferential full thickness rectal protrusion beyond the anal margin.

ANAL INCONTINENCE

Anal incontinence defined as “any involuntary loss of faecal material and/or flatus and/or mucus” and may be divided into:

- **Faecal incontinence**, any involuntary loss of faecal material

- **Flatus incontinence**, any involuntary loss of gas (flatus)

- **Mucus incontinence**, any involuntary loss of mucus only (not faeces)

* At the time of this consultation, these definitions are not included in the current ICS terminology.

2. EVALUATION

The following phrases are used to classify diagnostic tests and studies:

- **A highly recommended** test is a test of proven value that should be done on every patient.
- **A recommended test** is a test of proven value in the evaluation of most patients and its use is strongly encouraged during evaluation.
- **An optional test** is a test of proven value in the evaluation of selected patients; its use is left to the clinical judgement of the physician
- **A not recommended test** is a test of no proven value.

This section primarily discusses the Evaluation of Urinary Incontinence with or without Pelvic Organ Prolapse (POP) and Faecal Incontinence.

The recommendations are intended to apply to children and adults, including adults over the age of sixtyfive.

These conditions are highly prevalent but often not reported by patients. Therefore, the Consultation strongly recommends case finding, particularly in high-risk groups.

A. HIGHLY RECOMMENDED TESTS DURING INITIAL EVALUATION

The **main recommendations** for this consultation have been abstracted from the extensive work of the twenty-three committees of the 7th International Consultation on Incontinence (ICI, 2021).

Each committee has authored a report that reviews and evaluates the published scientific work in each field of interest to give Evidence Based recommendations. Each report ends with detailed recommendations and suggestions for a programme of research.

The main recommendations should be read in conjunction with the management algorithms for children, men, women, the frail older adult, neurogenic patients, as well as patients with bladder pain, pelvic organ prolapse, and faecal incontinence

The initial evaluation, by a clinician, should be undertaken in patients presenting with symptoms/ signs suggestive of these conditions.

1. HISTORY AND GENERAL ASSESSMENT

Management of a disease such as incontinence requires caregivers to assess the sufferer in a holistic manner. Many factors may influence a particular individual's symptoms, some may cause incontinence, and may influence the choice and the success of treatment. The following components of the medical history are particularly emphasised:

1.1. Review of Systems:

- Presence, severity, duration and bother of any urinary, bowel or prolapse symptoms. Identifying symptoms in the related organ systems is critical to effective treatment planning. The use of validated questionnaires to assess symptoms are recommended. It is also helpful to determine the impact that the leakage has on the patient's daily life and activities if incontinence limits the individual's activity and if the patient made lifestyle changes because of the risk of leakage.
- Effect of any symptoms on sexual function: validated questionnaires including impact on quality of life are a useful part of a full assessment.
- Presence and severity of symptoms suggesting neurological disease

1.2. Medical History:

- Previous conservative, medical and surgical treatment as these affect the genitourinary tract and lower bowel. The effectiveness and side effects of treatments should be noted.
- Coexisting diseases may have a profound effect on patients with incontinence and prolapse, for example, asthma patients with stress incontinence will suffer greatly during attacks. Diseases may also precipitate incontinence or make it more likely than not, particularly in frail older adults.
- Patient medication: it is always important to review every patient's list of medications and to make an assessment as to whether current treatment may be contributing to the patient's condition.
- Obstetric and menstrual history.
- Physical impairment: individuals who have compromised mobility, dexterity, or visual acuity may need to be managed differently

1.3. Social History:

- Environmental issues: these may include the social, cultural, and physical environment.
- Lifestyle: including exercise, smoking and the amount and type of fluid and food intake.

1.4. Other Treatment Planning Issues:

- ***Desire for treatment*** and the extent of treatment that is acceptable
- ***Patient goals*** and expectations of treatment
- ***Patient support*** systems (including caregivers).
- ***Cognitive function***: all individuals need to be assessed for their ability to fully describe their symptoms, symptom bother and quality of life impact, and their preferences and goals for care. They must be able to understand proposed management plans and to discuss, where appropriate, alternative treatment options. In some groups of patients, formal testing is essential e.g., cognitive function testing for individuals for whom the clini-

cian has concerns regarding memory deficits and/or inattention or confusion, and depression screening for individuals for whom the clinician has concerns about abnormal affect. Proxy respondents, such as family and caregivers, may be used to discuss the patient's history, goals of care, and treatment for individuals with dementia, but only if the individual is incapable of accurate reporting or weighing treatment decisions.

- Finally, it is important to emphasize the importance of establishing patient expectation of treatment and an understanding of the balance between the benefits and risks/burden/costs of available treatment options

2. PHYSICAL EXAMINATION

The more complicated the history and the more extensive and/or invasive the proposed therapy, the more complete the examination needs to be. Depending on the patient's symptoms and their severity, there are a number of components in the examination of patients with incontinence and/or pelvic organ prolapse.

Physical examination should be performed regardless of whether the patient is a child, a woman, a man, someone with neurological disease or a frail older adult with respect to the following domains

- General status:
- Mental status
- Obesity (BMI)
- Physical dexterity and mobility

2.1. External genitalia: for genitourinary syndrome of the menopause, incontinence associated dermatitis, hygiene, location of the urethral meatus and phimosis/paraphimosis.

2.2. Abdominal/flank examination: for masses, bladder distention, relevant surgical scars

2.3. Pelvic examination:

- Examination of the perineum and external genitalia including tissue quality and sensation.
- Vaginal (half-bivalve speculum/Sims) examination for pelvic organ prolapse (POP), which should ideally be done in the lithotomy as well as in the vertical position, as dictated by practicality. Ideally, the POPQ staging system should be used
- Bimanual pelvic and anorectal examination for pelvic mass and tenderness
- Digital rectal examination to assess pelvic floor muscle function, reflexes, urethral mobility, and the function of internal and external anal sphincter as well as puborectalis muscle. Assess for prostate size, texture, palpable masses, faecal loading, or impaction. An assessment for pelvic pain should be performed in appropriate patients.
- Stress test (supine /standing) for urinary incontinence in the presence of a comfortably full bladder

2.4. Neurological testing (see chapter on assessment)

3. URINALYSIS

A screening urinalysis is recommended as part of the testing for urinary incontinence. A positive dipstick urinalysis will prompt formal urine microscopy and culture to detect UTI and/or the use of additional tests such as endoscopy and urinary tract imaging. Detection of haemoglobin or glycosuria should, likewise, prompt further testing.

Conclusion

For many, a diagnosis can be made based upon relevant history, directed physical examination and urinalysis and treatment, particularly involving non- invasive and inexpensive therapies, may start without the need for the further investigations listed below.

B. RECOMMENDED FURTHER ASSESSMENT PRIOR TO, OR DURING, SPECIALIST ASSESSMENT

The tests below are recommended when the **appropriate indication(s) is present.** Some recommended tests become highly recommended in specific situations.

This section should also be read in conjunction with the relevant committee reports.

1. FURTHER SYMPTOM AND HEALTH-RELATED QOL ASSESSMENT

1.1. Bladder Diary

In patients with **urinary symptoms** the use of a **bladder diary** (examples in Annex 1) is highly recommended to document the frequency of micturition, the volumes of urine voided, incontinence episodes and the use of incontinence pads. Although never completely diagnostic, diary patterns may characterise normal and abnormal states (Level 2, Grade A).

1.2. Questionnaires

The use of the **highest quality questionnaires** (GoR A, where available) is recommended for the assessment of the patient's perspective of symptoms of incontinence and their impact on quality of life.

The ICIQ is highly recommended (GoR A) for the basic evaluation of the patient's perspective of urinary incontinence, with other GoR A questionnaires recommended for more detailed assessment.

2. RENAL FUNCTION & PROSTATE SPECIFIC ANTIGEN ASSESSMENT

Standard biochemical tests for renal function are recommended ONLY in patients with urinary incontinence when there is suspected renal impairment as a consequence. PSA testing is recommended only in selected males with LUTS, particularly when a diagnosis of prostate cancer could potentially affect the management or in patients receiving 5-alpha-reductase inhibitors.

3. UROFLOWMETRY

Uroflowmetry with the measurement of post void residual urine is recommended as a screening test for symptoms suggestive of urinary voiding dysfunction or physical signs of POP or bladder distension. Uroflowmetry should be part of the initial assessment if the result is likely to influence management e.g., in all children and older men with possible prostatic obstruction.

4. ESTIMATION OF POST VOID RESIDUAL URINE (PVR)

In all adults, PVR should be part of the initial assessment if the result is likely to influence management. Where possible this should, by preference be performed non-invasively.

5. IMAGING

Although routine imaging is not recommended, imaging of the lower urinary tract and pelvis is highly recommended in those with urinary symptoms whose initial evaluation indicates a possible co- existing lower tract or pelvic pathology. Initial imaging may be by ultrasound, or plain X-ray.

Imaging of the upper urinary tract is highly recommended in specific situations. These include:

- Haematuria,
- Neurogenic urinary incontinence e.g., myelodysplasia, spinal cord trauma,
- Incontinence associated with significant post-void residual,
- Co-existing renal disease such as pyelonephritis or reflux, or loin/kidney pain,
- Patients with chronic urinary retention
- In women with severe urogenital prolapse
- Suspected extra-urethral urinary incontinence,
- Children with incontinence and UTIs, where indicated
- Children with extraurethral incontinence
- Urodynamic studies which show evidence of poor bladder compliance or high-pressure detrusor overactivity.

6. INVESTIGATIONS IN FAECAL INCONTINENCE AND RECTAL PROLAPSE

- Endoanal US or MRI prior to anal sphincter surgery is highly recommended, even when obvious anatomic defects are not evident.
- Defaecating proctography or dynamic MRI is recommended in suspected rectal prolapse which cannot be adequately confirmed by physical examination.
- MRI offers no advantage over other imaging modalities except for the lack of ionising radiation and global view of the pelvis
- Evacuation defecography is indicated in patients with constipation, and in patients with obstructive defaecation associated with anal incontinence caused by overflow incontinence or post defaecation leakage
- Anorectal manometry is useful to assess resting and squeeze anal pressures. The resting and squeeze pressures represent the function of the internal and external anal sphincter, respectively.

7. ENDOSCOPY

Although routine cysto-urethroscopy is not recom- mended, LUT endoscopy is **highly recommended** when:

- initial testing is abnormal, e.g., haematuria and suggests other pathologies,
- pain or discomfort feature in the patient's LUTS, these may suggest an intravesical lesion
- appropriate in the evaluation of vesicovaginal fistula and extra-urethral urinary incontinence (in childbirth fistulae, endoscopy is often unnecessary).

In anorectal conditions, Referral for proctosigmoidoscopy and/or colonoscopy may be made at the time of initial assessment to assess for evaluation of specific conditions. Anoscopy and proctoscopy with a rigid instrument or flexible sigmoidoscopy are examinations of value in excluding potentially treatable causes of faecal incontinence

8. URODYNAMIC TESTING

8.1. Urodynamic (multi-channel pressure subtracted cystometry) evaluation is recommended when:

- the results may change management, such as prior to most invasive treatments for UI and POP,
- treatment fails, if more information is needed to plan further therapy,
- used as a prognostic tool, such as part of both initial and long-term surveillance programmes in some types of neurogenic lower urinary tract dysfunction,

- Indicated in “complicated incontinence” (for details please see relevant subcommittee reports).

8.2. The aims of urodynamic evaluation are often diagnostic, but may also relate to prognostic factors, direct management or assess response to prior therapy, and also to:
- reproduce the patient’s symptoms and correlate these with urodynamic findings
- assess bladder sensation
- detect filling pressures (e.g., detrusor overactivity) and bladder capacity
- assess urethral competence during filling
- determine detrusor function during voiding
- assess outlet function during voiding
- assess residual urine

9. SMALL BOWEL FOLLOW-THROUGH, CT ENTOGRAPHY OR CAPSULE ENDOSCOPY

These tests are recommended in those with faecal incontinence and the presence of unexplained diarrhoea or when Crohn’s disease is suspected.

C. FURTHER DIAGNOSTIC TESTS TO BE USED AS APPROPRIATE

1. ADDITIONAL URODYNAMIC TESTING

Video-urodynamics is an optional recommendation and may be useful in the assessment of UI in some children, in patients who fail surgery or who have known or suspected anatomical abnormalities of the lower urinary tract (e.g., diverticula, fistula, vesico-ureteric reflux) and in some neurogenic patients, to obtain additional anatomical information. Either X-ray or US imaging can be used depending on the needs of the individual patient and available resources.

If a more **detailed estimate of urethral function** is required, then the following optional tests may give useful information, in addition to standard multi-channel pressure subtracted cystometry
- Urethral pressure profilometry
- Abdominal leak point pressures
- Video-urodynamics
- Electromyography of pelvic floor or urethral sphincter

If initial urodynamics have failed to demonstrate the cause for the patient’s incontinence, then the following tests are optional:
- Repeated routine urodynamics or video-urodynamics
- The role of ambulatory urodynamics remains unclear in this setting

2. PAD TESTING

Pad testing is an optional test for the evaluation of urinary incontinence and, if carried out, either a 20 min-1 h ward/office test with fixed bladder volume or a 24 h home pad test during usual daily activity is recommended.

3. NEUROPHYSIOLOGICAL TESTING AND IMAGING

The information gained by clinical examination and urodynamic testing may be enhanced by uroneurophysiological tests in selected patient groups with suspected neurogenic urinary incontinence with lesions within the nervous reflex arcs of sacral segments 2 – 5. Concentric needle EMG to diagnose denervation and reinnervation of pelvic floor and perineal muscles, and sacral reflex testing to assess the continuity of the sacral reflex arc, are recommended tests in these circumstances

Appropriately trained personnel should perform these tests. The following neuro-physiological tests can be considered in patients to detect a neurological lesion in case of a urinary or anorectal disorder, to specify the importance, the lesion level and sometimes the prognosis. They may also be of utility in the investigation of idiopathic urinary retention in women and idiopathic faecal incontinence
- Concentric needle EMG
- Sacral reflex responses to electrical stimulation of penile or clitoral nerves.

Imaging of the nervous system (and neighbouring structures, including spine, the abdominal cavity and pelvis) by MRI or CT, may confirm suspected involvement of the nervous system, and the nature of the cause.

4. FURTHER IMAGING

Cysto-urethrography, US, CT and MRI may have an indication in:
- suspected pelvic floor dysfunction
- failed surgery, such as recurrent posterior vaginal wall prolapse or failed sling surgery
- suspected fixed urethra

5. CYSTO-URETHROSCOPY

This is an optional test in patients with complicated, persistent or recurrent UI (e.g., after failed SUI surgery)

3. MANAGEMENT CONSENSUS STATEMENTS

The consensus statements are derived from the **detailed work of the committees** on the management of incontinence in children, men, women, the frail older adult and neurological patients, as well as those with obstetric fistula, pelvic organ prolapse, bladder pain syndrome, and faecal incontinence. The management of incontinence is presented in **algorithm form** with **accompanying notes**.

The chapters analyse the evidence and give it a level of evidence (LoE), and this generates a grade of recommendation (GoR)

The Consultation recognises that no algorithm can be applied to every patient and each patient's management must be individualised.

There are algorithms for

I. Urinary Incontinence in Children

II. Urinary Incontinence in Men

III. Urinary Incontinence in Women

IV. Fistulae

V. Pelvic Organ Prolapse

VI. Urinary Incontinence in Patients with Neurological Disease

VII. Interstitial Cystitis/Bladder Pain Syndrome and Hunner Lesion Disease

VIII. Faecal Incontinence in Adults

IX. Urinary and Faecal Incontinence in frail Older Men and Women

These algorithms are divided into two for groups I to III, VII and X. The two parts, initial **management** and **specialised management** require a little further explanation.

Although the management algorithms are designed for patients whose predominant problem is incontinence, there are many other patients in whom the algorithms may be useful such as those patients with urgency and frequency, so-called "**OAB dry**

Management definitions

Management may be divided into

- Conservative, all methods that are non-medical and non-surgical, some of which do not target the disease process

- Conservative therapy includes

  - Lifestyle interventions e.g., weight loss, fluid management
  - Bladder training and behavioural toileting programmes
  - Pelvic floor muscle training (PFMT)
  - Containment products & appliances, e.g., pads, urinals
  - Dependent continence strategies e.g., regular toileting

Consensus does not exist as to the use of the term "behavioural therapy" as some state that this term only includes techniques where a behavioural change is promoted because of the management technique. Others consider that all conservative management contains a behavioural element, for example wearing and changing pads constitutes a change in behaviour. Hence the consultations recommendations list the elements of conservative management as relevant are intended for use by all clinicians

The algorithms for initial management

These algorithms are intended for use by **all healthcare providers**. The consultation has attempted to phrase the recommendations in the basic algorithms in such a way that they may be readily used by clinicians in all countries of the world, both in the developing and the developed world. For this consultation, conservative management has been incorporated into the algorithms, other than that for urogenital prolapse, where a specific algorithm has been constructed.

The specialised algorithms

The specialised algorithms are intended for use by **specialists**. The specialised algorithms, as well as the initial management algorithms are **based on evidence where possible**, and on the **expert opinion** of the expert clinicians who took part in the Consultation. In this consultation, committees ascribed levels of evidence to the published work on the subject and devised Grades of Recommendation (GoR) to inform patient management.

It should be noted that these algorithms, dated **November 2021**, represent the Consultation **consensus at that time**. There will undoubtedly be changes both in the short term and in the long term as research evidence evolves and continues to guide practice.

ESSENTIAL COMPONENTS OF BASIC ASSESSMENT

Each algorithm contains a core of recommendations in addition to several essential components of basic assessment listed in sections I to III.

- General assessment
- Symptom assessment
- Assessment of impact on quality of life
- Assessment of the desire for treatment
- Physical examination
- Urinalysis & initial investigations where relevant

JOINT DECISION MAKING

The patient's desires and goals for treatment: Treatment is a matter for discussion and joint decision making between the patient and the health care provider. This process of consultation includes the need to assess whether the patient wishes to receive treatment and, if so, what treatments he or she would favour. Implicit in this statement is the assumption that the health care provider will give an **appropriate explanation of the patient's problem**, the **alternative lines of management**, and the potential **benefits** and **risks of treatment**. The assumption that patients almost always wish to have treatment is flawed, and the need to incorporate patient values and preferences is paramount. Clinicians should also consider the **potential treatment burden** associated with their plans and incorporate this into their assessment.

In each algorithm, treatments are listed in **order of simplicity**, the least invasive being listed first. This order does not imply a scale of efficacy or cost, two factors which need to be considered in choosing the sequence of therapy. The order is likewise not meant to imply a suggested sequence of therapy, which should be determined jointly by the treating health care provider and the patient, considering all the relevant factors listed above. This stepwise approach may not be appropriate in all circumstances.

In the **initial management algorithms**, treatment is **empirically based**, whilst the **specialised management** algorithms usually rely on diagnostic information from urodynamics and other testing.

The assumption is made that patients will be reassessed at an appropriate time to evaluate their progress and to readjust management accordingly.

USE OF CONTINENCE PRODUCTS

The possible role of **continence products** to prevent, contain and/or manage bladder and/or bowel leakage should be considered at each stage of patient assessment and treatment, to maintain dignity and social functioning, and/or to support self-management or care by others.

Consider use of continence products:
- while treatment is awaited.
- when treatment is not chosen or not suitable for the individual
- when treatment does not achieve adequate improvement or resolution of symptoms
- for **intermittent use**, for example when the patient has a cough, exercise, or needs to travel without reliable toilet access
- for **continuous use** if incontinence is unpredictable and/or frequent or if complications related to incontinence (e.g., skin breakdown) are imminent or present
- where “check and change” regimens are the only means to achieve social continence

Most patients will benefit from using a **mixture** of continence products to optimise effectiveness and to reduce costs, e.g., assorted products for day and night; or for staying at home and for going out/travel/specific activities.

Further guidance on management with continence products is given in Chapter 19 and at the ICI/ICS supported website:

www.continenceproductadvisor.org

At the foot of each of the treatment algorithms below, the phrase “Consider appropriate use of CONTINENCE PRODUCTS,” emphasizes the importance of continence products for many sufferers of incontinence

I. URINARY INCONTINENCE IN CHILDREN

A INITIAL MANAGEMENT

Children present specific management problems for a variety of reasons: assessment requires help from their parents and caregivers; consent to treatment may be problematic; and cooperation in both assessment and treatment may be difficult.

Initial assessment should involve a detailed investigation of voiding and bowel habits using bladder/bowel diaries and structured and validated questionnaires.

The child's social environment and general and behavioural development should also be formally assessed and recorded. Physical examination should be done to detect a palpable bladder, faecal loading and exclude anatomical and neurological causes (e.g., sacral dimple). Urine analysis and culture is sufficient to exclude the presence of infection. If possible, the child should be observed voiding.

- Referrals for specialist treatment are recommended for children who have complicated incontinence associated with:
  - Recurrent and febrile urinary infection
  - Voiding symptoms or evidence of poor bladder emptying
  - Urinary tract anomalies
  - Previous pelvic surgery
  - Neuropathy or neuropathic origin
  - Bowel dysfunction not responsive to treatment
  - Comorbid behavioural (e.g., ADHD and ODD) and emotional disorders.

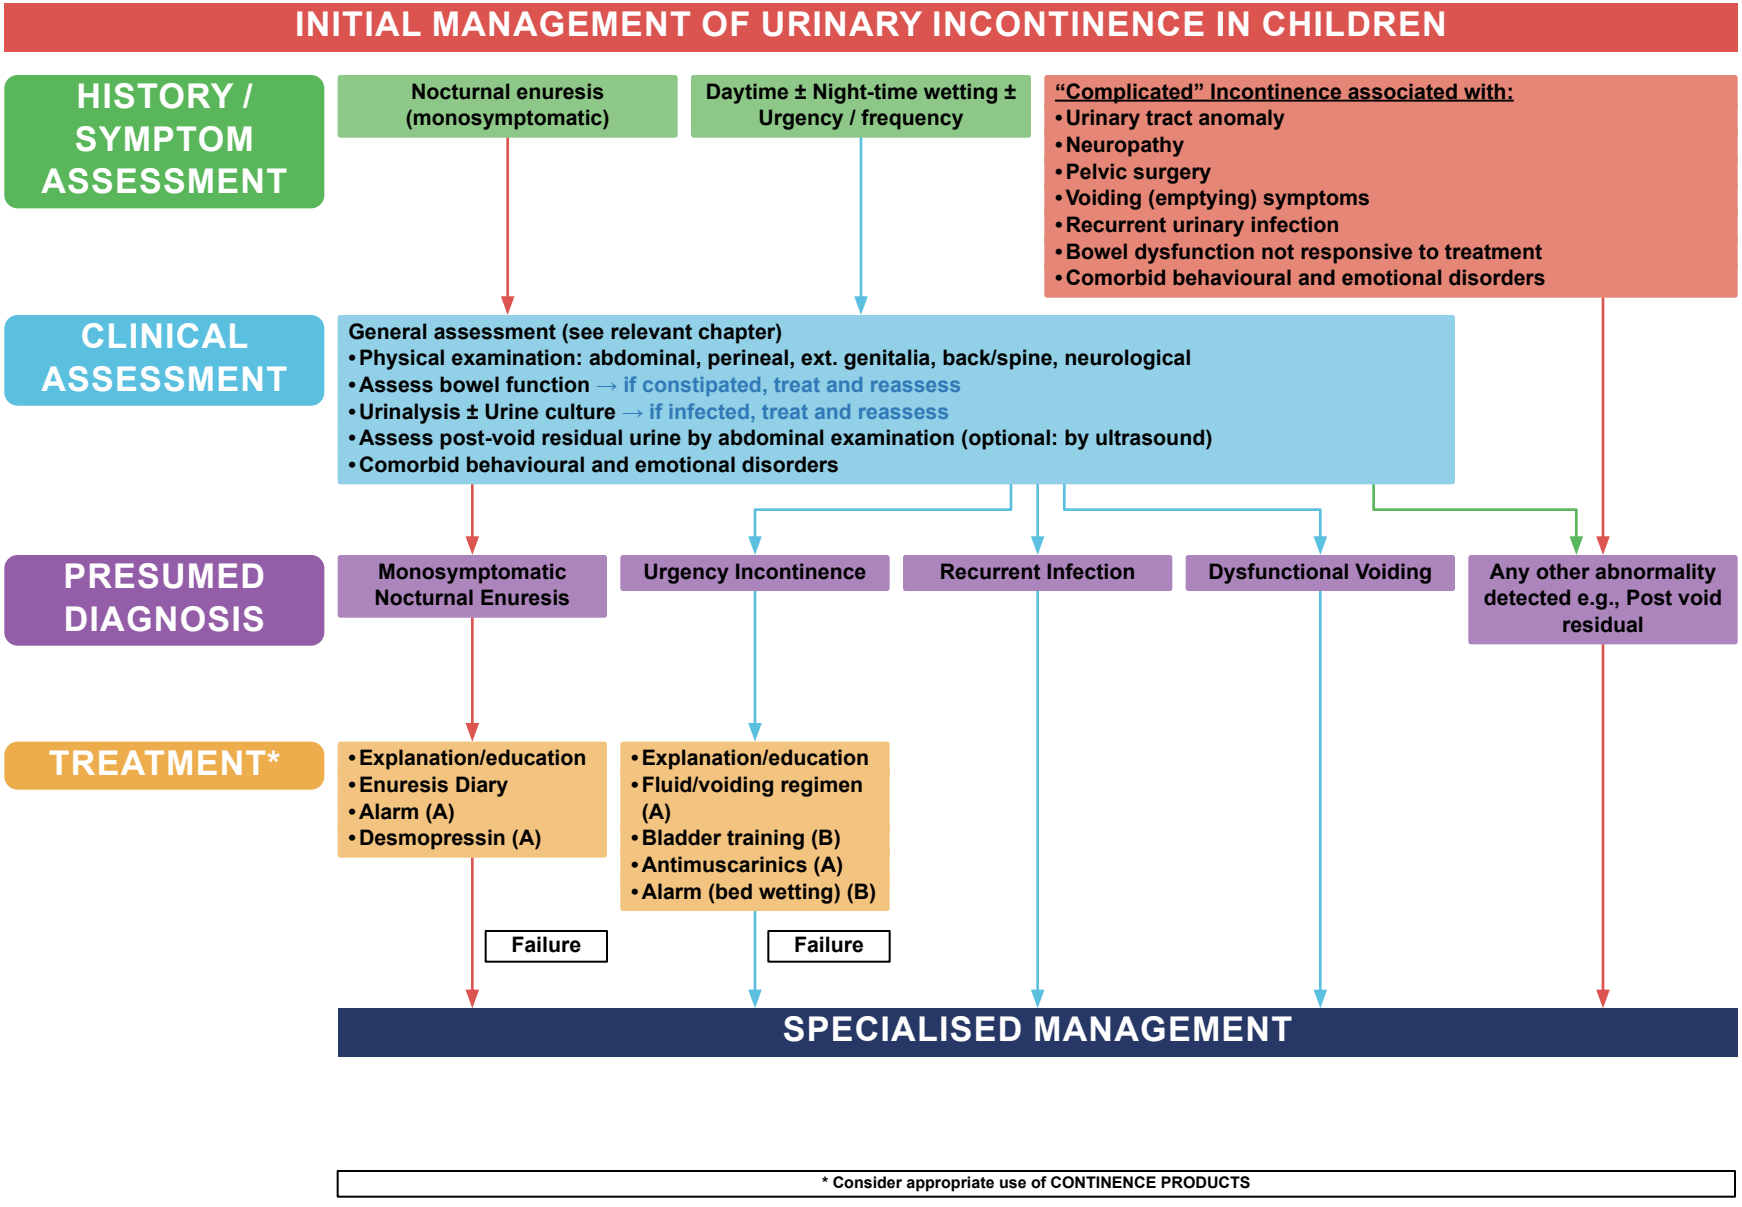
- **Initial treatment is recommended for the remaining patients who have:**
  - Nocturnal enuresis without other symptoms (monosymptomatic enuresis).
  - Daytime symptoms of frequency, urgency, voiding postponement, straining, interrupted voiding, urgency incontinence with or without nighttime wetting.

TREATMENT

- Initial treatment for **mono-symptomatic nocturnal** enuresis should include:
  - Parental and child counselling and motivation
  - Review of bladder diary with attention to night-time polyuria
  - Age-appropriate education and demystification or explanation

- A choice between either bed wetting alarm (GoR A) or anti-diuretic hormone analogues of desmopressin (GoR A). It may be a parental and child choice if advantages and disadvantages are well explained.

- Daytime incontinence should be managed holistically including:
  - Counselling, timed voiding, behaviour modification and bowel management when necessary (GoR B).
  - Antimuscarinics may be used if the child has OAB symptoms (GoR A)



INITIAL MANAGEMENT OF URINARY INCONTINENCE IN CHILDREN
HISTORY / SYMPTOM ASSESSMENT
Nocturnal enuresis (monosymptomatic)
Daytime ± Night-time wetting ± Urgency / frequency
"Complicated" Incontinence associated with:
• Urinary tract anomaly
• Neuropathy
• Pelvic surgery
• Voiding (emptying) symptoms
• Recurrent urinary infection
• Bowel dysfunction not responsive to treatment
• Comorbid behavioural and emotional disorders
CLINICAL ASSESSMENT
General assessment (see relevant chapter)
• Physical examination: abdominal, perineal, ext. genitalia, back/spine, neurological
• Assess bowel function → if constipated, treat and reassess
• Urinalysis ± Urine culture → if infected, treat and reassess
• Assess post-void residual urine by abdominal examination (optional: by ultrasound)
• Comorbid behavioural and emotional disorders
PRESUMED DIAGNOSIS
Monosymptomatic Nocturnal Enuresis
Urgency Incontinence
Recurrent Infection
Dysfunctional Voiding
Any other abnormality detected e.g., Post void residual
TREATMENT*
• Explanation/education
• Enuresis Diary
• Alarm (A)
• Desmopressin (A)
• Explanation/education
• Fluid/voiding regimen (A)
• Bladder training (B)
• Antimuscarinics (A)
• Alarm (bed wetting) (B)
Failure
Failure
SPECIALISED MANAGEMENT
* Consider appropriate use of CONTINENCE PRODUCTS

I. URINARY INCONTINENCE IN CHILDREN

B SPECIALISED MANAGEMENT

- Two groups of children with ‘‘complicated’’ incontinence should have spe- cialist management from the outset (Fig. 2).

- Children whose incontinence is due to, or associated with, **urinary tract anomalies** and **neuropathy**.

- **Children** without urinary tract anomalies, but with **recurrent febrile infection** and, proven or suspected, **lower urinary tract dysfunction**.

- Children who **fail the basic treatment**, but who have neither neurogenic nor anatomical problems, should also receive specialist management.

Children with comorbid behavioural and emotional disorders require referral to mental health services, as compliance and treatment outcomes are lower.

Assessment and treatment should follow evidence-based practice guidelines

ASSESSMENT

- As part of further assessment, the measurement of **urine flow** (in children old enough), together with the **ultrasound estimate of residual urine** and appearance of the bladder wall and rectum are highly recommended. An evaluation of the **upper urinary tracts with ultrasound is also highly recommended**.

Those who do not improve **with treatment** and have neither neurogenic nor anatomical problems **should be reassessed** using bladder diaries, symptom questionnaires, urinalysis, uroflowmetry and residual urine determination.

If there are recurrent and febrile infections, upper tract imaging and a VCUG should be considered. However, endoscopy is rarely indicated.

- **Urodynamics should be considered:**

- If the type and severity of lower tract dysfunction **cannot be explained by clinical findings** or in the presence of possible relevant neuropathy or urinary tract anomalies. (GoR B)

- If **invasive treatment** is under consideration, for example, stress incontinence surgery if there is sphincteric incompetence, or bladder augmentation if there is detrusor overactivity. (GoR B)

- **If upper tract dilation exists** and is thought to be due to bladder dysfunction. (Gor A)

- **Invasive urodynamic studies are generally not recommended** if the child has normal upper tract imaging and is to be treated by noninvasive means. (Gor B)

- **Spinal Imaging** (US/X-ray/MRI) may be needed if a bony abnormality or neuro-logical condition is suspected. (GoR A)

TREATMENT

The treatment of incontinence associated with **urinary tract anomalies** is complex and cannot easily be dealt with in an algorithm. In many children **more than one pathology** demands treatment. If there are **complex congenital abnormalities present**, the treatment is often surgical, and it should be individualised according to the type and severity of the problem (please see Children’s Committee Report).

Specialist children’s nurses and therapists should give care.

- **Initial treatment should be non-surgical.**

- **For stress urinary incontinence** (SUI): pelvic floor muscle training (GoR C).

- **For** OAB symptoms: fluid/voiding regimens and antimuscarinics (GoR A).

- **For voiding dysfunction:** timed voiding, voiding re-education, pelvic floor muscle relaxation (+/- biofeedback), alpha-blocker therapy, and intermittent catheterisation (when PVR >30% of bladder capacity) (GoR A/B).

- **For bowel dysfunction:** high fibre diet and laxatives as appropriate, and. transanal irrigation in severe cases (GoR A).

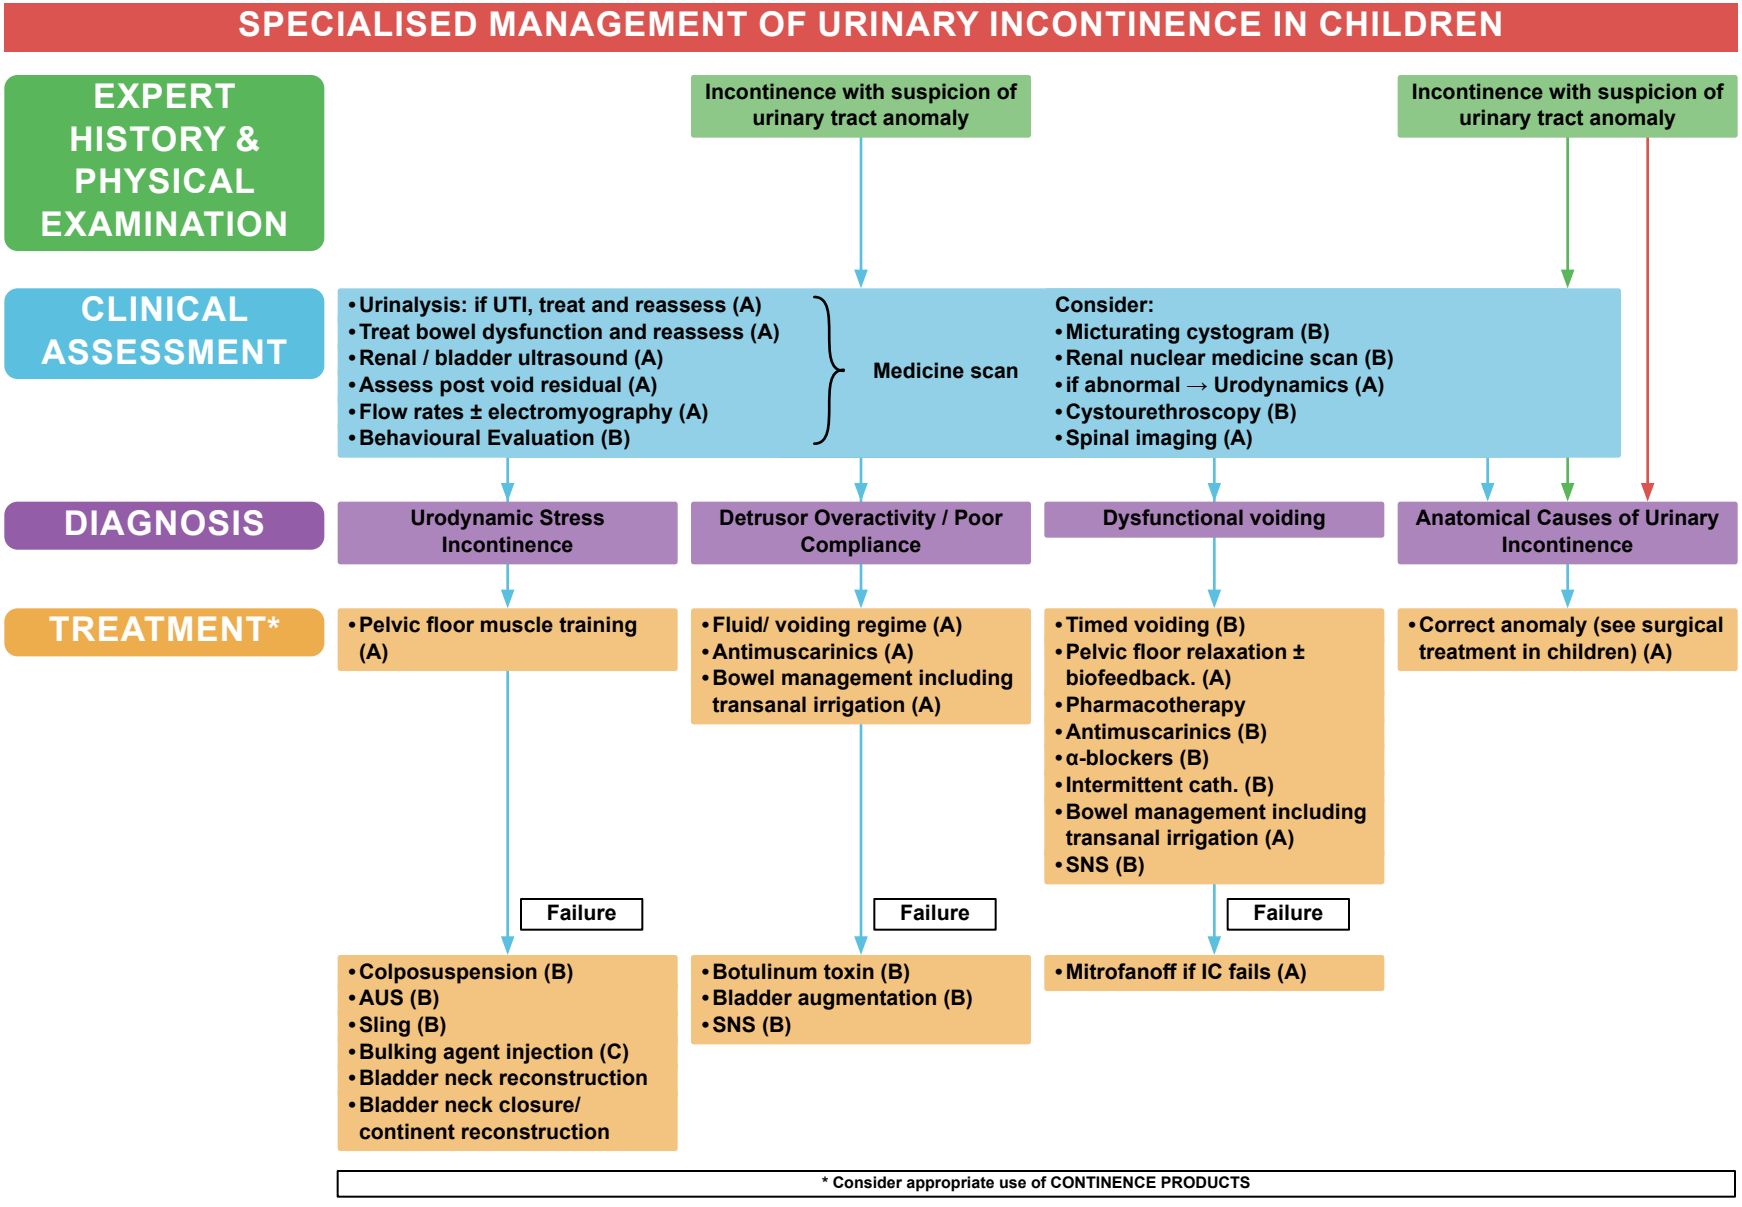
The child's progress should be assessed and, if quality of life is still significantly impaired, or if the upper urinary tracts are at risk, **surgical treatment** is likely to be necessary.

- **If surgical treatment is required**, then urodynamic studies are recommended to confirm the diagnosis.

- **For USI**, bladder neck reconstruction,colposuspension, sling surgery, bulking agent injection,AUS, and rarely, bladder neck closure and continent reconstruction may be considered (GoR B).

- **For DO/poor compliance**, botulinum toxin (for DO, and off-label) and bladder augmentation may be performed (GoR B).

- **If the child cannot do IC,** then a Mitrofanoff channel may be needed (GoR A).



SPECIALISED MANAGEMENT OF URINARY INCONTINENCE IN CHILDREN
EXPERT HISTORY & PHYSICAL EXAMINATION
Incontinence with suspicion of urinary tract anomaly
Incontinence with suspicion of urinary tract anomaly
CLINICAL ASSESSMENT
•Urinalysis: if UTI, treat and reassess (A)
•Treat bowel dysfunction and reassess (A)
•Renal / bladder ultrasound (A)
•Assess post void residual (A)
•Flow rates ± electromyography (A)
•Behavioural Evaluation (B)
Medicine scan
Consider:
•Micturating cystogram (B)
•Renal nuclear medicine scan (B)
•if abnormal → Urodynamics (A)
•Cystourethroscopy (B)
•Spinal imaging (A)
DIAGNOSIS
Urodynamic Stress Incontinence
Detrusor Overactivity / Poor Compliance
Dysfunctional voiding
Anatomical Causes of Urinary Incontinence
TREATMENT*
•Pelvic floor muscle training (A)
•Fluid/ voiding regime (A)
•Antimuscarinics (A)
•Bowel management including transanal irrigation (A)
•Timed voiding (B)
•Pelvic floor relaxation ± biofeedback. (A)
•Pharmacotherapy
•Antimuscarinics (B)
•α-blockers (B)
•Intermittent cath. (B)
•Bowel management including transanal irrigation (A)
•SNS (B)
•Correct anomaly (see surgical treatment in children) (A)
Failure
Failure

II. URINARY INCONTINENCE IN MEN

A INITIAL MANAGEMENT

INITIAL ASSESSEMENT SHOULD IDENTIFY:

- **"Complicated" incontinence group**

Those with pain or with haematuria, recurrent infection, suspected or proven poor bladder emptying (for example due to bladder outlet obstruction), or incontinence following pelvic irradiation or radical surgery, are recommended for **specialised management**.

Poor bladder emptying may be suspected from symptoms, physical examination or if imaging has been performed by X-ray or ultrasound after voiding.

- **Four other main groups** of men should be identified by initial assessment as being suitable for **initial management**.

- Those with post-micturition dribble alone,
- Those with overactive bladder (OAB) symptoms: urgency with or without urgency incontinence, together with frequency and nocturia
- Those with stress urinary incontinence (most often post-prostatectomy),
- Those with mixed urinary urgency and stress incontinence (most often post- prostatectomy)

MANAGEMENT

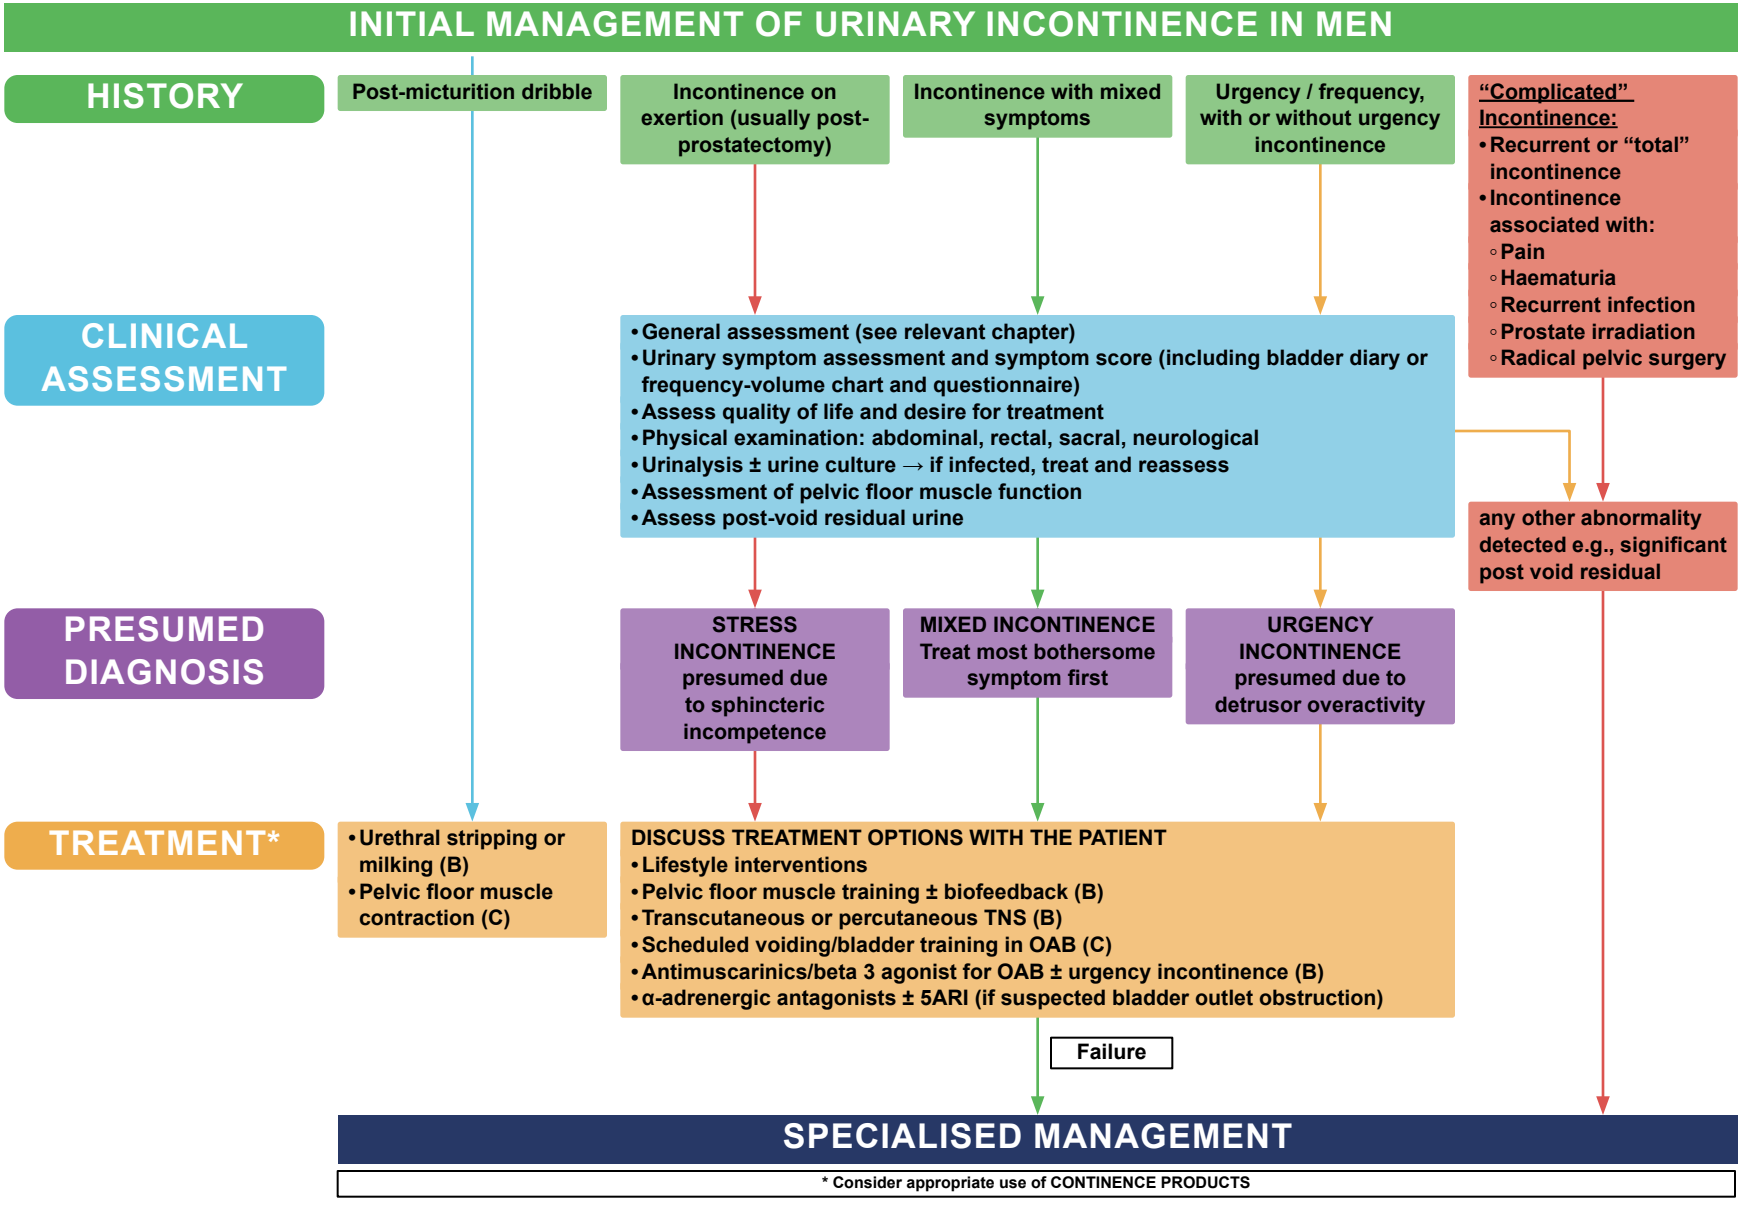
- For men with **post-micturition dribble**, this requires no assessment and can usually be treated by teaching the man how to do a strong pelvic floor muscle contraction after voiding, or manual compression of the bulbous urethra directly after micturition (urethral "stripping" or "milking". (GoR C (for strong PFM contraction))

- For men with **stress**, **urgency** or **mixed** urgency / stress incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, scheduled voiding regimens, behavioural therapies, and medication. In particular:

- Lifestyle interventions (e.g., weight loss GoR B)
- Supervised pelvic floor muscle training either pre-operatively or early post operatively for men with post radical prostatectomy SUI accelerates recovery time (GoR B)
- Scheduled voiding regimen for OAB (GoR C)
- Transcutaneous or percutaneous posterior tibial nerve stimulation for men who do not achieve satisfactory results from lifetsylt and behavioural management (GoR B)
- Antimuscarinic/beta 3 agonist drugs for OAB symptoms with or without urgency incontinence (GoR B) if the patient has no evidence of significant post-void residual urine
- α-adrenergic antagonists (a-blockers), alone or in combination with 5-alpha-reductase inhibitors (5ARI), can be added if it is thought that there may also be benign prostatic obstruction. (GoR C)

- **Should initial treatment be unsuccessful** after a reasonable time (for example, 8-12 weeks), **specialist advice** is highly recommended.

Clinicians are likely to wish to treat the **most bothersome symptom** first in men with symptoms of **mixed** incontinence.



INITIAL MANAGEMENT OF URINARY INCONTINENCE IN MEN
HISTORY
Post-micturition dribble
Incontinence on exertion (usually post-prostatectomy)
Incontinence with mixed symptoms
Urgency / frequency, with or without urgency incontinence
"Complicated" Incontinence:
• Recurrent or "total" incontinence
• Incontinence associated with:
◦ Pain
◦ Haematuria
◦ Recurrent infection
◦ Prostate irradiation
◦ Radical pelvic surgery
CLINICAL ASSESSMENT
• General assessment (see relevant chapter)
• Urinary symptom assessment and symptom score (including bladder diary or frequency-volume chart and questionnaire)
• Assess quality of life and desire for treatment
• Physical examination: abdominal, rectal, sacral, neurological
• Urinalysis ± urine culture → if infected, treat and reassess
• Assessment of pelvic floor muscle function
• Assess post-void residual urine
any other abnormality detected e.g., significant post void residual
PRESUMED DIAGNOSIS
STRESS INCONTINENCE presumed due to sphincteric incompetence
MIXED INCONTINENCE Treat most bothersome symptom first
URGENCY INCONTINENCE presumed due to detrusor overactivity
TREATMENT*
• Urethral stripping or milking (B)
• Pelvic floor muscle contraction (C)
DISCUSS TREATMENT OPTIONS WITH THE PATIENT
• Lifestyle interventions
• Pelvic floor muscle training ± biofeedback (B)
• Transcutaneous or percutaneous TNS (B)
• Scheduled voiding/bladder training in OAB (C)
• Antimuscarinics/beta 3 agonist for OAB ± urgency incontinence (B)
• α-adrenergic antagonists ± 5ARI (if suspected bladder outlet obstruction)
Failure
SPECIALISED MANAGEMENT
* Consider appropriate use of CONTINENCE PRODUCTS

II. URINARY INCONTINENCE IN MEN

B SPECIALISED MANAGEMENT

The specialist may first **reinstitute initial management** if it is felt that previous therapy had been inadequate.

ASSESSMENT

- Patients with **"complicated" incontinence** referred directly to specialised management, are likely to require **additional testing**, such as cytology, cystourethroscopy, and urinary tract imaging.

If additional testing is normal, then those individuals can be treated for incontinence by the initial or specialised management options as appropriate.

If symptoms suggestive of detrusor overactivity, or of sphincter incompetence **persist**, then **urodynamic** studies are optional to arrive at a precise diagnosis, prior to invasive treatment.

TREATMENT

When basic management has been unsuccessful and if the patient's incontinence markedly disrupts his quality of life, then **invasive therapies** should be considered.

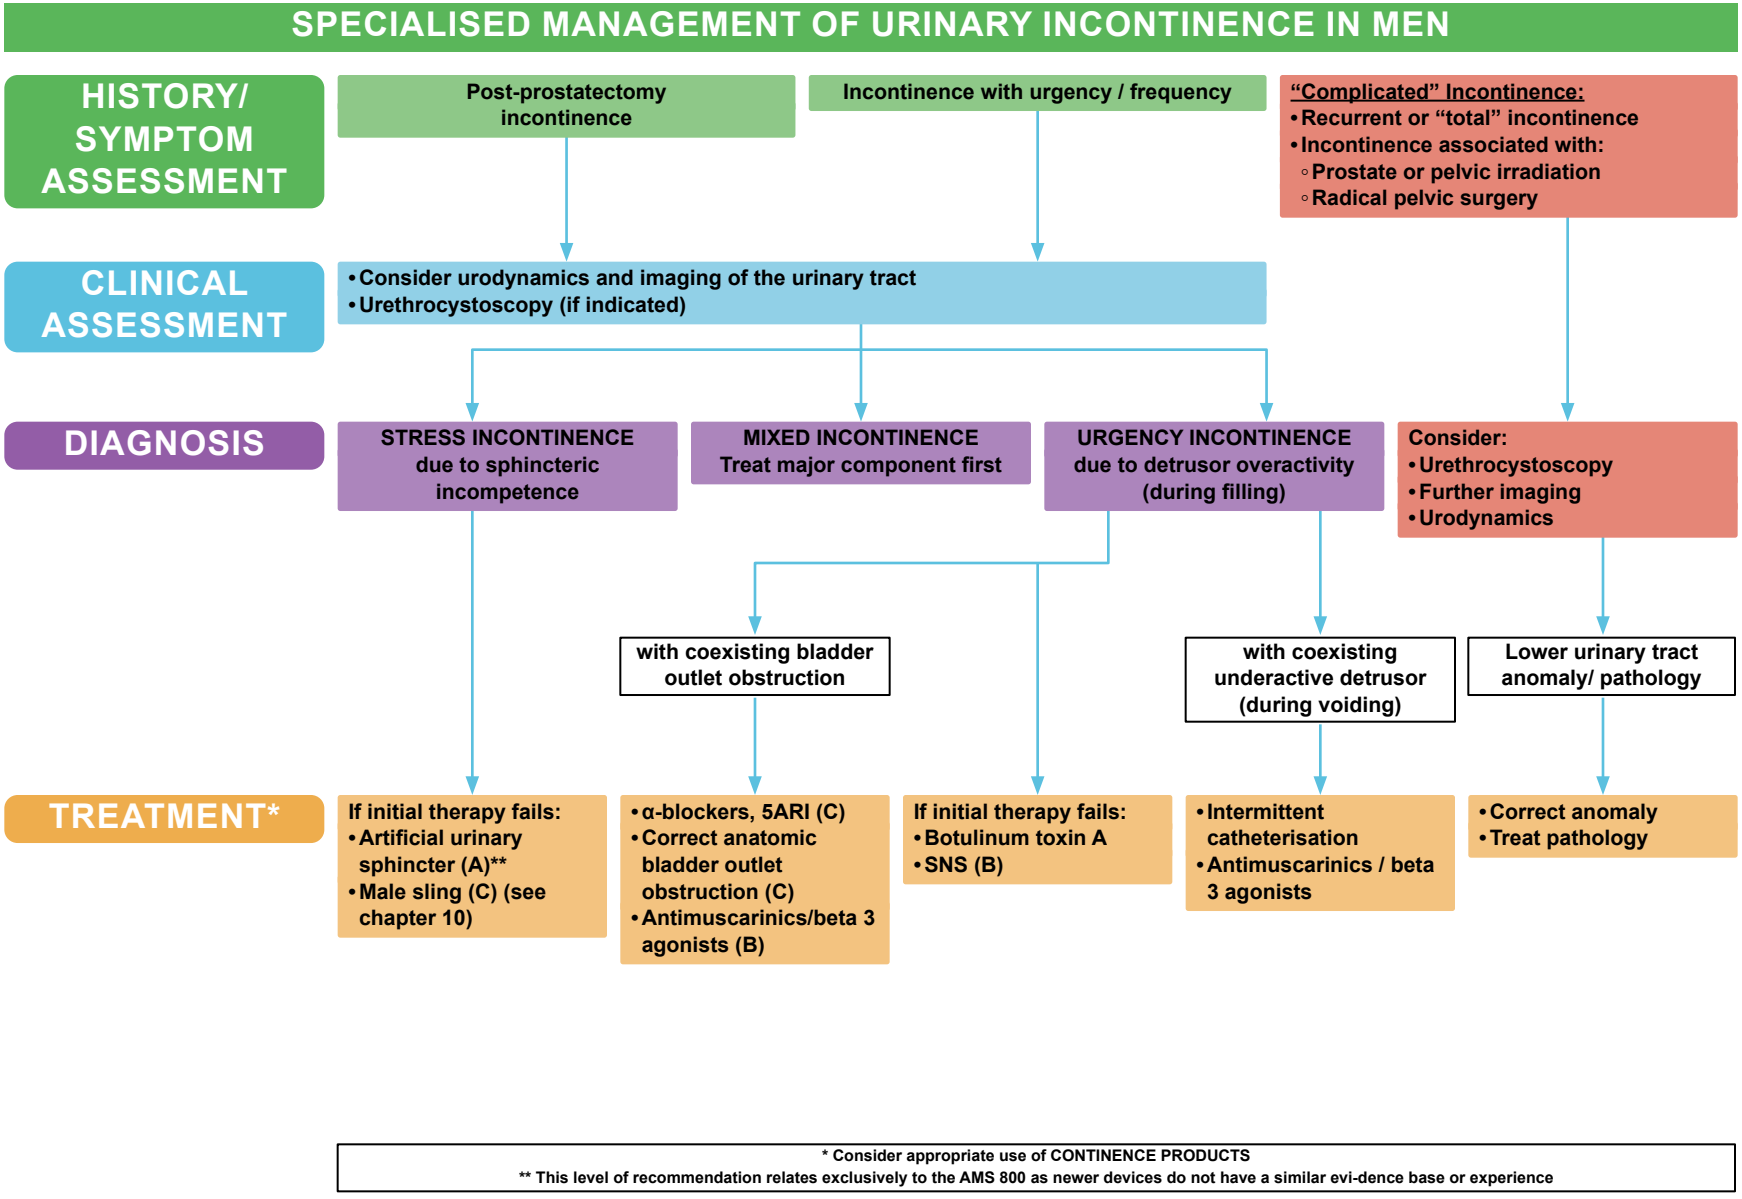
- **For sphincter incompetence** the recommended option is the artificial urinary sphincter (GoR B). Other options, such as a male sling, may be considered (GoR C).

- **For refractory idiopathic detrusor overactivity**, (with intractable overactive bladder symptoms) the recommended therapies are Botulinum toxin A (GoR B), and SNS (GoR C),

- When incontinence has been shown to be associated with **poor bladder emptying** due to **detrusor underactivity**, it is recommended that effective means are used to ensure bladder emptying, for example, intermittent catheterisation (GoR B/C).

- If incontinence is associated with bladder outlet obstruction, then consideration should be given to surgical treatment to relieve obstruction (GoR B). α-blockers and/or 5α-reductase inhibitors would be an optional treatment (GoR C).

- There is increased evidence for the safety of antimuscarinics for overactive bladder symptoms in men, chiefly in combination with an α-blocker. (Men presenting with a Qmax below 5 ml/seg and/or increased PVR (e.g., > 150 or 200 ml) were excluded from trials) (GoR B).



SPECIALISED MANAGEMENT OF URINARY INCONTINENCE IN MEN
HISTORY/ SYMPTOM ASSESSMENT
Post-prostatectomy incontinence
Incontinence with urgency / frequency
"Complicated" Incontinence:
• Recurrent or "total" incontinence
• Incontinence associated with:
◦ Prostate or pelvic irradiation
◦ Radical pelvic surgery
CLINICAL ASSESSMENT
• Consider urodynamics and imaging of the urinary tract
• Urethrocystoscopy (if indicated)
DIAGNOSIS
STRESS INCONTINENCE due to sphincteric incompetence
MIXED INCONTINENCE Treat major component first
URGENCY INCONTINENCE due to detrusor overactivity (during filling)
Consider:
• Urethrocystoscopy
• Further imaging
• Urodynamics
with coexisting bladder outlet obstruction
with coexisting underactive detrusor (during voiding)
Lower urinary tract anomaly/ pathology
TREATMENT*
If initial therapy fails:
• Artificial urinary sphincter (A)**
• Male sling (C) (see chapter 10)
• α-blockers, 5ARI (C)
• Correct anatomic bladder outlet obstruction (C)
• Antimuscarinics/beta 3 agonists (B)
If initial therapy fails:
• Botulinum toxin A
• SNS (B)
• Intermittent catheterisation
• Antimuscarinics / beta 3 agonists
• Correct anomaly
• Treat pathology
* Consider appropriate use of CONTINENCE PRODUCTS
** This level of recommendation relates exclusively to the AMS 800 as newer devices do not have a similar evi-dence base or experience

III. URINARY INCONTINENCE IN WOMEN

A INITIAL MANAGEMENT

INITIAL ASSESSMENT SHOULD IDENTIFY:

- **"Complicated" incontinence group.**

Those with pain or haematuria, recurrent infections, suspected or proven voiding problems, significant pelvic organ prolapse or who have persistent incontinence or recurrent incontinence after pelvic irradiation, radical pelvic surgery, previous incontinence surgery, or who have a suspected fistula, should be referred to a specialist.

- **Three other main groups** of patients should be identified by initial assessment.

- Women with **stress incontinence** on physical activity
- Women with **urgency, frequency** with or without urgency incontinence: overactive bladder (OAB)
- Those women with **mixed** urgency and stress incontinence

Abdominal, pelvic and perineal examinations should be a routine part of physical examination. Women should be asked to perform a "stress test" (cough and strain to detect leakage likely to be due to sphincter incompetence). Any pelvic organ prolapse, or urogenital atrophy should be assessed. Vaginal or rectal examination allows the assessment of voluntary pelvic floor muscle function, a key step prior to the teaching of pelvic floor muscle training.

TREATMENT

- For women with **stress, urgency or mixed** urinary incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, PFMT), scheduled voiding regimes, behavioural therapies, and medication. In particular:

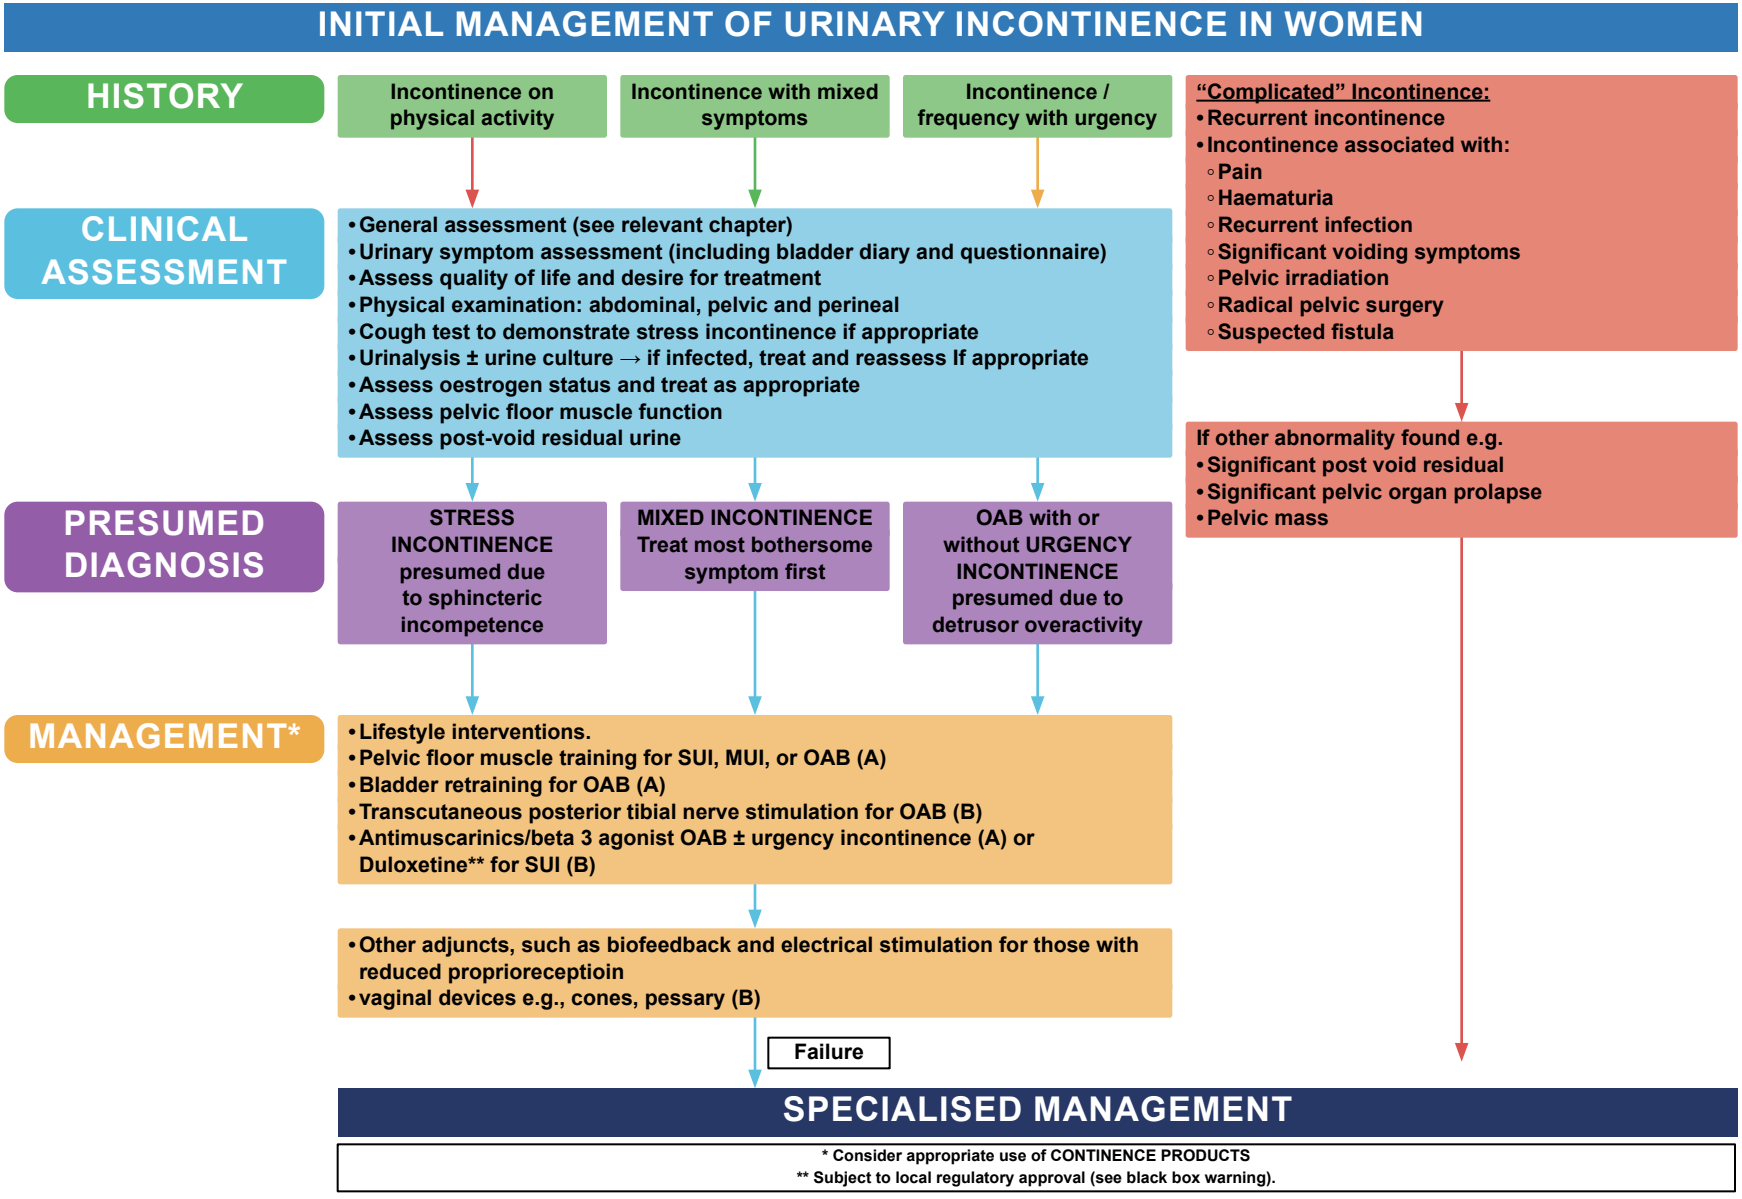
- **Advice** on caffeine reduction for OAB (GoR B) and weight reduction (GoR A). Fluid balance & regular physical activity should be maintained / encouraged.
- Supervised pelvic floor muscle training (GoR A), supervised vaginal cones training for women with stress incontinence (GoR B).
- Supervised bladder training (GoR A) for OAB.
- Transcutaneous or percutaneous posterior tibial nerve stimulation can be offered to adults who do not achieve satisfactory results from fist-line lifestyle and behavioral intervention (B)
- **If oestrogen deficiency** and/or **UTI** is found, the patient should be treated at initial assessment and then reassessed after using vaginal oestrogens for a suitable period (GoR B). Topical oestrogen may alleviate OAB symptoms in post menopausal women (GoR C)
- **Antimuscarinics/beta 3 agonist** for OAB symptoms with or without urgency incontinence (GoR A); duloxetine* may be considered for stress urinary incontinence (GoR B)

PFMT should be based on sound muscle training principles such as specificity, overload progression, correct contraction confirmed prior to training and use of "the Knack" for 12 weeks before reassessment and specialist referral.

Clinicians are likely to wish to treat the **most bothersome symptom first** in women with symptoms of mixed incontinence. (GoR C).

- Some women with significant pelvic organ prolapse can be treated by vaginal devices that treat both incontinence and prolapse (incontinence rings and dishes).

*Duloxetine is not approved for use in United States. In Europe it is approved for use in severe stress incontinence (see committee report on pharmacological management for information regarding efficacy, adverse events, and 'black box' warning by the Food and Drug Administration of the United States).



INITIAL MANAGEMENT OF URINARY INCONTINENCE IN WOMEN
HISTORY
Incontinence on physical activity
Incontinence with mixed symptoms
Incontinence / frequency with urgency
"Complicated" Incontinence:
• Recurrent incontinence
• Incontinence associated with:
◦ Pain
◦ Haematuria
◦ Recurrent infection
◦ Significant voiding symptoms
◦ Pelvic irradiation
◦ Radical pelvic surgery
◦ Suspected fistula
CLINICAL ASSESSMENT
• General assessment (see relevant chapter)
• Urinary symptom assessment (including bladder diary and questionnaire)
• Assess quality of life and desire for treatment
• Physical examination: abdominal, pelvic and perineal
• Cough test to demonstrate stress incontinence if appropriate
• Urinalysis ± urine culture → if infected, treat and reassess If appropriate
• Assess oestrogen status and treat as appropriate
• Assess pelvic floor muscle function
• Assess post-void residual urine
If other abnormality found e.g.
• Significant post void residual
• Significant pelvic organ prolapse
• Pelvic mass
PRESUMED DIAGNOSIS
STRESS INCONTINENCE presumed due to sphincteric incompetence
MIXED INCONTINENCE Treat most bothersome symptom first
OAB with or without URGENCY INCONTINENCE presumed due to detrusor overactivity
MANAGEMENT*
• Lifestyle interventions.
• Pelvic floor muscle training for SUI, MUI, or OAB (A)
• Bladder retraining for OAB (A)
• Transcutaneous posterior tibial nerve stimulation for OAB (B)
• Antimuscarinics/beta 3 agonist OAB ± urgency incontinence (A) or Duloxetine** for SUI (B)
• Other adjuncts, such as biofeedback and electrical stimulation for those with reduced proprioreceptioin
• vaginal devices e.g., cones, pessary (B)
Failure
SPECIALISED MANAGEMENT
* Consider appropriate use of CONTINENCE PRODUCTS
** Subject to local regulatory approval (see black box warning).

III. URINARY INCONTINENCE IN WOMEN

B SPECIALISED MANAGEMENT

ASSESSMENT

Women who have **"complicated" incontinence** (see initial algorithm) may need to have additional tests such as cytology, urodynamics, cystourethroscopy or urinary tract imaging. If these tests are normal, then they should be treated for incontinence by the initial or specialised management options as appropriate.

- Those women with persistent symptoms despite **initial management** and whose quality of life is impaired are likely to request further treatment. If initial management has been given an adequate trial, then **interventional therapy may be desired**. When the results of urodynamic testing may change management, we highly recommend testing prior to intervention to diagnose the incontinence type and, therefore, inform the management plan. Urethral function testing by urethral pressure profile or leak point pressure is optional.

- Systematic assessment for **pelvic organ prolapse** is highly recommended and the POP-Q method should be used in research studies. Women with co-existing pelvic organ prolapse should have their prolapse treated as appropriate.

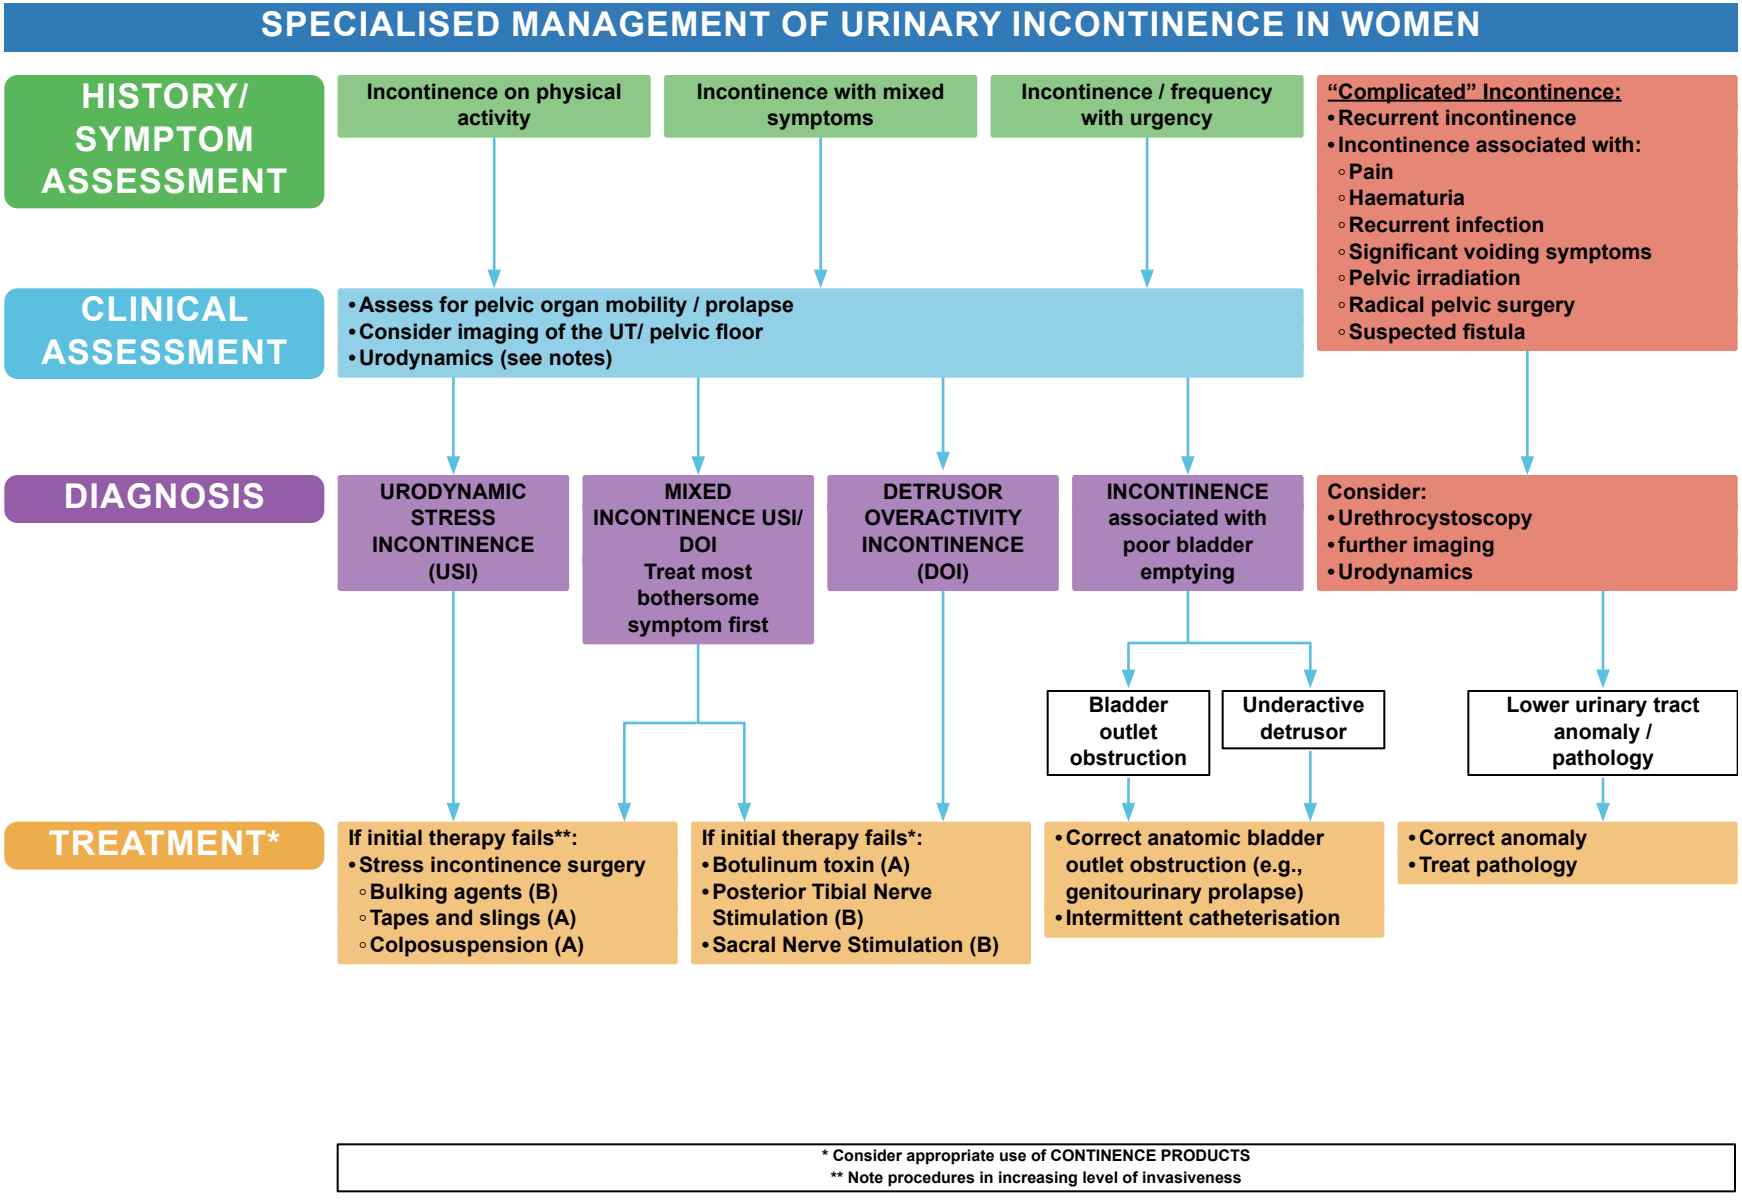
TREATMENT

- **If stress incontinence is confirmed** then the treatment options that are recommended for patients include the full range of non-surgical treatments, as well as colposuspension procedures, (GoR A) and bladder neck/sub-urethral sling operations (GoR A). All these procedures have potential risks and associated complications which should be discussed with the individual. **The correction of symptomatic** pelvic organ prolapse may be desirable at the same time. For selected patients injectable bulking agents (GoR B) and the artificial urinary sphincter (GoR C) can be considered.

- **Refractory urgency incontinence** (overactive bladder) secondary to idiopathic detrusor overactivity may be treated by botulinum toxin A (GoR A), posterior tibial nerve stimulation or sacral nerve stimulation (GoR B). Bladder augmentation/intestinal cystoplasty is recommended only for women with severely reduced bladder capacity who are willing to consider the complication rate and need for long term surveillance (GoR D).

- Those patients with **voiding dysfunction** leading to significant post-void residual urine (for example, >30% of total bladder capacity) may have bladder outlet obstruction or detrusor underactivity. Prolapse is a common reversible cause, of voiding dysfunction.

- For women with intractable incontinence or voiding dysfunction, long term urethral or suprapubic catheterisation may be offered if clean intermittent catheterisation is impractical



SPECIALISED MANAGEMENT OF URINARY INCONTINENCE IN WOMEN
HISTORY/ SYMPTOM ASSESSMENT
Incontinence on physical activity
Incontinence with mixed symptoms
Incontinence / frequency with urgency
"Complicated" Incontinence:
• Recurrent incontinence
• Incontinence associated with:
◦ Pain
◦ Haematuria
◦ Recurrent infection
◦ Significant voiding symptoms
◦ Pelvic irradiation
◦ Radical pelvic surgery
◦ Suspected fistula
CLINICAL ASSESSMENT
• Assess for pelvic organ mobility / prolapse
• Consider imaging of the UT/ pelvic floor
• Urodynamics (see notes)
DIAGNOSIS
URODYNAMIC STRESS INCONTINENCE (USI)
MIXED INCONTINENCE USI/ DOI
Treat most bothersome symptom first

INCONTINENCE associated with poor bladder emptying
Consider:
• Urethrocystoscopy
• further imaging
• Urodynamics
Bladder outlet obstruction
Underactive detrusor
Lower urinary tract anomaly / pathology
TREATMENT*
If initial therapy fails**:
• Stress incontinence surgery
◦ Bulking agents (B)
◦ Tapes and slings (A)
◦ Colposuspension (A)
If initial therapy fails*:
• Botulinum toxin (A)
• Posterior Tibial Nerve Stimulation (B)
• Sacral Nerve Stimulation (B)
• Correct anatomic bladder outlet obstruction (e.g., genitourinary prolapse)
• Intermittent catheterisation
• Correct anomaly
• Treat pathology
* Consider appropriate use of CONTINENCE PRODUCTS
** Note procedures in increasing level of invasiveness

IV. FISTULAE

In the developing world fistulae most often occur because of poor perinatal care. Despite vast surgical experience in some centres, published research is of low quality.

In the developed world, iatrogenic urogenital fistulae are known complications of pelvic surgery and oncological treatments such as radiotherapy, chemotherapy or a combination of both. In the oncological context, fistulae may also occur because of primary or recurrent malignancy. The development of fistula following radiotherapy for primary treatment should trigger a search for evidence of tumour recurrence (GoR D). The use of neoadjuvant or adjuvant therapies is likely to be associated with a greater risk of fistula development than the primary treatment alone.

The most common non-obstetric causes of fistulae involving the gastro-intestinal tract are diverticular disease, Crohn's disease, malignancy and radiotherapy.

Surgical fistulae

Immediate management

- If a vesico-vaginal fistula is diagnosed within (*three to*) six weeks of surgery, indwelling catheterisation should be considered for a period of up to (*six to*) 9 weeks (*i.e.* up to 12 weeks after the causative event
- Retrograde, ureteroscopically-assisted or antegrade ureteric stenting should be considered for immediate management for all uretero-vaginal fistulae

Timing of surgery

The timing of VVF repair should be tailored to the individual patient requirements, and can be undertaken as soon as any local oedema, inflammation, necrosis & infection resolved

Bowel preparation

No benefit from mechanical or laxative bowel preparation prior to colonic surgery; this can be extrapolated to include fistula surgery

Antibiotic prophylaxis

Perioperative antibiotic prophylaxis should follow local policies

Counselling & support

- Realistic counselling by the surgeon, nursing staff and/ or counsellors with experience of fistula patients is highly desirable
- Support from previously treated patients is appreciated and very valuable

Surgical approach

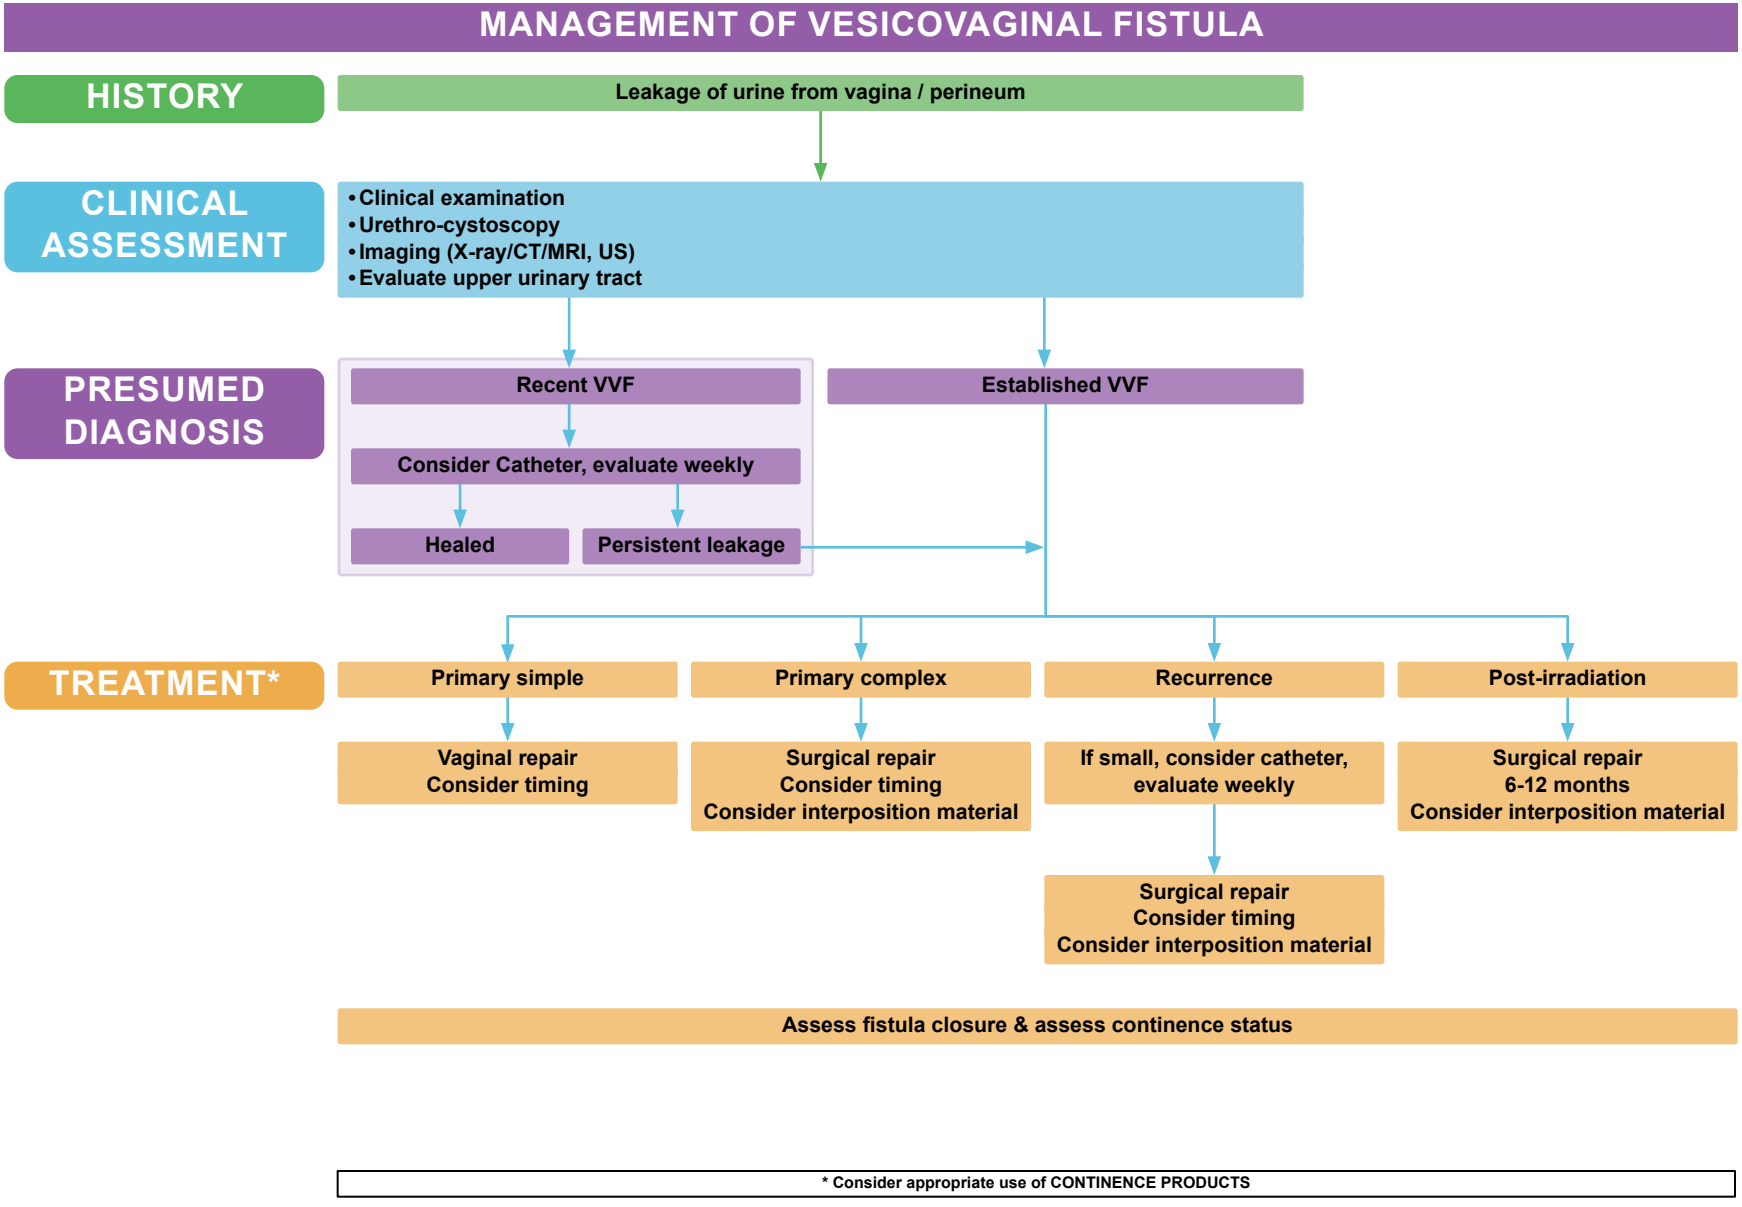
- Surgeons involved in fistula surgery should have appropriate training, skills, experience and versatility to select an appropriate procedure for any patient
- Both vaginal and abdominal approaches have an established role in fistula repair
- The majority of VVFs and all urethro-vaginal fistulae can be repaired vaginally, regardless of aetiology
- Where concurrent ureteric re-implantation or augmentation cystoplasty are required, and abdominal approach is essential
- A variety of interposition grafts are described for use in either abdominal or vaginal procedures, although there is no high level evidence to support their use
- Conventional and robotically-assisted laparoscopic approaches have both been shown to be feasible in selected cases; the place of these techniques is not yet clear

Postoperative drainage

A period of continuous bladder drainage is crucial to successful fistula repair

- 10-14 days for simple and/or surgical
- 14-21 days for complex and/or radiation

Treatment recommendations for surgical fistulae



MANAGEMENT OF VESICOVAGINAL FISTULA
HISTORY
Leakage of urine from vagina / perineum
CLINICAL ASSESSMENT
•Clinical examination
•Urethro-cystoscopy
•Imaging (X-ray/CT/MRI, US)
•Evaluate upper urinary tract
PRESUMED DIAGNOSIS
Recent VVF
Established VVF
Consider Catheter, evaluate weekly
Healed
Persistent leakage
TREATMENT*
Primary simple
Primary complex
Recurrence
Post-irradiation
Vaginal repair
Consider timing
Surgical repair
Consider timing
Consider interposition material
If small, consider catheter, evaluate weekly
Surgical repair
6-12 months
Consider interposition material
Surgical repair
Consider timing
Consider interposition material
Assess fistula closure & assess continence status
* Consider appropriate use of CONTINENCE PRODUCTS

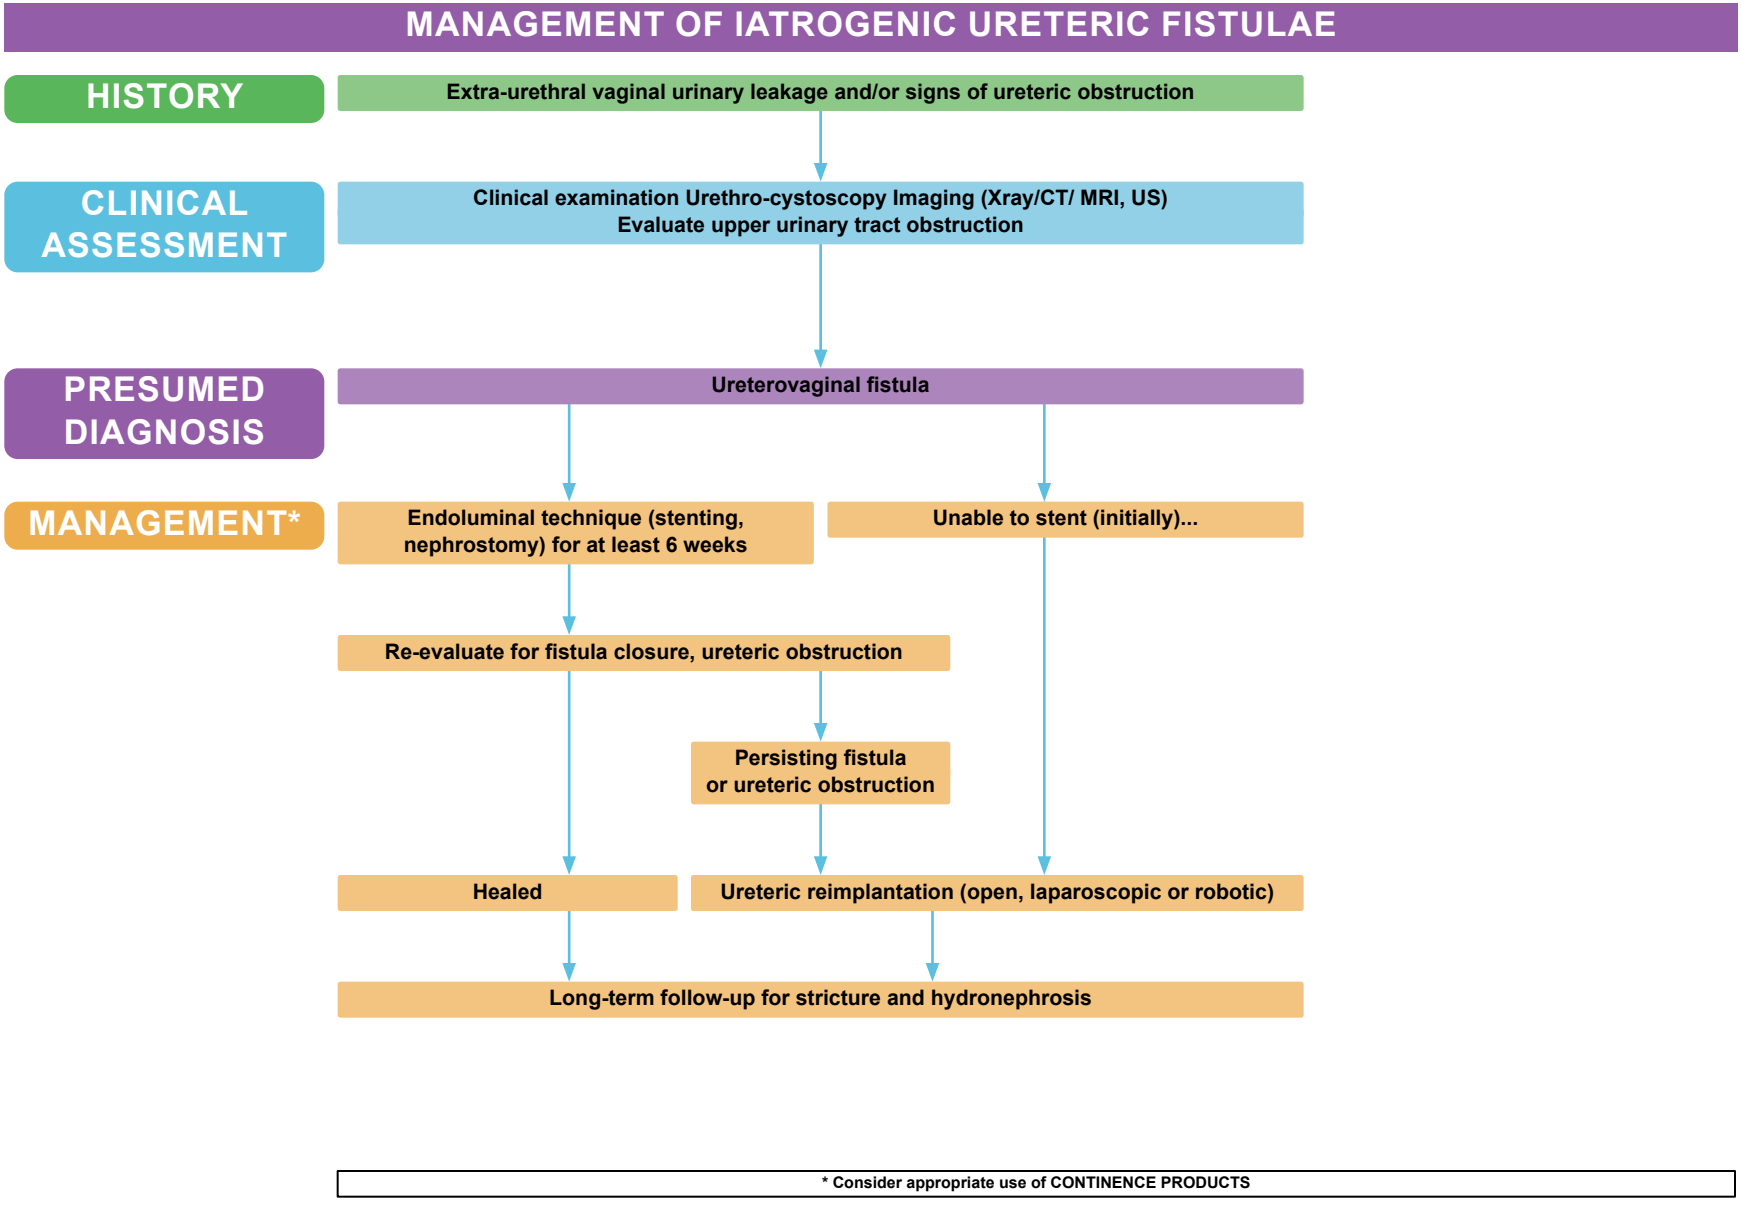
Radiotherapy fistulae

Spontaneous healing	Rare, if ever
Repair procedures	• Careful selection necessary as results poorer than in non-irradiated cases • Colpocleisis preferable to 'flap-splitting' • Consider interposition graft
Urinary/faecal diversion	• Required more often than in non-irradiated cases, but ONLY after careful consideration of alternatives • Avoid irradiated bowel if possible
Intractable incontinence, life expectancy poor	Consider nephrostomy or ureteric occlusion

Fistulae involving GIT

Investigations	May require several approaches especially CT & cystoscopy
Diverticular (colo-vesical) fistulae • Frail elderly, limited symptoms of urinary infection or diarrhoea	Consider trial of conservative management
Crohn's fistulae	Consider trial of *infliximab*, esp. for any external fistulae
Simple fistulae • Nutritional state good • No additional intra-abdominal pathology (*e.g.* severe inflammation, radiation injury, advanced malignancy, intestinal obstruction) • No major co-morbidity	One-stage surgery
Complex fistulae • Nutritional state poor • Severe inflammation • Radiation injury • Advanced malignancy • Intestinal obstruction • Major co-morbidity • Multiple organ involvement	Specialist referral centre for phased management • Proximal defunctioning and distal drainage • TPN, organ support, radiological planning • Joint urological and gastrointestinal surgery

Treatment recommendations for radiation fistula and fistula involving the gastro-intestinal tract



MANAGEMENT OF IATROGENIC URETERIC FISTULAE
HISTORY
Extra-urethral vaginal urinary leakage and/or signs of ureteric obstruction
CLINICAL ASSESSMENT
Clinical examination Urethro-cystoscopy Imaging (Xray/CT/ MRI, US)
Evaluate upper urinary tract obstruction
PRESUMED DIAGNOSIS
Ureterovaginal fistula
MANAGEMENT*
Endoluminal technique (stenting, nephrostomy) for at least 6 weeks
Unable to stent (initially)...
Re-evaluate for fistula closure, ureteric obstruction
Persisting fistula or ureteric obstruction
Healed
Ureteric reimplantation (open, laparoscopic or robotic)
Long-term follow-up for stricture and hydronephrosis
* Consider appropriate use of CONTINENCE PRODUCTS

V. PELVIC ORGAN PROLAPSE

INTRODUCTION

Pelvic organ prolapse includes vaginal and rectal prolapse. Treatment of pelvic organ prolapse is generally reserved for symptomatic prolapse. Clinicians should recognise that coexistent pelvic floor symptoms are frequently present and that these symptoms may or may not be related to the prolapse. Women with prolapse require a careful and detailed initial assessment not only of the prolapse but associated bladder, bowel and sexual function.

ASSESSMENT

Symptom assessment preferably with a validated pelvic floor questionnaire that assesses bladder, bowel, vaginal and sexual function and bothersomeness is required. (Grade C).

Physical examination should:

- Report the most distal site of vaginal descent in relation to a fixed point such as the hymen and include an assessment of the anterior posterior and apical vagina. While standardised reporting utilising tools such as the Pelvic Organ Prolapse Quantification (POP-Q) are encouraged. The system used to measure the extent of the prolapse should be documented.
- Be undertaken in the standing position to evaluate the full extent of the prolapse.
- Determine if coexistent pelvic pathology is present on careful bimanual examination. Cytological screening of the cervix should be undertaken if indicated.
- The prolapse should be reduced to document the presence of occult stress urinary incontinence (see chapter for prolapse and urinary incontinence pathway).
- Assess pelvic floor muscle function (see chapter for full review).
- Determine if epithelial/ mucosal ulceration is present.
- Evaluate anal sphincter tone and or the presence of rectal prolapse in those with bowel symptoms (refer to chapter for pelvic organ prolapse and bowel symptom pathway).

When examination findings of the extent of the prolapse are not consistent with the history the examination can be repeated in a few weeks' time. (GoR C).

Post void residual should be measured; while most elevated post-void residual urines (150mls) resolve with treatment of the prolapse, a specialist consultation is required.

CONSERVATIVE MANAGEMENT

Observation is appropriate when medically safe and the patient is not bothered (GoR C).

Lifestyle interventions include weight loss, treating constipation, avoiding straining at stool and heavy lifting (GoR C).

Pelvic floor muscle training:

- Reduces associated pelvic floor symptoms (GoR A).
- May reduce the symptom of vaginal bulge (GoR C).
- Does not reduce extent of prolapse on examination based on POP-Q stage (GoR B).

Vaginal Pessary: when successfully fitted

- May reduce prolapse symptoms (GoR B)
- Need to be regularly reviewed (GoR C)
- May be associated with high rates of discontinuation (GoR C)

Local Oestrogens are recommended in those with hypo-oestrogenic symptoms and in those with urethral prolapse or vaginal ulceration (GoR B)

Reconstructive surgery is reserved for those with symptomatic prolapse and is aimed at correcting the vaginal topography and functional pathology. Please see text for full recommendations.

Obliterative surgery is an important and effective treatment option in those who are willing to forgo future coital activity. (GoR C)

PATHWAY FOR THE MANAGEMENT OF PELVIC ORGAN PROLAPSE

CONSERVATIVE MANAGEMENT

- Lifestyle interventions (GoR B and C).
  - Educational intervention
  - weight loss
  - Treatment of constipation

- Pelvic floor muscle training (GoR A and B), either alone or with biofeedback or electrical stimulation in those with reduced proprioception
- Pessary GoR B).
- Pessary plus PFMT (GoR B)
  - Women should be informed about the advantages and disadvantages of different interventions.

SURGICAL MANAGEMENT

The pelvic organ prolapse (POP) surgery pathway was designed to provide an evidence-based guide for both clinicians and women for the surgical management of pelvic organ prolapse. Within the pathway green lines highlight the preferred option and yellow lines indicate reasonable options.

An early option in the treatment pathway for women not wanting to preserve sexual function is obliterative surgery (colpocleisis) which is an efficacious intervention that has low morbidity (LoE 3).

Most women will enter the reconstructive pathway. Apical suspension procedures should be considered in all cases with 10-year re-operation rates for prolapse being significantly reduced if apical suspensions are performed concomitantly with both anterior and posterior colporrhaphy as compared to those performed without apical support.

In those undergoing anterior and posterior colporrhaphy the evidence is supportive of traditional native tissue suture plications (LoE 1). In the anterior compartment permanent mesh could be considered for recurrent cases when the patient understands the risk benefit profile for these interventions and that the data for their use is scant. Evidence is not supportive of biological grafts in the anterior compartment (LoE 2).

In the posterior compartment, fascial plication is superior to site specific native tissue repair (LoE 2) and levatorplasty should be avoided due to higher rates of dyspareunia (LoE3). Data are not supportive of biological or permanent mesh grafts. Posterior colporrhaphy is superior to transanal repair of rectocele (LoE 1) and there is no data to support ventral rectopexy with or without vaginal graft for rectocele.

With recognition of the importance of apical vaginal support in minimising the risk of subsequent recurrence, the pathway separates those with post-hysterectomy (vault) prolapse from those with uterine prolapse.

Data are supportive of sacral colpopexy as the preferred intervention for vault prolapse with superior anatomical and functional outcomes when compared to a variety of vaginal based interventions with and without transvaginal mesh (LoE1). This preference is highlighted by a green preferred option arrow in the management pathway. In recognition that not all patients are suitable for sacral colpopexy, a yellow reasonable option is included for vaginal based apical support (uterosacral or sacrospinous colpopexy). Both uterosacral and sacrospinous colpopexy are equally effective vaginal options (LoE 1) and utilisation of transvaginal permanent mesh apical support is not supported by the data (LoE1).

When performing sacral colpopexy the laparoscopic approach is preferred with reduced peri-operative morbidity and cost when compared to both the open and robotic approach (LoE 2). The yellow reasonable option pathway exists for both open and robotic options in recognition of the longer learning curve associated with the laparoscopic approach (LoE3).

Apical support in those with uterine prolapse can be performed abdominally or vaginally and includes options for both uterine preservation (hysteropexy) and hysterectomy, with not insignificant relative contraindications for uterine preservation listed in Table 6. In post-menopausal women undergoing hysterectomy, bilateral salpngo-oopherectomy (BSO) significantly reduces the rate of ovarian cancer without increased morbidity. In those retaining ovaries at hysterectomy, bilateral salpingectomy also reduces rate of subsequent ovarian cancer.

Vaginal hysteropexy is equally effective as vaginal hysterectomy with apical suspension and is associated with reduced blood loss and operating time as compared to hysterectomy (LoE 1). Vaginal hysterectomy with apical support has a lower re-operation for prolapse than abdominal sacrohysteropexy (LoE1). Sacrohysteropexy has a higher re-operation for prolapse than sacral colpopexy with hysterectomy however sacral colpopexy with hysterectomy is not recommended due to the high rate of mesh exposure (LoE2). Supra-cervical hysterectomy at sacral colpopexy reduces the rate of mesh exposure associated with hysterectomy and sacral colpopexy however in a single retrospective study, recurrent prolapse was more common in the supracervical hysterectomy group. Although those data are not complete, vaginal based hysterectomy and hysteropexy with apical support should generally be considered as preferred options for uterine prolapse with sacral colpopexy reserved for vault prolapse.

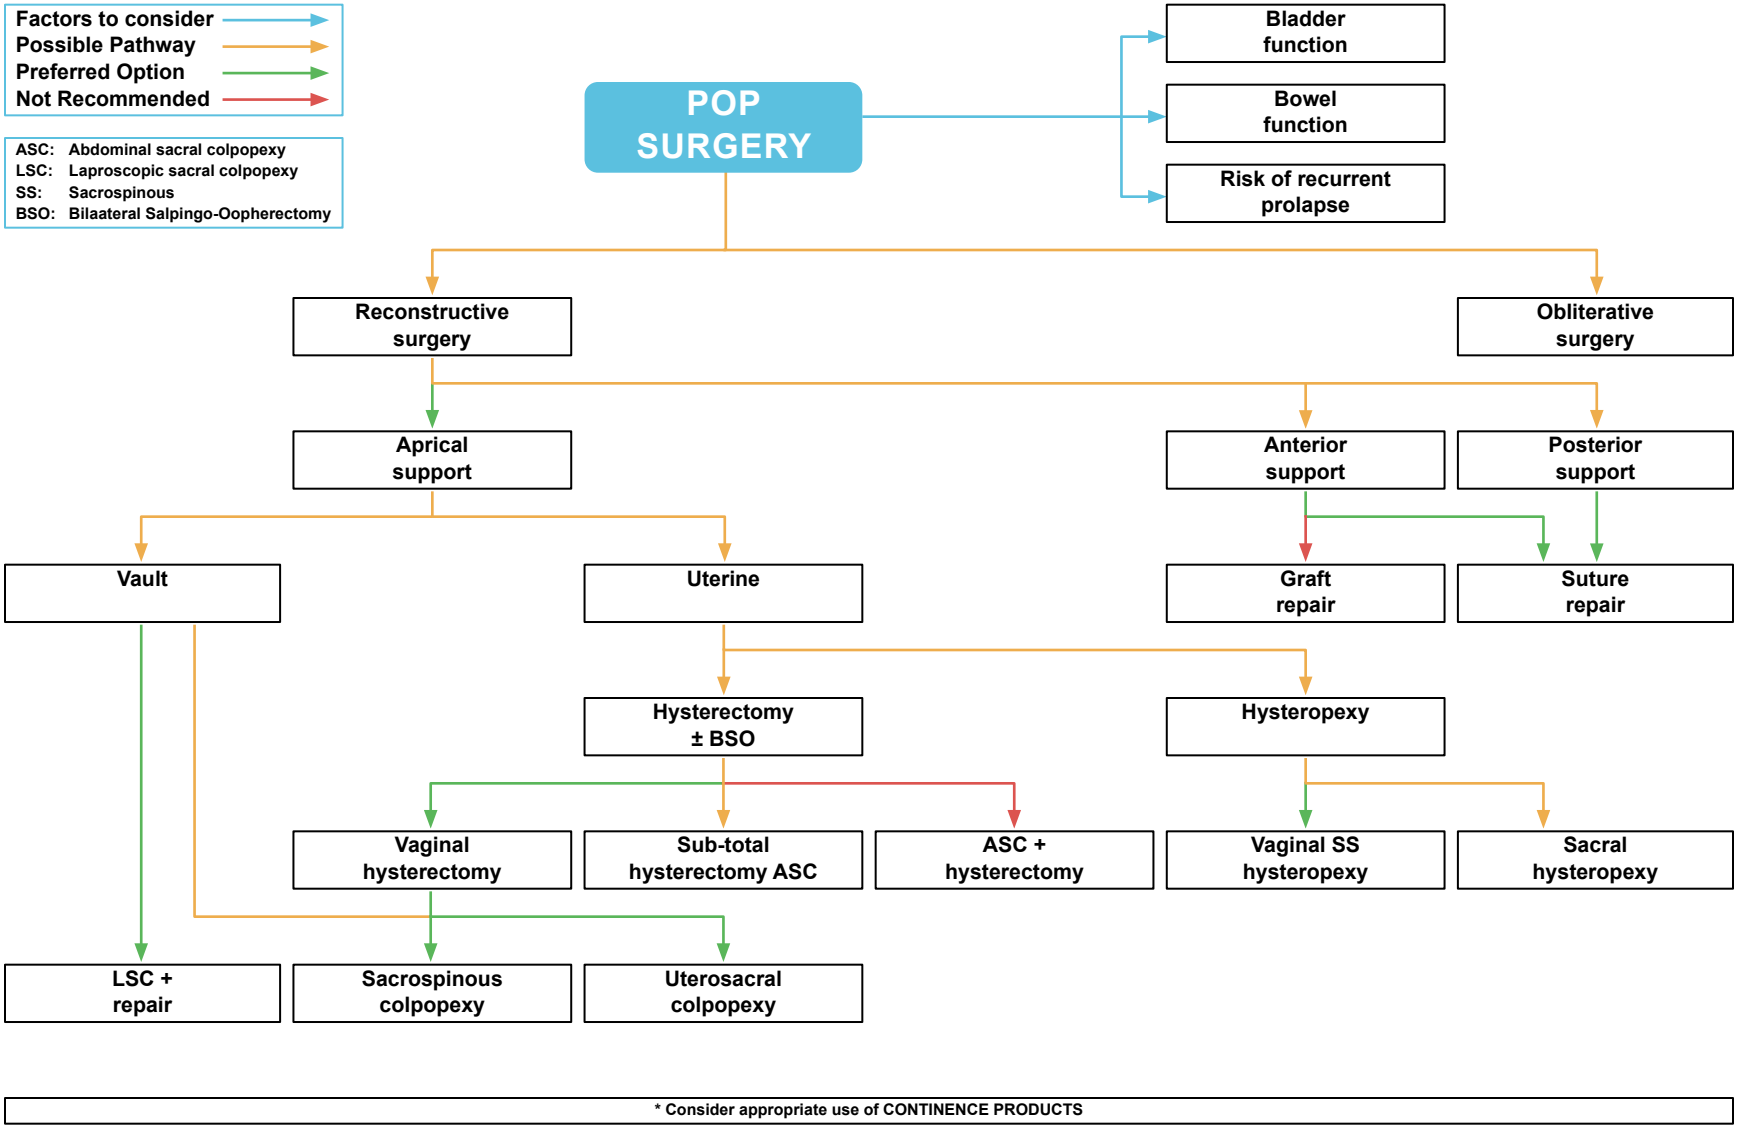
Those undergoing prolapse surgery with stress urinary incontinence (SUI) and occult SUI should generally have continence surgery performed at the time of prolapse surgery

(LoE1). Those with prolapse without SUI or occult SUI should not undergo continence surgery at time of prolapse surgery (LoE1).

Based largely upon expert opinion (LoE3) those with prolapse without bowel symptoms and those with impaired defaecation with rectocele should undergo prolapse surgery as per the above pathway. Those with POP and impaired defaecation without rectocele, and those with faecal incontinence require colorectal assessment. If rectal prolapse exists, these patients may benefit from combined colorectal and gynaecological interventions. Those with significant constipation and prolapse should be approached cautiously and may benefit from gastroenterology assessment prior to entering the POP surgery pathway.

Those undergoing POP surgery generally have improved sexual function post-operatively but a small number undergoing any POP surgery will experience painful intercourse post-operatively that may require subsequent intervention (LoE 1).

ICI 2021 SURGICAL TREATMENT OF PELVIC ORGAN PROLAPSE



VI. URINARY INCONTINENCE IN PATIENTS WITH NEUROLOGICAL DISEASE

A INITIAL MANAGEMENT

STRONG GENERAL RECOMMENDATIONS

- Patients with known neurological disease often need evaluation to exclude lower urinary tract dysfunction (LUTD), not only if symptoms occur, but as a standard assessment as neurogenic LUTD has a high prevalence in the disease.
- A possible neurological cause of “idiopathic” incontinence should always be considered. Diagnostic steps to evaluate this include basic assessments, such as history and physical examination, urodynamics and specialised tests.
- Incontinence in neurological patients does not necessarily relate to the neurologic pathology. Other diseases such as prostate pathology, pelvic organ prolapse, might have an influence. These factors should be evaluated as potential primary or contributory causes.
- Extensive diagnostic evaluation is often useful and necessary to tailor an individual treatment based on complete neurofunctional data. This may not be needed in every patient e.g., patients with suprapontine lesions or in patients where treatment will consist merely of bladder drainage when the person is frail or has limited life expectancy.
- There is often a need to manage lower urinary tract, sexual and bowel dysfunction simultaneously

INITIAL ASSESSMENT

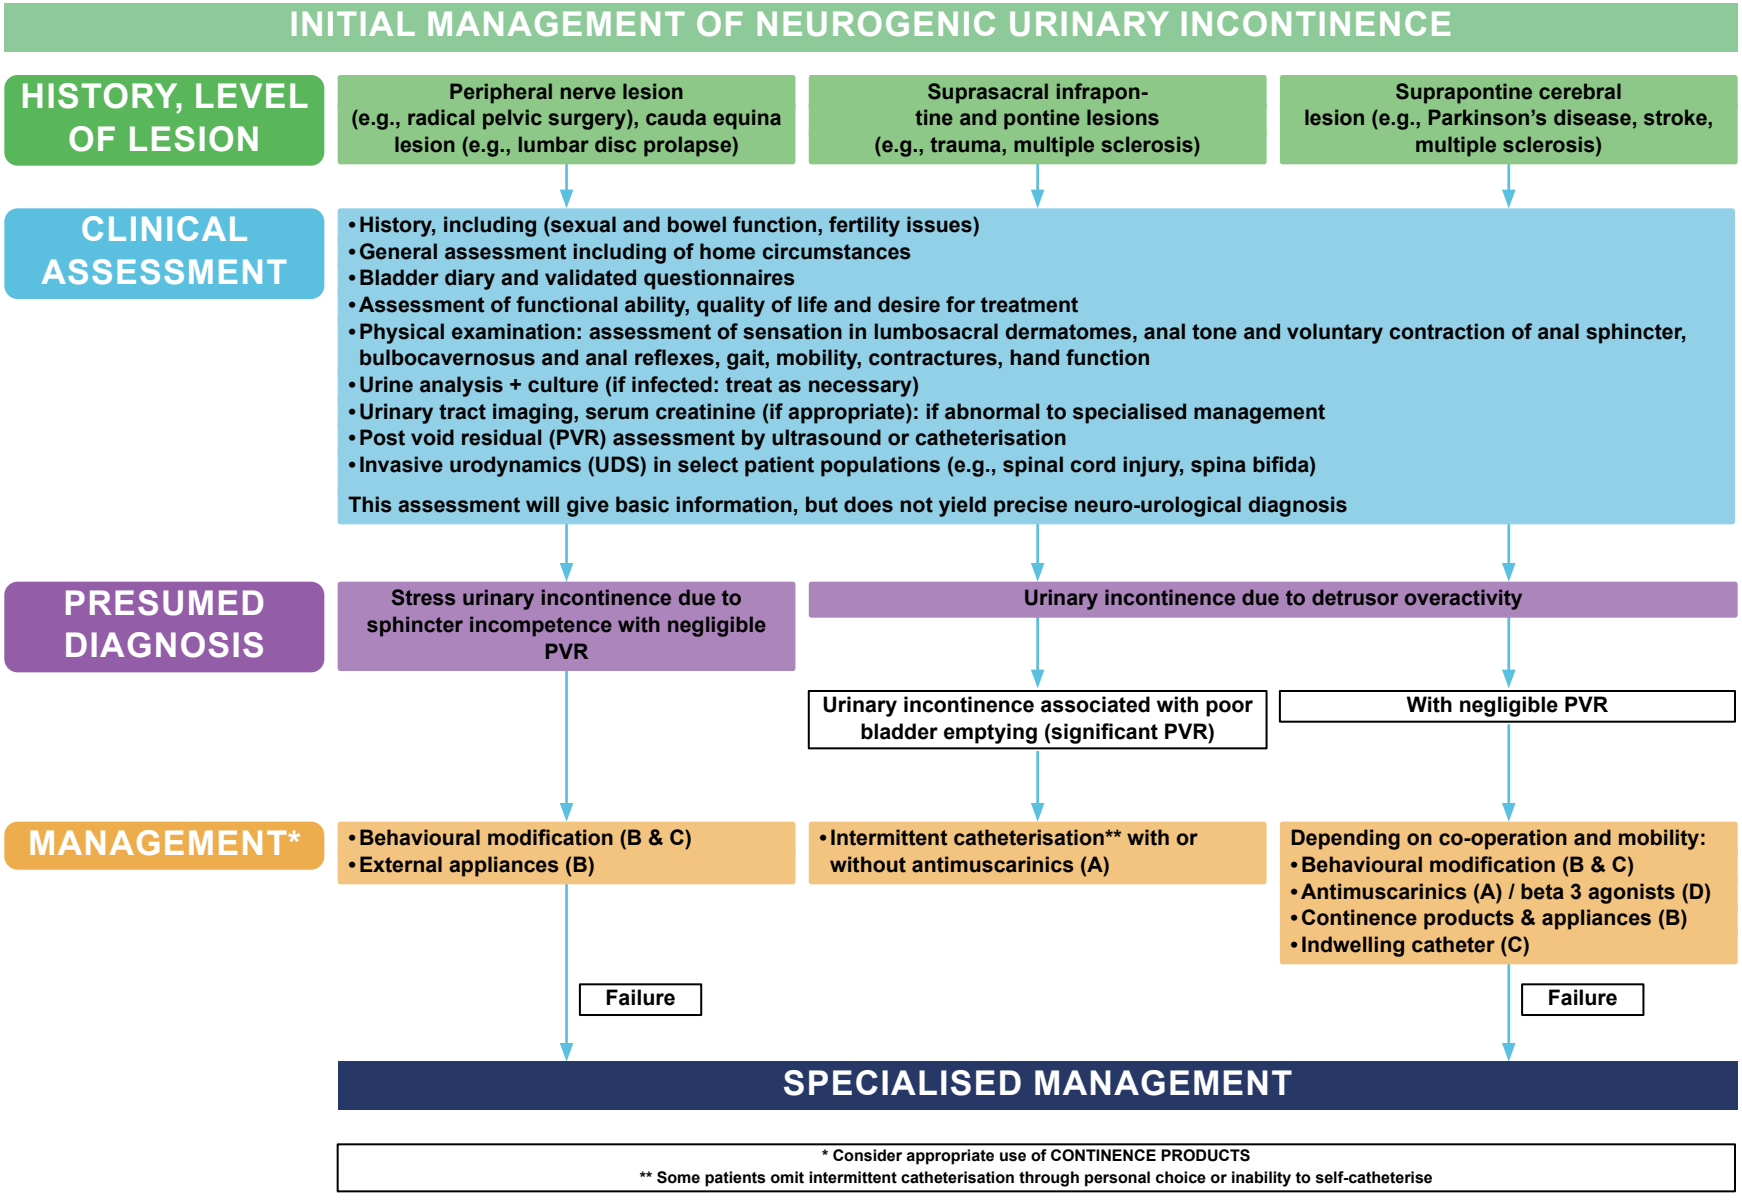
- The management of neurological urinary incontinence depends on an understanding of the likely mechanisms producing incontinence. This can in turn depend on the site and extent of the nervous system abnormality.
- Under current classifications, neurogenic incontinence patients can be divided into four groups. History and physical examination are important in helping distinguish these groups:
- peripheral lesions (as after major pelvic surgery) including those with lesions of the cauda equina (e.g., lumbar disc prolapse).
- sacral spinal cord lesions involving the sacral micturition centre
- suprasacral spinal cord lesions (suprasacral infrapontine spinal cord lesions).
- central lesions of the brain or brain stem (stroke, Parkinson’s disease).
- Assessment should be made using standardized questionnaires, urinalysis, bladder diary, uroflowmetry with assessment of PVR, and optional imaging of the urinary tract (ultrasonography); all provide basic data for the initial assessment of the NLUTD.
- Invasive urodynamics should be used as part of the initial assessment in select patient populations (SCI, spina bifida)
- Due to increasing data on organ cross-sensitisation and the debilitating effect of sexual and bowel dysfunction on QOL, a history of sexual and bowel function should be also included

INITIAL TREATMENT

- Patients with peripheral nerve lesions (e.g., denervation after pelvic surgery) and patients with spinal cord lesions (e.g., traumatic spinal cord lesions) should receive specialised urological management
- Initial treatment for patients with incontinence due to suprapontine pathology, such as stroke, need to be assessed for degree of mobility and ability to cooperate. Initial recommended treatments are behavioural therapy (GoR B & C) and anti-muscarinic drugs for presumed detrusor overactivity (GoR A). If incontinence persists and if operative procedures are not indicated, then continence products (GoR B) or catheters (GoR C) may be necessary on a long-term basis. These can also be necessary in non-cooperative or less mobile patients.

Pharmacological detrusor relaxation and/or antibiotics may be useful in cases of persistent bypass leakage and/or recurrent UTI (patients with continuous drainage)

In all cases, bowel management should complement management of NLUTD



INITIAL MANAGEMENT OF NEUROGENIC URINARY INCONTINENCE
HISTORY, LEVEL OF LESION
Peripheral nerve lesion (e.g., radical pelvic surgery), cauda equina lesion (e.g., lumbar disc prolapse)
Suprasacral infrapontine and pontine lesions (e.g., trauma, multiple sclerosis)
Suprapontine cerebral lesion (e.g., Parkinson's disease, stroke, multiple sclerosis)
CLINICAL ASSESSMENT
•History, including (sexual and bowel function, fertility issues)
•General assessment including of home circumstances
•Bladder diary and validated questionnaires
•Assessment of functional ability, quality of life and desire for treatment
•Physical examination: assessment of sensation in lumbosacral dermatomes, anal tone and voluntary contraction of anal sphincter, bulbocavernosus and anal reflexes, gait, mobility, contractures, hand function
•Urine analysis + culture (if infected: treat as necessary)
•Urinary tract imaging, serum creatinine (if appropriate): if abnormal to specialised management
•Post void residual (PVR) assessment by ultrasound or catheterisation
•Invasive urodynamics (UDS) in select patient populations (e.g., spinal cord injury, spina bifida)
This assessment will give basic information, but does not yield precise neuro-urological diagnosis
PRESUMED DIAGNOSIS
Stress urinary incontinence due to sphincter incompetence with negligible PVR
Urinary incontinence due to detrusor overactivity
Urinary incontinence associated with poor bladder emptying (significant PVR)
With negligible PVR
MANAGEMENT*
•Behavioural modification (B & C)
•External appliances (B)
•Intermittent catheterisation** with or without antimuscarinics (A)
Depending on co-operation and mobility:
•Behavioural modification (B & C)
•Antimuscarinics (A) / beta 3 agonists (D)
•Continence products & appliances (B)
•Indwelling catheter (C)
Failure
Failure
SPECIALISED MANAGEMENT
* Consider appropriate use of CONTINENCE PRODUCTS
** Some patients omit intermittent catheterisation through personal choice or inability to self-catheterise

VI. URINARY INCONTINENCE IN PATIENTS WITH NEUROLOGICAL DISEASE

B SPECIALISED MANAGEMENT

ASSESSMENT

- Most patients with neurogenic urinary incontinence require specialised assessment: Invasive urodynamic studies should be used with video urodynamics if available when surgical interventions are planned or when the “bladder may be unsafe”.
- Upper tract imaging is needed in some patients and more detailed renal function studies will be desirable if the upper tract is considered in danger: high bladder pressure, upper urinary tract dilation, recurrent or chronic upper tract infection, (major) stones, (major) reflux.
- In patients with peripheral lesions, clinical neurophysiological testing may be helpful for better definition of the lesion

TREATMENT

For specialised management, conservative treatment is the mainstay (GoR A). Management of neurogenic urinary incontinence has several options. The algorithm details the recommended options for different types of neurogenic LUTD. The dysfunction does not necessarily correspond to one type/level of neurological lesion and is defined best by urodynamic studies. One should always ascertain that the management ensures a safe lower and upper urinary tract (storage at low pressure and complete emptying)

Urinary, sexual and bowel function should be assessed together as symptoms and treatment of one system can influence the other, and *vice versa*.

As therapeutic approaches can differ in various neurological diseases, the most prevalent diseases are discussed separately in the chapter

TREATMENT MODALITIES (OFTEN IN COMBINATION)

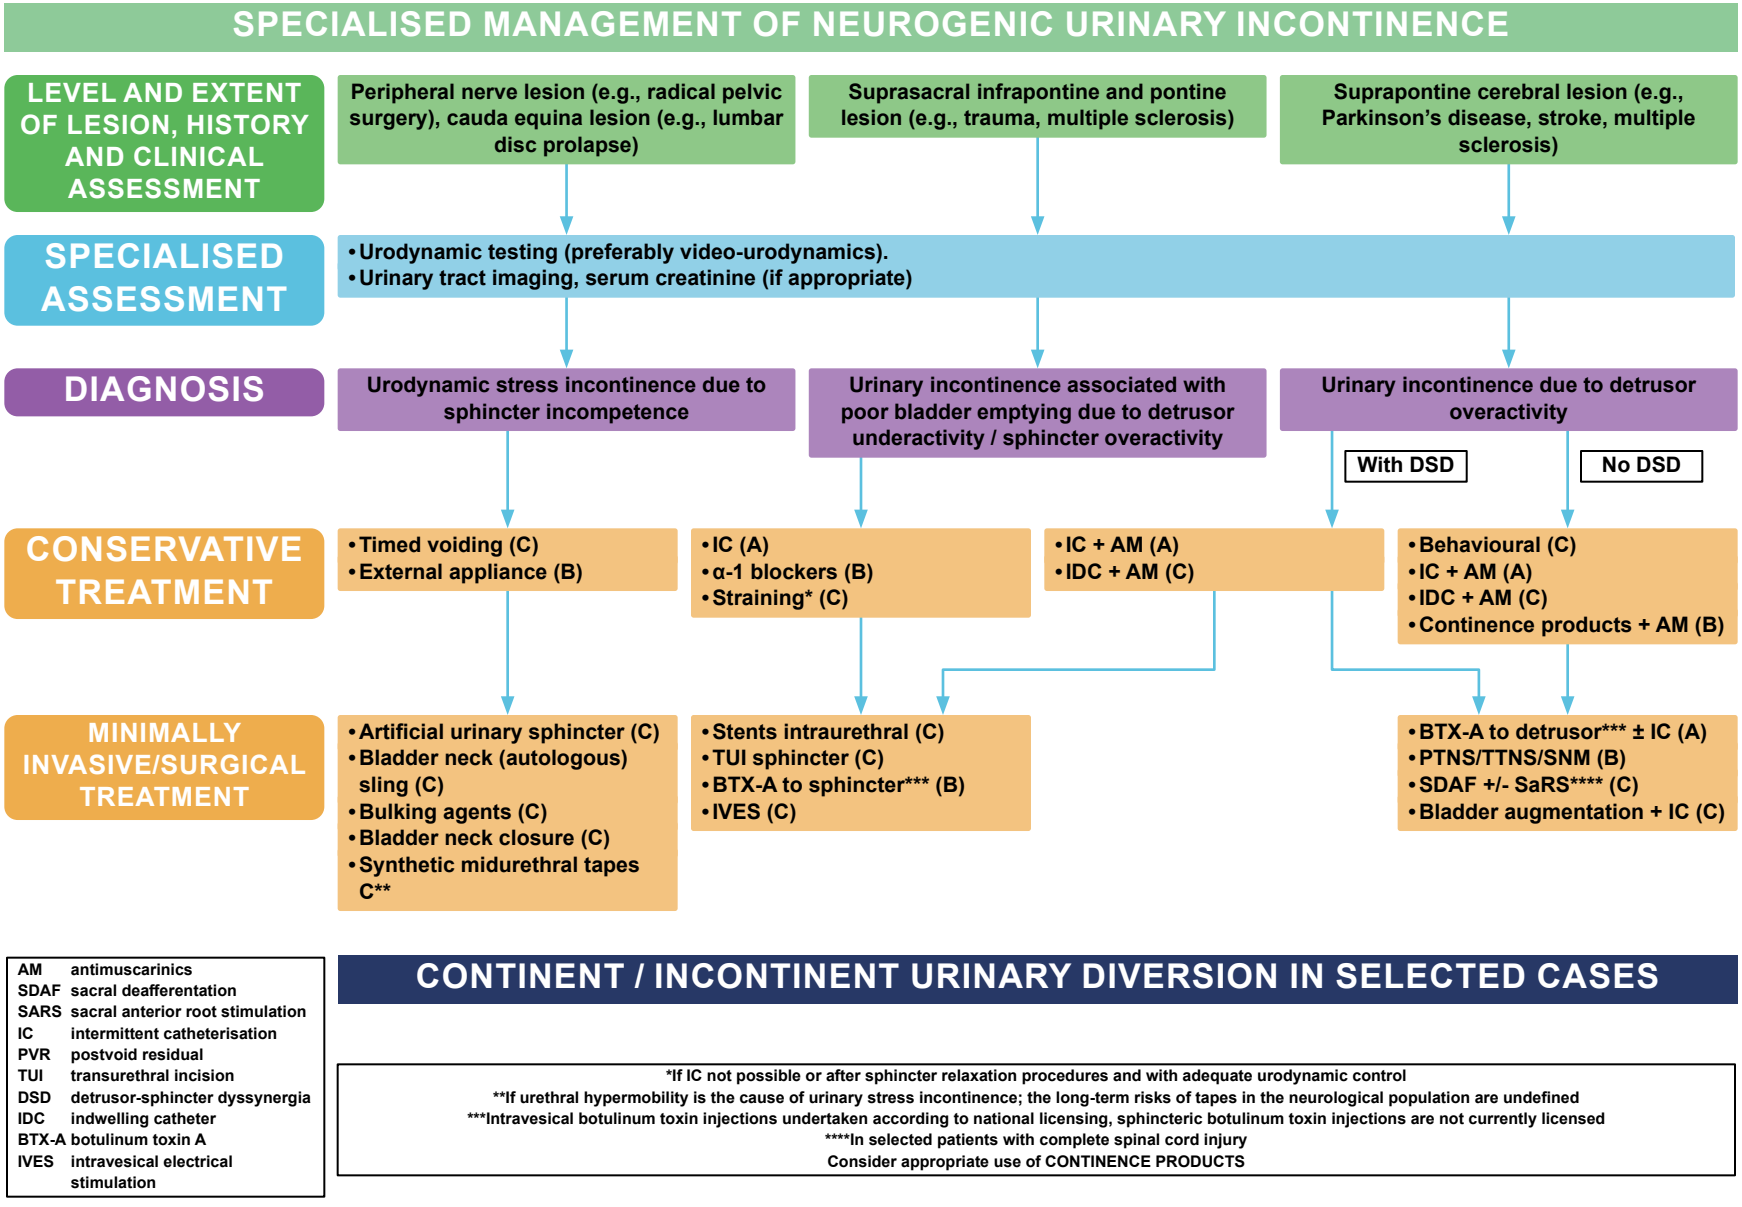
- **Conservative**
- Intermittent catheterisation (GoR A)
- PFMT for patients with MS & PD (GoR B)
- PTNS for OAB symptoms in patients with MS, PD, incomplete SCI & post- stroke (GoR C)
- TENS for post stroke patients with OAB (GoR B)
- Timed voiding (GoR C)
- Continence products (GoR B)
- Antimuscarinics (GoR A)
- Alpha-1-adrenergic blockers (GoR B)
- Oral cannabinoid agonists (MS) (GoR C)
- Beta-3-agonist alone or as an add-on to AM (GoR D)
- Bladder expression (GoR C)
- Triggered voiding (GoR C)
- Indwelling catheter (GoR C)

Minimally invasive treatments

- Botulinum toxin for: detrusor (A), sphincter (B)
- Intravesical electrical stimulation (C)
- PTNS / TTNS (B)
- SNM (stable disease only) (B)

Surgical treatment

- Artificial urinary sphincter (C)
- Bladder neck sling (C)
- Sub-urethral tapes (C)
- Bulking agents (C)
- Bladder neck closure (C)
- Stents intraurethral (C)
- TUI sphincter (C)
- Sacral deafferentation (C)
- Sacral anterior root stimulator (C)
- Bladder augmentation (C)



SPECIALISED MANAGEMENT OF NEUROGENIC URINARY INCONTINENCE
LEVEL AND EXTENT OF LESION, HISTORY AND CLINICAL ASSESSMENT
Peripheral nerve lesion (e.g., radical pelvic surgery), cauda equina lesion (e.g., lumbar disc prolapse)
Suprasacral infrapontine and pontine lesion (e.g., trauma, multiple sclerosis)
Suprapontine cerebral lesion (e.g., Parkinson's disease, stroke, multiple sclerosis)
SPECIALISED ASSESSMENT
•Urodynamic testing (preferably video-urodynamics).
•Urinary tract imaging, serum creatinine (if appropriate)
DIAGNOSIS
Urodynamic stress incontinence due to sphincter incompetence
Urinary incontinence associated with poor bladder emptying due to detrusor underactivity / sphincter overactivity
Urinary incontinence due to detrusor overactivity
With DSD
No DSD
CONSERVATIVE TREATMENT
•Timed voiding (C)
•External appliance (B)
•IC (A)
•α-1 blockers (B)
•Straining* (C)
•IC + AM (A)
•IDC + AM (C)
•Behavioural (C)
•IC + AM (A)
•IDC + AM (C)
•Continence products + AM (B)
MINIMALLY INVASIVE/SURGICAL TREATMENT
•Artificial urinary sphincter (C)
•Bladder neck (autologous) sling (C)
•Bulking agents (C)
•Bladder neck closure (C)
•Synthetic midurethral tapes C**
•Stents intraurethral (C)
•TUI sphincter (C)
•BTX-A to sphincter*** (B)
•IVES (C)
•BTX-A to detrusor*** ± IC (A)
•PTNS/TTNS/SNM (B)
•SDAF +/- SaRS**** (C)
•Bladder augmentation + IC (C)
AM antimuscarinics
SDAF sacral deafferentation
SARS sacral anterior root stimulation
IC intermittent catheterisation
PVR postvoid residual
TUI transurethral incision
DSD detrusor-sphincter dyssynergia
IDC indwelling catheter
BTX-A botulinum toxin A
IVES intravesical electrical stimulation
CONTINENT / INCONTINENT URINARY DIVERSION IN SELECTED CASES
*If IC not possible or after sphincter relaxation procedures and with adequate urodynamic control
**If urethral hypermobility is the cause of urinary stress incontinence; the long-term risks of tapes in the neurological population are undefined
***Intravesical botulinum toxin injections undertaken according to national licensing, sphincteric botulinum toxin injections are not currently licensed
****In selected patients with complete spinal cord injury
Consider appropriate use of CONTINENCE PRODUCTS

VII. INTERSTITIAL CYSTITIS/BLADDER PAIN SYNDROME, HUNNER LESION DISEASE

ASSESSMENT

Males or females whose symptoms meet the requirements of the definition of interstitial cystitis/bladder pain syndrome (IC/BPS) should be evaluated. The presence of commonly associated disorders including irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia in the presence of the cardinal symptoms of interstitial cystitis/bladder pain syndrome also suggests the diagnosis. Abnormal gynaecological findings in women and well-characterised, confusable diseases that may explain the symptoms must be ruled out.

All patients should be evaluated with cystoscopy to determine if they have a Hunner lesion. While presentation is similar, Hunner lesion disease (HLD) differs markedly from IC/BPS. Cystoscopy is the method of choice to identify Hunner lesions and histopathology the method to confirm it. HLD cannot be distinguished from IC/BPS by means of symptoms, physical examination, or laboratory testing. HLD is less common overall but commonly identified in older onset populations. They are not a continuum of conditions and IC/BPS does not progress to HLD in the vast majority of patients. IC/BPS is a symptom-based syndrome without specific objective finding. HLD has a typical pathology, typical findings on endoscopy, is not associated with other chronic pain syndromes (unlike IC/BPS), and uniquely responds to fulguration, excision, intralesional steroid injection, and oral cysclosporin. It should be considered a confounding disease rather than a phenotype of IC/BPS. Cystoscopy is recommended early in the evaluation of patients who meet the IC/BPS definition and can be done with flexible endoscopy without sedation in most patients.

The initial assessment consists of a bladder diary or frequency/volume chart, focused physical examination, urinalysis, and urine culture. In the absence of confusable disorders, a diagnosis can be made, and treatment instituted. Urine cytology and urodynamic evaluation are recommended if clinically indicated and/or the diagnosis is in doubt. Patients with urinary infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and microscopic or gross haematuria are evaluated with appropriate imaging and endoscopic procedures, and only if the findings are unable to explain the symptoms, are they diagnosed with BPS. GoR C

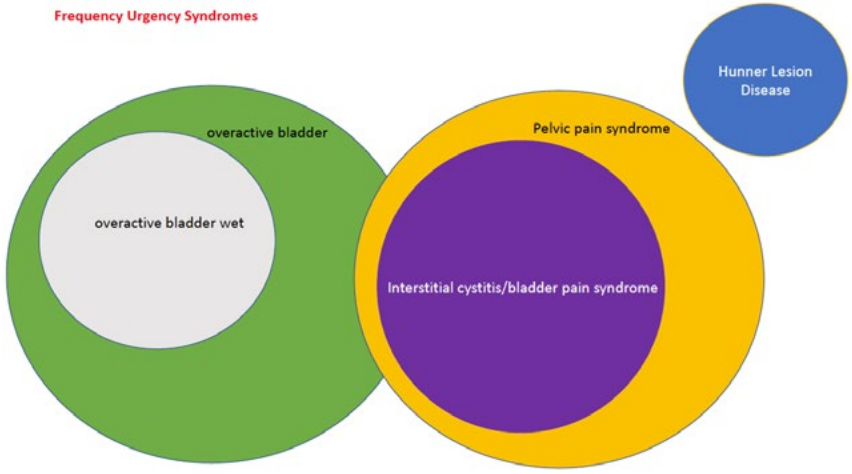


Figure 1

TREATMENT: IC/BPS

- Patient education, behavioral modification (GoR B)
- Dietary manipulation, (GoR B)
- Nonprescription analgesics, (GoR C)
- Stress reduction, (GoR C)
- Physical therapy, employing pelvic floor relaxation techniques, comprises the initial treatment of IC/BPS. In the patient with findings suggesting pelvic floor dysfunction, pelvic floor physical therapy with myofascial trigger point release and intravaginal Thiele massage is often an effective therapeutic intervention. The treatment of pain needs to be addressed directly, and in some instances referral to an anesthesia/pain centre can be an appropriate early step in conjunction with ongoing treatment of the syndrome. (GoR A)

When conservative therapy fails or symptoms are severe and conservative management is unlikely to succeed,

- Oral medication (GoR B) or
- Intravesical treatment can be prescribed. It is recommended to initiate a single form of therapy and observe results, adding other modalities or substituting other modalities as indicated by the degree of response or lack of response to treatment. (GoR B)

SECONDARY ASSESSMENT

If initial oral or intravesical therapy fails, or before beginning such therapy based on clinician judgment, it is reasonable to consider further evaluation which can include urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anaesthesia.

- Findings of detrusor overactivity suggest a trial of antimuscarinic or beta-3-agonist therapy.
- The presence of a Hunner lesion (10% may be missed on the initial office cystoscopy) suggests therapy with transurethral resection, fulguration of the lesion, or direct steroid injection into the lesion. (GoR B)
- Bladder distention itself can have therapeutic benefit in 30-50% of patients, though benefits rarely persist for longer than a few months. (GoR C)

REFRACTORY IC/BPS

Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive treatment modalities. Many of these are best administered within the context of a clinical trial if possible. These may include

- Sacral nerve stimulation, (GoR)
- Intradetrusor botulinum toxin, (GoR B)
- Clinical trials of newly described pharmacological management techniques.
- By this point and often before, most patients will benefit from the expertise of an anaesthesia pain clinic.

The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urinary stream.

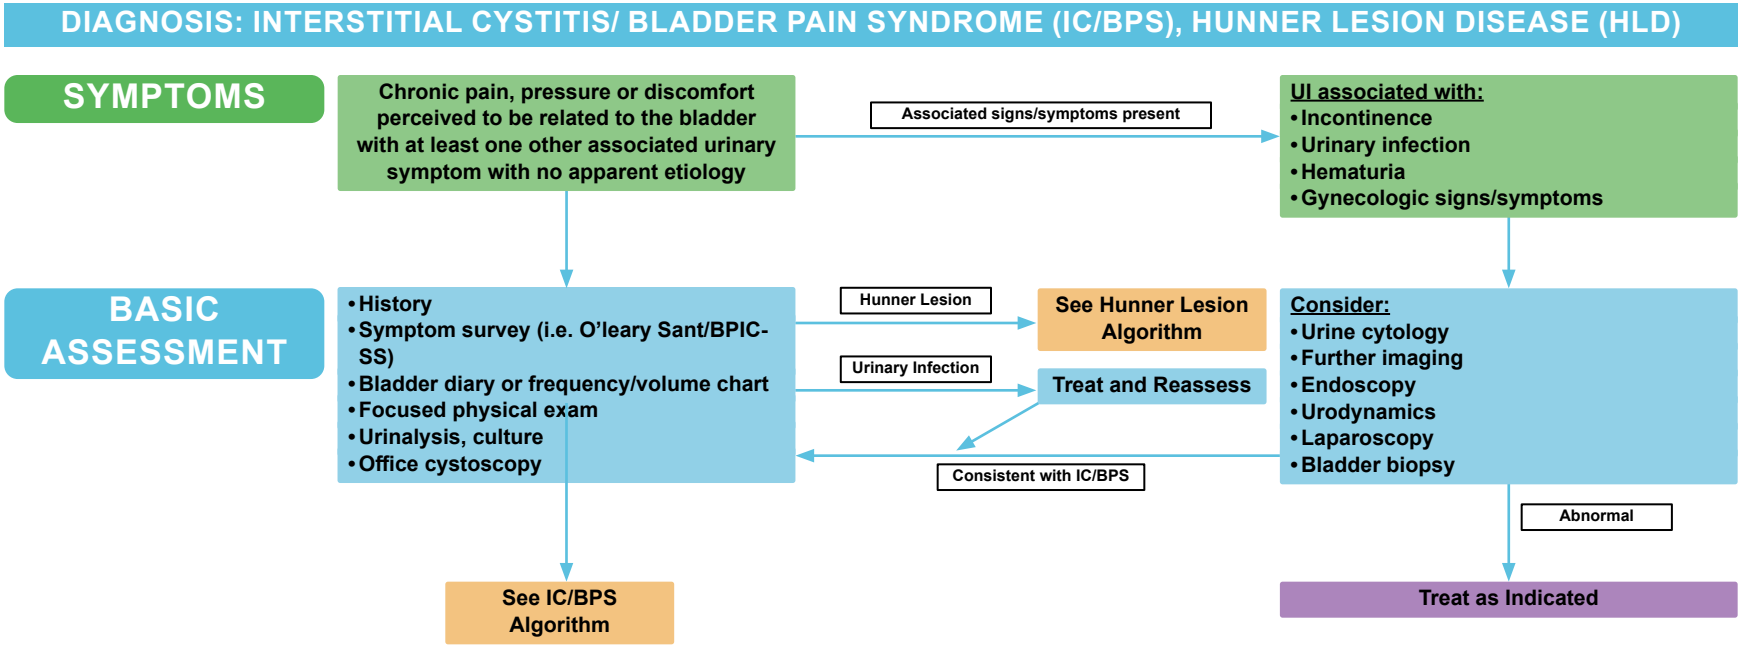
- Urinary diversion with or without cystectomy has been used as a last resort with good results in selected patients. Cystectomy and urethrectomy do not appear to add any additional efficacy to diversion alone. (GoR B)
- Augmentation or substitution cystoplasty seems less effective and more prone to recurrence of chronic pain in small reported series (GoR C)

HUNNER LESION DISEASE

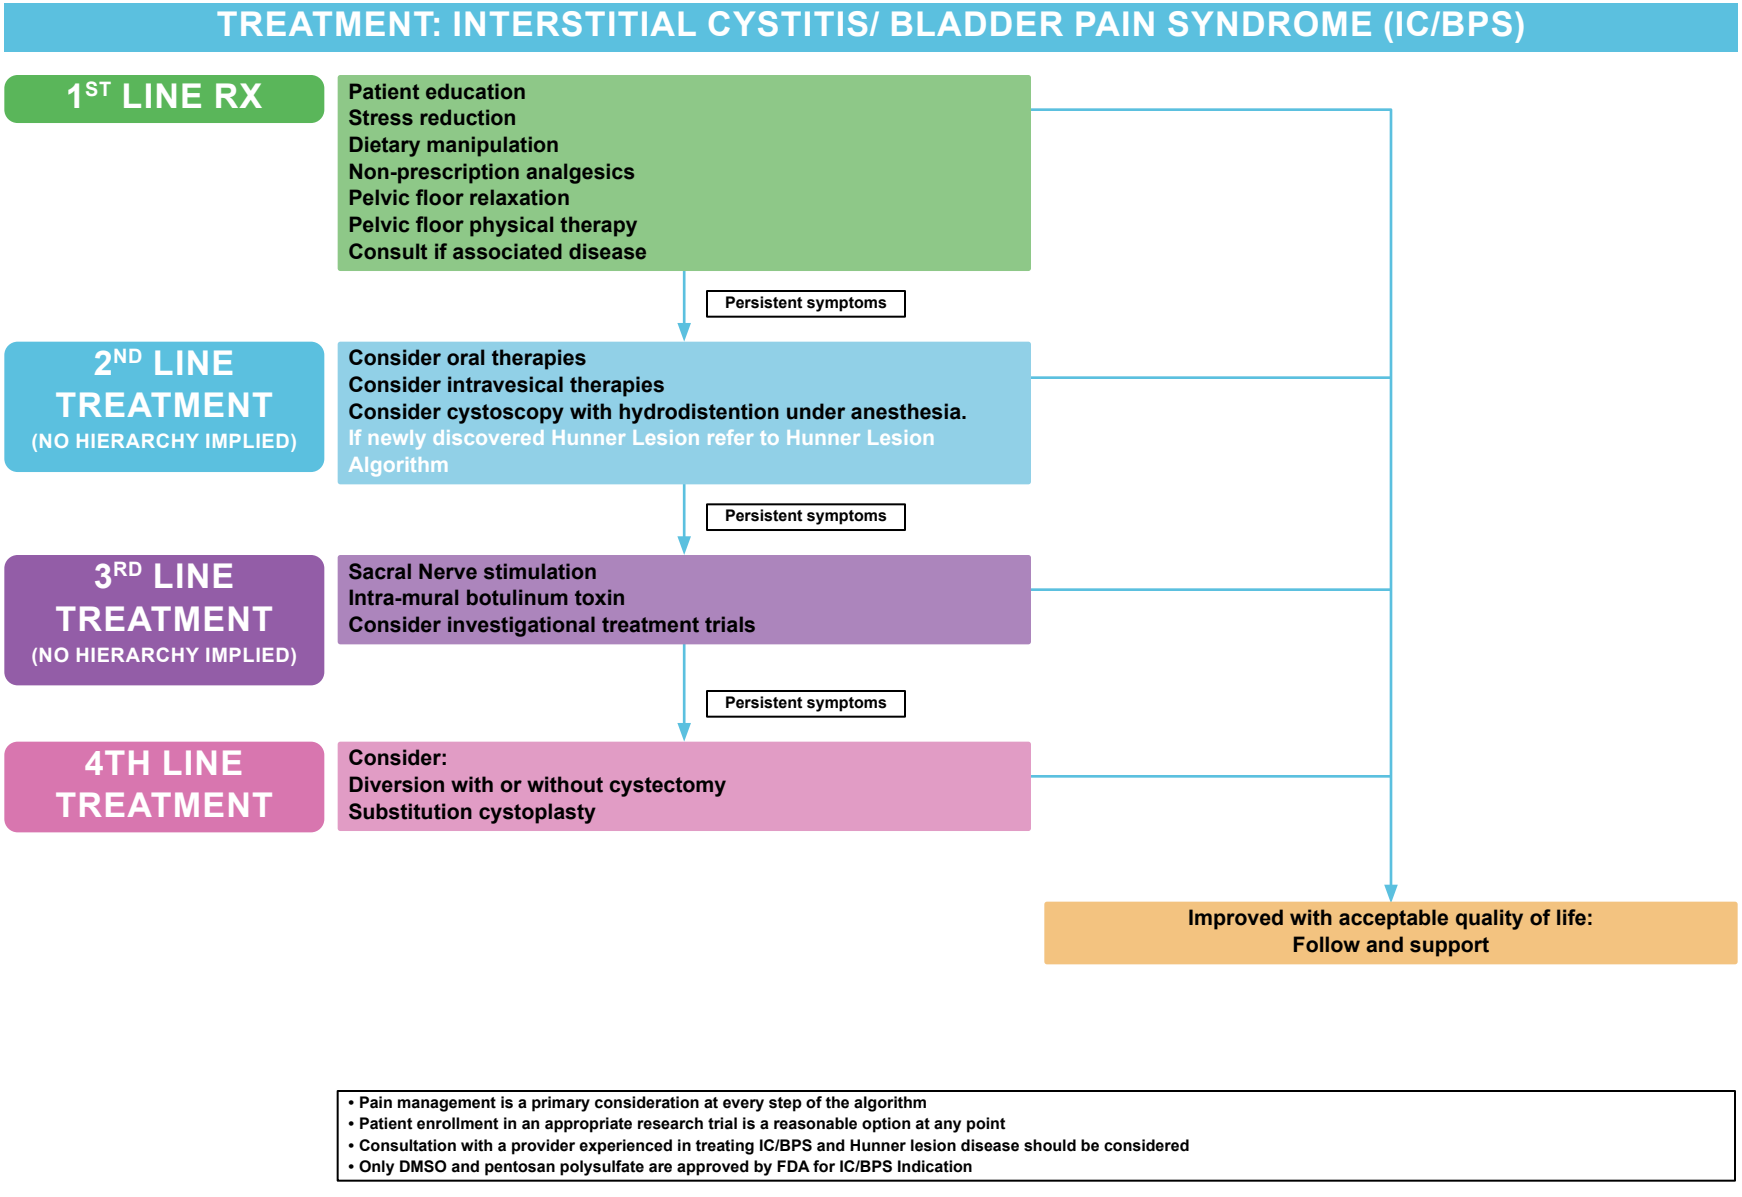
- Hunner lesion disease is treated initially with bladder distention under sedation to 60-80cm water pressure for 2-5 minutes followed by extensive fulguration or resection of Hunner lesion(s). (GoR A)
- Biopsy with a partially distended bladder is recommended if definitive diagnosis has not been previously made as required to rule out a malignant process or other treatable condition.

Symptoms often respond for periods up to 12 months or longer.

- Recurrence suggests the need to repeat the procedure and consider intralesional steroid Injection as an adjunct to fulguration or in addition to it.
- With tachyphylaxis or failure of the treatment to result in improvement consider
- Oral cyclosporin (GoR C)
- proceed to the IC/BPS treatment algorithm.

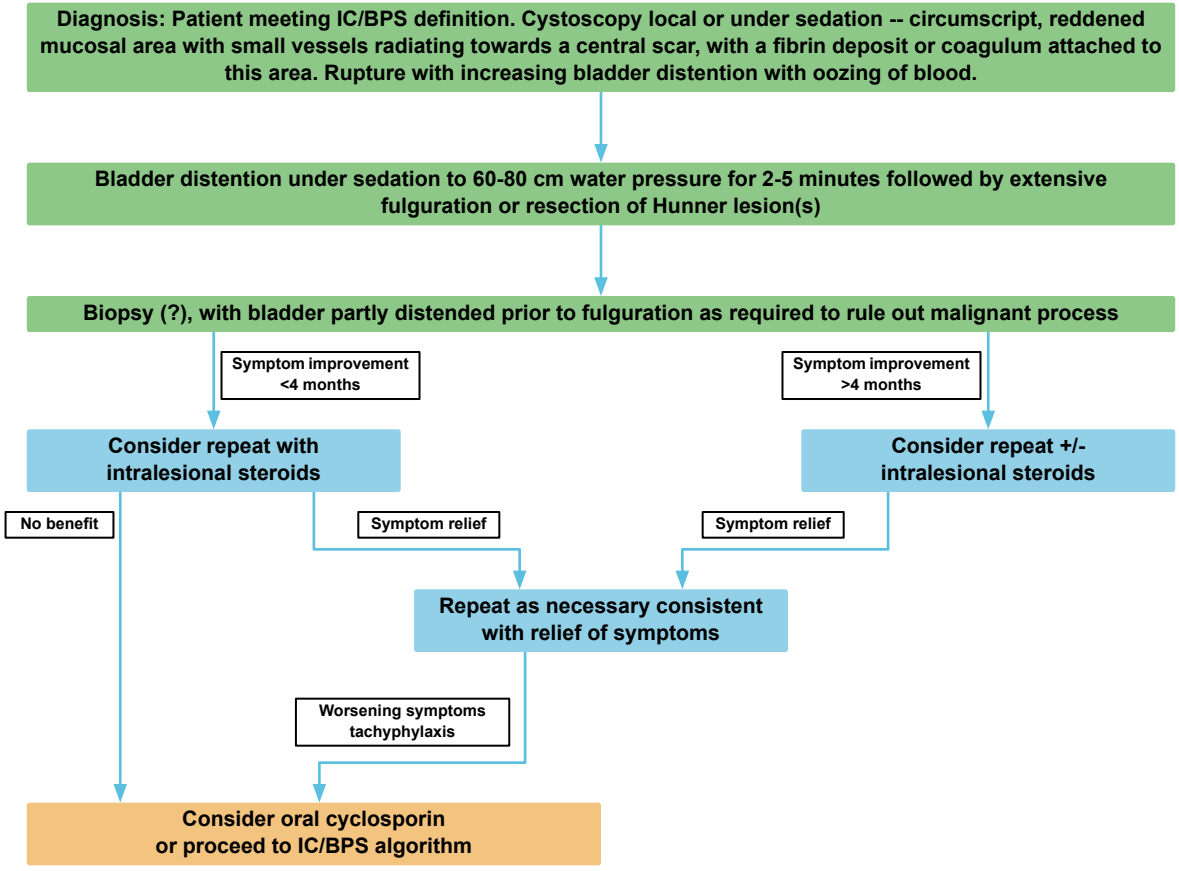


Algorithm for Diagnosis/C/BPS and HLD symptom complex: 2023 International Consultation an Incontinence.
Early cystoscopy is recommended to differentiate IC/BPS syndrome from MLD.



TREATMENT: INTERSTITIAL CYSTITIS/ BLADDER PAIN SYNDROME (IC/BPS)
1ST LINE RX
Patient education
Stress reduction
Dietary manipulation
Non-prescription analgesics
Pelvic floor relaxation
Pelvic floor physical therapy
Consult if associated disease
Persistent symptoms
2ND LINE TREATMENT
(NO HIERARCHY IMPLIED)
Consider oral therapies
Consider intravesical therapies
Consider cystoscopy with hydrodistention under anesthesia.
If newly discovered Hunner Lesion refer to Hunner Lesion Algorithm
Persistent symptoms
3RD LINE TREATMENT
(NO HIERARCHY IMPLIED)
Sacral Nerve stimulation
Intra-mural botulinum toxin
Consider investigational treatment trials
Persistent symptoms
4TH LINE TREATMENT
Consider:
Diversion with or without cystectomy
Substitution cystoplasty
Improved with acceptable quality of life:
Follow and support
• Pain management is a primary consideration at every step of the algorithm
• Patient enrollment in an appropriate research trial is a reasonable option at any point
• Consultation with a provider experienced in treating IC/BPS and Hunner lesion disease should be considered
• Only DMSO and pentosan polysulfate are approved by FDA for IC/BPS Indication

HUNNER LESION DISEASE



VIII. FAECAL INCONTINENCE IN ADULT PATIENTS

CLINICAL ASSESSMENT AND MANAGEMENT

INITIAL CLINICAL ASSESSMENT

- History will include review of daily bowel habit and the type and severity of bowel incontinence (optimally reported using a bowel diary), neurological diseases, other comorbidities and systemic disorders, and anorectal surgeries (e.g., haemorrhoidectomy), obstetric history for women, medications, diet, constipation and chronic straining, toileting ability, cognitive function, and effects of symptoms on quality of life. **(GoR C)**

- Assessing the type of bowel incontinence may help identify an aetiology. Types of bowel incontinence: Anal incontinence is the involuntary loss of faeces and/or flatus and/or mucus). Faecal incontinence is the involuntary loss of faeces. Flatus incontinence is the involuntary loss of rectal gas, which may indicate rectal sensory impairment and/or anal sphincter dysfunction. Mucus incontinence is the involuntary loss of mucus only. **(GoR C)**

- A subtype of faecal incontinence is urge faecal incontinence, which is the involuntary loss of faeces due to an inability to defer defaecation once the urge is perceived for long enough to reach a toilet. Passive faecal incontinence refers to incontinence without forewarning, which is typically related to internal anal sphincter dysfunction or poor closure of the external sphincter due to rectal prolapse or stage III/IV haemorrhoids. It also could occur as overflow faecal incontinence due to rectal faecal impaction. Functional (disability associated) faecal incontinence is due to limitations in mobility, toileting ability or delayed assistance.

- Physical examination should include a general health examination, anal and peri-anal inspection, abdominal palpation, a brief neurological examination, digital rectal examination and usually proctosigmoidoscopy or colonoscopy. **(GoR C)**

- Further diagnostic testing needs to be considered if there is an unexplained change in bowel habit, weight loss, anaemia, rectal bleeding, severe or nocturnal diarrhoea, or an abdominal or pelvic mass and bowel pathology or when organic conditions such as cancer, inflammatory bowel disease (IBD), a recto-vaginal fistula, full thickness rectal prolapse, or cloacal deformity are suspected. Condition specific management is indicated for these patients. **(GoR C)**

INITIAL CONSERVATIVE INTERVENTIONS

Initial conservative interventions include:

- Discussion with the patient of options and goals of management **(GoR B)**

- Education about faecal incontinence and conservative and self-management support **(GoR B)**

- Modification of diet, fluid, and eating pattern advice **(GoR B/C)**

- Supplementation with dietary fibre **(GoR A)**

- Anti-motility medication, especially if stools are loose **(GoR B)**

- Establishing a regular bowel habit **(GoR C)** and urgency training if relevant **(GoR C)**

- Pelvic floor muscle training (PFMT) **(GoR B)**

- Transanal irrigation to empty the rectum **(GoR B)**

- Use of absorbent products including various types and sizes of absorbent pads, briefs, etc., to contain leaked faeces and prevent skin damage **(GoR B)**

- Provide advice on practical coping skills when incontinence occurs **(GoR C)**

- Provide emotional support and empathy (Grade of Recommendation C)

- For individuals with faecal incontinence due to neurological diseases and conditions, prevention and management of constipation and rectal impaction are additional treatments that may be needed (Grade of Recommendation B)

SECONDARY INTERVENTIONS

If initial interventions fail to improve symptoms secondary interventions include:

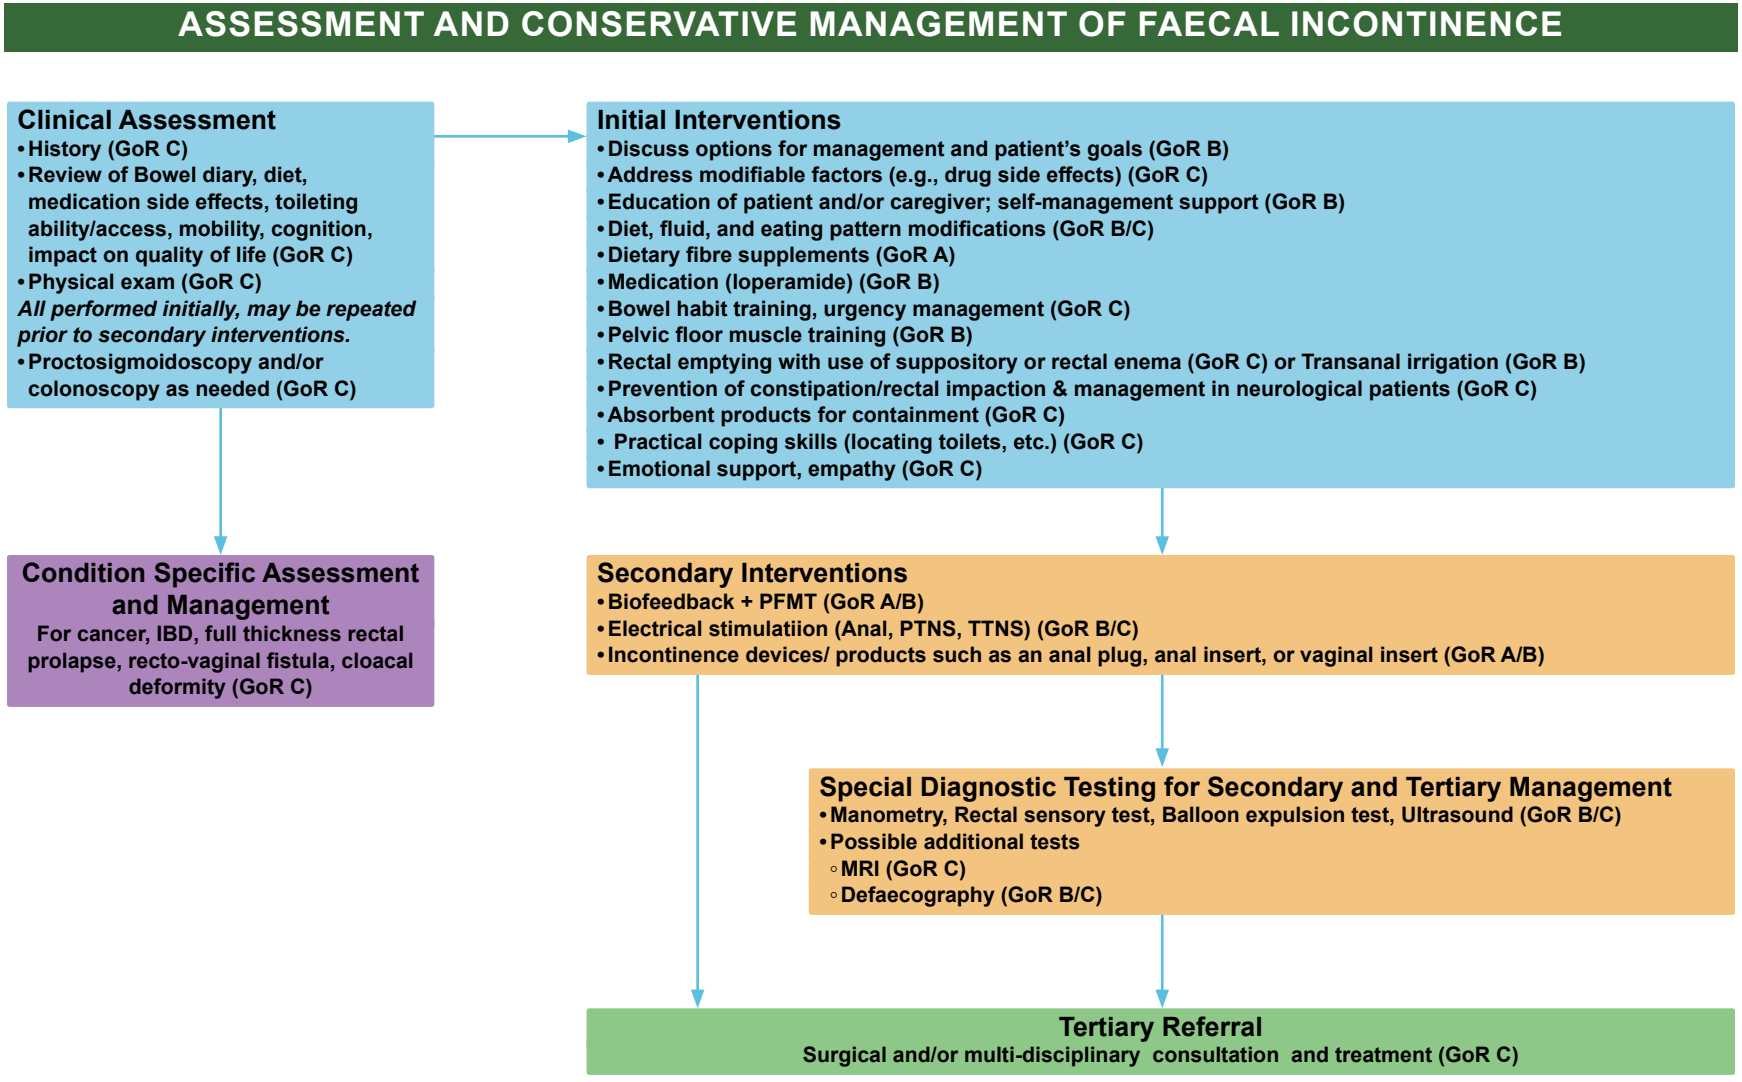
- Biofeedback therapy or biofeedback therapy combined with PFMT. **(GoR A/B)**
- Electrical simulation (can be combined with biofeedback). **(GoR B)**
- anal plug, or anal or vaginal insert, as temporary barriers blocking leakage from the rectum. **(GoR A/B)**

SPECIAL DIAGNOSIC TESTING FOR SECONARY AND TERTIARY MANAGEMENT OF FAECAL INCONTINENCE

- A variety of anorectal diagnostic investigations, including the rectal sensory test, balloon expulsion test, manometry, anal ultrasound, MRI, and defaecagraphy can help to define structural or functional abnormalities of anorectal function, determine whether surgery is indicated, and guide management if initial and/or secondary interventions are ineffective.

TERTIARY REFERRAL FOR SURGICAL OR MULTI-DISCIPLINARY CONSULTATION AND INTERVENTION

- Faecal incontinence that fails to respond to initial and secondary management requires specialised consultation from a colorectal surgeon, gastroenterologist, urogynecologist, and/or a multi-disciplinary team. **(GoR C)**



ASSESSMENT AND CONSERVATIVE MANAGEMENT OF FAECAL INCONTINENCE
Clinical Assessment
• History (GoR C)
• Review of Bowel diary, diet, medication side effects, toileting ability/access, mobility, cognition, impact on quality of life (GoR C)
• Physical exam (GoR C)
All performed initially, may be repeated prior to secondary interventions.
• Proctosigmoidoscopy and/or colonoscopy as needed (GoR C)
Initial Interventions
• Discuss options for management and patient's goals (GoR B)
• Address modifiable factors (e.g., drug side effects) (GoR C)
• Education of patient and/or caregiver; self-management support (GoR B)
• Diet, fluid, and eating pattern modifications (GoR B/C)
• Dietary fibre supplements (GoR A)
• Medication (loperamide) (GoR B)
• Bowel habit training, urgency management (GoR C)
• Pelvic floor muscle training (GoR B)
• Rectal emptying with use of suppository or rectal enema (GoR C) or Transanal irrigation (GoR B)
• Prevention of constipation/rectal impaction & management in neurological patients (GoR C)
• Absorbent products for containment (GoR C)
• Practical coping skills (locating toilets, etc.) (GoR C)
• Emotional support, empathy (GoR C)
Condition Specific Assessment and Management
For cancer, IBD, full thickness rectal prolapse, recto-vaginal fistula, cloacal deformity (GoR C)
Secondary Interventions
• Biofeedback + PFMT (GoR A/B)
• Electrical stimulatiion (Anal, PTNS, TTNS) (GoR B/C)
• Incontinence devices/ products such as an anal plug, anal insert, or vaginal insert (GoR A/B)
Special Diagnostic Testing for Secondary and Tertiary Management
• Manometry, Rectal sensory test, Balloon expulsion test, Ultrasound (GoR B/C)
• Possible additional tests
◦ MRI (GoR C)
◦ Defaecography (GoR B/C)
Tertiary Referral
Surgical and/or multi-disciplinary consultation and treatment (GoR C)

VIII. FAECAL INCONTINENCE IN ADULT PATIENTS

SURGERY FOR FAECAL INCONTINENCE

PATIENT ASSESSMENT

- The reader is referred to the relevant chapter sections in “Dynamic Testing” and “Conservative Treatment for Faecal Incontinence.” In general, patients referred for surgical management of faecal incontinence must either have failed conservative therapy or not be candidates for conservative therapy due to severe anatomic abnormality.
- Prior to surgical management of faecal incontinence, the integrity of the anal sphincter complex should be assessed. This assessment is best performed with clinical examination and endoanal ultrasound. Ancillary tests include anal manometry and defaecography.
- If the patient has persisting faecal incontinence, he or she should undergo repeat assessment, including endoanal ultrasound.

MANAGEMENT

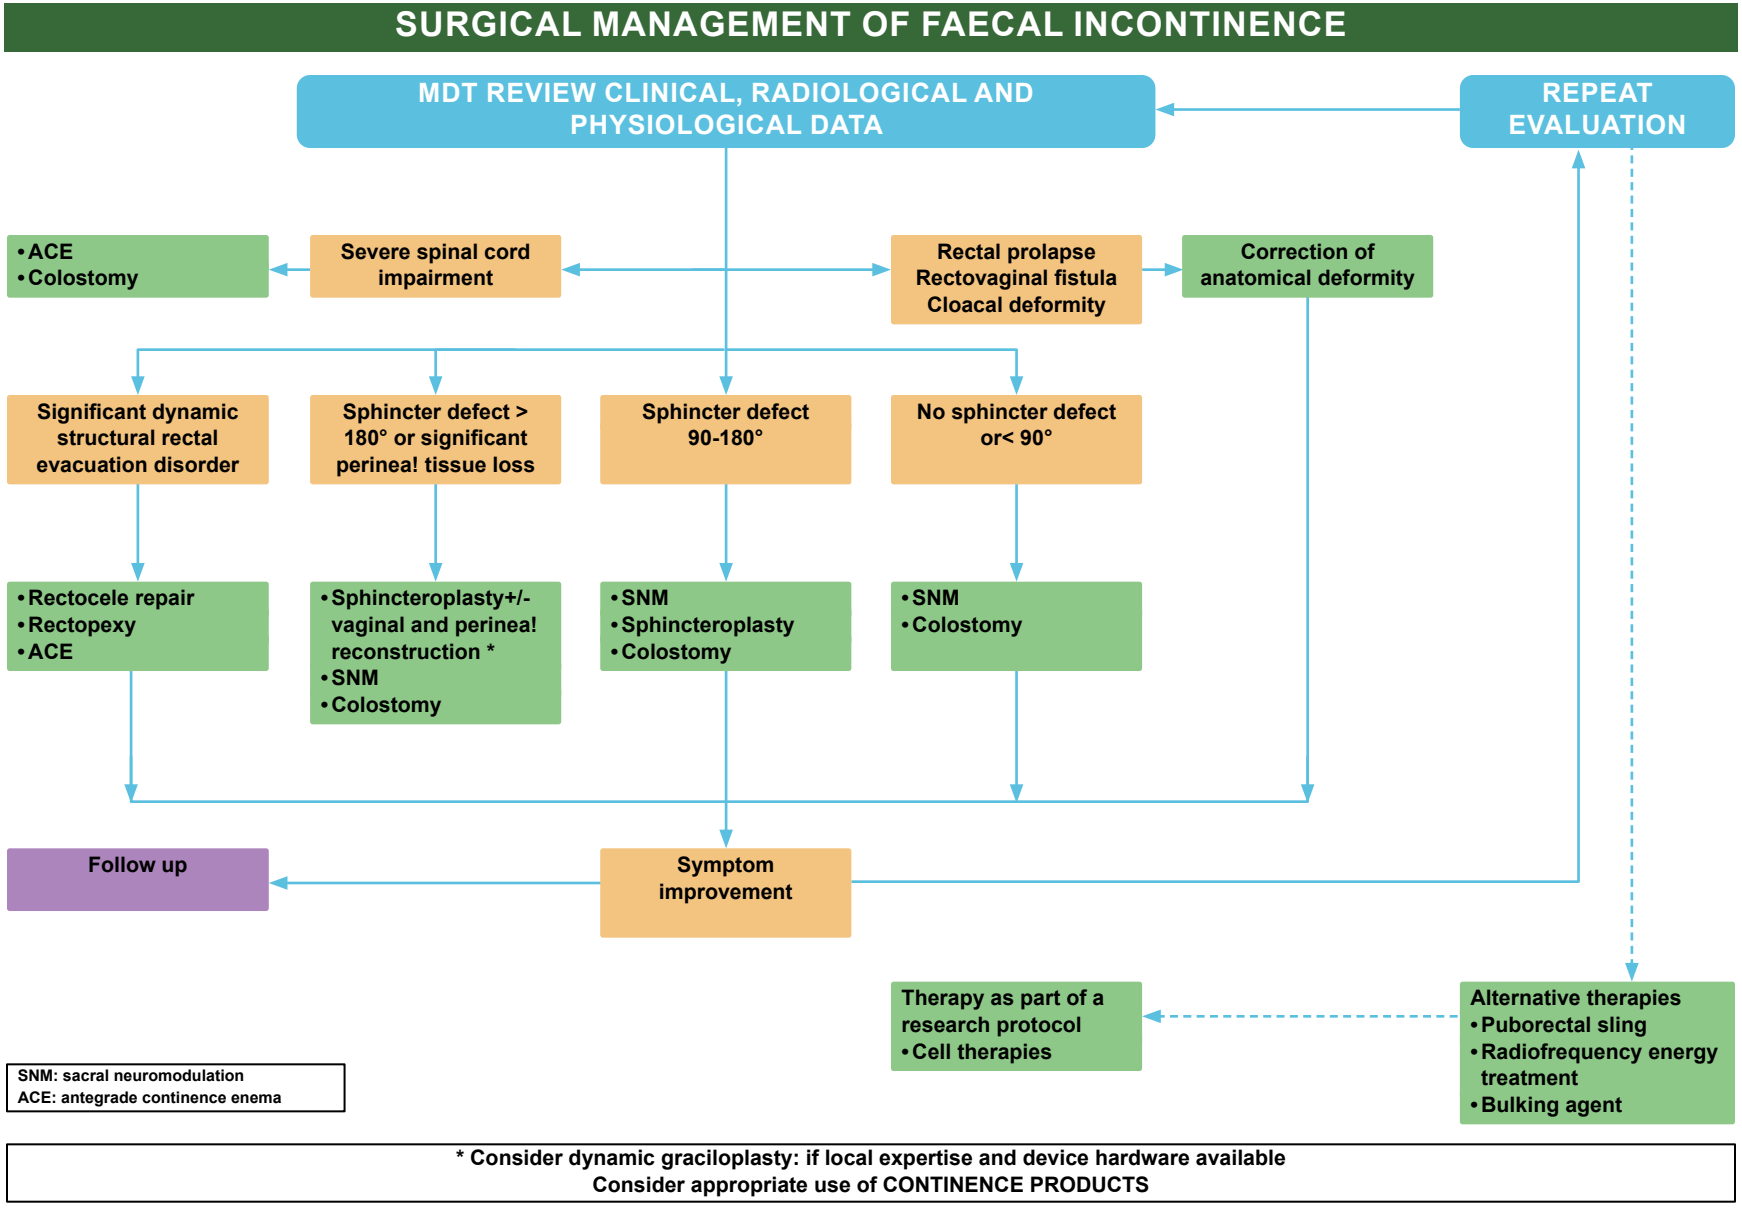
- The surgical approach is influenced by the presence and magnitude of an anatomical anal sphincter defect. If no defect is present, or if the sphincter defect is small, options include SNM (GoR B) and colostomy.
- Acute anal sphincter repair is usually required following obstetric or direct trauma. End to end or overlapping repair may be performed. When possible, the internal anal sphincter should be separately repaired. (GoR B)
- Patients with rectal prolapse, rectovaginal fistula or cloacal deformity often have associated faecal incontinence. Initial therapy should be directed at correction of the anatomical abnormality. (GoR D)
- Patients with concomitant symptoms of obstructed defaecation may have a dynamic structural abnormality leading to evacuatory impairment e.g., rectocele, intussusception, or both. These patients may benefit from primary treatment of this problem even if there is also sphincter dysfunction. (GoR C)
- For patients with moderate sphincter defects (90-180 degrees), sphincteroplasty, SNS or colostomy can be considered. For patients with large clinically overt defects, sphincteroplasty is likely to be the best option, though SNM can be considered. (GoR C)
- Patients with sphincter defects of greater than 180° or major perineal tissue loss require individualised treatment. Reconstruction may require major reconstructive surgery. Should incontinence persist, SNM can be used as an adjunct. Stimulated muscle transposition (usually gracilloplasty) is now rarely practiced. (GoR C)

ALTERNATIVE MANAGEMENT

- For patients who remain incontinent following sphincteroplasty, repeat endoanal ultrasound can reassess the status of the repair. If no defect is present, or if the defect is minimal, options include SNM. If there is a large persisting sphincter defect, repeat sphincteroplasty can be considered. (GoR C)
- Patients who fail reconstructive approaches and/or SNM or who do not wish to undergo extensive pelvic reconstruction, should consider end sigmoid colostomy. (GoR C) While this does not restore continence, it does restore substantial bowel control and appears to improve social function and quality of life.
- Injection of a biomaterial to bulk the sphincter remains an option but evidence to support use (and choice of agent to use) is poor. (GoR C)
- Novel therapies can also be considered under protocol: puborectal sling, radiofrequency ablation and cell therapies. (GoR C)

SPECIAL SITUATIONS

- Individuals with congenital abnormalities may be amenable to specialist abdominal and perineal surgical repair. Poor functional outcomes may be treated by an Antegrade Continence Enema (ACE) procedure or colostomy. Patients with cauda equina type neurological disorders, either congenital or acquired, should be considered for an ACE procedure or colostomy. (GoR C)



SURGICAL MANAGEMENT OF FAECAL INCONTINENCE
MDT REVIEW CLINICAL, RADIOLOGICAL AND PHYSIOLOGICAL DATA
REPEAT EVALUATION
•ACE
•Colostomy
Severe spinal cord impairment
Rectal prolapse
Rectovaginal fistula
Cloacal deformity
Correction of anatomical deformity
Significant dynamic structural rectal evacuation disorder
Sphincter defect > 180° or significant perinea! tissue loss
Sphincter defect 90-180°
No sphincter defect or< 90°
•Rectocele repair
•Rectopexy
•ACE

SNM: sacral neuromodulation
ACE: antegrade continence enema
* Consider dynamic graciloplasty: if local expertise and device hardware available
Consider appropriate use of CONTINENCE PRODUCTS

IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

INITIAL MANAGEMENT

Patients with known neurological disease may present with symptoms related to neurological bowel dysfunction, such as difficulty in defaecation, constipation and faecal incontinence which disturb their activities of daily living and impair quality of life. Many have permanent impairments and functional limitations and disabilities, which are due to neurological deficits and complications

INITIAL ASSESSMENT

- The history should include:
  - Neurological diagnosis and functional level
  - Previous and present lower gastrointestinal (LGIT) function and disorders
  - Severity of neurogenic bowel dysfunction
  - Current bowel care and management including diet, fluid intake, medications affecting bowel functions
  - Co-morbidity / complication e.g., urinary incontinence, autonomic dysreflexia, pressure ulcers, sexual dysfunction
  - Patient's satisfaction, needs, restrictions and quality of life
  - Environmental factors and barriers and facilitators to independent bowel management.
- Physical examination:
- Cognitive function; motor, sensory and sacral reflexes – voluntary anal sphincter contraction, deep perianal sensation, anal tone, anal and bulbo- cavernosus reflexes
- Spasticity of the lower limbs
- Abdominal palpation for faecal loading and rectal examination
- Functional assessment:
  - Hand and arm use, fine hand use, mobility – maintaining body position, transfer, and walking ability.
- Environmental factors assessment:
  - toilet accessibility; devices for bowel care and mobility; caregiver support and attitude.

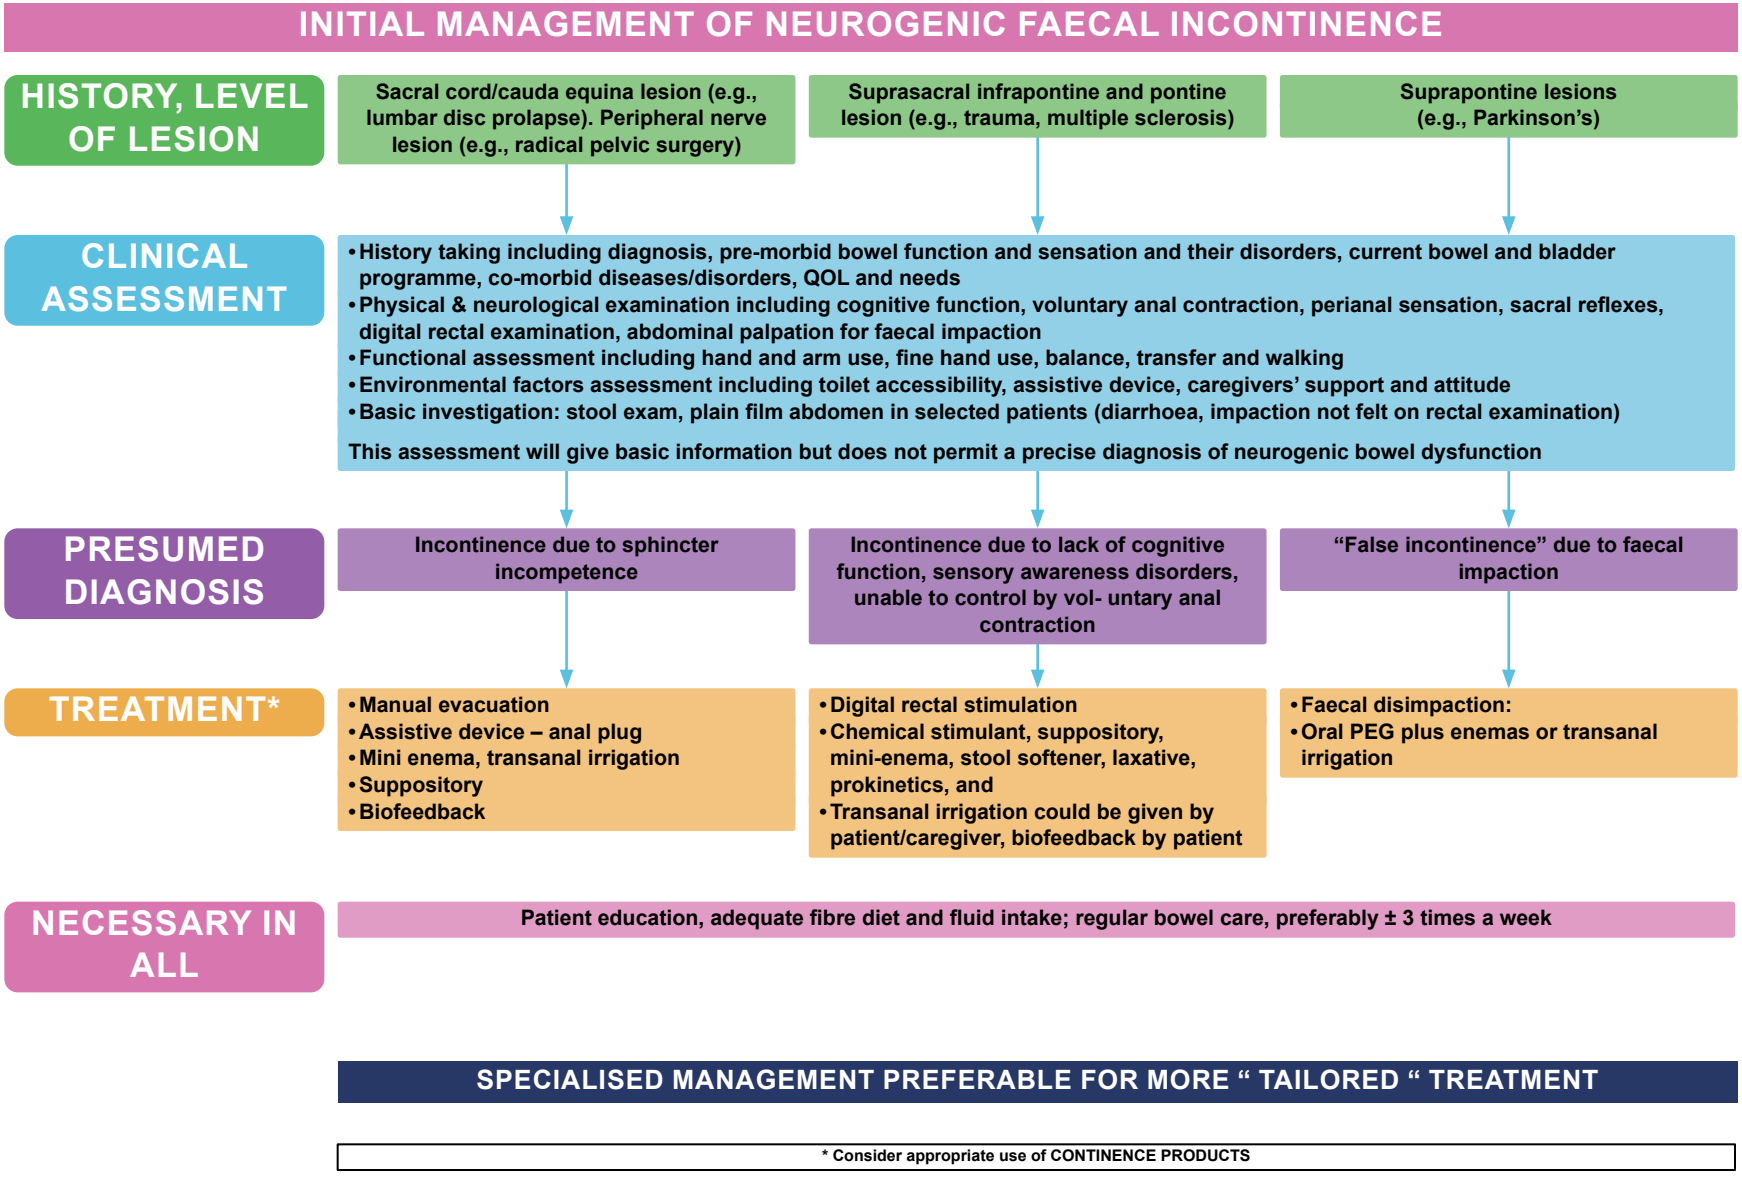
BASIC INVESTIGATIONS

Stool examination, plain abdominal X-Ray

INITIAL TREATMENTS

- Patient education and goals-setting to achieve complete defaecation on a regular basis and faecal continence based on right time, right place, right trigger, and right consistency
- Adequate fibre diet and fluid intake; appropriate trigger according to preservation of sacral (anorectal) reflex – digital rectal stimulation (GoR C); suppository and enema (GoR B); if no anorectal reflex, manual evacuation (GoR B); abdominal massage (GoR C) can also be helpful
- Prescribe medications – stool softener, laxative, prokinetic agents, anti-diarrhoeal drugs as necessary
- Assistive techniques may be necessary for
  - Defaecation – transanal irrigation (GoR A)
  - For incontinence – anal plug (GoR C)

The algorithm does not apply to management in acute neurological patients that need regular bowel emptying.



INITIAL MANAGEMENT OF NEUROGENIC FAECAL INCONTINENCE
HISTORY, LEVEL OF LESION
Sacral cord/cauda equina lesion (e.g., lumbar disc prolapse). Peripheral nerve lesion (e.g., radical pelvic surgery)
Suprasacral infrapontine and pontine lesion (e.g., trauma, multiple sclerosis)
Suprapontine lesions (e.g., Parkinson's)
CLINICAL ASSESSMENT
•History taking including diagnosis, pre-morbid bowel function and sensation and their disorders, current bowel and bladder programme, co-morbid diseases/disorders, QOL and needs
•Physical & neurological examination including cognitive function, voluntary anal contraction, perianal sensation, sacral reflexes, digital rectal examination, abdominal palpation for faecal impaction
•Functional assessment including hand and arm use, fine hand use, balance, transfer and walking
•Environmental factors assessment including toilet accessibility, assistive device, caregivers' support and attitude
•Basic investigation: stool exam, plain film abdomen in selected patients (diarrhoea, impaction not felt on rectal examination)
This assessment will give basic information but does not permit a precise diagnosis of neurogenic bowel dysfunction
PRESUMED DIAGNOSIS
Incontinence due to sphincter incompetence
Incontinence due to lack of cognitive function, sensory awareness disorders, unable to control by vol- untary anal contraction
"False incontinence" due to faecal impaction
TREATMENT*
•Manual evacuation
•Assistive device – anal plug
•Mini enema, transanal irrigation
•Suppository
•Biofeedback
•Digital rectal stimulation
•Chemical stimulant, suppository, mini-enema, stool softener, laxative, prokinetics, and
•Transanal irrigation could be given by patient/caregiver, biofeedback by patient
•Faecal disimpaction:
•Oral PEG plus enemas or transanal irrigation
NECESSARY IN ALL
Patient education, adequate fibre diet and fluid intake; regular bowel care, preferably ± 3 times a week
SPECIALISED MANAGEMENT PREFERABLE FOR MORE " TAILORED " TREATMENT
* Consider appropriate use of CONTINENCE PRODUCTS

IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

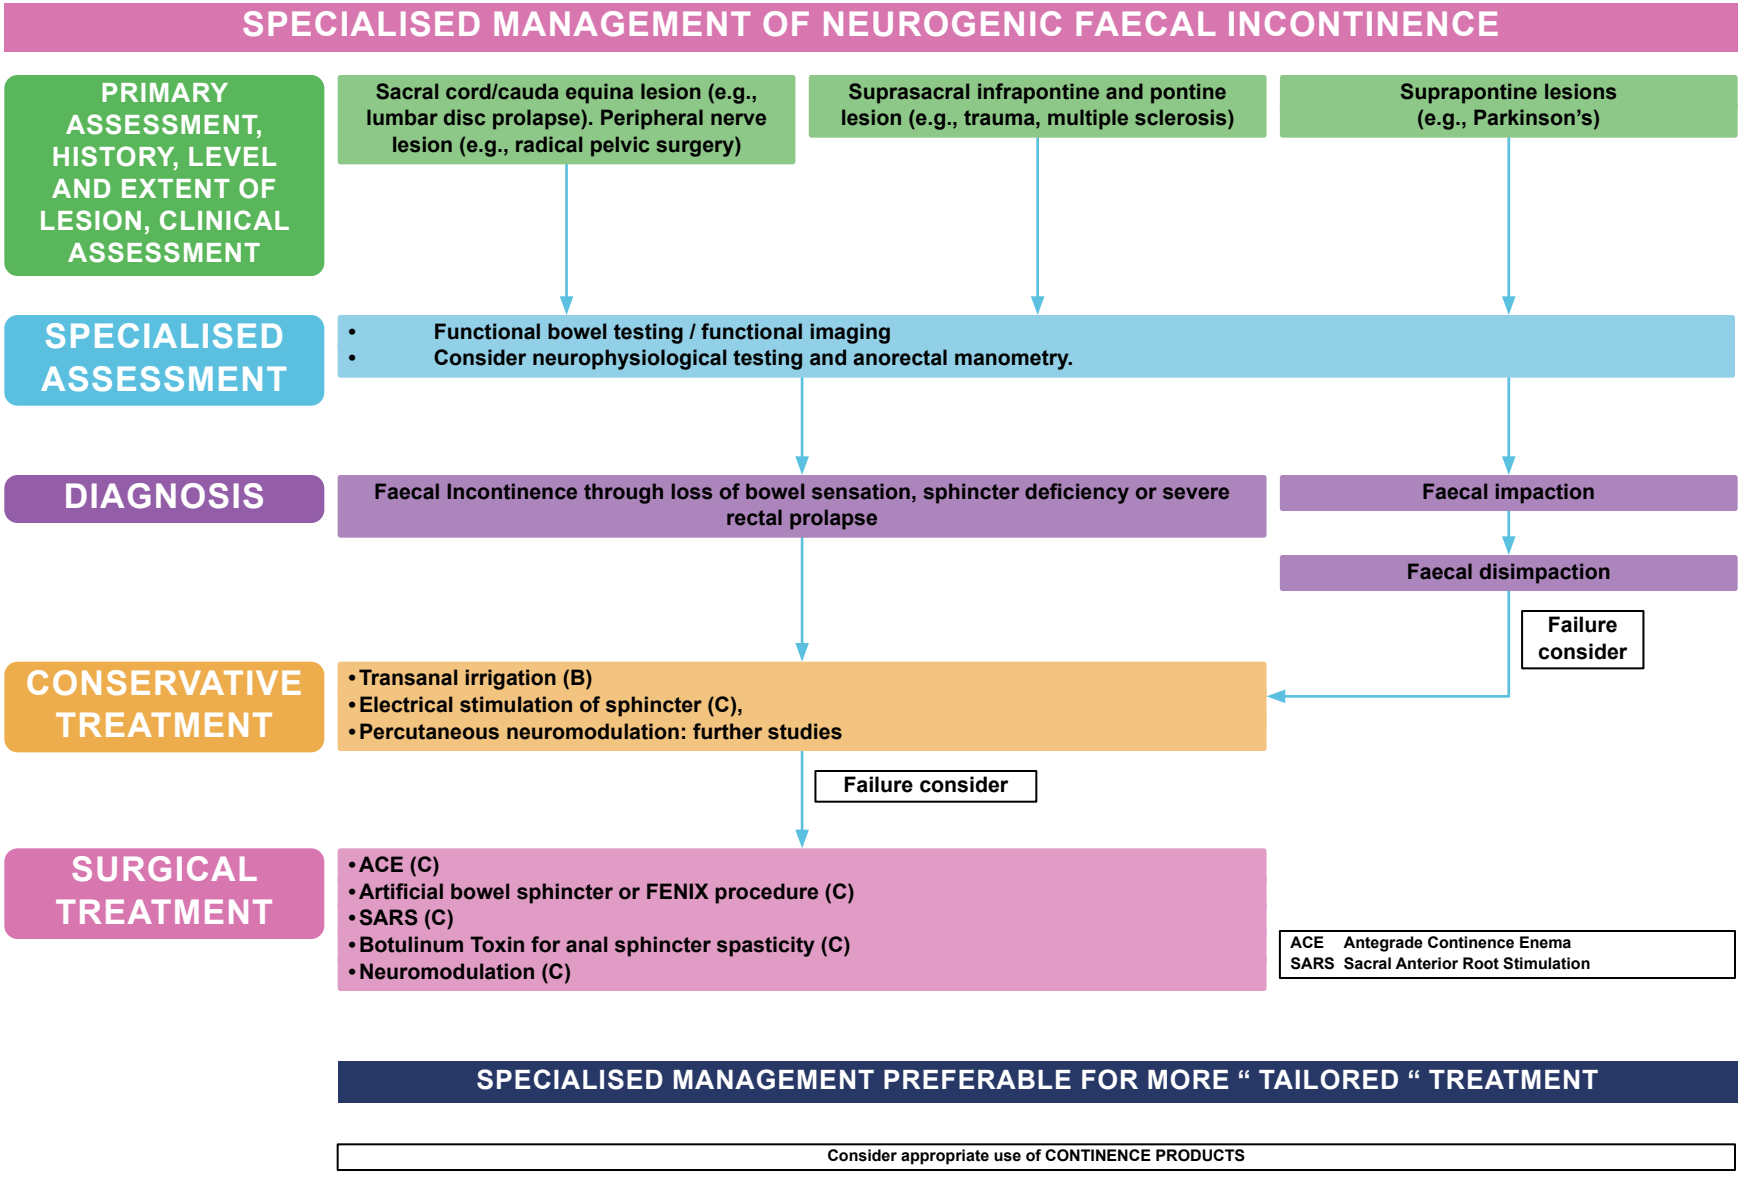
B SPECIALISED MANAGEMENT

ASSESSMENT

- Some patients with neurogenic faecal incontinence will need specialised assessment, especially if initial management is unsuccessful to look for comorbidity and certainly before performing invasive treatment
- Do not assume that all symptoms are due to neuropathy, e.g., women with neurological pathology might have had childbirth injury to the sphincter
- Special investigations: manometry, endoanal ultrasound, (dynamic) MRI, (needle) EMG. These specific bowel functional tests and electro-diagnostic tests must be considered optional, as their value in neurological pathology is not sufficiently demonstrated so far.

TREATMENTS

- Conservative treatment for neurological faecal incontinence is also the mainstay for specialised management, (GoR C).
- Management of neurological incontinence does not include very extensive treatment modalities and many conservative interventions are still empirical.
- Transanal irrigation (GoR B).
- Electrical stimulation sphincter, (GoR C).
- Percutaneous neuromodulation and sacral nerve stimulation: further research is required (GoR D).
- Surgical management of neurogenic faecal incontinence has different options which need a very strict patient selection
- Antegrade Continence Enema ACE (GoR C).
- Artificial bowel sphincter or FENIX procedure (GoR C).
- Sacral Anterior Root Stimulation SARS (GoR C).
- Botulinum Toxin (GoR C).
- Neuromodulation (GoR C).
- It is recommended that urinary and bowel function are assessed simultaneously if both systems are affected, as symptoms and treatment of one system can influence the other and vice versa (GoR A).
- As the therapeutic approach can differ in different neurological diseases, the most prevalent diseases are discussed separately in the chapter.



SPECIALISED MANAGEMENT OF NEUROGENIC FAECAL INCONTINENCE
PRIMARY ASSESSMENT, HISTORY, LEVEL AND EXTENT OF LESION, CLINICAL ASSESSMENT
Sacral cord/cauda equina lesion (e.g., lumbar disc prolapse). Peripheral nerve lesion (e.g., radical pelvic surgery)
Suprasacral infrapontine and pontine lesion (e.g., trauma, multiple sclerosis)
Suprapontine lesions (e.g., Parkinson's)
SPECIALISED ASSESSMENT
• Functional bowel testing / functional imaging
• Consider neurophysiological testing and anorectal manometry.
DIAGNOSIS
Faecal Incontinence through loss of bowel sensation, sphincter deficiency or severe rectal prolapse
Faecal impaction
Faecal disimpaction
Failure consider
CONSERVATIVE TREATMENT
• Transanal irrigation (B)
• Electrical stimulation of sphincter (C),
• Percutaneous neuromodulation: further studies
Failure consider
SURGICAL TREATMENT
• ACE (C)

• SARS (C)
• Botulinum Toxin for anal sphincter spasticity (C)
• Neuromodulation (C)
ACE Antegrade Continence Enema
SARS Sacral Anterior Root Stimulation
SPECIALISED MANAGEMENT PREFERABLE FOR MORE " TAILORED " TREATMENT
Consider appropriate use of CONTINENCE PRODUCTS

X. URINARY AND FAECAL INCONTINENCE IN FRAIL OLDER MEN AND WOMEN

- There is no reason to suspect why interventions which have proven efficacy in community dwelling older adults should not also be effective in frail older adults. Clinicians should, however, take due regard of the practicality, potential benefits, and risks of employing any single intervention in this population.
- Frail older adults do require a different approach which addresses the potential role of co-morbid disease, current medications (prescribed, over the counter and/or naturopathic), physical and cognitive impairment in urinary and faecal incontinence.
- The extent of the investigation and management should consider the degree of bother to the older adult and/or caregiver, the goals for care, the degree that the older person is able to undertake any intervention, considering treatment burden and the overall prognosis and life expectancy.
- Effective management to meet the goals of care should be possible for most frail older adults.

HISTORY AND SYMPTOM ASSESSMENT

- Active case finding for urinary and faecal incontinence should be done in all frail older adults (GoR A).
- History should include comorbid conditions and medications that could cause or worsen incontinence.
- Physical examination should include a rectal examination for faecal loading or impaction (GoR C), functional assessment (mobility, transfers, manual dexterity, dressing and undressing ability, ability to toilet) (GoR A), a screening test for depression (GoR B), and cognitive assessment (to assist in planning and management, (GoR C)).
- The mnemonic DIPPERS (see urinary and faecal incontinence algorithms) cover some of these comorbid conditions. Note that genitourinary syndrome of the menopause does not cause urinary incontinence and should not be treated for this purpose (GoR B).
- The patient and / or caregiver should be asked about the degree of bother of urinary incontinence and/or faecal incontinence (GoR B); goals for urinary and faecal incontinence care (dryness, decrease in specific symptoms, quality of life, reduction of comorbidity, lesser care burden) (GoR B); and ability to undertake management, given the burden of care for any associated comorbid conditions (GoR C).
- Evaluation for bowel “red flag” symptoms (rectal bleeding, positive blood screening from stool studies, obstructive symptoms, recent onset of constipation, weight loss, and a change in stool calibre) will need more extensive evaluation (GoR A)
- Urinalysis is recommended for all patients (GoR C).
- Treatment of otherwise asymptomatic bacteriuria/pyuria is not beneficial (GoR C), except in the setting of planned GU surgery, and it may cause harm by increasing the risk of antibiotic resistance and severe adverse effects. e.g., Clostridium difficile colitis (GoR C).
- Stool studies may not be needed in all patients with faecal incontinence. Patients with diarrhoea, especially those with more acute onset diarrhoea, may need to be tested for infectious causes of their diarrhoea. Other stool studies could involve testing for malabsorption syndromes.
- The utility of the Clinical Stress test in this population is uncertain (GoR D).
- Wet checks can assess urinary incontinence frequency in long-term care residents (GoR C).
- A post voiding residual volume (PVR) test is impractical in many care settings and there is no consensus for the definition of what constitutes a “high” PVR in any population. A PVR measurement is not recommended in the routine initial assessment of frail older people with urinary incontinence.
- However, there is compelling clinical experiential evidence for PVR testing in selected frail older people with: diabetes mellitus (especially long standing); prior urinary retention or high PVR; recurrent UTIs; medications that impair bladder emptying (e.g., opiates); severe constipation; persistent or worsening urgency urinary incontinence despite antimuscarinic/beta-3-agonist treatment; prior urodynamics showing detrusor underactivity and/or bladder outlet obstruction or prior to antimuscarinic therapy (GoR C). Treatment of contributing comorbidity may reduce PVR. Trial with catheter may be considered for PVR > 200-500 ml if the PVR is felt to contribute to UI or urinary frequency (GoR C).
- Nocturia Assessment of frail older adults with bothersome nocturia should identify potential underlying causes including nocturnal polyuria (by bladder diary/frequency-volume chart or wet checks; oedema on examination) (GoR C), primary sleep problems (e.g., sleep apnoea); and low voided volumes (e.g., from high PVR).

- Stool impaction/loading. If suspected on digital rectal examination, an abdominal x-ray may be necessary to further evaluate the degree and location of impaction/loading in frail older adults.

CLINICAL DIAGNOSIS

The most common types of Urinary Incontinence in frail older people are urgency, stress, and mixed urinary incontinence. Frail older people with urgency urinary incontinence also may have detrusor underactivity during voiding with a high PVR but without outlet obstruction. There is no evidence that antimuscarinics are less effective or cause retention in this situation (GoR D).

The most common types of faecal incontinence in frail older people are related to urgency and passive leakage. Passive leakage can refer to leakage, seepage and staining following bowel movements that are not associated with faecal urgency and may also occur with faecal impaction. Because constipation and impaction often contribute to faecal incontinence in older adults, these are considered separately in the algorithm.

INITIAL MANAGEMENT

- Initial treatment should be individualised and influenced by goals of care, treatment preferences and estimated remaining life expectancy, as well as the most likely clinical diagnosis (GoR C). In some frail older adults, the only possible outcome may be containment for social continence, especially for people with minimal mobility (require assistance of > 2 people to transfer), advanced dementia and /or nocturnal urinary and faecal incontinence.

- Conservative and behavioural therapy for UI includes lifestyle changes (GoR C), bladder training for more fit alert persons (GoR B), and prompted voiding for frailer, more impaired older people (GoR A).

- For the select cognitively intact older person with UI or FI, pelvic floor muscle therapy can be considered, but there are few studies (GoR C). Antimuscarinics or mirabegron may be added to conservative therapy of urgency UI (GoR A-C, depending on agent).

- For the select cognitively intact older with FI, biofeedback may be considered, but few studies exist among frail older adults.

- Alpha-blockers may be cautiously considered in frail men with suspected prostatic obstruction (GoR C). All drugs should be started at the lowest dose and titrated with regular review until either care goals are met, or adverse effects are intolerable.

- DDAVP (vasopressin) has a high risk of severe hyponatraemia in frail older persons and should not be used outside specialist centres. or without very careful monitoring and long term follow up (GoR A).

- Improving stool consistency can be done with dietary fibre and supplementary fibre in older adults (GoR C). In older adults with diarrhoea, loperamide may be considered at low doses to improve stool consistency. However, close monitoring for constipation and impaction is needed.

ONGOING MANAGEMENT AND REASSESSMENT

Optimal urinary and faecal incontinence management is usually possible with the above approaches. If initial management fails to achieve the desired goals, the next steps are reassessment and treatment of contributing comorbidity and/or functional impairment.

In chronic intractable incontinence, in frail and/or physically impaired older adults or those with limited life expectancy or in receipt of palliative care, long term urethral or suprapubic catheterisation may be an acceptable pragmatic solution for containment. (GoR D)

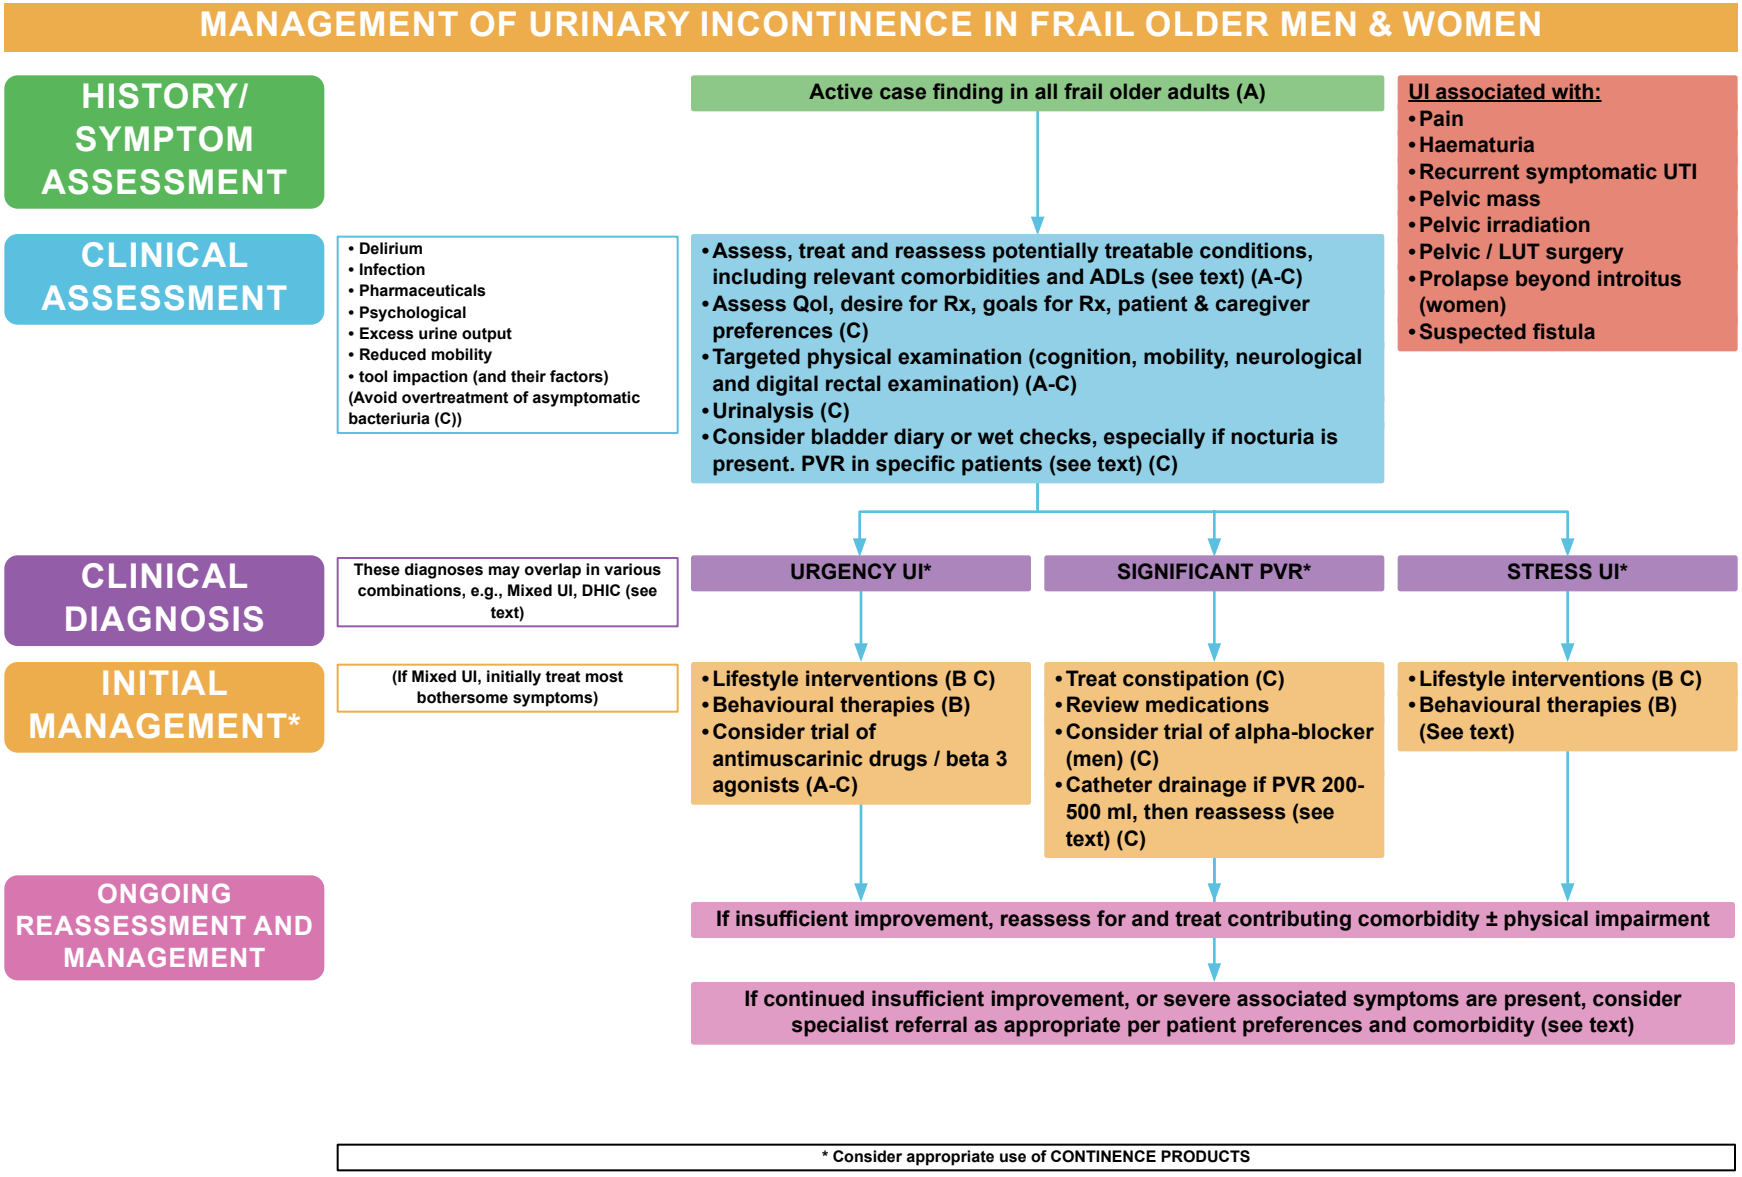
SPECIALISED MANAGEMENT

If frail older people have either other significant factors (e.g., pain, haematuria, bowel “red flag” symptoms), UI or FI symptoms that cannot be classified as urgency, stress, or mixed or overflow or other complicated comorbidity which the primary clinician cannot address (e.g., dementia, disability associated incontinence), then specialist referral should be considered. Referral may also be appropriate when there has been insufficient response to initial management. The type of specialist will depend on local resources and the reason for referral: surgical specialists (urologists, gynaecologists, colorectal surgeons), gastroenterologists, geriatricians or physical therapists (physical and cognitive impairment); or continence nurse specialists. Referral decisions should consider goals of care, patient/caregiver desire for invasive therapy and estimated remaining life expectancy.

Age *per se* is not a contraindication to UI or FI surgery (GoR C), but before sur- gery is considered, all patients should have:

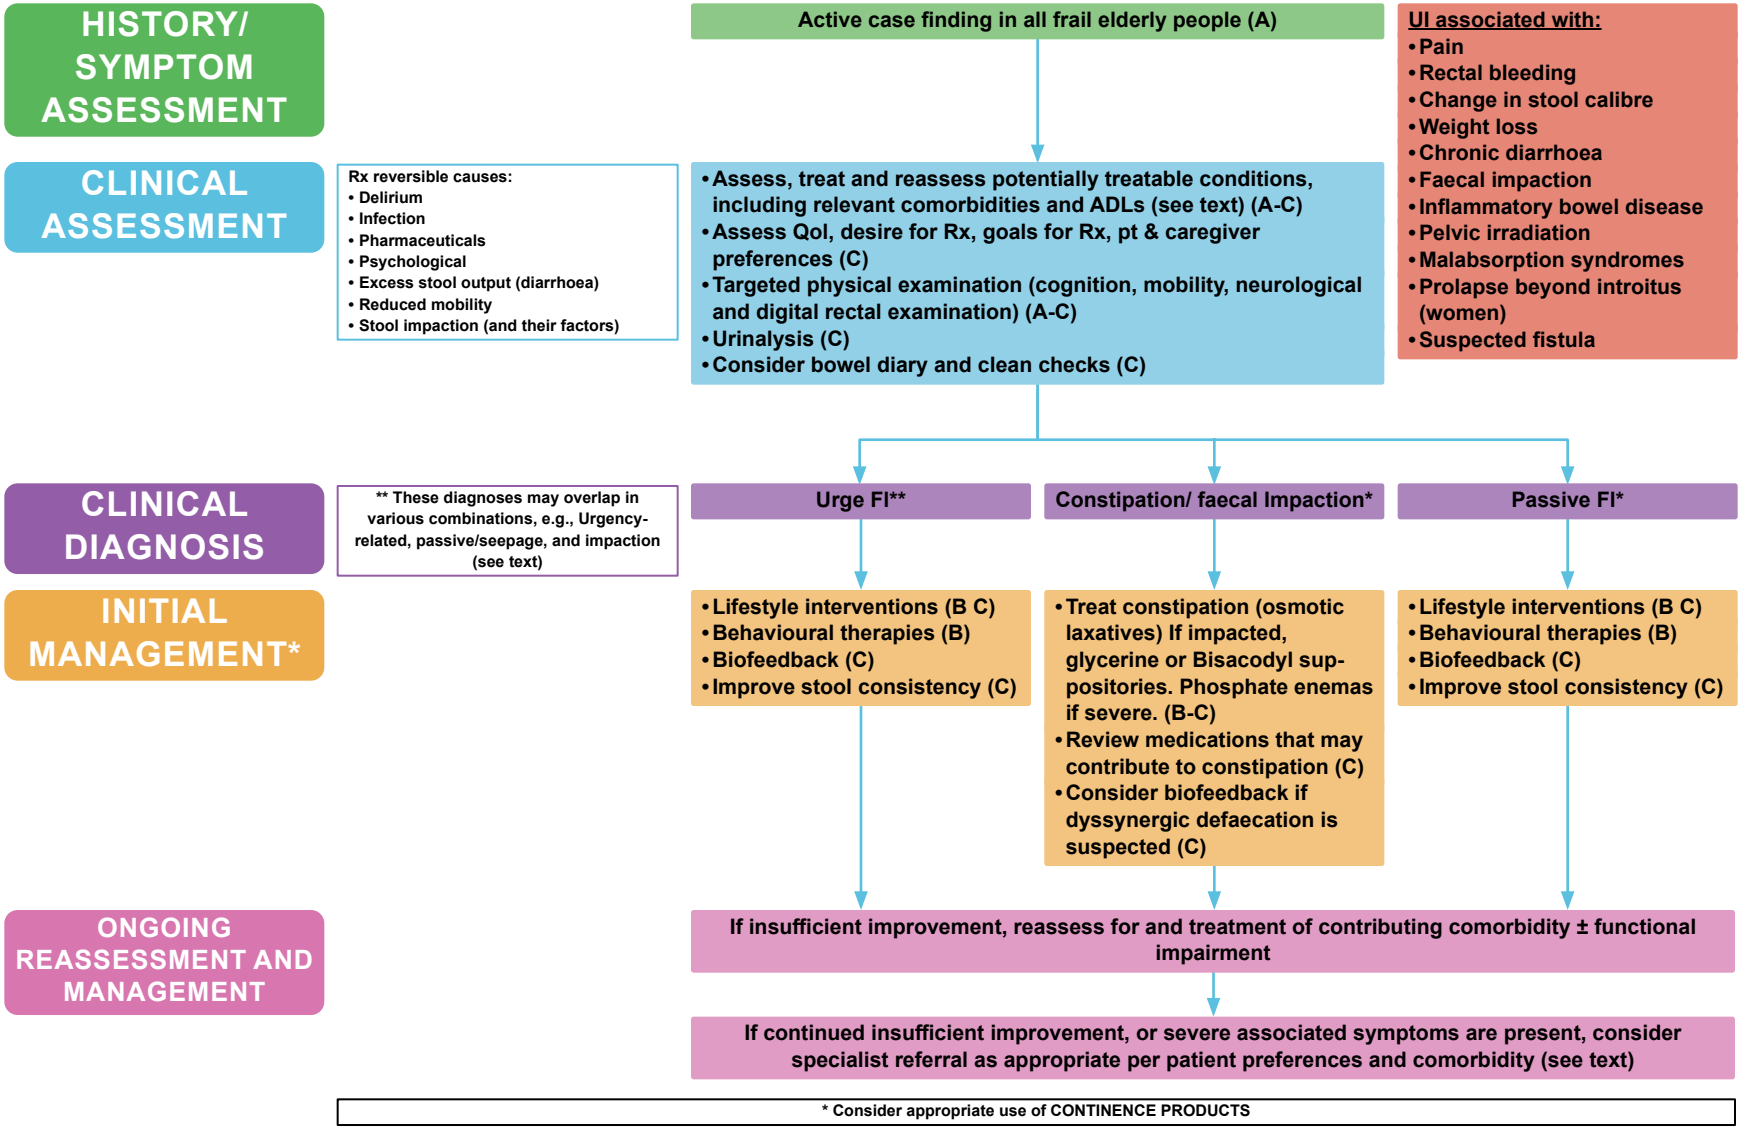
- Evaluation and treatment for any comorbidity, medications, and cognitive or functional impairments contributing to UI that could compromise surgical outcome (e.g., dementia that precludes patient ability to use artificial sphincter) (GoR C).

- Adequate trial of conservative therapy, including pharmacological therapies where relevant (GoR C).
- Discussion (including the caregiver) to ensure that the anticipated surgical outcome is consistent with goals of care in the context of the patient's life (GoR C).
- Urodynamic testing or imaging for fecal incontinence because clinical diagnosis may be inaccurate and prior to invasive surgery (GoR B).
- Preoperative assessment and perioperative care to establish risk of, and to minimise the risk of common geriatric post-operative complications such as delirium and infection (GoR A), dehydration and falls (GoR C).



MANAGEMENT OF URINARY INCONTINENCE IN FRAIL OLDER MEN & WOMEN
HISTORY/ SYMPTOM ASSESSMENT
Active case finding in all frail older adults (A)
UI associated with:
• Pain
• Haematuria
• Recurrent symptomatic UTI
• Pelvic mass
• Pelvic irradiation
• Pelvic / LUT surgery
• Prolapse beyond introitus (women)
• Suspected fistula
CLINICAL ASSESSMENT
• Delirium
• Infection
• Pharmaceuticals
• Psychological
• Excess urine output
• Reduced mobility
• tool impaction (and their factors)
(Avoid overtreatment of asymptomatic bacteriuria (C))
• Assess, treat and reassess potentially treatable conditions, including relevant comorbidities and ADLs (see text) (A-C)
• Assess QoI, desire for Rx, goals for Rx, patient & caregiver preferences (C)
• Targeted physical examination (cognition, mobility, neurological and digital rectal examination) (A-C)
• Urinalysis (C)
• Consider bladder diary or wet checks, especially if nocturia is present. PVR in specific patients (see text) (C)
CLINICAL DIAGNOSIS
These diagnoses may overlap in various combinations, e.g., Mixed UI, DHIC (see text)
URGENCY UI*
SIGNIFICANT PVR*
STRESS UI*
INITIAL MANAGEMENT*
(If Mixed UI, initially treat most bothersome symptoms)
• Lifestyle interventions (B C)
• Behavioural therapies (B)
• Consider trial of antimuscarinic drugs / beta 3 agonists (A-C)
• Treat constipation (C)
• Review medications
• Consider trial of alpha-blocker (men) (C)
• Catheter drainage if PVR 200-500 ml, then reassess (see text) (C)
• Lifestyle interventions (B C)
• Behavioural therapies (B) (See text)
ONGOING REASSESSMENT AND MANAGEMENT
If insufficient improvement, reassess for and treat contributing comorbidity ± physical impairment
If continued insufficient improvement, or severe associated symptoms are present, consider specialist referral as appropriate per patient preferences and comorbidity (see text)
* Consider appropriate use of CONTINENCE PRODUCTS

MANAGEMENT OF FAECAL INCONTINENCE IN FRAIL OLDER MEN & WOMEN



4. RECOMMENDATIONS FOR FURTHER RESEARCH IN EPIDEMIOLOGY

Much biomedical research is observational, and the reporting of such research is often inadequate which hampers the assessment of its strengths and weaknesses and of a study´s generalisability. The STROBE (Strengthening of the Reporting of Observational studies in Epidemiology) statement was introduced. It is a a checklist of items that should be addressed in articles reporting on the three main study designs of analytical epidemiology: cohort, case-control, and cross-sectional studies. The use of this checklist is highly recommended.

1. URINARY INCONTINENCE

It is recommended that more sustained research on measurement of UI should be performed including, its types and severity to move the research ahead. Longitudinal study designs are needed to estimate incidence of UI and describe the course of the condition and its different forms and to investigate its risk factors and possible protective factors.

There is still little knowledge regarding prevalence, incidence, and other epidemiological data in developing countries. A recent review on the global prevalence of UUI clearly showed that prevalence rates are unknown for many countries in the world. It is recommended that fundamental research regarding prevalence, incidence, and other epidemiological data in developing countries should be encouraged, and tailored to the cultural, economic and social environment of the population under study.

Crude prevalence studies (descriptive epidemiology) from USA and Europe are abundant, and further studies should be done only with recommended and validated questionnaires or to combine data from the prevalence study with studies of co-factors and predictors (analytical epidemiology). Control for confounders, stratification, and multivariate techniques should be increasingly used because of the need for more advanced epidemiological analyses of risk factors and comorbidity. Strength of associations should be determined by relative risks and odds ratios, and confidence limits should be given. We have still little knowledge of the absolute and relative importance of several risk factors, and almost no information about the attributable risk of the factors in the society.

Some potential risk and protective factors deserve more attention. For example, the role of pregnancy and childbirth in the development of UI must be studied in a fashion that links population-based methods to clinical assessment of pregnancy, delivery and the birth trauma and follows women over many years. Such a design is necessary because the effect of pregnancy and childbirth may become clear only years later when the woman is older and because the woman will not be able to report the exact nature of the tear or episiotomy, etc. There should be more emphasis on the associations between UI and specific diseases like stroke, diabetes, psychiatric disease and genital prolapse. Genetic components should be investigated.

Primary prevention is the main goal in the management of human disease. An important strategy would thus be to identify the individuals at risk, and then take measures to reduce the risk among those individuals or in certain risk groups. A predictive modelling system based on risk factors identified in population studies has been put forward. Primary prevention studies should be encouraged, but the epidemiological basis for choosing appropriate interventions is weak.

In surveys based on questionnaires or interviews symptoms can be registered. There are convincing data suggesting that the distinct types may reflect quite different pathologies and risk factors. Differentiating the types in future research might therefore prove very fruitful. Methodological work has still to be done in this area, but typical type descriptions should be included in new studies. Likewise, studies of risk factors should include important and known confounders such as age, parity, and weight.

Variations in definitions and measurement issues are fundamental and lead to problems with assessing the findings in epidemiological studies. We need to improve epidemiological studies by including variables that better characterise UI, so that more advanced and informative analyses may be conducted. It is therefore recommended that all epidemiological studies include a minimum data set, including elements of screening question, frequency measure, quantity of urine loss, duration, type, and severity. In addition, it is recommended that validated measures of bother/quality of life and LUTS other than UI should be included. We here also refer to the chapter from the committee on symptom and quality of life assessment.

In addition, it is recommended that validated measures of bother/quality of life and LUTS other than UI should be included.

2. FAECAL INCONTINENCE AND PELVIC ORGAN PROLAPSE

In these areas there is a need for more epidemiological research in all areas, prevalence, incidence, and risk factors. Many of the fundamental methodological issues relevant to UI discussed above are highly relevant to the fields of FI and POP.

The committee emphasises that uniform definitions of FI and POP should be used in studies, and there should be a move towards a standardization of measurement instruments in community surveys that can be used worldwide. Developing definitions is a scientific process requiring careful conceptualization of the condition considering its many clinical presentations and underlying mechanisms. This will require a multi-method approach and consideration of issues such a reliability and validity.

5. RECOMMENDATIONS FOR PRIMARY PREVENTION, CONTINENCE AWARENESS & PROMOTION, MODELS OF CARE AND EDUCATION

Primary prevention, continence promotion and advocacy, models of care and education involves informing and educating the public and health care professionals that UI and FI are not inevitable but are treatable or at least manageable. Other bladder disorders such as BPS/IC and POP can also be treated successfully. The committee found information about recent practice and research initiatives in all these areas but evidence-based research only on primary prevention of UI. Continence promotion and advocacy, and professional and non-professional education, require prioritisation by public health professionals, educationalists, clinicians and researchers to reduce the burden that UI, FI, BPS/IC and POP places on society, healthcare systems, caregivers, and above all, affected adults. As to models of care, the evidence supports nurse-led community services as leading to higher health-related QoL and in some instances, higher cure rates. The multidisciplinary referral settings are also reporting favourable outcomes.

PRIMARY PREVENTION

- Primary prevention of urinary and fecal incontinence remains in its nascent stage, but population aging, preventable obstetric incontinence outcomes, and significant advances in understanding bladder health and UI primary prevention are driving the need to develop effective primary prevention interventions across the human life-course. Foundational evidence has demonstrated that modifiable risk factors exist across multiple levels: intrapersonal, environmental, and societal. High quality RCTs are needed in men, women, and children at different life stages and across the life-course to develop evidence for the effectiveness of population and individual-level primary prevention intervention for UI and FI.
- Pelvic floor muscle exercises can prevent UI and FI in pregnant and postpartum women. (LoE: 1)
- Education designed for community dwelling older women can prevent UI. (LoE 1)
- Pelvic floor muscle exercises should be provided to pregnant women. (GoR A)
- Education to prevent UI for older women should be provided. (GoR : A)

CONTINENCE AWARENESS & PROMOTION

- Continence promotion is required to address broad gaps in knowledge about incontinence. This includes effective communication to and education of both HCPs and the public, through a variety of media, regarding UI and FI potentially affecting all age groups (LoE 3).
- Strategies to promote awareness about incontinence and its treatment can be strengthened using evidence-based theories and methods from the field of health promotion, including the social determinants of health (LoE 4)
- The internet represents an important source of information about incontinence, however the quality of information is variable (LoE 3)
- Evidence for the impact of continence advocacy worldwide was based on opinion (LoE 4) (No recommendation)

MODELS OF CARE

- Service delivery models for Continence Care can be effective. (LoE 4)
- A care delivery model should be based on the principles as described in the Optimum Continence Service Specification. (GoR C)
- Increased emphasis is needed on non-physician models of care (nursing, nurse practitioner, continence advisor, physiotherapy, physician assistants, etc.). (GoR: C)
- Despite the proliferation of guidelines, there is increasing evidence that practicing clinicians and nurses (in the community, acute care, and in long term care) are not consistently following them. Implementation models should be developed on how to translate guidelines into practice. (GoR C)

EDUCATION & CLINICAL GUIDELINES

- Professional and public education of UI, FI and POP is not evidence based on the materials reviewed (LoE: 3-4)
- There is a need for research on both educational content and methodology across all disciplines, particularly as the emphasis on primary care education increases and the opportunities for exposure to targeted content decreases GoR C)
- There is a need for additional research on interdisciplinary and team education, virtual education methods, and hands-on and simulation training related broadly to continence care (GoR C)
- There is a need for additional focused research on methods to enhance patient and public education about UI, FI, and POP, both at an individual and broader public level (GoR C)
- Research is needed to examine methods to improve efficiency of public education including group training, mass marketing, and other techniques (GoR C)
- The role of technology in public education for continence promotion should be examined in more depth (GoR C)
- Future research methodologies should incorporate the standardised methods and definitions as set out in new consensus and standardisation documents (GoR C)

- Guidelines for various aspects of continence evaluation and management have been established (LoE: 3 to 4)

- There is a need to continue to evaluate the quality and relevance of existing clinical guidelines, particularly in the context of updating these materials or creating new guidelines based on emerging evidence (GoR B)

- There is a need for additional research on guideline dissemination, awareness and adoption among clinicians, and the impact on a wide range of outcomes including incidence and prevalence of disease, treatment efficacy, prevention efforts, costs, and health care policies (GoR C)

6. RECOMMENDATIONS FOR PRIORITIES IN RESEARCH

A. PRIORITIES IN FUNDAMENTAL RESEARCH

Integrate data from reductionist experiments to inform the formulation of better systems-based approaches in the investigation of the pathology of the lower urinary tract (LUT), the genital tract (GT) and the lower gastrointestinal tract (LGIT) through:

- the development of animal models that accurately describe human pathological conditions, including the greater use of large-animal models
- the better use of reverse translational approaches for linking animal models to the human disease.

Encourage greater emphasis on basic research to characterise tissues receiving little attention: i.e., the lower gastrointestinal tract; the bladder neck and urethra; the ureter, pelvic floor musculature

Generate research programmes for foetal and neonatal research in LUT and LGIT function.

Use genome-wide bioinformatics and population health surveys to generate testable hypotheses regarding the physiological and pathophysiological functions of the LUT, GT and LGIT.

Generate improved experimental approaches to investigate the pathophysiology of the LUT and LGIT by:

- the use of human tissue from well-characterised patient groups.
- the development of emerging areas such as: tissue engineering; proteomics and metabolomics
- increased collaborations between biological, physical, and mathematical sciences.

Develop centres of excellence or consortia of excellence in LUT, GT and GIT research

integrate expertise from university departments, academic medical units and industry

Encourage translational approaches to research by development of inter-institutional research training programs to allow new researchers the opportunity to better interact and exchange ideas.

Additional emphasis on the importance of research to medical trainees and science graduates through:

- Establishing research training as a core component of postgraduate clinical development
- Increased access to support funds, especially scholarships and personal awards
- organisation of focused multidisciplinary research meetings, either stand-alone or as dedicated sessions during national and international conferences
- greater interaction between medical centres and Higher Education Institutions (HEIs).
- allowing researchers-in-training better access to international meetings through reduced registration charges and improved travel grants.
- inclusion in clinical meetings of point-counterpoint session(s) with both basic science and clinical viewpoints.
- development of research fora for exchange of ideas between active researchers and industry.
- lobbying research funding organisations about the medical and social importance of LUT and LGIT disorders.

Increase emphasis on research into LUT and LGIT in HEIs through greater representation on grant-funding agencies

B. PRIORITIES IN CLINICAL RESEARCH

1. RESEARCH PRIORITIES FOR TRIALS OF CONSERVATIVE TREATMENT

Use correct terminology to describe the intervention.

In trials of pelvic floor muscle exercise, report details of ability to perform correct contraction, dose-response issues and adherence.

Use recommended outcome measures with high responsiveness, reliability and validity.

Compare new methods with the best available intervention.

Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions.

For long-term follow-up studies report cross over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up

2. RESEARCH PRIORITIES FOR TRIALS OF PHARMACOTHERAPY

As effective drug therapy is available for most forms of incontinence, active drug comparator arms are recommended for most trials.

Long-term follow-up of RCT cohorts in an observational cohort is recommended.

Further studies focused on the anticholinergic load in frail older adults with OAB are recommended.

3. RESEARCH PRIORITIES FOR SURGICAL AND DEVICE TRIALS

An agreed and standardised technique for the surgical procedure or device application should be clearly defined

The safety and serious side effects of new operations or devices, especially implantable devices, and biologic materials, must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicentre cohort studies when RCTs are not practical.

Valid informed research consent is required in all trials of research surgical interventions; this research consent is separate from the main surgical consent.

Whenever possible, randomisation for surgical trials should occur at the time of surgery to minimise dropouts and switch of procedure

Reports of successful treatment should be limited to subjects with a minimum (not mean) of one-year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated.

Long-term follow-up of RCT cohorts in an observational cohort is recommended.

C. RESEARCH PRIORITIES FOR SPECIFIC PATIENT GROUPS

1. MEN AND WOMEN WITH LUTS

1.1. Men

Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is a potentially important variable, or to change during the intervention and follow up.

Maximum free flow rate and measurement of post-void residual urine should be recorded pretreatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. HIGH

Participants should be stratified by prostate size at randomisation when size is a potentially important determinant of treatment outcome.

Clinical evaluations of different male UI products, including strengths, limitations, and efficacy in clinically relevant subgroups.

1.2. Women

Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. HIGH

High quality, symptom and bother scores (e.g., ICIQ-FLUTS, KHO, PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes HIGH

Standardised assessment of pelvic organ pro lapse (by POP-Q) should be performed before treatment and at the time of other outcome assessments in all research where prolapse and continence outcomes are being assessed. HIGH

Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries, and pad tests.

Assessment of the impact of treatment on sexual function should be performed with other outcome assessments when appropriate.

2. CHILDREN, ADOLESCENTS & TRANSITIONAL CARE

Long-term follow-up is of critical importance in the paediatric population to ascertain the effect of a treatment on normal growth and development.

improve symptom-based classification to identify the degree of bladder and non-bladder symptoms.

Establish patient databases in different regions and conduct longitudinal follow-up to understand the natural history of the disease and to examine the differences in disease natural history among regions

Develop standardized outcome measures including validated, age specific symptom and disease specific quality of life outcome measures.

Research of problems specific to different age groups is needed. Especially, incontinence in preschool children and in adolescents is needed.

The transition and transfer from pediatric to adult care should be studied and evidence-based recommendations should be formulated.

Develop a practical multi-disciplinary care model and test it in various settings.

Develop an easy-to-use tool for non-specialists to readily identify co-morbid conditions that may impact on the need for additional consultation and suggest specific treatment pathways.

The specific incontinence problems of young adults aged 18-21 years need more attention in research.

Incontinence in children and adults with special needs is a neglected part of research and clinical care. These include individuals with intellectual disability, specific syndromes, autism spectrum and other disorders.

The interaction between brain and bladder and/or gut needs to be studied with new functional and structural imaging techniques of the CNS.

Treatment studies of daytime urinary incontinence, including pharmacotherapy and urotherapy, are needed.

The correlates of sleep in children with nocturnal enuresis needs to be elucidated in more detail.

Life span, longitudinal epidemiological studies from childhood to adulthood in a prospective design are required to procure representative data.

3. NEUROGENIC POPULATIONS

An area of high priority for research is the development of a more directly informative classification system which would include anatomical location and aetiology in association with corresponding urinary, faecal, and neurological symptoms, information from clinical neurophysiological testing and urodynamic abnormalities as well as prognostic biomarkers.

As such, the classification would describe a patient suffering from NLUTD and simultaneously inform about the most appropriate treatment, follow-up regimen, and long-term prognosis.

The thalamus may be a promising target for the development of new therapies for lower urinary tract dysfunction. Further investigation on this matter is needed before its potential role can be elaborated.

3.1. Diagnostics
Additional studies are needed to establish neurological populations and absolute indications for the use of invasive urodynamics as a primary and specialized assessment tool as well as to establish its best application for follow-up of treatment modalities

Research to establish what is 'urodynamic safety' in NLUTD, preferably by population studied

Identify clinical predictors of urodynamic findings in NLUTD

Further development of patient reported outcome measures needed in NLUTD

Further research into neuroimaging and its association with clinical neurourological practice

Further development and standardisation for the use of electrosensation tests to assess their role as a clinical test

Research to produce high level evidence to define UTIs in neurological patients

Need more evidence for the use of prophylactic antibiotics to reduce symptomatic urinary tract infections after invasive UDS

3.2. Management
Research into mechanisms and prognosis of the development of bladder cancer in patients with NLUTD

Further research on whether any CISC method or catheter type is advantageous

3.3. Pharmacotherapy
Further research is needed to establish the efficacy and safety of the newer antimuscarinics in NLUTD, long-term outcomes and safety, the efficacy and safety of mirabegron in NLUTD, as well as combination treatments

Oral and intravesical cannabinoid agonists should be further investigated for optimal balance between efficacy and safety

Further research on pharmacotherapy for detrusor-sphincter dyssynergia, sphincter deficiency and detrusor underactivity

3.4. Minimally Invasive Treatments
a. Botulinum Toxin

Further research is needed on long-term outcomes and safety, administration techniques, the bioequivalence of the various preparations, the concomitant use of anticholinergic drugs or beta-3 agonists, mechanisms of action, and wider effects

Future research should focus on PROs and patient satisfaction, tolerability, alternative techniques of application & ways to minimise posttreatment voiding dysfunction in patients who void freely

Larger studies in select patient populations are required.

b. Electrical Neuromodulation

Further studies on chronic pudendal nerve stimulation must be carried out to identify the best stimulation parameters and to verify the long-term results in patients with inadequate bladder emptying due to DBND, either as a first-line procedure or as a complementary approach to DBND following permanent urethral stenting.

controlled evidence is needed for the use of IVES to induce/improve bladder sensation and to enhance the micturition reflex in patients with incomplete central or peripheral nerve damage.

Research to establish indications for sacral neuromodulation in the care of DSD in neurological urinary dysfunction.

Effectiveness of tibial nerve stimulation (transcutaneous, percutaneous, and implantable)

c. Biomaterials

Preliminary results of bladder augmentation using biomaterials or tissue engineering is promising, but the need to be confirmed by larger studies.

3.5 Specific Neurological Conditions

There is a need for robust epidemiological research, insight into mechanisms, studies on utility of diagnostic tests, assessment of urinary tract risk factors, and randomised trials to assess benefits and harms of therapy for specific neurological diseases.

Urinary incontinence and faecal incontinence, both suffer from limited high-quality research. Priority research Topics include investigations into:

systematic cataloguing of the specific brain centres pertinent to lower urinary tract control, and how they are at risk in given neurological diseases

how medications for LUTS may influence specific neurological diseases or associated dysfunctions (e.g., blood pressure control)

The clinical relevance of functional brain imaging to clinical management

Indicators of neurological presentation or progression that may be first evident in urological clinics

Outcomes for interventions for detrusor sphincter dyssynergia.

4. RESEARCH PRIORITIES IN POPULATIONS AFFECTED BY BLADDER PAIN (INCLUDING INTERSTITIAL CYSTITIS)

Research that focuses identify bladder-specific pathology, a bladder pain syndrome-specific biomarker

Develop a simple, non-invasive diagnostic tools for Hunner Lesion Disease and Bladder Pain Syndromes BPS).

Research that focuses identifying specific pathology (the pathogenesis of a B-cell population abnormality in Hunner lesions) and biomarkers for HIC and NHIC/BPS.

Standardised methods of hydrodistension.

Research to develop a curative treatment for HLD and BPS.

Establish patient databases in different regions and conduct longitudinal follow-up to understand the natural history of the disease and to examine the differences in disease natural history between regions.

Develop a simple, non-invasive diagnostic test for BPS

Research that focuses identify bladder-specific pathology, a bladder pain syndrome-specific biomarker

Broaden the research scope to improve symptom-based classification to identify the degree of bladder and non-bladder symptoms.

Develop a practical multi-disciplinary care model and test it in various settings.

Develop an easy-to-use tool for non-specialists to readily identify co-morbid conditions that may impact on the need for additional consultation and suggest specific treatment pathways.

5. RESEARCH PRIORITIES IN POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

Uterine prolapse and its various treatment options

Surgery for recurrent prolapse

Identifying risk factors for recurrent prolapse

Re-evaluation of prolapse quality of life questionnaires to ensure they are sensitive to change

The utilisation and incorporation of tissue engineering in pelvic organ prolapse surgery

Impact of POP surgery on bladder overactivity.

Impact of POP surgery on urinary voiding dysfunction

Impact of rectocele repair on symptoms of obstructed defaecation and faecal incontinence

Impact of various types of POP surgery on OAB.

Impact of various types of POP surgery on SUI.

Impact of various types of POP surgery on urinary voiding dysfunction.

Impact of rectocele repair on obstructed defaecation and faecal incontinence.

Long-term follow-up of LUTs and other adverse events (including chronic pain and mesh extrusions) in cases treated with transvaginal mesh surgery.

Re-evaluate prolapse quality of life (P-QOL) questionnaires to ensure they are sensitive to changes after treatment.

Identifying risk factors and predictors for persistent/de-novo incontinence after POP surgery.

6. RESEARCH PRIORITIES IN FAECAL INCONTINENCE

Develop and test interventions for promoting care seeking and self-management of faecal incontinence (and associated odour and urgency)

Develop and test interventions for increasing coping skills and health literacy related to faecal incontinence for patients and family caregivers

Evaluate tailoring the management of faecal incontinence based on patients' goals, peer support, and the use of current technologies such as mobile devices for delivering management and support interventions to patients and family caregivers

Collect data on faecal incontinence, whenever practical, as part of research on urinary incontinence

Develop techniques for diagnosing faecal incontinence and its aetiologies using new and available diagnostic technologies

Develop user-friendly measures and instruments for quantifying the severity of faecal incontinence and other components of anal incontinence separately and in total

Investigate the epidemiology of the different types and subtypes of bowel and anal incontinence

Well-designed and adequately powered studies are needed to evaluate faecal incontinence treatment modalities currently available including:

- Effectiveness of lifestyle modifications including weight loss, exercise, diet and eating pattern modifications, and supplementing dietary fibre as an adjuvant or combined strategy

- Comparative effectiveness trials of instrumented biofeedback training versus neuromodulation

7. RESEARCH PRIORITIES IN ECONOMIC ANALYSIS

Cost analysis should be incorporated into clinical studies whenever possible.
