**FIGURE 1** Analysis of a 3-day bladder diary. On the first day, the person woke at 9 am (1), went to bed at 10 pm (3), and woke the following morning at 9 am (5). To calculate the first complete 24-h voided volume, we need to exclude the first morning void of Day 1 as that is part of the previous night's volume. Thus, the first 24 h voided volume includes the voids between points 2 and 5 (400 + 300 + 300 + 400 + 200 + 200 + 250 + 400 [1st morning void from Day 2]) = 2450 mL. The contribution of night-time voided volume is from point 4 to 5 (200 + 250 + 400) = 850. The nocturnal polyuria index (NPI) was 850/2450 = 35%. Nocturia is the voids between points 3 and 5 but excludes the voids at points 3 and 5 (so the voids at 2 am and 5 am), that is, nocturia was twice. For the second complete 24-h period, the voided volume should be taken from points 6 to 9, and totals 4050 mL. The nocturnal voided volume is from points 8 to 9, totaling 1050 mL. The NPI was 26% (1050/4050), and nocturia was twice (3 am and 6 am). This patient was 32 years old, so they had nocturnal polyuria (NPI >20% in a patient below the age of 65). Their body weight was 60 kg, so they also had 24-h polyuria (>40 mL/kg/24 h). A 3-day diary contains two complete 24-h periods and two complete nights, since there is no information to complete the third night (unless the patient keeps recording up until they wake on Day 4)

## 6 | EXPLAINING THE PROBLEMS

For anyone with nocturia, a basic interpretation of the bladder diary can be used to categorise likely contributory factors,<sup>10</sup> and thereby guide subsequent evaluation and treatment.<sup>11,12</sup>

- 24-h polyuria; caused by a range of medical problems, such as diabetes insipidus, salt loss, or poorly controlled diabetes mellitus. These people often report constant thirstiness.
- NP; caused by problems such as obstructive sleep apnoea or peripheral oedema.
- LUTD; generally associated with storage LUTS, and with increased bladder sensation scores on the bladder diary.
- Sleep disturbance; should be considered if the patient describes anxiety, restless legs, nightmares, and sleep-walking.

Simple behavioral tendencies should be considered, for example identification of a high fluid intake in someone who does not experience constant thirst. LUTD is actually a relatively uncommon explanation for nocturia in the wider population, so urologists or urogynecologists should identify the other possible situations and avoid urological or gynecological interventions, where not specifically indicated.

## 7 | ENURESIS

Enuresis is a symptom in which the patient complains of intermittent incontinence that occurs during periods of sleep. It is also a sign of “wetting” while asleep. This is not the same as waking with urinary urgency and having insufficient time to reach the toilet, which is urgency urinary incontinence.

Enuresis may have more in common with voiding dysregulation (urination in situations which are generally regarded as socially inappropriate) or involuntary voiding (sporadic bladder emptying when awake)<sup>13</sup> than nocturia. Thus, they must be clearly distinguished when both nocturia and enuresis are reported by a patient.

## 8 | CONCLUSION

The symptom of nocturia is present if the patient reports waking at night to pass urine and nocturia is also a sign indicated by the number of times an individual passes urine during their main sleep period. NP is present if the patient reports passing large volumes of urine at night, and this can be quantified with the nocturnal polyuria index. The bladder diary is an important diagnostic tool, helping identify 24-h polyuria, NP, LUTD, and sleep disturbance. Enuresis is distinguished from nocturia, as the patient fails to wake up for passing urine.

**Aims:** To introduce basic concepts and definitions in the International Continence Society (ICS) Standardisation of Terminology in adult Neurogenic Lower Urinary Tract Dysfunction (NLUTD).

**Methods:** Fundamental terminology in the ICS Standardisation of Terminology of Adult NLUTD was identified and summarized.

**Results:** NLUTD is often associated with impairment of cognitive, motor, sensory, and/or autonomic functions. Lesions are categorized into suprapontine, pontine/suprasacral spinal, sacral spinal, cauda equina/peripheral nerve, or mixed lesions. People affected with neurological disease are also at risk of the conditions seen in the general population, such as benign prostate enlargement. Symptoms of NLUTD include alterations in bladder or urethral sensation and incontinence. Loss of urine can result from incontinence, involuntary passing of urine and factors that impair toilet use, incorporating problems such as impaired cognition urinary incontinence, impaired mobility urinary incontinence, and voiding dysregulation. Signs may be discerned by physical examination and recording of a frequency volume chart or bladder diary. Urodynamic observations during filling cystometry may include altered sensations, neurogenic detrusor overactivity, and reduced bladder compliance. During pressure flow studies, there may be detrusor underactivity or bladder outlet obstruction (BOO). BOO may be caused by various forms poorly co-ordinated muscle activity in the bladder outlet. Symptoms, signs, and urodynamic observations may be useful in diagnosing the presence and specific location of neurological impairment.

**Conclusion:** The review provides a succinct summary of symptoms, signs, and urodynamic observations as set out in the ICS Standard on Adult NLUTD.

## KEYWORDS

incontinence, LUTS, neurological disease, standardization

## 1 | INTRODUCTION

Adult neurogenic lower urinary tract dysfunction (NLUTD) refers to abnormal or difficult function of the bladder, urethra

(and/or prostate in men) in mature individuals in the context of clinically confirmed relevant neurologic disorder. NLUTD is a key subgroup of the broad range of lower urinary tract symptoms (LUTS), due to the severity of the symptoms, and the implications of urinary dysfunction for wider health. The International Continence Society (ICS) categorizes symptoms, signs, urodynamic observations, and conditions

Alan Wein led the peer-review process as the Associate Editor responsible for the paper.

associated with lower urinary tract dysfunction (LUTD) in relationship to the storage and voiding phases of the micturition cycle. Neurological disease brings additional dimensions to the LUTD as experienced in the lives of affected individuals. The current document is a summary of core terminology in NLUTD for use in the wider context of LUTS in people known to have a neurological disease, or suspected of potentially having one which has not yet been diagnosed.

## 2 | METHODS

Recommendations in the ICS Standard on Adult Neurogenic Lower Urinary Tract Dysfunction<sup>1</sup> were reviewed and summarized. Definitions and key terms are generally transcribed verbatim and highlighted in bold. In the original document, many of the definitions are accompanied by explanatory or exemplary footnotes which have been adapted or excluded for the current review for the sake of brevity. Readers requiring more detailed information are referred to the full ICS Standard, and other documents produced by the ICS Standardisation Steering Committee.

## 3 | NEUROLOGICAL CONTROL

The nervous system controls many facets that are essential for the normal micturition cycle (storage and voiding). Particularly crucial are cognition (eg, decision making, anticipation, awareness of environment/social context, and conscious perception of sensation), motor functions (eg, mobility, balance, and dexterity), sensory nerve activity, and autonomic functions (eg, regulation of the detrusor and sphincter). The neurological functions act together to make sure that both urine storage and voiding reflect timings and contexts appropriately, with full voluntary control (Figure 1).

Neurological diseases are diverse and differ in terms of the parts of the nervous system affected (eg, the cognitive-predominant effects of dementia) and their behavior (eg, progressive, such as multiple sclerosis, or non-progressive, such as spinal cord injury). Thus, neurological disease may have differing effects on cognitive, sensory, motor, and autonomic functions which manifest in the specific NLUTD experienced by the patient. Inevitably, the consequences of neurological disease extend beyond LUTD, and mean that affected patients have a range of issues that influence treatment potential and health risk. Problems with bowel function, sexual and reproductive function, cognition, mobility, and blood pressure control are particularly relevant.

In describing the features of an individual patient's dysfunction, clinicians should appreciate the distinction between symptoms, signs, and urodynamic observations as

set out in the ICS Standardisation of Terminology of Lower Urinary Tract Function<sup>2</sup> (for summary see<sup>3</sup>). A summary of the classification of neurological lesions,<sup>1</sup> including the potential clinical and urodynamic features, is given in Figure 2.

## 4 | NLUTD SYMPTOMS

People with NLUTD may describe storage, voiding, and post voiding symptoms consistent with the definitions used for the general population.<sup>2,3</sup> Sometimes, a patient may not express that a symptom is present, so it is appropriate to discuss with the caregiver as well when establishing the presenting complaint. Storage symptoms may converge in **Neurogenic Overactive Bladder, which is a symptom syndrome characterized by urgency, with or without urgency urinary incontinence, usually with increased daytime frequency and nocturia in the setting of a clinically relevant neurologic disorder with at least partially preserved sensation.**

### 4.1 | Bladder and urethral sensation

Neurologically healthy people are intermittently aware of bladder sensations related to filling and voiding, and urethral sensation with voiding. Someone with NLUTD may describe alterations, for example:

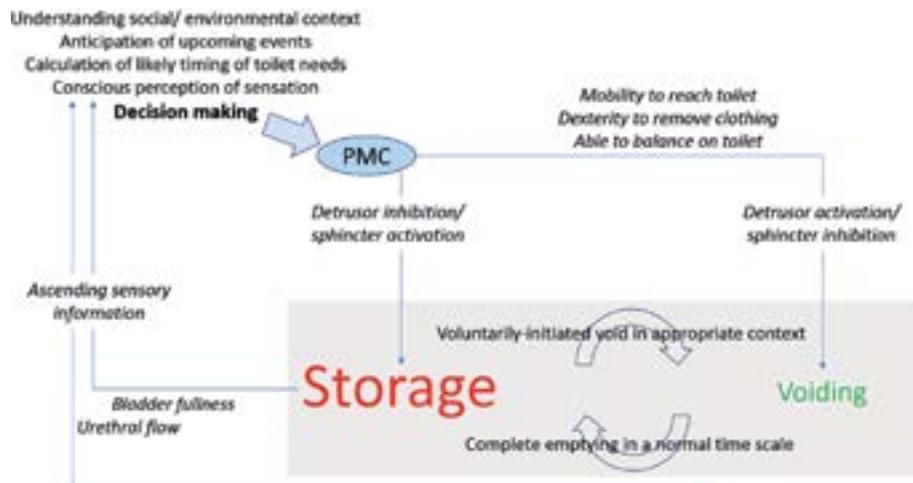

**Increased bladder sensation:** the desire to void during bladder filling occurs earlier or is more persistent than that previously experienced. **Reduced:** the definite desire to void occurs later to that previously experienced despite an awareness that the bladder is filling. **Absent:** the individual reports no sensation of bladder filling or desire to void. Such patients may have a significant post voiding residual in the bladder, without any sensation of incomplete emptying.

**Non-specific bladder awareness:** the individual reports no specific bladder sensation, but may perceive, for example, abdominal fullness, vegetative symptoms, urethral sensations, or spasticity as bladder filling awareness or a sign of bladder fullness. This may indicate that the usual sensory nerve pathways are not communicating centrally. Instead anatomical routes which do not usually contribute to everyday sensations may be intact and functional.

In addition, some people report they are unable to feel flow of urine along the urethra. They may report that they can only discern whether bladder emptying is finished by looking, or listening for the splash of urine in the toilet to stop.

### 4.2 | Loss of urine

Mature CNS regulation ensures storage (detrusor relaxation with outlet contraction) and the transition to voiding (detrusor

**FIGURE 1** The micturition cycle viewed from the context of the person's social and environmental context. PMC, pontine micturition center

contraction with outlet relaxation) is under voluntary control. Various situations in NLUTD may lead to a loss of urine:

1. Incontinence; categorized into stress urinary incontinence, urgency incontinence and mixed urinary incontinence, and reflecting LUT dysfunction. Definitions used in NLUTD are the same as those used in the general population.
2. Involuntary passing of urine; no LUT abnormality is necessarily present, but instead the voiding reflex may activate at times not consciously initiated by the patient. This may be during occasions generally considered socially inappropriate. It may reflect a dysfunction in the cerebrum, for example, a stroke or dementia. Abnormal voiding reflexes, or disinhibition, may result in the person passing urine without voluntary control.
3. Factors that impair toilet use, such as immobility, cognitive disability, and decreased motivation.

Thus, some additional incontinence definitions are standardized in NLUTD:

- **Impaired cognition urinary incontinence** is periodic urinary incontinence that the individual with cognitive impairment reports to have occurred without being aware of it.
- **Impaired mobility urinary incontinence** is inability to reach the toilet on time for voiding because of physical or medical disability. This inability includes (any combination of) the individual's physical as well as social causes or reasons. Other signs or symptoms of LUTD should not be present, or should be reported by the professional (as primary or as accessory) (eg, "Urgency urinary incontinence" with "mobility impairment"; or

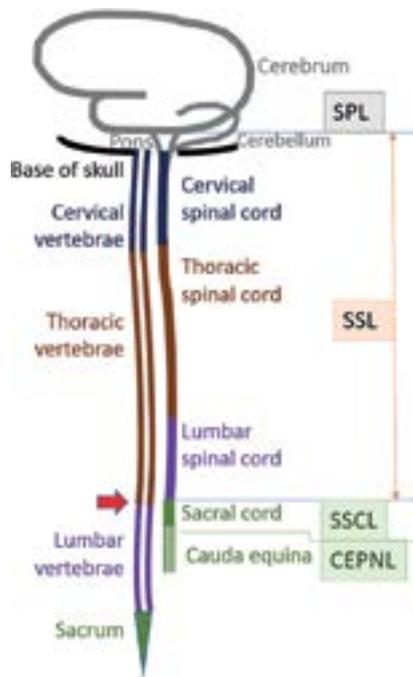

"Mobility impairment urinary incontinence" with "stress urinary incontinence.

- **Voiding dysregulation** is urination in situations which are generally regarded as socially inappropriate, such as while still fully dressed, or in a public setting away from toilet facilities.
- **Involuntary voiding** is both a symptom and a diagnosis of sporadic bladder emptying when awake, without intention to void. Usually the voiding reflex is preserved, and there is only lack of proper inhibition of the voiding reflex. If that happens when asleep it is called Acquired Enuresis.
- **Enuresis** is intermittent incontinence that occurs during periods of sleep. Enuresis is considered different from urgency urinary incontinence. Confirming the precise underlying mechanism(s) is often not possible in routine clinical practice.
- **Continuous (urinary) incontinence: complaint of continuous involuntary loss of urine.**

#### 4.3 | Signs

NLUTD evaluation incorporates the examination used for the general population, since people with neurological disease are the same risk of aging-related and other changes as any other person. Accordingly, physical examination must include abdominal, pelvic and perineal examination, and should elicit the following where present:

- Incontinence
- Pelvic organ prolapse
- Pelvic floor muscle function

**FIGURE 2** Classification of neurological lesions. Suprapontine Lesion (SPL) is a neurological lesion above the pons (forebrain or midbrain). NLUTD in SPL: there is a reflex contraction of the detrusor with impaired cerebral regulation and central inhibition and usually synergistic voiding/bladder emptying. Suprasacral spinal cord/pontine lesion (SSL) is a neurological lesion in suprasacral spine and/or pons. NLUTD in SSL: Detrusor overactivity (DO) and DO incontinence are common, with or without detrusor-urethral sphincter dyssynergia (DSD), often resulting in a significant post void residual (PVR) and “high pressure” bladder. Sacral Spinal Cord Lesion (SSCL) is a neurological lesion in the sacral spinal cord. NLUTD in SSCL; findings include acontractile detrusor with or without decreased bladder compliance and usually with impaired sphincter activity. Intrasacral (cauda equina and peripheral nerves) Lesion (CEPNL) is a neurological lesion affecting the cauda equina and/or peripheral nerves. NLUTD in CEPNL: acontractile detrusor and/or SUI may be present. Mixed Neuronal Lesion results from lesions of the neural pathway at different levels of the central nervous system concurrently. Note that in the adult, vertebral levels and spinal cord levels do not lie adjacent. Thus a T12/L1 prolapsed intervertebral disc (classified by its vertebral level) will affect the sacral part of the spinal cord (red arrow)

- Palpable bladder after voiding
- Pad testing

A frequency micturition chart, frequency volume chart, or bladder diary<sup>2</sup> is needed within the constraints of patient capacity or carer availability. This may be particularly

important in NLUTD, where the underlying condition may give rise to an endocrine dysfunction, such as central diabetes insipidus.

Physical examination is also used to identify signs which could point toward the localization of the exact neurological deficits caused by the responsible condition, for example, perineal numbness.

## 5 | URODYNAMIC OBSERVATIONS

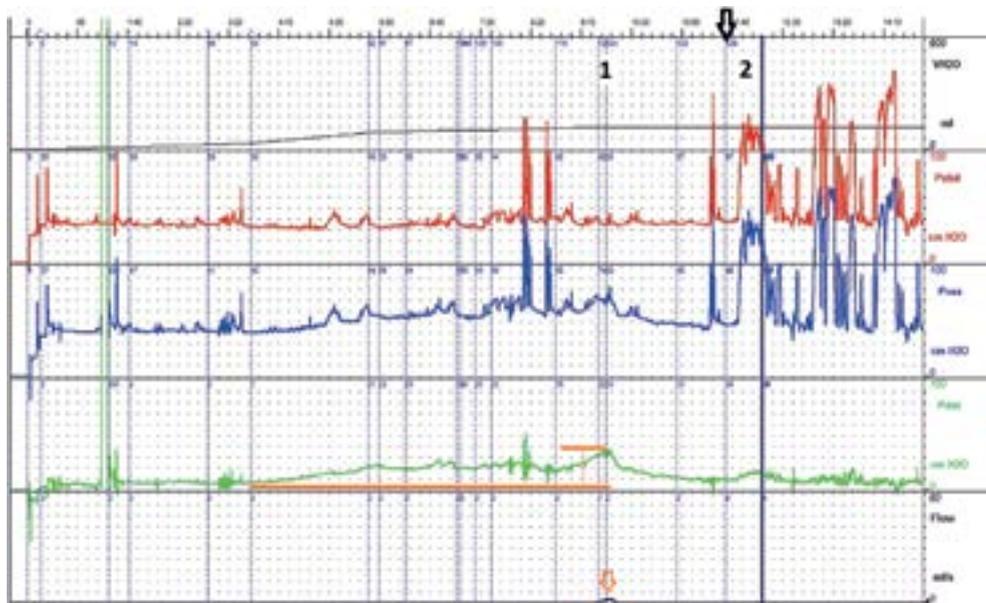

Bladder and bladder outlet function both need to be considered for a full understanding of a person's LUT. Since the pathophysiology is complex in NLUTD, and symptoms cannot be relied on for understanding mechanism, urodynamic testing provides a valuable insight into mechanisms and may identify observations that could indicate a risk to the patient's future health.

### 5.1 | Filling cystometry

- **Neurogenic detrusor overactivity** is characterized by involuntary detrusor contractions during the filling phase which may be spontaneous or provoked in the setting of a clinically relevant neurologic disease. Provoked contraction may be elicited by cough, change of position, etc., or by urethral/sphincter to bladder reflex. Neurogenic Detrusor Overactivity Incontinence is incontinence due to involuntary neurogenic detrusor overactivity.
- **Detrusor Overactivity Leak Point Pressure (DOLPP)** is defined as the lowest detrusor pressure rise with detrusor overactivity at which urine leakage first occurs in the absence of voluntary detrusor contraction or increased abdominal pressure. This is in contrast to Detrusor Leak Point pressure where urine leakage occurs in the absence of either a detrusor contraction or increased abdominal pressure.<sup>2</sup>

Reduced **bladder compliance** (the relationship between change in bladder volume and change in detrusor pressure<sup>2</sup>) is an important observation (Figure 3) in interpreting the clinical risk for renal function.

In neurogenic LUTD, the cystometric capacity cannot be defined in the same terms as for filling cystometry for the general population. In the absence of sensation, the cystometric capacity is the volume at which the clinician decides to terminate filling. The reason(s) for terminating filling should be defined in the report, for example, high detrusor filling pressure, large infused volume or pain. If there is uncontrollable voiding/bladder emptying, it is the volume at which this begins. In the presence of sphincter incompetence the cystometric capacity may be significantly increased by occlusion of the urethra, for example, by a Foley catheter balloon.

**FIGURE 3** Filling cystometry in a sacral spinal cord lesion (SSCL) showing reduced compliance; the lower orange line indicates the phase during which the detrusor pressure (green trace, second from bottom) is climbing, even though the filling rate is slow (10 mL/min). The upper orange line indicates the detrusor leak point pressure. The change in volume over this time was  $123-34 = 89$  mL, and the change in pressure was  $33-7 = 26$  cm H<sub>2</sub>O. Compliance (change in volume divided by change in pressure) was thus  $89/26 = 3.4$  mL/cm H<sub>2</sub>O. Detrusor Leak Point Volume (DLPV) is defined as a bladder volume at which first urine leakage occurs (1), either with detrusor overactivity or low compliance (orange arrow). The leakage is seen in the flow trace (black, bottom trace), and the leakage causes the elevated detrusor pressure to dissipate. The arrow indicates permission to void. However, there is no flow generated, and the patient does several Valsalva strains, shown by the substantial pressure rises in both abdominal pressure, and hence bladder pressure (2), signifying neurogenic acontractile detrusor. At time of urodynamics, neurological diagnosis had not previously been suspected, and subsequently he was identified to have multiple system atrophy

## 5.2 | Pressure flow studies

When passing urine, a slow stream may be explained by impaired detrusor contraction, bladder outlet obstruction (BOO), or a combination of both. Potential causes of neurogenic BOO include:

- **Non-relaxing urethral sphincter**, characterized by a non-relaxing, obstructing urethral sphincter resulting in reduced urine flow.
- **Delayed relaxation of the urethral sphincter**, characterized by impaired and hindered relaxation of the sphincter during voiding attempt resulting in delay of urine flow.
- **Detrusor-Sphincter Dyssynergia (DSD)**, which describes a detrusor contraction concurrent with an involuntary contraction of the urethral and/or peri-urethral striated muscle. Occasionally flow may be prevented altogether.

DSD is an indicator that the pontine micturition center is not communicating effectively with the sacral spinal cord, and occurs in people with a suprasacral spinal cord/pontine lesion. The term should not be used in other forms of NLUTD, and it is not a general term for neurogenic BOO.

Other causes of BOO present in the general population, such as benign prostatic obstruction, bladder neck obstruction, or urethral stricture in men, can also be present in people with neurological disease, and videourodynamics may be appropriate to discern the proximal site of BOO.

Impaired detrusor contraction can indicate:

- **Neurogenic detrusor underactivity**; a contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span in the setting of a clinically relevant neurologic disorder.

- **Neurogenic acontractile detrusor**; the detrusor cannot be demonstrated to contract during urodynamic studies in the setting of a clinically relevant neurologic lesion (Figure 3).

Balanced bladder emptying is a bladder emptying with physiological detrusor pressure and low residual as perceived by the investigator, and should be defined in the report.

## 6 | NLUTD CLINICAL DIAGNOSES

- **Spinal Shock Phase** is usually temporary following acute neurologic insult or SCI that is characterized by loss of sensory, motor, and reflex activity below the level of injury. NLUTD in Spinal Shock is usually a temporary complete painless urinary retention.
- **Autonomic Dysreflexia** is a syndrome resulting from an upper thoracic or cervical spinal cord injury above T6, elicited by a stimulus in the field of distribution of the autonomous sympathetic nucleus, characterized by unregulated sympathetic function below the lesion and compensatory autonomic responses. It is potentially a medical emergency characterized by hypertension, bradycardia, severe headaches, and flushing above, with pallor below the cord lesion, and sometimes convulsions. An increase of blood pressure without any other symptoms is called Asymptomatic Autonomic Dysreflexia.

**Urinary retention** is an inability to properly empty the bladder. Retention may be complete or incomplete:

- **Acute retention of urine** is an acute event of painful, palpable or percussable bladder, when the patient is unable to pass any urine when the bladder is full. Although acute retention is usually thought of as painful, in certain circumstances pain may not be a presenting feature, for example, when due to prolapsed intervertebral disc, post-partum, or after regional anesthesia such as an epidural anesthetic. The retention volume should be significantly greater than the expected normal bladder capacity.
- **Chronic retention** is a non-painful bladder, which remains palpable or percussable after the patient has passed urine. Such patients may be incontinent. Chronic retention, excludes transient voiding difficulty, for example, after surgery for stress incontinence, and implies a significant residual urine.

## 7 | DIAGNOSING NEUROLOGICAL DYSFUNCTION

In order to understand the full picture of the neurological deficit, the history may be used to identify features which could localize the site of a problem or suggest the causative condition and its behavior. Such observations can be helpful to a patient's neurologist in localising areas of deficit. These features are important in defining a patient's condition, since it guides subsequent testing (such as the anatomical sites and scan protocols for MRI). For example, retrograde ejaculation reported by a man who has not had bladder neck or prostate surgery may indicate a neurological deficit in the thoracolumbar spine or related peripheral nerves; this may be accompanied by visualization of an open bladder neck during videourodynamic filling cystometry. Signs can also help; for example, loss of the anal reflex indicates a lesion affecting the sacral spinal cord or its sensory or motor nerves.

In rare but important cases, urinary dysfunction may present for urological evaluation in a patient with no known neurological background whose ultimate cause may subsequently prove to be a neurological disease. This can occur for example in MS, normal pressure hydrocephalus, multiple system atrophy, and early Parkinson's disease.<sup>4</sup> Key symptoms include erectile dysfunction, retrograde ejaculation, enuresis, loss of filling sensation, or unexplained stress urinary incontinence.<sup>4</sup> If there is any suspicion that an undiagnosed neurological disease could be present, questioning should enquire about visual symptoms, back pain, anosmia, bowel dysfunction and incontinence, or memory loss.<sup>4</sup> Specialist evaluation is likely to be needed.

## 8 | CONCLUSIONS

NLUTD is categorized into: suprapontine; pontine/suprasacral spinal; sacral spinal; cauda equina/peripheral nerve; mixed lesions. Loss of urine can result from impaired cognition urinary incontinence, impaired mobility urinary incontinence, and voiding dysregulation. Urodynamic observations during filling cystometry may include altered sensations, neurogenic detrusor overactivity, and reduced bladder compliance. During pressure flow studies, there may be detrusor underactivity or bladder outlet obstruction (BOO). BOO may be caused by various forms poorly co-ordinated muscle activity in the bladder outlet. Symptoms, signs, and urodynamic observations may be useful in diagnosing the presence and specific location of neurological impairment.

**Aims:** Chronic pelvic pain (CPP) is defined as a noncyclical pain that has duration of at least 6 months and can lead to decreased quality of life and physical performance. The pain can be attributed to problems in the pelvic organs and/or problems in related systems, and possible psycho-social attributes may contribute to the manifestation. Due to the complex nature, CPP syndromes are multifactorial and the terminology needs to reflect the setting.

**Methods:** The current review is a synthesis of key aspects of the recent International Continence Society Standardization for Terminology in CPP Syndromes.

**Results:** Nine domains can be used for a detailed description of CPP. They include four domains specific to the pelvic organs (lower urinary tract, female genital, male genital, gastrointestinal), two related to other sources of pain which may be perceived in the pelvis (musculoskeletal, neurological) and three which may influence the response to the pain or its impact on the individual (psychological, sexual, and comorbidities). For an individual patient with CPP, each domain should be reviewed in terms of symptoms and signs, noting that positive findings could reflect either a primary cause or a secondary consequence. The findings will guide further evaluations and subsequent treatment.

**Conclusion:** We present a synthesis of the standard for terminology in CPP syndromes in women and men, which serves as a systematic framework to consider possible sources of pain (pelvic organs or other sources) and the individual responses and impact.

## KEYWORDS

## 1 | INTRODUCTION

CPP is defined as a noncyclical pain that has duration of at least 6 months, and it can lead to decreased quality of

life and physical performance.<sup>1</sup> The presentation can be a challenge to assess and treat. This is because the pain can potentially be attributed to several contributory factors, in the context of the varied nature of pain responses manifested by individuals. Healthcare professionals (HCPs) need to consider gynecological, urological, gastrointestinal, musculoskeletal, neurological, or

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

rheumatological factors, with possible psycho-social attributes. Due to its complex nature, CPP syndromes are multifactorial and the current terminology aims to standardize descriptions, regardless of which type of specialist is performing the evaluation.

**2 | METHODS**

A standard for terminology in CPP syndromes was developed in accordance with the International Continence Society (ICS) Standardization Steering Committee methodology.<sup>2</sup> The current review is a synthesis of the key aspects of the standard for practical use in everyday practice.

**3 | OVERVIEW**

For a patient presenting with pelvic pain, thorough history is crucial, including establishing that the pain has been present for at least 6 months, identification of any potential inciting event and/or triggers, character, radiation, and severity. An indication of the source of pain is vital, yet it can be obscured in individual cases by the range of possible primary sources and secondary consequences, and the varied responses. To ensure a systematic approach, the ICS sets out a series of “domains” which facilitate consideration of possible issues.

The domains of chronic pelvic pain (CPP) syndromes include four which consider the pelvic organs;

1. Lower urinary tract domain
2. Female genital domain
3. Male genital domain
4. Gastrointestinal domain

Two domains consider other sources of pain which may be perceived in the pelvis, even if the actual site of the problem may not be within the pelvis;

5. Musculoskeletal domain
6. Neurological domain

The final three domains relate to general factors that could influence the response to the pain or its impact on the individual;

7. Psychological domain
8. Sexual domain
9. Comorbidities

In any domain, features may be present as a result of a primary problem, or a secondary consequence. Each domain is evaluated with directed history-taking and a comprehensive physical examination done with a focus on the lower abdomen/pelvis to identify pain triggers and patterns of referred pain. The HCP can surmise the possible source of the

**TABLE 1** Lower urinary tract domain

Symptoms	Signs	Evaluation	Syndrome/Disease
Bladder			
Increased daytime frequency	Suprapubic tenderness	Questionnaires	Hypersensitivity bladder
Increased night-time frequency	Tenderness of bladder	Voiding diary	Interstitial cystitis/bladder pain syndrome
Urgency	Tenderness of the pelvic floor muscles	Urine analysis	Interstitial cystitis/Hunner lesion
Hypersensitivity		Optional: urine culture/ cytology Intravesical anesthetic challenge	
Pain, pressure, discomfort with filling		Urodynamics Cystoscopy (biopsy)	
Hesitancy			
Intermittency			
Feeling of incomplete bladder emptying			
Urethra			
Frequency/urgency painful urination	Tenderness of the urethra	Urine analysis	Urethral pain

**FIGURE 1** The endoscopic appearances of bleeding and ulceration during general anesthetic cystoscopy indicate that the lower urinary tract domain is a contributory factor in CPP, especially if there are pain reactions such as tachycardia, tachypnoea, and hypertension

pain, relevant additional factors, and potential secondary consequences. Specific assessment and treatment requires access to multidisciplinary support, and awareness of the initiatives and guidance developed by a range of organizations and expert groups.<sup>3-5</sup> Imaging, endoscopy and special tests may be needed for evaluation of each domain considered influential for a patient. With the individual evaluation in mind, further investigation and initial therapy can be planned based on the multidisciplinary support and up-to-date awareness of clinical recommendations and guidelines.

As an example, chronic prostatitis will be associated with history and examination features in the male genital domain (the primary site of the problem), and the lower urinary tract and musculoskeletal domains (where secondary problems such as increased urinary frequency and muscle spasms may be experienced). The full scope of impact on the patient may be further driven by issues in the psychological and sexual domains.

### 3.1 | Domains related to the pelvic organs

The lower urinary tract domain (Table 1) incorporates the bladder and urethra. The global definitions for bladder pain syndrome (BPS) and interstitial cystitis (IC) are not fully standardized, as several professional organizations have an interest in the area. Society for Urodynamics, Female Pelvic Medicine and Urogenital Reconstruction proposed the definition of IC/BPS as “an unpleasant sensation (pain pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than 6 weeks duration in the absence of other identifiable causes.”<sup>6</sup> For the bladder, patients may complain of increased urinary frequency (day and night), urgency, hypersensitivity, pain, pressure, discomfort, hesitancy, pain with filling, and sensation of incomplete emptying. The situation may be associated with relevant findings on general anesthetic cystoscopy (Figure 1). If the urethra is a significant contributor, pain is perceived usually when voiding and can be combined with a dull pressure that may radiate towards the groin or perineum.

The genital domains comprise the female genital domain (Table 2) and the Male Genital Domain (Table 3). Female patients may report pain with menstruation, abnormal bleeding, dyspareunia, vaginal discharge or itching, voiding/defecatory pain, and/or abdominal/pelvic pain. Pain mapping with a Q-tip is done to elicit localized areas of tenderness, which may be identified in the vagina or external genitalia. Generalized vulvar pain syndrome refers to pain/burning that cannot be localized by pain mapping. It is important to identify any ulcers, fissures, or cysts of the vulva. In addition, intra-abdominal signs related to the uterus and adnexa may indicate other pathology, such as fibroids, cysts, pelvic masses, endometriosis, or adhesive disease. These can present with uterine tenderness, cervical discharge or tenderness, or adnexal tenderness

Male patients may reports symptoms related to the lower urinary tract and sexual dysfunction. There may be complaints of dysuria, sensation of incomplete emptying,

**TABLE 2** Female genital domain

Symptoms	Signs	Evaluation	Syndrome/Disease
Vagina			
Dyspareunia Sharp burning and/or stabbing Provocation of pain with touch	Tenderness Erythema	Pain mapping Q-tip touch sensitivity	Vaginal/vulvar/perineal pain
Intraabdominal female genital			
Dysmenorrhea Abnormal uterine bleeding Dyspareunia Itching, stabbing, burning pain Cyclic (episodic or persistent)	Tenderness: uterine/adnexal	Laboratory testing Pelvic ultrasound Laparoscopy/biopsy CT-scan	Ovarian Pelvic congestion Uterine Tubal

**TABLE 3** Male genital domain

Symptoms	Signs	Evaluation	Syndrome/Disease
Pain	Tenderness on rectal/genital examination	Questionnaires	Prostate pain
LUTS	Urethral discharge	Culture	
Dyspareunia		PSA/biopsy	
Erectile dysfunction (Persistent) or episodic		Cystoscopy/biopsy	
		Ultrasound	
	Tenderness on physical examination	Questionnaires	Scrotal pain
	Scars	Ultrasound	Epididymal pain
			Testicular pain
			Penile pain

**TABLE 4** Gastrointestinal domain

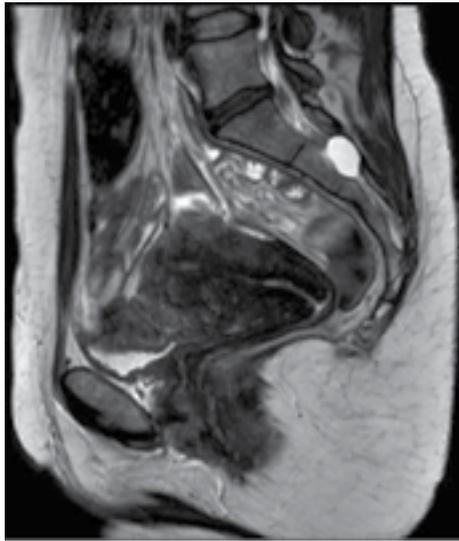

Symptoms	Signs	Evaluation	Syndrome/Disease
Pain with defecation	Tenderness on rectal exam	Questionnaires	Anorectal pain
Evacuation dysfunction		Culture	
Pain/pressure with sitting		Colonoscopy/biopsy	
Abdominal pain	Abdominal tenderness	Ultrasound CT/barium enema/MRI	Colorectal pain
Nausea	Bloating		
Constipation/diarrhea			
Persistent or episodic			

**TABLE 5** Musculoskeletal domain

Symptoms	Signs	Evaluation	Syndrome/Disease
Abdominopelvic pain	Altered muscle tone	Questionnaires	Pelvic muscle pain syndrome
	Tension: spasms	Pain mapping	Coccyx pain syndrome
Pain at rest, with movement/sitting/sexual activity	Stiffness	Ultrasound	Pelvic joint, ligament, bony pain
Pain with voiding/defecation	Trigger point tenderness		
Unilateral/bilateral	Taut band		
Persistent or episodic	Twitch response, referred pain		

**TABLE 6** Neurological aspects domain

Symptoms	Signs	Evaluation	Syndrome/Disease
Characteristic sensation of:	Tenderness (nerve distribution)	Questionnaires	Somatic neuropathic pain
Burning	Referred pain	Quantitative sensory testing	Complex regional pain syndrome
Throbbing	Possible skin change	Pain mapping	
Stabbing		Nerve block	
Shooting		imaging: Ultrasound MRI	
Electric shock-like Sensation			
paresthesia			
Atrophy			
Persistent or episodic			

**FIGURE 2** Observation of a sacral nerve root “Tarlov” cyst suggests the neurological domain may be a factor in a patient’s CPP

increased daytime frequency, change in urinary stream, urgency, and dyspareunia (assuming infection, surgical complications, or other pathology have been excluded). The assessment of CPP in males should prompt questioning to assess for onset, duration, inciting factors, laterality and any effect on urination and sexual function. A rectal examination is needed, and thorough evaluation of the genitalia, which may be performed in the supine and standing positions to identify any lesions, masses, and discharge.

Patients affected in the gastrointestinal domain (Table 4) commonly report constipation, diarrhea, defecatory pain, obstructive defecation, abdominal cramping, or rectal pain/pressure/burning. The main components are the anorectum or colorectum. Anorectal problems may result from hemorrhoids, abscesses, fissures, ulcers, levator ani syndrome, or chronic proctalgia. Colorectal problems may give rise to abdominal tenderness, watery/bloody diarrhea, or rectal bleeding and systemic features (weight loss and fever). Inflammatory bowel disease and malignancy must be excluded. Functional disorders should be ruled out, including irritable bowel syndrome.<sup>7</sup>

**TABLE 7** Psychological aspects domain

Symptoms	Signs	Evaluation	Syndrome/Disease
Worry	Helplessness	Formal psychological assessment	Worry/anxiety/fear/depression
Anxiety	Hopelessness	Asking patient what is wrong and what worries him/her about pain	
Fear	Avoidance of certain activities	Questionnaires	
Catastrophizing			
Persistent or episodic			

**TABLE 8** Sexual aspects domain

Symptoms	Signs	Evaluation	Syndrome/Disease
Lack of desire, arousal, orgasm	Depression	Questionnaires	Sexual dysfunction
Dyspareunia	Relationship issues	Laboratory	
Persistent or episodic		Doppler ultrasound	

**TABLE 9** Comorbidities

Symptoms	Signs	Evaluation	Syndrome/Disease
Allergies	Fatigue	General medical evaluation	Allergies
Fatigue	Skin lesions	Laboratory Imaging	Chronic pain and fatigue syndrome
Widespread muscular and joint pain	Dry eye		Systemic autoimmune diseases
Irritation of the eyes	Muscular skeletal tenderness		
Dryness			
Sleep disorder			

### 3.2 | Domains related to other causes of pain

Musculoskeletal problems are common, and sometimes are hard to localize for the patient. In CPP, they may be the principle cause of pain, or they may be consequential as the patient makes physical adaptations to deal with their primary problem (Table 5). Features that indicate a primary or secondary musculoskeletal problem include; tenderness, abnormal movement and alterations in the muscle (tone, stiffness, tension, spasms, cramping, fasciculation, and trigger points). Pain may originate from muscles, fascia, ligaments, joints, or bones, so familiarity with the anatomy and approaches to clinical examination is needed. Particularly key regions include;

- Muscular: the pelvic floor<sup>8</sup> (levator ani group/perineum), the lower abdominal wall, or posterior pelvic and gluteal regions.
- Joints, ligaments and bones: Coccyx pain syndrome, sacroiliac or pubic symphysis joints, sacrospinous or sacrotuberous ligaments, or the pubic ramus, ilium, and ischial spine

Where there is an issue in the neurological domain (Table 6), patients commonly use characteristic terms to describe pain (burning, stabbing, throbbing, tingling, stinging, electric shock-like) or they may report paresthesia. Somatic Neuropathic pain is secondary to a specific nerve injury, and is associated with symptoms related to the nerve distribution. In CPP, the relevant nerves could be sacral (Figure 2), pudendal, thoracolumbar, ilioinguinal, iliohypogastric, genitofemoral or obturator. A neuroma secondary to surgery or other trauma may give a localized tender point in the specific location, and if present should be identified and removed.

Complex regional pain syndrome (CRPS)<sup>9</sup> is a situation whose precise etiology is uncertain, but it can be categorized by burning pain and changes in the skin (increased sensitivity, and changes in skin temperature, color, and/or texture). CRPS type 1 is triggered by tissue injury without an underlying nerve injury and CRPS type 2 is attributed to a history of a nerve injury.

Pain in someone with a history of surgery which involved placement of synthetic is a specific issue. It can present as pain during physical activity, dyspareunia, vaginal discharge, and/or exposure of the mesh in the vagina or surrounding tissues.

### 3.3 | Domains affecting response or impact

Psychological aspects are an important element in the individual situation (Table 7). Patients may report symptoms of anxiety, worry, low mood, sleep disturbances, helplessness, hopelessness, difficulty concentrating, and pain impairing enjoyment. Alternatively, people close to the affected person may observe these features.

Sexual function may be affected by CPP in both men and women, and relationships may be affected (Table 8). Patients may report decreased libido, inability to become aroused, dyspareunia, and difficulty achieving an orgasm, and there may also be partner concerns. Several disorders can be identified;

- Sexual desire disorders; Hypoactive sexual disorder or Sexual aversion disorder
- Sexual arousal disorder
- Orgasmic disorder
- Sexual pain disorder

A comorbidities domain is also included (Table 9), as patients with CPP syndromes have a higher prevalence of problems such as allergies, chronic fatigue syndromes, fibromyalgia, and autoimmune diseases that may affect multiple systems.

## 4 | CONCLUSIONS

The current document extracts some of the pertinent elements that should be identified in order to understand fully the range of factors potentially present in CPP. The domain structure serves as a checklist to aid consideration of the several issues, and thereby ensure key relevant factors are not overlooked. The approach aids a logical sequence in considering the pelvic organs, other potential sources of pain, and factors that affect individual pain response and its impact.

**Aims:** To set out the basic description of pelvic organ prolapse (POP) using the International Continence Society/International Urogynecology Association Pelvic Organ Prolapse Quantification (POP-Q) system.

**Methods:** The basic approach to use of the POP-Q was identified and summarized.

**Results:** Six defined points in the vagina are identified; points Aa and Ba for the anterior vagina, Ap and Bp for the posterior vagina, and C and D for the cervix/vault. Point D is not used in women who previously had a hysterectomy. The patient is asked to strain, ideally when in the standing position, to elicit the POP to its maximum extent. The location of the defined points is then gauged relative to the hymenal ring and recorded on a grid. Three additional measurements are taken to achieve a full description; the genital hiatus length, perineal body length, and total vaginal length. Staging a POP relies on identifying the lowest extent of any part of the six defined points; if any point reaches close to the hymenal ring (at least stage 2), the prolapse is usually symptomatic.

**Conclusions:** The POP-Q system is readily cataloged and offers detailed description of considerable benefit in clinical practice and research.

## KEYWORDS

Pelvic organ prolapse quantification. POP-Q, Prolapse assessment

## 1 | INTRODUCTION

The International Continence Society (ICS), the American Urogynecologic Society, and the Society of Gynecologic Surgeons published a consensus document in 1996 to describing an objective system to describe female pelvic organ prolapse, which was called the Pelvic Organ Prolapse Quantification system (POP-Q).<sup>1</sup> This is the classification system that should be used to describe pelvic organ prolapse, as recommended by the ICS/International Urogynecology Association (IUGA) joint report on terminology for female

pelvic floor dysfunction.<sup>2,3</sup> The POP-Q has been used variably in both clinical practice and research.<sup>4,5</sup> The ICS/IUGA have recently made some suggestions to better define the disease of pelvic organ prolapse.<sup>3</sup> The aim of this article is to briefly summarize the key points in performing the POP-Q examination system to assist in its routine use.

## 2 | METHODOLOGY

The technique of performing the POP-Q has been described in detail in the ICS/IUGA documents.<sup>2,3</sup> We have summarized the key points that should be considered while performing the POP-Q examination.

Jan-Paul Roovers led the peer-review process as the Associate Editor responsible for the paper.

**TABLE 1** Showing the POPQ measurements (Adapted from Haylen et al<sup>2</sup>)**POPQ: Measurements**

The locations of the six defined points when the prolapse is fully reduced.

## Anterior vaginal wall:

- Point Aa:** A point located in the midline of the anterior vaginal wall three (3) cm proximal to the external urethral meatus. The potential range of position of Point Aa relative to the hymen is  $-3$ , indicating no anterior vaginal POP, to  $+3$  cm which is full prolapse
- Point Ba:** A point that represents the most distal (ie, most dependent) position of any part of the upper anterior vaginal wall (between the vaginal cuff or anterior vaginal fornix and Point Aa). Point Ba coincides with Point Aa ( $-3$  cm) in a woman who has no anterior POP. In a woman with severe POP, Ba coincides with Point C.

## Upper vagina:

- Point C:** A point on either the most distal (ie, most dependent) edge of the cervix or the leading edge of the vaginal cuff (hysterectomy scar).
- Point D:** The posterior fornix in a woman who still has a cervix.<sup>a</sup>

## Posterior vaginal wall:

- Point Ap:** A point located in the midline of the posterior vaginal wall three (3) cm proximal to the hymen. The potential range of position of Point Ap relative to the hymen is  $-3$  to  $+3$  cm
- Point Bp:** A point that represents the most distal position of any part of the upper posterior vaginal wall (between the vaginal cuff or posterior vaginal fornix and Point Ap).

## Three further descriptive landmarks and measurements.

- The **genital hiatus (GH)** is measured from the middle of the external urethral meatus to the posterior margin of the hymen.
- The **total vaginal length (TVL)** is the length of the vagina (cm) from posterior fornix to hymen when Point C or D is reduced to its full normal position.
- The **perineal body (PB)** is measured from the posterior margin of the hymen to the mid-anal opening.

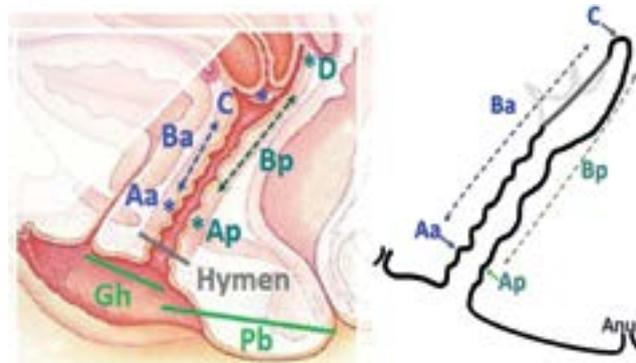

<sup>a</sup>Point D is included as a point of measurement to differentiate suspensory failure of the uterosacral-cardinal ligament "complex" from cervical elongation. When the location of Point C is significantly more positive than the location of Point D, this is indicative of cervical elongation which may be symmetrical or eccentric. Point D is omitted in the absence of the cervix.

**3 | RESULTS**

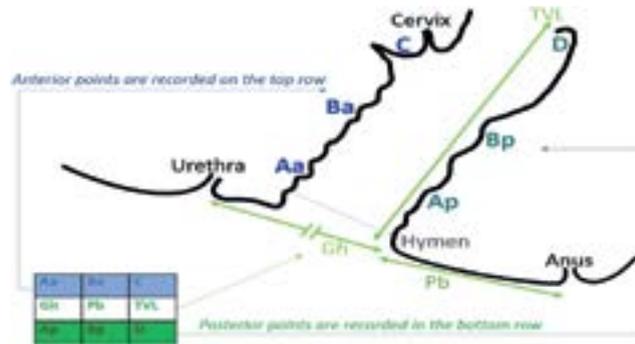

POP-Q can be performed using the following four steps:

Step1: Pre-procedure considerations

Examination should be performed with an empty bladder and if possible an empty rectum. A full bladder is potentially associated with underestimation of the POP-Q severity.<sup>6</sup> Any position that best demonstrates the maximum extent of the

**FIGURE 1** The six defined points used to quantify POP in women without (left) or with (right) a previous hysterectomy. Aa and Ap are 3 cm from the hymen when there is no POP, or any POP is fully reduced. POP-Q identifies where these points come to lie relative to the hymenal plane with the POP fully evident. Ba and Bp reflect the lowest point reached by a POP, relative to the hymenal plane. Any part of the vagina could potentially descend furthest, so Ba may lie anywhere from Aa-C. Bp may lie anywhere from Ap-D, or Ap-C in a woman post hysterectomy, from respectively reaching the locoincide with Aa and Ap in a woman who does not have POP. Three measurements complete the description; the genital hiatus (Gh), the perineal body (Pb), and the total vaginal length (not shown)

**FIGURE 2** How the six defined point and three measurements relate to a 3 × 3 grid used for clinical documentation. Gh, genital hiatus; Pb, perineal body; TVL, total vaginal length

prolapse and which can be confirmed by the woman, by digital palpation or use of a mirror, should be used (left lateral, standing, lithotomy, or standing). Use a Sim’s speculum if necessary to retract the anterior and posterior vaginal walls to assess for prolapse. The techniques and positions used should be recorded, as they may influence findings.<sup>7</sup>

Step 2: Measurements (“points to remember”) (Table 1, Figure 1):

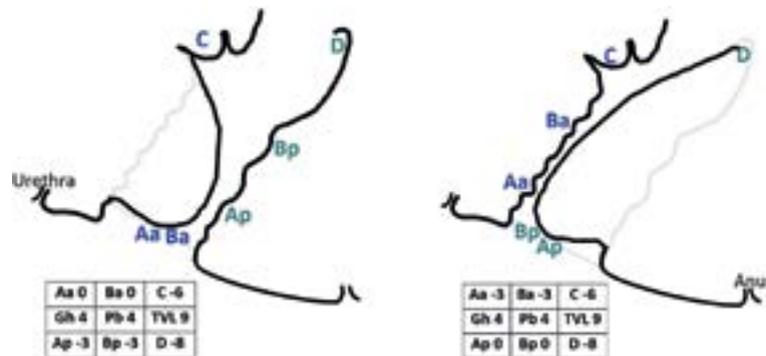

- There are six defined points (Aa, Ba, C, D, Ap, Bp) that are considered while recording the POP-Q, which are used to report the extent of descent or prolapse of the anterior vaginal wall, vaginal apex, and posterior wall.
- The positions of these six defined points are measured during maximal Valsalva or cough in relation to the hymen. If the point descends to the hymen it is measured as 0 cm, if it remains above the hymen it is measured in centimeters and described as negative integers and if it descends beyond the hymen it is

measured in centimeters and described as positive integers. For example, if point C remains 4 cm above the hymen during Valsalva/cough it is recorded as -4 cm. If point C descends 4 cm beyond the hymen during Valsalva/cough it is recorded as +4 cm.

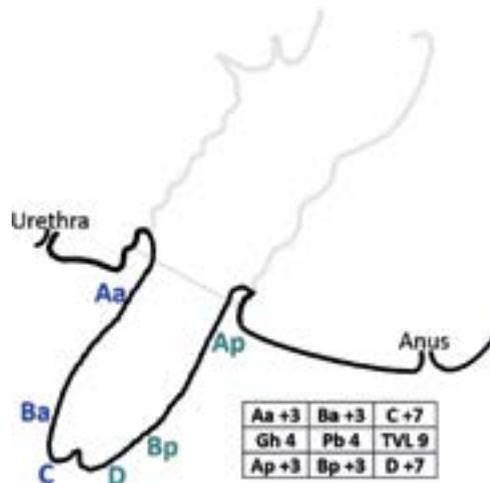

- There are three further descriptive measurements, which are also recorded independent of the hymen (genital hiatus-point GH, perineal body-point PB, and total vaginal length at rest-point TVL). Of note, all of the POP-Q points are recorded during maximal Valsalva or cough except for point TVL which is recorded at rest with the prolapse reduced.

Step 3: Recording the measurements (Figure 2):

The above measurements are recorded on a 3 × 3 grid. The anterior vaginal wall and the cervix or vault are documented on the top row, the posterior vaginal wall, and the posterior fornix on the bottom row. The descriptive measurements of the genital hiatus, perineal

**FIGURE 3** POPQ staging of a second stage anterior (left) and second stage posterior (right) vaginal wall prolapse

**FIGURE 4** POPQ staging of a stage 4 pelvic organ prolapse (procidentia)

body, and total vaginal length at rest are recorded in the middle row.

**Step 4: Staging of the prolapse**

Depending on the measurements, prolapse of each of the compartments is staged based on its relationship to the hymen.

- Stage 0: No prolapse is demonstrated (points Aa, Ba, C, D, Ap, and Bp are all  $\leq -3$  cm).

- Stage I: The most distal portion of the prolapse is more than 1 cm above the level of the hymen (points Aa, Ba, C, D, Ap, and Bp are all  $< -1$  cm).
- Stage II (Figure 3): The most distal portion of the prolapse is situated between 1 cm above the hymen and 1 cm below the hymen (any of the points Aa, Ba, C, D, Ap, and Bp has a value between  $-1$  cm and  $+1$  cm).
- Stage III: The most distal portion of the prolapse is more than 1 cm beyond the plane of the hymen, but not completely everted meaning no value is  $\geq TVL - 2$  cm (any of the points Aa, Ba, C, D, Ap, Bp is  $\geq +2$  and  $\leq tvl - 3$  cm)
- Stage IV (Figure 4): Complete eversion or eversion to within 2 cm of the total vaginal length of the lower genital tract is demonstrated (any of the Points Ba, C, D, or Bp is  $\geq TVL - 2$  cm).

The steps of performing a POP-Q are summarized in Figure 5 and some examples of POPQ recording and staging of various prolapse are demonstrated in Figures 3 and 4.

**4 | DISCUSSION**

Since its introduction in 1996, POP-Q has been used variably in peer-reviewed publications.<sup>8</sup> It may be perceived as complex, but it has shown good inter-observer agreement and is the most common system used in peer-reviewed literature.<sup>9-11</sup> It has been criticized as being too complicated, difficult to use, teach, and communicate.<sup>12</sup> Various approaches and tools have been used to teach POP-Q and have all been shown to be effective.<sup>13,14</sup>

**FIGURE 5** Practical aspects of performing POP-Q

#### 4.1 | Clinical relevance of POP-Q

Women with POP generally present with several complaints of bladder, bowel, and pelvic dysfunction; however, the symptom of a vaginal bulge is considered specific to prolapse and correlates well with the severity for the prolapse.<sup>15,16</sup> POP is generally considered to be symptomatic when the leading edge of the prolapse is at or beyond the level of the hymen ( $\geq$ stage 2 POP-Q).<sup>17</sup> Another study suggested that the prolapse becomes symptomatic if it descends lower than a level 0.5 cm above the hymen ( $\geq$ Stage 2 POP-Q).<sup>18</sup> Genital hiatus size is associated with and predictive of apical vaginal support loss.<sup>19,20</sup> These factors need to be taken in to consideration when diagnosing and offering treatment options to women with prolapse.

#### 5 | CONCLUSION

POP-Q is a useful way of objectively assessing and recording pelvic organ prolapse and helps in better communication of findings. Stage 2 or above POP-Q seems to correlate well with a symptomatic prolapse.

**Aims:** To review the recommendations on uroflowmetry in the International Continence Society (ICS) Standardization documents in order to identify a systematic approach to the delivery and interpretation of free flow rate testing in clinical practice.

**Methods:** Expectations of service and good practice in uroflowmetry described in the ICS standards on Urodynamic Practice, Urodynamic Equipment, and Terminology for Lower Urinary Tract Function were identified and summarized.

**Results:** Urodynamic centers should provide a suitable uroflowmetry testing environment. Equipment should be calibrated and maintained according to manufacturer requirements. Patients should be well-informed in advance of the test. They should be advised to avoid: knocking the machine; allowing the stream to move; squeezing the urethra; and body movements. It is generally appropriate to get more than one flow trace for each patient. Voided volume should be representative for the patient, for example by comparing with values recorded on a Bladder Diary. Post void residual (PVR) should be measured soon after testing. After the test, the urodynamicist should review the trace and ensure maximum flow rate and end of micturition are correctly identified in case the equipment has inappropriately taken the values from a trace artefact.

**Conclusions:** The summary provides a systematic approach to ensure a representative, high quality, non-invasive flow test is carried out for individual patients.

**KEYWORDS**

free flows, standards

## 1 | INTRODUCTION

Urodynamics is the general term to describe the measurements that assess the function and dysfunction of the lower urinary tract (LUT) by any appropriate method. In

the clinical assessment of LUT symptoms (LUTS), evaluating the nature of an individual's voiding is a fundamental component of the diagnostic pathway, especially for men. Uroflowmetry is a non-invasive urodynamic test in which specific measurements are made of the rate of flow of urine and the volume voided. It is normally followed by an ultrasonically scanned measurement of post void residual (PVR) urine volume, and an interpretation of the flow pattern recorded by the machine over the duration of the void.

The work was undertaken at Bristol Urological Institute, Southmead Hospital, Bristol, UK.

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

A recent think tank on uroflowmetry<sup>1</sup> recommended that specific, practical guidance be made available to increase the quality of uroflowmetry testing. Accordingly, the current article reviews the recommendations on uroflowmetry in the International Continence Society (ICS) Standardization documents in order to identify a systematic approach to the delivery and interpretation of free flow rate testing in clinical practice.

## 2 | METHODS

The ICS, through its Standardization Steering Committee (SSC), has an ongoing strategy to standardize LUT terminology and functional assessment, and link it to published evidence.<sup>2</sup> We reviewed key expectations of service and good practice in uroflowmetry described in the ICS standards on Urodynamic Practice,<sup>3,4</sup> Urodynamic Equipment,<sup>5</sup> and Terminology for LUT Function.<sup>6,7</sup> The current document is a synthesis of the key aspects applicable to uroflowmetry.

## 3 | GENERAL COMMENTS

A good urodynamic practice comprises: a clear indication for, and appropriate selection of, relevant test measurements and procedures; precise measurement with data quality control and complete documentation; accurate analysis and critical reporting of results. These general principles apply to all forms of urodynamic testing, including uroflowmetry.

Departments should develop uroflowmetry protocols on the basis of the ICS Urodynamic standards,<sup>3–5</sup> they should facilitate specific staff training and undertake regular evaluation of performance and adherence.<sup>3</sup> ICS Terminology Standards should be used when alluding to LUT symptoms, signs, and urodynamic observations.<sup>6,7</sup> Equipment should meet the requirements of the ICS guideline on equipment performance.<sup>5</sup>

Uroflowmetry is a test that measures the urinary stream as volume passed per unit time in milliliters per second (mL/s).<sup>4</sup> Maximum flow rate ( $Q_{max}$ ) and total volume voided must be reported.<sup>4</sup> The PVR should also be reported. This is the remaining intravesical fluid volume determined immediately after completion of voiding. The technique (eg, ultrasound or catheter) used to measure the PVR should be specified.

## 4 | EQUIPMENT AND ENVIRONMENT

The basic set up for a flow test environment is illustrated in Figure 1. The requirement of a uroflowmeter is that it can continuously measure the flow rate of urine voided and the total volume voided. The method used to make this measurement is not clinically significant. Accuracy need only

be to  $\pm 1$  mL/s of true flow rate and to  $\pm 5\%$  of true volume voided (or  $\pm 2$  mL if that is greater than 5%).<sup>5</sup>

Units should regularly check the performance of their system and calibrate according to manufacturer recommendation.<sup>5</sup> Flowmeter calibration can be verified by pouring a precise volume into the flowmeter and checking the recorded volume. Calibration should be verified regularly, for example, at the start of every clinic or week of clinics, and documented. If frequent recalibration is necessary, the flow transducer might need to be replaced.

Uroflowmetry equipment should be placed in a private, quiet environment<sup>3</sup> that can be easily cleaned, with the machine ready for immediate use, as many LUTS patients having flow rate testing will experience urgency. PVR measurement is ideally done in the same room and immediately following the void. A sluice room with connecting door to the flow test room is preferable to an unconnected room.

## 5 | PREPARATIONS IN ADVANCE OF A UROFLOWMETRY TEST

An explanatory leaflet about uroflowmetry with sufficient information, which uses clear, unambiguous wording, will be appreciated by most patients. To reduce possible waiting time, patients can be asked to attend the clinic with a comfortably full bladder.

When sent the explanatory leaflet, the patient can also be asked to complete a frequency volume chart (FVC) or Bladder Diary. A FVC records the time of each micturition and the voided volumes, while a Bladder Diary also captures symptoms and events such as fluid intake, urgency, pain, incontinence episodes, and pad usage.<sup>6,8</sup> Average and maximum voided volumes, voiding frequency, and day/night urine production can be determined.

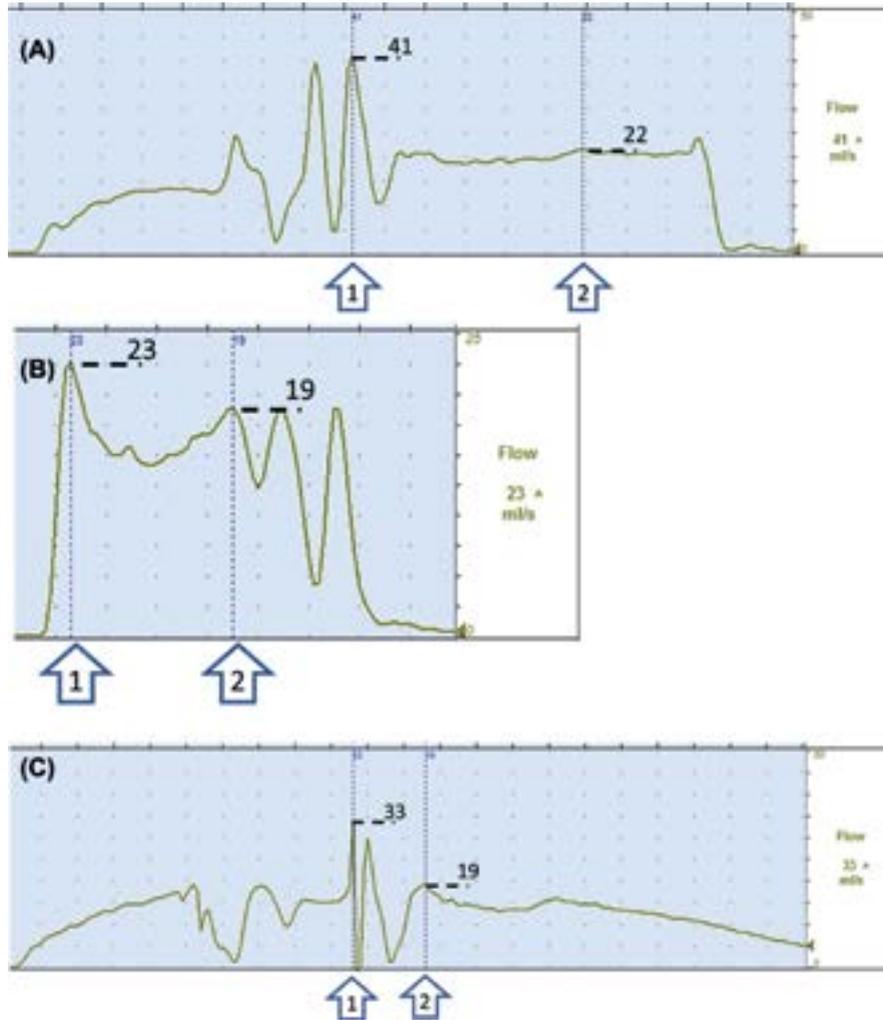

**FIGURE 1** A suitable environment for uroflowmetry. The flowmeter can be accessed quickly from the waiting area if the patient experience urgency, achieves privacy (here by having a curtain in addition to a locked doorway), is easy to clean, and has direct access to a sluice room (not in above picture). Female uroflowmetry would have a commode seat in addition to the funnel

## 6 | FLOW RATE TESTING

Patients should be asked to pass urine when they feel a “normal” desire to void,<sup>4</sup> and should undergo uroflowmetry in their preferred position. Intracorporeal modulations of the

flow rate should be minimized, for example, by asking the patient to relax and not to strain.<sup>4</sup> Men should be asked not to move the urine stream around the funnel, and not to squeeze the penis, both of which will affect the flow rate measurement (Figure 2).<sup>7</sup>

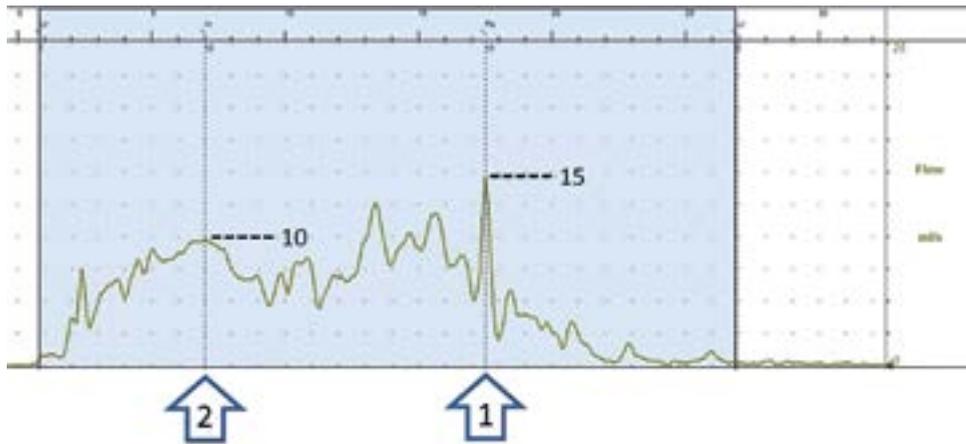

**FIGURE 2** Some artefacts encountered in uroflowmetry, and the importance of correcting for the error in  $Q_{max}$  to establish the representative parameter. A, A male patient moving the urine stream back-and-forth across the funnel. B, A male squeezing and releasing the urethra at the start of flow, with straining toward the end of flow. C, A “knock artefact” (arrowed), resulting from a patient inadvertently kicking the uroflowmetry machine. In each case, the uroflowmetry machine has given a  $Q_{max}$  value which is a result of the artefact, displayed on the right hand side, and taken from the point marked with arrow “1.” This is not representative of the patient’s own function, so the urodynamicist has scrutinized the trace after the test and selected the highest point in the trace that does appear to result from the patient’s own unimpeded bladder and outlet behavior, at the point marked with arrow “2.” This means the representative values change, for instance in A from 41 to 22 mL/s, which may well result in a clinically significant difference in interpretation. Before a flow test, the patient should be instructed to keep his stream in the same part of the funnel, not to squeeze his penis, and try to avoid knocking the machine

**TABLE 1** Task list to assist good practice in uroflowmetry

Task No.	Good practice question	If “No,” correction needed
1	Has equipment calibration been checked?	Check calibration
2	Is the patient aware of the reason for the test and what is required of them?	Explain to patient
3	Has the bladder diary been completed and examined?	Discuss with patient to gain estimates
4	Does the patient have a normal desire to void?	Wait until normal desire
5	Is the equipment set at the right height and position?	Adjust to suit patient
6	After the void, has urinalysis been carried out?	Perform urinalysis
7	Is the void known to be a representative normal void?	Repeat flow test after drinking
8	Is the trace clear of artefacts from movement of body, flowmeter or urine stream?	Adjust trace markers if possible, and instruct patient for improved next flow
9	Is $Q_{max}$ marked at a point away from artefacts?	Move $Q_{max}$ marker to smoothed maximum position
10	Are the markers for start and end of void away from artefacts or drops of urine?	Move markers away from artefacts
11	Does the scale of printing make the flow trace clearly visible?	Adjust scale of display/print
12	Has the residual urine volume been measured immediately after voiding?	Measure volume, including comment on any time delay
13	Does the report include: $Q_{max}$ , voided volume, residual volume, Void%, flow and voiding times, flow trace shape description, whether flow is representative? The report may also include if required: Clinical history summary, urinalysis, bladder diary summary and any lifestyle advice given.	Complete report

Practitioners should check if the voiding is representative, based on the patient's report, and comparing with other information, such as Bladder Diary volumes. Increasing bladder volume increases the potential bladder power,<sup>4</sup> notably in the

range from empty up to 150-250 mL. At volumes higher than 400-500 mL, the detrusor may become overstretched and contractile strength may decrease. Thus, interpretation should evaluate the bladder volume at time of testing (voided volume plus PVR).

**FIGURE 3** Example of a female patient who may have some pelvic floor contractions during voiding, leading to the uneven shape of the curve. This patient may also have moved about on the commode seat, giving rise to the particularly sharp spike. The computer-generated report reads  $Q_{max}$  = 15 mL/s, taking the value at arrow “1.” After the test, the urodynamicist identified this is not representative, and moved the cursor to the position of arrow “2;” where a portion of the flow unaffected by pelvic floor contraction and patient movement suggests an interpretable and representative flow.  $Q_{max}$  value was accordingly corrected to 10 mL/s, and should be recorded as such, with comment on whether the flow was representative

Consider repeating the uroflowmetry if the result has not been representative for the patient or it indicates abnormality, with reasonable fluid intake and diuresis time before the flow is repeated.<sup>9</sup>

A list of tasks to aid good practice is contained in Table 1.

## 7 | QUALITY CONTROL

Several artefacts can occur which are readily identified: knocking of the flowmeter (Figure 2C), passing of feces or disposal of tissues result in high, sudden values of flow rate and/or volume. If such fast changes are observed and confirmed with the patient, instruction of the patient will improve the next flow test.

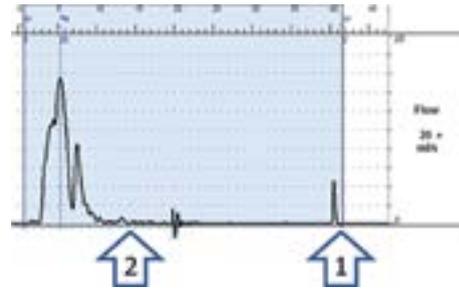

Moving the urine stream back and forth across the funnel results in phasic variations around the true flow rate (Figure 2A). Some men have developed the habit of squeezing the penis to build up pressure, in order to give a faster flow after release. This “squeeze and release” habit gives gaps in the flow followed by high flow rate spurts, illustrated in Figure 2B. In both cases, the patient should be instructed not to do so, in order to better evaluate the LUT itself. For some patients, pelvic floor muscle action or body movement can result in smaller, artefactual variations in flow rate, see Figure 3. Uroflowmetry machines will automatically, and perhaps wrongly, measure the highest peak of flow, rather than smooth out the flow rate to remove these artefacts. Accordingly, in each of these situations, the operator will need to move the  $Q_{\max}$  marker to a nearby point, or smooth the flow signal by eye, in order to establish the clinically representative value (Figures 2 and 3). A moving average using a 2 s window is advised.<sup>3</sup>

If the flow and voiding times are being reported, the operator will need to check that the end of flow is correctly marked by the machine. If drops due to coughs or other movement are included in the voiding time, the final marker will need to be moved back to the true end of micturition (Figure 4) and only then should the time values be recorded.

## 8 | REPORTING

All results and observations should be carefully reported. It is good clinical practice to integrate the uroflowmetry results with the history, examinations and Bladder Diary summary. A urinalysis should also be evaluated and reported with the flow results, since current urinary tract inflammation could alter the patient's flow characteristics.

The report after uroflowmetry should include; voiding position,  $Q_{\max}$  (corrected for any artefacts), voided volume and PVR. Flow time and voiding time may be reported if required. The ICS suggests a standard reporting format of “VOID: Maximum Flow Rate/Volume Voided/Post Void Residual

**FIGURE 4** Similar to correcting the  $Q_{\max}$  value after a test, the indicator identifying the end of micturition may need to be moved, from the point marked by arrow “1” to the point marked by arrow “2” arrow, if the patient experiences a post micturition dribble, or if the machine gets knocked as the patient moves away

Volume,” where flow rate is rounded to the nearest integer and volume rounded to the nearest 10 mL.<sup>3</sup> Scaling of the printout has been suggested as follows: 1 mm can equal 1 s on the x-axis and 1 mL/s and 10 mL voided volume on the y-axis,<sup>3</sup> but the trace must be clearly readable whatever scale is used.

Nomograms have been produced (summarized in Gammie et al<sup>1</sup>) that show the likelihood of the  $Q_{\max}$  and voided volume recorded resulting from a normal urinary tract. Clinicians must be aware that these nomograms are not diagnostic, but may be a useful screening tool for dysfunction.

Comment may also be made when reporting on the voided percentage (Void%) and the flow curve shape. Void% is the numerical description of the voiding efficiency, which is the proportion of bladder content emptied. Calculation: volume voided/(volume voided + PVR) \*100%.

The shape or pattern of the flow curve may suggest specific types of abnormality, but reliable and specific information about the cause cannot be derived from a flow curve alone.<sup>1,3</sup> The shape of the flow curve can be described as continuous or intermittent, and smooth or fluctuating.<sup>6</sup>

## 9 | CONCLUSIONS

This summary provides a systematic approach to ensure a representative, high quality, non-invasive flow test is carried out for individual patients. Adherence to the fundamentals of the ICS Standards, as synthesized in this review and summarized in Table 1, will enable urodynamic units to deliver high quality of uroflowmetry studies.

**Aims:** To review the recommendations on basic urodynamic testing in the International Continence Society (ICS) standardization documents, specifying key recommendations for delivery and interpretation in clinical practice.

**Methods:** Fundamental expectations described in the ICS standards on good urodynamic practices, urodynamic equipment, and terminology for lower urinary tract (LUT) function were identified and summarized.

**Results:** The ICS standard urodynamic protocol includes clinical history, including symptom and bother score(s), examination, 3-day voiding chart/diary, representative uroflowmetry with post-void residual, and cystometry with pressure-flow study (PFS). Liquid filled catheters are connected to pressure transducers at the same vertical pressure as the patient's pubic symphysis, taking atmospheric pressure as the zero value. Urodynamic testing is done to answer specific therapy-driven questions for treatment selection; provocations are applied to give the best chance of reproducing the problem during the test. Quality of recording is monitored throughout, and remedial steps taken for any technical issues occurring during testing. Labels are applied during the test to document events, such as patient-reported sensation, provocation tests, and permission to void. After the test, the pressure and flow traces are scrutinized to ensure artefacts do not confound the findings. An ICS standard urodynamic report details the key aspects, reporting clinical observations, technical, and quality issues. Urodynamic services must maintain and calibrate equipment according to manufacturer stipulations.

**Conclusions:** The review provides a succinct summary of practice expectations for a urodynamic unit offering cystometry and pressure flow studies (PFS) to an appropriate standard.

### KEYWORDS

LUTS, overactive bladder, standardization, urodynamics

Alan Wein led the peer-review process as the Associate Editor responsible for the paper.

## 1 | INTRODUCTION

Urodynamics is the general term to describe the measurements that assess the function and dysfunction of the lower urinary tract (LUT) by any appropriate method. The aim of urodynamics is to make clinical observations while taking these measurements, in order to surmise the underlying causes for the symptoms, and to quantify the related pathophysiological processes. This should establish objectively the presence of a dysfunction and understand its clinical implications. This may either confirm a clinical diagnosis or give a new, specifically urodynamic, diagnosis.

The International Continence Society (ICS), through its Standardization Steering Committee (SSC), has an ongoing strategy to standardize LUT terminology and functional assessment, and link it to published evidence.<sup>1</sup> Several ICS publications underpin the professional standard in Urodynamic testing, and describe in detail the underlying thinking and the evidence base. The current document is a synthesis of the key aspects applicable for the more common Urodynamic tests used in clinical pathways.

## 2 | METHODS

We reviewed recommendations in the ICS standards on urodynamic practice,<sup>2,3</sup> pressure flow studies (PFS),<sup>4</sup> urodynamic equipment,<sup>5</sup> terminology for LUT function,<sup>6,7</sup> and a publication on artefacts.<sup>8</sup> The review focusses on cystometry and PFS in adults without relevant neurological abnormalities and with intact “normal” anatomy of the LUT. Flow rate testing<sup>9</sup> and video-urodynamics<sup>10</sup> are described in separate documents.

### 2.1 | General comments

A good urodynamic practice comprises: a clear indication for and appropriate selection of relevant test measurements and procedures; precise measurement with data quality control and complete documentation; accurate analysis; reporting of results which evaluates urodynamic observations and places them into the patient's clinical context.

Departments should develop urodynamic practice protocols on the basis of the ICS urodynamic standards,<sup>2,3,5</sup> they should facilitate specific staff training and undertake regular evaluation of performance and adherence.<sup>2</sup> ICS terminology standards should be used when alluding to LUT symptoms, signs, and urodynamic observations.<sup>6,7</sup> Equipment, including the catheters and transducers, should meet the requirements of the ICS guideline on equipment performance.<sup>5</sup>

### 2.2 | Equipment

The basic requirement of a standard urodynamic system is that it can measure at least two pressures and calculate

detrusor pressure ( $p_{det}$ ) in real time, defined as the simultaneous difference between intravesical ( $p_{ves}$ ) and abdominal ( $p_{abd}$ ) pressures. It can measure the flow rate of the voided volume and regulate the rate of fluid infusion. It has an on-line display of pressures and flow, with adequate scale and resolution; no information should be lost electronically when tracings go off-scale on display. It is possible to record standard information about sensation and additional comments (event recording).<sup>5</sup>

Systems using liquid-filled catheters and external transducers are recommended by the ICS.<sup>2,3</sup> The transducer is levelled to the pubic symphysis, an anatomical landmark for the bladder, and the zero-point set to atmospheric pressure. Equipment should have the facility to move the transducers vertically in order to bring the transducers back to the level of the symphysis pubis, since patients may change position during a test. Micro-tip or air-filled catheters are not interchangeable with liquid-filled systems<sup>2</sup>; centers that utilize them should provide reference values for their data.

Using ICS standard pressures based on liquid-filled systems allows comparison of data between patients and centres. New technologies need to prove their usefulness and accuracy compared to existing ICS standard urodynamic tests before clinical application.<sup>11</sup> To date, there are no standardized pressure measurements for air-charged catheters.

### 2.2.1 | Calibration

Pressure transducer calibration is achieved by exposing the catheter tip to two different well-defined pressures (a pressure difference of  $\geq 50$  cmH<sub>2</sub>O is recommended).<sup>5</sup> The calibration should be verified regularly (eg, every 10 urodynamic measurements for non-disposable transducers) and documented.

Flowmeter calibration can be achieved by pouring a precise volume at a constant flow into the flowmeter and checking the recorded volume. Calibration should be verified regularly (eg, every 10 urodynamic measurements). If frequent recalibration is necessary, the flow transducer might need to be replaced.

Infusion pumps are tested by measuring the time to deliver a known volume. The filling catheter should be connected, as peristaltic type pumps (where a series of rollers compress a flexible tube) may show errors due to downstream resistance. Load cell measurement of infused volume is advised, as peristaltic pumps may turn even when the downstream tube is blocked.

### 2.3 | Preparations in advance of a urodynamic test

A leaflet clearly explaining urodynamic investigation in adequate detail will be appreciated by most patients. A table suggesting content to include in an information leaflet is

available.<sup>2</sup> Instructions must be given to the patient regarding continuation of usual LUT management (eg, medication).

A urinalysis to screen for infection or haematuria should be evaluated.

Patients should attend with a completed frequency volume chart (FVC) or bladder diary.<sup>6,12</sup> They can be used to determine fluid intake, maximum and average voided volume, voiding frequency, and day/night urine production. This information supports the patient's symptom reporting, and aids plausibility control of subsequent urodynamic studies (eg, to prevent over-filling of the patient's bladder).

Urodynamic tests should be requested with the goal of answering a specific question.<sup>3</sup> "Formulating the urodynamic question" is a process of reviewing the clinical assessment already available and what potential therapy options may subsequently be appropriate, so the test can identify appropriate treatment options and potential adverse effects.

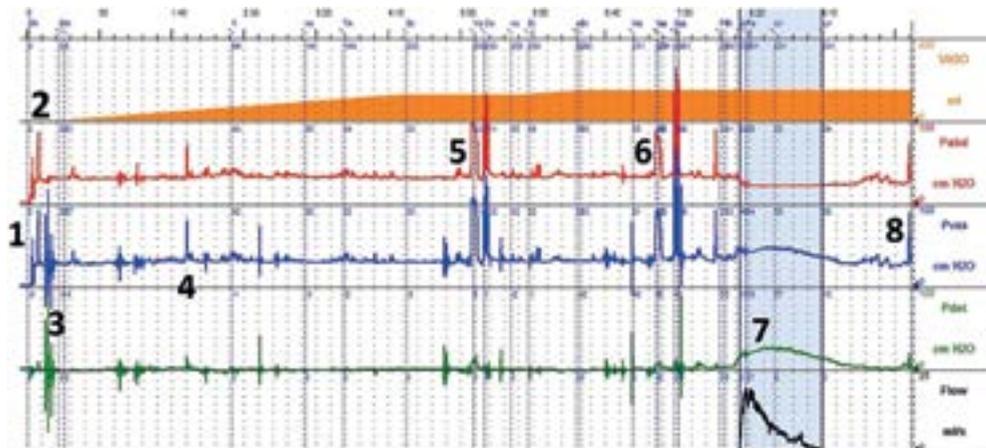

## 2.4 | ICS standard urodynamics protocol

- Clinical history, including valid symptom and bother score (s) and medication list.

- Relevant clinical examination (abdominal/pelvic/genital examination, and checking for possible neurological disease or oedema).
- Three day FVC or bladder diary.<sup>13</sup>
- Representative uroflowmetry with post-void residual (PVR).<sup>9</sup>
- A complete ICS standard urodynamic test<sup>2</sup>: Uroflowmetry and PVR plus cystometry and pressure-flow study (PFS).

Cystometry<sup>2</sup>: Continuous liquid filling of the bladder via a transurethral (or other route eg, suprapubic) catheter, at least with intravesical and abdominal pressure measurement and display of detrusor pressure, including quality checks and provocations to aid eliciting symptoms. Cystometry ends with "permission to void" or with severe incontinence. The fluid type and temperature, filling method and rate, catheter sizes, pressure recording technique, and patient position should all be specified.

Pressure-Flow study<sup>2</sup>: The intravesical and abdominal pressures are measured, from "permission to void," while uroflowmetry is performed with a transurethral (or suprapubic) catheter in place. The position of the patient, the catheter sizes and the pressure and flow recording technique should be specified.

**FIGURE 1** A specimen urodynamic test for a female patient. Transducers are zeroed to atmosphere at the start, as the  $p_{abd}$  and  $p_{ves}$  are at zero (1), before patient pressures are exposed to the transducers. When the transducers are connected to the patient (2), the clear rises in  $p_{abd}$  and  $p_{ves}$  are termed the "resting pressures"; the resting pressures of  $p_{abd}$  and  $p_{ves}$  are never zero (unless the urodynamic practitioner makes the technical mistake of zeroing the displayed pressures while recording from the patient, or the transducers are not placed in the required plane level with the pubic symphysis). In this case,  $p_{abd}$  and  $p_{ves}$  are both within normal limits, and similar magnitude, so  $p_{det}$  is zero. A cough test shows equal response on  $p_{abd}$  and  $p_{ves}$  (2). Some artefactual noise is recorded when the  $p_{ves}$  line is knocked (3). Cough tests are carried out and live signal is present throughout the test (4). At (5), filling is paused and a Valsalva manoeuvre and a stress cough test is carried out, but no leak occurs. Further filling is done, and these two tests repeated at (6) where leakage occurs on both (markers confirm this, and small changes in the flow trace have occurred but are not visible at this scale). After "permission to void" is given, the patient voids (7) and care is taken with the placement of the  $Q_{max}$  marker, and with the slight fall in  $p_{abd}$  at this point. Finally, a cough test (8) verifies that pressure transmission has remained good throughout the voiding phase

## 2.5 | Practice of cystometry and pressure flow studies

A good urodynamic investigation is performed interactively with the patient.<sup>3</sup> It should be established how the patient's symptoms relate to what they experienced during the test. There should be continuous observation of the signals as they are collected, and assessment of the plausibility of all signals. Direct inspection of the raw pressure and flow data before, during, and at the end of micturition is essential, because it allows artefacts and untrustworthy data to be recognized and eliminated.<sup>4</sup> The flow pattern in a PFS should be representative of free flow studies in the same patient. An overall study trace is illustrated in Figure 1.

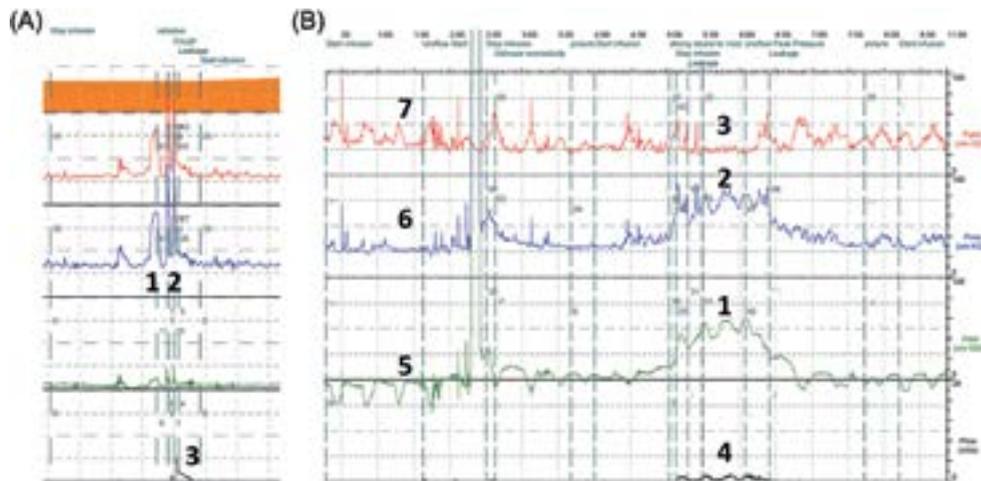

Electronic marking of events is important for subsequent analysis; the position of event markers should be adjustable after the test has finished, and the meaning of any abbreviations used for labels should be clear.<sup>5</sup>

### 2.5.1 | Pressure recording

Zero pressure is the value recorded when a liquid-filled transducer is open to the environment (either disconnected

from any tubes, or when the open end of a connected liquid-filled tube is at the same vertical level as the transducer). "Set zero" or "balance" can then be undertaken, making atmospheric pressure the zero baseline for the test. Intravesical pressure ( $p_{ves}$ ) or abdominal pressure ( $p_{abd}$ ) is thus the excess pressure above atmosphere at the hydrostatic level of the symphysis pubis. "Set zero" is not done when catheters are already recording from the patient; this is a common mistake in many urodynamic units.

- ICS standard cystometry is performed using liquid filled catheters, with external transducers at the reference level of the top of the symphysis pubis.<sup>2,3,6</sup> To achieve this, most urodynamic machines have a movable platform for the transducers, so they can easily be placed at the same height from the ground as the patient's symphysis.
- Use the thinnest possible transurethral double or triple lumen catheter or a suprapubic catheter. Two-catheter techniques (separate filling and pressure recording catheters) are an acceptable alternative.<sup>2</sup>
- Fix the catheters as close as possible to the anus and urethral meatus with tape, without blocking the urinary meatus.

**FIGURE 2** Urodynamic observations during filling cystometry. A, USI; the filling pump is stopped, and the patient is asked to do a Valsalva manoeuvre (1) and to do a sequence of 2 or 3 good coughs (2). This patient leaked with the coughs (3), and no DO was present, so the urodynamic observation of USI was documented. B, DO is the presence of a bladder contraction during filling (1), which may be spontaneous or provoked. It is essential to review all the lines in the trace before reporting DO, to confirm there is a bladder contraction (2) and minimal abdominal activity (3); though a small abdominal contraction might be seen if the patient tries to prevent leakage by contracting their pelvic floor). In this case, there is also incontinence (4), so the urodynamic observation here is DO incontinence (DOI). In the same trace, there are also fluctuations in the calculated detrusor pressure (5) which might be misinterpreted as DO. However, these are below the baseline, and there is no change in bladder pressure associated with them (6). Instead, there are phasic pressure changes visible in the abdominal pressure trace (7), indicating the presence of rectal contractions. Practitioners need to recognise that a true change in abdominal pressure shows up in both  $p_{ves}$  and  $p_{abd}$ ; a phasic change in one line which is absent in the other indicates a contraction of the organ containing the catheter tip (bladder or rectum, respectively)

- Rectal placement of a fully liquid filled open catheter, or punctured balloon catheter, to measure  $p_{abd}$  is ICS standard. Vaginal or stoma placement is used only if rectal placement is impossible.

Prevention of liquid leaks and air bubbles in the pressure tubing system is needed throughout testing, and should be corrected when identified.<sup>3</sup> Coughs or other abdominal pressure rises are used to ensure that the abdominal and intravesical pressure signals respond equally (see Figure 3).

### 2.5.2 | Cystometry

Filling cystometry is done in the upright/vertical position (standing or normally seated) whenever physically possible. Detection of detrusor overactivity (DO) and urodynamic stress incontinence (USI) are influenced by the position of the patient; sitting or standing has a higher sensitivity.<sup>2</sup>

### 2.5.3 | Filling rate

Maximum physiological filling rate is estimated by body weight in kg divided by four,<sup>6</sup> thus typically in the range of 20-30 mL/min. More rapid filling is referred to as non-physiological filling rate.<sup>3</sup>

For a balance between a filling rate that is slow enough to be representative and fast enough to complete the cystometry efficiently, consider a filling rate in mL/min of roughly 10% of the largest voided volume (reported on a FVC; and allowing for PVR).<sup>2</sup>

Diuresis adds bladder volume that is not recorded by the urodynamics system, but that is relevant for interpretation of the results. Cystometric capacity is most reliably determined by calculation of voided volume plus PVR immediately after PFS.<sup>3</sup>

### 2.5.4 | Sensations

Three sensation parameters are recorded<sup>6</sup>: first sensation of filling (FSF), first desire to void (FDV), and strong desire to void (SDV). The patient also may report sensation(s) suggesting “urgency,” which can be marked specifically. When indicating the volumes at which these sensations occurred, the report should make allowance for the fact that the volume instilled into the bladder by the machine is not necessarily the actual liquid volume in the bladder (eg, if the bladder was not empty at the start of the filling cystometry, or if the patient is experiencing diuresis).

1. FSF: “Tell me the moment when you perceive that your bladder is not empty anymore.”<sup>2</sup>

2. FDV: “Tell me when you have the sensation that normally tells you to go to the toilet, without any hurry, at the next convenient moment.”<sup>6</sup>
3. SDV: “The moment that you would definitely visit the nearest toilet to pass urine.” There should be no pain or any fear of losing urine.

The end of filling should relate to a “strong but not uncomfortable need to void,” indicated by SDV on the urodynamic graph. A specific marker to indicate permission to void must be used if there is a delay between halting the pump and permission to void. If another reason is chosen for concluding filling, this should be indicated.

Incontinence, fear of leakage, pain, or other signs or symptoms during the test should be specifically marked on the urodynamic graph.

### 2.5.5 | Provocation

Urodynamic stress test<sup>2</sup> (Figure 2) is used for any physical effort of the person tested, to elevate abdominal pressure during cystometry, with the aim of examining USI. The exact approach to stress testing during urodynamics has not been standardized. Thus, the provocation method, pressure measuring catheter (size) and method, the leak detection method, and the intravesical volume(s) may be reported.

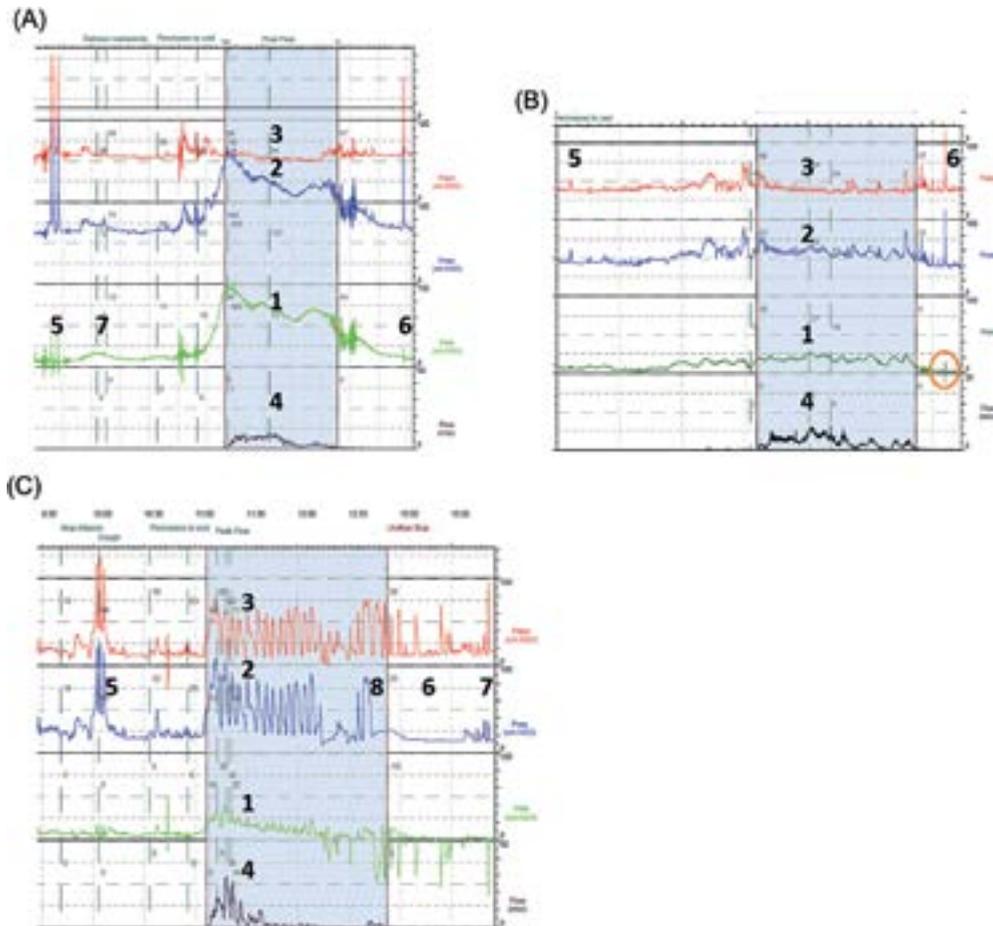

Leak point pressure (LPP)<sup>2</sup> is the pressure (spontaneous or provoked) that has caused fluid to be expelled from the bladder at the moment that it is visible outside the urethra. No ICS (or commonly agreed) standard technique or protocol is available and a variety of terms and techniques are used.

DO (Figure 2) is characterised by involuntary detrusor contractions during the filling phase which may be spontaneous or provoked.<sup>6</sup> Cough-associated DO<sup>2</sup>: Reported when the onset of the DO (with or without leakage) occurs immediately following the cough pressure peak. Cough-associated DO incontinence is a form of DO and must not be confused with USI.

### 2.5.6 | Pressure-flow studies

The relevance of instruction, position, and privacy while undertaking PFS is equal to uroflowmetry. PFS is done comfortably seated (women, some men) or standing if that is the preferred position (men). Pressure-flow analysis is only validated for voluntarily initiated micturitions and not for incontinence.

- PFS begins immediately after permission to void and ends when the detrusor pressure has returned to the baseline

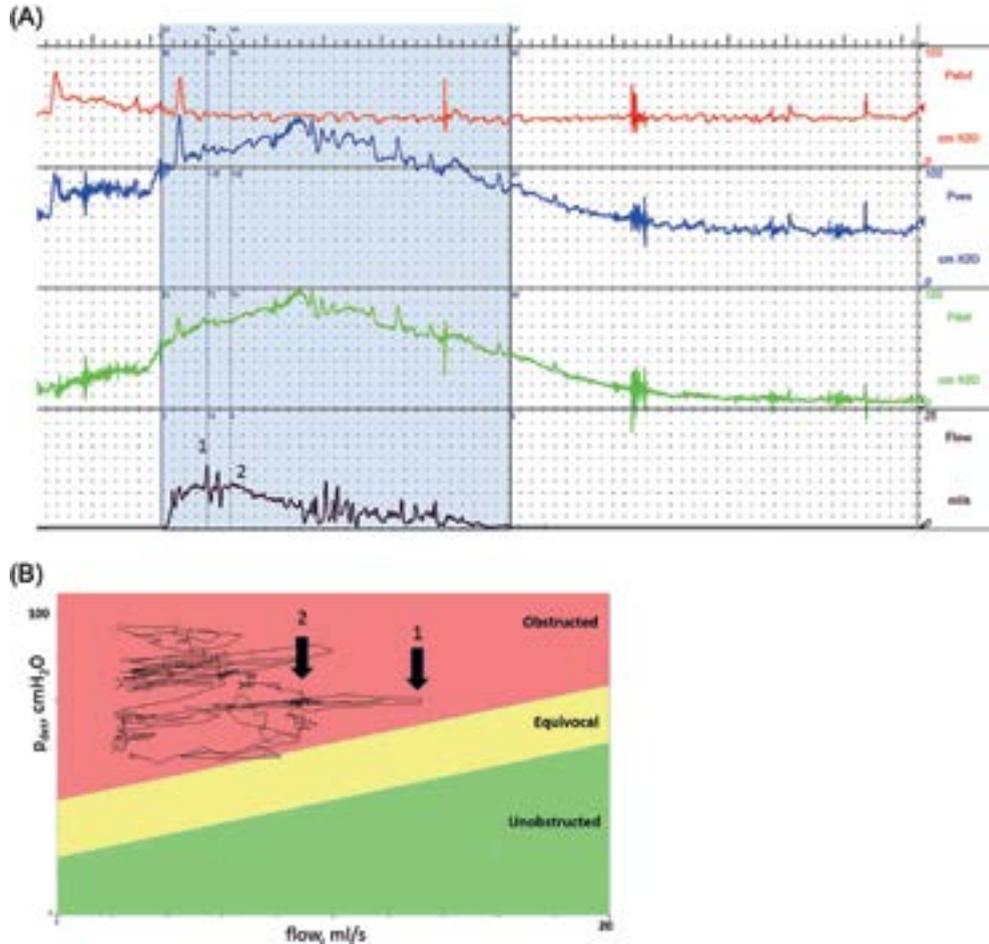

**FIGURE 3** Urodynamic observations during PFS.<sup>4</sup> A, Bladder outlet obstruction (BOO) is indicated by a high pressure generated yet only a slow stream. It is ascertained by evaluating the detrusor pressure ( $P_{\text{det}Q_{\text{max}}}$ ; 1) at the time of maximum flow rate ( $Q_{\text{max}}$ : 4). It is important to check that the detrusor pressure reflects the bladder pressure (2), rather than a drop in the abdominal pressure (3). In this male case,  $Q_{\text{max}}$  was 8,  $P_{\text{det}Q_{\text{max}}}$  was 72, and there was no drop in abdominal pressure, so the bladder outlet obstruction index ( $P_{\text{det}Q_{\text{max}}}-2Q_{\text{max}}$ ) was 56, that is, BOO was present. Fidelity of pressure recording must always be checked by asking patient to cough before (5) and after (6) voiding to be sure both  $P_{\text{ves}}$  and  $P_{\text{abd}}$  detect the pressure spike equally. This patient also had DO (7). B, Detrusor underactivity (DUA); Detrusor underactivity is defined as a contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span.<sup>6</sup> In this case, detrusor pressure is low (1) and  $Q_{\text{max}}$  (4) is slow, with a weak bladder contraction (2) and no change in  $p_{\text{abd}}$  (3). There is a marked delay between permission to void (5) and start of flow. Cough subtraction before (5) and after (6) the void are good. At 6, the cough subtraction (orange circle) shows a biphasic artefact, meaning a slight deflection upwards and an equal deflection downwards: this is acceptable, and is a consequence of the slight discrepancy in the exact moment the impulse reaches the respective transducer for the two measured pressures ( $p_{\text{ves}}$  and  $p_{\text{abd}}$ ). C, Straining is sometimes done by a patient to try and help initiate or sustain voiding, or to speed it up. In this case, there is a small detrusor contraction during voiding (1), but at the same time there are marked strains indicated by the intermittent peaks in vesical (2) and abdominal (3) pressure. Caution is needed to decide the corrected value of  $Q_{\text{max}}$  (4), as it should not be taken during a strain. The cough subtraction before voiding is fine (5), but not so after voiding (6), where this is a spike elicited by coughing only in the  $p_{\text{abd}}$  trace. A reduced signal is seen in the  $p_{\text{ves}}$  at (7), explaining the poor post void cough subtraction. The last moment of proper vesical pressure recording is at (8), and since this is after the completion of flow, the PFS can be considered meaningful

value and/or the flowrate to zero and/or the patient considers the micturition completed.

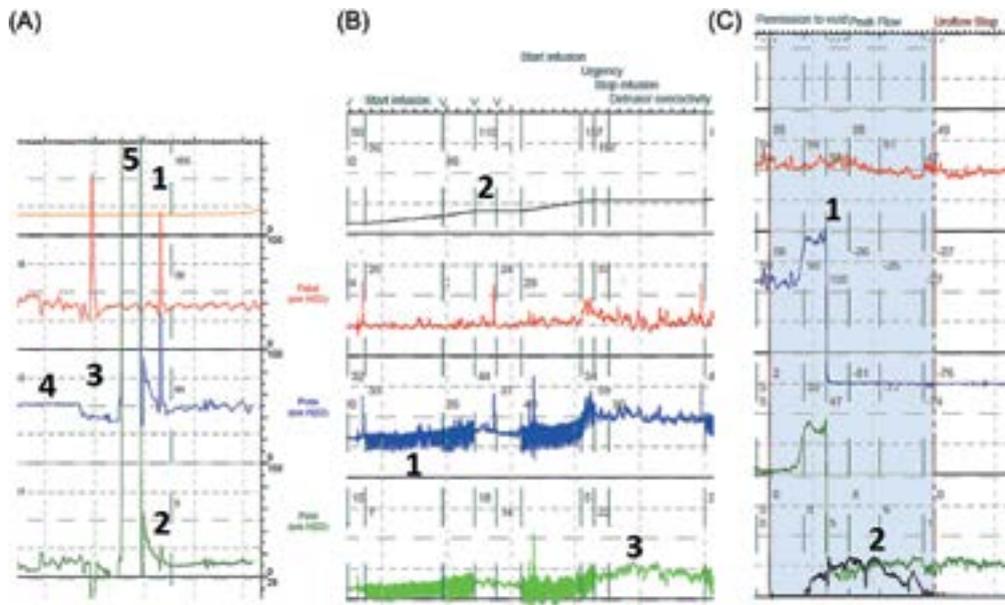

- Use the shortest possible meatus-to-flowmeter distance, raising the flowmeter to suit the individual patient.

Correction for delay between pressure and flow recording may be needed.

- Cough checking of catheter response is always required after pressure-flow.

**FIGURE 4** Calculating the bladder outlet obstruction index (BOOI) and bladder contractility index (BCI), for describing PFS in men (no equivalent parameters have been identified as yet for women). A, Pressure flow study for a man with voiding LUTS. The machine placed the maximum flow rate at point 1. However, this was on the tip of an unnatural spike, so the urodynamicist checked the shape of the flow trace, and considered that point 2 reflected the flow of the patient's urine most faithfully. Thus, this was considered the corrected maximum flow rate ( $Q_{max}$ ), with a value of 9 mL/s.  $p_{det}$  at this point ( $p_{detQ_{max}}$ ) was 74. From the equation  $BOOI = p_{detQ_{max}} - 2 \cdot Q_{max}$ , the value for this patient was  $74 - 18 = 56$ . Any value of BOOI above 40 in a man (with a prostate) indicates obstruction. From the equation  $BCI = p_{detQ_{max}} + 5 \cdot Q_{max}$ , the value of BCI for this patient was  $74 + 45 = 119$ . Any value of BCI above 100 in a man (also with a prostate) indicates normal contractility. B, The ICS recommends that the PFS is plotted graphically on a P/Q plot. On the P/Q plot, "1" shows the artefactual peak due to the flow spike. The P/Q plot allows the investigator to see how the artefact almost changes the diagnosis, by nearly crossing one of the lines on the nomogram. "2" shows the corrected position, away from the flow spike and clearly in the obstructed region. Failure of machine software using current technology to identify artefacts, like that shown at 1, means that traces must be checked for plausibility, since otherwise obstruction and contractility may be wrongly derived from the pressure flow study, leading to inappropriate treatment decisions for the patient

**FIGURE 5** Artifacts that can cause difficulty with identifying representative information and misinterpretation of urodynamic findings. A, A cough pressure peak (1) is recognizable during post-test evaluation as a phasic positive pressure change observed in  $p_{ves}$  and in  $p_{abd}$ . With liquid-filled catheters, it is usual that the bladder line is of smaller diameter than the abdominal line, so complete cancellation of a cough in the detrusor trace is unlikely. Thus, a symmetric biphasic wave on the detrusor trace (2) is acceptable. Poor pressure transmission is suggested when the cough pressure peak signals on  $p_{ves}$  and  $p_{abd}$  are not nearly equal, or one of them is absent, as illustrated at 3. This follows a phase of “dead signal,” meaning that it is not showing small pressure fluctuations and is not adequately responding on straining, patient movements, or coughing (4). Flushing the vesical pressure line (5) is a common approach to solving a dead signal or poor pressure transmission, and should be verified with a subsequent cough test, as illustrated at 3. B, Pump vibrations: visible as stable frequency oscillations of small but constant amplitude if a dual-lumen is used, or if the filling tube touches the pressure connecting tube and the pump is switched on (1), clearly identified as they stop when the pump is off (2). This patient was observed to have DO (3; pump turned off at this time). C, Expelled catheter: this is observed as a sudden drop in either  $p_{ves}$  or  $p_{abd}$ , usually below zero (1). In this case, the vesical catheter was expelled before  $Q_{max}$  (2) in a pressure flow study, which means it is not possible to interpret the pressure-flow relationship at this key point during voiding. If this hinders answering the urodynamic question, the test will have to be repeated

Normal voiding function: Flow rate (and pressure rise) are within normal limits; flow begins more or less directly after permission to void, and ends with an empty bladder.

“Situational inability to void” or “Situational inability to void as usual”<sup>2</sup>; when the person performing the test, communicating with the patient, feels the attempted voiding has not been representative.

Bladder outflow obstruction (BOO) (Figure 3) is defined as a (specified) cut-off of bladder outflow resistance based on the pressure/flow relation (ratio) that is considered clinically relevant.<sup>2</sup>

A slow stream may be caused by BOO or detrusor underactivity (Figure 3). Presentation of pressure-flow studies should be with a plot of the flow rate (delay corrected) rate on the X-axis and the synchronous detrusor pressure on the Y-axis, in addition to the time-based graphs.<sup>2</sup> The ICS pressure flow

nomogram can be used to present this data for male patients, for whom BOO can be quantified with the BOO Index, and underactivity with the bladder contractility index<sup>14</sup> (Figure 4). While these indices are often stated by the urodynamic software, the urodynamicist is duty-bound to check the plausibility of the results, as the machine may wrongly identify an artefact as the  $Q_{max}$ , and give entirely wrong results with potentially disastrous consequences for the patient.

### 2.5.7 | Repeat testing

- When an error or artefact is observed, the person performing the test should act accordingly, and prevent continuation in case of an error.
- Do not routinely undertake immediate repetition of invasive urodynamics “for confirmation” if the test was

technically adequate and representative, and has answered the clinical question.

- Immediate repetition of the test is appropriate when doubt exists as to whether the test has answered the clinical question.
- Repetition of a urodynamic test subsequently is needed when technical errors and artefacts have been observed at post-test analysis.

Artefacts such as a signal which is non-responding (dead), has stepwise changes in pressure, or has negative pressures, often can be corrected only with speculation about the underlying causes. Studies with such artefacts should be repeated. A few common artefacts can be accepted, for example, rectal activity, biphasic spikes at cough tests (Figure 3B), or insufficient  $p_{abd}$  response during straining.

The urodynamic findings and the interpretation of the results should be documented immediately, that is, before the patient has left the urodynamic laboratory. Doing so allows for a second test if required.

## 2.6 | Technical and clinical quality control

The following three criteria form the minimum recommendations for ensuring quality control of pressure recordings:

1. Resting values for abdominal, intravesical, and detrusor pressure are in a typical range (see below);
2. The abdominal and intravesical pressure signals are “live,” with minor variations caused by breathing or talking being similar for both signals; these variations should not appear in  $p_{det}$ ;
3. Coughs or other abdominal pressure rises are used throughout, including before and after voiding, to ensure that the abdominal and intravesical pressure signals respond equally. This is because pressure recording quality can deteriorate quickly during a test, and wrong conclusions might be drawn if not identified quickly. Since the test is used to recommend treatment options, possibly including surgery, the consequence of a wrong conclusion can be detrimental for the patient.

Initial resting pressure<sup>2</sup> is the  $p_{ves}$  and the  $p_{abd}$  pressure at the beginning of the cystometry. Typical ranges for  $p_{ves}$  and  $p_{abd}$  are: supine 5–20 cmH<sub>2</sub>O; sitting 15–40 cmH<sub>2</sub>O; standing 30–50 cmH<sub>2</sub>O.<sup>3</sup> Usually both recorded pressures are almost identical (and they must not be zero: see Figure 1), so that the initial  $p_{det}$  is between –5 and +5 cmH<sub>2</sub>O in the majority.<sup>15</sup> Gentle flushing of both catheter channels and/or filling 20–30 mL into the bladder may be needed before the initial resting pressures are registered.

The use of rectal transducers assumes they measure resting abdominal pressure, but they can also measure rectal

contractions,<sup>5</sup> seen as positive waves on  $p_{abd}$  and reflected as negative  $p_{det}$  waves. If either detrusor or rectal contractions occur, the recorded pressures in  $p_{ves}$  and in  $p_{abd}$  will differ. The relation between signal changes and patient sensation/activity are checked for plausibility and documented during the test.

### 2.6.1 | Features, artefacts, and errors

Patient movement, external manipulation of the catheter and other influences cause signal patterns that should be recognized during the test and at (re-) evaluation of graphs.

- Position change<sup>2</sup>: A change in patient position, either active or passive (eg, tilting), is visible on the cystometry trace by a lasting change of equal magnitude in both  $p_{ves}$  and  $p_{abd}$ .

A position change should be followed by adjustment of the external pressure sensors height to the new level of the pubic symphysis, so that the physiological  $p_{ves}$  and  $p_{abd}$  are observed again;  $p_{det}$  should be unaffected.

- Rectal contractions: temporary phasic increases visible in the  $p_{abd}$  trace, without synchronous change in  $p_{ves}$ , resulting in negative deflections of  $p_{det}$  (Figure 2B).
- Dropped  $p_{abd}$  at void: during the voiding time,  $p_{abd}$  decreases below the previous resting pressure (as a consequence of pelvic [and abdominal] muscle relaxation). This will artefactually increase  $p_{det}$ , and so affect the pressure-flow analysis result.
- Straining: observable as a temporary increase in both  $p_{ves}$  and  $p_{abd}$  pressure.
- After-contraction: a continued or new detrusor pressure rise immediately after flow ends. It is important to note if this occurs with the complete emptying of the bladder. This may be the reason why some patients feel they have an urgency sensation at the end of voiding.

Artefacts affect interpretation of urodynamic findings (Figure 5), and could lead to mis-diagnosis in severe examples. Step-wise or prolonged constant slope pressure changes imply a non-physiological cause (eg, movement, blockage or disconnection, or leakage of a catheter), which should be resolved.<sup>3</sup> A detailed review of urodynamic artefacts has been published.<sup>8</sup>

### 2.6.2 | Post-test analysis

Once a test is completed, it should be scrutinized to confirm technical quality and exclude the possibility that artefacts have influenced key observations. Liquid leaks and air

**TABLE 1** Checklist for fundamentals of urodynamic practices

Question	What is the urodynamic question? Will patient management change as a result? Does the bladder diary/symptom score affect these? Does the patient's report match the above?
Setup	
Calibrate	Check that the equipment is registering pressure and volume accurately
Prepare	Fill the domes and tubes with water, and mount them on the transducers  Catheterise the patient, connect tubes and flush with water  Level transducers with symphysis pubis bone
Quality	
Zero to atmosphere	Ensure taps are closed to patient, and open to air when zero is pressed.
Check resting pressures are normal	Supine: $p_{abd}$ and $p_{ves}$ 5-20 cmH <sub>2</sub> O Seated: $p_{abd}$ and $p_{ves}$ 15-40 cmH <sub>2</sub> O Standing: $p_{abd}$ and $p_{ves}$ 30-50 cmH <sub>2</sub> O for all positions, $p_{det}$ -5-+5 cmH <sub>2</sub> O
Continuous monitoring	Check regularly that pressure transmission is equal on both lines, for example, coughs, blowing  Check that live patient signal is present throughout  Check that baseline pressures do not drift  Troubleshoot above during the test, temporarily stopping recording/filling if necessary  Stop or reduce fill rate if urgency is excessive, or compliance poor  Change patent position as required (eg, discomfort, stress testing)  Consider repeating test if urodynamic question not answered
Interpretation	Place markers on the trace frequently, for example, sensation, patient position, stress tests, permission to void  Adjust positions of markers after completion of test if needed  Take a when interpreting, for example, rectal contractions, knocking of flowmeter
Report	Bladder during filling Urethra during filling Bladder during voiding Urethra during voiding Reproduction of symptoms Management plan

bubbles in the pressure tubing system should be recognized and reported during post-test analysis, if not identified during the procedure, to prevent mis-diagnosis.<sup>8</sup>

Post-processing automated analysis is an optional extra in urodynamic equipment, and established nomograms and calculated parameters may also be provided. Such analysis could be affected by artefacts (eg,  $Q_{max}$  caused by knocking the flow meter,  $p_{max}$  from cough),<sup>5</sup> and the urodynamicist must check the trace to be certain that misinterpretation does not result. The user should have the ability to check the values for feasibility and change the relevant ones if necessary. Software should not filter or remove artefacts, but should be able to ignore them for analysis.

**2.7 | The urodynamics report**

Bladder storage function should be described according to bladder sensation, detrusor activity, bladder compliance, and bladder capacity.<sup>6</sup> The urethral closure mechanism during storage may be competent or incompetent. Voiding is described in terms of detrusor and urethral function and assessed by measuring urine flow rate and voiding pressures. An “ICS standard urodynamic (time based) graph” and an “ICS standard pressure-flow plot” are required elements in the ICS standard urodynamics report.

- Reporting includes the following elements (summarized from GUP2016<sup>2</sup>):
  - a Overall judgement of the technical quality, clinical reliability, representativeness, and methods of assessment.
  - b Uroflowmetry: voiding position,  $Q_{max}$ , voided volume, PVR.
  - c Introduction of catheters: sensation, muscular defence, obstruction(s).
  - d Patient position(s) during cystometry and PFS.
  - e Patient's ability to report filling sensations and/or urgency and/or urine loss.
  - f Method of urodynamic stress test and accessory tests (if applicable).
  - g Diagnoses: filling sensation (with volumes); cystometry; PFS (bladder outflow function, detrusor contraction).

All results and observations should be carefully reported. It is good clinical practice to integrate the urodynamic test results with the history, examinations, and other tests.

Table 1 gives a proposed checklist for Fundamentals of Urodynamic Practice.

**3 | CONCLUSIONS**

A good study is one that is easy to read and one from which any experienced urodynamicist will abstract the same

results and come to the same conclusions (GUP2002). Adherence to the fundamentals of the ICS standards, as synthesized in this review, will enable urodynamic units to ensure the quality of urodynamic studies and compare findings with other units.

### CONFLICT OF INTEREST

Dr. Drake reports grants, personal fees, and non-financial support from Astellas, Allergan, and Ferring, outside the submitted work. Dr. Doumouchsis has nothing to disclose. Dr. Hashim reports personal fees and non-financial support from Ferring and Allergan, personal fees from Astellas, Medtronic, and Boston, outside the submitted work. Dr. Gammie reports other from Astellas and Ipsen, grants from Andromeda, Digitimer, and Laborie, outside the submitted work.

**Aims:** Videourodynamics is the addition of imaging to invasive urodynamics and one of the methods to ensure objective diagnosis in persons with signs or symptoms of lower urinary tract dysfunction. This manuscript has the aim to outline the basics of the practice of videourodynamics and to elementary explain interpretation of the results.

**Methods:** Literature sources and expert opinion were arranged to provide the reader with an introductory overview of current knowledge.

**Results:** Videourodynamics was—like most diagnostics in health care—introduced on the basis of plausibility and expert conviction but has stood the test of time. Videourodynamics has, especially in patients with congenital or acquired neurogenic dysfunction of the lower urinary tract, undisputedly although not precisely quantifiable, added to (lower urinary tract) health care quality.

**Conclusion:** The manuscript summarizes the basic elements of indication, practice, and interpretation of videourodynamics.

**KEYWORDS**

meningomyelocele, neurogenic lower urinary tract dysfunction, practice recommendations, spinal cord injury, videourodynamics

## 1 | DEFINITION

The ICS good urodynamic practice<sup>1</sup> states that standard invasive urodynamics may be combined with imaging. Invasive urodynamics performed with contrast fluid as the filling medium is termed videourodynamics: X-ray (image amplifier) pictures or cine-loops are made at relevant moments.<sup>1</sup> This report states that the contrast medium should be specified and the total patient radiation dose should be reported. Videourodynamics is not further discussed in the good urodynamic practices document and we provide the basic principles of this technique in this manuscript, with the goal to briefly introduce the practice

and technique as well as the clinical purpose and application of the test to the not-expert.

## 2 | REQUIREMENTS

In addition to the standard urodynamic (UDS) set-up,<sup>1</sup> videourodynamics (VUDS) requires that the bladder is filled with (iodine) contrast fluid. The technique of VUDS has been introduced in the early seventies of last century<sup>2,3</sup> and the technique as was introduced in those early days has remained throughout the years.<sup>4,5</sup> All publications that explain the principles are expert opinion driven and all clinical studies, describing the application of the technique are single center retrospective reviews. We have extracted practical elements from a few reviews and instructional manuscripts.<sup>6,7</sup>

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

Diverse brands and types of contrast fluid are available. In general it is reasonable to use the contrast that is used on the radiology department to perform cysto-urethrography. As an example, the American College of Radiology provides a detailed description of the technique<sup>8</sup> and links, to documents that list available contrast agents. Recent studies about the type of contrast media and the quality of imaging are rare but earlier fundamental research demonstrates that very dense medium may obscure details.<sup>9</sup> Contrast agents have a different density compared to that of urine and or saline, which are usually applied for urodynamic measurements. The difference in weight requires specific calibration of the UDS equipment; the infusion pump and the flow meter, to ensure the machine does not overestimate volumes, because of the larger relative weight of the fluid.

A fixed X-ray unit that can move from 90° to 180° (allowing an antero-posterior, lateral as well as an oblique view), or a C-arm can provide for imaging in a fluoroscopy-proof room. Modern image intensifier, flat-panel and digital radiology equipped systems significantly reduce radiation dose when compared to the “old” x-ray film. Fluoroscopy rooms (also for VUDS) require shielded walls, shielded door(s) and usually have an x-ray glass control window. Shielding must be calculated by a physicist or radiation expert and is based on the specific imaging equipment utilized. The shielding typically will involve several different lead thicknesses depending upon primary beam and secondary scatter radiation fields, surrounding occupancy factors and other considerations. The patient and the medical team involved should be adequately protected and wear dosimeters.

VUDS should be performed in the patient's natural position, if possible. This will require a radiolucent toilet seat to allow fluoroscopy of voiding in a sitting position. A standing position should also be available to enable (stress) evaluation of urinary incontinence in men and women and or voiding in the standing position. Many patients, however, especially those with neurogenic dysfunction of the lower urinary tract (LUT) never void and or are unable to sit or stand. For those patients it should be considered, or preferred, to perform UDS in supine position. Both in seated as well as in supine position the relevant elements of the system should be upholstered adequately to prevent skin damage, especially again, for the patients with loss of sensation and LUT dysfunction.

VUDS software combining the X-ray images with the UDS trace, and presenting the data either on a split screen or by superposition, is widely commercially available although the precise association of the images with synchronous pressures is rarely reported.

Radiation exposure should be As Low As Reasonably Achievable (ALARA) without sacrificing diagnostic

accuracy, and the radiation time and dose should always be reported, making patient dose monitoring essential.<sup>1</sup> Urodynamicists that wish to perform VUDS, as well as physicians should be well-trained to ensure that video-monitoring is performed adequately. Snapshots at clinically relevant moments (eg, during provocative measures or bladder pressure rises) are usually sufficient and long cine-loops are rarely relevant. The radiation field should be limited to the anatomical region of interest (sparing the gonads if possible). Pulsed digitally enhanced or low-dose setting continuous fluoroscopy with spectral beam filtration, optimal selection of the tube current and high voltage by an automatic brightness control system should be used to reduce radiation exposure. Certainly regular servicing as per local maintenance plan is important. A relatively low effective dose is achievable, as was demonstrated in a cohort with historical controls. A mean fluoroscopic time of around 60 s for VUDS including filling, stress testing, and voiding observations has been possible.<sup>10</sup> Plausibly, observations done do not often need reconfirmation (with repeated images), and a few snapshots at critical moments are conceivably sensitive to observe anatomical abnormalities in combination with the (dys) function of the LUT. Regrettably not much scientific evidence is published, regarding this.

### 3 | VIDEO-URODYNAMIC FINDINGS

The possible findings during VUDS are listed in Table 1. The key to VUDS is to adequately relate the anatomical findings (see Figures 1-4) to the urodynamic observations.

For example, a critical part in the follow-up and management of patients with neurogenic dysfunction (NLUTD) is to ensure low-pressure urine storage, thereby protecting the upper urinary tract (UUT). An unsafe bladder, prone to cause UUT damage, was defined in adult patients with spinal dysraphism as a bladder with a high end filling pressure (>40 cmH<sub>2</sub>O), poor compliance (<10 mL/cmH<sub>2</sub>O) and high detrusor leak point pressure (>40 cmH<sub>2</sub>O)<sup>11</sup> criteria that can be deducted from conventional UDS.<sup>12</sup> High bladder pressures during the storage phase can, however, cause vesico-ureteral reflux (VUR) (eg, Figure 4). Secondary, this VUR can create a pop-off of bladder pressure as (one of) the UUT(s) now absorbs the pressure. This may lead to overestimation of bladder compliance. Therefore, VUDS have a clear advantage over conventional UDS when hydronephrosis was documented in the patient or when VUR is suspected or known by other means. VUR can be related to bladder function; passive VUR at low intravesical pressures, for example, due to an insufficient ureteric orifice as is frequently existing in congenital ureteral anomalies, for example, doubling versus active VUR occurring during

**TABLE 1** Video-urodynamic observations in relation during anatomical site and urodynamic phase

Anatomical site	Video-urodynamic finding
Ureters and renal pelvis	Vesico-ureteral reflux + grade
Bladder	Trabeculation Diverticula Christmas tree appearance Postvoid residual (+ quantification) Vesico-vaginal fistula Filling “defect” (eg, prostate median lobe, bladder tumor, bladder stone)
Bladder base	Cystocele + grade (at rest, during stress testing, and during voiding)
Bladder neck	Filling: Bladder neck incompetence (during stress testing) Filling: Bladder neck opening during detrusor overactivity contractions Voiding: Bladder neck dysfunction or dyssynergia Voiding: Bladder neck fibrosis
Urethra	Urinary incontinence Urethral stricture Urethral diverticula Urethrovaginal fistula (Neurogenic) detrusor—(external urethral) sphincter dyssynergia

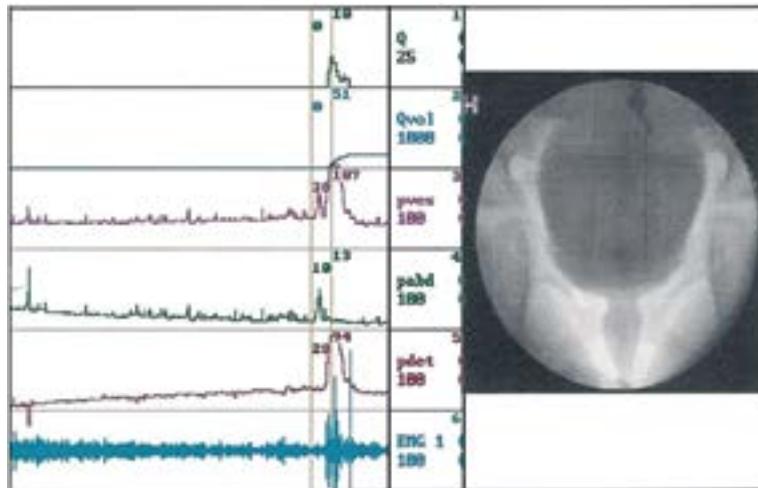

elevated pressure as a consequence of reduced compliance or synchronous with a detrusor contraction during filling or during—high pressure—dyssynergic voiding. It is important to note that in patients with spinal dysraphism, anatomical

abnormalities of the LUT are more prevalent than in patients with acquired NLUTD due to the abnormal muscle functional as well as anatomical development of the LUT and pelvic floor even before birth, as a consequence of the lack of (early) normal innervation.

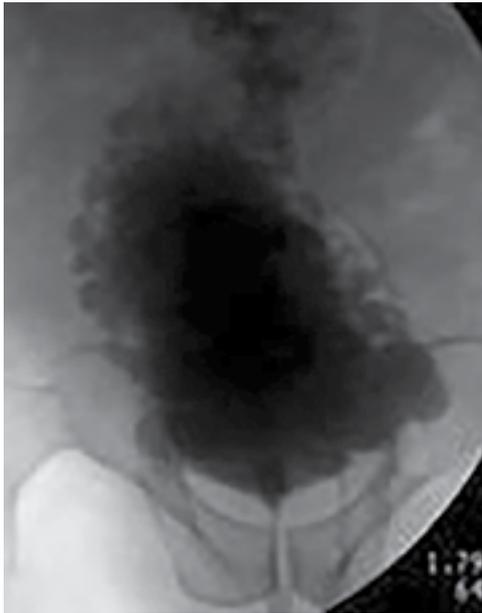

Abnormalities in the shape or outline of the bladder should be related to the functional and the cystometric capacity. Bladder diverticula, for example, can serve as a pressure sink or can be responsible for postvoid residual (eg, Figure 3).

VUDS can also aid in the diagnosis of urinary incontinence. Male (post-prostatectomy) PRP-UI has been suggested as an indication for VUDS on the basis of expert conviction.<sup>13,14</sup> Whether VUDS is of advantage in uncomplicated PRP-UI; men without any other urological history or (neuro-) urological co-morbidity, than UDS has not been assessed yet. In women with recurrent signs and symptoms of UI on the other hand, VUDS can aid in the evaluation and may guide the management, but this also has not been evaluated prospectively with regard to improvement in management selection and or outcome. Therefore, the added value of fluoroscopy to UDS in women with recurrent UI after initial (surgical) intervention has yet to be determined. In NLUTD, VUDS can also be used to determine detrusor leak point pressure; it is possible to observe contrast fluid entering the urethra via the X-ray; however, all leak points are designed or calibrated with externally visible leakage.

In young men with non-neurogenic LUTS, a single center report suggests that VUDS can offer guidance in diagnosing

**FIGURE 1** Voiding phase of VUDS bladder contour has normal appearance and bladder neck and prostatic urethra are clearly visible. Pressure flow analysis demonstrate that this patient has a normal contraction (BCI 144) and a bladder outflow obstruction grade 4 (or ICS-BOOI: 74)

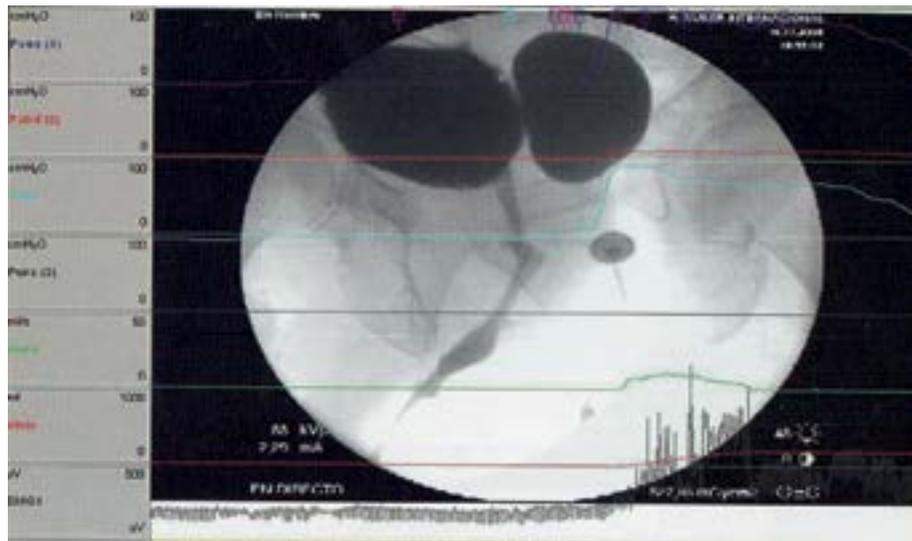

**FIGURE 2** Cystogram showing trabeculation over the entire bladder

the location or cause of bladder outflow obstruction (BOO): bladder neck dysfunction versus bladder neck fibrosis<sup>15</sup> versus urethral stricture. Some reports also suggest that VUDS can be useful for women with voiding difficulties to distinguish the effect of pelvic organ prolapse or dyssynergia in women with consistent intermittent or fluctuating flow,<sup>16,17</sup> however, the precise predictive value of observations with the video-part of the study are poorly described and difficult to reproduce.

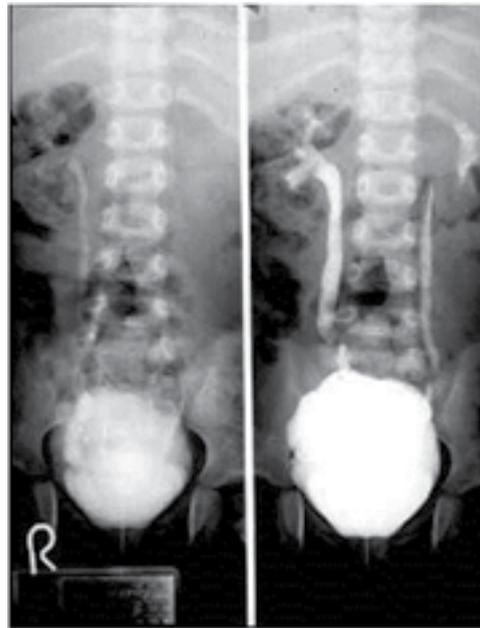

Other indications for VUDS are listed in Table 2. In general, fluoroscopy can be added to the urodynamic evaluation if there is suspicion of an anatomical anomaly contributing to the patient's LUTD or when a relevant neurological disease is causing the dysfunction and an anatomical cause or consequences are expected.

#### 4 | GUIDELINES

The evidence supporting VUDS in non-neurogenic LUTS is low grade; sparse, incomplete, and almost exclusively based on expert opinion and single center uncontrolled studies.<sup>18</sup> Data on the effect of VUDS with or without comparison with UDS on management selection and outcomes are also lacking. Nevertheless, the aim of VUDS is to achieve a more accurate diagnosis in these patients and hence improve the therapeutic decision-making, however, usually at the cost

**FIGURE 3** A relatively large diverticulum, filled during voiding; normal appearance of urethra, but pressure flow parameters (over-projected: not zeroed to atmosphere as per ICS standard; low flow and relatively high detrusor pressure) indicate bladder outflow obstruction (should be graded on [ICS] pressure flow plot)

**FIGURE 4** Vesico-ureteral reflux initially at the right hand side and subsequently on both sides

**TABLE 2** Indications for considering fluoroscopy during the urodynamic evaluation

Neurological findings or history of relevant neurologic disease

(History of) congenital genitourinary anomaly (eg, ectopic ureter, posterior urethral valves, prune-belly syndrome, vesico-ureteral reflux)

Bladder outflow obstruction or urinary retention associated with complex history

History of pelvic radiotherapy or intrapelvic surgery

History of pelvic reconstructive surgery, SUI surgery, urethral stricture repair, POP reconstruction, urethral diverticulectomy

Suspicion of vesico-vaginal or urethro-vaginal fistula

Suspicion of urethral diverticulum

Pre- and post-renal transplant

of patient comfort, making the chance of not representative outcome of studies more likely, especially in patients without neurological disease.

The European Association of Urology (EAU) recommends, based on level 4 evidence, VUDS as the optimum procedure for invasive UDS in neuro-urological patients.<sup>19,20</sup> In male LUTS VUDS are considered applicable if this is needed for the clinician to understand the pathophysiological mechanism of a patient's LUTS although this is also based on experts impressions.<sup>21</sup> The British National Institute for "Health" and Care Excellence (NICE) recommends to offer VUDS to people who are known to have a high risk of renal complications from their LUT function (eg, people with spina bifida, spinal cord injury, or anorectal abnormalities).<sup>22</sup>

The American Urological Association (AUA) and Society of Urodynamics, Female Pelvic Medicine and Urogenital Reconstruction (SUFU) states that, when available, clinicians may perform VUDS in patients with relevant neurologic disease at risk for neurogenic bladder dysfunction, in patients with other neurologic disease and elevated PVR.<sup>23</sup> Clinicians may also perform VUDS in properly selected patients to urodynamically grade and to anatomically localize bladder outflow obstruction, based on this association statement.<sup>23</sup>

## 5 | CONCLUSION

Medical imaging has developed in a century.<sup>24</sup> Imaging finds its application in healthcare via the evolution of technical

possibilities in combination with plausibility, and expert opinion. Randomized prospective studies that demonstrate the effect of diagnosis with and without imaging, on outcome of management have not been published. The development of videourodynamic evaluation is no exception. It is difficult to precisely delineate the indications for the study, as well as to assess its precise surplus for predictive value of the diagnostic strategy, however, it is undoubtedly plausible and useful to combine reliable objective functional physiological measurements (UDS) with anatomical information of synchronous imaging in a proportion of patients with lower urinary tract dysfunction.

## Why ICS standardization of lower urinary tract symptoms matters

Why does a red traffic light mean “STOP” everywhere? Or why are you able to browse the Internet from anywhere over the world? These are just a few examples from our daily life that illustrate the need for standardization and the use of a common and correct terminology.

Standards make the world a safer place. Our health is dependent on standards, going from the definition of safe drinking water, over the quality of medical equipment to the creation of terminology, standards, and guidelines in healthcare.

Standards and terminology define what is being talked about. This is especially necessary in critical communication, but also to ensure the safe diagnosis and treatment of patients. It is important that the term for a symptom, condition or disease has the same meaning for every healthcare professional on this planet. If you hear of a new development at a congress or in publication, you need to understand it fully in order to adopt it properly into your practice. When talking with patients, both of you need to understand what the other is saying. Achieving this is the aspiration of the International Continence Society (ICS) standardizations.<sup>1</sup> They are a series of evidence based pragmatic documents, some of them developed in partnership with other professional bodies, covering the field of lower urinary tract function and dysfunction, and urodynamic assessment.<sup>2–4</sup>

Similar words can have different meanings in different languages, or translation. Notably an English term in another language can change the linguistic meaning or can have different connotations than in the original language. For example many languages do not make a distinction between urinary urge and urinary urgency. The ICS has clearly defined this difference to make it clear that urgency is pathological, as in overactive bladder, and urge is the normal sensation associated with a strong desire to pass urine. So as to be consistent for inclusion of patients in clinical trials on Overactive Bladder Syndrome potentially being run in several countries, correct interpretation of the inclusion and exclusion criteria is essential. For these trials it is of paramount importance to recruit only patients with urgency, and not those describing the normal sensation of urge. Standards help in managing cultural and linguistic diversity and differences. Such terminology efforts are crucial for the advancement of research and clinical practice.

Standards allow sharing of technology and innovation and information. If we would not use a standardized terminology and a set of standards in urodynamics, results from one center would not be interchangeable with those from another center. This would lead to an unnecessary duplication of examinations, when a patient would be referred to another center. Technology is highly dependent on terminology and standardization.<sup>5</sup> Standards also make information retrievable and speed up research. Every book or published article can be found with internet search engines or through library systems, thanks to unique identifiers that have been attributed according to international standards. Just imagine to have gone back in time and to be dependent on an old-fashioned librarian and his reference system on little cards, before you could read an interesting article or book. Standards help tremendously in speeding-up research and interaction between researchers.

We strongly encourage all healthcare professionals to engage with the ICS standardizations, so as to push forward the progress in this field. Once it is in universal use, the ICS terminology offers a backbone for communications between professionals and also with patients.

**Aims:** Standardization on the basis of systematic assessment of evidence has become an indispensable element of modern healthcare. International Continence Society (ICS) has initiated and produced extremely well cited standardization documents. The process of standardization is recently depicted in a published manuscript, to keep up with modern society healthcare demands.

**Methods:** A narrative review of the ICS history and current state of standardizations for the terms, assessment and the management of patients with lower urinary tract dysfunction.

**Results:** This article highlights the philosophy and the historical context of standardization and explains the core elements of modern day standardization. The article also demonstrates the scientific relevance of the ICS standards, on the basis of reference-counts.

**Conclusion:** The history and the relevance of ICS standards are summarized.

**KEYWORDS**

health care quality, lower urinary tract dysfunction, systematic assessment and diagnosis

## 1 | INTRODUCTION

The Mars Climate Orbiter was a space probe launched by NASA on December 11, 1998 to study the Martian climate. However, on September 23, 1999, communication with the spacecraft was lost as the spacecraft went into orbital insertion, due to ground-based computer software which produced output in non-SI units of pound (force)-seconds (lbf/s) instead of the SI units of newton-seconds (N/s) specified in the contract between NASA and Lockheed. The spacecraft encountered Mars on a trajectory that brought it too close to the planet, causing it to pass through the upper atmosphere and disintegrate.<sup>1</sup> SI units are standard units of technical measurement, allowing communication about

technical issues. Standardization is relevant, in technical science as well as in medical science. Standard terms, classifications and disease and management patterns were sought, in fact since the early days of healthcare, for example, by Hippocrates. Maybe in the more modern society further standardization began in the 16th century, where parish clerks were asked to classify mortality and standard terms were developed with this aim. This can be seen as the later basis for health epidemiological observations. In the beginning of 20th century a standard nomenclature for diseases was developed that progressed into the nowadays International Classification of Diseases (ICD) and Systematized Nomenclature of Medicine (SNOMED, now SNOMED-CT).<sup>2</sup>

Medical societies are established around (clinical-medical) specialisms to improve knowledge and accountability. The Continence Club was established in Exeter (UK) in 1971, renamed to International Continence Society that same year and had the purpose to “. . . provide a link for the interchange of ideas and results for clinicians and physicists interested in

Clinical trial: No.

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

The third column shows the number of citations to the specific document as obtained from Scopus.com (May 2018).

urodynamic studies . . . treating related disorders.”<sup>3</sup> To this aim, as a logical consequence, “. . . to set it [the new society (ICS)] on the way to becoming a professional body”<sup>3</sup> a “standardization of terminology of lower urinary tract function” was developed and published simultaneously in diverse journals.<sup>4</sup> Terms for urodynamic observations were developed since then and refined, together with improvements in the techniques used to objectively measure lower urinary tract functions, independent from the patients expression of symptoms. New ICS standardization documents have been published in the years that followed.

## 2 | MATERIAL AND METHODS

A narrative review of the evolution of the process of standardization in healthcare, in general and specific for ICS is presented. Scopus—website counts are used to demonstrate

the scientific relevance of the published manuscripts of ICS standards.

## 3 | RESULTS

### 2.1 | Standard for standards

Early standards in health care have been eloquence based. A group of renowned experts sat together and developed the text of the standard, on the basis of their knowledge. That actual knowledge failed against big data was demonstrated in the late 1960s. A clinical epidemiological book discussed the complexity of medical decision making, and was the starting point for nowadays clinical epidemiology. Clinical epidemiology became a tool to be the more reliable basis for (more) systematic diagnosis and management.<sup>5</sup> This clinical epidemiology, and systematic reviewing of research data were deployed into evidence based medicine later.<sup>6</sup>

Also early ICS standards have been developed in the “good old boys sat around the table” (GOBSAT)—manner. In 2012, however, the ICS standardization committee has published a standard to deviate from GOBSAT and to introduce—evidence based—(healthcare and) ICS standards.<sup>7</sup> This manuscript highlights also that the ICS standardization committee had modernized itself and became a standardizing steering committee, with the aim to oversee and guide (ad hoc) working groups to deliver new ICS standards. The renewed process and structure of standards production were defined, to ensure careful inclusion of evidence in the standard and to explicitly grade evidence and also indicate expert opinion where evidence is lacking. In summary of the earlier published document, the process consists of a proposal stage, a preparatory stage, a committee stage and an approval stage

and has also defined an implementation stage.<sup>7</sup> An idea for a new standard should be proposed to the ICS standardization steering committee who will establish an opinion- and background-balanced working group with a chairperson. The “balance,” referred to in the standard<sup>7</sup> includes that the background should as diverse as possible, around the topic of the standardization, not only in opinion and profession but also including partnership of other organizations (outside ICS) when that is deemed potentially rewarding. The working group, when established, searches for relevant evidence and makes summaries of answers for clinical questions associated with the topic of the standard. Terms may also be searched for existence in scientific databases or in the, here above mentioned, international nomenclature—sets, or medical dictionaries, before introduction in the (new) standard.

**TABLE 2** The top ranking documents with (clinical OR practice) standard\* in the title with the number of citations to the specific document (may 2018) are showed

<b>Scopus EXPORT DATE: 15 May 2018 Search quote: “Standard*”- in Title.</b>

Design and standardization of PCR primers and protocols for detection of clonal immunoglobulin and T cell receptor gene recombinations in suspect lymphoproliferations: Report of the BIOMED 2 concerted action BMH4- CT98-3936 (2003) Leukemia, 17 (12), pp. 2257–2317.	Cited 1834 times.
<b>The standardization of terminology in lower urinary tract function: Report from the standardization sub-committee of the International Continence Society (2003) Urology, 61 (1), pp. 37–49.</b>	<b>Cited 1583 times.</b>
A Specific Laboratory Test for the Diagnosis of Melancholia: Standardization, Validation, and Clinical Utility (1981) Archives of General Psychiatry, 38 (1), pp. 15-22	Cited 1579 times.
Revised Recommendations of the International Working Group for diagnosis, standardization of response criteria, treatment outcomes, and reporting standards for therapeutic trials in acute myeloid leukemia (2003) Journal of Clinical Oncology, 21 (24), pp. 4642–4649.	Cited 1471 times.
Standardization of uveitis nomenclature for reporting clinical data. Results of the first international workshop (2005) American Journal of Ophthalmology, 140 (3), pp. 509-516	Cited 1435 times.
A working formulation for the standardization of nomenclature in the diagnosis of heart and lung rejection: Heart rejection study group (1990) Journal of Heart Transplantation, 9 (6), pp. 587-592	Cited 1301 times.

When the number of citations to the three versions of the 2002 document are added (4360 + 1583 + 607), 3th not shown, see Table 1), the total of 6650 would rank this document number 1 clinical standard in healthcare. Note also that the number 6 document is an “ICS-collaboration-endorsed” standard.

Objective evidence for management in new standard should be systematically gathered with structured searches of literature and Oxford grading. Theoretically a Delphi process would be applicable for sub-topics where evidence is lacking, however, this procedure is not without pitfalls, for example, has the danger of devaluating to the “old GOBSAT” manner,<sup>8,9</sup> by overestimation of the experts knowledge<sup>8</sup> and underestimation of the existence of evidence. Potential other pitfalls are, for example, imposing preconceptions of a problem and not allowing for the contribution of other related perspectives; poor techniques of summarizing and presenting the group responses; not exploring disagreements and; underestimating the demanding nature of a Delphi.<sup>8</sup> A recent systematic review of reports based on the Delphi method found substantial variation in quality as consequence of lack of rigorousness of the application of the process.<sup>9</sup> Ultimately the (new) standard terms are selected on the basis of arguments made transparent. Sensitive and systematic searching for existing evidence prevents reinvention of knowledge and has to provide the evidence base for the practice recommendations or for the terms. Finally the members and board of the ICS will see the draft standard and control, for process and structure, but also for missed evidence that may change the recommendations. Details of this process are given in the original publication but essentially the draft document is made available for all ICS members via the ICS website, and is also submitted to internal invited peer review and or discussed during an annual society meeting. The finally approved standard is published and, for example, relevant committees can take out relevant elements and make these into educational modules to be published as presentation on the ICS website to enhance implementation of standard good practice and terms by education.

### 3.2 | Scientific relevance

The International Continence Society has produced one of the most cited standards in healthcare.<sup>10</sup> Table 1 shows the number of citations for the most “general” ICS standards on the basis of the counts given in Scopus.com website on May 15, 2018. Table 2 shows that the number of citations to the 2002 standardization document exceeds all documents with “practice guideline” or “practice standard” in the title when the three versions of the 2002 document (see Table 1) are grouped. (source: scopus.com). The references total of 6650 contains that the document is referred to every single day since its publication.

## 4 | DISCUSSION

The modern era standards should aim at that level and be the basis for good practice. ICS is still leading in the development of careful objective assessment of lower urinary tract

dysfunction as has been aimed in 1971. Objective assessment of dysfunction meets patients expectations also (or especially?) to date.<sup>11</sup> Modern era healthcare, however, also demands, more than in the early days of ICS, that patients quality of life and well-being are taken into account and that minimal or not invasive management is recommended to them, where possible. Not only terms and techniques for objective assessment and diagnosis should be renewed, in an evidence based fashion, also the assessment of the patients well-being deserves evidence based standardization. Furthermore standards for management may lead the way to improvements. The ICS standard for standardization may become the basis for systematic evidence based documents to enforce the International Consultation on Incontinence management recommendations<sup>12</sup> and may also expand to management of lower urinary tract dysfunctions without urinary incontinence.

## 5 | CONCLUSION

Standardization prevents miscommunication and therefore mismanagement, also in healthcare. ICS started with standardization, based on scientific progress and development and has continued this, in the lead, for almost 50 years. ICS Standardization is now standardized within the framework of Evidence Based Medicine and apart from further standardization of urodynamic assessment and evidence based objective pelvic floor muscle function evaluation standardization of quality of life assessment as well as standards for management may be future goals.

### 3. THE INTERNATIONAL CONSULTATION ON INCONTINENCE ALGORITHMS

Since its inception in 1998, the International Consultation on Incontinence, now in its 6th iteration, has brought together many of the world's leading experts to produce a unique scholarly knowledge synthesis of scientific work in the field of continence. Viewed by many senior and junior academics and clinicians as the “bible” of continence, the 6th edition is part of a productive partnership with the International Continence Society, seen by many as the “natural” home of the consultation. Its 23 or so chapters cover the range of scientific endeavour, from fundamental cellular mechanisms underlying incontinence and pelvic floor dysfunction to applied research in policy and health services research. In addition to providing an expert view of the state of the science, each committee rigorously examines the latest scientific evidence using the Oxford Grading system to produce recommendations for research and clinical practice in its areas of focus.

Each committee's findings were presented to a wide audience of ICS members at the 2016 ICS Annual Scientific Meeting in Tokyo where feedback was offered and considered prior to publication of the book “Incontinence”. As part of its work, committees with a clinical focus produce an evidence informed algorithm for assessment and care for both initial and specialist assessment and management. The algorithms and their accompanying notes are published in *Neurourology and Urodynamics* as part of the Scientific Report from the Consultation<sup>1</sup> and are reproduced here as part of the programme of knowledge dissemination for the Consultation. Clearly production of such work is irrelevant without use, we therefore hope that you use these algorithms in practice and in presentation form in order to enhance to promote the highest quality of clinical care to patients.

**and the members of the committees**

## INTRODUCTION

The 6th International Consultation on Incontinence met between September 13-15th 2016 in Tokyo and was organised by the International Consultation on Urological Diseases and the International Continence Society (ICS), in order to develop consensus statements and recommendations for the diagnosis, evaluation and treatment of urinary incontinence, faecal incontinence, pelvic organ prolapse and bladder pain syndrome.

The consensus statements are evidence based following a thorough review of the available literature and the global subjective opinion of recognised experts serving on focused committees. The individual committee reports were developed and peer reviewed by open presentation and comment. The Scientific Committee, consisting of the Chairs of all the committees then refined the final consensus statements. These consensus statements published in 2017 will be periodically reevaluated in the light of clinical experience, technological progress and research.

# 1. DEFINITIONS

The consultation agreed to use the current International Continence Society definitions (ICS) for lower urinary tract dysfunction (LUTD) including incontinence, except where stated. These definitions were published in the journal *Neurourology and Urodynamics* (2002; 21:167-178 and 2006; 25: and can be viewed on the ICS website: [www.ics.org](http://www.ics.org)

The following ICS definitions are relevant:

## 1. LOWER URINARY TRACT SYMPTOMS (LUTS)

LUTS are divided into storage and voiding symptoms.

Urinary incontinence is a storage symptom and defined as the complaint of any involuntary loss of urine. This definition is suitable for epidemiological studies, but when the prevalence of bothersome incontinence is sought, the previous ICS definition of an “Involuntary loss of urine that is a social or hygienic problem”, can be useful.

Urinary incontinence may be further defined according to the patient’s symptoms

- **Urgency Urinary Incontinence** is the complaint of involuntary leakage accompanied by or immediately preceded by urgency.
- **Stress Urinary Incontinence** is the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing.
- **Mixed Urinary Incontinence** is the complaint of involuntary leakage associated with urgency, and also with effort, exertion, sneezing and coughing.
- **Nocturnal Enuresis** is any involuntary loss of urine occurring during sleep.
- **Post-micturition dribble** and **continuous urinary leakage** denotes other symptomatic forms of incontinence.

**Overactive bladder** is characterised by the storage symptoms of urgency with or without urgency incontinence, usually with frequency and nocturia.

## 2. URODYNAMIC DIAGNOSIS

- **Detrusor Overactivity** is a urodynamic observation characterised by involuntary detrusor contractions during the filling phase, which may be spontaneous or provoked.

Detrusor overactivity is divided into:

- **Idiopathic Detrusor Overactivity**, defined as overactivity when there is no clear cause
- **Neurogenic Detrusor Overactivity** is defined as overactivity due to a relevant neurological condition.
- **Urodynamic stress incontinence** is noted during filling cystometry, and is defined as the involuntary leakage of urine during increased abdominal pressure, in the absence of a detrusor contraction.

## 3. BLADDER PAIN SYNDROME

Bladder pain syndrome is defined by ESSIC as chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent desire to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.

## 4. PELVIC ORGAN PROLAPSE

- **Urogenital prolapse** is defined as the symptomatic descent of one or more of: the anterior vaginal wall, the posterior vaginal wall, and the apex of the vagina (cervix/uterus) or vault (cuff) after hysterectomy. Urogenital prolapse is measured using the POP-Q system.
- **Rectal prolapse** is defined as circumferential full thickness rectal protrusion beyond the anal margin.

## 5. ANAL INCONTINENCE

**Anal incontinence** defined as “any involuntary loss of faecal material and/or flatus and/or mucus” and may be divided into:

- **Faecal incontinence**, any involuntary loss of faecal material
- **Flatus incontinence**, any involuntary loss of gas (flatus)
- **Mucus incontinence**, any involuntary loss of mucus only (not faeces)

\* At the time of this consultation, these definitions are not included in the current ICS terminology.

## 2. EVALUATION

The following phrases are used to classify diagnostic tests and studies:

- **A highly recommended test** is a test that should be done on every patient.
- **A recommended test** is a test of proven value in the evaluation of most patients and its use is strongly encouraged during evaluation.
- **An optional test** is a test of proven value in the evaluation of selected patients; its use is left to the clinical judgement of the physician
- **A not recommended test** is a test of no proven value.

This section primarily discusses the Evaluation of Urinary Incontinence with or without Pelvic Organ Prolapse (POP) and Faecal Incontinence.

The recommendations are intended to apply to children and adults, including healthy persons over the age of 65.

These conditions are highly prevalent but often not reported by patients. Therefore, the Consultation strongly recommends case finding, particularly in high risk groups.

### A. HIGHLY RECOMMENDED TESTS DURING INITIAL EVALUATION

The **main recommendations** for this consultation have been abstracted from the extensive work of the 23 committees of the 6th International Consultation on Incontinence (ICI, 2016).

Each committee has written a report that reviews and evaluates the published scientific work in each field of interest in order to give Evidence Based recommendations. Each report ends with detailed recommendations and suggestions for a programme of research.

The main recommendations should be read in conjunction with the management algorithms for children, men, women, the frail older person, neurogenic patients, bladder pain, pelvic organ prolapse, and anal incontinence

The initial evaluation should be undertaken, by a clinician, in patients presenting with symptoms/ signs suggestive of these conditions.

### 1. HISTORY AND GENERAL ASSESSMENT

Management of a disease such as incontinence requires caregivers to assess the sufferer in a holistic manner. Many factors may influence a particular individual's symptoms, some may cause incontinence, and may influence the choice and the success of treatment. The following components of the medical history are particularly emphasised:

#### 1.1. Review of Systems:

- Presence, severity, duration and bother of any urinary, bowel or prolapse symptoms. Identifying symptoms in the related organ systems is critical to effective treatment planning. The use of validated questionnaires to assess symptoms are recommended.
- Effect of any symptoms on sexual function: validated questionnaires including impact on quality of life are a useful part of a full assessment.
- Presence and severity of symptoms suggesting neurological disease

#### 1.2. Past Medical History:

- Previous conservative, medical and surgical treatment, in particular, as they affect the genitourinary tract and lower bowel. The effectiveness and side effects of treatments should be noted.
- Coexisting diseases may have a profound effect on incontinence and prolapse sufferers, for example asthma patients with stress incontinence will suffer greatly during attacks. Diseases may also precipitate incontinence, particularly in frail older persons.
- Patient medication: it is always important to review every patient's medication and to make an assessment as to whether current treatment may be contributing to the patient's condition.
- Obstetric and menstrual history.
- Physical impairment: individuals who have compromised mobility, dexterity, or visual acuity may need to be managed differently

#### 1.3. Social History:

- Environmental issues: these may include the social, cultural and physical environment.

- Lifestyle: including exercise, smoking and the amount and type of fluid and food intake.
- 1.4. Other Treatment Planning Issues:**
- **Desire for treatment** and the extent of treatment that is acceptable
  - **Patient goals** and expectations of treatment
  - **Patient support** systems (including caregivers).
  - **Cognitive function:** all individuals need to be assessed for their ability to fully describe their symptoms, symptom bother and quality of life impact, and their preferences and goals for care. They must be able to understand proposed management plans and to discuss, where appropriate, alternative treatment options. In some groups of patients, formal testing is essential e.g. cognitive function testing for individuals for whom the clinician has concerns regarding memory deficits and/or inattention or confusion, and depression screening for individuals for whom the clinician has concerns about abnormal affect. Proxy respondents, such as family and caregivers, may be used to discuss the patient's history, goals of care, and treatment for individuals with dementia, but only if the individual is incapable of accurate reporting or weighing treatment decisions.

**2. PHYSICAL EXAMINATION**

The more complicated the history and the more extensive and/or invasive the proposed therapy, the more complete the examination needs to be. Depending on the patient's symptoms and their severity, there are a number of components in the examination of patients with incontinence and/or pelvic organ prolapse.

Physical examination should be performed regardless of whether the patient is a child, a woman, a man, someone with neurological disease or a frail elderly person.

**2.1. General status:**

- Mental status
- Obesity (BMI)
- Physical dexterity and mobility

**2.2. Abdominal/flank examination:** for masses, bladder distention, relevant surgical scars

**2.3. Pelvic examination:**

- Examination of the perineum and external genitalia including tissue quality and sensation.
- Vaginal (half-speculum/Sims) examination for pelvic organ prolapse (POP), which should be done in the vertical position

- Bimanual pelvic and anorectal examination for pelvic mass,
- Digital rectal examination to assess pelvic floor muscle function and the function of internal and external anal sphincter as well as puborectalis muscle.
- Stress test for urinary incontinence.

**2.4. Neurological testing (see chapter on assessment)**

**3. URINALYSIS**

In patients with LUTS, the possibility of a urinary tract infection should be evaluated, with appropriate testing (ranging from dipstick to urine microscopy and culture when indicated as UTI is a readily detected, and easily treatable cause of LUTS,

**Conclusion**

For simple treatments, particularly non-invasive and inexpensive therapies, management may start without the need for the further investigations listed below.

**B. RECOMMENDED FURTHER ASSESSMENT PRIOR TO, OR DURING, SPECIALIST ASSESSMENT**

The tests below are recommended when the **appropriate indication(s) is present**. Some recommended tests become highly recommended in specific situations.

This section should also be read in conjunction with the relevant committee reports.

**1. FURTHER SYMPTOM AND HEALTH-RELATED QOL ASSESSMENT**

**1.1. Bladder Diary**

In patients with **urinary symptoms** the use of a **bladder diary** (examples in Annex 1) is highly recommended to document the frequency of micturition, the volumes of urine voided, incontinence episodes and the use of incontinence pads.

**1.2. Questionnaires**

The use of the **highest quality questionnaires** (GoR A, where available) is recommended for the assessment of the patient's perspective of symptoms of incontinence and their impact on quality of life.

The ICIQ is highly recommended (GoR A) for the basic evaluation of the patient's perspective of urinary incontinence, with other GoR A questionnaires recommended for more detailed assessment. **Further development is required in the areas** of pelvic organ prolapse, bladder pain syndrome, and for specific patient groups, as only GoR B questionnaires are currently available (see Assessment Chapter).

## 2. RENAL FUNCTION ASSESSMENT

Standard biochemical tests for renal function are recommended in patients with urinary incontinence when there is the possibility of renal impairment.

## 3. UROFLOWMETRY

Uroflowmetry with the measurement of post void residual urine is recommended as a screening test for symptoms suggestive of urinary voiding dysfunction or physical signs of POP or bladder distension. Uroflowmetry should be part of the initial assessment if the result is likely to influence management eg in older men with possible prostatic obstruction.

## 4. ESTIMATION OF POST VOID RESIDUAL URINE (PVR)

In patients with suspected voiding dysfunction, PVR should be part of the initial assessment if the result is likely to influence management, for example, in neurological patients.

## 5. IMAGING

Although routine imaging is not recommended, imaging of the lower urinary tract and pelvis is highly recommended in those with urinary symptoms whose initial evaluation indicates a possible co-existing lower tract or pelvic pathology. Initial imaging may be by ultrasound, or plain X-ray.

Imaging of the upper urinary tract is highly recommended in specific situations. These include:

- Haematuria,
- Neurogenic urinary incontinence e.g. myelodysplasia, spinal cord trauma,
- Incontinence associated with significant post-void residual,
- Co-existing renal disease such as pyelonephritis or reflux, or loin/kidney pain,
- Severe pelvic organ prolapse, not being treated
- Suspected extra-urethral urinary incontinence,
- Children with incontinence and UTIs, where indicated

- Urodynamic studies which show evidence of poor bladder compliance or high pressure detrusor overactivity.

## 6. INVESTIGATIONS IN FAECAL INCONTINENCE AND RECTAL PROLAPSE

- Endoanal US or MRI prior to anal sphincter surgery is highly recommended, even when obvious anatomic defects are not evident.
- Defaecating proctography or dynamic MRI is recommended in suspected rectal prolapse which cannot be adequately confirmed by physical examination.
- Anorectal manometry is useful to assess resting and squeeze anal pressures. The resting and squeeze pressures represent the function of the internal and external anal sphincter, respectively.

## 7. ENDOSCOPY

Although routine cysto-urethroscopy is not recommended, LUT endoscopy is **highly recommended**:

- When initial testing is abnormal, e.g. haematuria and suggests other pathologies,
- When pain or discomfort feature in the patient's LUTS, these may suggest an intravesical lesion
- When appropriate in the evaluation of vesicovaginal fistula and extra-urethral urinary incontinence (in childbirth fistulae, endoscopy is often unnecessary).

**In anorectal conditions**, proctoscopy or flexible sigmoidoscopy should routinely be performed in the evaluation of patients with faecal incontinence. Colonoscopy, air contrast barium enema or CT colography is highly recommended in the presence of unexplained change in bowel habit, rectal bleeding or other alarm symptoms or signs (see Basic Assessment chapter).

## 8. URODYNAMIC TESTING

### 8.1. Urodynamic (multi channel pressure subtracted cystometry) evaluation is recommended

- When the results may change management, such as prior to most invasive treatments for UI and POP,
- After treatment failure, if more information is needed in order to plan further therapy,

- As part of both initial and long-term surveillance programmes in some types of neurogenic lower urinary tract dysfunction,
- In “complicated incontinence” (for details please see relevant subcommittee reports).

**8.2. The aims of urodynamic evaluation are often diagnostic, but may also relate to prognostic factors, direct management or assess response to prior therapy, and also:**

- To reproduce the patient's symptoms and correlate these with urodynamic findings
- To assess bladder sensation
- To detect detrusor overactivity
- To assess urethral competence during filling
- To determine detrusor function during voiding
- To assess outlet function during voiding
- To assess residual urine

## 9. SMALL BOWEL FOLLOW-THROUGH, CT ENTOGRAPHY OR CAPSULE ENDOSCOPY

These tests are recommended in those with faecal incontinence and the presence of unexplained diarrhoea or when Crohn's disease is suspected.

## C. FURTHER DIAGNOSTIC TESTS TO BE USED AS APPROPRIATE

### 1. ADDITIONAL URODYNAMIC TESTING

**Video-urodynamics** may be useful in the management of UI in children, in patients who fail surgery and in some neurogenic patients, to obtain additional anatomical information. Either X-ray or US imaging can be used depending on the needs of the individual patient.

If a more **detailed estimate of urethral function** is required, then the following optional tests may give useful information:

- Urethral pressure profilometry
- Abdominal leak point pressures
- Video-urodynamics
- Electromyography of pelvic floor or urethral sphincter

**If initial urodynamics have failed** to demonstrate the cause for the patient's incontinence then the following tests are optional:

- Repeated routine urodynamics or video-urodynamics
- Ambulatory urodynamics

## 2. PAD TESTING

Pad testing is an optional test for the routine evaluation of urinary incontinence and, if carried out, a 24 hr test is suggested.

## 3. NEUROPHYSIOLOGICAL TESTING AND IMAGING

The information gained by clinical examination and urodynamic testing may be **enhanced by neurophysiological testing** of striated muscle and nervous pathways.

Appropriately trained personnel should perform these tests. The following neuro-physiological tests can be considered in patients with peripheral lesions prior to treatment for lower urinary tract or anorectal dysfunction.

- Concentric needle EMG
- Sacral reflex responses to electrical stimulation of penile or clitoral nerves.

Imaging of the nervous system (and neighbouring structures, including spine, the abdominal cavity and pelvis) by MRI or CT, may confirm suspected involvement of the nervous system, and the nature of the cause.

## 4. FURTHER IMAGING

Cysto-urethrography, US, CT and MRI may have an indication:

- Suspected pelvic floor dysfunction
- Failed surgery, such as recurrent posterior vaginal wall prolapse or failed sling surgery
- Suspected fixed urethra

## 5. CYSTO-URETHROSCOPY

This is an optional test in patients with complicated, persistent or recurrent UI (e.g. after failed SUI surgery)

## 6. ANORECTAL PHYSIOLOGY TESTING

**Endocoil MRI** has high accuracy for detecting anal sphincter injury but is second line after endoanal ultrasound. Patients with faecal incontinence may benefit from assessment with MRI, particularly those with

anorectal malformations and/or previous anal sphincter surgery.

**Defaecography** may be useful and is recommended in patients with faecal incontinence, who have failed conservative therapies, and are possible candidates for laparoscopic ventral rectopexy.

# 3. MANAGEMENT CONSENSUS STATEMENTS

The consensus statements are derived from the **detailed work in the committee reports** on the management of incontinence in children, men, women, the frail elderly and neurological patients, as well as those with obstetric fistula, pelvic organ prolapse, bladder pain syndrome, and faecal incontinence. The management of incontinence is presented in **algorithm form with accompanying notes**.

The chapters analyze the evidence and give it a level of evidence (LoE) and this generates a GoR of recommendation (GoR)

**The Consultation recognises that no algorithm can be applied to every patient and each patient's management must be individualised.**

There are algorithms for

- I. **Urinary Incontinence in Children**
- II. **Urinary Incontinence in Men**
- III. **Urinary Incontinence in Women**
- IV. **Fistulae**
- V. **Pelvic Organ Prolapse**
- VI. **Urinary Incontinence in Neurological Patients**
- VII. **Bladder Pain Syndrome**
- VIII. **Faecal Incontinence in Adults**
- IX. **Urinary and faecal Incontinence in frail Older Men and Women**

These algorithms are divided into two for groups I to III, VII and X. The two parts, **initial management** and **specialised management** require a little further explanation.

Although the management algorithms are designed for patients whose predominant problem is incontinence, there are many other patients in whom the algorithms may be useful such as those patients with urgency and frequency, so-called **"OAB dry"**

Management definitions

Management may be divided into

- Conservative, all methods that are non-medical and non-surgical, some of which do not target the disease process
- Medical (pharmacological) therapy

- Surgical therapy
- Conservative therapy includes
  - Lifestyle interventions e.g. weight loss
  - Bladder training
  - Pelvic floor muscle training (PFMT)
  - Containment products e.g. pads
  - Dependent continence strategies eg regular toileting

Consensus does not exist as to the use of the term "behavioural therapy" as some state that this term only includes bladder training and PFMT, whilst others consider that all conservative management contains a behavioural element, for example wearing and changing pads constitutes a change in behaviour. Hence the consultations recommendations list the elements of conservative management as relevant are intended for use by all clinicians including health care assistants/aides, nurses, physiotherapists, generalist doctors and family doctors as well as by specialists such as urologists, geriatricians and gynaecologists. The consultation has attempted to phrase the recommendations in the basic algorithms in such a way that they may be readily used by clinicians in all countries of the world, both in the developing and the developed world.

## The algorithms for initial management

are intended for use by all **clinicians** including health care assistants/aides, nurses, physiotherapists, generalist doctors and family doctors as well as by specialists such as urologists, geriatricians and gynaecologists. The consultation has attempted to phrase the recommendations in the basic algorithms in such a way that they may be readily used by clinicians in all countries of the world, both in the developing and the developed world.

## The specialised algorithms

The specialised algorithms are intended for use by **specialists**. The specialised algorithms, as well as the initial management algorithms are **based on evidence where possible**, and on the **expert opinion** of the 400 healthcare professionals who took part in the Consultation. In this consultation, committees ascribed levels of evidence to the published work on the

subject and devised GoRs of recommendation to inform patient management.

It should be noted that these algorithms, dated **April 2017**, represent the Consultation **consensus at that time**. Our knowledge, developing from both a research base and because of evolving expert opinion, will inevitably **change with time and relate to the unique context of individual patients seeking care**. The Consultation does not wish those using the algorithms to believe they are “carved in tablets of stone”: there will be changes both in the relatively short term and in the long term.

## 1. ESSENTIAL COMPONENTS OF BASIC ASSESSMENT

Each algorithm contains a core of recommendations in addition to a number of essential components of basic assessment listed in sections I to III.

- General assessment
- Symptom assessment
- Assessment of quality of life impact
- Assessment of the desire for treatment
- Physical examination
- Urinalysis

## 2. JOINT DECISION MAKING

**The patient’s desires and goals for treatment:** Treatment is a matter for discussion and joint decision making between the patient and his or her health care advisors. This process of consultation includes the specific need to assess whether or not the patient wishes to receive treatment and, if so, what treatments he or she would favour. Implicit in this statement is the assumption that the health care provider will give an **appropriate explanation of the patient’s problem** and the **alternative lines of management**, and the potential **benefits** and **risks of treatment**. The assumption that patients almost always wish to have treatment is flawed, and the need to incorporate patient values and preferences is paramount.

**In each algorithm**, treatments are listed in **order of simplicity**, the least invasive being listed first. This order does not imply a scale of efficacy or cost, two factors which need to be considered in choosing the sequence of therapy. The order is likewise not meant to imply a suggested sequence of therapy, which should be determined jointly by the treating health care provider and the patient, considering all the relevant factors listed above.

In the **initial management algorithms**, treatment is **empirically based**, whilst the **specialised management** algorithms usually rely on precise diagnosis from urodynamics and other testing.

The assumption is made that patients will be reassessed at an appropriate time to evaluate their progress.

## 3. USE OF CONTINENCE PRODUCTS

The possible role of **continence products** to prevent, contain and/or manage bladder and/or bowel leakage should be considered at each stage of patient assessment and treatment, to maintain dignity and social functioning, and/or to support self-management or care by others.

Consider **temporary** use of continence products:

- While treatment is awaited.
- **In addition** to treatment; for example using pads and/or urinals when taking anti-muscarinics or carrying out pelvic floor exercises, until sufficient improvement is achieved.

Consider **permanent** use of continence products:

- When treatment is not chosen or not suitable for the individual
- When treatment does not achieve (complete) cure
- For **intermittent use**; for example when the patient has a cough, or needs to travel without reliable toilet access
- For **continuous use** if incontinence is unpredictable and/or frequent or if complications related to incontinence (e.g. skin breakdown) are imminent or present

Consider offering a **mixture** of continence products (disposable/washable; absorbent/non-absorbent) to optimise effectiveness and to reduce costs; e.g. different products for day and night; or for staying at home and for going out/travel/specific activities.

Further guidance on management with continence products is given in Chapter 20 and at the ICI/ICS supported website:

[www.continenceproductadvisor.org](http://www.continenceproductadvisor.org)

At the foot of each of the treatment algorithms below, the phrase “Consider CONTINENCE PRODUCTS for temporary support during treatment”, emphasizes the importance of continence products for many sufferers of incontinence

## I. URINARY INCONTINENCE IN CHILDREN

### A. INITIAL MANAGEMENT

Children present specific management problems for a variety of reasons: assessment requires help from their parents and caregivers; consent to treatment may be problematic; and cooperation in both assessment and treatment may be difficult.

#### 1. INITIAL ASSESSMENT SHOULD INVOLVE A DETAILED INVESTIGATION OF VOIDING AND BOWEL HABITS USING BLADDER/BOWEL DIARIES AND STRUCTURED AND VALIDATED QUESTIONNAIRES.

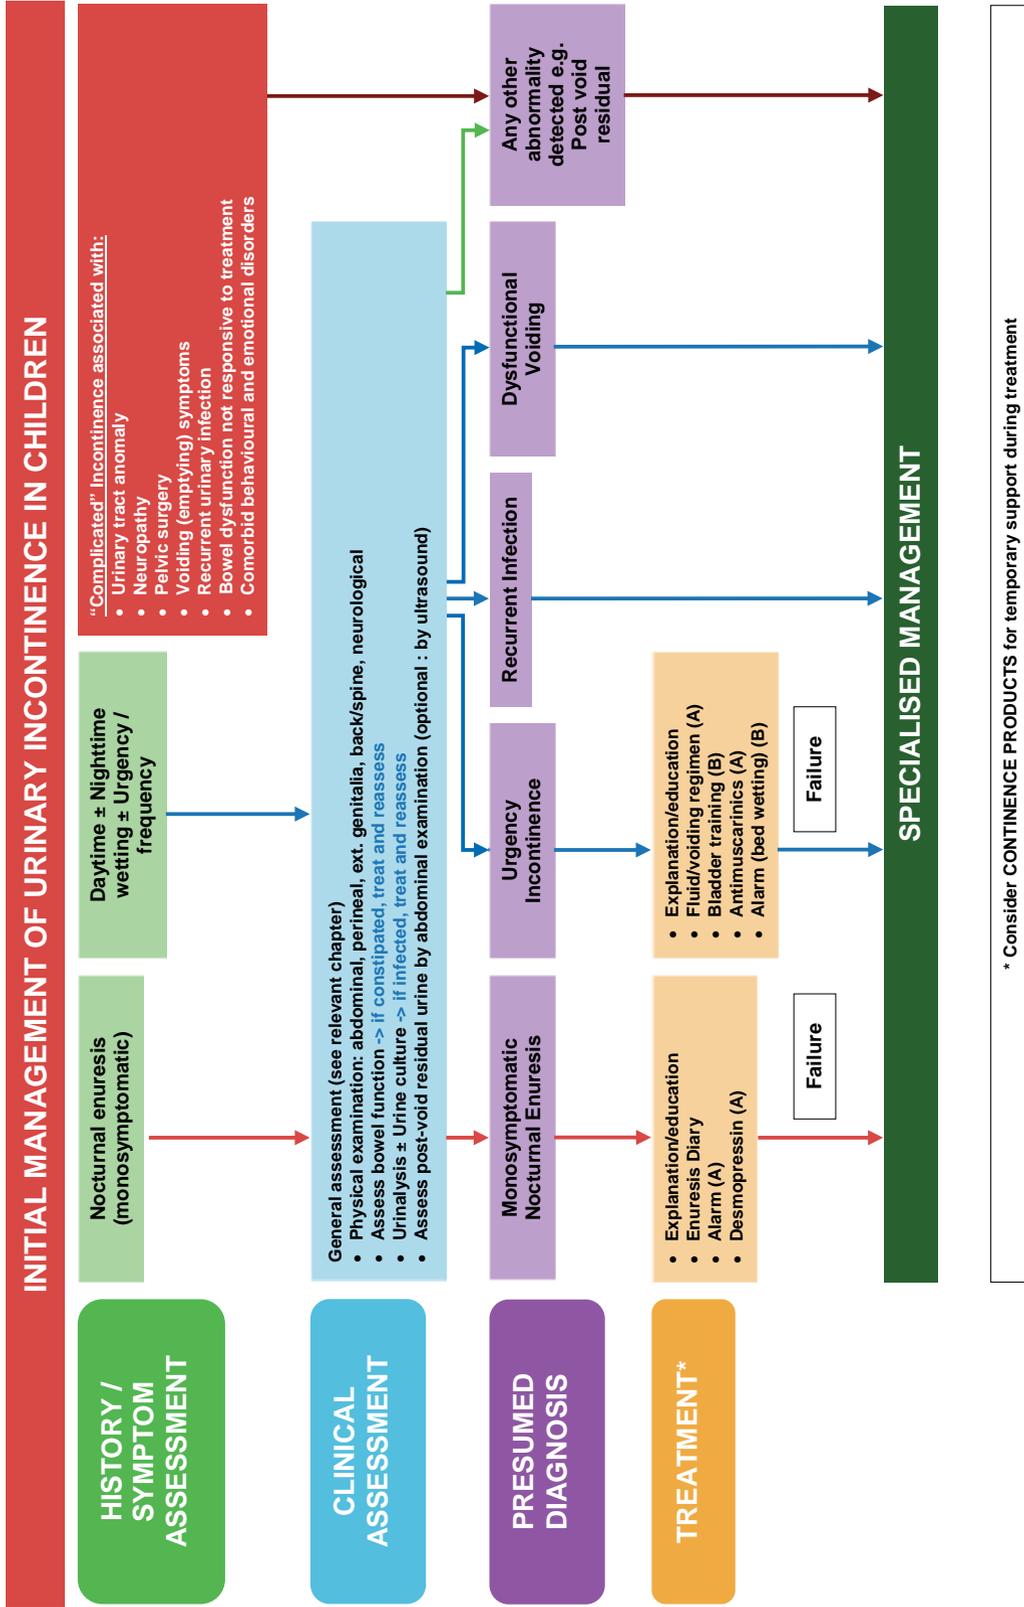

The child's social environment and general and behavioural development should also be formally assessed and recorded. Physical examination should be done to detect a palpable bladder, faecal loading and exclude anatomic and neurological causes. Urine analysis and culture is sufficient to exclude the presence of infection. If possible, the child should be observed voiding.

- **Referrals for specialist treatment are recommended for children who have complicated incontinence associated with:**
  - Recurrent and febrile urinary infection
  - Voiding symptoms or evidence of poor bladder emptying
  - Urinary tract anomalies
  - Previous pelvic surgery
  - Neuropathy or neuropathic origin
  - Bowel dysfunction not responsive to treatment

- Comorbid behavioural (e.g. ADHD and ODD) and emotional disorders.
- **Initial treatment is recommended for the remaining patients who have:**
  - Nocturnal enuresis without other symptoms (monosymptomatic enuresis).
  - Daytime symptoms of frequency, urgency, voiding postponement, straining, interrupted voiding, urgency incontinence with or without nighttime wetting.

### 2. TREATMENT

- Initial treatment for **mono-symptomatic nocturnal enuresis** should include:
  - Parental and child counselling and motivation
  - Review of bladder diary with attention to night-time polyuria
  - Age appropriate education and demystification or explanation
- A choice between either bed wetting alarm (GoR A) or anti-diuretic hormone analogues of desmopressin (GoR A). It may be a parental and child choice if advantages and disadvantages are well explained.
- Daytime incontinence should be managed holistically including:
  - Counselling, timed voiding, behaviour modification and bowel management when necessary (GoR B);
  - Antimuscarinics may be used if the child has OAB symptoms (GoR A)

## I. URINARY INCONTINENCE IN CHILDREN

### B. SPECIALISED MANAGEMENT

- **Two groups of children with “complicated” incontinence** should have specialist management from the outset (Fig. 2).
    - Children whose incontinence is due to, or associated with, **urinary tract anomalies and neuropathy**.
    - **Children** without urinary tract anomalies, but with **recurrent febrile infection** and, proven or suspected, **lower urinary tract dysfunction**.
    - Children who **fail the basic treatment**, but who have neither neurogenic nor anatomical problems, should also receive specialist management.
  - Children with comorbid behavioural and emotional disorders require referral to mental health services, as compliance and treatment outcomes are lower.
- Assessment and treatment should follow evidence-based practice guidelines

### 1. ASSESSMENT

- As part of further assessment, the measurement of **urine flow** (in children old enough), together with the **ultrasound estimate of residual urine** and appearance of the bladder wall and rectum are highly recommended. An evaluation of the **upper urinary tracts with ultrasound is also highly recommended**.
- Those who do not improve **with treatment** and have neither neurogenic nor anatomical problems **should be reassessed** using bladder diaries, symptom questionnaires, urinalysis, uroflowmetry and residual urine determination.
- If there are recurrent and febrile infections**, upper tract imaging and possibly a VCUG should be considered. However, endoscopy is rarely indicated.
- **Urodynamics should be considered:**
  - If the type and severity of lower tract dysfunction **cannot be explained by clinical findings** or in the presence of possible relevant neuropathy or urinary tract anomalies. (GoR B)

- If **invasive treatment** is under consideration, for example, stress incontinence surgery if there is sphincteric incompetence, or bladder augmentation if there is detrusor overactivity. (GoR B)
- If **upper tract dilation exists** and is thought to be due to bladder dysfunction. (GoR A)
- **Invasive urodynamic studies are generally not recommended** if the child has normal upper tract imaging and is to be treated by noninvasive means. (GoR B)
- **Spinal Imaging** (US/X-ray/MRI) may be needed if a bony abnormality or neuro-logical condition is suspected. (GoR A)

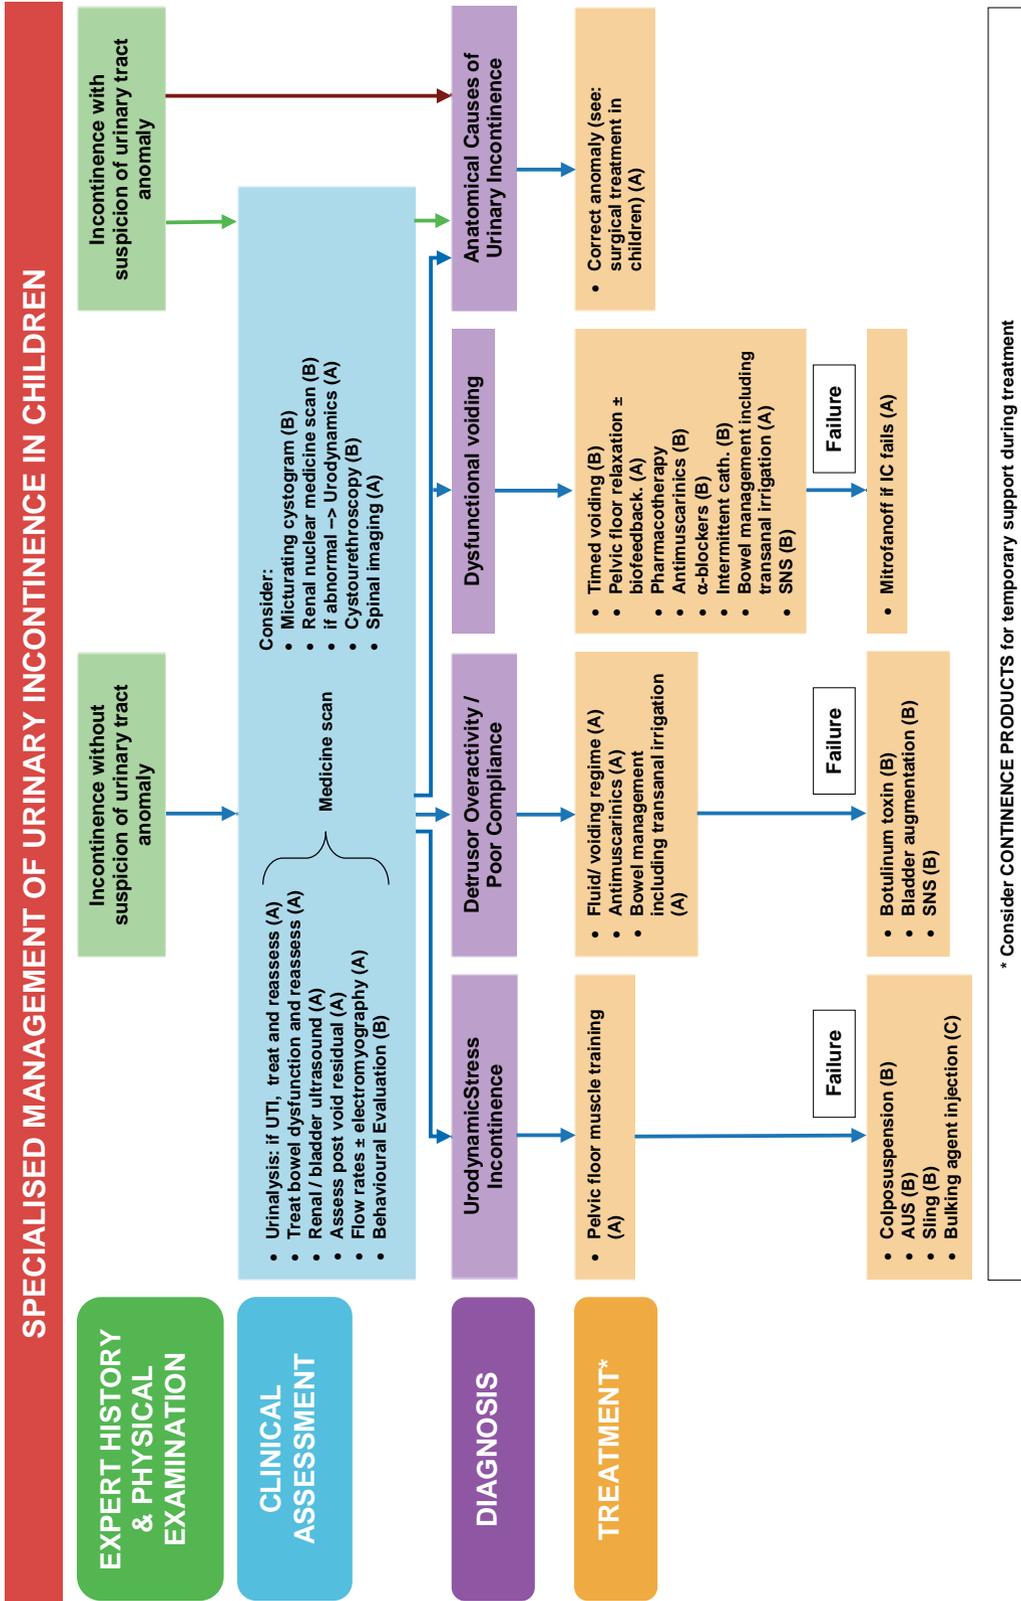

### 2. TREATMENT

The treatment of incontinence associated with **urinary tract anomalies** is complex and cannot easily be dealt with in an algorithm. In many children **more than one pathology** demands treatment. If there are **complex congenital abnormalities present**, the treatment is mostly surgical and it should be individualised according to the type and severity of the problem (please see Children’s Committee Report). Care should be given by specialist children’s nurses and therapists.

- **Initial treatment should be non-surgical.**
  - **For stress urinary incontinence (SU):** pelvic floor muscle training (GoR C).
  - **For OAB symptoms:** fluid/voiding regimens and antimuscarinics (GoR A).
  - **For voiding dysfunction:** timed voiding, voiding re-education, pelvic floor muscle relaxation (+/- biofeedback), alpha-blocker therapy, and intermittent catheterisation (when PVR >30% of bladder capacity) (GoR A/B).
  - **For bowel dysfunction:** high fibre diet and laxatives as appropriate, and transanal irrigation in severe cases (GoR A).

- The child's progress should be assessed and, if quality of life is still significantly impaired, or if the upper urinary tracts are at risk, **surgical treatment** is likely to be necessary.
- **If surgical treatment is required**, then urodynamic studies are recommended to confirm the diagnosis.
  - **For USJ**, colposuspension, sling surgery, bulking agent injection and AUS may be considered (GoR B).
  - **For DO/poor compliance**, botulinum toxin (for DO, and off-label) and bladder augmentation may be performed (GoR B).
  - **If the child cannot do IC** then a Mitrofanoff channel may be needed (GoR A).

2562

## II. URINARY INCONTINENCE IN MEN

2564

### A. INITIAL MANAGEMENT

#### 1. INITIAL ASSESSEMENT SHOULD IDENTIFY:

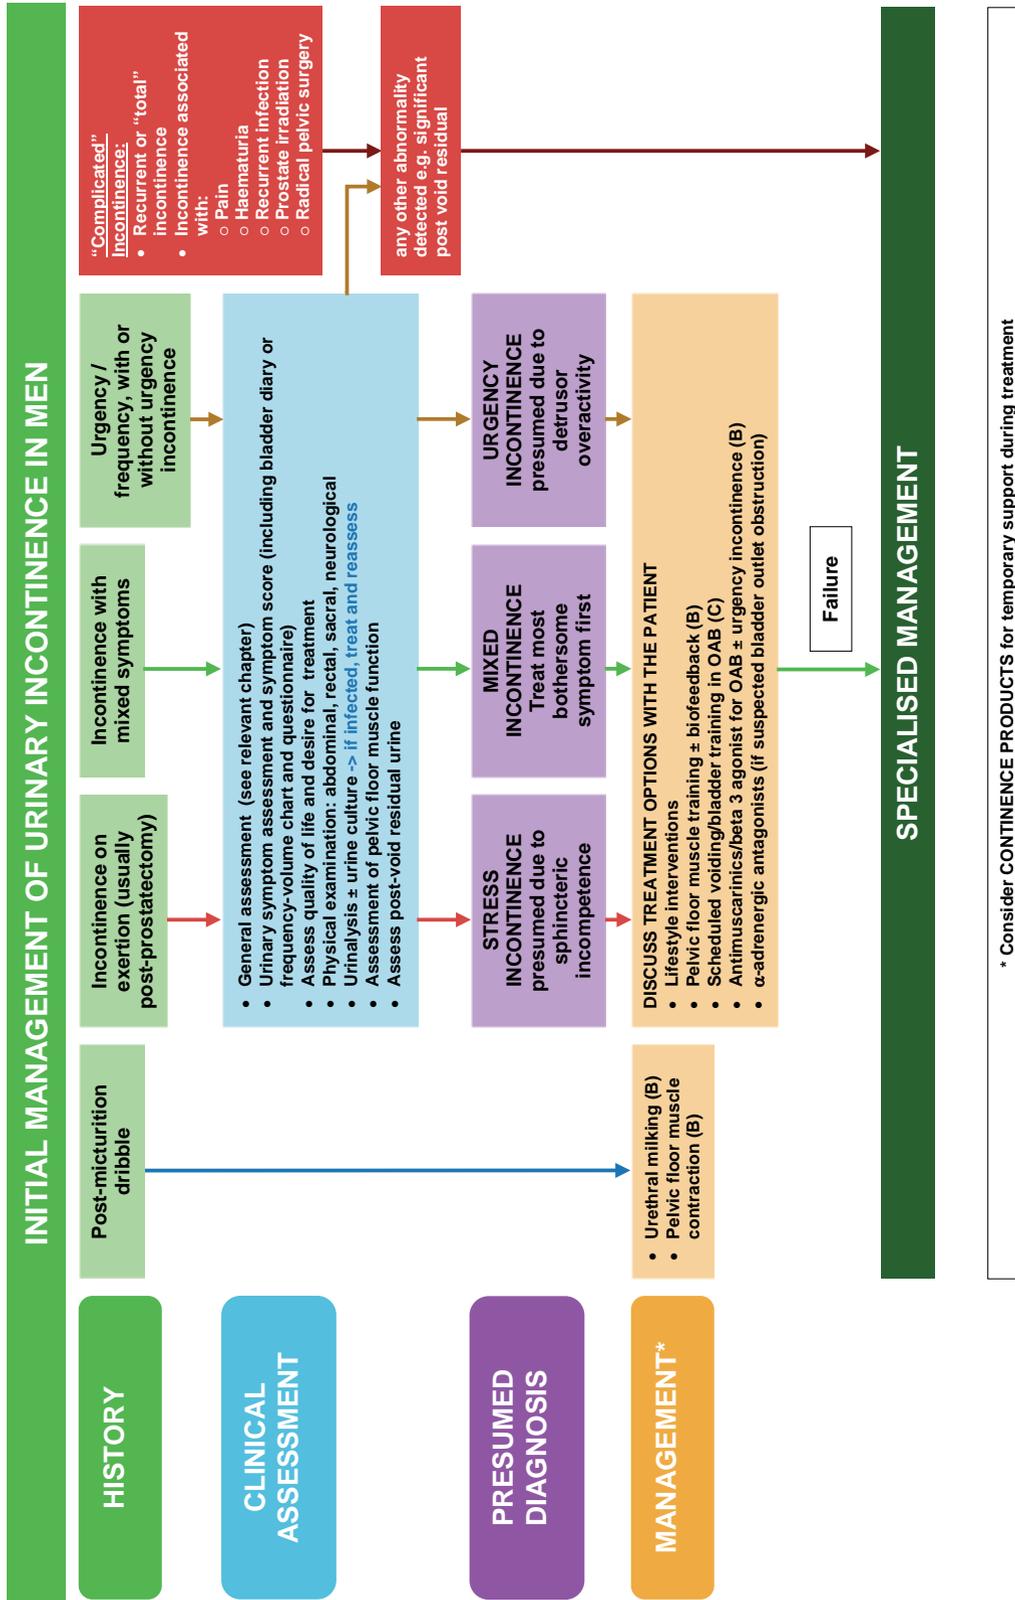

- “Complicated” incontinence group
  - Those with pain or with haematuria, recurrent infection, suspected or proven poor bladder emptying (for example due to bladder outlet obstruction), or incontinence following pelvic irradiation or radical surgery, are recommended for **specialised management**.
- **Poor bladder emptying** may be suspected from symptoms, physical examination or if imaging has been performed by X-ray or ultrasound after voiding.
- **Four other main groups** of men should be identified by initial assessment as being suitable for **initial management**.
  - Those with post-micturition dribble alone,
  - Those with overactive bladder (OAB) symptoms: urgency with or without urgency incontinence, together with frequency and nocturia
  - Those with stress urinary incontinence (most often post-prostatectomy),
  - Those with mixed urinary urgency and stress incontinence (most often post-prostatectomy)

➤ For men with **stress, urgency or mixed urgency** / stress incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, scheduled voiding regimens, behavioural therapies and medication. In particular:

- Lifestyle interventions (eg weight loss GoR B)
  - Supervised pelvic floor muscle training for men with post radical prostatectomy  
SUL accelerates recovery time(GoR B)
  - Scheduled voiding regimen for OAB (GoR C)
  - Antimuscarinic/beta 3 agonist drugs for OAB symptoms with or without urgency incontinence (GoR B) if the patient has no evidence of significant post-void residual urine
  - $\alpha$ -adrenergic antagonists (a-blockers) can be added if it is thought that there may also be bladder outlet obstruction. (GoR C)
- **Should initial treatment be unsuccessful** after a reasonable time (for example, 8-12 weeks), **specialist advice** is highly recommended.
- Clinicians are likely to wish to treat the **most bothersome symptom** first in men with symptoms of **mixed** incontinence.

#### 2. MANAGEMENT

- For men with **post-micturition dribble**, this requires no assessment and can usually be treated by teaching the man how to do a strong pelvic floor muscle contraction after voiding, or manual compression of the bulbous urethra directly after micturition. (GoR B)

\* Consider CONTINENCE PRODUCTS for temporary support during treatment

## II. URINARY INCONTINENCE IN MEN

2566

### B. SPECIALISED MANAGEMENT

The specialist may first **reinstitute initial management** if it is felt that previous therapy had been inadequate.

#### 1. ASSESSMENT

- Patients with “**complicated**” **incontinence** referred directly to specialised management, are likely to require **additional testing**, such as cytology, cystourethroscopy and urinary tract imaging.

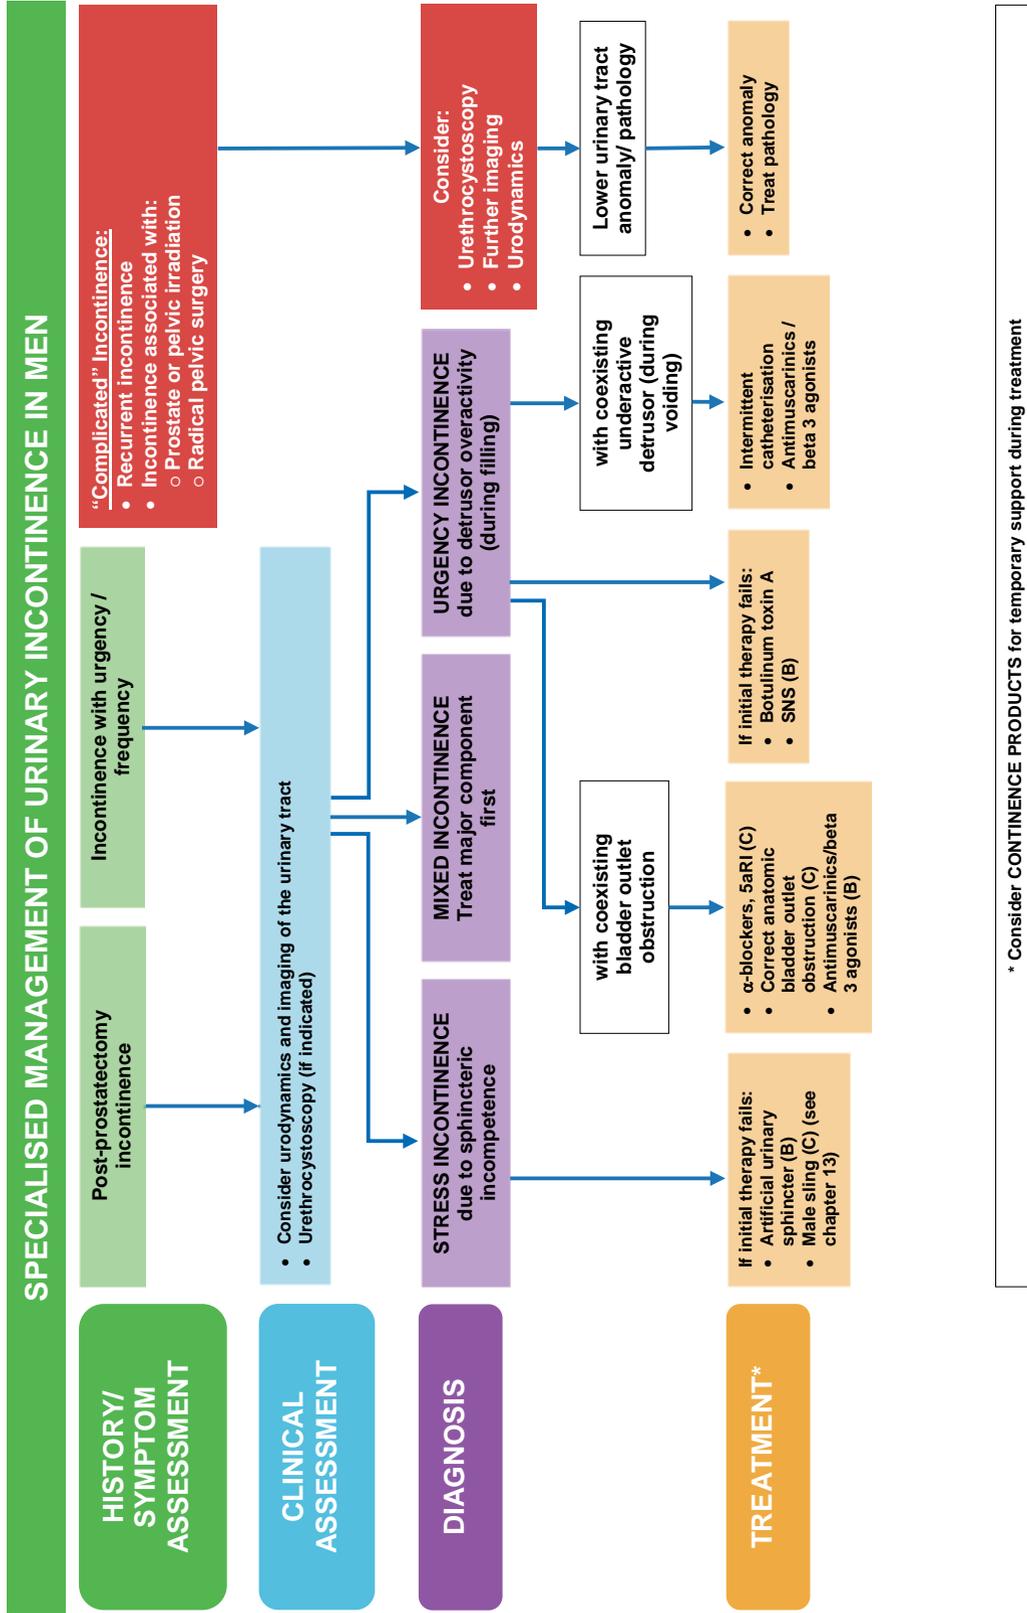

**If additional testing is normal** then those individuals can be treated for incontinence by the initial or specialised management options as appropriate.

**If symptoms** suggestive of detrusor overactivity, or of sphincter incompetence **persist**, then **urodynamic** studies are advisable in order to arrive at a precise diagnosis, prior to invasive treatment.

#### 2. TREATMENT

When basic management has been unsuccessful and if the patient's incontinence markedly disrupts his quality of life then **invasive therapies** should be considered.

- For **sphincter incompetence** the recommended option is the artificial urinary sphincter (GoR B). Other options, such as a male sling, may be considered (GoR C).
- For **refractory idiopathic detrusor overactivity**, (with intractable overactive bladder symptoms) the recommended therapies are: Botulinum toxin A (GoR B), and SNS (GoR C).
- When incontinence has been shown to be associated with **poor bladder emptying** due to **detrusor underactivity**, it is recommended that **effective means** are used to ensure bladder emptying, for example, intermittent catheterisation (GoR B/C).
- If incontinence is associated with bladder outlet obstruction, then consideration should be given to surgical treatment to relieve obstruction (GoR B).  $\alpha$ -blockers and/or 5 $\alpha$ - reductase inhibitors would be an optional treatment (GoR C).
- There is increased evidence for the safety of antimuscarinics for overactive bladder symptoms in men, chiefly in combination with an  $\alpha$ -blocker (GoR B).

### III. URINARY INCONTINENCE IN WOMEN

2568

#### A. INITIAL MANAGEMENT

##### 1. INITIAL ASSESSMENT SHOULD IDENTIFY:

- **“Complicated” incontinence group.**  
Those with pain or haematuria, recurrent infections, suspected or proven voiding problems, significant pelvic organ prolapse or who have persistent incontinence or recurrent incontinence after pelvic irradiation, radical pelvic surgery, previous incontinence surgery, or who have a suspected fistula, should be referred to a specialist.
  - **Three other main groups** of patients should be identified by initial assessment.
    - Women with **stress incontinence** on physical activity
    - Women with **urgency, frequency** with or without urgency incontinence: overactive bladder (OAB)
    - Those women with **mixed** urgency and stress incontinence
- Abdominal, pelvic and perineal examinations should be a routine part of physical examination. Women should be asked to perform a “stress test” (cough and strain to detect leakage likely to be due to sphincter incompetence). Any pelvic organ prolapse or urogenital atrophy should be assessed. Vaginal or rectal examination allows the assessment of voluntary pelvic floor muscle function, an important step prior to the teaching of pelvic floor muscle training.

##### 2. TREATMENT

- For women with **stress, urgency or mixed** urinary incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training,

PFMT), scheduled voiding regimes, behavioural therapies and medication. In particular:

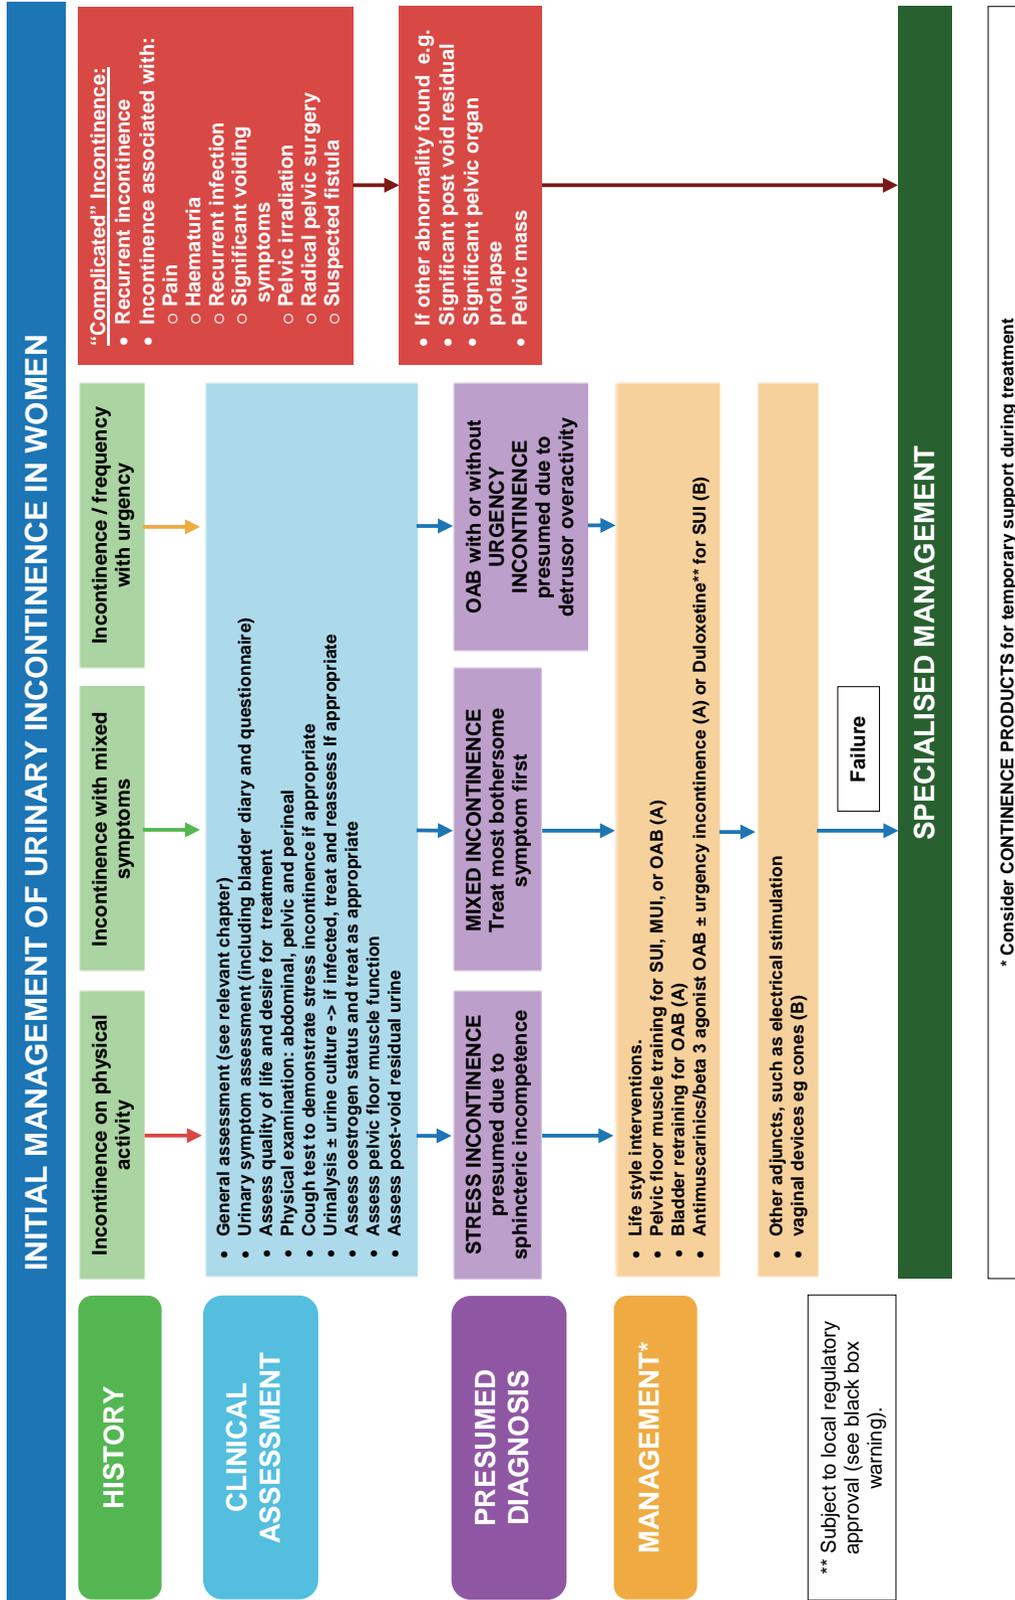

- **Advice** on caffeine reduction for OAB (GoR B) and weight reduction (GoR A).
- Supervised pelvic floor muscle training (GoR A), supervised vaginal cones training for women with stress incontinence (GoR B).
- Supervised bladder training (GoR A) for OAB.
- **If oestrogen deficiency** and/or **UTI** is found, the patient should be treated at initial assessment and then reassessed after using vaginal oestrogens for a suitable period (GoR B).
- **Antimuscarinics/beta 3 agonist** for OAB symptoms with or without urgency incontinence (GoR A); duloxetine\* may be considered for stress urinary incontinence (GoR B)

PFMT should be based on sound muscle training principles such as specificity, overload progression, correct contraction confirmed prior to training and use of “the Knack” for 12 weeks before reassessment and possible specialist referral.

Clinicians are likely to wish to treat the **most bother some symptom first** in women with symptoms of mixed incontinence. (GoR C).

- Some women with significant pelvic organ prolapse can be treated by vaginal devices that treat both incontinence and prolapse (incontinence rings and dishes).

\*Duloxetine is not approved for use in United States. In Europe it is approved for use in severe stress incontinence (see committee report on pharmacological management for information regarding efficacy, adverse events, and ‘black box’ warning by the Food and Drug Administration of the United States).

\*\* Subject to local regulatory approval (see black box warning).

\* Consider CONTINENCE PRODUCTS for temporary support during treatment

### III. URINARY INCONTINENCE IN WOMEN

2570

#### A. SPECIALISED MANAGEMENT

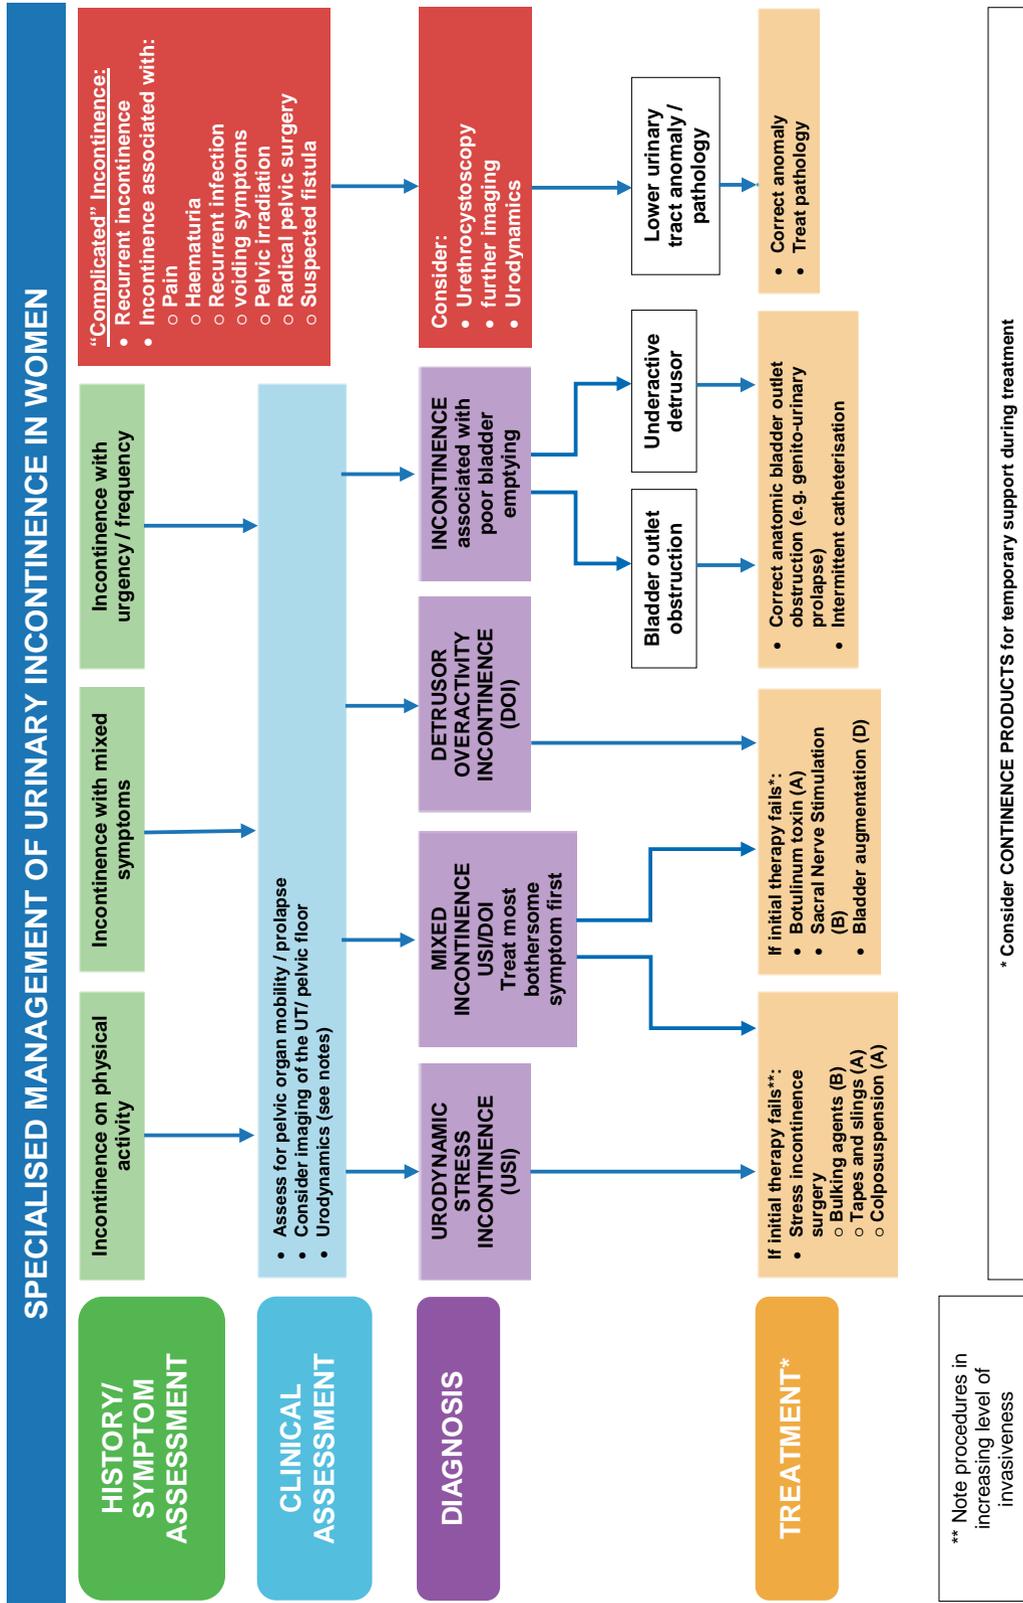

##### 1. ASSESSMENT

Women who have “**complicated**” incontinence (see initial algorithm) may need to have additional tests such as cytology, urodynamics, cystourethroscopy or urinary tract imaging. If these tests are normal then they should be treated for incontinence by the initial or specialised management options as appropriate.

- Those women with persistent symptoms despite **initial management** and whose quality of life is impaired are likely to request further treatment. If initial management has been given an adequate trial then **interventional therapy may be desired**. When the results of urodynamic testing may change management, we highly recommend testing prior to intervention in order to diagnose the incontinence type and, therefore, inform the management plan. Urethral function testing by urethral pressure profile or leak point pressure is optional.
- Systematic assessment for **pelvic organ prolapse** is highly recommended and the POP-Q method should be used in research studies. Women with co-existing pelvic organ prolapse should have their prolapse treated as appropriate.

##### 2. TREATMENT

- If **stress incontinence is confirmed** then the treatment options that are recommended for patients include the full range of non-surgical treatments, as well as colposuspension procedures, (GoR A) and bladder neck/sub-urethral sling operations (GoR A). All of these procedures have potential risks and associated complications which should be discussed with the individual. **The correction of symptomatic** pelvic organ prolapse may be desirable at the same time. For selected patients injectable bulking agents (GoR B) and the artificial urinary sphincter (GoR C) can be considered.
- **Refractory urgency incontinence** (overactive bladder) secondary to idiopathic detrusor overactivity may be treated by botulinum toxin A (GoR A), sacral nerve stimulation (GoR B) or bladder augmentation/intestinal cystoplasty (GoR D).
- Those patients with **voiding dysfunction** leading to significant post-void residual urine (for example, >30% of total bladder capacity) may have bladder outlet obstruction or detrusor underactivity. Prolapse is a common reversible cause, of voiding dysfunction.

## IV. FISTULAE

In the developing world, fistulae occur as a consequence of poor perinatal care. Despite vast surgical experience in some centres, published research is of low quality.

In the developed world, iatrogenic urogenital fistulae are known complications of pelvic surgery and oncological treatments such as radiotherapy, chemotherapy or a combination of both. In the oncological context, fistulae may also occur as a result of primary or recurrent malignancy. The development of fistula following radiotherapy for primary treatment should trigger a search for evidence of tumour recurrence (GoR D). The use of neoadjuvant or adjuvant therapies is likely to be associated with a greater risk of fistula development than the primary treatment alone.

The most common non-obstetric causes of fistulae involving the gastro-intestinal tract are diverticular disease, Crohn's disease, malignancy and radiotherapy.

### 1. INITIAL ASSESSMENT

Early detection of fistulae could be improved by examining all women after their delivery, or prevented by Caesarian section for women who suffer prolonged labour and who are at risk of developing an obstetric fistula. Associated pathologies should be actively searched for and should be taken into account in the treatment plan: all components of the 'obstructed labour injury complex' should be examined. Prevention by better health education, and by avoiding harmful practices must be encouraged.

Classification of fistulae is recommended. Although many classification systems exist, the committee recommends the use of the Goh, WHO or Tafesse classification systems (GoR B)

The formal classification of the fistula should be done under anaesthesia when the patient is on the operation table, just before surgery.

- Leakage of stool, urine, or possibly both is the hallmark sign of a fistula. The leakage is usually painless, may be intermittent if it is position dependent, or may be constant.
- CT and cystoscopy appear more consistent in the confirmation and location of possible intestino-vesical fistulae, than other investigations (GoR C)

- Level 3 evidence indicates that the routine use of cystoscopy with dye testing at gynaecological surgery has high sensitivity, specificity and negative predictive value in the detection of ureteric injury, although false positive tests do occur. (GoR C)

- Ureteric injury or fistula may be suspected in patients following pelvic surgery if a fluid leak or pelvi-calyceal dilatation occurs postoperatively. (GoR D)

- Uretero-arterial fistula may be suspected in patients presenting with haematuria with a history of relevant pelvic surgery and indwelling ureteric stent. (GoR D)

- Elevated levels of creatinine in drainage fluid following pelvic surgery are suggestive of urine leaking due to a urinary tract injury. (GoR D)

### 2. MANAGEMENT OF NEW AND ESTABLISHED VVF

Management of VVF depends on whether the fistula is diagnosed within a few weeks of its occurrence or whether the woman presents late with an established fistula.

Early fistulae are those which are not re-epithelialised, and ischaemic and necrotic tissue can be present at the time of examination. There is evidence that early catheter care will result in the cure of a significant minority of VVFs. (GoR C)

Established fistulae are re-epithelialised and show no oedema, ischaemic changes or inflammation. These fistulae and those that fail catheter treatment should be treated surgically by an experienced surgeon. (GoR C)

### 3. TREATMENT

If catheter drainage fails, then fistula repair will be necessary. There are certain principles behind fistula repair:

- Necrotic tissue must be removed prior to fistula repair.
- Fistula repair must only be undertaken by a properly trained surgeon.
- Adequate post-operative care is essential.

- Proper follow-up should be arranged.

In principle, most fistulae can be dealt with by the vaginal approach, but an abdominal approach may be needed in some cases (e.g. concomitant reconstructive procedures e.g. ureteral reimplantation or bladder augmentation). (GoR C)

A tension-free single layer closure of the bladder wall and closure of the vaginal wall in a separate layer is advocated. A Martius flap in primary fistula repair is not recommended.

When reporting on outcome after fistula repair, authors should make a clear distinction between fistula closure rates and post-operative incontinence rates and the time at which the follow-up was organised.

Prevention of post-operative stress incontinence must be added to the surgical procedure if the urethral closing mechanism is involved. This can be done by a good repair of the pubocervical fascia and refixation or by adding a sling procedure.

Attention should be given as appropriate to skin care, nutrition, rehabilitation, counselling and support prior to and following fistula repair. (GoR D)

There is no proven benefit to delayed repair of vesicovaginal fistulae; the timing of repair should be tailored to the individual patient and surgeon requirements, but can be undertaken as soon as any oedema, inflammation, tissue necrosis, and infection have resolved. (GoR B)

There are no high quality data to indicate greater cure rates for any one technique as compared to others; level 3 evidence indicates similar success rates for vaginal and abdominal, and for transvesical and transperitoneal approaches. (GoR C)

A variety of interpositional grafts can be used in either abdominal or vaginal procedures, although there is little evidence to support their use in any specific setting. (GoR C)

Conventional and robotically-assisted laparoscopic approaches have both been shown to be feasible in selected cases; the indications for, or optimal patient for these techniques is not yet clear. (GoR C)

A period of continuous bladder drainage is crucial to successful fistula repair; there are no high level data to support any particular type, route, or duration of catheterisation. Current practice suggests, 10-14 days for simple and/or post-surgical fistulae, 14-21 days for complex and/or post-radiation fistulae. (GoR D)

Whilst diversion is used more widely in radiation-associated fistulae of all types as compared to non-radiated fistulae, there is low-level evidence that repair procedures can achieve successful fistula closure and continence in appropriately selected cases. (GoR C)

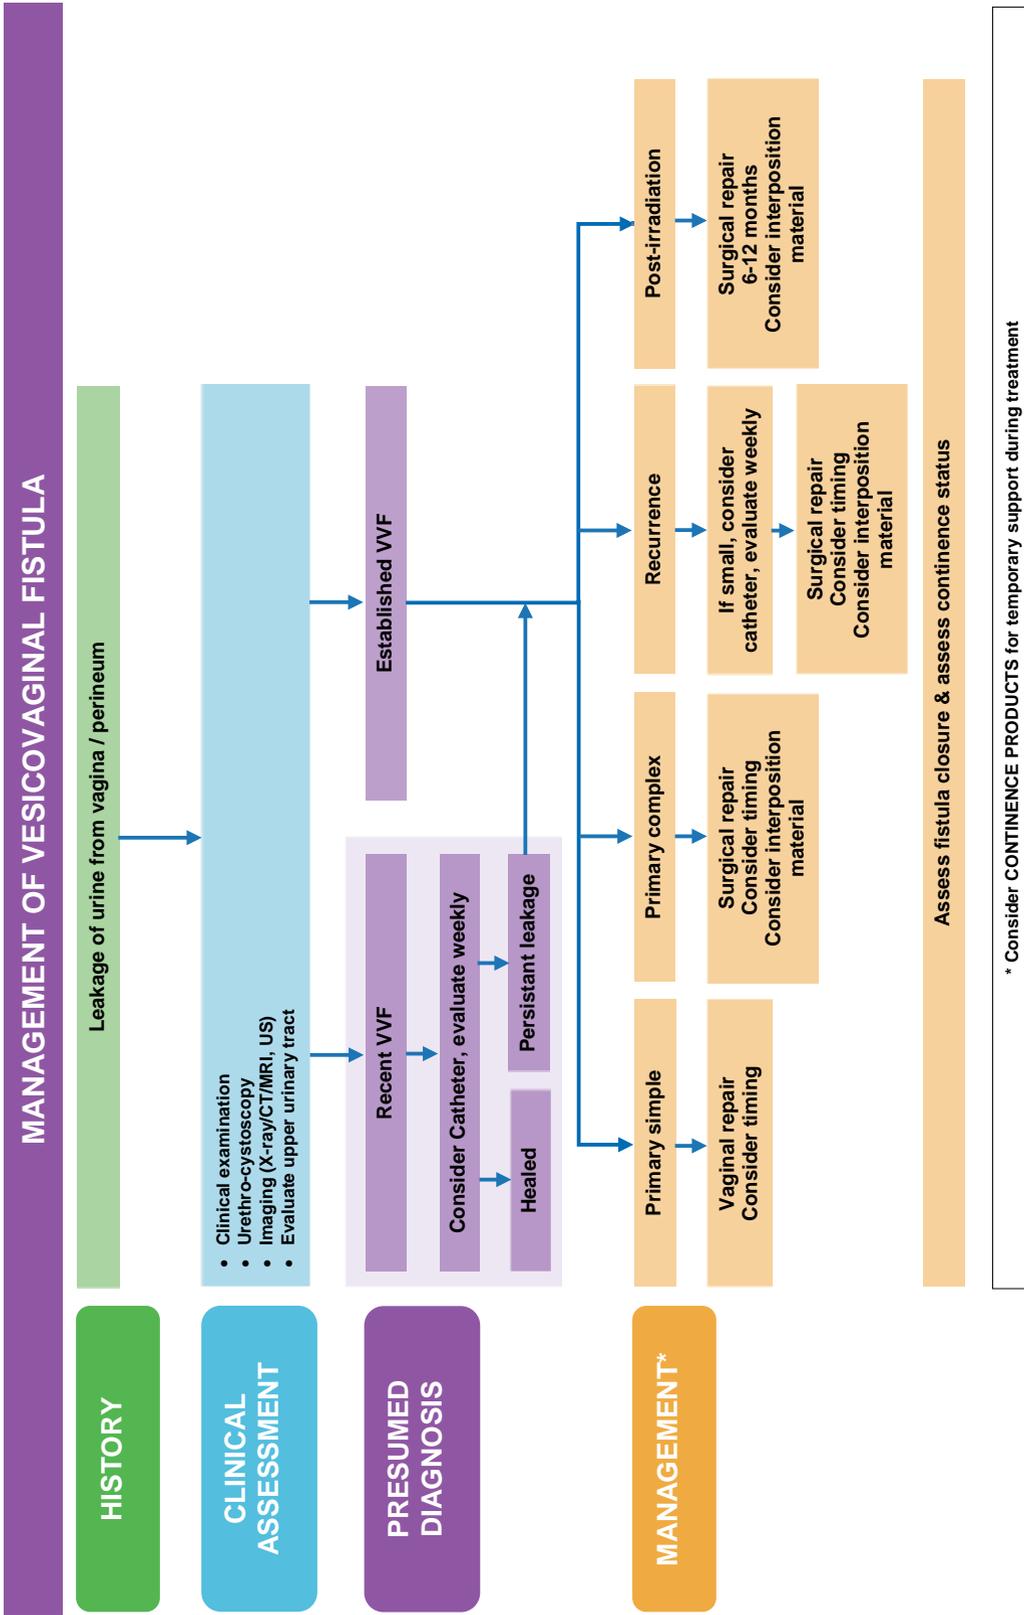

Where urinary and/or faecal diversions are required, attempts should be made to avoid using irradiated tissues wherever possible, and to minimise the potential for anastomotic complications. (GoR C)

There is low-level evidence to support the use of interposition grafts when repair of radiation-associated fistulae is undertaken. (GoR C)

#### 4. MANAGEMENT OF THE COMPLICATIONS OF VVF

The complications of vesico-vaginal fistulae are many but include:

- Persistence or recurrence of urinary incontinence
- Persistence of lower urinary tract symptoms or occurrence of new lower urinary tract symptoms, including overactive bladder
- Urinary tract infections
- Upper urinary tract symptoms, including loin pain
- Dyspareunia and sexual dysfunction
- Infertility
- Neurological symptoms
- Psychological problems and mental illness

2574

### 1. MANAGEMENT OF FISTULAE INVOLVING BOWEL

- There is limited evidence to support a non-surgical or conservative surgical approach in colo-vesical fistulae where there are minimal symptoms or evidence of limited bowel involvement. (GoR C)
- A one-stage approach to surgery for intestino-vesical fistulae is appropriate in many cases, but should be limited to those patients whose nutritional state is good, and where there is no evidence of additional intra-abdominal pathology (e.g. severe inflammation, radiation injury, advanced malignancy, intestinal obstruction) or major co-morbidity. (GoR B)
- A laparoscopic/robotic approach to one-stage management is feasible, although there is no high level evidence to allow comparison of outcomes with open surgery. (GoR D)

### 2. MANAGEMENT OF URETERIC FISTULAE

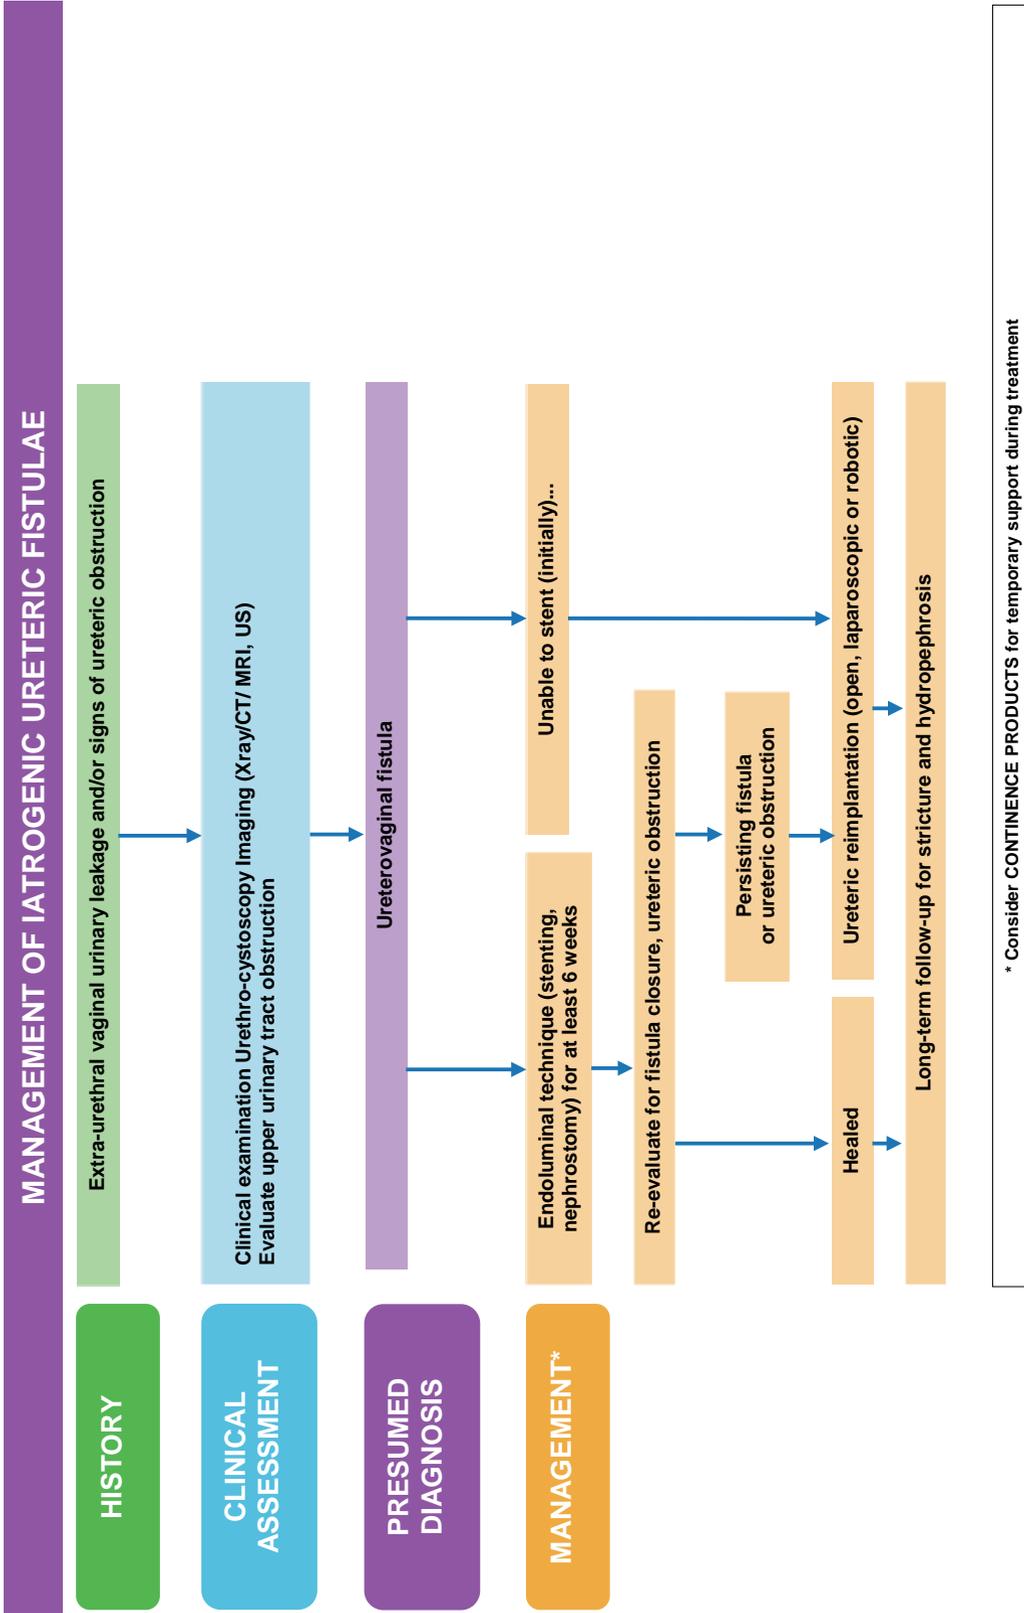

- Surgeons undertaking complex pelvic surgery should be competent at identifying, preserving and repairing the ureter. (GoR D)
- Ureteric stents are not required as prophylaxis against injury during routine gynaecological surgery, while their role in more extensive surgery remains to be established. (GoR B)

- Most upper urinary tract fistulae should be initially managed by conservative or endoluminal techniques where such expertise and facilities exist. (GoR B)
- Persistent ureterovaginal fistulae should be repaired by an abdominal approach using open, laparoscopic or robotic techniques according to availability and competence. (GoR D)
- For patients with ureteric fistulae associated with advanced pelvic cancer and poor performance status, palliation by nephrostomy tube diversion and endoluminal distal ureteric occlusion is an option. (GoR C)

### 3. MANAGEMENT OF URETHRO-VAGINAL FISTULAE

#### Recommendations

- Urethrovaginal fistulae are preferably treated by a vaginal approach. (GoR C)
- A variety of autologous tissue interposition techniques have been described, but their value remains uncertain. (GoR C)
- Urethrovaginal fistulae repair may be complicated by stress incontinence, urethral stricture and urethral shortening necessitating long-term follow-up. (GoR C)

2576

## V. PELVIC ORGAN PROLAPSE

### 1. INTRODUCTION

Pelvic organ prolapse includes vaginal and rectal prolapse. Treatment of pelvic organ prolapse is generally reserved for symptomatic prolapse. Clinicians should recognise that coexistent pelvic floor symptoms are frequently present and that these symptoms may or may not be related to the prolapse. Women with prolapse require a careful and detailed initial assessment not only of the prolapse but associated bladder, bowel and sexual function.

### 2. ASSESSMENT

Symptom assessment preferably with a validated pelvic floor questionnaire that assesses bladder, bowel, vaginal and sexual function and bothersomeness is required. (Grade C).

Physical examination should:

- Report the most distal site of vaginal descent in relation to a fixed point such as the hymen and include an assessment of the anterior posterior and apical vagina. While standardised reporting utilising tools such as the Pelvic Organ Prolapse Quantification (POP-Q) are encouraged. The system used to measure the extent of the prolapse should be documented.
- Be undertaken in the standing position to evaluate the full extent of the prolapse.
- Determine if coexistent pelvic pathology is present on careful bimanual examination. Cytological screening of the cervix should be undertaken if required.
- The prolapse should be reduced to document the presence of occult stress urinary incontinence (see chapter for prolapse and urinary incontinence pathway).
- Assess pelvic floor muscle function (see chapter for full review).
- Determine if epithelial/ mucosal ulceration is present.
- Evaluate anal sphincter tone and or the presence of rectal prolapse in those with bowel symptoms (refer to chapter for pelvic organ prolapse and bowel symptom pathway).

When examination findings of the extent of the prolapse are not consistent with the history the examination can be repeated in a few weeks' time. (GoR C).

Post void residual should be measured; while most elevated post-void residual urines (150mls) resolve with treatment of the prolapse, a specialist consultation is required.

### 3. MANAGEMENT

*Observation* is appropriate when medically safe (GoR C).

Lifestyle interventions include weight loss, treating constipation, avoiding straining at stool and heavy lifting (GoR C).

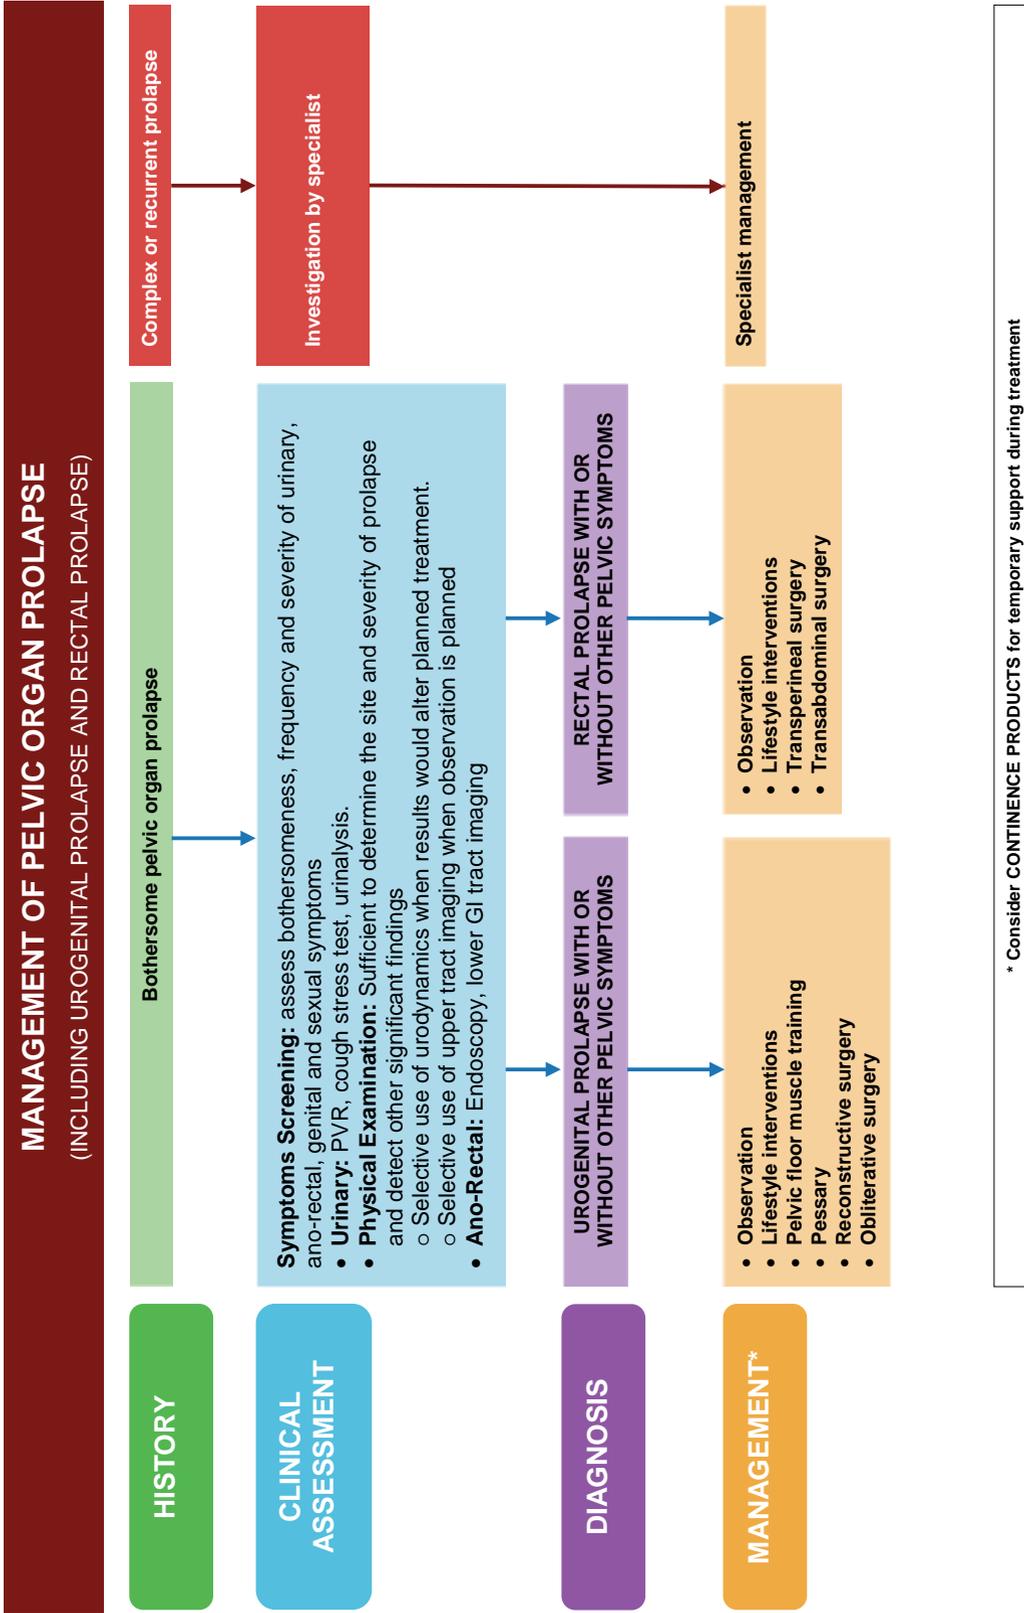

*Pelvic floor muscle training:*

- Reduces associated pelvic floor symptoms (GoR A).
  - May reduce the symptom of vaginal bulge (GoR C).
  - Does not reduce extent of prolapse on examination based on POP-Q stage (GoR B).
- Vaginal Pessary:* when successfully fitted
- May reduce prolapse symptoms (GoR B)
  - Need to be regularly reviewed (GoR C)
  - Have high rates of discontinuation (GoR C)

*Local Oestrogens* are recommended in those with hypo-oestrogenic symptoms and in those with urethral prolapse or vaginal ulceration (GoR B)

*Reconstructive surgery* is reserved for those with symptomatic prolapse and is aimed at correcting the vaginal topography and functional pathology. Please see text for full recommendations.

*Obliterative surgery* is an important and effective treatment option in those who are happy to sacrifice coital activity. (GoR C)

2578

## PATHWAY FOR THE SURGICAL MANAGEMENT OF PELVIC ORGAN PROLAPSE

The pelvic organ prolapse (POP) surgery pathway was designed to provide an evidence based guide for both clinicians and women for the surgical management of pelvic organ prolapse. Within the pathway green lines highlight the preferred option and yellow lines indicate reasonable options.

An early option in the treatment pathway for women not wanting to preserve sexual function is obliterative surgery (colpocleisis) which is an efficacious intervention that has low morbidity (LoE 3).

The majority of women will enter the reconstructive pathway. Apical suspension procedures should be considered in all cases with 10-year re-operation rates for prolapse being significantly reduced if apical suspensions are performed concomitantly with both anterior and posterior colporrhaphy as compared to those performed without apical support.

In those undergoing anterior and posterior colporrhaphy the evidence is supportive of traditional native tissue suture plications (LoE 1). In the anterior compartment permanent mesh could be considered for recurrent cases when the patient understands the risk benefit profile for these interventions and that the data for their use is scant. Evidence is not supportive of biological grafts in the anterior compartment (LoE 2).

In the posterior compartment, fascial plication is superior to site specific native tissue repair (LoE 2) and levatorplasty should be avoided due to higher rates of dyspareunia (LoE3). Data are not supportive of biological or permanent mesh grafts. Posterior colporrhaphy is superior to transanal repair of rectocele (LoE 1) and there is no data to support ventral rectopexy with or without vaginal graft for rectocele.

With recognition of the importance of apical vaginal support in minimising the risk of subsequent recurrence, the pathway separates those with post-hysterectomy (vault) prolapse from those with uterine prolapse.

Data are supportive of sacral colpopexy as the preferred intervention for vault prolapse with superior anatomical and functional outcomes when compared to a variety of vaginal based interventions with and without transvaginal mesh (LoE1). This preference is highlighted by a green preferred option arrow in the management pathway. In recognition that not all patients are suitable for sacral colpopexy, a yellow reasonable option is included for vaginal based apical support (uterosacral or sacrospinous colpopexy). Both uterosacral and sacrospinous colpopexy are

equally effective vaginal options (LoE 1) and utilisation of transvaginal permanent mesh apical support is not supported by the data (LoE1).

When performing sacral colpopexy the laparoscopic approach is preferred with reduced peri-operative morbidity and cost when compared to both the open or robotic approach (LoE 2). The yellow reasonable option pathway exists for both open and robotic options in recognition of the longer learning curve associated with the laparoscopic approach (LoE3).

Apical support in those with uterine prolapse can be performed abdominally or vaginally and includes options for both uterine preservation (hysterectomy) and hysterectomy, with not insignificant relative contraindications for uterine preservation listed in Table 6. In post-menopausal women undergoing hysterectomy, bilateral salpingo-oophorectomy (BSO) significantly reduces the rate of ovarian cancer without increased morbidity. In those retaining ovaries at hysterectomy, bilateral salpingectomy also reduces rate of subsequent ovarian cancer.

Vaginal hysterectomy is equally effective as vaginal hysterectomy with apical suspension and is associated with reduced blood loss and operating time as compared to hysterectomy (LoE 1). Vaginal hysterectomy with apical support has a lower re-operation for prolapse than abdominal sacrohysteropexy (LoE1). Sacrohysteropexy has a higher re-operation for prolapse than sacral colpopexy with hysterectomy however sacral colpopexy with hysterectomy is not recommended due to the high rate of mesh exposure (LoE2). Supra-cervical hysterectomy at sacral colpopexy reduces the rate of mesh exposure associated with hysterectomy and sacral colpopexy however in a single retrospective study, recurrent prolapse was more common in the supracervical hysterectomy group. Although those data is not complete, vaginal based hysterectomy and hysterectomy with apical support should generally be considered as preferred options for uterine prolapse with sacral colpopexy reserved for vault prolapse.

Those undergoing prolapse surgery with stress urinary incontinence (SUI) and occult SUI should generally have continence surgery performed at the time of prolapse surgery (LoE1). Those with prolapse without SUI or occult SUI should not undergo continence surgery at time of prolapse surgery (LoE1).

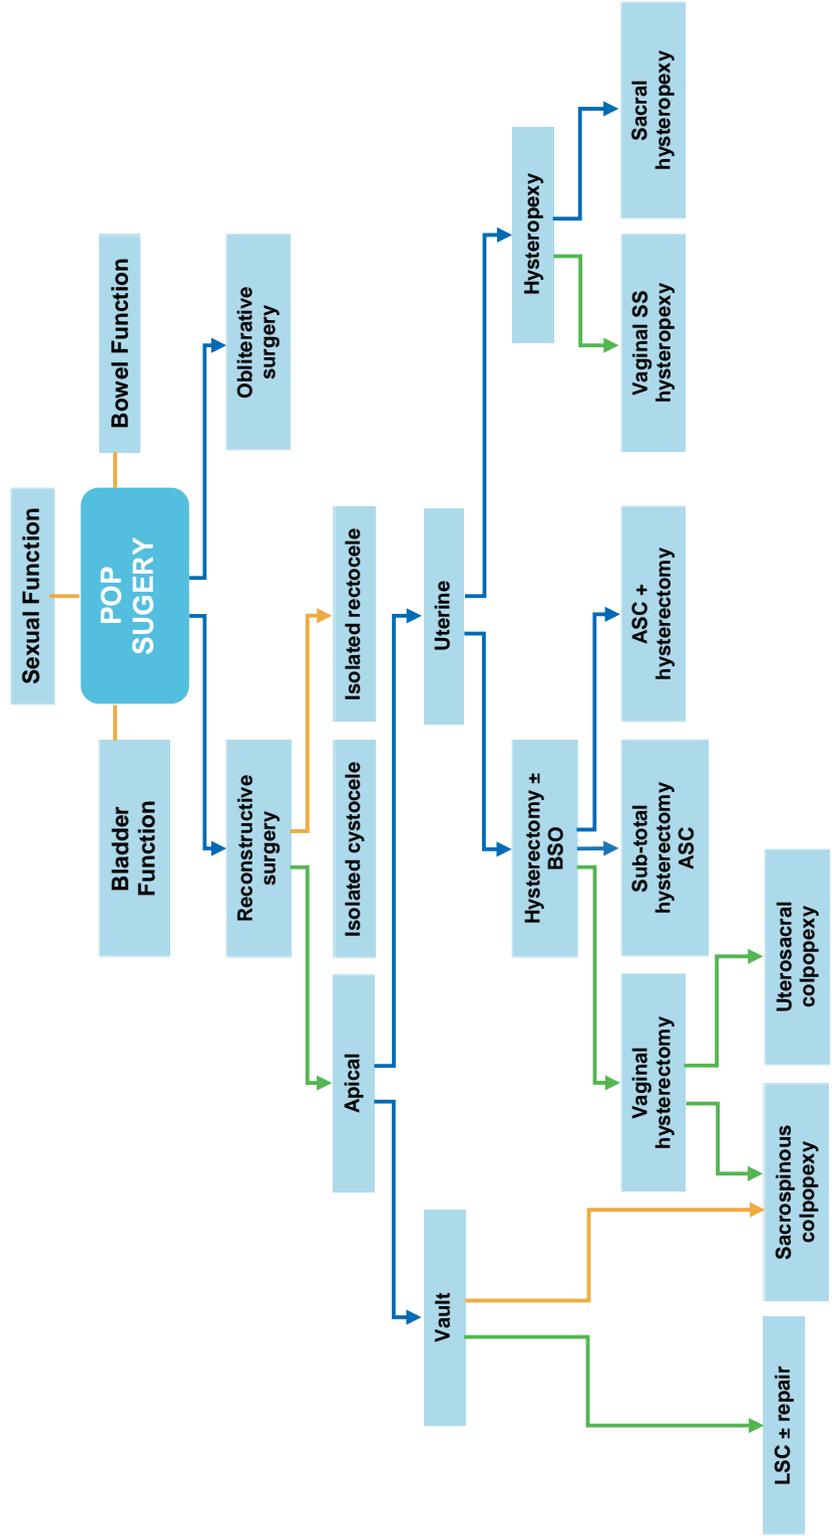

Based largely upon expert opinion (LoE3) those with prolapse without bowel symptoms and those with impaired defaecation with rectocele should undergo prolapse surgery as per the above pathway. Those with POP and impaired defaecation without rectocele, and those with faecal incontinence require colorectal assessment. If

Those undergoing POP surgery generally have improved sexual function post-operatively but a small number undergoing any POP surgery will experience painful intercourse post-operatively that may require subsequent intervention (LoE 1).

rectal prolapse exists, these patients may benefit from combined colorectal and gynaecological interventions. Those with significant constipation and prolapse should be approached cautiously and may benefit from gastroenterology assessment prior to entering the POP surgery pathway.

2580

**PATHWAY FOR THE SURGICAL MANAGEMENT OF PELVIC ORGAN PROLAPSE**

Consider CONTINENCE PRODUCTS for temporary support during treatment

## VI. URINARY INCONTINENCE IN NEUROLOGICAL PATIENTS

2582

### A. INITIAL MANAGEMENT

#### 1. STRONG GENERAL RECOMMENDATIONS

- Patients with known neurological disease often need evaluation to exclude bladder dysfunction, not only if symptoms occur, but as a standard assessment as neurogenic bladder has a high prevalence in the particular disease (for prevalence figures see chapter)
- A possible neurological cause of "idiopathic" incontinence should always be considered. Diagnostic steps to evaluate this include basic assessments, such as history and physical examination, urodynamics and specialised tests.
- Incontinence in neurological patients does not necessarily relate to the neurologic pathology. Other diseases such as prostate pathology, pelvic organ prolapse, might have an influence. These factors should be evaluated as potential primary or contributory causes.
- Extensive diagnostic evaluation is often useful and necessary to tailor an individual treatment based on complete neurofunctional data. This may not be needed in every patient e.g. patients with suprapontine lesions or in patients where treatment will consist merely of bladder drainage when the person is frail or has limited life expectancy.
- There is often a need to manage both bladder and bowel dysfunction simultaneously

#### 2. INITIAL ASSESSMENT

- The management of neurological urinary incontinence depends on an understanding of the likely mechanisms producing incontinence. This can in turn depend on the site and extent of the nervous system abnormality.
- Under current classifications, neurogenic incontinence patients can be divided into four groups. History and physical examination are important in helping distinguish these groups:

- peripheral lesions (as after major pelvic surgery) including those with lesions of the cauda equina (eg lumbar disc prolapse);
- sacral spinal cord lesions involving the sacral micturition centre
- suprasacral spinal cord lesions (suprasacral infrapontine spinal cord lesions);
- central lesions of the brain or brain stem (stroke, Parkinson's disease).
- Assessment should be made using Questionnaires, urinalysis, bladder diary, uroflowmetry with assessment of PVR, and imaging of the urinary tract (ultrasoundography); all provide basic data for the initial assessment of the NLUUD.
- Invasive urodynamics should be used as part of the initial assessment in select patient populations (SCI, meningomyelocele)
- Due to increasing data on organ cross-sensitisation and the debilitating effect of faecal incontinence on QOL, a history of bowel function should be also included

#### 3. INITIAL TREATMENT

- Patients with peripheral nerve lesions (e.g. denervation after pelvic surgery) and patients with spinal cord lesions (e.g. traumatic spinal cord lesions) should receive specialised urological management (GoR A).
  - Initial treatment for patients with incontinence due to suprapontine pathology, like stroke, need to be assessed for degree of mobility and ability to cooperate. Initial recommended treatments are behavioural therapy (GoR C) and antimuscarinic drugs for presumed detrusor overactivity (GoR A). If incontinence persists and if operative procedures are not indicated then continence products (GoR B) or catheters (GoR C) may be necessary on a long-term basis. These can also be necessary in non-cooperative or less mobile patients.
- Pharmacological detrusor relaxation and/or antibiotics may be useful in cases of persistent bypass leakage and/or recurrent UTI (patients with continuous drainage)
- In all cases, bowel management should complement management of NLUUD

## VI. URINARY INCONTINENCE IN NEUROLOGICAL PATIENTS

2584

### B. SPECIALISED MANAGEMENT

#### 1. ASSESSMENT

- Most patients with neurogenic urinary incontinence require specialised assessment: Invasive urodynamic studies should be used with videourodynamics if available when surgical interventions are planned or when the "bladder may be unsafe".
- Upper tract imaging is needed in some patients and more detailed renal function studies will be desirable if the upper tract is considered in danger: high bladder pressure, upper urinary tract dilation, recurrent or chronic upper tract infection, (major) stones, (major) reflux.
- In patients with peripheral lesions, clinical neurophysiological testing may be helpful for better definition of the lesion

#### 2. TREATMENT

For specialised management, conservative treatment is the mainstay (GoR A). Management of neurogenic urinary incontinence has several options. The algorithm details the recommended options for different types of neurological dysfunction of the lower urinary tract. The dysfunction does not necessarily correspond to one type/level of neurological lesion and is defined best by urodynamic studies. One should always ascertain that the management ensures a safe lower urinary tract (storage at low pressure and complete emptying)

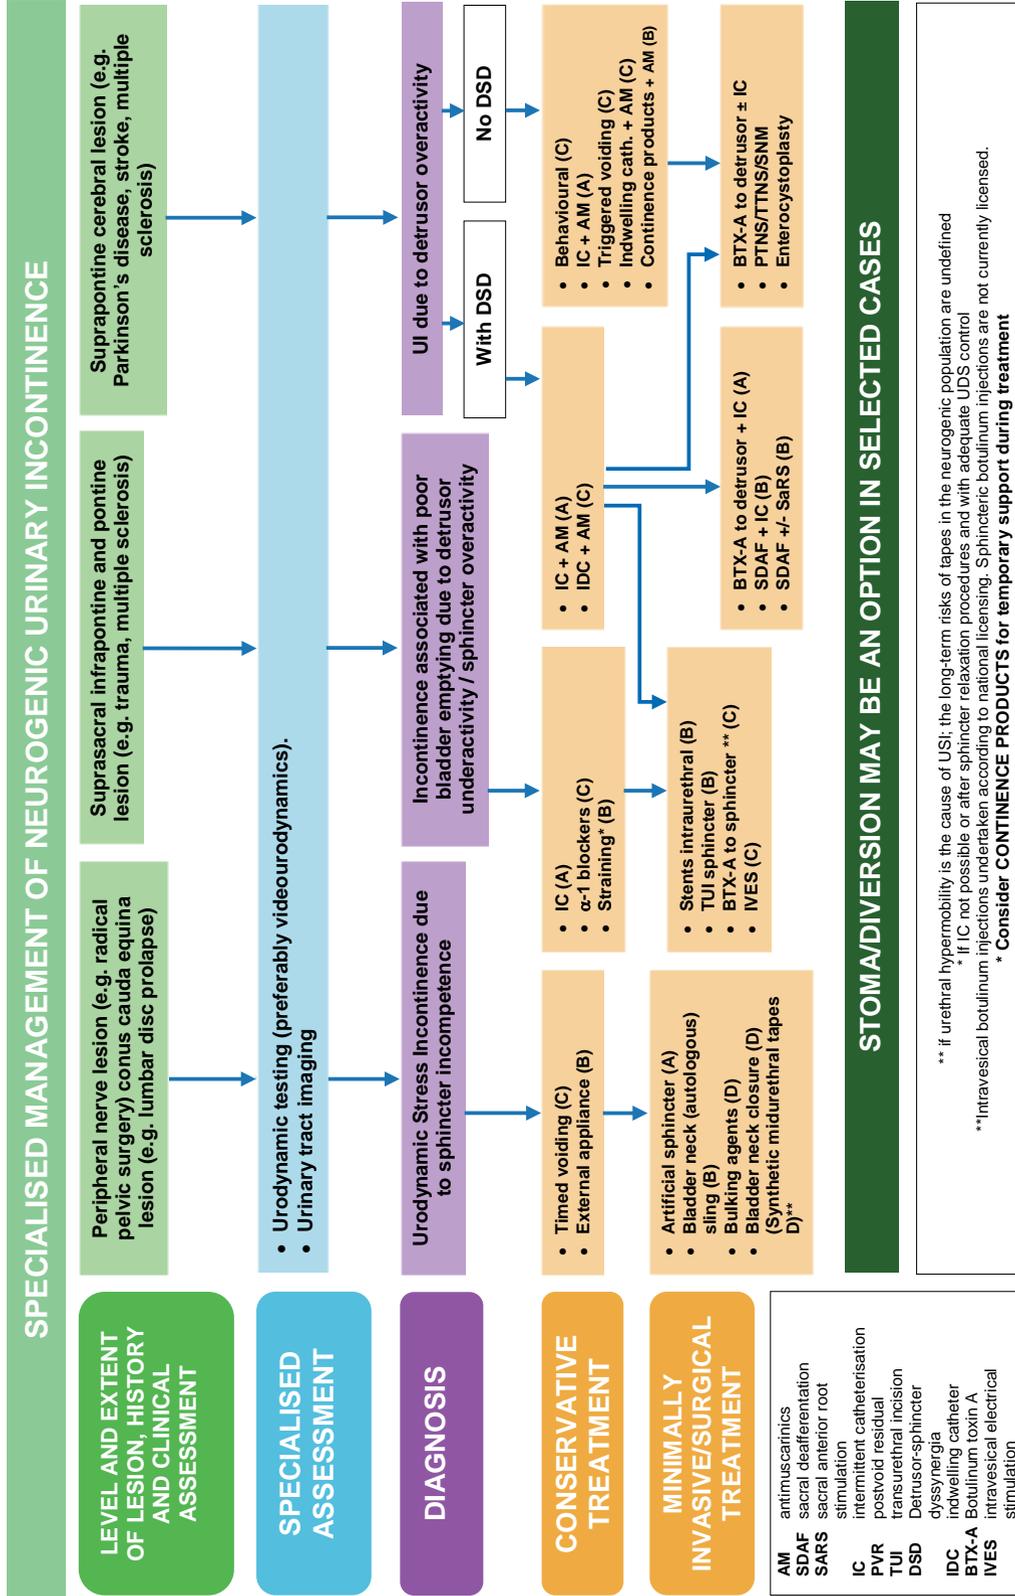

Both urinary and bowel function should be assessed together if both systems are affected, as symptoms and treatment of one system can influence the other, and vice versa (GoR A).

As therapeutic approaches can differ in various neurological diseases, the most prevalent diseases are discussed separately in the chapter

#### 3. TREATMENT MODALITIES (OFTEN IN COMBINATION)

- Conservative
  - Intermittent catheterisation (GoR A)
  - Behavioural treatment (GoR C)
  - Timed voiding (GoR C)
  - Continence products (GoR B)
  - Antimuscarinics (GoR A)
  - Alpha-1-adrenergic blockers (GoR C)
  - Oral cannabinoid agonists (MS) (GoR C)
  - Beta-3-agonist alone or as an add-on to AM (GoR D)
- Bladder expression (GoR B)
- Triggered voiding (GoR C)
- Indwelling catheter (GoR C)
- Minimally invasive treatments
  - Botulinum toxin for: sphincter (C) detrusor (A)
  - Intravesical electrical stimulation (C)
  - PTNS/TTNS (C)
  - SNM (stable disease only) (C)

- Surgical treatment
  - Artificial sphincter (A)
  - Bladder neck sling (B)
  - Sub-urethral tapes (D)
  - Bulking agents (D)
  - Bladder neck closure (D)
- Stents intraurethral (B)
- TUI sphincter (B)
- Sacral deafferentation (B)
- Sacral anterior root stimulator (B)
- Enterocystoplasty (B)

## VII. BLADDER PAIN SYNDROME

### Definition

Bladder Pain Syndrome (BPS): in the absence of a universally agreed definition, the International Society for the Study of Interstitial Cystitis – ESSIC definition is given (1).

ESSIC: Chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent desire to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.

There are no published data as to what duration of symptoms indicates that early spontaneous resolution of symptoms is unlikely. While ESSIC arbitrarily uses a 6 month duration, the American Urological Association Guideline suggests that a 6 week history is long enough to initiate diagnosis and treatment of BPS (2). Without further data, the Consultation cannot make a recommendation and believes that it is up to the discretion of the physician and patient as to the proper interval between symptom onset and evaluation and diagnosis of a chronic condition.

### 1. NOMENCLATURE

The scientific committee of the International Consultation voted to use the term “bladder pain syndrome” for the disorder that has been commonly referred to as interstitial cystitis (IC). The term painful bladder syndrome was dropped from the lexicon. The term IC implies an inflammation within the wall of the urinary bladder, involving gaps or spaces in the bladder tissue. This does not accurately describe the majority of patients with this syndrome. Painful Bladder Syndrome, as defined by the International Continence Society, is too restrictive for the clinical syndrome.

Properly defined, the term Bladder Pain Syndrome appears to fit in well with the taxonomy of the International Association for the Study of Pain (IASP) (see below), and focuses on the actual symptom complex rather than what appears to be long-held misconception of the underlying pathology.

Bladder Pain Syndrome (XXIII-2) (per IASP)

Bladder pain syndrome is the occurrence of persistent or recurrent pain perceived in the urinary bladder region, accompanied by at least one other symptom, such as

pain worsening with bladder filling and day-time and/or night-time urinary frequency. There is no proven infection or other obvious local pathology. Bladder pain syndrome is often associated with negative cognitive, and behavioural, sexual, or emotional consequences, as well as with symptoms suggestive of lower urinary tract and sexual dysfunction.

The Consultation believes that, based on the pathology and endoscopic finding characteristics of the Hunner lesion, the epidemiological pattern that distinguishes it from bladder pain syndrome, the clinical response to local treatment of the lesion by resection, fulguration, or steroid injection, the response to cyclosporine, and the

Figure 1

absence of reports in the literature that non-Hunner patients go on to develop Hunner lesions (ie, the finding of a Hunner lesion does not represent a continuum in the natural history of bladder pain syndrome), that the presence of a Hunner lesion should be considered a distinct disease. It therefore should drop out of the bladder pain syndrome construct, much like we do not consider other painful conditions like radiation cystitis, ketamine cystitis, or urinary tract infection a part of bladder pain syndrome.

The Consultation concludes that it would be reasonable to designate the Hunner lesion in symptomatic patients with the term “interstitial cystitis”, thus indicating a true interstitial inflammation. It would be defined much as Hunner defined it 100 years ago, and harmonise the largely Asian, European, and North American concepts of interstitial cystitis. The Consultation will continue to refer to the symptom complex as “bladder pain syndrome”. Hunner lesion will be considered a distinct phenotype, but in the future may be classified as a separate disorder entirely, albeit with local symptoms that are difficult to differentiate from bladder pain syndrome in the absence of endoscopy. In other words, we may be coming full circle in the historical perspective Figure 1.

## 2. HISTORY / INITIAL ASSESSMENT

Males or females whose symptoms meet the requirements of the definition of bladder pain syndrome should be evaluated. The presence of commonly associated disorders including irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia in the presence of the cardinal symptoms of bladder pain syndrome also suggests the diagnosis. Abnormal gynaecological findings in women and well-characterised, confusable diseases that may explain the symptoms must be ruled out.

The initial assessment consists of a bladder diary or frequency/volume chart, focused physical examination, urinalysis, and urine culture. In the absence of confusable disorders (uncomplicated disease), a diagnosis can be made and treatment instituted. Urine cytology, cystoscopy, and urodynamic evaluation are recommended if clinically indicated and/or the diagnosis is in doubt (complicated disease). Patients with urinary infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and microscopic or gross haematuria are evaluated with appropriate imaging and endoscopic procedures, and only if the findings are unable to explain the symptoms, are they diagnosed with BPS. GoR C

## 3. INITIAL TREATMENT

- Patient education, (GoR B)
- Dietary manipulation, (GoR B)
- Nonprescription analgesics,
- Stress reduction,
- Pelvic floor relaxation techniques comprise the initial treatment of BPS. In the patient with findings suggesting pelvic floor dysfunction, pelvic floor physical therapy with myofascial trigger point release and intravaginal Thiele massage is often an effective therapeutic intervention. The treatment of pain needs to be addressed directly, and in some instances referral to an anaesthesia/pain centre can be an appropriate early step in conjunction with ongoing treatment of the syndrome. (GoR A)

When conservative therapy fails or symptoms are severe and conservative management is unlikely to succeed,

- Oral medication (GoR B) or
- Intravesical treatment can be prescribed. It is recommended to initiate a single form of therapy and observe results, adding other modalities or substituting other modalities as indicated by the degree of response or lack of response to treatment. (GoR B)

## 4. SECONDARY ASSESSMENT

If initial oral or intravesical therapy fails, or before beginning such therapy based on clinician judgment, it is reasonable to consider further evaluation which can include urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anaesthesia.

- Findings of detrusor overactivity suggest a trial of antimuscarinic or beta-3-agonist therapy.
- The presence of a Hunner lesion suggests therapy with transurethral resection, fulguration of the lesion, or direct steroid injection into the lesion. (GoR B)

- Bladder distention itself can have therapeutic benefit in 30-50% of patients, though benefits rarely persist for longer than a few months. (GoR C)

## 5. REFRACTORY BPS

Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive treatment modalities. Many of these are best administered within the context of a clinical trial if possible. These may include

- Sacral nerve stimulation, (GoR B)
- Intradetrusor botulinum toxin, (GoR B)

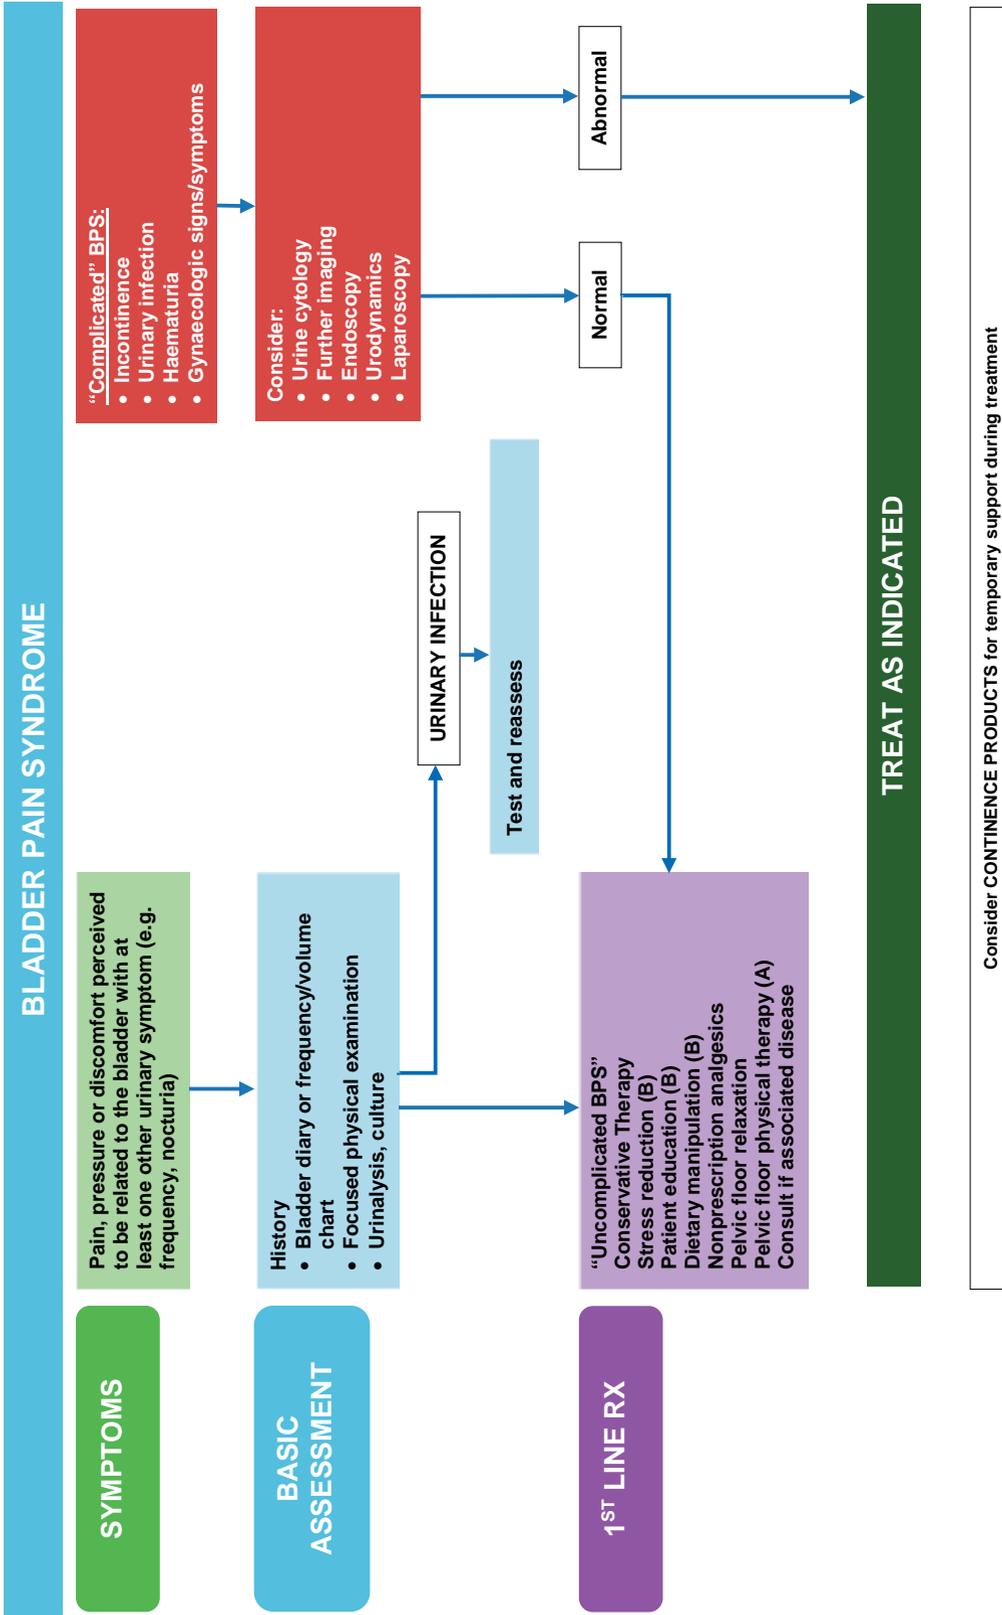

- Oral cyclosporine A (GoR C), or

- Clinical trials of newly described pharmacological management techniques. At this point, most patients will benefit from the expertise of an anaesthesia pain clinic.

The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urinary stream.

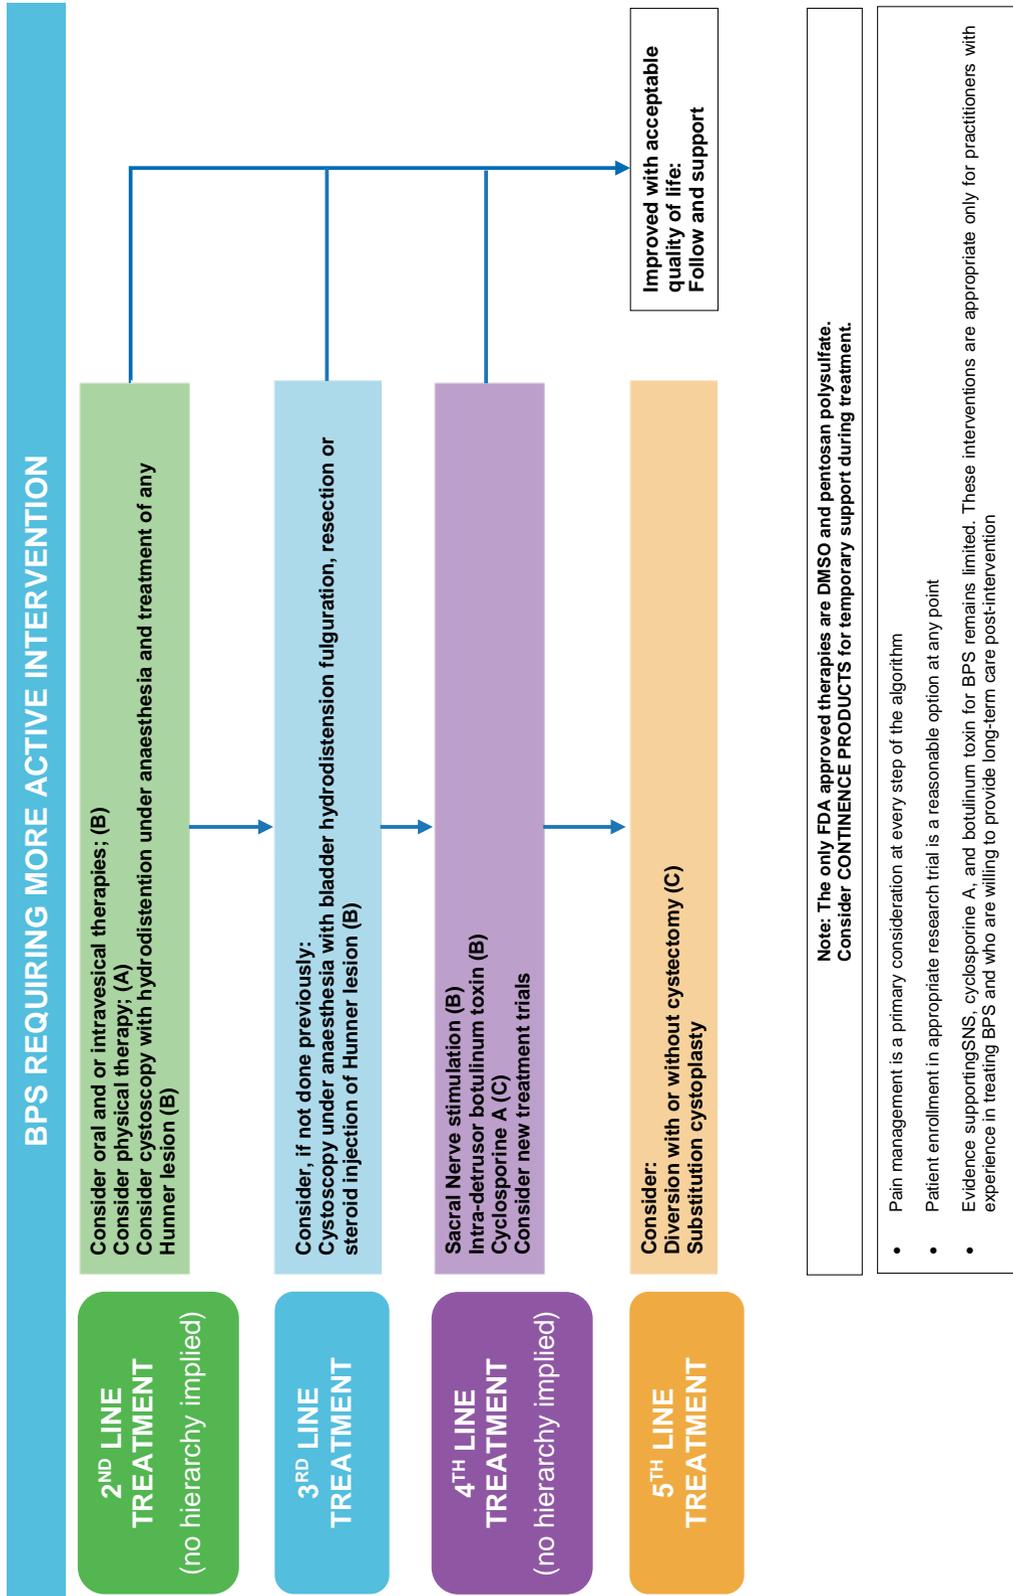

- Urinary diversion with or without cystectomy has been used as a last resort with good results in selected patients. Cystectomy and urethrectomy do not appear to add any additional efficacy to diversion alone.

Augmentation or substitution cystoplasty seems less effective and more prone to recurrence of chronic pain in small reported series (GoR C)

2590

Consider CONTINENCE PRODUCTS for temporary support during treatment

## VIII. FAECAL INCONTINENCE IN ADULT PATIENTS

2592

### ASSESSMENT AND MANAGEMENT

#### 1. INITIAL CLINICAL ASSESSMENT

Adult patients with faecal incontinence present with a variety of symptom complexes. As many people are reluctant to admit to having faecal incontinence, it is important to proactively enquire about it, especially in known high risk groups (such as older community-living individuals, post partum women who might have had an obstetric injury and patients with loose stools).

History will include symptoms such as loose stools and urgency, the type and severity of bowel incontinence, systemic disorders, neurological disorders, and ano-rectal surgeries (e.g., haemorrhoidectomy), obstetric history for women, medications, diet, chronic straining, cognitive status, and effects of symptoms on quality of life.

- Physical examination will include anal inspection, abdominal palpitation, a brief neurological examination, digital rectal examination and usually procto-sigmoidoscopy or colonoscopy.
- Further diagnostic testing needs to be considered if the patient has symptoms such as an unexplained change in bowel habit, weight loss, anaemia, rectal bleeding, severe or nocturnal diarrhoea, or an abdominal or pelvic mass and bowel pathology when organic conditions such as cancer, inflammatory bowel disease (IBD), a recto-vaginal fistula, full thickness rectal prolapse, or cloacal deformity are suspected. Condition specific management is indicated for these patients.
- Reversible factors (such as inadequate access to toilets and side effects of medications resulting in loose stools) should be assessed and addressed at the outset.

#### 2. INITIAL INTERVENTIONS

- Assessing the type of bowel incontinence may help identify an aetiology. Types of bowel incontinence: Anal incontinence is the involuntary loss of faeces and/or flatus and/or mucus). Faecal incontinence is the involuntary loss of faeces. Flatus incontinence is the involuntary loss of rectal gas, which may indicate rectal sensory impairment and/or anal sphincter dysfunction. Mucus incontinence is the involuntary loss of mucus only (See Figure 1).
  - Some subtypes of faecal incontinence are urgency faecal incontinence, which is the involuntary loss of faeces due to an inability to defer defaecation, once the desire is perceived, for long enough to reach a toilet. Urgency faecal incontinence is often a symptom of external anal sphincter dysfunction. The symptom of urgency does not necessarily result in urgency faecal incontinence. Functional faecal incontinence is due to limitations in mobility or toileting ability or delayed assistance. Passive faecal incontinence, incontinence without forewarning, is typically related to internal anal sphincter dysfunction or poor closure of the external sphincter due to rectal prolapse or stage III/IV haemorrhoids.

- Some initial management can often be performed in primary care. After environmental factors and local or systemic pathology have been excluded, initial interventions include:
  - Discussion of options and goals of management with the patient
  - Provision of patient or caregiver information and education (GoR A)
  - Adjustment of diet and fluid advice, fibre intake (GoR A)
  - Establishing a regular bowel habit (GoR C) or urgency training if relevant (GoR C)
  - Anti-diarrhoeal medication can help if stools are loose (GoR B)
  - Use of continence products including various types and sizes of absorbent pads, briefs, etc., to contain leaked faeces and prevent skin damage
  - Provide advice on practical coping skills when incontinence occurs (GoR C)

### 3. SECONDARY INTERVENTIONS

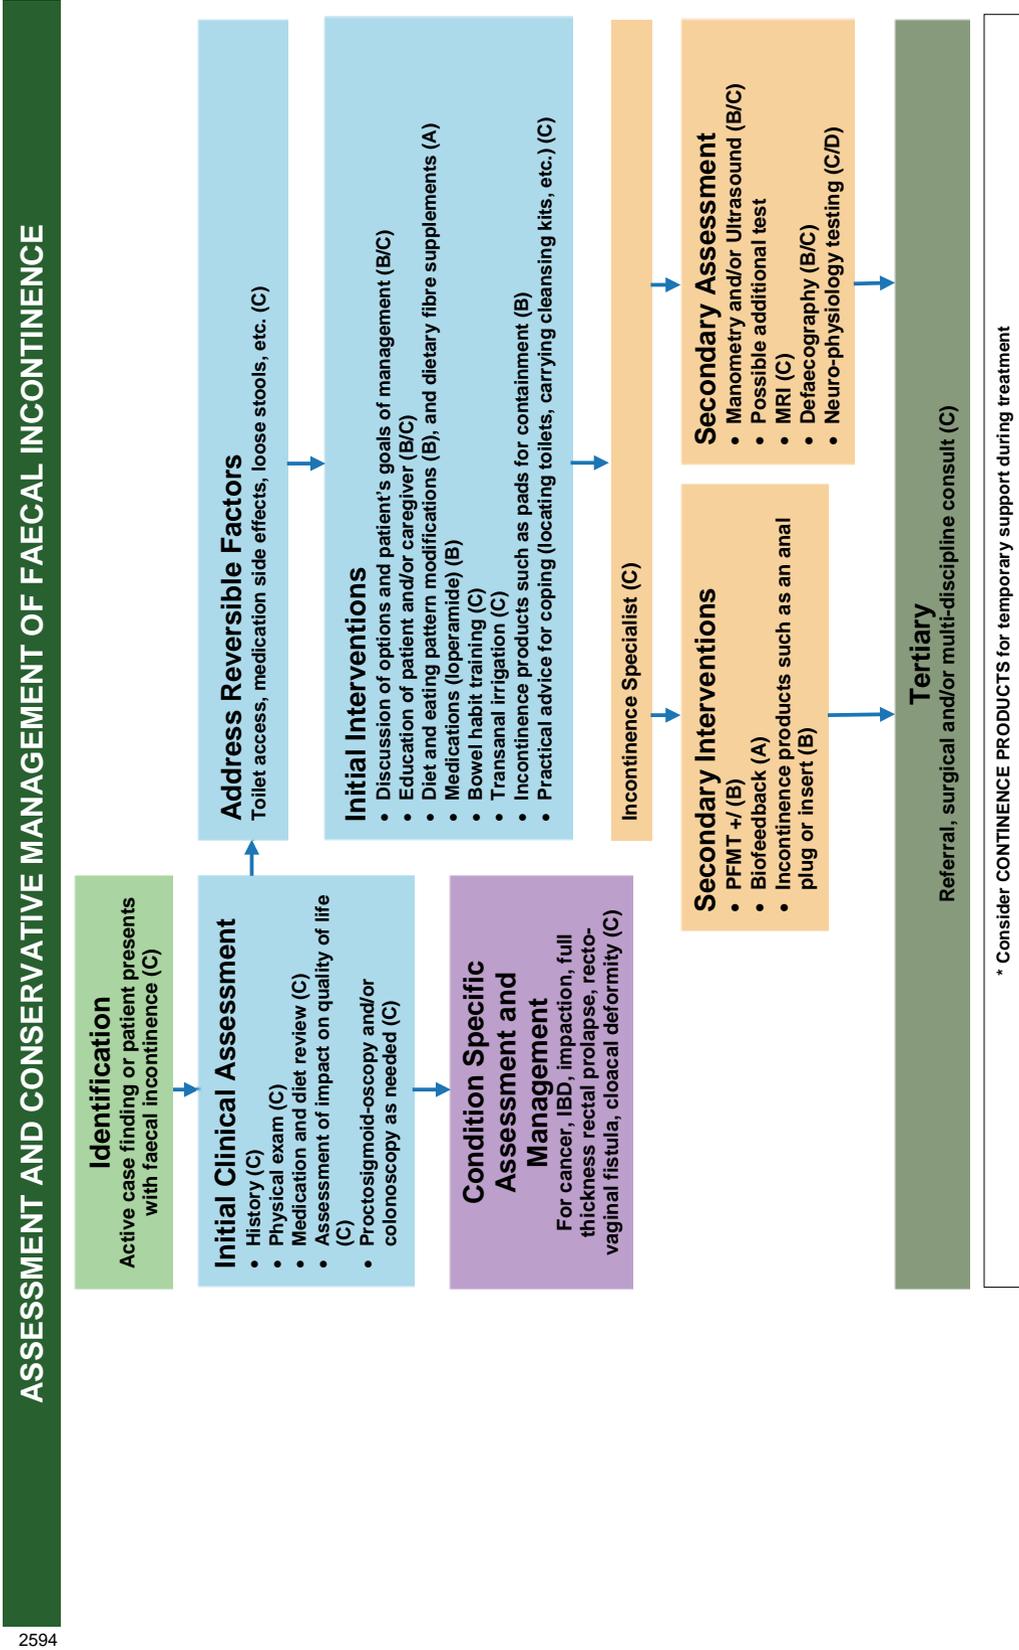

- If initial interventions fail to improve symptoms after 8-12 weeks, consideration should be given to referral to an incontinence specialist (e.g., gastroenterologist, continence nurse, advisor physiotherapist, or colorectal surgeon) for other interventions or further assessment.
- Pelvic floor muscle training (PFMT) – contraction of pelvic floor muscles, multiple times per day to improve strength of contraction and increase awareness of anorectal muscle function. (GoR C)
- Biofeedback therapy – behavioural treatment designed to enhance the strength of sphincter contraction and improve rectal sensation using specialised equipment. Biofeedback therapy can be combined with PFMT to improve strength. (GoR B)
- Transanal Irrigation to maximise bowel emptying and minimise faecal incontinence primarily in patients with incomplete elimination, passive faecal incontinence, or faecal incontinence with defaecation difficulty, (GoR C)

### 4. SECONDARY ASSESSMENT

- A variety of anorectal investigations, including manometry, anal ultrasound, and possibly MRI, defaecography, and neurophysiological testing can help to define structural or functional abnormalities of anorectal function and guide management if initial and/or secondary interventions are ineffective

### 5. TERTIARY REFERRAL, SURGICAL OR MULTI-DISCIPLINARY CONSULTATION

- Faecal incontinence that fails to respond to initial and secondary management requires specialised consultation by a gastroenterologist, colorectal surgeon, urogynaecologist, and/or a multi-disciplinary team

2594

## VIII. FAECAL INCONTINENCE IN ADULT PATIENTS

### SURGERY FOR FAECAL INCONTINENCE

#### 1. PATIENT ASSESSMENT

- The reader is referred to the relevant chapter sections in “Dynamic Testing” and “Conservative Treatment for Faecal Incontinence.” In general, patients referred for surgical management of faecal incontinence must either have failed conservative therapy or not be candidates for conservative therapy due to severe anatomic or neurological dysfunction.
- Prior to surgical management of faecal incontinence, the integrity of the anal sphincter complex should be assessed. This assessment is best performed with endoanal ultrasound, though pelvic MRI may also be useful. Ancillary tests include anal manometry, electromyography, and defaecography.
- If the patient has persisting faecal incontinence, he or she should undergo repeat assessment, including endoanal ultrasound.

#### 2. SPECIALISED MANAGEMENT

- The surgical approach is influenced by the presence and magnitude of an anatomical anal sphincter defect. If no defect is present, or if the sphincter defect is minimal, options include SNS and biomaterial injection therapy.
- Acute anal sphincter repair is usually required following obstetric or direct trauma. End to end or overlapping repair may be performed. When possible the internal anal sphincter should be separately repaired. (GoR C)
- Patients with rectal prolapse, rectovaginal fistula or cloacal deformity often have associated faecal incontinence. Initial therapy should be directed at correction of the anatomical abnormality. (GoR C)
- For patients with moderate sphincter defects, sphincteroplasty, SNS or biomaterial injection therapy can each be considered. For patients with large sphincter defects (>120 degrees), sphincteroplasty is likely to be the best option, though a PNE trial for SNS can be considered. (GoR C)

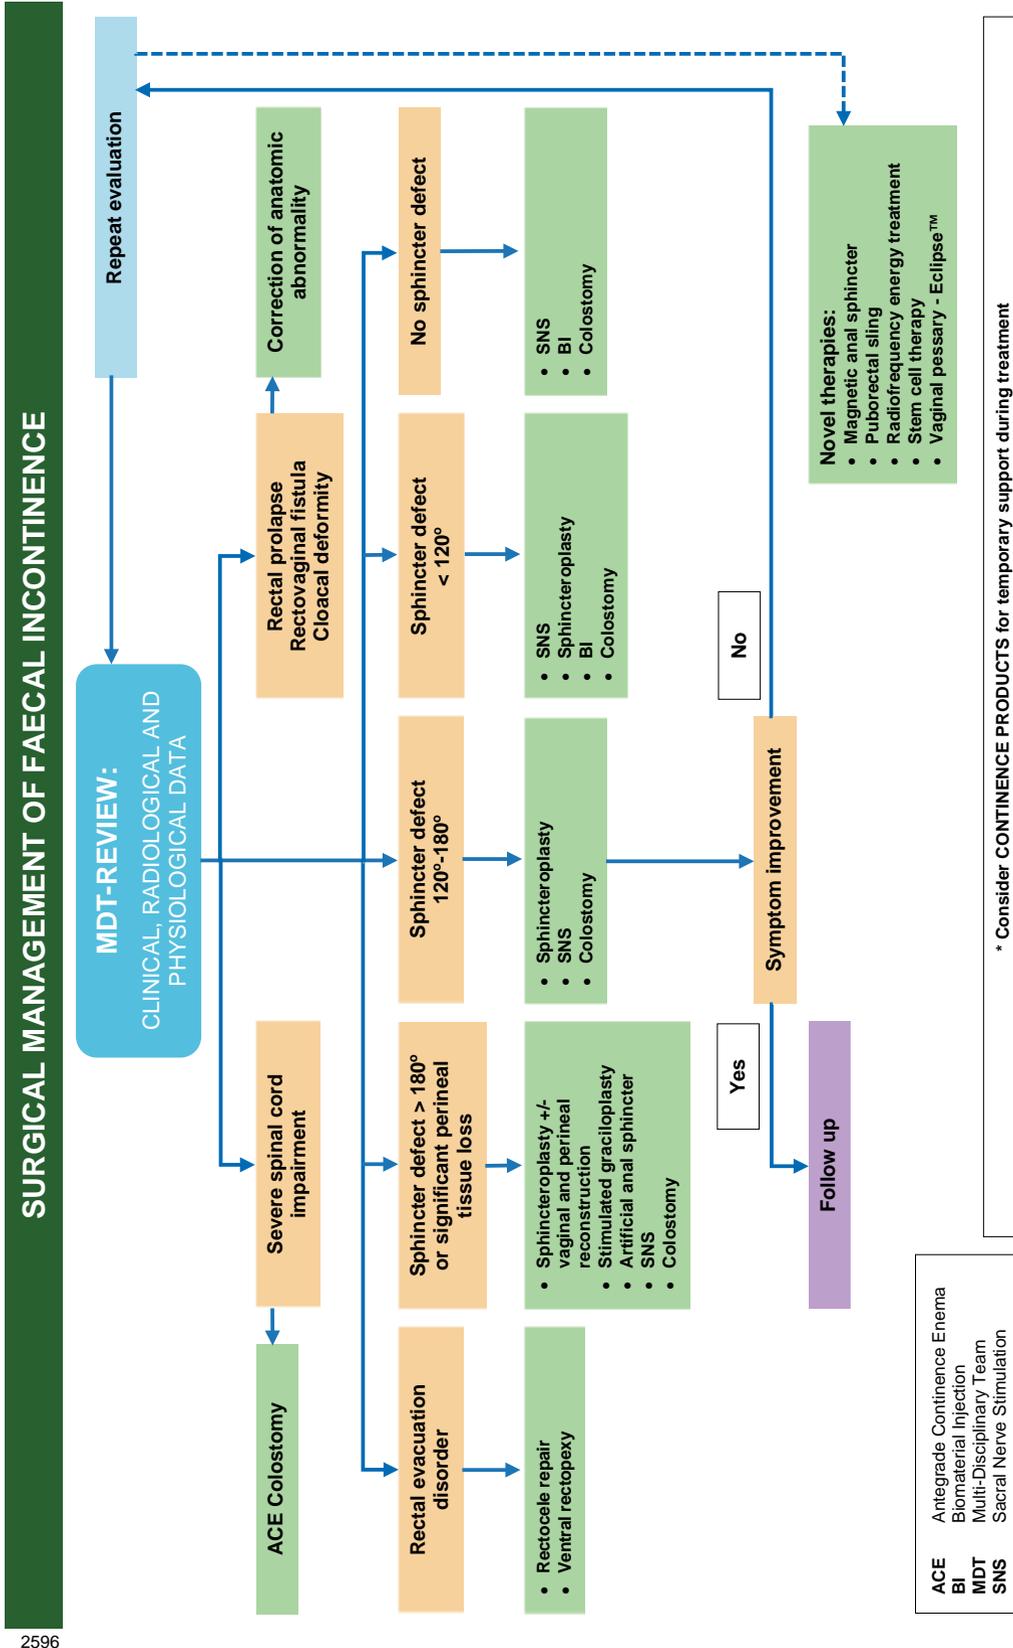

- Patients with sphincter defects of greater than 180° or major perineal tissue loss require individualised treatment. In some cases, initial reconstruction can be performed. Should incontinence persist, alternatives include stimulated muscle transposition (usually graciloplasty) artificial anal sphincter implantation, or SNS. (GoR C)

#### 3. SALVAGE MANAGEMENT

- For patients who remain incontinent following sphincteroplasty, repeat endo-anal ultrasound should be undertaken to reassess the status of the repair. If no defect is present, or if the sphincter defect is minimal, options include SNS and biomaterial injection therapy. If there is a large persisting sphincter defect, repeat sphincteroplasty can be considered. (GoR C)
- Patients who have failed SNS can be considered for biomaterial injection therapy or sphincteroplasty if a sphincter defect is present. Other alternatives include stimulated graciloplasty and implantation of an artificial anal sphincter. (GoR C)
- Patients who fail surgical therapy for faecal incontinence, or who do not wish to undergo extensive pelvic reconstruction, should consider placement of an end sigmoid colectomy. (GoR C) While this procedure does not restore continence, it does restore substantial bowel control and appears to improve social function and quality of life. Novel therapies can also be considered under protocol: PTNS, the magnetic anal sphincter, SECCATM, vaginal pessary (EclipseTM) and sling procedures. (GoR D)

#### 4. SPECIAL SITUATIONS

- Individuals with congenital abnormalities may be amenable to surgical repair. Often this will involve both laparoscopic abdominal and perineal approaches. Poor functional outcomes may be treated by an Antegrade Continence Enema (ACE) procedure or colostomy. Patients with cauda equina type neurological disorders, either congenital or acquired, should be considered for an ACE procedure or colostomy. (GoR C)

2596

## IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

### A. INITIAL MANAGEMENT

- Patients with known neurological disease may present with symptoms related to neurological bowel dysfunction, such as; difficulty in defaecation, constipation and faecal incontinence which disturb their activities of daily living and impair quality of life. Many have permanent impairments and functional limitations and disabilities, which are due to neurological deficits and complications

#### 1. INITIAL ASSESSMENT

- The history should include:
  - Neurological diagnosis and functional level
  - Previous and present lower gastrointestinal (LGIT) function and disorders
  - Severity of neurogenic bowel dysfunction
  - Current bowel care and management including diet, fluid intake, medications affecting bowel functions
  - Co-morbidity / complication e.g., urinary incontinence, autonomic dysreflexia, pressure ulcers, sexual dysfunction
  - Patient's satisfaction, needs, restrictions and quality of life
  - Environmental factors and barriers and facilitators to independent bowel management.
- Physical examination:
  - Cognitive function; motor, sensory and sacral reflexes – voluntary anal sphincter contraction, deep perianal sensation, anal tone, anal and bulbo-cavernosus reflexes
  - Spasticity of the lower limbs
  - Abdominal palpation for faecal loading and rectal examination

- Functional assessment:
  - Hand and arm use, fine hand use, mobility – maintaining body position, transfer and walking ability.
  - Environmental factors assessment:
    - toilet accessibility; devices for bowel care and mobility; caregiver support and attitude;

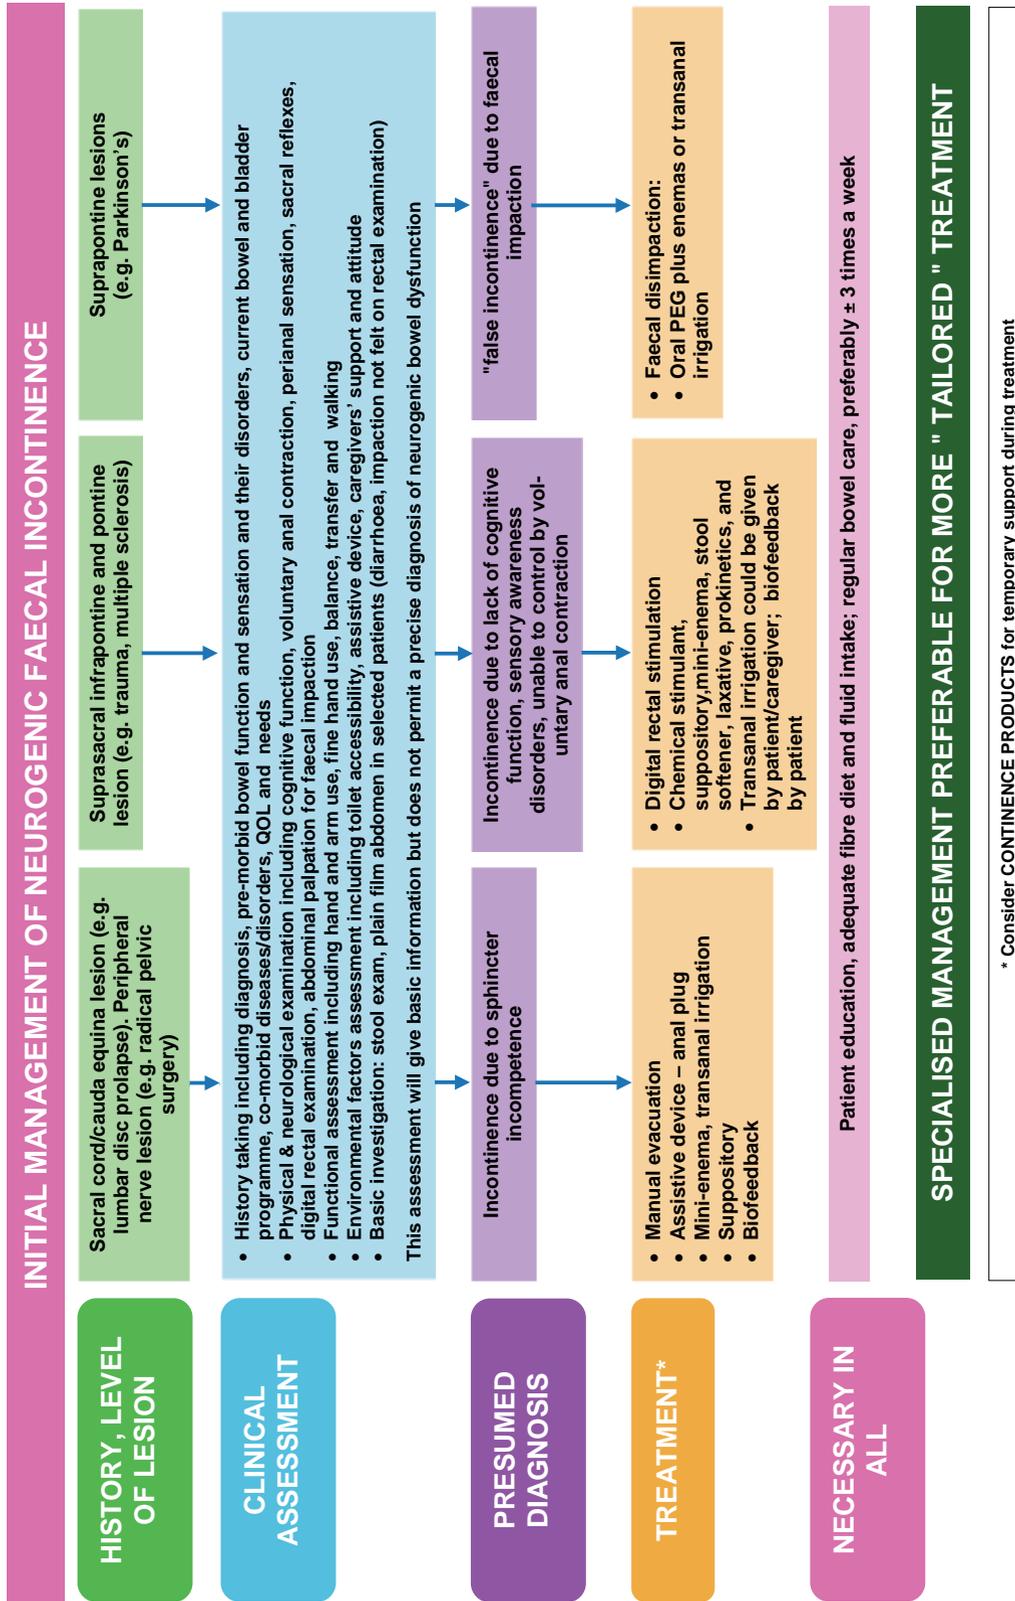

#### 2. BASIC INVESTIGATIONS

Stool examination, plain abdominal X-Ray

#### 3. INITIAL TREATMENTS

- Patient education and goals-setting to achieve complete defaecation on a regular basis and faecal continence based on right time, right place, right trigger and right consistency
- Adequate fibre diet and fluid intake; appropriate trigger according to preservation of sacral (anorectal) reflex – digital rectal stimulation (GoR C); suppository and enema (GoR B); if no anorectal reflex, manual evacuation (GoR B); abdominal massage (GoR C) can also be helpful
- Prescribe medications – stool softener, laxative, prokinetic agents, anti-diarrhoeal drugs as necessary
- Assistive techniques may be necessary for
  - Defaecation – transanal irrigation (GoR A)
  - For incontinence – anal plug (GoR C)

The algorithm does not apply to management in acute neurological patients that need regular bowel emptying.

2598

## IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

### B. SPECIALISED MANAGEMENT

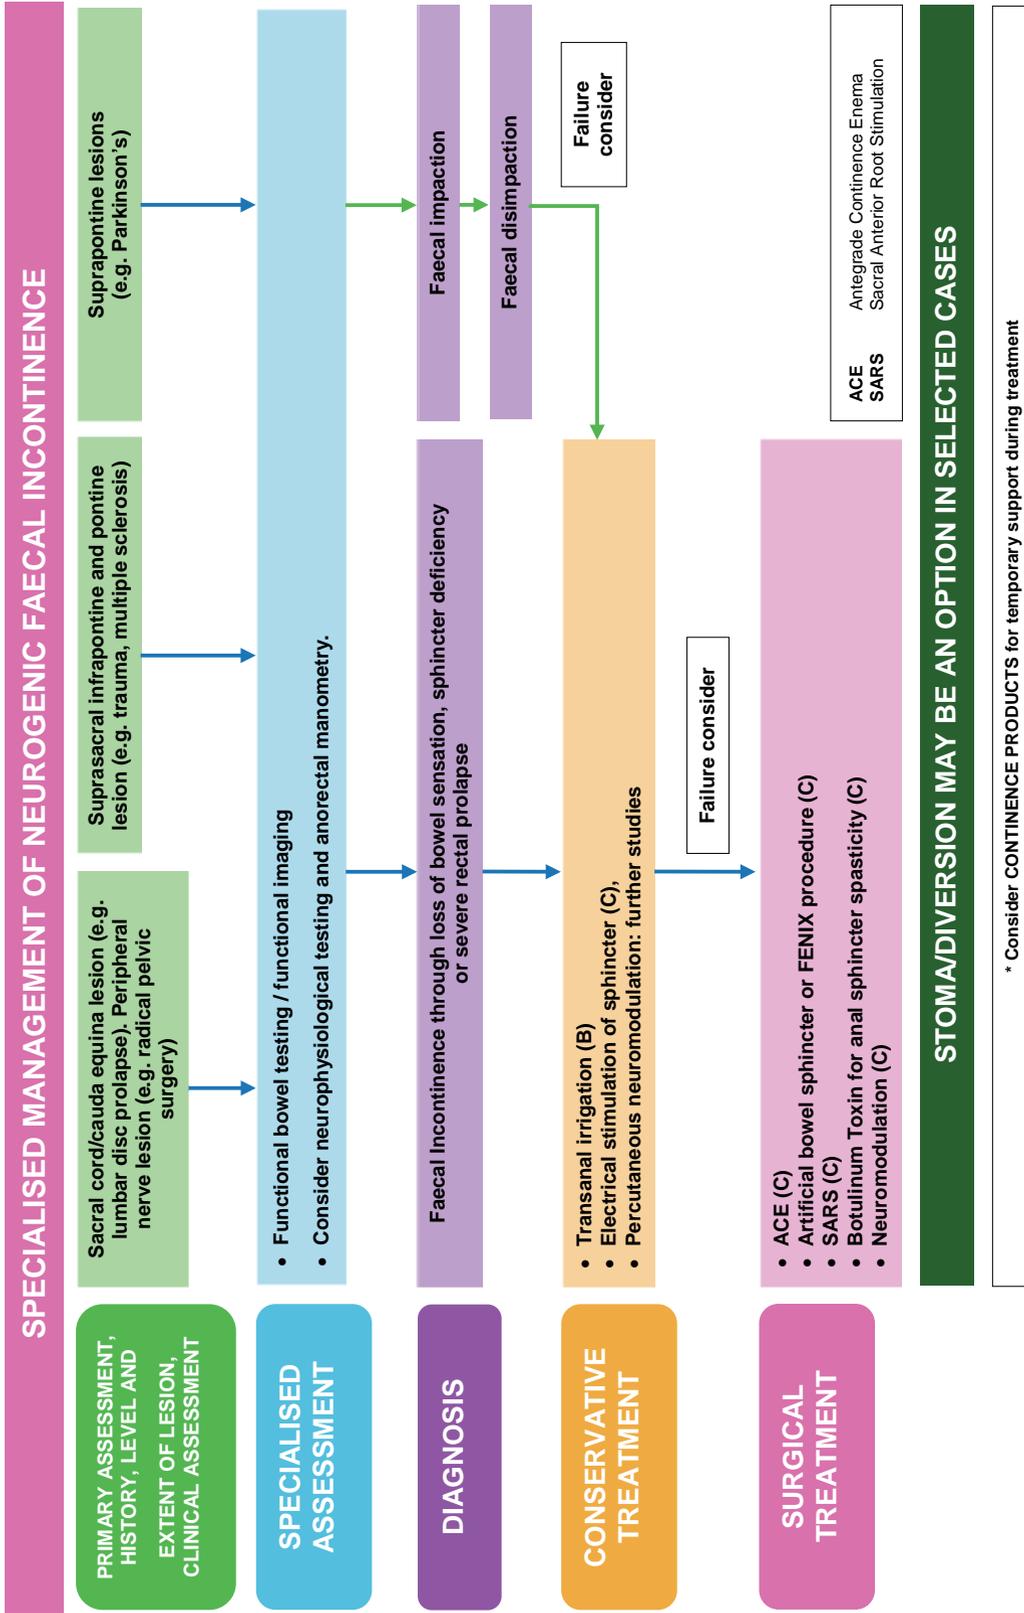

#### 1. ASSESSMENT

- Some patients with neurogenic faecal incontinence will need specialised assessment, especially if initial management is unsuccessful to look for comorbidity and certainly before performing invasive treatment
- Do not assume that all symptoms are due to neuropathy, e.g. women with neurological pathology might have had childbirth injury to the sphincter
- Special investigations: manometry, endoanal ultrasound, (dynamic) MRI, (needle) EMG. These specific bowel functional tests and electro-diagnostic tests must be considered optional, as their value in neurological pathology is not sufficiently demonstrated so far.

#### 2. TREATMENTS

- Conservative treatment for neurological faecal incontinence is also the mainstay for specialised management, (GoR C).
- Management of neurological incontinence does not include very extensive treatment modalities and many conservative interventions are still empirical.
- Transanal irrigation (GoR B).

- Electrical stimulation sphincter, (GoR C).
- Percutaneous neuromodulation and sacral nerve stimulation : further research is required (GoR D).
- Surgical management of neurogenic faecal incontinence has different options which need a very strict patient selection
  - Antegrade Contenance Enema ACE (GoR C).
  - Artificial bowel sphincter or FENIX procedure (GoR C).
  - Sacral Anterior Root Stimulation SARS (GoR C).
  - Botulinum Toxin (GoR C).
  - Neuromodulation (GoR C).
- It is recommended that urinary and bowel function are assessed simultaneously if both systems are affected, as symptoms and treatment of one system can influence the other and vice versa (GoR A).
- As the therapeutic approach can differ in different neurological diseases, the most prevalent diseases are discussed separately in the chapter.

2600

## X. URINARY AND FAECAL INCONTINENCE IN FRAIL OLDER MEN AND WOMEN

- There is no reason to suspect why interventions which have proven efficacy in the community dwelling elderly should not also be effective in frail older people. Clinicians should, however, take due regard of the practicality, potential benefits and dangers of employing any single intervention in this population.
- Frail older people do require a different approach addressing the potential role of co-morbid disease, current medications (prescribed, over the counter and/or naturopathic), and functional and cognitive impairment in urinary and faecal incontinence.
- The extent of the investigation and management should take into account the degree of bother to the older person and/or caregiver, the goals for care, the degree that the older person is able to undertake any intervention and the overall prognosis and life expectancy.
- Effective management to meet the goals of care should be possible for most frail older people.

### 1. HISTORY AND SYMPTOM ASSESSMENT

- Active case finding for urinary and faecal incontinence should be done in all frail older people (GoR A).
- History should include comorbid conditions and medications that could cause or worsen incontinence.
- Physical examination should include a rectal examination for faecal loading or impaction (GoR C), functional assessment (mobility, transfers, manual dexterity, dressing and undressing ability, ability to toilet) (GoR A), a screening test for depression (GoR B), and cognitive assessment (to assist in planning and management, (GoR C)).
- The mnemonic DIPPERS (see urinary and faecal incontinence algorithms) covers some of these comorbid conditions. Note that urogenital atrophy does not, in itself, cause urinary incontinence and should not be treated for this purpose (GoR B).
- The patient and / or caregiver should be asked about the degree of bother of urinary incontinence and/or faecal incontinence (GoR B); goals for urinary and

faecal incontinence care (dryness, decrease in specific symptoms, quality of life, reduction of comorbidity, lesser care burden) (GoR B); and likely cooperation with management (GoR C).

- Evaluation for bowel “alarm” symptoms (rectal bleeding, positive blood screening from stool studies, obstructive symptoms, recent onset of constipation, weight loss, and a change in stool calibre) will need more extensive evaluation (GoR A)
- Urinalysis is recommended for all patients, primarily to screen for haematuria (GoR C).
- Treatment of otherwise asymptomatic bacteriuria/pyuria is not beneficial (GoR C), and it may cause harm by increasing the risk of antibiotic resistance and severe adverse effects. e.g., *Clostridium difficile* colitis (GoR C).
- Stool studies may not be needed in all patients with faecal incontinence. Patients with diarrhoea, especially those with more acute onset diarrhoea, may need to be tested for infectious causes of their diarrhoea. Other stool studies could involve testing for malabsorption syndromes.
- The utility of the Clinical Stress test in this population is uncertain (GoR D).
- Wet checks can assess urinary incontinence frequency in long-term care residents (GoR C).
- A post voiding residual volume (PVR) test is impractical in many care settings and there is no consensus for the definition of what constitutes a “high” PVR in any population. A PVR measurement is not recommended in the routine initial assessment of frail older people with urinary incontinence.
- However, there is compelling clinical experiential evidence for PVR testing in selected frail older people with: diabetes mellitus (especially long standing); prior urinary retention or high PVR; recurrent UTIs; medications that impair bladder emptying (e.g., opiates); severe constipation; persistent or worsening urgency urinary incontinence despite antimuscarinic/beta-3-agonist treatment; or prior urodynamics showing detrusor underactivity and/or bladder outlet obstruction (GoR C). Treatment of contributing comorbidity may reduce PVR. Trial with catheter may be considered for PVR > 200-500 ml if the PVR is felt to contribute to UI or urinary frequency (GoR C).

- may be added to conservative therapy of urgency UI (GoR A-C, depending on agent).
- For the select cognitively intact older with FI, biofeedback may be considered, but few studies exist among frail older adults.
- Alpha-blockers may be cautiously considered in frail men with suspected prostatic obstruction (GoR C). All drugs should be started at the lowest dose and titrated with regular review until either care goals are met or adverse effects are intolerable.
- DDAVP (vasopressin) has a high risk of severe hyponatraemia in frail older persons and should not be used outside specialist centres or without very careful monitoring and long term followup (GoR A).
- Improving stool consistency can be done with dietary fibre and supplemental fibre in older adults (GoR C). In older adults with diarrhoea, loperamide may be considered at low doses to improve stool consistency. However, close monitoring for constipation and impaction is needed.

#### 4. ONGOING MANAGEMENT AND REASSESSMENT

Optimal urinary and faecal incontinence management is usually possible with the above approaches. If initial management fails to achieve the desired goals, the next steps are reassessment and treatment of contributing comorbidity and/or functional impairment.

### 5. SPECIALISED MANAGEMENT

If frail older people have either other significant factors (e.g., pain, haematuria, bowel "alarm" symptoms), UI or FI symptoms that cannot be classified as urgency, stress, or mixed or overflow or other complicated comorbidity which the primary clinician cannot address (e.g. dementia, functional impairment), then specialist referral should be considered. Referral may also be appropriate when there is been insufficient response to initial management. The type of specialist will depend on local resources and the reason for referral: surgical specialists (urologists, gynecologists, colorectal surgeons), gastroenterologists, geriatricians or physical therapist (functional and cognitive impairment); or continence nurse specialists (homebound patients). Referral decisions should consider goals of care, patient/caregiver desire for invasive therapy and estimated remaining life expectancy.

- Nocturia Assessment of frail elders with bothersome nocturia should identify potential underlying causes including nocturnal polyuria (by bladder diary/frequency- volume chart or wet checks; oedema on examination) (GoR C), primary sleep problems (e.g., sleep apnoea); and low voided volumes (e.g., from high PVR).
- Stool impaction/loading. If suspected on digital rectal examination, an abdominal x-ray may be necessary to further evaluate the degree and location of impaction/loading in frail older adults.

## 2. CLINICAL DIAGNOSIS

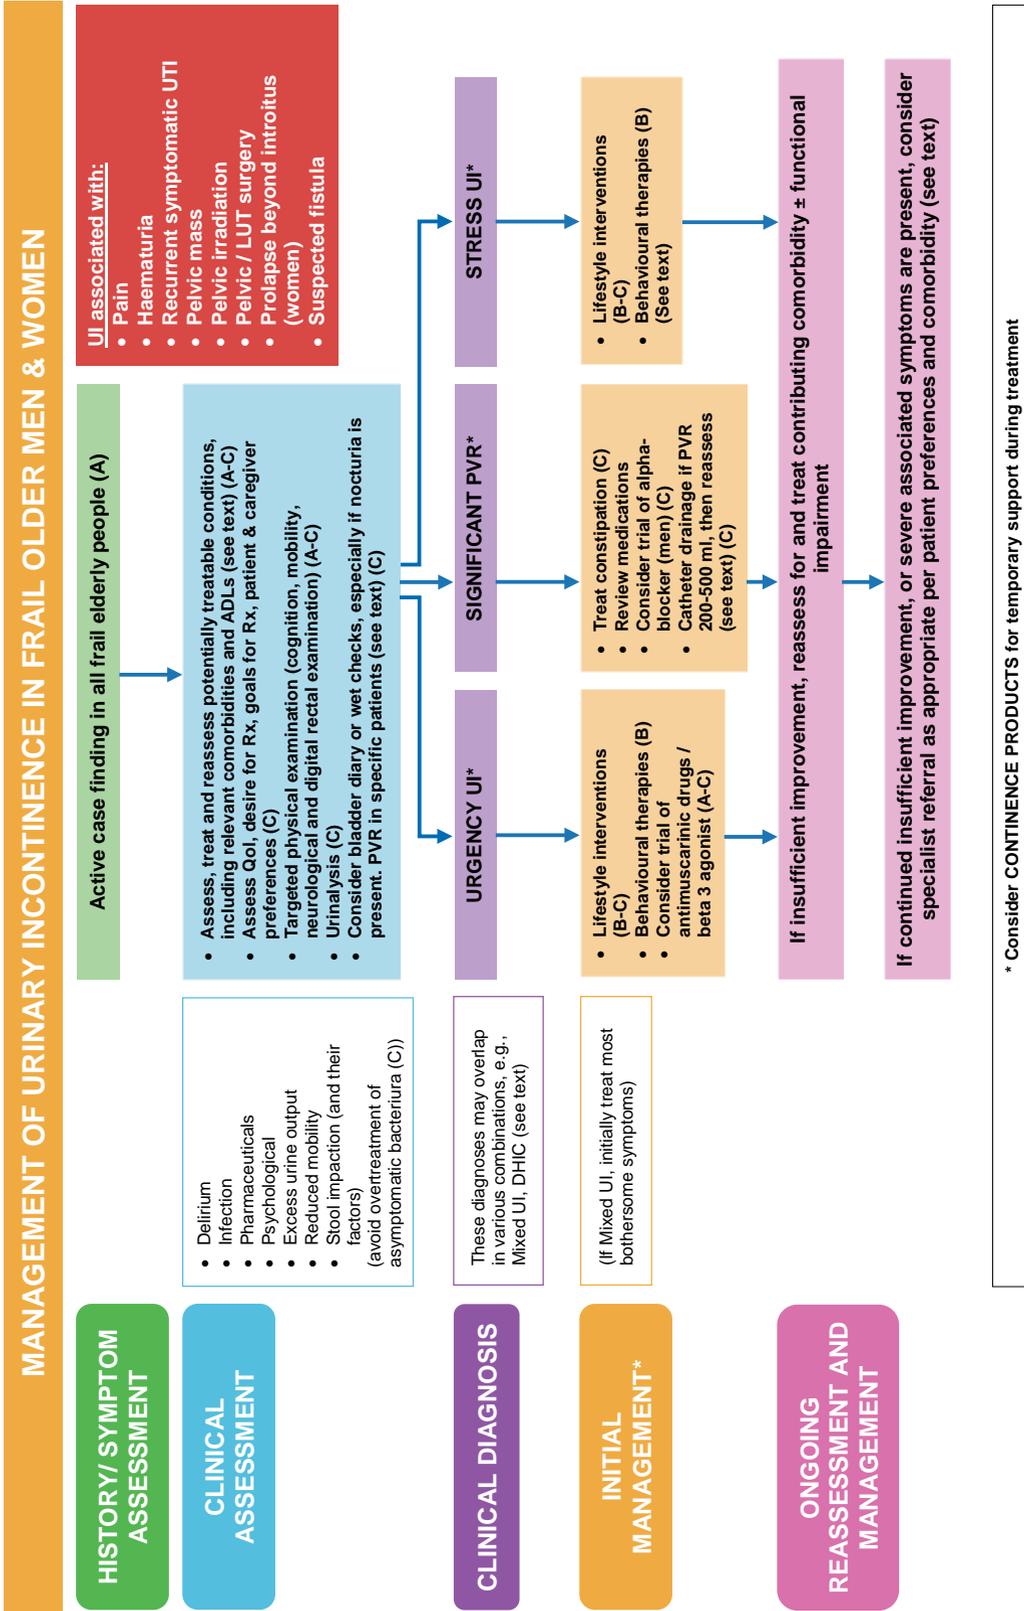

The most common types of Urinary Incontinence in frail older people are urgency, stress, and mixed urinary incontinence. Frail older people with urgency urinary incontinence also may have detrusor underactivity during voiding with a high PVR but without outlet obstruction. There is no evidence that antimuscarinics are less effective or cause retention in this situation (GoR D).

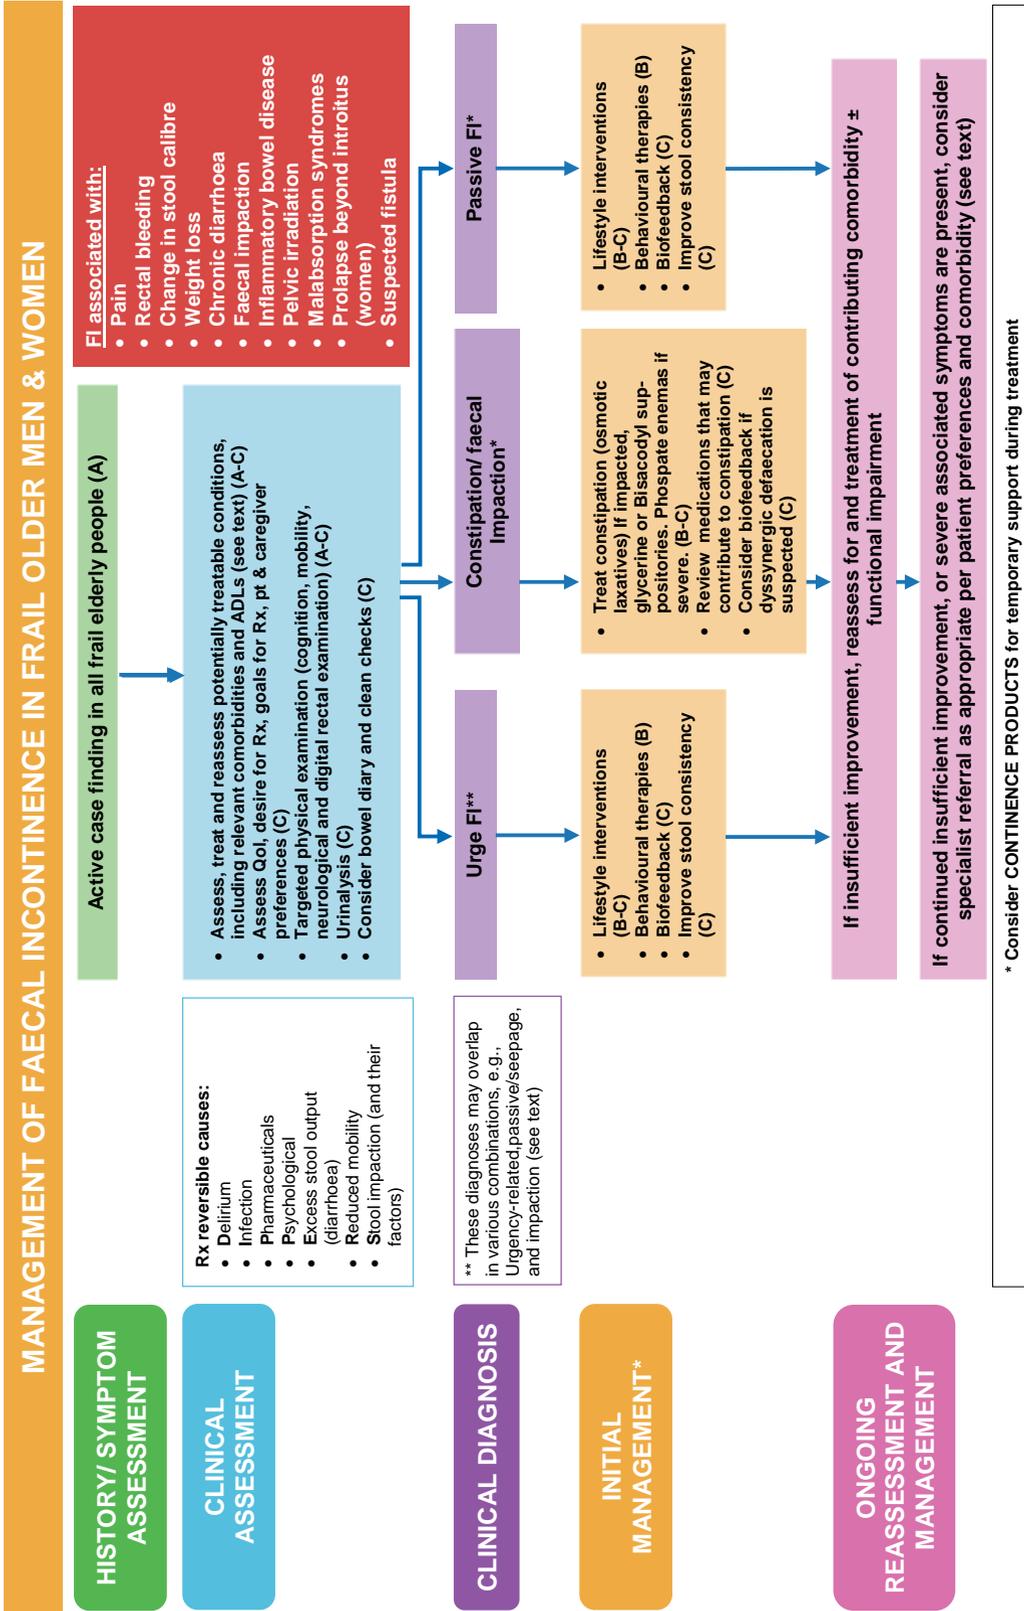

The most common types of faecal incontinence in frail older people are related to urgency and passive leakage. Passive leakage can refer to leakage, seepage and staining following bowel movements that are not associated with faecal urgency and may also occur with faecal impaction. Because constipation and impaction often contribute to faecal incontinence in older adults, these are considered separately in the algorithm.

## 3. INITIAL MANAGEMENT

- Initial treatment should be individualised and influenced by goals of care, treatment preferences and estimated remaining life expectancy, as well as the most likely clinical diagnosis (GoR C). In some frail older persons the only possible outcome may be containment; management with continence products, especially for people with minimal mobility (require assistance of > 2 people to transfer), advanced dementia (unable to state their name), and/or nocturnal urinary and faecal incontinence.
- Conservative and behavioural therapy for UI includes lifestyle changes (GoR C), bladder training for more fit alert persons (GoR B), and prompted voiding for frailer, more impaired older people (GoR A).
- For the select cognitively intact older person with UI or FI, pelvic floor muscle therapy can be considered, but there are few studies (GoR C). Antimuscarinics

- Age *per se* is not a contraindication to UI or FI surgery (GoR C), but before surgery is considered, all patients should have:
  - Evaluation and treatment for any comorbidity, medications, and cognitive or functional impairments contributing to UI that could compromise surgical outcome (e.g., dementia that precludes patient ability to use artificial sphincter) (GoR C).
  - Adequate trial of conservative therapy, including pharmacological therapies where relevant (GoR C).
- Discussion (including the caregiver) to ensure that the anticipated surgical outcome is consistent with goals of care in the context of the patient's remaining life expectancy (GoR C).
- Urodynamic testing or anorectal manometry, because clinical diagnosis may be inaccurate (GoR B).
- Preoperative assessment and perioperative care to establish risk of, and to minimise the risk of common geriatric post-operative complications such as delirium and infection (GoR A), dehydration and falls (GoR C).

## 4. RECOMMENDATIONS FOR FURTHER RESEARCH IN EPIDEMIOLOGY

---

1. Longitudinal study designs are needed to: (i) estimate the incidence and remission rates of urinary incontinence (UI) anal incontinence (AI) and pelvic organ prolapse (POP) and to (ii) describe the natural course of these conditions and (iii) to investigate risk factors and possible protective factors. In addition, similar studies regarding other lower urinary tract symptoms (LUTS) should be initiated.
2. Although there is now more information regarding prevalence, incidence, and other epidemiological data in developing countries, further information is still needed. It is recommended that fundamental research regarding prevalence, incidence and other epidemiological data in developing countries should be encouraged, and tailored to the cultural, economic and social environment of the population under study.
3. Some potential risk and protective factors deserve more attention. For example, the role of pregnancy and childbirth in the development of UI, AI and POP must be studied in a fashion that links population-based methods to clinical assessment of pregnancy, delivery and birth trauma and follows women over many years. Such a design is necessary because the effect of pregnancy and childbirth may become clear only years later when the woman is older and because the woman will not then be able to report the exact nature of the tear, episiotomy, etc.
4. There should be more emphasis on the associations between UI, AI and POP and specific diseases like stroke, diabetes, and psychiatric diseases.
5. The variation of disease occurrence in groups of different racial origin yet similar environmental exposures, lend support to the presumed genetic influence on the causation of UI, AI and POP. This again provides circumstantial evidence for a genetic contribution to pelvic floor muscle disorders since most of these studies have been unable to control for heritability in relation to the complex interaction of environmental factors.
 

The aetiology of UI, AI and POP is widely recognised to be multifactorial, yet the complex interaction between genetic predisposition and environmental influences is poorly understood. Genetic components require further investigation. Twin studies provide a possible means of studying the relative importance of genetic predisposition and environmental factors. By comparing monozygotic female twins with identical genotype, and dizygotic female twins who, on average, share 50 percent of their segregating genes, the relative proportions of phenotypic variance resulting from genetic and environmental factors can be estimated. A genetic influence is suggested if monzygotic twins are more concordant for the disease than dizygotic twins whereas evidence for environmental effects comes from monozygotic twins who are discordant for the disease.

## 5. RECOMMENDATIONS FOR FURTHER BASIC SCIENCE RESEARCH

The following proposals for research come from the Committees' work in reviewing the current literature on Basic Science:

1. Integrate data from reductionist experiments to inform the formulation of better systems-based approaches in the investigation of the pathology of the lower urinary tract (LUT), the genital tract (GT) and the lower gastro-intestinal tract (LGIT).
2. Encourage greater emphasis on basic research to characterise tissues receiving relatively little attention: ie the lower gastrointestinal tract; the bladder neck and urethra; the ureter, pelvic floor musculature.
3. Generate research programmes for fetal and neonatal research in LUT and LGIT function.
4. Use genome-wide bioinformatic and population health surveys to generate testable hypotheses regarding the physiological and pathophysiological functions of the LUT, GT and LGIT.
5. Generate improved experimental approaches to investigate the pathophysiology of the LUT and LGIT by:
  - The development of animal models that accurately describe human pathological conditions, including the greater use of large-animal models
  - The better use of reverse translational approaches for linking animal models to the human disease.
  - The use of human tissue from well-characterised patient groups.
  - The development of emerging areas such as: tissue engineering; proteomics and metabolomics
  - Increased collaborations between biological, physical and mathematical sciences.
6. Develop centres of excellence or consortia of excellence in LUT, GT and GIT research
  - Integrate expertise from university departments, academic medical units and industry
  - Encourage translational approaches to research.
    - Develop inter-institutional research-training programmes to allow new researchers the opportunity to better interact and exchange ideas.
7. Bring about a greater emphasis on the importance of research to medical trainees and science graduates through:
  - Establishing research training as a core component of postgraduate clinical development
  - Increased access to support funds, especially scholarships and personal awards
  - Organisation of focused multidisciplinary research meetings, either stand-alone or as dedicated sessions during national and international conferences
  - Greater interaction between medical centres and Higher Education Institutions (HEIs).
  - Allowing researchers-in-training better access to international meetings through reduced registration charges and improved travel grants.
  - Inclusion in clinical meetings of point-counterpoint session(s) with both basic science and clinical viewpoints.
  - Development of research forums for exchange of ideas between active researchers and industry.
  - Lobbying research-funding organisations about the medical and social importance of LUT and LGIT disorders.
8. Increase emphasis on research into LUT and LGIT in HEIs through:
  - Greater representation on grant-funding agencies
  - Encouragement of submission to high impact factor journals and recognition of research published in specialty journals
  - More integrated teaching and training opportunities

# 6. RECOMMENDATIONS FOR PRIMARY PREVENTION, CONTINENCE PROMOTION, MODELS OF CARE AND EDUCATION

Primary prevention, continence promotion and advocacy, models of care and education involves informing and educating the public and health care professionals that UI and FI are not inevitable, but are treatable or at least manageable. Other bladder disorders such as BPS/IC and POP can also be treated successfully. The committee found information about recent practice and research initiatives in all of these areas but evidence-based research only on primary prevention of UI. Continence promotion and advocacy, and professional and non-professional education, require prioritisation by public health professionals, educationalists, clinicians and researchers to reduce the burden that UI, FI, BPS/IC and POP places on society, healthcare systems, caregivers, and above all, affected adults. As to models of care, the evidence supports nurse-led community services as leading to higher health-related QoL and in some instances, higher cure rates. The multidisciplinary referral settings are also reporting favourable outcomes.

## 1. PRIMARY PREVENTION

- Pelvic floor muscle exercises can prevent UI in pregnant and postpartum women. (Level of Evidence: 1)
- Education designed for community-dwelling older women can prevent UI. (Level of Evidence: 1)
- No recent RCTs or case-control studies were located for prevention of FI. (Level of Evidence: 4)
- Pelvic floor muscle exercises should be provided for pregnant women. (GoR A)
- Education of older women to prevent UI should be provided. (GoR A)
- Continence promotion is required to address broad gaps in knowledge about incontinence (GoR C)
- Strategies to promote awareness about incontinence and its treatment can be strengthened by the use of evidence based theories and methods from the field of health promotion, including the social determinants of health (GoR D)
- The Internet represents an important source of information about incontinence, however the quality of information is variable (GoR C)
- For help-seeking behaviour, no RCTs or case-control studies were located (Level of Evidence 4)
- Continence promotion programmes need to accommodate varying levels of health literacy and access to health information in different populations (Level of Evidence: 4)
- Public health campaigns about incontinence and other pelvic floor disorders need to use terminology targeted to consumers' understandings (Level of Evidence: 4)
- Satisfaction surveys about continence care could yield relevant and detailed information by using open-ended, rather than closed-ended questions (Level of Evidence: 1)
- Evidence for the use of leaflets or brochures in raising awareness about UI and different treatment options is inconclusive (Level of Evidence: 1).
- Evidence for the impact of continence advocacy worldwide was based on opinion (Level of Evidence: 1)
- Recommendation for help-seeking behaviour: No recommendation was possible based on the level of evidence provided by the available research.
- Worldwide Advocacy (GoR D)

## 2. MODELS OF CARE

- Effectiveness of service delivery models. (Level of Evidence: 4)
- A care delivery model should be based on the principles as described in the Optimum Continence Service Specification. (GoR C)
- Increased emphasis is needed on non-physician models of care. (GoR C)
- Despite the proliferation of guidelines, there is increasing evidence that practicing clinicians and nurses are not consistently following them. Implementation models should be developed on how to translate guidelines into practice. (GoR C)

## 3. EDUCATION

- Professional education of UI, FI, BPS/IC, and POP is not evident as determined by materials reviewed. (Levels of Evidence: 3-4)

- Effectiveness of guidelines in clinical practice has not been determined. (Levels of evidence: 3 to 4).
- There is a continued need for evaluation research to explore impact of guidelines on clinical care both at individual and population levels. This evaluation strategy needs to include impact on a wide range of outcomes, including incidence and prevalence of disease, treatment outcomes, prevention efforts, costs, and health care policy. (GoR: C)
- Effectiveness of public education efforts through various channels including education, public media and mass communications (Levels of Evidence 3-4)
- There is a need for additional focused research on methods to enhance patient and public about pelvic disorders, both at an individual and broader public level. (GoR C)
- The role of technology in public education for continence promotion should be examined in more depth. (GoR C)

# 7. RECOMMENDATIONS FOR TRANSLATIONAL AND CLINICAL RESEARCH

## A. RECOMMENDATIONS ON STUDY CONDUCT AND STATISTICAL METHODS

The role of quality RCTs as providing the strongest level of evidence in incontinence research should be fully acknowledged by researchers, journal reviewers, and editors. (GoR A)

Careful attention to the planning and design of all research, especially RCTs, is of the utmost importance. (GoR A)

Appropriate expertise in biostatistics and clinical trial design should be employed at the design phase of a RCT and thereafter on an ongoing basis. For Phase 4, phase 5, and implementation trials, health economists should be included in trial design to support questions of value (cost-effectiveness). (GoR A)

The design, conduct, analysis and presentation of RCTs must be fully in accordance with the CONSORT Statement. (GoR A)

The design, conduct, analysis and presentation of observational studies should follow STROBE guidelines. (GoR A)

The design, conduct, analysis and presentation of meta-analyses should follow QUORUM guidelines. (GoR A)

Reporting studies of diagnostic tests, including urodynamics, should follow the STARD statement guidelines. (GoR A)

## B. RECOMMENDATIONS ON RESEARCH CONDUCT

### 1. RECOMMENDATIONS FOR CONSERVATIVE TREATMENT TRIALS

Use correct terminology to describe the intervention. (GoR A)

Report details of ability to perform correct contraction, dose-response issues and adherence. (GoR A)

Use recommended outcome measures with high responsiveness, reliability and validity. (GoR A)

Compare new methods with the best available intervention. (GoR A)

Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions. (GoR A)

For long-term follow-up studies report cross-over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up. (GoR A)

### 2. RECOMMENDATIONS FOR SURGICAL AND DEVICE TRIALS

- The safety and serious side effects of new operations must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicentre cohort studies when RCTs are not practical. (GoR A)
- Safety and serious side effects of incontinence devices must be completely defined with adequate follow-up, especially for use of implantable devices and biological materials, so that risks can be weighed against efficacy. (GoR A)
- Valid informed research consent is required in all trials of surgical interventions, which is separate from the consent for surgery. (GoR A)
- We recommend ongoing research into the usefulness of pre- and post-operative predictive testing (such as urodynamics, ultrasound, MRI, etc) in surgical trials. (GoR A)
- Reports of successful treatment should be limited to subjects with a minimum (not mean) of one-year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated. (GoR A)

- Randomisation for surgical trials should occur at the time of surgery to minimise drop-outs and switch of procedure (GoR A)
- Long-term follow-up of RCT cohorts in an observational cohort is recommended (GoR A)

### 3. RECOMMENDATIONS ON COST ANALYSIS IN INCONTINENCE

- Cost analysis should be incorporated into clinical studies whenever possible (137). (GoR A)
- Cost analysis should describe the perspective of the analysis and analyses using the societal perspective and the payer perspective are useful. (GoR A)

## C. RECOMMENDATIONS FOR SPECIFIC PATIENT GROUPS

### 1. MEN AND WOMEN WITH LUTS

#### 1.1. Men with LUTS

- Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a variable, or to change during the intervention and follow up. (GoR A)
- Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. (GoR A)
- Participants should be stratified by prostate size at randomisation when size is considered to be a potentially important determinant of treatment outcome. (GoR C)

#### 1.2. Women with LUTS

- Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. (GoR A)
- High quality, symptom and bother scores (e.g., ICIQ-FLUTS, ICIQ-SF, ICIQ-QoL(KHQ), PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes. (GoR A)
- Standardised assessment of pelvic organ prolapse should be performed before treatment and at the time of other outcome assessments in all

research where prolapse and continence outcomes are being assessed. (GoR A)

- Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests. (GoR A)
- Assessment of the impact of treatment on sexual function should be performed with other outcome assessment when appropriate. (GoR B)

### 2. CHILDREN

- Long-term follow-up is of critical importance in the paediatric population in order to ascertain the effect of a treatment on normal growth and development. (GoR A)
- Research is needed to develop standardised outcome measures including validated, age-specific symptom and disease-specific quality of life outcome measures. (GoR B)

### 3. NEUROGENIC POPULATIONS

- Detailed urodynamic studies are recommended for classification of neurogenic lower urinary tract disorders in research studies because the nature of the lower tract dysfunction cannot be accurately predicted from clinical data. Videourodynamic studies are preferred but are not mandatory. (GoR C)
- An area of high priority for research is the development of a classification system to define neurogenic disorders. Relevant features could include the underlying diagnosis, the symptoms, a precise documentation of the neuromuscular lesion by clinical neurophysiologic testing, and the nature of the urodynamic abnormality. (GoR C)

### 4. POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS)

- Broader entry criteria should be used to reflect the full spectrum of the BPS/IC patient population. (GoR B)
- The primary endpoint of BPS/IC trials should be patient driven and the Global Response Assessment is recommended. A wide spectrum of secondary endpoints will be useful in defining the effect of treatments. (GoR B)

## 5. POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

- A validated standardised assessment of prolapse (eg POP-Q) should be used for baseline and outcome assessments. (GoR A)
- Complete reporting of outcomes including a validated assessment of anatomy, functional status, and complications is essential. (GoR A)
- Complications/adverse events (especially for mesh) must be explicitly and completely reported in any research. (GoR A)
- Long term outcomes (> 2 years) of intervention studies are needed. (GoR A)

## D. RECOMMENDATIONS FOR ETHICS IN RESEARCH

The GoR for this section is A.

Continuity in clinical direction from design through authorship is mandatory. Investigators should be involved in the planning stage and a publications committee should be named at the beginning of the clinical trial. The Uniform Requirements for Manuscripts

Submitted to Biomedical Journals, from the International Committee of Medical Journal Editors should be followed. Authorship requires:

- Substantial contributions to conception and design or acquisition of data or analysis and interpretation of data,
  - Drafting the article or revising it critically for important intellectual content,
  - Final approval of the version to be published
- Authors should provide a description of what each contributed and editors should publish that information.
- Authors should have access to all raw data from clinical trials, not simply selected tables

Clinical trial results should be published regardless of outcome. The sponsor should have the right to review manuscripts for a limited period of time prior to publication but the manuscript is the intellectual property of its authors, not the sponsor.

- All authors should be able to accept responsibility for the published work and all potential conflicts of interest should be fully disclosed

# 8. INTERNATIONAL CONSULTATION ON INCONTINENCE MODULAR QUESTIONNAIRE (ICIQ): QUESTIONNAIRES AND BLADDER DIARY

## A. INTERNATIONAL CONSULTATION ON INCONTINENCE MODULAR QUESTIONNAIRE (ICIQ)

The scientific committee which met at the end of the 1st ICI in 1998 supported the idea that a universally applicable questionnaire should be developed, that could be widely applied both in clinical practice and research and should reflect the patients' perspective of their situation.

The hope was expressed that such a questionnaire would be used in different settings and studies and would allow cross-comparisons, for example, between a drug and an operation used for the same condition, in the same way that the IPSS (International Prostate Symptoms Score) has been used.

An ICIQ Advisory Board was formed to steer the development of the ICIQ and met for the first time in 1999. The project's early progress was discussed with the Board and a decision made to extend the concept further and to develop the ICIQ Modular Questionnaire to include assessment of urinary, bowel and vaginal symptoms(1). The first module to be developed was the ICIQ Short Form Questionnaire for urinary incontinence: the ICIQ-UI Short Form (2) (Fig 1). The ICIQ-UI Short Form is now widely used globally and since 2004 its use or further development has been reported in almost 100 publications.

Given the intention to produce an internationally applicable questionnaire, requests were made for translations of the ICIQ-UI Short Form at an early stage, for which the Advisory Board developed a protocol for the production of translations of its modules. The ICIQ modules have been translated into over 40 languages to date across the various modules.

Since the fifth consultation a further two modules have been published and are available for use: the ICIQ Bladder Diary (3,4) and ICIQ-LTCqol(5). The bladder diary is the first fully validated bladder diary, which notably incorporated patient and clinician input during its development. The ICIQ-LTCqol questionnaire provides an assessment of symptoms, impact and bother associated with indwelling catheter use. This brings the total number of available modules to sixteen.

With increasing demand for electronic versions of questionnaires, a study has been conducted by the ICIQ group to evaluate the equivalence of the ICIQ's psychometric properties in alternative formats (6). With equivalence demonstrated, app development for the eICIQ is underway.

www.ICIQ.net provides details of the validation status of the modules under development for urinary symptoms, bowel symptoms and vaginal symptoms and provides information regarding the content of existing modules. Information regarding production of translations and the ICIQ development protocol is also available for those interested in potential collaborations to continue development of the project.

Table 1: Fully validated ICIQ modules and derivation

MODULES AVAILABLE FOR USE	
<b>ICIQ-MLUTS(7)</b> (ICS <sub>male</sub> Short Form)	Urinary symptoms (male)
<b>ICIQ-FLUTS(8)</b> (BFLUTS Short Form)	Urinary symptoms (female)
<b>ICIQ-VS(9)</b>	Vaginal symptoms and quality of life
<b>ICIQ-B(10,11)</b>	Bowel symptoms and quality of life
<b>ICIQ-UI Short Form(2)</b>	Urinary incontinence short form
<b>ICIQ Bladder diary(3,4)</b>	Bladder events and fluid intake
<b>ICIQ-N(12,13)</b> (ICS <sub>male</sub> /BFLUTS)	Nocturia symptoms
<b>ICIQ-OAB(12,13)</b> (ICS <sub>male</sub> /BFLUTS)	Overactive bladder symptoms
<b>ICIQ-MLUTS Long Form(12)</b> (ICS <sub>male</sub> )	Urinary symptoms long form (male)
<b>ICIQ-FLUTS Long Form(13)</b> (BFLUTS)	Urinary symptoms long form (female)
<b>ICIQ-LUTSqol(14)</b> (KHQ)	Urinary symptoms quality of life
<b>ICIQ-Nqol(15)</b> (N-QoL)	Nocturia quality of life
<b>ICIQ-OABqol(16)</b> (OABq)	Overactive bladder quality of life
<b>ICIQ-LTCqol(5)</b>	Long term catheter symptoms and quality of life
<b>ICIQ-MLUTSsex(12)</b> (ICS <sub>male</sub> )	Sexual matters related to urinary symptoms (male)
<b>ICIQ-FLUTSsex(13)</b> (BFLUTS)	Sexual matters related to urinary symptoms (female)

## B. ANNEX 1 BLADDER CHARTS AND DIARIES

The ICS defines three types of Bladder Charts and Diaries which can be used to collect data:

### MICTURITION TIME CHART

- times of voiding and
- incontinence episodes

### FREQUENCY VOLUME CHART

- times of voiding with voided volumes measured,
- incontinence episodes and number of changes of incontinence pads or clothing

### BLADDER DIARIES

- the information above, but also
- assessments of urgency,
- degree of leakage (slight, moderate or large) and descriptions of factors leading to symptoms such as stress leakage, eg. running to catch a bus. It is important to assess the individual's fluid intake, remembering that fluid intake includes fluids drunk plus the water content of foods eaten. It is often necessary to explain to a patient with LUTS that it may be important to change the timing of a meal and the type of food eaten, particularly in the evenings, in order to avoid troublesome nocturia.

The recent development and publication of the ICIQ Bladder Diary provides the first fully validated bladder diary that incorporated patient, clinician and statistical

input during its development (3,4). This rigorous development methodology has ensured the provision of a psychometrically robust tool that reflects the key issues from a patient's and clinical perspective to enable the gathering of required information to treat patients with LUTS (Fig 1). The diary is intended to be a standalone tool that provides instructions and an example to guide completion. The diary is intended for completion over three days and fits onto two sides of A4 to optimise administration and completion. Data collected are:

- Fluid intake
- Urine output
- Leakage episodes
- Time of sleep and waking
- Pads used
- Optional bladder sensation scale

The bladder sensation scale is intended to be an interchangeable variable that can be replaced with a more pertinent measure for an intended use, for example, a pain scale. It is advised that any scale used in this manner should be validated.

#### INSTRUCTIONS FOR USING THE BLADDER DIARY

This diary helps you and us to understand why you get trouble with your bladder. The diary is a very important part of the tests we do, so that we can try to improve you symptoms. On the chart you need to record:

9. When you get out of bed in the morning, show this on the diary by writing 'GOT OUT OF BED'.
10. During the day please enter at the correct time the drinks you have during the day, eg. 8.00am – two cups of coffee (total 400 ml).
11. The time you pass your urine, eg. 7.30am. Do this every time you pass urine throughout the day and night.
12. Each time you pass urine, collect the urine in a measuring jug and record the amount (in mls or fluid ozs) next to the time you passed the urine, eg. 1.30pm/320ml.
13. Each time you pass your urine, please write down how urgent was the need to pass urine:
  - 'O' means it was not urgent.
  - + means I had to go within 10 minutes.
  - ++ means I had to stop what I was doing and go to the toilet.
14. If you leak urine, show this by writing an 'W' on the diary at the time you leaked.
15. If you have a leak, please add 'P' if you have to change a pad and 'C' if you have to change your underclothes or even outer clothes. So if you leak and need to change a pad, please write 'WP' at the time you leaked.
16. If you have a leakage please write in the column called 'Comments' whether you leaked a small amount or a large amount and what you were doing when you leaked, eg. 'leaked small amount when I sneezed three times'.
17. Each time you change a pad or change clothes, please write in the 'Comments' column.
18. When you go to bed at the end of the day show it on the diary - write 'Went to Bed'.

**ICIQ-BLADDER DIARY** (12/13)

**YOUR NAME:** \_\_\_\_\_

DAY 1 DATE: \_\_\_\_ / \_\_\_\_ / \_\_\_\_

Please complete this **3 day** bladder diary. Enter the following in each column against the time. You can change the specified times if you need to. In the time column, please write **BED** when you went to bed and **WOKE** when you woke up.

**Drinks** Write the amount you had to drink and the type of drink.

**Urine output** Enter the amount of urine you passed in millilitres (mls) in the urine output column, day and night. Any measuring jug will do. If you passed urine but couldn't measure it, put a tick in this column. If you leaked urine at any time write **LEAK** here.

**Bladder sensation** Write a description of how your bladder felt when you went to the toilet using these codes

- 0** - If you had no sensation of needing to pass urine, but passed urine for "social reasons", for example, just before going out, or unsure where the next toilet is.
- 1** - If you had a normal desire to pass urine and no urgency. 'Urgency' is different from normal bladder feelings and is the sudden compelling desire to pass urine which is difficult to defer, or a sudden feeling that you need to pass urine and if you don't you will have an accident.
- 2** - If you had urgency but it had passed away before you went to the toilet.
- 3** - If you had urgency but managed to get to the toilet, still with urgency, but did not leak urine.
- 4** - If you had urgency and could not get to the toilet in time so you leaked urine.

**Pads** If you put on or change a pad put a tick in the pads column.

Here is an example of how to complete the diary:

Time	Drinks		Urine output	Bladder sensation	Pads
	Amount	Type			
6am WAKE			350ml	2	
7am	300ml	tea		2	
8am			✓

## 4. ICS CONSENSUS AND COMMITTEE DOCUMENTS

A 'medical consensus' is defined by the Council of Europe as "a public statement on a particular aspect of medical knowledge that is generally agreed upon as an evidence-based, state-of-the-art knowledge by a representative group of experts in that area".

The document is usually developed by a multidisciplinary independent panel of experts convened either by a medical association or by a governmental authority to review and summarise the scientific literature in order to:

1. Advance the understanding of an issue, procedure, or method;
2. Outline standards of care and good practice;
3. Provide guidance to health care professionals, especially on controversial or poorly understood aspects of care;
4. Support and promote good clinical practice in the best interest of the patient;
5. Improve the quality and effectiveness of health care.

The consensus documents by summarising the published literature on a specific topic should be considered as a comprehensive summary of the opinions and the expression of the general opinion of the panel of experts that does not necessarily imply unanimity. Since they provide a "snapshot in time" they must be re-evaluated periodically.

There are different ways of producing a consensus document. The Delphi method is a useful process that involves sending out questionnaires of statements; collating and anonymizing feedback; sharing them in a number of cycles within the experts who can adjust their answers in subsequent rounds. It allows to avoid bringing experts together for a physical meeting, to facilitate interaction between experts and to reduce individual bias. However, consensus documents do not provide algorithms or guidelines for practice that are usually issued by any organization for healthcare providers and commissioners to promote best care for patients.

In this e-book we will describe how the International Continence Society consensus documents are developed. These are usually commissioned by the Board of Trustees or by ICS committees and aim to set out the organisation's position or philosophy about a specific topic.

We will also describe the criteria that Working /Committee groups which wish to produce a consensus document for the ICS should adhere to.

Finally, we will discuss the Standard Operating Procedure that has been compiled by the International Continence Society. This includes a Proposal Stage, a Preparatory Stage, a Review Stage, a Publication Stage and a Implementation Stage. A set of step-by-step instructions for the creation of the consensus documents will be described in detail including: creation of a working group and appointment of a chair; submission of the proposal sent to ICS Office; review and approval of the proposal by Board of Trustees and Editor of NeuroUrology & Urodynamics Journals (NUUJ); preparation of the consensus document; review of the content by relevant committees and Board of Trustees; submission of the consensus document NUUJ; publication of the consensus document on the ICS website and advertised."

Inflammatory bowel disease  
Crohn's disease  
Ulcerative colitis

### ABSTRACT

**Introduction:** Potential consequences of inflammatory bowel disease (IBD) need evaluation for patients considering urinary tract reconstruction for benign disease. A working group was formed by the International Continence Society, which considered urinary tract reconstruction in IBD.

**Methods:** Nominal group technique was used to derive consensus. Principal aspects of IBD assessment and surgery decision-making were agreed. A questionnaire was used to facilitate the generation of statements by a core focus group of experts, which were modified and ratified by the wider working group. This was followed by final voting by the full working group.

**Results:** General considerations included identifying the importance of the specialist IBD multi-disciplinary team. Peri-operative considerations recommended avoiding pre-operative fasting from midnight, and using an enhanced recovery after surgery (ERAS) protocol. Selection of bowel segment, pre-operative optimisation and post-operative issues were considered for both Ulcerative colitis (UC) and Crohn's disease. UC is not an absolute contraindication to urinary tract reconstruction using small or large bowel. Elective reconstructive surgery should wait at least three months following resolution of any acute UC flare-up to correct all abnormalities. Crohn's disease is a high-risk disease for urinary tract reconstruction, even if in remission. In Crohn's, reconstructive surgical options are limited by the location and extent of gastrointestinal segment(s) affected and the phenotype of disease.

**Conclusion:** The consensus opinion indicates that urinary tract reconstruction using bowel segments is feasible in carefully selected and optimised patients with IBD lacking alternative management options, provided there is access to appropriate multidisciplinary skills. UC is relatively low risk for surgical procedures, whereas Crohn's has considerably increased risk of morbidity. The potential risks must be properly discussed with patients considering reconstructive urological procedures. Outcomes should be carefully monitored and published to identify the safety and efficacy of reconstructive surgery in IBD, including full description of the disease status.

## 1. Introduction

Urinary diversion and urinary tract reconstruction often employ bowel isolated on a vascular pedicle to augment the bladder, create a new urinary reservoir or conduit, act as a continent catheterisable channel, or an interposition chute for ureteric reconstruction. Such surgery requires the ability to safely harvest a segment of healthy bowel to help achieve good surgical outcomes for the urinary tract reconstruction and ensure effective gastrointestinal healing without compromising bowel function.

Although there is literature available on the sequelae of lower urinary tract reconstruction using bowel, the potential consequences of pre-existing bowel disease or dysfunction also need to be considered. There are many complications that can occur following urinary tract reconstruction using bowel [1], including infection, anastomotic leaks, bowel obstruction, metabolic disturbance, change in bowel habit, renal impairment, stricture formation, urolithiasis and malignancy. Risks may be exacerbated if the patient has pre-existing bowel disease, such as inflammatory bowel disease (IBD), notably ulcerative colitis (UC) and Crohn's disease. Crohn's disease, in particular, is associated with post-operative intra-abdominal septic complications related to anastomotic breakdown, especially in patients with low serum albumin, re-operative surgery and steroid use [2]. Appropriate patient selection and post-operative medical treatment and follow-up are therefore pertinent to any bowel surgery in such patients [3]. Due to the relatively high risk of post-operative complications, patients must undergo a thorough assessment beforehand and must be fully optimised, addressing areas specifically related to peri- and post-operative morbidity, such as malnutrition, active inflammation and immunosuppression [4]. UC is not considered as high risk for surgery, but outcomes after elective surgery are variably defined [5]. Nonetheless, appropriate precautions must be taken in patients with this condition, as there is still a recognised risk of morbidity [6].

Concerns that the underlying bowel disease may affect the outcomes when used for urinary tract reconstruction further compound the challenges of such procedures [7]. The high rate of complications from surgery in IBD, and the uncertain implications for the reconstruction, necessitate caution. Accordingly, a working group was set up under the auspices of the International Continence Society (ICS) to develop recommendations regarding the safe use of bowel for urinary reconstruction in adult patients with IBD.

## 2. Methods

A working group was formed by open advertisement to members of the International Continence Society (ICS), European Society of Coloproctology (ESCP) and the American Society of Colon and Rectal Surgeons (ASCRS) with the remit of developing consensus documents on the use of bowel in disease states for urinary tract reconstruction. Detailed literature searches were conducted using Ovid MEDLINE and PubMed databases from inception until December 2021.

A core focus group of experts in the fields of IBD and urinary tract reconstruction was assembled from this working group. The working group considered the use of bowel for urinary tract reconstruction in patients with IBD under the subheadings of 'General considerations' and 'Peri-operative considerations' for all patients with IBD and then specifically 'Pre-operative' and 'Post-operative considerations' for Ulcerative Colitis and Crohn's disease individually.

The nominal group technique (NGT), a semi-quantitative structured interview procedure [8,9], was used to identify the principal aspects of IBD assessment and surgery decision-making, and for prioritisation to achieve consensus on urinary tract reconstruction. In order to facilitate the generation of the initial statements, a questionnaire was drawn up under the headings: General Considerations, Pre-operative, Intra-operative and Post-operative (supplementary material).

Online meetings were structured to include: 1. Introduction and explanation, 2. Silent generation of ideas (as individuals), 3. Sharing ideas (round-robin format), until saturation of concepts, 4. Group discussion, 5. Ranking. This process enabled generation of an initial series of statements, which were revised on serial rounds of review by the focus group. It was followed by ratification by the wider working group and final voting by the sub-specialist expert focus group and working group (Fig. 1). All members of the working group and focus group voted and agreed on the final statements. In total the consensus statements underwent nine rounds of discussion.

## 3. Results

### 3.1. General considerations in IBD

**3.1.1 All patients must be discussed with a specialist IBD multi-disciplinary team (MDT) to provide an assessment on the feasibility of surgery and on the segment and length of bowel that can be harvested, whilst weighing up the risk of current or future problems pertaining to risk of progression and likelihood of short bowel syndrome.**

*The MDT should ideally include a team of colorectal surgeons and gastroenterology physicians. Input from dietetics, radiologists, specialist nurses and pathologists may also be required. This MDT discussion is in addition to the specialist urology MDT discussion, which also involves continence nurses and pelvic floor physiotherapists.*

**3.1.2 A plan from the IBD MDT should be sought pre-operatively regarding medical therapy and may require re-discussion should the clinical course change in the post-operative setting.**

**3.1.3 Anyone with a history of complex peri-anal disease or fistulae, arthropathy, ankylosing spondylitis or a family history of Crohn's disease should be referred for a review by a gastroenterologist or colorectal surgeon with a special interest in Crohn's disease to exclude the possibility of undiagnosed Crohn's disease prior to use of bowel in urinary tract reconstruction.**

*Features suggestive of Ankylosing Spondylitis include a history of lower back pain and stiffness, typically worse after recumbency with a hallmark 'stooped' posture.*

### 3.2. Peri-operative considerations in IBD

**3.2.1 In IBD, pre-operative overnight fasting should be avoided and an enhanced recovery after surgery (ERAS) protocol should be used instead.**

*Prolonged pre-operative fasting can exacerbate an insulin resistant state resulting in increased morbidity in the peri-operative period. Following the recommendations of the ERAS protocol, solid food should not be consumed beyond 6 h pre-surgery. However, clear fluids are permitted up to 2 h pre-surgery [10]. Carbohydrate loading drinks can also be administered at 2 h pre-surgery to further minimise the morbidity associated with this transient insulin resistant state, resulting in a quicker post-operative recovery [11].*

**3.2.2 In IBD, bowel preparation products should not be routinely administered pre-operatively, as per the ERAS protocol. They can be considered in select cases, such as when performing a colonic conduit or colonic augmentation cystoplasty.**

*The role of pre-operative mechanical bowel preparation (MBP) remains controversial. There is limited evidence to support the role of MBP reducing complications in patients undergoing cystectomy and ileal conduit or ileal neobladder urinary diversion [12,13]. The concern is that it can impact electrolyte haemostasis and bowel motility.*

*As there is some emerging evidence to support the role of MBP (coupled with oral antibiotics) in elective colorectal surgery, the working group have recommended that MBP can be considered in select cases using colonic reconstruction.*

*A full colon can also pose a challenge during major pelvic surgery. Hence, MBP can be considered in select cases, e.g. patients with congenital anomalies and more challenging anatomy.*

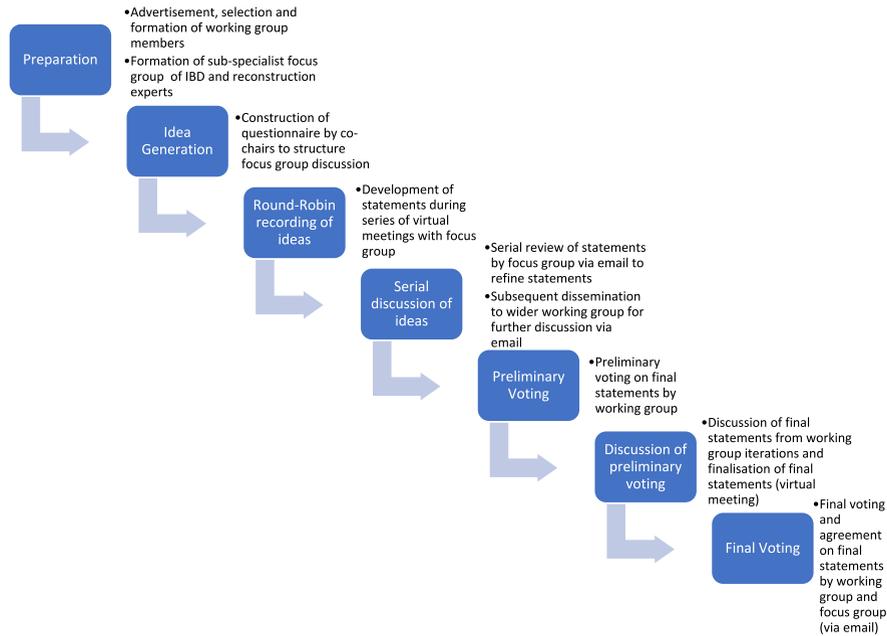

Fig. 1. Process for generation of consensus statement.

### 3.2.3 Nasogastric tubes may be used intra-operatively in IBD, but should be removed at the end of the case, unless at high risk of post-operative ileus.

Recent evidence suggests that routine nasogastric tube insertion does not significantly reduce the risk of peri-operative morbidity but instead can result in delayed gut recovery.

The working group recommend that nasogastric tubes should be left in situ in patients with an increased risk of post-operative ileus to minimise risk of pulmonary aspiration and pneumonia. Risk factors for post-operative ileus include those with a prior history of delay in resolution of gut function, polypharmacy including anti-cholinergics and opiates, pre-existing electrolyte abnormalities and obesity.

## 3.3. Ulcerative colitis

### 3.3.1 Disease specific pre-operative considerations in UC

#### 3.3.1.1 Ulcerative colitis is not an absolute contraindication to urinary tract reconstruction using small or large bowel.

Urinary tract reconstruction using bowel can be performed in patients with UC, but must only be performed when the disease is in a stable state, preferentially utilising ileum.

#### 3.3.1.2 Ulcerative colitis is considered to be a low-risk disease in those due to undergo urinary tract reconstruction using bowel, provided the disease is in remission.

The overall morbidity in patients with stable disease is thought to be low, especially when compared to those with Crohn's disease.

#### 3.3.1.3 Ulcerative colitis can be a progressive disease. The disease is often contiguous from the rectum, extending to a variable extent proximally, and can result in pan-colitis. There are, however, different phenotypes, and there may be sparing of the rectum in rare cases.

This highlights the importance of a specialist assessment by the colorectal and/or gastroenterology specialists to assess which segment of bowel can be safely harvested.

#### 3.3.1.4 An acute UC flare is an absolute contraindication to any urinary tract reconstructive procedure using bowel. All elective reconstructive surgery should be performed after a minimum of three months following resolution of the acute flare, to allow for correction of all abnormalities, including protein and electrolyte deficiencies, and appropriate weaning of steroids.

A specialist colorectal or gastroenterology opinion is advisable to confirm if the patient is fit to proceed with elective bowel surgery.

### 3.2.2 Selection of UC bowel segment

#### 3.2.2.1 Ileum is the preferred choice for bowel harvest, as it is rarely affected by ulcerative colitis. However, backwash ileitis can be seen in rare cases. When using ileum for reconstruction, the length harvested should be kept to the minimum required and should be proximal to the terminal ileum. This allows for the possibility that the patient may later require a total colectomy and ileal pouch-anal anastomosis if they were to develop advanced pan-colitis.

Ileum should be harvested ideally >30 cm proximal to the ileo-caecal valve, to reduce the risk of bile acid malabsorption and subsequent diarrhoea.

Although it is generally safe to use ileum in patients with UC, a specialist assessment is still mandatory, as there is a risk of backwash ileitis which may contraindicate use of ileum. Patients with advanced UC may end up requiring a total colectomy and accordingly may be more heavily reliant on their small bowel function, again re-iterating the importance of a specialist assessment.

#### 3.2.2.2 Using colonic segments in UC is a relative contraindication and should be avoided whenever possible. Previous colonoscopic evidence of pan-colitis is a contraindication to using colon, unless limited small bowel is available and colonic disease has been quiescent for a prolonged period of time.

There is no specified time frame for which the disease must remain quiescent. We recommend at least one year as a guide to the minimum suitable period of disease quiescence.

3.3.2.3 Reconstruction using colonic segments can be performed in select cases with isolated proctitis as the only manifestation of UC. The small bowel should be preserved in case a pan-proctocolectomy becomes necessary.

3.3.2.4 In the rare circumstances of using colon in patients with isolated proctitis, patients must be counselled of the risk of disease progression affecting the colonic segment utilised for reconstruction, whereby they may require further medical therapy with or without the need for additional surgery. A full colonoscopy should be performed within three months prior to the surgery to identify disease activity and extent of involvement.

*The use of colonic segments should always be ratified after discussion with a specialist IBD MDT and only used in the absence of a viable alternative.*

### 3.3.3 Pre-operative optimisation in UC

3.3.3.1 Concurrent steroid use is an absolute contraindication to elective reconstructive surgery, due to an increased risk of poor tissue healing. Steroids should be stopped at least six weeks prior to proceeding with reconstructive surgery.

*This is particularly relevant to patients that are on 20mg once daily Prednisolone (or equivalent) for more than six months [6].*

*A plan from the IBD MDT should be sought pre-operatively regarding medical therapy and may require re-discussion should the clinical course change in the post-operative setting.*

3.3.3.2 Biologics (e.g. anti-TNF-alpha drugs Infliximab and Adalimumab) and most immune modulators (e.g. Methotrexate and Azathioprine) can be continued pre-, intra- and post-operatively at their normal dose.

*A plan from the IBD MDT should be sought pre-operatively regarding medical therapy and may require re-discussion should the clinical course change in the post-operative setting.*

3.3.3.3 In addition to the pre-operative correction of any underlying electrolyte abnormalities, anaemia, diabetic control and renal insufficiency, patients should be strongly encouraged regarding smoking cessation, and referred to available smoking cessation support services if necessary.

3.3.3.4 A nutritional assessment should always be conducted. Dietetic input must be sought pre-operatively in patients with extremes of BMI or a recent history of rapid weight loss or weight gain.

*The validated Malnutrition Universal Screening Tool (MUST; [https://www.bapen.org.uk/pdfs/must/must\\_full.pdf](https://www.bapen.org.uk/pdfs/must/must_full.pdf)) can be used to help identify malnutrition. However if there is any concern, an expert opinion should be obtained.*

### 3.3.4 Post-operative complications in UC

3.3.4.1 Abdominal wall hernias are more common in patients with a history of prolonged steroid use and those deconditioned pre-operatively. Accordingly, efforts must be made to discontinue steroids and improve muscle mass pre-operatively through early involvement of physiotherapists.

3.3.4.2 There is an increased risk of adhesions and subsequent adhesional bowel obstruction in those with a history of previous extensive colonic disease and/or prior surgery.

3.3.4.3 UC with concomitant primary sclerosing cholangitis suggests an aggressive form of disease. These patients may be at higher risk of anastomotic complications (i.e. anastomotic leak).

*These patients should be counselled accordingly and fully optimised before embarking on any elective surgery. All reasonable alternatives should be explored first.*

3.3.4.4 The risk of anastomotic complications can be modest, providing a disease-free segment has been harvested and the patient is not on concomitant steroid treatment. The presence of renal failure or liver derangement can increase the risk of anastomotic breakdown and therefore requires specialist input and optimisation pre-operatively. This risk is considerably higher in patients requiring dialysis.

*It is important to note that both renal impairment (usually defined as a GFR <30mL/min/1.73m<sup>2</sup>) and hepatic dysfunction are contraindications to performing urinary tract reconstruction using bowel [14].*

3.3.4.5 The presence of bowel in a reconstructed urinary tract will often result in mucus production. Excessive mucus production can occur when larger segments of bowel are harvested or when actively diseased bowel segments are used. In those with excessive mucus production and inadequate bladder emptying, there is a resultant increased risk of infection, stones and pyocystis.

*A specialist assessment as part of the surgical planning can help to mitigate this risk. If patients are using clean intermittent self-catheterisation (ISC), the ISC regimen (e.g. number of catheterisations, type of catheter) may need to be reviewed to cope with mucus production and poor bladder emptying, and minimise risk of complications such as rupture of the reconstructed bladder.*

3.3.4.6 The incidence and severity of urinary tract infections may be exacerbated by the concurrent use of immunosuppressive treatment.

3.3.4.7 Patients must be counselled about the increased risk of post-operative morbidity and sepsis whilst taking any form of immunosuppressive therapy. Clinicians must have a low threshold for suspecting sepsis in these patients.

3.3.4.8 Trimethoprim should be avoided for the treatment of UTIs in patients on Methotrexate, due to significantly increased risk of myelosuppression and nephrotoxicity.

### 3.3.5 Post-operative follow-up and management in UC

3.3.5.1 Patients with UC are often hypercoagulable. Although there is limited evidence in the literature, we recommend that UC patients undergoing major pelvic surgery should be given extended pharmacological thromboprophylaxis (e.g. low molecular weight heparin for 28 days post-operatively), provided there are no contraindications.

*Due to limited evidence, the working group recommend venous thromboembolism prophylaxis to reflect the practice of pelvic oncological surgery.*

3.3.5.2 Bile acid malabsorption can occur in patients who have undergone terminal ileum resection. Hence, those with significant bowel disturbance after surgery need gastroenterology input. Due to this risk, it is recommended to retain the terminal ileum in continuity with the gastrointestinal tract where possible.

*Bile salt diarrhoea becomes increasingly likely for longer extents of terminal ileum harvesting. Fat malabsorption is likely to be encountered additionally when more than 100 cm is harvested.*

3.3.5.3 All patients with diarrhoea persisting for more than six weeks following their procedure should be referred for a gastroenterology review, with a view to commencing therapy.

*This is often treated with bile acid sequestrants (e.g. cholestyramine) but is best managed by the gastroenterologists.*

3.3.5.4 Vitamin B12 deficiency is also common following terminal ileum resection. B12 should be monitored with annual blood tests and replaced as necessary. Terminal ileum should be spared in any reconstructive surgery where possible. Follow-up should be lifelong, as it can take several years for this to become evident.

*Management needs to recognise the importance of early identification of vitamin deficiency to prevent serious complications, notably anaemia or neurological problems, and should be undertaken in accordance with applicable guidance, e.g. [15]. For those with no neurological involvement, 1mg intramuscular hydroxycobalamin is required three times a week for two weeks. This is usually continued every two to three months for life but specialist haematology input should be sought [15]. If neurological involvement is evident, urgent specialist advice from a haematologist is needed.*

3.3.5.5 Folate should be monitored and replaced as necessary in those who have had extensive small bowel resection.

*Management needs to recognise the importance of identifying vitamin deficiency to prevent serious complications, notably pancytopenia and megaloblastic anaemia in severe folate deficiency. Treatment should be undertaken in accordance with applicable guidance, e.g. [15]. Patients should be*

prescribed 5mg oral folic acid once daily and will often require this lifelong. Dietary advice can also be given and a specialist haematology opinion should be sought [15].

3.3.5.6 A mild, subclinical hyperchloraemic metabolic acidosis is encountered in almost all patients undergoing urinary diversion using bowel segments. Monitoring of bicarbonate and chloride is recommended when there are concerns about clinical metabolic acidosis (e.g. those with resorptive bone disease).

3.3.5.7 Although there is an increased risk of colorectal adenocarcinoma with UC, robust evidence is lacking to support mandatory surveillance following reconstructive surgery. We therefore recommend following local unit surveillance policies pertaining to method of urinary reconstruction, pending further research. Nonetheless, all patients must be counselled about the importance of seeking urgent medical advice if they were to develop any red flag symptoms.

*There is no clear consensus on the frequency and duration of surveillance following urinary tract reconstruction with bowel but it is recommended due to the small risk of developing adenocarcinoma. Common surveillance protocols involve lifelong annual cystoscopic surveillance of the reconstructed bladder after 10 years [15] but earlier cystoscopy should be performed in the presence of any red flag symptoms, such as haematuria or recurrent urinary tract infections.*

*All patients with UC should undergo specialist investigation to determine the extent of their disease. This would also provide the opportunity to exclude any overt malignancy prior to reconstruction.*

#### 3.4. Crohn's disease

##### 3.4.1 Disease specific pre-operative considerations in Crohn's disease

3.4.1.1 Crohn's disease *per se* is not an absolute contraindication to urinary tract reconstruction. However, pan-enteric disease is an absolute contraindication to the use of bowel in urinary tract reconstruction.

3.4.1.2 Crohn's disease is considered a high-risk disease in those potentially considering urinary tract reconstruction, even if the disease is in remission.

3.4.1.3 Active Crohn's disease, or an acute flare, is an absolute contraindication and all elective reconstructive surgery should be performed after a minimum of three months following resolution of the acute flare. This is to allow for correction of all abnormalities, including protein and electrolyte deficiencies, and appropriate weaning of steroids.

*A specialist colorectal or gastroenterology opinion is advisable to confirm if the patient is fit to proceed with elective bowel surgery.*

3.4.1.4 Crohn's disease can be a progressive disease and the anticipated course of the disease should be considered when planning surgery.

3.4.1.5 Disease progression patterns can be predicted in some cases, but specialist input is required to help assess the phenotype and subsequent likelihood of progression.

3.4.1.6 Risk factors for progression include early age of onset, multi-focal disease, multiple skip lesions, stricture disease and/or fistulating disease, and the presence of more proximal disease. These factors should all be taken into careful consideration, as urinary tract reconstruction may not be feasible or safe in this cohort.

3.4.1.7 Bowel conservation (where possible) should be a key priority to try and reduce the risk of short bowel syndrome, as these patients are likely to require further bowel resection for their Crohn's disease.

##### 3.4.2 Selection of bowel segment in Crohn's disease

3.4.2.1 Reconstructive surgical options may be limited depending on the location and extent of gastrointestinal segment(s) affected and the phenotype of disease (mucosal vs muscular stricture vs penetrative).

3.4.2.2 In disease limited to the colon, ileum may be used, but patients must be appropriately counselled about the risk of disease progression with subsequent ileal involvement which could affect their reconstructed urinary tract.

3.4.2.3 In those with pan-enteric disease in whom urinary tract reconstruction cannot be avoided, alternative reconstructive techniques should be considered, including cutaneous ureterostomy urinary diversion or gastric conduit.

3.4.2.4 In localised segmental disease, the segment of bowel chosen must not be in proximity to a site of current or previously active disease.

3.4.2.5 If small bowel needs to be harvested in an individual with terminal ileal disease, we recommend harvesting the most distal macroscopically-healthy segment of gut.

3.4.2.6 Gastric conduits are seldom performed. However, acknowledging the importance of bowel conservation, gastric and jejunal segments can be considered if necessary when there is extensive ileal disease precluding its use.

3.4.2.7 All patients with suspected Crohn's disease should undergo specialist investigation to determine the extent of their disease, including assessment of both the colon and small bowel, prior to planning reconstructive surgery (i.e. endoscopic evaluation + magnetic resonance enterography +/- capsule endoscopy).

##### 3.4.3 Pre-operative optimisation in Crohn's disease

3.4.3.1 Concurrent steroid use is an absolute contraindication to elective reconstructive surgery, due to an increased risk of poor tissue healing. Steroids should be stopped for at least six weeks prior to proceeding with reconstructive surgery.

*This is particularly relevant to patients that are on 20mg once daily Prednisolone (or equivalent) for more than six months [6].*

*A plan from the IBD MDT should be sought pre-operatively regarding medical therapy and may require re-discussion should the clinical course change in the post-operative setting.*

3.4.3.2 Biologics (e.g. anti-TNF-alpha drugs Infliximab and Adalimumab) and most immune modulators (e.g. Methotrexate and Azathioprine) can be continued pre-, intra- and post-operatively at their normal dose.

*A plan from the IBD MDT should be sought pre-operatively regarding medical therapy and may require re-discussion should the clinical course change in the post-operative setting.*

3.4.3.3 Electrolyte abnormalities, anaemia, diabetic control and renal insufficiency should be corrected pre-operatively.

3.4.3.4 Smoking cessation is paramount for Crohn's disease pre-operative optimisation and strong consideration must be made for referral for further support to help achieve this. Cessation is recommended for at least four weeks prior to surgery.

3.4.3.5 A nutritional assessment should always be conducted. Where appropriate, dietetic input should be sought pre-operatively (i.e. extremes of BMI, recent history of rapid weight loss or gain).

*The validated Malnutrition Universal Screening Tool (MUST; [https://www.bapen.org.uk/pdfs/must/must\\_full.pdf](https://www.bapen.org.uk/pdfs/must/must_full.pdf)) can be used to help identify malnutrition. However if there is any concern, an expert opinion should be obtained.*

##### 3.4.4 Post-operative complications in Crohn's disease

3.4.4.1 The presence of bowel in a reconstructed urinary tract will often result in mucus production. Excessive mucus production can occur when larger segments of bowel are harvested, or when actively diseased bowel segments are used. In those with excessive mucus production and inadequate bladder emptying, there is a resultant increased risk of infection, stones and pyocystis.

Any ISC regimen (e.g. number of catheterisations, type of catheter) may need to be reviewed to cope with mucus production and poor bladder emptying, and minimise risk of complications such as rupture of the reconstructed bladder.

3.4.4.2 Patients must be counselled about the increased risk of post-operative morbidity and sepsis whilst taking any form of immunosuppressive therapy. Clinicians must have a low threshold for suspecting sepsis in these patients.

3.4.4.3 The incidence and severity of urinary tract infections may be exacerbated by the use of immunosuppressive treatment for managing Crohn's.

3.4.4.4 Urinary tract infections (UTIs) can commonly occur in patients with penetrating fistulating disease +/- recurrent abscess formation. Due to the resulting frequent use of antibiotics (e.g. Ciprofloxacin and Metronidazole), there is a potential increased risk of multi-drug resistant bacteria.

3.4.4.5 Trimethoprim should be avoided for the treatment of UTIs in patients on Methotrexate, due to significant risk of increased myelosuppression and nephrotoxicity.

3.4.4.6 There is an increased risk of adhesions and subsequent adhesion bowel obstruction in those with a history of previous extensive colonic disease and/or prior abdominal surgery.

3.4.4.7 Stomal stenosis can occur in patients with a stricturing Crohn's phenotype and this should be considered when planning reconstruction. Parastomal pyoderma gangrenosum can occur in patients with more aggressive Crohn's disease and should also be considered when planning reconstruction.

3.4.4.8 The risk of post-operative fistula formation is modified by ensuring the reconstruction has not used any active diseased segments. The risk may be slightly higher in those with a penetrative disease phenotype, but this is mitigated by ensuring reconstruction is performed when the disease is in remission.

3.4.4.9 The risk of anastomotic complications is less severe if a disease-free segment has been harvested and the patient is not on concomitant steroid treatment. The presence of renal failure or liver derangement can increase the risk of anastomotic breakdown and therefore requires specialist input and optimisation pre-operatively. This risk is considerably higher in patients requiring dialysis.

*It is important to note that both renal impairment (usually defined as a GFR <30mL/min/1.73m<sup>2</sup>) and hepatic dysfunction are relative contraindications to performing urinary tract reconstruction using bowel [14].*

3.4.4.10 Abdominal wall hernias are more common in patients with a history of prolonged steroid use and those deconditioned pre-operatively. Hence, effort must be made to discontinue steroids and improve muscle mass pre-operatively through early involvement of physiotherapists.

### 3.4.5 Post-operative follow-up and management in Crohn's disease

3.4.5.1 Patients with Crohn's disease are often hypercoagulable. Although there is limited evidence in the literature, we recommend that all patients undergoing major pelvic surgery should be given extended pharmacological thromboprophylaxis (e.g. low molecular weight heparin for 28 days post-operatively), provided there are no contraindications.

*Due to limited evidence, the working group recommends venous thromboembolism prophylaxis to reflect the practice of pelvic oncological surgery.*

3.4.5.2 Bile salt malabsorption is likely to be encountered following reconstruction using bowel, especially when terminal ileum is harvested, resulting in chronic diarrhoea. Those with significant bowel disturbance after surgery need gastroenterology input, however terminal ileum should be spared in any reconstructive procedure where possible.

*Bile salt diarrhoea becomes increasingly likely for longer extents of terminal ileum harvesting. Fat malabsorption is likely to be encountered additionally when more than 100 cm is harvested.*

3.4.5.3 All patients with diarrhoea following their procedure persisting for more than six weeks should be referred for a gastroenterology review, with a view to commencing therapy.

*This is often treated with bile acid sequestrants (e.g. cholestyramine), but is best managed by the gastroenterologists.*

3.4.5.4 There is an increased risk of chronic diarrhoea if large lengths of bowel are harvested and/or the ileocaecal valve is resected.

3.4.5.5 Vitamin B12 deficiency is common following terminal ileum resection. B12 should be monitored with annual blood tests and replaced as necessary. Follow-up should be lifelong, as it can take several years for this to manifest.

*Management needs to recognise the importance of early identification of vitamin deficiency to prevent serious complications, notably anaemia or neurological problems, and should be undertaken in accordance with applicable guidance, e.g. [15]. For those with no neurological involvement, 1mg intramuscular hydroxycobalamin is required three times a week for two weeks. This is usually continued every two to three months for life, but specialist haematology input should be sought [15]. If neurological involvement is evident, urgent specialist advice from a haematologist is needed.*

3.4.5.6 Folate should be monitored and replaced as necessary in those who have had more extensive small bowel resection.

*Management needs to recognise the importance of identifying vitamin deficiency to prevent serious complications, notably pancytopenia and megaloblastic anaemia in severe folate deficiency. Treatment should be undertaken in accordance with applicable guidance, e.g. [15]. Patients should be prescribed 5mg oral folic acid once daily and will often require this lifelong. Dietary advice can also be given and a specialist haematology opinion should be sought [15].*

3.4.5.7 Patients who have undergone multiple previous resections for Crohn's disease are at higher risk of electrolyte disturbance and should be counselled and monitored appropriately. This risk is even higher in patients that already have an ileostomy, due to the possibility of a concurrent high stoma output.

3.4.5.8 A mild, subclinical hyperchloraemic metabolic acidosis is encountered in almost all patients undergoing urinary diversion using bowel segments. Monitoring of bicarbonate and chloride is recommended when there are concerns about clinical metabolic acidosis (e.g. those with resorptive bone disease).

3.4.5.9 Although small intestinal bacterial overgrowth (SIBO) is common in patients with Crohn's disease undergoing bowel surgery (especially following ileo-caecal valve resection), there is limited evidence to support routine antibiotic administration. This is because there is a high likelihood of persistent or recurrent bacterial overgrowth and a single course of antibiotics is unlikely to offer a definitive treatment. If the patient reports a change in bowel function (including abdominal distension, diarrhoea, steatorrhoea or weight loss), a referral to gastroenterology or an IBD specialist is recommended for appropriate assessment and treatment.

*Hydrogen and methane breath tests are often used as non-invasive tests to help diagnose SIBO. However, there is a risk of false positive breath tests in this context, resulting in incorrect diagnosis of bacterial overgrowth and subsequent risk of antibiotic resistance if repeated antibiotics are used.*

3.4.5.10 Although there is an increased risk of colorectal adenocarcinoma with Crohn's disease, especially in those with colonic involvement, robust evidence is lacking to support mandatory surveillance. We therefore recommend following local unit surveillance policies pertaining to method of urinary reconstruction, pending further research. Nonetheless, all patients must be counselled about the importance of seeking urgent medical advice if they were to develop any red flag symptoms.

*There is no clear consensus on the frequency and duration of surveillance following urinary tract reconstruction with bowel but it is recommended, due*

to the small risk of developing adenocarcinoma. Common surveillance protocols involve lifelong annual cystoscopic surveillance of the reconstructed bladder after 10 years due to the small risk of adenocarcinoma [15].

All patients with Crohn's disease should undergo specialist investigation to determine the extent of their disease. This would also provide the opportunity to exclude any overt malignancy prior to reconstruction.

**3.4.5.11 If the segment of bowel used for reconstruction becomes diseased at a later stage, an urgent specialist gastroenterology/colorectal and urological assessment is required.**

#### 4. Discussion

The use of bowel for urinary tract reconstruction in IBD patients is a rare occurrence and there is a clear paucity of literature reporting outcomes. Indeed, it is a challenging area to study with prospective trials. Consequently, the majority of evidence is reliant on retrospective data and expert opinion. This limits the ability to develop evidence-based recommendations. The current consensus report, developed using rigorous qualitative methodology, provides a framework for clinicians potentially considering urinary tract reconstruction in this cohort. It is applicable to open surgery and, in appropriate cases and with sufficient experience, may also be appropriate for minimally invasive approaches (laparoscopic and robot-assisted laparoscopic surgery).

This consensus statement focuses on urinary tract reconstruction in patients with non-malignant urinary tract disease. Many such patients also have neurological disease, which potentially can affect gut function [16]; in these patients the multifactorial nature of gut dysfunction should also be considered when evaluating the potential implications of IBD.

The consensus opinion indicates that urinary tract reconstruction using bowel segments is feasible in carefully selected and optimised patients with IBD lacking alternative management options. Within IBD, UC is a relatively low risk disease for surgical procedures, although still greater than the risk of a patient without any co-morbidities. Crohn's is a higher risk condition, in which there is a considerably increased risk of morbidity. The potential risks of this type of surgery must be properly discussed with patients considering reconstructive urological procedures.

Patients must be discussed with a team of healthcare professionals with appropriate multidisciplinary skills. Specialist assessment of the IBD disease state (active vs quiescent) is needed, as it is crucial for establishing suitability of bowel use, and consensus on which bowel segment to use and the safe permissible length. Patients should be maximally optimised pre-operatively. In certain cases, input from a colorectal surgeon with IBD experience may be required intra-operatively, and input from an IBD specialist may also be required post-operatively if the patient has any unexplained gastrointestinal symptoms such as persistent diarrhoea. In order to optimise post-operative recovery, ERAS protocols are recommended for most patients, including avoidance of pre-operative fasting, avoiding bowel preparation products, and early removal of nasogastric tubes. However, this is not always suitable for all patients and care should be tailored accordingly.

The long-term effects of using bowel for urinary tract reconstruction in this cohort is not known, both in terms of efficacy of the reconstruction and subsequent gastrointestinal function. In addition, there is a risk of skip lesions developing in the bowel used for reconstruction, generally in Crohn's cases. The management and complications of this type of IBD activity is not yet established. Patients should therefore be carefully counselled about the uncertainties of long-term outcomes, and should undergo regular and thorough follow-up with both IBD and urological teams.

In conclusion, bowel use for urinary tract reconstruction in patients with IBD is feasible, provided the potential implications for serious adverse events are considered carefully. It should be carried out in specialist centres with access to expert multidisciplinary professionals in both urological reconstruction and IBD surgery. Outcomes should be carefully monitored and published to confirm the safety and efficacy of this procedure in the IBD cohort, including full description of the IBD status.

Autoimmune diseases  
Peripheral neuropathy

### ABSTRACT

The management of patients with neurogenic lower urinary tract dysfunction has been well-described, however this is most frequently discussed for common conditions such as spinal cord injury or multiple sclerosis. Our objective was to review uncommon neurologic disorders and summarize both the underlying disease process, and the relevant disease-specific research on the impact of the neurologic condition on the lower urinary tract. Among the degenerative and traumatic brain disorders, we have included frontotemporal dementia, amyotrophic lateral sclerosis, Huntington's Disease, progressive supranuclear palsy, corticobasal degeneration, multiple system atrophy, and traumatic brain injury. Among the autoimmune disorders, we reviewed transverse myelitis, neuromyelitis optica spectrum disorders, Myelin oligodendrocyte glycoprotein antibody-associated disease, glial fibrillary acidic protein astrocytopathy, and meningitis-retention syndrome (a form of aseptic meningitis that presents with urinary retention). Hereditary spastic paraplegia, VACTERL association, and several peripheral neuropathies (Guillain Barre syndrome, chronic inflammatory demyelinating polyneuropathy, autoimmune autonomic gangliopathy, Wolfram syndrome spectrum disorder (a progressive peripheral neuropathy disorder with early onset diabetes, optic atrophy and megacystis in the early stage), Charcot Marie Tooth disease, and amyloid neuropathy are included. Practice points specific to the disorders are included where appropriate.

### 1. Introduction

The extensive regulation of the lower urinary tract (LUT) at all levels of the neuraxis [1,2] makes neurological disease a substantial part of functional urology practice. The large number of neurological diseases with potential urological impact may appear daunting, but an understanding of fundamental LUT regulation provides general themes

which facilitate anticipation of potential relevant effects of most conditions [3]. When starting to consider how neurological disease might affect the LUT, the basic functions include:

1. Motor; nerves make muscles contract
2. Sensory; nerves carry information that underpins reflexes in the spine and brainstem (subconscious) and the perception of sensations (which is a higher order function)

3. Reflex; Specific processes coordinated by particular nerve groups and connections
4. Higher order; Cerebral functions that ensure LUT regulation is suitable for daily life, for example social appropriateness and planning ahead

Structurally, the nerve cell bodies are grouped in centers (sometimes called nuclei) while their processes extend in the white matter or peripheral nerves. Some key structures for the LUT are:

#### 1. Motor

- (a) The parasympathetic nucleus, which controls the detrusor muscle, is located in the intermediolateral horn of the spinal cord gray matter.
- (b) Onuf's nucleus in the anterior horn of the sacral spinal cord. Damage here leads to sphincter weakness, hence stress urinary incontinence and fecal incontinence.
- (c) The sympathetic nucleus in the intermediolateral horn of the thoracolumbar spinal cord. Damage here affects blood pressure regulation. In men, it impairs bladder neck control, so the bladder neck is seen to be open during the filling phase in videourodynamics.

#### 2. Sensory

- (a) The bladder has proprioceptive nerves responsible for the ordinary filling sensations which travel via the pelvic and hypogastric nerves to the sacral cord and then through the dorsal columns of the spinal cord. This overlaps with the nerves that provide rectal and lower body sensation.
- (b) The bladder also has noxious/pain sensory nerve fibers in the pelvic and hypogastric nerves which are triggered by stimuli such as overdistension or inflammation. These go to the thoracolumbar part of the spinal cord.
- (c) The sensory nerves of the urethra travel via the pudendal nerve, delivering information important for voiding [4], and generating the sensation of urine flow.
- (d) Sensory signals relay at the periaqueductal gray (PAG), which is a key midbrain center vital in numerous sensory and reflex functions, including determining what sensory information progresses to become a consciously perceived sensation.

3. For reflexes affecting the LUT, by far the most important location is the pontine micturition center (PMC) in the brainstem. It functions to keep the spinal nuclei of the lower spinal cord in the appropriate configuration for LUT functions. By default, the LUT is held in storage mode by the PMC, with the detrusor nucleus actively inhibited and Onuf's nucleus activated to keep the sphincter contracted.
4. Higher order functions are complex and not easily mapped onto specific parts of the brain [5]. Functions such as conscious perception of sensation, planning and social appropriateness are underpinned by multiple cerebral centers and their interconnections. However, a clear importance can be ascribed to the prefrontal cortex (PFC), which has a strong input to the brainstem and regulates whether the PMC can transition from storage mode to voiding.

A sound knowledge of the above basics enables anticipation of the likely LUT consequences for most neurological conditions, including unfamiliar ones. It is important to remember that neurologic dysfunction can also impact sexual and bowel function. Damage to either the cell body or its process leads to loss of function, so a lesion can affect functions of the centers located there, but also fibers transiting through that area. Hence the location and severity of the neurological lesion determines how badly the function is affected:

1. For motor nerves, partial lesions cause weakness, while complete lesions cause paralysis. For the detrusor, partial or complete intermediolateral horn lesions may manifest as underactivity or an acontractile bladder, respectively. People with a partial or complete Onuf's nucleus lesion could develop stress incontinence or continuous leakage, respectively. Since there is an Onuf's nucleus and an intermediolateral horn on each side of the spinal cord, a unilateral lesion causes partial loss of function.
2. For sensory nerves, there can be partial or complete loss of sensation, since there is a lack of information reaching the PAG. This can lead to acontractility, since reflexes require sensory input. Partial loss of sensory information can lead to a post-void residual (PVR) emerging, since the reduced information wrongly suggests complete emptying has been achieved. Because of the different routes taken in the periphery by different sensory nerves there can be partial preservation of LUT sensory reporting. For example, it is fairly common for people with loss of the normal filling sensations to experience the noxious feelings of bladder overdistension, since the hypogastric nerves conveying the latter enter the spinal cord at a higher level, potentially above a lesion affecting the other bladder nerves.
3. Damage to the brainstem or midbrain (PMC and PAG) is not commonly seen, due to their roles in vital functions such as breathing. However, these centers may be impaired in early stages of some conditions, like multiple system atrophy, or rarely with infarction or hemorrhage. Much more likely is impairment of the tracts related to these structures, which can occur at a spinal level. The result is likely to include detrusor overactivity (since storage function includes active inhibition of the detrusor nucleus), and may also include detrusor sphincter dyssynergia (DSD), difficult initiating a micturition reflex or detrusor underactivity.
4. The higher order functions are at risk in diseases of the cerebral cortex. Detrusor overactivity is common, again due to the importance of detrusor inhibition in the default storage mode. Less well recognized are aspects such as urinary retention (if impaired function of the frontal lobe prevents the signal permitting the PMC to switch to voiding mode). Alternatively voiding dysregulation, detrusor underactivity, involuntary voiding [6] or enuresis can occur, if cortical impairment affects its role in ensuring situational appropriateness of behavior.

If the physician understands the likely distribution of neurologic deficit the potential consequences can be derived for the LUT. The physician should be aware of potential simultaneous urologic or gynecologic conditions that may affect voiding (and not assume that the neurologic disease is the only potential etiology), the impact of pharmacologic interventions associated with these neurologic conditions, and the patients functional and cognitive status. Clinical acumen is then needed to match the effects to the symptoms the patient is describing. For complete lesions, this is usually fairly clear-cut. However, for partial lesions and progressive diseases, careful attention is needed to establish the current situation, with a view to deciding on therapy and follow up (surveillance) requirements. This understanding must be combined with a careful history and physical exam [7], and in most cases urodynamic studies. A careful assessment of sacral sensation (dull touch (which travels via the posterior column) and sharp touch/pain (which travel via the spinothalamic tract)), sacral reflexes and anal tone is important, and very relevant when assessing for a potentially undiagnosed neurologic disease [8]. The objective of this report is to summarize selected uncommon neurological diseases (listed in Tables 1–4) and review the available literature relevant to the associated LUT dysfunction. For some diseases, important practice points are highlighted in Table 5. Diseases and conditions were nominated by the International Continence Society neuro-urology promotion committee members, and then categorized into groups. For our first report,

**Table 1**  
Characteristics of selected degenerative and traumatic disorders of the brain.

Disease/Disorder	Estimated Frequency in the population	Usual Onset	Progressive?	Average lifespan of patient	Gene (if known)	Neurological site of lesion (if known)
<i>Frontotemporal dementia (FTD)</i>	10%–20% of dementia cases	40–65 years of age	Yes	6–8 years	20%–50% of cases are familial. Mutations in hexanucleotide expansion repeats in the open reading frame of chromosome 9 (C9ORF72), MAPT (microtubule-associated protein tau) or (granulin) GRN are found in 60% of these cases	Brain
<i>Amyotrophic Lateral Sclerosis (ALS)</i>	3–6/100,000	Very rare before 35, more common onset after 45 with maximum prevalence between 55–70 years.	Yes	2.5 years without treatment. Multidisciplinary specialized care may reduce the risk of death by 45% at 5 years.	90% sporadic, 5%–10% familial. Of the known genes, mutations in SOD1 (encodes for copper/zinc ion-binding superoxide dismutase), TARDBP (also known as TDP-43; encodes for TAR DNA binding protein), FUS (encodes fusion in sarcoma), ANG (encodes angiogenin, ribonuclease, RNase A family, 5), and OPTN (encodes optineurin) cause a typical clinical phenotype.	Upper (in the brainstem and the spinal cord) and lower motor neuron involvement
<i>Huntington's disease (HD)</i>	0.4–7.3/100,000	Childhood to middle adulthood age (average onset age: 40 years)	Yes	Survival from onset to death averages 17–20 years (later onset is associated with slower progression)	HD gene located on chromosome 4p16.32. The genetic alteration which causes the disease is associated with the number of repetitions of three nucleic acids (C, A, and G) in the coding region of the first exon of the HD gene	Suprapontine and pontine lesions — basal ganglia pathology
<i>Progressive supranuclear palsy (PSP)</i>	6–10/100,000	60–70 years	Yes	6–7 years	Heredity (MAPT gene) is extremely uncommon	Basal ganglia including pallidum, cerebellum, midbrain tegmentum
<i>Corticobasal degeneration (CBD)</i>	<5/100,000	50–70 years	Yes	7–8 years	Heredity (MAPT gene) is extremely uncommon	Cerebral cortex with laterality in addition to pathology of PSP
<i>Multiple system atrophy (MSA)</i>	0.6–3.3/100,000	40–60 years	Yes	7–10 years	Rarely hereditary.	basal ganglia, cerebellum, brainstem, spinal cord (intermediolateral nuclei, Onuf's nucleus)
<i>Traumatic Brain Injury (TBI)</i>	Mean 258/100,000 per year	Children: 0–4 years, Adolescents 15–19 years, Older Adults >75 years	Possibly. Neurodegenerative processes may occur post injury	Average life expectancy reduced by 9 years	NA	Brain

we selected degenerative brain disorders, autoimmune disease of the brain and spinal cord, and peripheral neuropathies as the focus. Each topic was researched by a committee member using medical database searches of key words related to that disease and lower urinary tract dysfunction, with no date limits.

## 2. Degenerative and traumatic disorders of the brain

### 2.1. Frontotemporal dementia (FTD)

Dementia is an overarching term that includes memory loss/dis-orientation, problems with communication, reasoning, and mood

**Table 2**  
Characteristics of selected autoimmune and inflammatory disorders of the central nervous system.

Disease/Disorder	Estimated Frequency in the population	Usual Onset	Progressive?	Average lifespan of patient	Gene (if known)	Neurological site of lesion (if known)
<i>Transverse myelitis (TM) in general</i>	1–4/100,000	Adolescents, 30–39year	No	Normal	NA	Spinal cord
<i>Neuromyelitis optica spectrum disorder (NMOSD) with transverse myelitis</i>	1–10/100,000 (greater frequency in individuals of Asian and African descent; Female:male ratio is 9:1)	Adulthood	Yes	May be shortened based on neurological disabilities	Genetic role not clear	Spinal cord and optic nerve
<i>Myelin oligodendrocyte glycoprotein antibody disease (MOGAD) +/- transverse myelitis</i>	1.6–3.4/100,000	Childhood to early adulthood	Usually not	Normal for most patients; varies with neurological disabilities	Genetic role not clear	Acute disseminated encephalomyelitis, spinal cord and/or optic nerve
<i>Glial fibrillary acidic protein (GFAP) astrocytopathy</i>	0.6/100,000	Adulthood	Usually not	Normal for most patients; varies with neurological disabilities	Genetic role not clear	Cerebrum, meninges, spinal cord and optic nerve
<i>Meningitis-retention syndrome</i>	Unknown	Any age	No	Normal	Genetic role not clear	Presumably meninge and spinal cord

**Table 3**  
Characteristics of selected spinal cord disorders.

Disease/Disorder	Estimated Frequency in the population	Usual Onset	Progressive?	Average lifespan of patient	Gene (if known)	Neurological site of lesion (if known)
<i>Hereditary Spastic Paraplegia (HSP)</i>	2–5/100,000	Childhood to early adulthood	Yes	Normal for most patients	SPAST(formerly SPG4), most common gene, found in up to 25%–50%	Spinal cord
<i>VATER Syndrome/VACTERL association</i>	2–10/100,000	Congenital	No	Reduced lifespan due to complications of the disease	TRAP1 has been identified as the first autosomal-recessive disease-causing gene for the full clinical picture of the VATER/VACTERL association.	Cauda equina/sacral/peripheral lesion

changes. FTD is one of the less common forms of dementia. It can affect the frontal or the temporal lobes. Damage to these areas can lead to one of three distinct forms: primary progressive aphasia, behavioral variant and movement disorder predominant.

It is estimated that 1.3% of the population can be affected with dementia in general, and the prevalence is set to rise with advancing age with 7.1% above 65 years [24]. It is estimated that between 53 and 90% of people with any type of dementia can be affected with urinary symptoms [25]. The main predictors of incontinence in dementia are degree of immobility and severity of cognitive impairment. A combination of declining cognitive function, polypharmacy, reduced mobility and decreased bladder capacity contribute to urinary incontinence [26]. It has been suggested that impaired mobility has a stronger correlation with incontinence than cognitive decline in patients with dementia.

Among people with FTD, neurogenic lower urinary tract dysfunction (NLUTD) can be both psychogenic and neurogenic (due to neurogenic detrusor overactivity from a lack of inhibition of the spinobulbospinal micturition reflex) [27]. The proportion of FTD patients with incontinence is between 19%–26% in two case series [28,29]. A small case series of five patients found that neurogenic detrusor overactivity was the most common finding (4/5 patients), and two patients had evidence of NLUTD (one with a large PVR, and one with detrusor overactivity) [27]. FTD and Alzheimer's disease have lower rates of

incontinence (25%–40%) compared to Lewy body and vascular dementia (80%–90%) [27]. The treatment of dementia often involves cholinesterase inhibitors, which increase acetylcholine levels. This may result in new urinary incontinence [30]. A systematic review on the use of cholinesterase inhibitors and OAB anticholinergic medications identified four studies (with limited methodological quality), and none demonstrated that this combination resulted in significantly worsened cognitive function [11,12].

## 2.2. Amyotrophic lateral sclerosis (ALS, also known as Motor neuron disease)

ALS is an idiopathic, progressive neurodegenerative disease of the motor neuron system that leads to death. ALS can be familial, with a Mendelian pattern of inheritance disease in 5%–10%, however the majority (90% of the cases) are sporadic. ALS usually appears with a focal clinical onset in a muscle group. During the disease progression, signs and symptoms of involvement of both upper (UMN) and lower motor neuron (LMN) in the brainstem and spinal cord develop. The entire clinical and neuropathological spectrum of ALS includes progressive muscular atrophy, primary lateral sclerosis, progressive bulbar palsy and pseudobulbar palsy [31,32]. In most cases, there is a relative sparing of neurons innervating the extraocular muscles and

**Table 4**  
Characteristics of selected peripheral neuropathies.

Disease/Disorder	Estimated Frequency in the population	Usual Onset	Progressive?	Average lifespan of patient	Gene (if known)	Neurological site of lesion (if known)
<i>Guillain Barre Syndrome (GBS)</i>	1.2-2.3/100,000	All ages	No	Normal for most patients	NA	Peripheral neuropathy
<i>Chronic inflammatory demyelinating polyneuropathy (CIPD)</i>	1-9/100,000	All ages	Yes	Normal for most patients	NA	Peripheral neuropathy
<i>Autoimmune autonomic ganglionopathy (AAG)</i>	Unknown	Adulthood	Unknown	Unknown	Unknown	Autonomic ganglion
<i>Wolfram Syndrome</i>	0.18/100,000	Childhood	Yes	Reduced - 65% mortality by age 35 years	Recessive autosomal disorder caused by mutations in the Wolfram1 (WFS1) gene; a less common variant (WFS2) is caused by mutation in the CISD2 gene which encodes protein ERIS (endoplasmic reticulum intermembrane small protein)	Limited data available suggest neurologic findings are progressive and result from general brain atrophy most prominently of the cerebellum, medulla, and pons; optic nerves and the posterior part of hypothalamus
<i>Charcot Marie Tooth disease</i>	40/100,000	First two decades of life	Yes	Normal for most patients	Hereditary with >1000 genetic mutations in 80 genes implicated	Motor and Sensory Neuropathy
<i>Amyloid neuropathy</i>	1/100,000	Adulthood	Yes	Normal for most patients; severely reduced if cardiac involvement	Heterogeneous group of acquired and inherited disorders. TTR gene (autosomal dominant, variable penetration) in hereditary cases	Peripheral and autonomic neuropathy, myopathy

sphincters [33]. Direct involvement of the autonomic system does not occur. Mobility (inability to visit the toilet) and life expectancy (usually short after diagnosis) play an important role in management decisions.

In a cohort study of 43 ALS patients, there was an increased prevalence of urgency incontinence and a high burden of LUTS, especially in patients aged more than 60 years [34]. In another similar cross-sectional study with 54 ALS patients, 41% of them reported LUTS and 35% had a PVR > 50 ml. Storage LUTS were reported in 27% of patients; voiding and post micturition LUTS were reported in 59% [35]. In a recent cohort study with 30 patients, LUTS increased from 24% before to 76% after the ALS diagnosis and the prevalence of storage symptoms increased from 3% before, to 25% after the diagnosis of ALS [36]. The clinical profile of the disease does not seem to impact the development of LUTS, as there was no difference in patients with classical ALS compared to progressive muscular atrophy or primary lateral sclerosis [37].

There are little urodynamic data available, however a study of 55 ALS patients found that 24 of them experienced significant LUTS, and of the 10 that underwent UDS the most frequent finding was detrusor overactivity with obstruction due to detrusor sphincter dyssynergia [38].

### 2.3. Huntington's Disease (HD)

HD is a degenerative disease with autosomal dominant inheritance that often presents in middle adulthood. The pathophysiology of the disease consists of a progressive neuronal loss in the basal ganglia, especially in the caudate nucleus and cerebral cortex [39,40]. Clinically, HD is characterized by progressive motor, cognitive, and emotional symptoms. Later onset of the disease is usually associated with slower progression.

The literature regarding the NLUTD in patients with HD is extremely limited. In a case series study of 6 subjects, there were 4 patients

with detrusor overactivity and normal sphincter function [41]. Their symptoms (urinary frequency, urgency, nocturia, and incontinence), appeared 6 years after the onset of HD [41]. A survey of 1283 symptomatic HD patients found that LUTS usually arise in the late stage of the disease, typically more than 10 years after onset [42]. In a cohort study of 54 HD patients and 10 asymptomatic HD gene carriers [43], the authors reported OAB (women/men: 40%/54%), urgency urinary incontinence (women/men: 43%/29%), and voiding symptoms (women/men: 40%/25%). In another study with 63 HD pts and 21 pre-manifest mutation carriers, autonomic dysfunction including urinary symptoms, and erectile and ejaculatory dysfunction in men, were significantly more prevalent in HD pts compared to the control group [44].

Urodynamics were performed on 12 patients with HD and revealed detrusor overactivity in 2 pts (17%), DSD in 5 pts (42%), and detrusor underactivity in 2 pts (17%) [43].

### 2.4. Progressive supranuclear palsy (PSP)

PSP primarily affects the brain, particularly the substantia nigra, globus pallidus subthalamic nucleus (basal ganglia, gait pathway), dorsal midbrain (eye movement pathway), dentate nucleus, cerebellum, frontal lobe, limbic system (cognitive pathway), and to a much lesser extent, the spinal cord. In these areas, affected neurons show neurofibrillary tangles that are 4-repeat tau positive. Tau imaging helps to diagnose PSP. Clinically PSP shows several subtypes: PSP-Richardson syndrome (common, supranuclear gaze palsy, parkinsonism, dementia; MRI shows midbrain atrophy called 'hummingbird' or 'emperor penguin' sign), PSP-parkinsonism (parkinsonism without tremor/laterality with axial [neck, trunk] rigidity; and parkinsonism presenting pure akinesia), PSP-cortical (overlap symptoms with frontotemporal lobar degeneration) and PSP-cerebellar.

**Table 5**  
Relevant neuro-urological practice points for selected uncommon neurological diseases.

Disease	Practice points
Frontotemporal dementia	<ol style="list-style-type: none"> <li>1. It is important to consider mobility, dexterity, the level of care assistance, and disease progression/life expectancy. In many cases, diapers, condom (external) catheters or indwelling suprapubic catheters may be appropriate management options.</li> <li>2. The reversible causes of LUT dysfunction should be explored and treated where possible. [9] The treatment is generally conservative with emphasis on understanding the cognitive and functional aspects.</li> <li>3. Bladder retraining and pelvic floor exercises may have a role in the setting of cognitive impairment or behavioral disturbances and dementia. [10] They may be most appropriate in patients with the ability to learn. Timed voiding or alarm devices might be helpful if caregivers are able to provide consistent support.</li> <li>4. If necessary, the use of both a cholinesterase inhibitor and OAB anticholinergic medication may be appropriate with careful observation; the level of evidence on this topic is limited by methodological flaws, and studies have reported mixed results [11,12]</li> </ol>
Progressive supranuclear palsy	<ol style="list-style-type: none"> <li>1. Although a treatment strategy that is specific for PSP is not available, patient's older age and susceptibility to cognitive decline should be considered when selected medical treatment for OAB symptoms. [13,14]</li> <li>2. Patients may have autonomic instability, and therefore alpha-blockers should be used with caution. Patients may be on midodrine (an alpha agonist) for hypotension and in this case use of an alpha blocker may not be appropriate. [15]</li> </ol>
Corticobasal degeneration	<ol style="list-style-type: none"> <li>1. Like PSP, it may be preferable to start with a beta3 adrenergic agonists or antimuscarinics that do not easily penetrate the blood-brain barrier. [14,16]</li> </ol>
Multiple system atrophy	<ol style="list-style-type: none"> <li>1. Patients may visit a urologist before the correct diagnosis is made; therefore, collaboration of neurologists and urologists is highly recommended. Video-urodynamics, sphincter EMG and neuroimaging will help with making the diagnosis.</li> <li>2. NLUTD might change from OAB to urinary retention during the course of MSA; therefore, for those with initial urgency incontinence, beta3 antagonists or antimuscarinics can be used but the patient's PVR should be monitored for changes over time.</li> <li>3. Elevated PVRs (&gt;100 mL) can start in the second year of MSA [17]; therefore, the specialist continence nurse has an important role to teach intermittent self-catheterization (ISC) in this group of patients with symptomatic PVRs.</li> <li>4. Transurethral resection of the prostate should be avoided because the retention is mostly caused by detrusor underactivity, and there is an increased risk of urinary incontinence due to impaired external urethral sphincter function [18–20].</li> <li>5. Patients may have autonomic instability and hypotension, and therefore alpha-blockers should be used with caution. Patients may be on midodrine (an alpha agonist) and in this case use of an alpha blocker may not be appropriate [15].</li> </ol>
Hereditary Spastic Paraplegia	<ol style="list-style-type: none"> <li>1. Given the potential for renal deterioration, patients should have neuro-urological monitoring if there are significant risk factors at presentation.</li> <li>2. If patients are using botulinum toxin for leg spasticity, any intravesical doses should be administered a few weeks apart from the skeletal muscle treatments; total botulinum toxin dose that the patient is receiving should be monitored [21].</li> </ol>
Guillain-Barré syndrome	<ol style="list-style-type: none"> <li>1. Post-void ultrasonography is recommended in patients with a higher Hugh's motor grade, higher age and defecation dysfunction. The management of urinary symptoms is mainly supportive [22].</li> </ol>
Amyloid Neuropathy (AN)	<ol style="list-style-type: none"> <li>1. Alpha blockers must be used with caution since they might trigger or exacerbate postural hypotension that often co-exists with amyloidosis. [23]</li> </ol>

PSP causes significant NLUTD; [45–48] most commonly this includes urinary urgency and frequency that are often more severe compared to Parkinson's disease. This is probably a reflection of PSP's more severe and diffuse brain lesions in areas relevant to micturition control compared to Parkinson's disease. Other autonomic disorders (gastrointestinal dysfunction, orthostatic hypotension, etc., reflecting mostly peripheral lesion) are not as severe in PSP compared to Parkinson's Disease. In a comparison of patients with PSP, MSA and Parkinson's disease, the magnitude of NLUTD of PSP was similar to MSA, and generally more severe than that of Parkinson's disease [46].

Common urodynamic abnormalities in PSP are detrusor overactivity with reduced bladder capacity; and to a lesser extent, PVR and neurogenic sphincter electromyogram presumably reflecting sacral spinal cord lesion in this disease [49,50].

### 2.5. Corticobasal degeneration (CBD)

CBD affects the brain, particularly the cerebral cortex (cognitive and higher function pathway), subcortical white matter, substantia nigra, striatum, globus pallidus (basal ganglia, gait pathway), thalamus, subthalamic nucleus, basal nucleus of Meynert, locus ceruleus and other brainstem nuclei. The areas overlap with PSP, but the distinct feature of CBD is cortical involvement with laterality. The affected areas show ballooned neurons and threads/coiled bodies that are 4-repeat tau positive. Therefore, CBD and PSP are both referred to as 4-repeat tauopathies. Tau imaging also helps diagnosing CBD. Clinically, CBD

patients show cortical signs, such as 'alien limb' syndrome (arms or legs may seem to move independently), apraxia (loss of coordinated movement in one hand), aphasia (loss of other focal cognitive problem); and basal ganglia signs, such as unilateral limb dystonia/rigidity.

NLUTD in CBD is mostly OAB (from urinary urgency and increased voiding frequency, to urgency urinary incontinence), the severity of which is similar to Parkinson's Disease [16]. This is probably a reflection of CBD's cortical and basal ganglia lesions, which are relevant to micturition control. In contrast to multiple system atrophy, PVR and neurogenic sphincter electromyogram is not observed in CBD [16].

### 2.6. Multiple system atrophy (MSA)

MSA is defined as a combination of a) motor (parkinsonian MSA [MSA-P] and/or cerebellar MSA [MSA-C]) and b) autonomic (orthostatic hypotension and/or NLUTD) disorders [51]. Pathologically, MSA affects both the brain (basal ganglia, cerebellum, brainstem pontine nuclei, locus ceruleus, raphe, cardiovascular and respiratory nuclei; on imaging it typically shows as 'hot cross bun' sign) and the spinal cord (intermediolateral nucleus innervating the arteries and the internal sphincter, and sacral Onuf's nucleus innervating the external sphincter). The affected areas show glial cytoplasmic inclusion that are alpha-synuclein positive.

NLUTD occurs in up to 90%–100% of MSA patients, with symptoms or signs such as urinary urgency/frequency, elevated PVR, and urinary

retention [47,52]. Up to 18% of MSA patients may present with NLUTD alone, and urinary retention may be a presenting feature [17].

Urodynamics typically demonstrate detrusor overactivity (during filling), detrusor underactivity (on voiding), or their combination (so called DHIC, detrusor overactivity with impaired contraction), with or without DSD, and neurogenic sphincter electromyography (EMG) is specific for differentially diagnosing MSA from Parkinson's disease [53]. On video-urodynamics, an open bladder neck early in filling with detrusor overactivity is sometimes observed in MSA [47].

### 2.7. Traumatic Brain Injury (TBI)

TBI results principally from vehicular accidents, falls, acts of violence and sports injuries. This mechanical force acting on the brain damages neuron tissue; this may be temporary or may lead to permanent disability. NLUTD following TBI may result from a direct consequence of brain damage, cognitive, language, motor, or coordination deficits. Patients may have associated spinal cord injury, pelvic/bladder injury, or any combination of the above, which makes interpretation of the NLUTD more challenging. Frontotemporal lesions may lead to dysregulation of the learned bladder behaviors, and socially inappropriate voiding. It is important to note that urinary incontinence is a risk factor for falls, and in the elderly these falls could result in a TBI [54].

Although NLUTD is common post TBI, literature on the subject is sparse. Giannantoni et al. reported that 86% of severe TBI patients complained of urinary symptoms, with 61% reporting symptoms of OAB alone, 14% reporting voiding symptoms alone and 25% reporting both OAB and voiding phase symptoms [55]. Symptoms may be influenced by the increased secretion of brain natriuretic peptide and resulting polyuria during the early injury period [56]. The incidence of incontinence correlates with frontal lesions and with TBI severity, with patients having diffuse/bilateral injuries, aphasia, a longer acute length of stay and a poor functional status being more likely to develop urinary incontinence [57,58]. Chua et al. reported urinary incontinence in 62% patients during the early phase, which improved with time, with 18% having persistent urinary incontinence at 6 months [57]. Resolution rates of urinary incontinence appear to be related to TBI severity, and impaired cognition/mobility may contribute to urinary incontinence. Urinary retention is relatively uncommon, being seen in 8% patients during the early phase, with only 2% requiring intermittent catheterization at the time of discharge from rehabilitation [57].

Urodynamic studies have demonstrated detrusor overactivity and impaired bladder contractile function in 49%–66% and 32% of patients, respectively. Right hemisphere injuries have been found to correlate with detrusor overactivity and left hemisphere injuries with impaired bladder contractility. Synergistic urinary sphincters are the norm [55, 58].

## 3. Autoimmune and inflammatory disorders of the central nervous system

### 3.1. Transverse Myelitis (TM)

TM is a clinical syndrome caused by an immune-mediated process disrupting the spinal cord. It is characterized by a varying degree of general weakness to paralysis, sensory alterations, and autonomic dysfunction [59]. Although general weakness might vary between individuals, nearly all patients have NLUTD, which may outlast general motor and sensory deficit and recovery [60]. Symptoms related to NLUTD range from urinary urgency and incontinence to incomplete bladder emptying and urinary retention. Since TM is an immune-mediated process, treatment of the neurological symptoms usually consists of corticoids and or plasma exchange [61]. Only approximately 1/3 patients will have complete resolution of their urinary symptoms

with time (usually among those with mild motor, sensory and LUT symptoms at presentation) [60,62,63].

Symptoms and consequences are similar to patients with traumatic SCI. Video-urodynamic evaluation is warranted, since detrusor overactivity and DSD have often been reported, which can jeopardize the upper urinary tract [60,64]. TM extending over a significant length of the spinal cord is significantly predictive of NDO [65]. Since NLUTD might be the only sequel, long-term and individualized follow up is necessary.

Treatment of NLUTD is based upon the urodynamic results and consists of intermittent self-catheterization and or treatment for detrusor overactivity by means of anticholinergics and intradetrusor onabotulinumtoxinA injections, and beneficial effects of sacral neuromodulation have also been reported [66,67]. Patients should be carefully monitored, as upper tract deterioration can occur, and persistent urodynamic abnormalities despite motor improvement are common [60, 62,63]. Two diseases that include a transverse myelitis component (Neuromyelitis Optica spectrum disorders and Myelin oligodendrocyte glycoprotein antibody-associated disease) are discussed below.

### 3.2. Neuromyelitis Optica spectrum disorders (NMOSD)

NMOSD are inflammatory diseases of the central nervous system that preferentially affect the optic nerves and the spinal cord (causing TM). They frequently follow a relapsing course, with disabling episodes of Optic Neuritis and Longitudinally Extensive Transverse Myelitis (LETM) [68]. A serum reactivity that targets aquaporin-4 (AQP-4), a water channel in the CNS, has been described in patients with NMO and distinguishes NMO from other demyelinating disorders. It is termed AQP-4 immunoglobulin G (AQP4-IgG) and is detectable in 60%–90% of patients with NMO and, with lower frequency, in patients with limited forms such as those with a first episode of LETM [68–70]. NMOSD unifies all clinical variants, and is further stratified by serologic testing (NMOSD with or without AQP4-IgG). The basic characteristics required for patients with NMOSD with AQP4-IgG include clinical syndromes or MRI findings related to optic nerve, spinal cord, brainstem, diencephalic, or cerebral presentations. More stringent clinical criteria are required for diagnosis of NMOSD without AQP4-IgG or when serologic testing is unavailable [68].

The prevalence of NMOSD varies throughout the world, and in most regions, NMOSD is less prevalent than MS [71]. NLUTD is present in 78%–83% of the patients and has a significant negative impact on quality of life [72,73]. A combination of storage and voiding symptoms including urgency, nocturia, frequency, weak urinary stream and incomplete emptying is common. A high prevalence (87%) of bowel dysfunction has also been reported [73]. In one cross-sectional study with 30 patients none had upper urinary tract abnormalities and 7/30 (23%) had bladder wall thickening.

Video-urodynamics show DSD and detrusor overactivity in most patients [72]. These findings are consistent with disease affecting the cervical and/or thoracic spinal cord level, which is present in most patients with NMOSD. The severity of neurological disability seems to be a predictive factor for the occurrence of NLUTD.

### 3.3. Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD)

MOGAD is a recently described inflammatory disease of the central nervous system driven by antibodies that target myelin oligodendrocyte glycoprotein on myelin sheaths, causing oligodendrocyte damage and primary demyelination [74]. Clinical manifestations include acute disseminated encephalomyelitis (ADEM), mostly in young children, and an opticospinal presentation in adults (including TM). Although MOGAD has clinical and radiological similarities with NMOSD and MS, these conditions have distinct demographics and are immunologically and pathologically different [69,70]. Studies indicate that 40% of NMOSD

AQP4-IgG negative patients are MOG antibody positive. In addition, MOG antibodies can be present in 10%–20% of idiopathic atypical demyelinating diseases not meeting NMOSD criteria. MOGAD has distinct clinical and radiological characteristics compared to NMOSD and MS, and a recent study showed that a combination of MRI and clinical measures could achieve an accuracy of 85% and 93% for the classification of MOGAD versus AQP4+ NMOSD and MOGAD versus MS, respectively [70]. MOGAD is considered milder and less relapsing than NMOSD, but clinical outcomes and predictors of relapses remain unknown [69,70,75,76]. MOGAD can present at any age, with a slight female preponderance and no apparent ethnic bias [75]. It typically has a favorable outcome and early diagnosis is important since prompt immunotherapy improves the prognosis.

In a study with 75 patients, permanent LUTD affected 21 (28%) patients and was more common than motor disability (7%) [75]. All patients with NLUTD had TM affecting the thoracic cord or conus and 13/21 (62%) required long-term catheterization. Overall bladder outcome was not affected by age of onset, disease duration or gender. In other studies, the prevalence of long-term LUTD was 55%–59%, and up to 20% required long-term catheterization. The presence of a conus lesion is a risk factor for the need of long-term catheterization [76,77].

Urodynamic findings in patients with a history of TM predominantly showed detrusor overactivity and/or DSD, consistent with a supraconal lesion [77].

### 3.4. Glial fibrillary acidic protein (GFAP) astrocytopathy

GFAP (an intracellular astrocytic intermediate filament) astrocytopathy is an autoimmune inflammatory CNS disease first defined in 2016 [78]. Most patients have a meningoencephalomyelitis and can rarely manifest with isolated myelitis. Preceding flu-like symptoms are present in 40%–66% [79]. The disorder is confirmed by detection of IgG reactive with GFAP in the cerebrospinal fluid (CSF). Some patients may also have GFAP-IgG detected in serum [80]. Coexisting autoimmune diseases such as diabetes mellitus, autoimmune thyroid disease and rheumatoid arthritis are present in approximately 20% of the patients [81]. A characteristic MRI hallmark has recently been described, consisting of a linear perivascular enhancement radially oriented around the ventricles (radial enhancement), while the myelitis component is generally associated with a longitudinally extensive T2 lesion on spinal cord MRI, similar to that typically encountered in aquaporin-4-IgG (AQP4-IgG) related myelitis. Most patients with GFAP have a monophasic course, but about 20% may have a relapsing course. Approximately one in four patients have a coexisting neoplasm, most commonly ovarian teratoma. Occasional patients may have coexisting AQP4-IgG or MOG-IgG and their neurological phenotypes are indistinguishable from those positive for GFAP-IgG alone [80].

Lower urinary tract symptoms have not been characterized in patients with GFAP but studies mention a rate of 21%–28% of autonomic dysfunction (most commonly unspecified “urinary dysfunction”), which can persist after disease remission [82].

### 3.5. Meningitis-retention syndrome (MRS)

MRS is an inflammatory neurological condition [83–86]. Clinically MRS is defined as a combination of a) aseptic meningitis (increased reflexes without leg weakness might be seen; abnormal cerebrospinal fluid (CSF) alone may also be found [87]) and b) acute urinary retention. Aseptic meningitis is a common condition, which is caused by many viruses but may also be from autoimmune etiologies. MRS occurs in 8% of aseptic meningitis cases. Average latencies from the onset of meningeal irritation to urinary symptoms is 0–8 days. However, in some cases, urinary retention precedes fever and headache, and in such cases patients with MRS may be seen by urologists first before the correct diagnosis is made. The duration of urinary retention in MRS is mostly 7–14 days, but can last up to 10 weeks. Mild ADEM

is considered an underlying mechanism of MRS, because some patients show elevated myelin basic protein in the CSF and a reversible splenial lesion on brain MRI. As it is observed in ADEM, antecedent/comorbid infections or conditions with MRS include Epstein - Barr virus, herpes simplex virus, varicella-zoster virus, West Nile virus, listeria, etc. In addition to these, elevated CSF adenosine deaminase levels or decreased cerebrospinal fluid/serum glucose ratio may be predictive factors for MRS development [85]. It is not known whether steroid pulse therapy can shorten the period of urinary retention.

Urodynamics show that all patients had detrusor underactivity during their period of urinary retention. Repeated urodynamics showed that the underactive detrusor changed to an overactive detrusor after a 4-month period. While urinary retention in MRS resolves in most cases, care must be taken to prevent bladder injury from chronic overdistension by performing intermittent catheterization.

The term “Elsberg syndrome” is occasionally assigned to urinary retention of diverse etiologies. Kennedy, Elsberg, and Lambert (1913) reported five cases of pathology-demonstrated cauda equina radiculitis [88]. Their clinical/pathological features were: rare CSF abnormalities; no clinical meningitis; a subacute/chronic course; presentation with typical cauda equina motor-sensory-autonomic syndrome; Wallerian degeneration of the spinal afferent tracts; and mild upper motor neuron signs. All these are different from those of MRS.

## 4. Spinal cord disorders

### 4.1. Hereditary Spastic Paraplegia (HSP)

HSP is a rare group of genetic disorders that lead to degeneration of the long tracts of the corticospinal tract and dorsal column of the spinal cord; it is most commonly inherited as an autosomal dominant condition, although it can also be autosomal recessive, and up to 40% can be sporadic. Clinically, patients present with gait problems that progress to leg spasticity. A minority of patients present with “complex HSP” which has additional features such as peripheral neuropathy, epilepsy, ataxia, retinopathy, cognitive problems, hearing loss, and impaired speech/swallowing [89]. This is a disease that can present in childhood and throughout adulthood.

Small case series have supported significant urinary symptoms in the majority of patients: urgency/frequency, incontinence, and voiding symptoms such as poor stream and hesitancy [90–93]. In the largest case series (49 patients from Estonia), storage symptoms were most common, incontinence was reported by the majority of patients, and a PVR >100mL was found in only 10% [90]. Other reports have noted a significant PVR in more than 50% of patients [93]. There was a high frequency of coexisting detrusor overactivity with detrusor underactivity [91,92]. Up to 2/3 patients may have DSD [91,93]. Risk of renal deterioration are conflicting. Renal ultrasound assessment of 29 HSP patients (after a mean of 22 years of HSP followup) did not find any significant hydronephrosis or renal atrophy [91]. Conversely, a series of 33 HSP people found that 8% had hydronephrosis, 20% had stone disease, and 17% had chronic renal failure [93]. Some of these differences in urinary disease presentation is likely a result of either case series recruited from neuro-urological practices (with a higher rate of LUTS) as opposed to neurological practices. It is possible that the spinothalamic pathways are partially impacted, or that pelvic floor spasticity results in secondary bladder changes over time.

### 4.2. VATER syndrome/VACTERL association

VATER is an acronym to describe an association of congenital malformation including vertebral abnormalities (V), anal atresia (A), trachea-esophageal fistula (T), esophageal atresia (E), renal dysplasia (R). Because of the occurrence of further non-random abnormalities described in literature, the acronym was extended as VACTERL, to include cardiac and limb malformations. There is no consensus regarding the

criteria for the definitive diagnosis. Some authors proposed that at least three of the above-mentioned features should be present [94]. Vertebral abnormalities are one of the most common defects, occurring in about 65%–95% of patients [95]; this can include missing vertebrae, vertebral malformations (fusions, clefts and hemivertebrae), sacral agenesis, spina bifida and tethered spinal cord. These abnormalities may cause NLUTD mainly secondary to a cauda equina/sacral lesion. A proportion of these patients may have spina bifida occulta, and MRI of the spine is appropriate depending on the initial spinal xrays [96]. The surgical correction of pelvic abnormalities (such as imperforate anus) may lead to peripheral nerve damage.

Symptomatic urinary infections are often an early urologic manifestation, due to the co-existence of hydronephrosis and vesico-ureteral reflux. This is related to congenital abnormalities of the upper urinary tract, although it may also be due to high pressure from reduced bladder compliance [97]. Patients with VATER/VACTERL disease should be always be referred to a neuro-urologist and a nephrologist to evaluate the bladder and kidneys, and to prevent kidney failure and/or further renal deterioration [98].

## 5. Peripheral neuropathies

### 5.1. Guillain-Barré syndrome (GBS)

GBS is a group of acute demyelinating and axonal autoimmune polyneuropathies, triggered by a bacterial or viral infection, and characterized by rapidly evolving limb weakness and loss of tendon reflexes, with or without sensory and autonomic disturbances. Despite available treatment, GBS is associated with significant mortality (3%–10% of patients die), and 20% of patients may have residual permanent severe disability. The form and severity of the disease is possibly determined by the type of preceding infection and patient factors [99].

Among 65 of patients with GBS, 28% had NLUTD. The most prevalent symptom was voiding dysfunction (9% had urinary retention), 8% had urgency symptoms and none of the patients were incontinent [100]. An Australian study reported the prevalence and long-term impact of NLUTD in patients in the chronic phase of GBS. Of the 66 patients, with a mean of 6 years since the diagnosis, more than half reported nocturia and one-third reported urgency and frequency. In addition, nearly one-half of the patients reported interference in their daily life due to urinary problems [101].

Urodynamic studies were performed in 9 patients within 8 weeks of diagnosis, with variable results: 3 patients had a significant PVR, 1 had decreased bladder sensation, 8 had detrusor overactivity (of which 5 also showed detrusor underactivity), 1 patient had low compliance and 2 had a non-relaxing sphincter [22]. In another report, 10 of 38 patients had urinary symptoms (all voiding difficulty), and in 50% urinary retention was present at some point of the illness. Urodynamic abnormalities were seen in 23 patients, mostly detrusor underactivity (15 patients) [100].

### 5.2. Chronic inflammatory demyelinating polyradiculoneuropathy (CIPD)

CIPD is a group of acquired immune-mediated disorders that affect the peripheral nerves. They are, by definition, chronically progressive or relapsing for over 8 weeks [102]. The management is supportive [103].

The literature regarding the relation of LUTS and CIPD is scarce. A series of 32 patients with CIPD showed that 8 of the 32 (25%) patients had LUTS [103]. Four patients had voiding difficulties, four urinary urgency (one had associated urgency incontinence), and several had increased day- and night-time frequency. None of the patients had urinary retention. Figueroa and colleagues reported genitourinary symptoms in 8/47 patients (17%). However, these symptoms were retrospectively derived from a standardized chart review and were not further specified [104].

Urodynamic data were available for 4 patients and it showed abnormal bladder sensation in two, “bladder acontractility” in one and neurogenic changes of the external sphincter in one [103].

### 5.3. Autoimmune autonomic ganglionopathy (AAG)

AAG, was formerly known as subacute autonomic neuropathy or autoimmune autonomic neuropathy. It is a rare disease with an unknown prevalence and is difficult to diagnose. It is an immune-mediated disorder of the autonomic nervous system that mostly spares the motor and sensory nerves. Autoantibodies to the ganglionic acetylcholine receptor (nAChR) can be measured in a subset of patients [105]. These nicotinic acetylcholine receptors are present in the entire nervous system. In the peripheral autonomic nervous system, the ganglionic nAChR mediates fast synaptic transmission in sympathetic, parasympathetic and enteric ganglia. Therefore autoantibodies to the ganglionic acetylcholine receptor can potentially disrupt the entire autonomic nervous system. Patients with high levels of ganglionic nAChR antibodies, usually at the extreme end of disease severity, present with severe autonomic failure and NLUTD [106].

Koay and colleagues conducted a study in patients with ganglionic nAChR positive neuropathy, and 9/13 patients had urinary retention. Eight patients performed a uroflowmetry, six of whom had an abnormal flow with prolonged voiding times, intermittent flow and evidence of straining, and two had a normal flow after immunotherapy. In addition, erectile dysfunction and ejaculatory dysfunction were also common. Importantly, urinary symptoms improved in most patients following immunotherapy [107].

### 5.4. Wolfram syndrome spectrum disorder (WSSD)

WSSD is a progressive neurodegenerative disorder characterized by the onset of diabetes mellitus (DM) and optic atrophy (OA) by the age of 16, and typically associated with other endocrine abnormalities, sensorineural hearing loss, and progressive neurological abnormalities (cerebellar ataxia, peripheral neuropathy, dementia, psychiatric illness, and urinary tract atony) [108,109]. WSSD is also known as a DIDMOAD (diabetes insipidus, early-onset diabetes mellitus, optic nerve atrophy and deafness) and two subtypes of this syndrome have been described, each associated with a specific gene, wolframin (WFS1) and CISD2 (WFS2). These genes encode a transmembrane protein and an endoplasmic reticulum intermembrane protein, respectively [108]. They are detected in different organs and account for the pleiotropic features of this syndrome. Wolfram syndrome type 1 (WFS1) is the most frequent and best characterized disorder. In a patient with suggestive clinical features and family history, the diagnosis is confirmed by molecular genetic testing [109].

NLUTD affects up to 90% of the patients with WSSD and may lead to end-stage renal disease [109,110]. Marked dilation of the bladder, often labeled megacystis, has been described as a common finding in patients with WSSD but other clinical presentations are common, including small and non-compliant bladder and DSD [109–111]. The megacystis has been attributed to polyuria from diabetes insipidus, but it has been shown that the NLUTD in WSSD is also from progressive neurodegeneration [110,111]. Studies have shown that brain volume is decreased in patients with WSSD and decreased pons volume is associated with worse NLUTD [111]. Bowel dysfunction is also common in WSSD and deserves proper attention [109]. Treatment of NLUTD in patients with WSSD follows the same principles of those with other etiologies. Periodical evaluation is strongly recommended based on the potential severity of LUTD [109,111].

### 5.5. Charcot Marie Tooth Disease (CMT)

First described in 1886, CMT is the commonest form of hereditary neuromuscular disease and includes a large number of different genetic mutations which result in a common clinical phenotype [112]. The disease usually presents in early in life with a classical clinical appearance that includes muscle wasting and deformities — firstly of the lower limbs (callosities, high arch, foot deformities), and later involving the

upper limbs (main en griffe, claw hand). The disease can present in different forms, classified as demyelinating, axonal, X-linked and various combinations of sensory and motor neuropathies. Initially distal in onset, there is progressive involvement of more proximal neural structures. Many genetic defects have now been identified which usually (but not always) involve autosomal dominant transmission [112].

The prevalence of NLUTD in CMT is uncertain. In a series of 58 patients (36 women; mean age  $52.8 \pm 13.4$  years), LUTS were more common than in age-matched controls. Symptoms included a sense of incomplete evacuation and urgency incontinence in men and nocturia, urgency, hesitancy, straining and interrupted stream in women. Urinary symptoms had an impact on quality of life. Bowel symptoms and sexual dysfunction were also common in both sexes [113,114].

In a small series of 9 patients, 7 patients (3 men) were evaluated by urodynamics. Findings included neurogenic acontractility (2 patients), underactivity (1 patient), neurogenic detrusor overactivity (1 patient), delayed opening time (1 patient) and normal urodynamics (1 patient). Bladder outlet obstruction was not seen in any patient. One of the nine patients presented with end stage kidney disease, but it is unclear whether this was causally related to the diagnosis of CMT disease [115].

In view of the varied presentation, treatment needs to be individualized based on the patient's presentation.

### 5.6. Amyloid Neuropathy (AN)

Amyloidosis refers to a heterogeneous group of conditions involving mis-folding of protein molecules and resulting in deposition of sheets of insoluble beta configuration amyloid fibrils that can be either localized or systemic. The condition can be acquired (AL, the commonest), genetic (ATTR hereditary variant), or result from chronic inflammation (AA) [116]. There are 18 different proteins identified in systemic amyloidosis and 22 proteins identified in localized form. Nomenclature consists of the capital letter 'A' followed by a letter(s) identifying the protein involved and small case suffix for additional qualifiers (such as 'wt', wild type) [117]. AL (light immunoglobulin chain) and ATTRv (hereditary transthyretin variant) amyloidosis commonly involve the nervous system. Deposition of amyloid can also be a part of other disease processes not generally recognized currently as 'amyloidosis', such as Alzheimer's or Parkinson's disease [117]. The absence of any unique pathognomonic feature makes the diagnosis elusive (the "great mimicker"); a high index of suspicion is necessary and diagnosis is confirmed by tissue biopsy [116].

Systemic amyloidosis commonly results in peripheral sensorimotor neuropathy, myopathy or autonomic dysfunction. There is axonal degeneration involving the small myelinated and unmyelinated nerve fibers. Autonomic dysfunction may be noted in 65%–75% of those with neuropathy and about 30% of these patients have urinary tract involvement [23,116]. In patients with hereditary ATTR, a systematic review noted urinary symptoms in 83% patients [118]. Onset was noted in the 4th decade (mean age 30 years in males and 34 years in females) with age-associated progression [119]. LUTS include voiding difficulty, frequency, urgency, urinary incontinence and propensity for urinary tract infection [23,118]. Ultrasonography often shows elevated PVR urine and may identify hydronephrosis (secondary to lower tract dysfunction) or an open bladder neck at rest (signifying autonomic dysfunction) [118].

On urodynamics, detrusor underactivity is a consistent finding and is noted in 78% of patients with familial amyloidotic polyneuropathy [23,119]. Other findings are impaired sensation, poor compliance, urethral incompetence, failure of sphincteric relaxation and DSD [23,119,120]. Timed voiding, use of alpha-adrenergic blockers (in men) and intermittent self-catheterization are key components of management.

## 6. Conclusions

We selected neurological diseases that may not all be immediately familiar to specialists providing care for NLUTD. For each of these diseases, we have provided a brief review of the neurologic disease process, and the specific clinical and urodynamic data where available. We plan to provide additional review papers summarizing the neuro-urological management of other uncommon diseases that we could not include in this review.

The management of NLUTD is often complex, and must always follow the general principles of careful patient assessment and proper urodynamic investigation when appropriate. The final decision on LUT management and any potential interventions should be done in the context of the patient's neurological disease, functional capabilities, prognosis, and their wishes.

## Abstract

Urinary incontinence is a common problem among older adults that is often complicated by many nuanced ethical considerations. Unfortunately, there is a lack of guidance for healthcare professionals on how to navigate such concerns. This International Continence Society white paper aims to provide healthcare professionals with an ethical framework to promote best care practices in the care of older adults with urinary incontinence.

## KEYWORDS

dementia, elderly, frailty, geriatrics, goals of care, multimorbidity

## 1 | INTRODUCTION

Urinary incontinence (UI) is common among older adults, occurring in 30%–40% of women and men over the age of 65 and in 60%–70% living in long-term care facilities.<sup>1,2</sup> Alongside other multi-aetiological conditions such as delirium, falls, dementia, and weight loss, UI is considered to be a geriatric syndrome.<sup>3</sup> As the proportion of older adults in the population continues to grow, the absolute number of older adults with UI will also greatly increase. Importantly, caring for these older adults is no longer just about prolonging life, but it is also about

ensuring that these later years are healthy, meaningful, and dignified.<sup>4</sup> *Ageism*, defined as a process of systemic stereotyping of and discrimination against people because of their age,<sup>5</sup> is both common and unethical, and can be a major challenge to older adults in achieving these meaningful and important goals. Unfortunately, however, there is little guidance for healthcare professionals on how to best ethically care for older adults with UI in the face of these, and other, challenges.

Some examples of ethical considerations specific to caring for older adults with UI include *how to best deliver care that reflects the dignity of the individual*, *how to*

*manage urinary incontinence in an individual living with dementia who cannot express their own preferences, and, if at all, how should age factor into treatment options presented to the patient.*

Fortunately, several ethical frameworks that can help guide this discussion exist and will be further discussed and applied herein. Among them are the Four Ethical Principles and the Ethics of Care Model. The Four Ethical Principles can aid in the moral decision-making process and includes (1) autonomy (the moral right to self-determination concerning one's own health care), (2) beneficence (acting in a way to benefit someone other than oneself), (3) nonmaleficence (doing no harm), and (4) justice (the extent to which healthcare is delivered in an equitable fashion).<sup>6</sup> The Ethics of Care model is another tool that can be used to help guide moral decision-making. It is a context-bound ethics model where moral practices are grounded on the recognition of the needs of particular persons. It recognizes the importance of personal relationships, paying particular attention to the attributes of compassion, sympathy/empathy, and a sincere concern for caring for others.<sup>7-9</sup> These frameworks serve as a starting point for this document.

The purpose of this International Continence Society white paper is to provide guidance in addressing some of the ethical dilemmas that arise in caring for older adults with UI, taking into account the various perspectives of the patient, the caregiver, and the healthcare professional (inclusive of physicians, nurses, physiotherapists, and other types of care aides). This paper does not provide definitive solutions to ethical problems, as many of these issues are nuanced and individualized beyond the ability of a formal document to adequately address them. As ethical dilemmas are always context-bound, we will begin the paper by revisiting the varying contexts and cultural considerations wherein continence care is provided for older adults. Thereafter, we propose the following guiding principles to help healthcare professionals provide ethical care for older adults with UI:

- Health systems should create environments that support ethical continence care
- All older adults should be treated with dignity
- The healthcare team should elicit the patient's own goals of care
- Advanced communication should be employed in intimate continence care interactions with older adults
- Treatment should be aligned with goals of care
- The healthcare team should consider the potential burden of the treatment that they recommend in the setting of multimorbidity, frailty, physical, and cognitive impairments

These statements serve as a starting point to raise awareness of the important ethical issues associated with the care of older adults with UI. While this paper focuses specifically on UI, these same guiding principles will also apply to other lower urinary tract disorders in this population.

## 1.1 | The contexts of care for older adults

The Ethics of Care is an approach to moral thinking that was originally developed in moral psychology and political philosophy,<sup>8-11</sup> but which has been also addressed in nursing philosophy and theoretical medicine.<sup>12-14</sup> It is grounded on the argument that practices of care give rise to moral thinking that is specifically suited to meeting the needs of others. This approach complements justice-based ethical guidelines, where the aim is to treat everyone equally, often through universal guidelines for justice.<sup>12</sup> Ethics of Care emphasizes that justice and ethical conduct take more than just following a set of rules. In this approach, ethics is about *responding caringly to the needs of particular persons in the specific contexts where the needs emerge*. Thus, to provide ethical guidance for continence care for older adults, we first must briefly elaborate the different contexts where this care takes place.

Depending on the country-specific system of health and social care, the contexts of care for older adults can be divided roughly into two distinct settings: (1) institutionalized settings of care (including clinics, hospitals, and nursing homes) and (2) home-based health and social care, provided by care professionals in the clients' own homes, by family members, or by care assistants who may not have official healthcare qualifications. In many societies, older adults with heavy care needs live in nursing homes or serviced housing, where they have access to professional nurses' and caregivers' help at all times. These resources are increasingly limited, however, in formerly strong welfare systems, where access to 24/7 care services has become restricted.<sup>15</sup> Institutionalized care is also not a universally accepted solution to coordinate care for older adults. In many societies, older adults age at home, being cared for by other, usually female members of the family. Additionally, paid domestic help may also be utilized. Thus, on the global scale, the majority of older adults with UI problems live at home, depending on family members or other informal caregivers, which may or may not be complemented with services provided by health professionals working in community care.

All of this places limitations on what continence care experts can do to improve the care for older adults with

UI: while most day-to-day continence care for older adults is provided by personal care workers and nurses providing intimate care, the most up-to-date specialist knowledge of treatments and forms of incontinence is often found in the clinic and in hospitals. When older adults with incontinence problems do not have access to such specialists, their continence issues may not be adequately treated or mitigated. Simultaneously, the continence experts working in the clinic may not always have a realistic picture of practices of intimate continence care, or the set of skills that the caregivers in those contexts require when seeking to meet the needs of their clients competently, compassionately, and with dignity. We will return to this in a subsequent section. However, our recommendations are mainly directed towards healthcare professionals who care for older adults. This would mean, first, that those working in the clinic or hospitals comprehend the day-to-day realities in which most continence care for older adults is provided. Second, it would mean that those providing intimate care in the clients' homes, or in nursing homes, be provided with knowledge of continence issues as part of their training in elder care.

The geographical context of care matters, too. While the rapid aging of demographics is also a reality in low- and middle-income countries (LMICs), a number of stressors are more common in these parts of the world, including poor housing, lack of access to standard toilets, poor access to medical services, limited digital facilities, lack of appropriate medications, poor hospital care, and insufficient security and social support. Medical education is lacking in continence care for professionals and caregivers, and there are limited educational resources translated into local languages. Furthermore, while the lack of sanitation and inadequate waste management make safe disposal of continence products difficult in LMICs, the products may remain entirely inaccessible to large segments of these populations. This applies both to absorbent products and to safe catheter care. Studies

show, for instance, that catheter insertion, indication and monitoring are lacking in many health centers in LMIC contexts.<sup>16</sup>

There are thus several societal issues that need to be considered to support ethical continence care in the context of LMICs.<sup>4</sup> Furthermore, like in high-income countries (HICs), in LMICs, knowledge of incontinence tends to be low among the general population, and remains a gendered taboo that is not discussed. There may also be specific cultural constraints to discussing urine and fecal leakage. In Islamic law, for instance, urine is considered "Najis" (ritually unclean), meaning that if one's garments are contaminated with urine, one will be limited in doing daily rituals and in participating in social activities such as going to the mosque. Non-Muslim communities have similar social limitations. Across societies, many still believe that UI is an inevitable part of aging, and this belief is easily entangled with derogatory forms of ageism. In many languages, there may still not be an adequate translation for the clinical term "incontinence,"<sup>17</sup> making the problem difficult to address in ways that are comprehensible to older adults.

While various inequalities and inequities shape continence care for older adults globally, the same applies to inequalities and inequities within societies. In HICs, older adults living in poverty may have difficulties in accessing adequate and safe continence care, treatments, and products. Medical illiteracy may affect the possibilities to access care, as well as language skills among migrant populations. While individual healthcare professionals may not be able to influence these inequalities in their day-to-day work, it is important that they are aware of these different contexts in which their older patients need care, and thereby the patients' social determinants of health. In the following section, we turn to the socioeconomic structures, which shape the space for ethical interaction among health professionals.

#### Section 1 Summary

- Care for older adults takes place in institutionalized settings and in people's own homes. Globally, the majority of older adults with continence problems live at home, depending on family members or other informal caregivers for help.
- Many older adults do not have access to specialist care.
- A number of stressors in low- and middle-income countries, including poor housing, limited access to standard toilets, poor access to medical services, lack of appropriate medications, poor hospital care, and insufficient security and social support, may make continence care more complicated.

## 2 | HEALTH SYSTEMS SHOULD CREATE ENVIRONMENTS THAT SUPPORT ETHICAL CONTINENCE CARE

The concept of *socioeconomic structures*, generically used in the social and political sciences, refers to the ways in which different social, political, and economic factors *shape and constrain, or influence, individual or group action*.<sup>18–20</sup> Whilst some structural conditions can hinder health professionals from ethical interaction, others can facilitate ethical care. In continence care for older adults, this term can refer to the material, temporal, epistemic, and human resources that are available for treating or caring for a patient. For example: *Is there an adequate number of staff members available to meet the needs of the patient? Are training and skills appropriate to meet patient needs, while respecting the patient's dignity? Is there enough time for the caregiver to listen to the patient and understand their individual needs, before making decisions about treatments? Are there adequate diagnostic tools and technologies available? Are there adequate human resources available to assist patients after treatment, for a safe recovery? What social and environmental determinants of health influence the patient's condition, and their possibilities of self-care? Does the health system provide the patient with access to the necessary treatments and care, regardless of their wealth and status in society?*

Accounting for the global inequalities and inequities of health care described above, it is helpful to think of the influence of socioeconomic structures on care through different levels of analysis that overlap and interact (Figure 1).

First, on the *macro-level*, the socioeconomic structures are shaped by the national health system. Here, legislation and policies form a structure that defines the patients' rights to care, while outlining the system of payments. For instance, insurance or out-of-pocket based health systems form very different macro-structures for care provision, compared to the more universal systems of social and health care, where services are tax-funded and generally more accessible. These macro-structures are shaped not only by national policies and jurisdiction, but also internationally. Trade agreements, for instance, may have an impact on treatments and medications that are available in particular contexts.

Second, on the *meso-level*, the institutional context of care sets up its own structures. As noted above, continence care for older adults occurs in different environments: hospital wards, clinics, nursing homes, and households. In each setting, the staff qualifications, skills, as well as staff resources and available technologies, shape the possibilities for ethical action.

Third, as described in more detail in the subsequent sections of this white paper, the ethical interaction between healthcare professionals and their

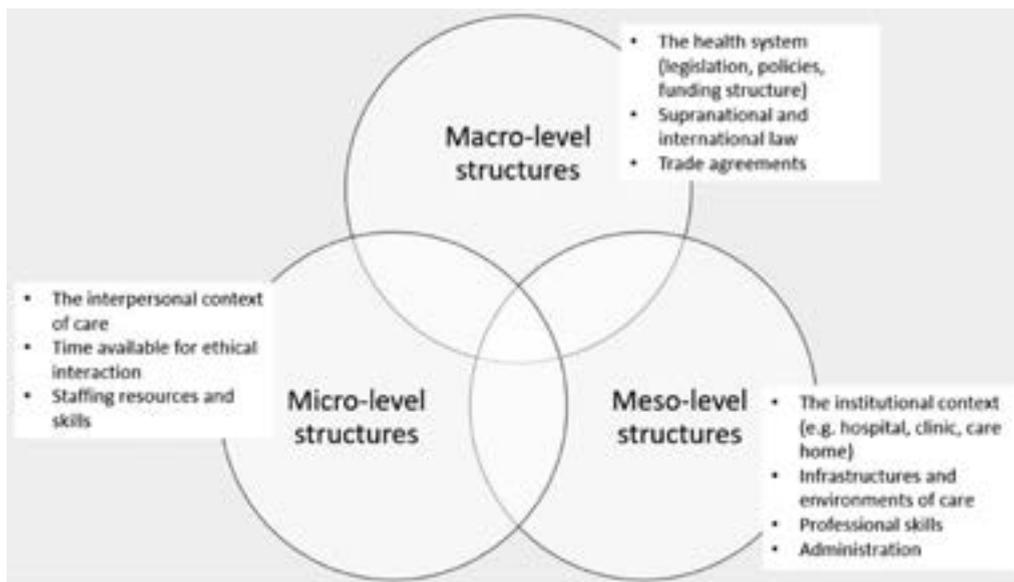

FIGURE 1 Socioeconomic structures: intersecting levels of analysis

older patients always takes place via interpersonal encounters between individual human beings. In this *micro-level*, there are various structural constraints and possibilities at work. A crucial factor is time available for listening and understanding the patients' needs from their own perspective. Temporal constraints and possibilities, however, are often placed at either meso- or macro-levels. An awareness of such structural influences on care *expands the ethical responsibility for good care, from a focus on the actions of individual healthcare professionals to the administrators making decisions on how resources are allocated on different levels of the healthcare system.*

Indeed, on all levels of analysis, socioeconomic structures are political. In the micro-level encounters, politics is present in the inter-personal power relations between the healthcare professionals and their older patients. On the macro- and meso-levels, in turn, there is the day-to-day level of political, administrative, and fiscal decisions regarding the health system, how it operates, and how it is funded. These decisions have a crucial impact on equality and equity in patients' access to care—and, respectively, on the kinds of ethical possibilities that are available to healthcare professionals in their practices of care. Healthcare professionals often struggle to provide care that meets their own ethical standards of work leading to moral distress.<sup>21–23</sup> Such situations require the redesigning of socioeconomic structures, rather than attributing blame to individual healthcare professionals. Indeed, if the socioeconomic structures hinder ethical action for healthcare professionals, it is not only possible, but morally necessary to redesign the structures so that they support ethical interaction in care. In the subsequent sections, we describe what such ethical interaction looks like when caring for older adults with UI in different contexts.

## 2.1 | Environments that support ethical continence care in older adults

To respond ethically to the continence care needs of older adults in organizational settings, there is a need to address the socioeconomic structures that influence the quality of care. Two quantitative studies highlight the importance of considering organizational structural factors such as staffing. One study analyzed the minimum data set for 46 044 residents in 162 nursing homes in New York State, from June 2006 to July 2007, and survey responses from 7418 workers in the same facilities. The study found that rates of incontinence were significantly lower in homes that had higher rates of staff cohesion, a higher percentage of staff in daily care teams, and a higher percentage of staff with consistent assignments.<sup>24</sup> Similar findings were reported in another study that examined the impact of organizational factors on the quality of incontinence care in Korean long-term care hospitals. This study found that higher Registered Nurse to patient ratios were significantly associated with better resident UI outcomes in long-term care hospitals.<sup>25</sup>

We suggest that structures that support ethical continence care for older adults in organizational settings align with those that privilege the older person's dignity. Based on a concept analysis, dignity-protective continence care' for care-dependent older adults is characterized by: (1) time to deliver care and flexible work practices; (2) staff knowledge and beliefs about incontinence; (3) adequate number of staff as well as staff who are trained; (4) managerial support and leadership; (5) a predictable work environment; (6) regulation that does not constrain caring practices; (7) a health system that ensures an equitable access to adequate and appropriate care and treatment, across the population. These findings can be used as guiding principles in an ethic of care for older adults who require continence care.

### Section 2 Summary

- The Ethics of Care framework emphasizes that care must be provided in ways that meet each person's specific needs, within the contexts in which their care is delivered.
- Elder care is primarily home-based or institutional, but the availability of knowledgeable and competent caregivers, educational aids, incontinence products, and infrastructure that supports the delivery of proper continence care vary widely depending on systems of care, geography, and cultural norms.
- Care practices are shaped by the socioeconomic structures in which the care is delivered. This expands the ethical responsibility of good care to include not only the healthcare professionals, but also the policymakers, hospital, and home care administrators.

### 3 | ALL OLDER ADULTS SHOULD BE TREATED WITH DIGNITY

Whilst the concept of dignity is contested, difficult to define, and difficult to measure, few would argue that UI represents a threat to a person's subjective dignity. Dignity appears as a duty and a right in professional codes in human rights frameworks. Article 1 of the Universal Declaration of Human Rights (UDHR) states "all human beings are born free and equal in dignity and rights."<sup>26</sup> The International Council of Nurses Code of Ethics<sup>27</sup> states "*Inherent in nursing is a respect for human rights, including cultural rights, the right to life and choice, to dignity and to be treated with respect*" (p. 1). Thus, dignity is linked to respect, equality and rights.

Leget<sup>28</sup> identifies three versions of dignity:

- *Intrinsic dignity* pertains to the idea that all human beings have inherent dignity that cannot be diminished or taken away as long as the person lives.
- *Subjective dignity* is the experience of one's own dignity tied to self-respect and self-esteem.
- *Social and relational dignity* is based on merit or rank and upon recognition by other people.

The concept of dignity has particular salience for healthcare professionals who have a professional obligation to acknowledge and protect all humans regardless of their agency and autonomy.

However, in recent years, attention has been drawn to the fact that many older adults are not accorded the respect they deserve, particularly if they have cognitive challenges that affect their ability to self-advocate or if they require care in an institution such as a nursing home or hospital. Indeed, details about neglect and abandonment in the form of not being fed, bathed, or toileted during the COVID-19 pandemic are emerging from long-term care homes from multiple countries. In Canada, armed forces found cockroach infestations, short staffing, neglect of residents, and uninfected residents sharing rooms with those who were symptomatic.<sup>29,30</sup> In Spain, Belgium, and Canada, the military was called in to care homes for standards of care collapsed amid reports of lack of personal protective equipment (PPE), staff sickness, and negligence complaints against the management of care homes.<sup>31</sup>

Similarly, a Royal Commission of Aged Care Quality and Safety,<sup>32</sup> investigating the quality and safety of residential and in-home aged care in Australia reported several examples of practices that the Commissioners viewed as violations of older peoples' dignity. They included:

- Using continence containment products as a substitute for toileting
- Rationing the use of incontinence products
- Failing to respond when residents need help to change wet or soiled products
- Failing to respond when residents need help to use the toilet, causing them to experience an episode of incontinence.

Concerns about the quality of continence care in institutions are longstanding and international. Artero-Lopez et al.<sup>33</sup> described the care of hospitalized patients with UI in Spain as therapeutic inertia. The researchers conducted 132 non-participative observations of practice and reviewed 600 medical records and reported a pattern of severely compromised action in the assessment of the pattern of urinary elimination, in actions related to urinary continence, in therapeutic behavior, and in-patient satisfaction.<sup>33</sup> Drawing on an ethnographic study within five hospitals in England and Wales, Boddington and Featherstone<sup>34</sup> claimed the twin assaults on agency of a diagnosis of dementia and of UI threatened patients' personhood. These findings suggest that subjective dignity and the social construction of moral personhood are both threatened and maintained in such a setting. We claim the preservation of dignity should form a guiding principle in ethical care of older adults who require support to either manage or maintain continence.

Given this background and the absence of quantitative data about violations to the dignity of older people who require care, Ostaszkievicz et al.<sup>35</sup> attempted to clarify the attributes of practice that protect the dignity of people who require support to manage incontinence or to maintain continence. Using a method established by Rogers et al.<sup>36</sup> from 14 empirical studies that met the inclusion criteria, the authors identified 50 antecedents and attributes of continence care practices that protect a person's dignity, that is, dignity-protective continence care. Based on this analysis, dignity-protective continence care is operationalized through practices that promote respect, empathy, trust, privacy, autonomy, and communication.<sup>35</sup> For example, continence care practices that promote autonomy focus on offering a choice and support to make decisions about the gender of caregivers, toileting preferences, and choice of products. Dignity-protective care requires carers to have adequate verbal and non-verbal communication skills. These communication strategies include managing negative emotions, adopting a soft, calm tone, picking up on verbal and nonverbal cues, and using touch appropriately. Respect is conveyed through practices that treat the person as an individual rather than an episode of care, and by taking time. The researchers also identified

23 consequences of undignified continence care that they categorized into three levels of impact (i.e., resident/family member, staff member, and organization).

Whilst the researchers anticipate the domains of respect, empathy, trust, privacy, autonomy, and communication to be universal, a limitation of the concept analysis is the reliance on published research in the English language that does not take account of cultural differences between and within countries and nations. Depending on the class, gender, generation, ethnicity, religion, urban/rural positioning of both the caregiver and care recipient, dignity protective practices are likely to be culturally specific.

Understanding these attributes of dignity-protective continence care could allow caregivers and healthcare professionals to challenge practices that violate dignity, and recognize caring opportunities for protecting the dignity of vulnerable and care-dependent older adults. The researchers plan to use their findings to develop an instrument to evaluate whether continence care is delivered in a way that protects the dignity of care-dependent older people.

caregiver have differing experiences or expectations of UI and goals of care.

#### 4.1 | Framework for eliciting goals of care

The process of eliciting the patient's own goals of care starts with understanding their values and how they may be affected by their condition. To learn about an individual's values, the care team must communicate empathically and listen actively to learn and understand, rather than solely acting to solve or "cure" the patient's problem.<sup>38</sup> The care team should ask open-ended questions to facilitate articulation of the patient's own preferences. For example, to understand an individual's dominant care goal, one could ask, "what is most important to you at this point in your life?" To further understand the individual's values, one could ask, "What makes life worth living for you?"<sup>39</sup> Responses to questions such as these can help the care team to better understand the patient's values and preferences and aid in

##### Section 3 Summary

- Incontinence represents a threat to an individual's subjective dignity and healthcare professionals have an obligation to respect and maintain this dignity.
- It is imperative to acknowledge and address contexts in which dignity may not be maintained, such as in those who are living with cognitive impairment or older adults with frailty living in institutional care who are unable to advocate for themselves.
- Dignity-protective care requires good verbal and non-verbal communication strategies and treating the person respectfully as an individual and autonomous being.

## 4 | THE CARE TEAM SHOULD ELICIT THE PATIENT'S OWN GOALS OF CARE

Eliciting the patient's own goals of care is paramount to the ethical treatment of older adults with UI. When it comes to caring for older adults, communicating with cognitively intact patients is not fundamentally different from communicating with younger patients. However, in people living with cognitive impairment, challenges may occur in the patient's ability to understand information, make decisions, and communicate preferences clearly. In this section, we consider how to approach those older adults who may not be able to communicate their own goals of care and to the relationship-centered care (RCC) model as a means of communication.<sup>37</sup> We also address the challenges that arise when the patient and the

appropriate treatment selection aligned with these goals. Ethical concerns can arise when the person's wishes and available resources and care are misaligned.

#### 4.2 | What happens when the patient is unable to communicate their goals of care

Autonomy, the concept that an individual has agency to choose to undertake or decline a particular medical intervention, is paramount to consider when eliciting an individual's goals of care. However, autonomy in the case of cognitively impaired adults is less clear and may not be binary. These overriding principles are supplemented by the *Four Box* model of medical decision-making, which places medical indications, patient preferences, quality of life, and contextual features on equal footing within the

process of finding an agreed plan between the care team and patient.<sup>40</sup>

Many older adults living with cognitive impairment retain the capacity to make decisions regarding their health. Involving others in discussions should always be based on informed consent. When this is not possible, an assessment of capacity should be conducted. In cases when individuals are not able to make decisions regarding their own care (following an assessment of capacity), substitute decision-makers, usually those nominated in a personal directive or similar document, assume the responsibility of being involved in discussions. Substitute decision-makers may also be called “proxy,” “surrogate,” or “assisted” decision-makers. As substitute decision-makers face difficult decisions between the utility and futility of treatments that impact the wellbeing of persons who are often their loved ones, the position is psychologically demanding. The same applies to decisions regarding continence care. They may feel confused over mixed messages or guilt for the choices they have made, and they may have to negotiate difficult choices with a wider family group, sometimes leading to family disagreements. It is therefore crucially important that the healthcare professionals involved in elucidating choices provide adequate time and support for surrogate decision-makers, that they communicate the choices and their consequences clearly, in plain language, and without medical jargon, and that they are ready to listen empathetically, seeking to understand their concerns.<sup>41</sup>

For those older adults who are unable to retain or understand information, it becomes the responsibility of their surrogate decision-maker working with the treating professionals to establish what course of action is in the person's *best interests*—that is, aligned with what they believe would be consistent with the person's own values and preferences. These discussions can be challenging, particularly when views differ between professionals and surrogates. Here, RCC provides an ethical framework.

### 4.3 | Relationship-centered care as a means of communicating across differences

Originating from the Pew-Fetzer Task Force on Advancing Psychosocial Health Education,<sup>37,42</sup> RCC seeks to recognize the nature and the quality of relationships as central to healthcare practices and health systems. Going beyond both patient-centered care and the old-fashioned doctor-centered approach, RCC portrays *healthcare delivery as a network of human relationships* that involves the patient, their substitute decision-makers, and health

professionals involved in the delivery of care. As Nolan et al.<sup>42</sup> describe, “[in RCC] the interactions between these groups constitute the ‘defining force’ in health care, as they are the medium for exchanging the information, feelings, and concerns needed for a better understanding of the meaning of illness”—and hence the patient's best interest.

First, RCC requires that the personhood of *all* the participants be considered, including care team members, who need to be aware of their own values, biases, and reactions, and how they shape the healthcare relationships in which they participate.<sup>37</sup> Second, RCC challenges the idea that healthcare professionals should be detached from their emotions to maintain neutrality, and empathizing with the patient is strongly encouraged. Third, RCC recognizes the value of reciprocal influence in care relationships, where the patients and their family members may influence the healthcare professionals. Allowing the patient and the surrogate decision-makers to have an impact on the healthcare professional respects their personhood, and allows for ethically sustainable healthcare praxis. Fourth, RCC maintains, in line with the message of this white paper, that the formation and maintenance of genuine relationships in healthcare are morally valuable.

### 4.4 | The importance of gaining trust

RCC is likely to improve care delivery through an increased overall commitment to care practices, for as social animals, “humans are more morally committed to those with whom they are in a personal relationship.”<sup>37</sup> Similarly, keeping family members regularly updated about continence care as well as other care increases trust in a manner that makes them feel they are involved and respected. It is also imperative not to “talk over” the person living with cognitive impairment, but rather to *include* them in a discussion at a level appropriate for their cognitive and communication ability. Furthermore, RCC reveals that communicating the goals of care is not a singular event between two persons, but part of a wider network of relationships, where each actor's views and experiences, and trust in the system, can influence the patient's wellbeing. Whether making decisions for one's own care, or for someone else as a substitute decision-maker, the patient and their family members, or surrogates, must be able to trust healthcare professionals and the health system as a whole.<sup>41</sup> As RCC emphasizes, trust is gained over time; the ethics of communicating and eliciting goals of care is, therefore, an ongoing process.

“Mixed messages” and contradictory practices can undermine the patient's and their representatives’

trust in the system's capacity to understand their best interests. To assess the patient's continence problems holistically, it is important that healthcare professionals communicate clearly within the team, and that all team members appreciate each other's knowledge and professional views.

#### 4.5 | When opinions between the individual and caregiver differ

When individuals living with dementia and their caregivers have different views and opinions regarding their continence care, conflict can arise. A common situation exists when a person with dementia is untroubled by their UI, but the caregiver is quite burdened, for example by purchasing and changing containment products, helping with toileting, doing laundry, or experiencing disturbed sleep. This can lead to an ethical dilemma—to what extent can healthcare professionals force continence care, like washing, that they know is imperative for the person's wellbeing, but which the person aggressively resists? It is known that “intentions associated with determining and agreeing [on] care goals can be ambiguous.”<sup>41</sup> There is no prescriptive or “correct” answer here. Open communication between the patient, the caregiver, and the medical team is essential to ensure the best compromise is reached, seeking the least restrictive option that provides acceptable symptom resolution and treatment burden, tailored to the individual is achieved. Fundamentally, the wellbeing and dignity of the patient are central, as discussed earlier in this publication.

## 5 | ADVANCED COMMUNICATION SHOULD BE EMPLOYED IN INTIMATE CONTINENCE CARE INTERACTIONS WITH OLDER ADULTS

Most continence care for older adults is provided by family caregivers, nurses, and care aides, who often have direct responsibility for helping dependent persons to use the toilet, clean themselves after an episode of UI, and change and dispose of incontinence products. These intimate care encounters take place in a range of different settings, including people's own homes, nursing homes, and hospitals. They typically occur in private and behind closed doors. For a long time, accounts of care work played down the bodily aspects, including practices of continence care, “emphasizing instead, the social, emotional and interpersonal aspects of the body and its decline.”<sup>43</sup> Nursing and biomedical literature still remain curiously silent about how to deliver care to clients who may require assistance to perform basic bodily functions. The literature provides no guidance about the psychological aspects of breaching social norms about touch, how to manage embarrassment, and minimize distress, including distressed behavioral responses. Norton, for instance, has claimed that although there are a small number of specialty texts about fecal incontinence, “prominent nursing texts that devote a whole chapter to elimination, give no guidance, other than outlining the practicalities of changing the incontinent person.”<sup>44</sup> This is problematic because a lack of guidance for practice can lead to variations in care that are potentially harmful.

#### Section 4 Summary

- The healthcare team should strive to elicit the patient's own goals for their care, considering their personal context.
- If upon assessment the patient is deemed not capable of making his/her own medical decisions, a substitute decision-maker is required to determine the treatment plan that best aligns with the patient's goals and values. Surrogate decision-makers may require considerable support in making decisions according to the best interests of the care recipient.
- Trustful, open, relationship-centered care provides a means by which older adult's goals of care can be established and well-being maintained.
- Relationship-centered care takes into account the reciprocal relationships of the patients, the substitute decision-maker, and all members of the health care team.

When the person lives with severe cognitive impairment, such as in advanced dementia, caregivers require advanced knowledge and skills to manage the care interaction in ways that minimize the risk of harm and protect the person's dignity. Given the progressive deterioration in cognition, persons with advanced dementia are often not able to interpret bladder and bowel signals or understand the care provided to them. Due to its transgressive nature, intimate continence care is particularly prone to triggering distress and combative behavior.<sup>45-49</sup> Individuals may interpret touch as an unwelcome sexual advance, an assault on their dignity, or a violation of their body,<sup>50</sup> especially if they have experienced abuse earlier in life.<sup>43,51</sup> People living with dementia are also likely to respond badly to rushed continence care. They may resist care, sometimes non-aggressively,<sup>43,52</sup> but often aggressively. In dementia care, both professional nurses and informal caregivers are regularly exposed to

non-verbal communication. Research on nursing practices has identified several strategies that nurses employ in such circumstances.<sup>59</sup> Vaittinen, for instance, has mapped techniques of “caring self-protection.” These are three-pronged practical skills, which caregivers can employ to [1] “protect themselves from the physical violence” of care recipients who behave aggressively, while [2] “simultaneously ensuring they do not hurt them, and that [3] good care is provided regardless of the violent situation.”<sup>57</sup> Based on Vaittinen's pilot study, a guideline for these skills can be found in Box 1. To promote ethical practices of intimate continence care for patients who respond behaviorally, there is a need to: (i) acknowledge the inherent complexities of providing this type of care, and (ii) systematically study the often unappreciated skills of “caring self-protection,” so they can be systematically mapped, and included in carers' professional training.

#### Section 5 Summary

- When cognitive conditions involve aggressive behavior and resistance to intimate continence care practices, both the caregiver and the care recipient are at risk of harm.
- In intimate continence care for older adults with cognitive impairment, caregivers require advanced knowledge and skills to manage the care interaction in ways that minimize the risk of harm to both the carer and to the care recipient, while also protecting the person's dignity and providing good continence care.
- There is a lack in guidance for practicing communication and interaction with older adults with neurodegenerative conditions. This can lead to variation in care.

physical and verbal violence, where they may be kicked, hit, bitten, and assaulted verbally, racially, or sometimes sexually.<sup>53-56</sup> Carers' or nurses' education tends not to include systematic training of skills in how to respond caringly in situations where they face aggressive behavior, so that they can provide good care while protecting *both* the aggressively behaving client *and* oneself from the physical harm. Yet, many develop such skills and suitable responses on the job.<sup>57</sup> These skills should be mapped in detail and included in training programs. Despite the risk of being harmed whilst providing continence care, family caregivers, nurses, and nursing assistants have little choice but to engage with the person. They cannot withdraw. Indeed, if family carers are unable to grapple with UI, then their caregiving role is likely to be relinquished.<sup>58</sup>

The care must be provided, since not doing so would result in neglect of the person's care needs and could result in an uncontrolled, uncontained UI, which in turn could undermine personal dignity, or lead to incontinence-associated dermatitis, and thereby to physical harm. It is in situations like these, caregivers need advanced communication skills, including the ability to adopt both verbal and

## 6 | TREATMENT SHOULD BE ALIGNED WITH GOALS OF CARE

It is increasingly important that healthcare and treatment decisions be aligned with the patient's goals of care with input from the healthcare professional and the caregivers, where appropriate. Goals of care should be patient-centered, respectful, and culturally competent. Treatment selection should similarly be patient-centered and aligned with the patient's goals of care, with special considerations given to remaining life expectancy, the risk/benefit of the proposed treatment (or lack thereof), and impact on quality of life. Beneficence must always be at the forefront of any discussion safeguarding the patient and always first do no harm.

### 6.1 | Life expectancy and risk/benefit of intervention

Consideration of remaining life expectancy and how this affects medical decision-making and management is an important component of an ethical discussion between the

**Box 1 Techniques of caring self-protection to minimize distress, combative behavior, and harm during continence care interactions (following Vaittinen 2020)**

- When caring for a client known for aggressive behavior, prepare yourself for the situation in advance. This may mean managing your fears, so the client does not sense your anxiety.
- Seek to understand the lived reality that the *client* occupies: what do they sense in the situation of care, and why? Adjust your verbal and non-verbal communication as well as the care practices to meet *that* reality.
- Account for the entire sensual experience of the situation from the viewpoint of the care recipient: Does the room echo, can something be done about the acoustics? Do reflections from the mirror appear threatening, can they be covered? Is the room cold, or too warm? Would music or singing help to calm down this person? Can something be done about the smells, or “taste” of the situation (e.g., putting a piece of chocolate in the client’s mouth)? Pay attention to how the client senses your touch. For example, an intricate modification in the position of your thumb may change the touch on the care recipient’s shoulder from threatening to caring: the thumb evenly pressed next to the other fingers may feel gentle, whereas if the thumb is separated from the other fingers it may feel as if someone is grabbing the shoulder in a threatening manner.
- Work in pairs where necessary, but provide the main responsibility for speaking to one carer only. This provides the care recipient space to participate in the interaction, rather than just being worked upon by a team of people. When issues in personal chemistry occur between the carers and the care recipient, changing the carer in the lead may tame aggressions before or once they erupt.
- Consider, what kind of verbal and non-verbal communication best suits the personality of the client in situations of aggression: is it jokes and humor for this person, or rather more professional biomedical language? Or perhaps just stepping back, silently, while letting them get their aggression out? Adjust your tone of voice and speed of speech to the resident’s personality: this is particularly important, when they no longer understand the words being spoken. If the client has no words to express their frustration, you may try and verbalize their anxiety, while giving it adequate time to develop—and pass.
- Pay attention to how the client senses your presence. For example, standing next to (and above) the person sitting on the toilet may appear dominant, whereas squatting so the carer’s face is on an even level with that of the care recipient, may appear friendly.
- Use clothing to innovatively: If the client is likely to scratch the carers, you may cover their hands with soft mittens. Or, if the care recipient is very reserved, it may help to partly cover them with towels while showering, so the person does not feel naked and exposed.

healthcare professional and the patient, their family, and/or their caregivers.<sup>60</sup> The intervention may likely be altered based on an individual’s life expectancy and individuals may choose to undergo less aggressive treatments for their UI.

Patients and their family/caregivers must be fully informed of the risks and benefits of each treatment option and on how they may either improve or possibly impair their quality of life. All aspects should be examined when assessing the risks and benefits of any proposed plan of action, including that of no intervention. Preservation of the patient’s autonomy and ethical right to veracity are important aspects of the open communication process of any informed consent as it relates to treatment planning. Older adults may be at greater risk for treatment-related adverse events, such as more frequent drug-related side effects than in younger people (i.e., dry mouth, constipation, and cognitive side effects associated with antimuscarinics; headache, elevated

blood pressure, and elevated heart rate associated with beta-3 agonists). For surgical procedures, compared to younger adults, older adults experience higher rates of postoperative complications, longer hospital stays, and a greater likelihood of discharge to institutional facilities rather than to home.<sup>61</sup>

## 6.2 | Consideration of comorbidities and treatment guidelines

Many other conditions and medications affect urinary function and continence. Urinary function in neurodegenerative conditions, such as Alzheimer’s Disease, Multiple Sclerosis, and Parkinson’s Disease, are often associated with UI. It is important to consider that a treatment or intervention for UI in the present time may not be as effective in the future if/when the underlying

neurodegenerative or other comorbid condition worsens. In these situations, discussion of the invasiveness and/or time commitment required for the intervention is important. Patient-centered goals of care should be repeatedly discussed and updated often.<sup>62</sup>

While clinical guidelines are often helpful, they may be inappropriate for some older adults due to their comorbidities, goals of care, or social circumstances. For example, the American Urological Association (AUA) and the Society of Urodynamics, Female Pelvic Medicine, and Urogenital Reconstruction (SUFU) have published guidelines for the diagnosis and treatment of non-neurogenic overactive bladder. Per these guidelines, individuals are instructed to try treatments for their overactive bladder in sequential order, starting with behavioral therapies, then pharmacologic management, followed by neurostimulation (both sacral and percutaneous) and onabotulinumtoxinA.<sup>63</sup> However, this “one size fits all” model may be inappropriate for use in all older adults due to various special considerations such as frailty, functional and cognitive impairment, coexisting multimorbidity and polypharmacy, and estrogen deficiency.<sup>64</sup>

### 6.3 | Considerations around testing and evaluation

Ethical use of testing and evaluation in the older population should also be based on goals of care and a shared decision-making process. Overutilization of diagnostic testing and overdiagnosis should be avoided. Favorable risk-benefit analysis and fiduciary responsibility should play a role in the use of diagnostic testing and investigation of older (and all) adults. There should always be a clear clinical question for the use of invasive testing that is aligned with the patient's goals of care. Over-testing and overdiagnosis may lead to anxiety, patient discomfort, and wasted resources, potentially causing harm or burden to the patient.<sup>65</sup>

## 7 | THE HEALTHCARE TEAM SHOULD CONSIDER THE POTENTIAL BURDEN OF THE TREATMENT THAT THEY RECOMMEND IN THE SETTING OF MULTIMORBIDITY, FRAILTY, PHYSICAL, AND COGNITIVE IMPAIRMENTS

Within the traditional ethical principles of medicine, “first do no harm” holds special significance for many older adults due to the presence of vulnerabilities related to frailty, physical and cognitive impairments. The older adult population requires a thoughtful and holistic approach to the evaluation and management of problems such as UI. In this context, one of the greatest barriers to providing ethically appropriate care to older adults is ageism.

Ageism is defined as “stereotyping, prejudice, or discrimination against individuals on the basis of their age.”<sup>66</sup> Recent studies suggest that ageism is becoming more prevalent in medicine and in society in general.<sup>67,68</sup> It is clear that such a pervasive and deep-seated bias will seriously constrain the ability to objectively evaluate and treat older adults. Signs of such inherent bias include disrespect for dignity or autonomy, minimizing the severity of a patient's symptoms, rejecting patient concerns and acting in a patronizing fashion as well as withholding treatments or resources. At its worst, systematic or institutional ageism can result in dehumanization of the affected individuals.<sup>34</sup> Such dehumanization constitutes a form of moral exclusion in which older persons are not afforded the protection of the core bioethical principles leaving them vulnerable to neglect, overt harm, or injustice.<sup>69</sup> It is therefore incumbent upon clinicians responsible for the care of older adults to be sensitive to ageist bias in themselves and others and to recognize the negative attitudes that signal such prejudice.

#### Section 6 Summary

- While clinical guidelines are often helpful, they may be inappropriate for some older adults due to their comorbidities, goals of care, or social circumstances. Treatment decisions should reflect special considerations of this population.
- Patient-centered goals of care should be repeatedly discussed and updated often and reflect consideration of progressive comorbid conditions.
- Avoid over-testing and overdiagnosis, as these may lead to anxiety, patient discomfort, and wasted resources, potentially causing harm or burden to the patient.
- Beneficence and dignity must always be at the forefront of any discussion safeguarding the patient and to always first do no harm.

There are a number of factors to be considered in shared decision-making that are not so much related to age as they are to a patient's mental and physical capacity. In this context, it is important to recognize the distinction between chronological age and *biological* or *functional* age. Physiological status and mental acuity must be measured by objective means to make an accurate assessment of medical vulnerability.<sup>70</sup> In particular, frailty, the multidimensional syndrome characterized by “decreased homeostatic reserve and [consequent] diminished resistance to stressors due to cumulative declines across multiple physiologic systems that result in vulnerability to adverse outcomes” is increasingly important.<sup>71</sup> Multiple scales measure frailty; the early iterations assess phenotypic frailty<sup>72</sup> or accumulated deficits.<sup>73,74</sup> Later versions, such as the Edmonton Frail Scale<sup>75</sup> and Clinical Frailty Scale<sup>76</sup> are generally easier to apply in routine clinical practice. Although no frailty tools have been developed for predicting outcomes of continence treatments, frailty affects outcomes for many treatments offered to older adults including surgical treatments.<sup>77</sup>

Likewise, cognition is an extremely important factor to consider when evaluating older adults for any medical or surgical therapies. Not only are the cognition screening elements used to evaluate a patient's perioperative risk in all types of surgery,<sup>78</sup> but they also provide diagnostic information and clues to guide management. The recognition of an underlying neurocognitive disorder is key to developing treatment plans for older adults. Impaired cognition predicts a higher risk of delirium with new medications or surgical procedures and relevant decision-making may require a formal surrogate.<sup>79</sup>

Before any clinical encounter with an older adult, practitioners should screen for sensory impairment, particularly in vision and hearing deficits, to ensure that the patient is able to engage in the clinical interaction, this is even more important if cognitive testing is planned. Ensuring that patients are wearing their glasses and hearing aids respects their autonomy and ensures that they are best able to fully participate in decision-making. Healthcare professionals should also consider investing in voice amplifying devices for patients where hearing impairment may affect their participation in the interview and/or cognitive testing.

Appropriate physical, cognitive, and situational assessments and the resultant interventions not only reflect clinicians' professional responsibility to their patients, but also represent an ethical and moral imperative to respect a patient's values and goals of care, and provide the most appropriate, practical, and safe management plans.

There has been a marked rise in the absolute number of older people with multimorbidity.<sup>80</sup> Many medical conditions require a considerable effort in terms of self-management,<sup>81,82</sup> and the average patient spends 86 min per day managing a single condition.<sup>83</sup> Little consideration is given to capacity, ability, or limitations in managing daily care, particularly in the multimorbid patient. Although professionals are often encouraged to understand a patient's perspective, including their values and priorities, the factors underlying these values are poorly understood and often ambiguous, varying with disease diagnosis, the context in which the patient experiences that disease, and the decision at hand.<sup>84</sup> Adding additional workload may lead to diminished self-care, lower adherence to medications, worse treatment outcomes, and additional impairment in quality of life, and even potentially in blame and loss of the therapeutic relationship.

A useful framework when considering these matters in the context of management plans may be that of minimally disruptive medicine (MDM).<sup>85</sup> MDM describes a patient-centered and context-sensitive approach to care that focuses on achieving patient (and here also informed by the care partner) goals for health while imposing the smallest possible treatment burden on their lives. This approach requires a comprehensive view of the context in which the patient exists, and adjusting practice to fit patient needs, expectations, and complicated circumstances. The MDM framework recognizes the pre-existing impact of care upon the patient and care partner and strives to ensure that this is minimized, whilst maximizing healthcare outcomes in accordance with patient/care partner wishes and expectations.

When the burden of caring for any condition outstrips the available capacity to do so, patients may deprioritize care, making treatment failure more likely. This may affect UI more than other conditions, as it is often viewed as “less important” by clinicians and even patients themselves, but which potentially has a greater impact on the quality of daily existence.

To be ethical and effective, the MDM approach must be holistic, sensitive to context, and capable of accounting for and addressing the complex ways in which relevant factors exist and interact: this requires wisdom and empathy on the part of the clinician at multiple levels.

Such an approach may be contrary to modern interventionist medicine,<sup>86</sup> or may fly in the face of fee-for-service based compensation models, but it effectively facilitates legitimate patient partnership and engagement and respects the values and preferences of patients and

their care partners. The approach considers ways to acceptably fit health care into patient's lives and achieve the healthcare outcomes that they desire.

The MDM model requires that the care (which is agreed by clinician and patient) is identified and delivered in a timely and safe manner. This approach prioritizes those services which can deliver the most appropriate care, not necessarily the "best" care nor the most invasive. This care requires the participation of a multi-professional team, including the day-to-day caregiver, as noted by the recommendations of the International Consultation.<sup>37</sup> Here, to provide equitable, beneficial care the clinician needs to consider the impact of comorbid conditions which affect the ability of the older adult to successfully toilet and maintain continence, and that also take into account the impact of caring for those conditions when adding in management for UI.

To summarize, when engaging with older adults in shared decision-making around treatment options, it is critical that the assessment and subsequent discussion be based on objective assessment, not merely the patient's age, and take into account the burden of management of other coexisting medical conditions.

## 8 | CONCLUSIONS

Considering the aging of populations worldwide and the prevalence of UI in older adults, as well as barriers to care including ageism, there is a critical need for defining and promulgating ethical structures to model and guide equitable care for UI globally. This document addresses this imperative by expanding on contemporary ethical frameworks that provide the tools to allow healthcare administrators and medical professionals at all levels to construct and implement beneficent and just policies and protocols governing the care continuum from patient evaluation to treatment to aftercare. These ethical frameworks include the Four Ethical Principles and the Ethics of Care Model, augmented by the philosophies of RCC and MDM, each of which advocates holistic, compassionate, and individualized care that takes into account patient goals of care, thus respecting patient autonomy and preserving patient dignity. Extensive systematic transformation, which is thus being advocated, requires overcoming the inertia that commonly leads to the maintenance of a lower standard of care. This white paper is therefore intended to motivate and enable those who advocate for and effect reform in the delivery of continence care to older adults worldwide.

### Section 7 Summary

- Healthcare professionals should be aware of biases related to ageism, which can threaten the dignity and autonomy of certain older individuals.
- Healthcare professionals should be aware that chronological age is a poor predictor of physical and cognitive function, and should consider using objective measures to identify frailty and cognitive impairment.
- Healthcare professionals should take a holistic approach when treating and caring for older adults with urinary incontinence, with a particular emphasis on vulnerabilities such as frailty, impaired cognition, sensory impairment, and multimorbidity.
- Urinary incontinence is seldom the only medical problem that older adults face, therefore, care plans/approaches should be considered using a patient- and context-sensitive model, as exemplified by that of minimally disruptive medicine (MDM).

## Abstract

Urodynamics testing forms the cornerstone of investigations when it comes to lower urinary tract dysfunction. It has to be done to the highest standards by following the International Continence Society Good Urodynamics Practice protocols. However, with the COVID-19 pandemic, certain adaptations to the urodynamics procedure need to be considered especially when it comes to quality control. This article aims to define these adaptations to help urodynamicists in their daily practice.

## KEYWORDS

adaptations, COVID-19, International Continence Society, urodynamics

## 1 | INTRODUCTION

Urodynamics (UDS) forms the cornerstone investigation to assess the function and dysfunction of the lower urinary tract (LUT) and good urodynamics practice (GUP) guidelines have been published by the International Continence Society (ICS)<sup>1,2</sup> and the United Kingdom Continence Society.<sup>3</sup>

The spread of COVID-19 across the world has obviously affected the delivery of healthcare services. Female and functional urology (FFU) has probably been the hardest hit subspeciality in urology with massive cut down (Figure 1) in outpatient urological investigations and procedures and urological operations.<sup>4</sup> Most, if not all, guidelines have categorized FFU procedures into low priority with possibility of delaying such procedures beyond 3 months<sup>5-7</sup> unless there is an infected prosthetic device causing individuals to become unwell. Healthcare professionals have also been redeployed to help in other services and maintaining emergency care for COVID-19 patients.

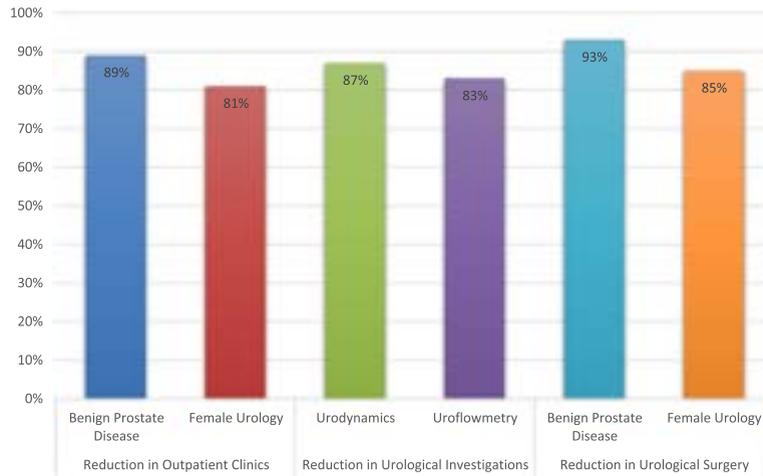

To that effect, several guidelines have been published prioritizing surgeries and suggested converting face-to-face consultations to telephone or video consultations to reduce person-to-person contact.<sup>8</sup> However, none of these guidelines cater for adaptations of an invasive UDS test during the COVID-19 pandemic which obviously involves coming into close contact with patients and patients coughing during the investigation to check for quality control or effort/stress leakage. Below we describe the adaptations necessary in an UDS investigation during the COVID-19 pandemic to reduce the risk of infection to patients and urodynamicists while maintaining GUP.

## 2 | ADAPTATIONS OF PRIORITISING UDS TESTING

It is reasonable to suppose that in several centers the availability of UDS services (in terms of human resources, offices availability, and reduction of the executable examinations per day, due to social distancing) will

This is an open access article under the terms of the Creative Commons Attribution-NonCommercial-NoDerivs License, which permits use and distribution in any medium, provided the original work is properly cited, the use is non-commercial and no modifications or adaptations are made.

**FIGURE 1** Overall percentage reduction in female and functional urology activity worldwide

be reduced while the pandemic subsides. In this case, centers should consider different priorities for different cases. The priority criteria used for surgical procedures (Table 1) could also be used to prioritize urodynamic studies.<sup>9</sup> The main considerations would be whether performing the UDS test would alter the current treatment of the patient and also when after the UDS test will an operation be performed. There are no P1 (Emergency/Urgent) priority indications for invasive UDS that we have identified.

**2.1 | High priority (P2)**

Neurogenic patients at risk for upper urinary tract deterioration (eg, spinal cord injury or spinal dysraphism patients and some multiple sclerosis patients<sup>10-12</sup>) should be given the higher priority.<sup>12</sup> Same priority may be given to patients with suspected poor compliance (eg, affected

by radio-cystitis) in which a urinary diversion or bladder augmentation is or could be planned as a P2 priority or those due for a kidney transplant.

If UDS is considered necessary or useful in patients waiting for second stage surgery for sacral neuromodulation (eg, implant of the pulse generator) then they should be investigated as soon as possible before the surgical procedure and ideally within 4 weeks of the advanced timed lead implant.

**2.2 | Intermediate priority (P3)**

Male patients with benign prostatic obstruction have low priority for surgery unless they have an indwelling urinary catheter which is getting blocked with calcifications or needing regular changes; in this case, urodynamic investigation, if indicated, should be performed just before the surgical procedure which needs to be planned as soon as possible after the acute phase of the pandemic.<sup>5,12</sup> These patients may be considered in the intermediate priority group, thus not to be postponed more than 3 to 4 months. The same priority may be given to female patients with pelvic organ prolapse and hydronephrosis or vaginal ulcers.

**2.3 | Low priority (P4)**

All other indications for urodynamic investigation (overactive bladder, urgency or stress urinary incontinence, male

**TABLE 1** Prioritization of urological procedures

Priority level (P)	Type	Timing of operation/procedure
P1a	Emergency	Needed within 24 h
P1b	Urgent	Needed with 72 h
P2	High	Can be deferred up to 4 wk
P3	Intermediate	Can be delayed for up to 3 mo
P4	Low	Can be delayed for more than 3 mo

LUTS, neurogenic bladder without risk for the upper urinary tract) may be given a low priority.

### 3 | ADAPTATIONS PRIOR TO UDS TESTING

#### 3.1 | Patient risk assessment

When deliberating the order of patient bookings, a basic risk assessment may be beneficial. Clinical need is the priority (as above), but subsequent to this there should be a consideration of patient risk. An assessment based on reported risk criteria<sup>13</sup> may allow departments to identify low, moderate, and high-risk patients. The latter of which requires careful consideration and elevated levels of COVID-19 risk management.

#### 3.2 | Preurodynamic appointment

Departmental variation is common for urodynamic procedures, but for those who perform an in-depth patient history, it is recommended that this is conducted via a telephone consultation before the hospital-based appointment. This ensures that exposure time is minimized for both staff and patients.

A comprehensive patient history should also ensure the appropriateness of the referral, guaranteeing patient appointments are well utilized. On consultation, it is also advisable to outline the precautions the department is taking to reduce the COVID-19 risk; allowing patients the opportunity to postpone investigations should they wish.

#### 3.3 | Number of cases

In accordance with Public Health England guidance,<sup>14</sup> urodynamic tests are not considered to be aerosol-generating procedures. As such, there is no current need for full air change in the room and thus no regulations pertaining to the period of time between patients. This said, there are a number of factors which will dictate the volume of patients that are seen safely. These include sufficient time to perform an intensive room clean as agreed by local infection control, as well as the overall volume of patients within waiting areas and transiting corridors, where 2 m distancing is problematic. The risk of patients crossing in confined areas can be mitigated by introducing one-way systems. However, it is important to be mindful of patients' mobility and the distance they are requested to walk especially from reception to the UDS suite.

#### 3.4 | Route into the department

Independent travel to the hospital should be encouraged, with patients using personal forms of transport rather than public transport where possible. Upon arrival at the department, they should be promptly collected from general waiting areas and escorted to a Personal Protective Equipment (PPE) station, where they can be assessed in private. Current symptoms (fever, new-onset cough, loss of taste/smell etc) can be enquired about (see GOV.UK for up to date symptom list), patient temperature performed (>37.8°C need to be rebooked), and basic preventative measures such as hand-gel and face masks can be administered. Staff should be encouraged to take responsibility for their own safety and PPE outside of the clinical rooms. Face masks may be an appropriate measure, but local agreement on the use of PPE is recommended. Patients should be escorted in and out of the department in a timely fashion, ensuring their hospital visit is as short as possible. The UK government has now suggested that anyone going into hospital, including staff, should use a face covering.

### 4 | ADAPTATIONS DURING UDS TESTING

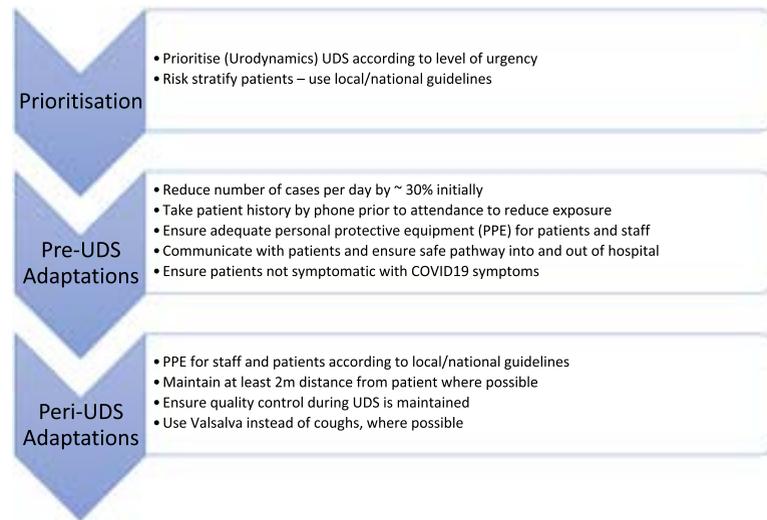

Guidelines for preventing infection transmission carried by airborne or surface droplets will clearly have an impact on urodynamic procedures.

#### 4.1 | Personal protective equipment

In addition to the normal use of single-use gloves and aprons by the urodynamicist, single-use surgical face masks are recommended for both patients and staff.<sup>15</sup> Given that body fluids, contact and coughs are conducted in UDS procedures, eye protection in the form of a face visor is also recommended.<sup>15</sup> Standard UDS clinic rooms are acceptable, since negative pressure rooms are not required and positive pressure rooms are not recommended,<sup>15</sup> however a period for cleaning the room is needed between each patient. There is no need for patients to wear gloves as per advice from infection control staff but patients will either use hand-gel or wash their hands for 20 seconds before entering and leaving the UDS room. We recommend that local and national guidelines are adhered to with regard to PPE.

#### 4.2 | Physical distance

Wherever possible, a distance of 2 m should be maintained between staff and patient. Clearly, for procedures

**FIGURE 2** Summary of adaptations for urodynamic testing

such as catheterization and examination of the patient this is impossible. Precautions must, therefore, be taken in the form of PPE as above and adjusting elements of the test to allow observation from a distance of at least 2 m. Where urinary leakage needs to be observed, especially in women, the patient should be asked to stand or squat over a pad on the floor, rather than sit on the flow-meter, in order that leakage can be seen from further away. During video UDS, fluoroscopic screening can provide evidence of urethral leakage and will be sufficient for a diagnosis of urodynamic stress incontinence (USI).

### 4.3 | Coughing and Valsalva

A key test for signal quality and for USI is coughing by the patient. As this will result in airborne particles being generated, coughing should be kept to an absolute minimum and always with a mask in place. Quality control can be carried out effectively by a Valsalva manoeuvre<sup>16</sup> or even by gentle external pressure on the abdomen by the patient, thus coughing is not needed in this case. For stress testing, again a Valsalva manoeuvre or other physical provocations can be attempted first, and only then if required, the patient be asked to cough. In that case, the cough must be directed away from others in the room and shielded by an elbow or by a handheld tissue that is then discarded, since the mask itself must not be touched during use.<sup>15</sup> The patient is then given a hand-gel to use. For the same reason, if the patient is unable to push against a closed glottis to perform a Valsalva,

they can again use a tissue over the mask to close their nose and mouth while raising lung pressure.

## 5 | CONCLUSION

Urodynamic tests are crucial diagnostic tests in FFU. It is, therefore, imperative that these tests are carried out according to the ICS GUP guidelines. However, in view of the COVID-19 pandemic, certain adaptations need to be followed to maintain good quality testing and obtaining meaningful results (Figure 2).

## Abstract

Coronavirus disease-2019 (COVID-19) pandemic significantly altered our daily life as well as our professional practice. COVID-19 has disrupted our lives both professionally and personally. We know the urological management in a neurogenic patient needs to be tailored to the individual circumstances, this is even more pertinent during these uncertain times. International Continence Society is the premier international organization in functional urology. Lately, it has established an institute to facilitate teaching and training opportunities all over the world. The School of Neurourology teamed with the School of Modern Technology and set up a Webinar—"How to manage the neurourological patients in the current pandemic." This was set up as a case-based discussion to deliberate the management of our patients in the present climate and examine the role of modern technology in overcoming the current barriers.

## KEYWORDS

COVID-19, neurourology, technology, telemedicine

## 1 | CURRENT STATUS OF COVID-19 DISEASE AROUND THE GLOBE: THE ROLE OF ICS SCHOOLS IN THIS PERIOD—WEBINAR-BASED TEACHING

We are living in an unprecedented time. Coronavirus disease-2019 (COVID-19) has disrupted our lives both professionally and personally. In these challenging times, the demand on health care has put enormous pressure on all of us. We not only have to look after patients with COVID-19 but additionally have to provide ongoing care to our existing patients, quite a significant proportion of them have challenging health care needs. We know the urological management in a neurogenic patient needs to be tailored to the individual circumstances, this is even more pertinent during these uncertain times.

International Continence Society (ICS) is the premier international organization in functional urology. Lately, it has established an Institute to facilitate teaching and training opportunities all over the world. The ICS Institute brings together experts from around the globe. The directors of the institute feel at this time of international crisis to utilize ICS platform to share the challenges we are all facing in managing our patients. We feel in the current environment that our colleagues need support with some recommendations that can not only help to keep our patients safe but also alleviate apprehensions in both health care givers and patients which we are still looking after our neurogenic patients in the current climate in the best way possible, in addition to, playing our part in supporting the wider efforts to control the crises facing us.

The School of Neurourology teamed with the School of Modern Technology and set up a Webinar—“How to manage the neuro-urological patients in the current pandemic.” This was set up as a case-based discussion to deliberate the management of our patients in the present climate and examine the role of modern technology in overcoming the current barriers.

## 2 | COMMENTS AND QUESTIONS FROM DELEGATES IN WEBINAR AND OUR COMMENTS

Institute Directors Rizwan Hamid (School of Neurourology) and Emre Huri (School of Modern Technology) conducted a live case-based discussion on Friday, 24th April 2020. The experts discussed the challenges in current management of neurogenic bladder with a case of multiple sclerosis as a reference. The main aim was how to use modern technology, alternative management strategies, and how functional urologists and neurourologists can manage their patients in the current pandemic with COVID-19.

The webinar was very well attended, and there were 25 comments from the participants. As one would expect, the comments reflected the varying practice from different parts of the world. However, there was a common theme that all physicians have stopped elective surgery and face to face consultations for neurogenic patients. There appeared to be an increasing use of modern technology with telemedicine and apps to communicate with patients. There was some concern with regard to the patients with high pressure bladders, it was felt that without adequate follow-up and not performing botulinum toxin A (BTX-A) injections, the upper tracts may be at risk. It was also suggested to carry out local anesthesia procedures with adequate personal protection to ensure the patients at risk continue to receive the treatment they require.

## 3 | EVALUATION OF GUIDELINES FOR MANAGEMENT OF NEUROUROLOGY PATIENTS

There has been a variety of recommendations and guidelines from various international organizations during this pandemic. This includes European Association of Urology,<sup>1</sup> ICS,<sup>2</sup> British Association of Urological Surgeons,<sup>3</sup> and National Institute for Health and Care Excellence.<sup>4</sup> All organizations acknowledge that most of these are recommendations based on expert opinion and need to be tailored to local health care systems and needs.

In addition, it must be emphasized that different countries are at different points of the pandemic. All have unique set of challenges that need to be taken into account whilst adjusting services in these uncertain times.

Accepting these limitations, most of the organizations have proposed the following recommendations in the management of a neurourological patient.

1. All planned surgical procedures for neurourological indications should be postponed (except as listed below).
2. All face to face out-patients appointments should be cancelled.
3. Encourage clinicians to undertake telephone and video consultations where possible. This will not only help alleviate patients concerns that they have not been forgotten but can also identify those patients in need for urgent consultations.
4. The patients already admitted to rehabilitation units and neurology wards would have ongoing neurourological issues. These patients need to be provided with urological input but adequate personal protection equipment should be worn as per local protocols to minimize the risks to health care professionals.
5. No elective surgical procedures should be undertaken (except as below).
6. All urodynamic studies should be postponed both on in-patients and out-patients.

### 3.1 | Emergencies

These would continue to be managed as per existing protocols. The specific indications for our patients would be: problems with catheter blockage, urosepsis requiring hospitalization, and patient is going into renal failure

### 3.2 | Modern technology

We feel modern technology and telemedicine have acquired a central role at this time. Many of our neurourological patients are young and “tech savvy” and with recent modifications can use smart phones.

## 4 | NEUROUROLOGY PATIENTS CHALLENGES IN COVID-19 OUTBREAK

Patients with neurogenic bladder dysfunction are challenging because of their potential susceptibility to COVID-19 infection. All scheduled elective surgeries and

office visits were cancelled by many national health authorities.<sup>5</sup> As patients cannot be diagnosed with urodynamic evaluation or treated with invasive therapies like BTX-A, we have to devise alternative ways to keep patients safe and provide reassurance. During this unprecedented period, when there can be problems with patient safety due to the recommendation for deferring even minimally invasive surgery. The possible overlap of COVID-19 clinical syndrome with different conditions, such as urosepsis in neurourology patients, should be recognized and merits appropriate investigation. Regular follow-up with telemedicine or phone calls for preservation of continent status, avoidance of urinary tract infection, upper urinary tract safety, preservation of quality of life, and evaluation of economic and social circumstances should be considered. In high risk patients with maximum detrusor pressure greater than 40 cm H<sub>2</sub>O, low bladder compliance, risk of autonomic dysreflexia, recurrent urinary tract infections, and recent changes in the upper urinary tract, it is probably advisable to undertake intradetrusor BTX-A injections under local anesthesia where possible.<sup>6</sup> Though, this would be dependent on local protocols and the changing situation in the country.

## 5 | TECHNOLOGY-BASED TOOLS IN PANDEMIC: TELEMEDICINE, 3D PRINTING TECHNOLOGY, AI-BASED APPLICATIONS AND DIGITAL HEALTH

The use of modern technology by health care professionals is not only dependent on the availability of the technological services in a country but also related to cultural, economical, and social values. This results in varied utilization of technology from country to country during COVID-19 outbreak. However, a number of neurourology patients are young and tech savvy and keen to use various platforms to get more information regarding diagnosis and treatment of their condition. The health care professional should encourage the neurological patients to use technology to identify the urological problems and discuss with health care givers to formulate appropriate management strategies during this COVID-19 epidemic.

Telemedicine is the main technology-based tool to keep neurourological patients out of hospital environment. It is bridging the gap between people, physicians, and health systems, enabling everyone, especially symptomatic patients, to stay at home and communicate with physicians through virtual ways, helping to decrease the spread of the virus to populations and the medical staff

on the frontlines. For patients on medication, to continue the prescriptions, official software approved by local regulators will be helpful to the patients that need topping up of long-term medication.

Telemedicine use has increased 10-fold after the outbreak. However, it should be kept in mind that this enhanced usage of telemedicine for patient communication raises a number of medicolegal issues, concerns about informed consent, adherence to data protection and security law, and the technical support to run these systems. Some of these can be minimized by use of self-control system like Chatbot. This can help the patients in getting information about one's own situation by inputting the required data and following the computer-generated advice. The simplest telemedicine application is phone call or videoconference. It is recommended to use a licensed product and that would not only be reliable but would also have adequate safeguards for data protection. The appointments can be scheduled as routine but in place of face to face the patient would have a telephone consultation. In addition the physiotherapy and teaching session like self catheterization can be taught and monitored over video consultations.

We need to advise the patients for using artificial intelligence-based smartphone applications for prevention and follow-up for COVID-19. Giving instruction to the relatives of patients is the most important issue that we should take into account. On the other hand, 3D medical printing for production mask and shield, or small useful medical apparatus, is another technology-based solution for health care professionals.

COVID-19 can negatively effect to mental health of the population as people are forced to stay indoors for many days. In these trying times, digital health apps are providing help. On the other hand, with over 3 billion social media users worldwide, social media has a good tool outreach across all age groups.<sup>7</sup>

## 6 | SUMMARY

The aim is to keep our neurourological patients out of the hospital environment as much as possible. A significant proportion would be considered a high risk group in the current circumstances. However, we need to reassure them, probably with virtual clinics, that their urgent issues (as mentioned above) need to be dealt with in the most safe and effective manner. It would be imperative to follow the local protocols and guidelines in the ever changing fight against this pandemic so the management can be tailored to the individual needs in the context of local available resources. Telemedicine provides face to face communication better than phone calls providing

the evaluation of patient environment, patient physical status, and is also helpful for solving catheterization problems. Virtual channels, including contact tracing systems, wearables, and AI-based applications, should be used by patients to increase the awareness of COVID-19 risks.

## 7 | FUTURE DIRECTIONS

There is a lot of evidence<sup>8,9</sup> that the patients and health care physicians feel quite comfortable with the use of telemedicine, AI-based apps, and modern technology to deliver at least some aspects of health care. This is even more relevant for our neurourology patients who want to keep in touch with health care providers and want reassurance that they are safe but quite often do not want to make the long journey to the hospital with their complex needs.

It is envisaged that there will be a significant use of modern technology to communicate with neurourology patients even after the COVID-19 pandemic is over. Telemedicine will be used to evaluate the patients and carry out follow-up consultations. This can keep the most vulnerable patients out of the hospital and help to fast track patients that need to be seen for necessary investigations and offered appropriate treatment.

We wish the best to all our colleagues and patients.

## Abstract

**Aim:** Lower urinary tract symptoms (LUTS) are a common urological referral, which sometimes can have a neurological basis in a patient with no formally diagnosed neurological disease ("occult neurology"). Early identification and

This is an open access article under the terms of the Creative Commons Attribution-NonCommercial License, which permits use, distribution and reproduction in any medium, provided the original work is properly cited and is not used for commercial purposes.

© 2020 The Authors. *Neurourology and Urodynamics* published by Wiley Periodicals LLC

specialist input is needed to avoid bad LUTS outcomes, and to initiate suitable neurological management.

**Methods:** The International Continence Society established a neurological working group to consider: Which neurological conditions may include LUTS as an early feature? What diagnostic evaluations should be undertaken in the LUTS clinic? A shortlist of conditions was drawn up by expert consensus and discussed at the annual congress of the International Neurourology Society. A multidisciplinary working group then generated recommendations for identifying clinical features and management.

**Results:** The relevant conditions are multiple sclerosis, multiple system atrophy, normal pressure hydrocephalus, early dementia, Parkinsonian syndromes (including early Parkinson's Disease and Multiple System Atrophy) and spinal cord disorders (including spina bifida occulta with tethered cord, and spinal stenosis). In LUTS clinics, the need is to identify additional atypical features; new onset severe LUTS (excluding infection), unusual aspects (eg, enuresis without chronic retention) or “suspicious” symptoms (eg, numbness, weakness, speech disturbance, gait disturbance, memory loss/cognitive impairment, and autonomic symptoms). Where occult neurology is suspected, healthcare professionals need to undertake early appropriate referral; central nervous system imaging booked from LUTS clinic is not recommended.

**Conclusions:** Occult neurology is an uncommon underlying cause of LUTS, but it is essential to intervene promptly if suspected, and to establish suitable management pathways.

#### KEYWORDS

incontinence, lower urinary tract symptoms, neurology, neurourology, overactive bladder, overactive bladder

## 1 | INTRODUCTION

Lower urinary tract symptoms (LUTS) are highly prevalent and a major cause of urological referral. The majority reflect uncomplicated presentations, such as overactive bladder (OAB) or benign prostate enlargement. LUTS are also a significant feature in neurological disease.<sup>1</sup> Notably, there are some neurological conditions where LUTS can be an early symptom in the presentation of the disease. Consequently, a situation can arise where LUTS assessment might be requested and the underlying neurological disease is still undiagnosed. Two major dangers inherent in failing to identify an undiagnosed neurological etiology are risks of deterioration of the neurological conditions, and of poor outcomes for LUTS treatment, potentially due to inappropriate surgery or symptom deterioration. Suitable neurological management for the underlying condition is needed

- to establish a correct diagnosis and prognosis,

- to actively manage the neurological condition by obtaining early specialist input,
- to minimize disease progression through early treatment (especially for multiple sclerosis [MS]),
- to avoid predictable adverse events during invasive diagnostics and after surgical therapy,
- for the maintenance of a patient-centered approach to management, and
- for patients to adapt their life according to prognosis.

Healthcare professionals (HCPs) from various disciplines, notably doctors, nurses, continence advisors, and physiotherapists, may be responsible for initial assessment of these patients. Accordingly, these HCPs need to remain alert to patients with subtle symptoms and clinical signs that should be further explored and who might need an additional referral to exclude or identify an, as yet, undiagnosed neurological condition. For this to be effective, they must be aware of potential pathways

of evaluation, to ensure the possibility is appropriately addressed.

This consensus considers situations where LUTS could be a presenting complaint preceding the identification of an underlying neurological disease,<sup>2</sup> hereafter referred to as “occult neurology.” This consensus document gives brief outlines of neurological conditions in which LUTS arise relatively early in the disease course, and presents an approach to assessment of a patient where the receiving clinician suspects there could be an undiagnosed neurological condition.

## 2 | METHODS

The International Continence Society (ICS) established a working group whose remit was to consider:

1. Which neurological conditions may include LUTS as an early feature?
2. What diagnostic evaluations should be undertaken in the LUTS clinic, and which should be left to specialist expertise?

The qualitative method of nominal group technique was utilized to generate initial content (key relevant conditions) in response to the remit. An iterative group dialogue for a panel of neurological and neurosurgical specialists was used to draw up a shortlist of conditions, with two rounds of blind voting to finalize the list. The list was then presented for open discussion at the annual congress of the International Neurourology Society, Istanbul, 2020. The ICS then established a multidisciplinary working group to generate recommendations for identifying clinical features and management, which worked remotely due to the widely dispersed international representation.

## 3 | RESULTS

### 3.1 | Neurological conditions where LUTS can be an early feature

The following conditions may present for LUTS assessment before a neurological condition has been recognized, because LUTS are potentially an early feature in the disease course. The underlying processes commonly involve demyelination, neurodegeneration, or developmental abnormality, for which some archetypal conditions are listed in Table 1. The main conditions responsible include the following.

#### 3.1.1 | MS and related neuroinflammatory disorders

The most common progressive neurological disease affecting younger people with onset around 20 to 40 years of age. It is more common in women than men. It can impair function of any part of the central nervous system by demyelination and axonal loss (Table 1). It is a progressive condition, but the rate and pattern of progression varies (the progressive clinical course usually becoming evident after 10-20 years after diagnosis). Commonly, there is abrupt deterioration (relapse) lasting days to weeks as a new demyelination event starts, followed by (often incomplete) improvement. Neurological symptoms are typically monocular loss of vision, double vision, sensory loss, weakness, and ataxia. A variety of disease-modifying medications are available. The exact pattern of LUTS is diverse, while severe incontinence is mainly seen in the late stages of the disease.

Transverse myelitis due to other inflammatory causes can occasionally present as urinary retention with few neurological signs because of predilection for conus involvement, particularly when associated with antibodies against Myelin oligodendrocyte glycoprotein (MOG antibody transverse myelitis); persisting urogenital and bowel dysfunction is common despite motor recovery at followup.<sup>15</sup>

#### 3.1.2 | Multiple system atrophy

A progressive sporadic adult-onset neurodegenerative disorder (Table 1). Prevalence is 8 per 100 000 among people older than 40 years of age. It affects men and women equally and has an average age onset of approximately 55 to 60 years. The mean life expectancy is 6 to 10 years following diagnosis. Clinical symptoms are subdivided into extrapyramidal, pyramidal, cerebellar, and autonomic symptoms (notably postural hypotension). Extrapyramidal symptoms include bradykinesia, rigidity, and postural instability, resembling Parkinson's disease (PD). Nonmotor symptoms, such as sleep and cognitive disorders, respiratory problems, and emotional/behavioral symptoms, might also occur during disease development. The different symptoms can be used to categorize multiple system atrophy (MSA) into the Parkinsonian subtype (MSA-P) and the cerebellar subtype (MSA-C). MSA-P predominates in Western countries, while MSA-C is more common in Japan. The condition may initially present with bladder dysfunction, particularly urinary retention.<sup>16,17</sup> For men, erectile dysfunction (ED)<sup>18</sup> is commonly an earlier feature than LUTS; the

**TABLE 1** Archetypal neurological conditions, which may include lower urinary tract symptoms as an early feature

Classification (mechanism)	Archetypal condition	Early urological features	Early neurological features	Epidemiology	Similar conditions
Demyelinating disorder Focal CNS white matter demyelination	Multiple sclerosis	Urinary urgency (62%–65%), frequency (50%), UUI (45%), nocturia (33%), <sup>3,4</sup> SUI 31%. ED 53%. UDS; DO with DSD, detrusor underactivity. Fecal incontinence and/or constipation (40%) <sup>5</sup>	May report unilateral painful loss of vision, paraesthesias or motor deficit <sup>6</sup>	Peak onset: 30–40 y. Rare before puberty and in the elderly. Estimated incidence (Europe) <20 - >200/100 000 <sup>7</sup> Median time to death 30 y from onset depending on subtype <sup>6</sup>	Transverse myelitis. Neuromyelitis optica
Neurodegenerative disorder	Multiple system atrophy	Difficulty voiding/nocturia are most common, also urgency and UUI <sup>8</sup> ED is an early feature In cerebellar MSA, 83% have ED at diagnosis, 58% have urinary incontinence and 50% have OAB	Postural hypotension and incoordination are common presenting symptoms. Slow movement, slurred speech, poor balance, and fainting (syncope) also commonly occur	Mean age of onset is 54 y, with survival 7–9 y. UK prevalence 4.4/100 000 <sup>9</sup> Slight male preponderance	Alzheimer's dementia. Parkinson's disease. Progressive supranuclear palsy
Developmental disorder	Ocult spinal dysraphism, including SBO and tethered cord	Variable features. SBO, OAB, <sup>10</sup> incontinence, enuresis. With tethered cord, urgency and UUI are common. UDS; DO 42%, low compliance 67%. <sup>11</sup> DSD and sensory abnormalities can occur <sup>12</sup>	SBO often asymptomatic. Dimple/hair tuft on the back. Maybe posture changes, with altered spinal curvature. Tethered cord can include impaired lower limb or bowel function <sup>13</sup>	Congenital, reducing prevalence. <sup>14</sup> Unlikely to influence survival	Syringomyelia (developmental or acquired)

Abbreviations: CNS, central nervous system; DO, detrusor overactivity; DSD, detrusor sphincter dyssynergia; ED, erectile dysfunction; MSA, multiple system atrophy; NPH, normal pressure hydrocephalus; OAB, overactive bladder; SBO, spina bifida occulta; SUI, stress urinary incontinence; UDS, Urodynamics; UUI, urgency urinary incontinence.

reviewing HCP considering this possibility needs to enquire about ED, since men commonly do not report the symptom unless the topic is raised.

### 3.1.3 | Parkinson's disease

A neurodegenerative condition with the key motor symptoms of tremor, rigidity, and bradykinesia affecting motor control, which is also associated with prominent nonmotor symptoms. Early PD can cause storage LUTS, and motor symptoms may be mild. A useful feature to look out for is a unilateral low frequency pill-rolling tremor affecting the upper limb (or leg). Established PD manifests obvious motor features (shaking, rigidity, slowness of movement, and difficulty with walking); once it has reached this stage, PD will generally have been diagnosed.

PD patients usually report nocturia, urgency, and difficulty voiding and present with detrusor overactivity (DO) on urodynamics.<sup>19,20</sup> Voiding dysfunction increases with neurological disability (for men and women), correlating with the extent of dopamine depletion.<sup>21,22</sup> In some male patients, benign prostatic obstruction can occur concomitantly with PD, and therefore selection of patient for possible prostate surgery should be done with great care to avoid possible urinary incontinence.

### 3.1.4 | Normal pressure hydrocephalus

Normal pressure hydrocephalus (NPH) is characterized by communicating enlargement of cerebrospinal fluid (CSF) ventricles, with normal intraventricular pressures. The enlargement is associated with stretching of periventricular fibers of the corticospinal tract in the brain, which impairs bladder control. DO is a typical finding on urodynamics. As it is substantially underdiagnosed, the actual worldwide incidence and prevalence have not been defined; in Japan it was estimated at around 1% of older adults (over 65).<sup>23</sup> The classic triad is abnormal broad-based shuffling gait, urinary incontinence and dementia (short term memory impairment), but about half present with gait abnormality only as the initial feature. There may be only mild cognitive impairment at the time the patient starts to experience urinary symptoms. Treatment is with placement of a ventriculoperitoneal shunt by a neurosurgeon and can lead to symptom resolution/prevention of progression.

### 3.1.5 | Dementia

A group of neurodegenerative conditions (including Alzheimer's disease, vascular dementia, dementia with

Lewy bodies and frontotemporal dementia), with wide-ranging effects on memory, cognition, and personality. LUTS are more common in people living with dementia than those without dementia.<sup>24</sup> In certain forms of dementia, such as dementia with Lewy bodies, LUTS are more likely to be an early feature of the disease. LUTS tend to be a later feature in Alzheimer's disease.<sup>25</sup>

### 3.1.6 | Spinal cord conditions

A range of situations may affect the spinal cord directly (Table 1), while degenerative spine conditions may affect the spinal cord secondarily, for example, by causing lumbar spinal stenosis or cervical myelopathy. There may be little in the way of localizing symptoms. The archetypal condition is spina bifida occulta (SBO) and tethered cord, in which a developmental abnormality fixes the lower part of the spinal cord, placing it at risk by stretching and distortion as the person grows. Affected patients are often asymptomatic until late childhood or adulthood, then presenting with back pain and LUTS. Syringomyelia is a problem with the central CSF canal in the spinal cord, which can lead to compression of the surrounding spinal cord tracts; this can occur in SBO.

Other conditions include:

- a tumor of the spinal cord or vertebral column and
- spinal stenosis, leading to claudication and LUTS.

Prolapsed intervertebral disc (lumbar disc prolapse) is usually easily diagnosed from the association of urinary retention (painless) with severe back pain, nerve root pain (eg, sciatica), loss of range of movement, and bowel dysfunction. However, back pain is sometimes not prominent, notably where there is central disc prolapse with little impingement on the spinal roots.

## 3.2 | Evaluation where there is a possible occult neurological mechanism

For the HCP, the fundamental issue is to identify a situation where LUTS are present alongside other unexplained symptoms, which are atypical for a LUTS presentation. This must then trigger an onward referral to an appropriate specialist (neurology or neurosurgery), or an alert to the patient's primary care physician. HCPs in the LUTS clinic are not required to make the neurological diagnosis, but they must remain vigilant to the possibility of a neurological disorder and seek relevant expertise (neurological consultation) where needed.

Situations in which HCPs should suspect possible occult neurology:

- New onset severe LUTS not caused by urinary tract infection.
- Association with unusual features not typically seen in LUTS presentations.
- Presence of other “suspicious” symptoms, such as altered speech, vision, or balance.

- Exclusion of features, which are possible indicators of serious underlying mechanism, for example, infection/inflammation, or malignancy.
- Concomitant bowel or sexual dysfunction.

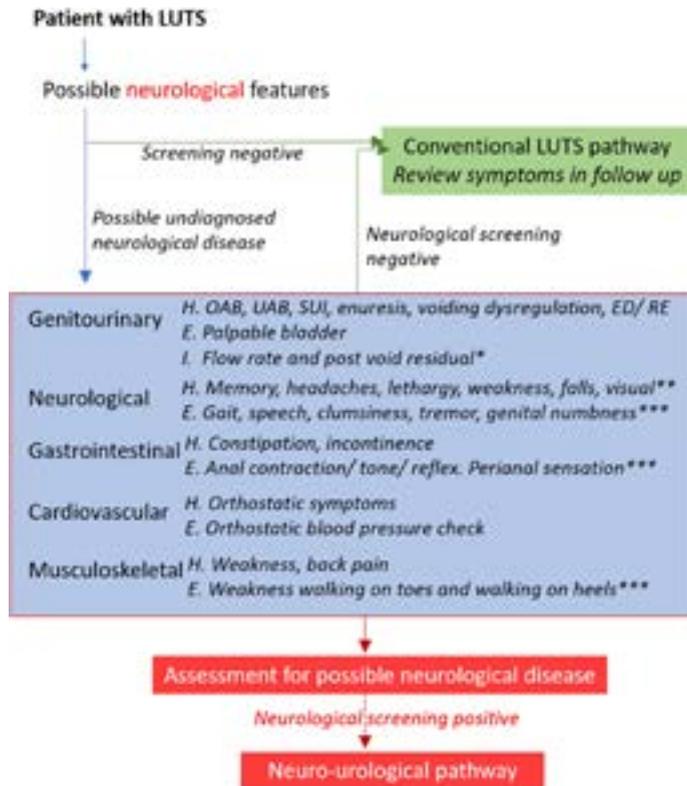

Any neurological feature might, but not necessarily, have a similar time course to the LUTS. If the initial impression suggests there could be an occult neurological problem, the practitioner should evaluate key indicators that may increase the index of suspicion. A summary is presented in Figure 1. This assessment includes looking for:

### 3.2.1 | History and examination

All consultations on LUTS involve a basic assessment undertaken according to the relevant guidelines.<sup>18,26,27</sup> The details of basic LUTS assessment are not given in detail here, but guidelines include assessment of:

- Evaluation of the severity and bother associated with each LUTS.
- Consideration of possible pathophysiology and differential diagnosis.

1. Urological symptoms or findings
  - (a) Severe/rapid onset OAB maybe with urgency incontinence.
  - (b) Difficulty initiating voiding and prolonged duration. Flow rate test may suggest straining, and there may be a post void residual.
  - (c) Changes in bladder sensation, including reduced or absent bladder sensations.
  - (d) Dysuria in the absence of urinary tract infection (this may indicate detrusor sphincter dyssynergia).

**FIGURE 1** Summary of key clinical evaluations in LUTS clinic in the event of a possible undiagnosed neurological disease. E, examination; ED, erectile dysfunction; H, history; I, investigation; LUTS, Lower urinary tract symptoms; RE, retrograde ejaculation. \*Flow rate test may suggest straining/post void residual. \*\*Double vision/loss of acuity. Multiple sclerosis can cause transient unilateral loss of vision some years previously. \*\*\*Nerve supply is from the sacral spinal cord, and is a consequence of weak plantar flexion and dorsiflexion

2. Unusual urological symptoms or examination findings
  - (a) Enuresis.
  - (b) Voiding dysregulation, that is, urination in situations, which are generally regarded as socially inappropriate, such as while still fully dressed, or in a public setting away from toilet facilities.<sup>28</sup>
  - (c) Involuntary voiding, that is, sporadic bladder emptying when awake, without intention to void.<sup>28</sup>
3. Indicators of lower urinary tract muscle weakness
  - (a) Abdominal straining for voiding.
  - (b) Stress urinary incontinence (and possibly fecal incontinence), particularly in nulliparous women and younger men with no previous lower urinary tract surgery.
  - (c) Retrograde ejaculation.
4. Symptoms or findings in other organ systems, which are heavily dependent on neurological control or likely to be affected by a relevant condition
  - (a) Gastrointestinal, for example gastroparesis, constipation, reduced anal tone.
  - (b) Cardiovascular for example orthostatic hypotension.
  - (c) Musculoskeletal.
  - (d) Autonomic, for example loss of salivation, loss of sweating, and impaired thermoregulation. In PD and MSA there may be drooling (sialorrhoea).
5. Features of one of the neurological conditions listed above
  - (a) MS; motor or sensory deficit, transient unilateral visual disturbance (previous optic neuritis).
  - (b) MSA; ED, orthostatic hypotension, unilateral tremor, slow movement, postural instability.
  - (c) PD; Stooped posture, lack of facial expression, quiet and hoarse speech, slowness of movement especially visible during walking, and shaking (tremor)—more often seen unilaterally in the hand while walking or at rest and classically “pill-rolling” in nature.
  - (d) NPH; gait disturbance, urinary incontinence, cognitive impairment.
  - (e) Dementia; memory and personality changes.
  - (f) Spinal cord problem; limb weakness, sensory changes, back pain.

Observation of or assessment for gait, tremor, speech, and clumsiness can easily be made in clinic. It is worth noting any history of essential tremor, as this might be confused with a parkinsonian tremor, but does not need neurology referral. Essential tremor typically presents with bilateral postural hand tremor and can also affect the head and voice, has a family history, and improves with beta blockers or alcohol.

### 3.3 | Additional assessment for possible neurological disease

In the event that history and examination are consistent with the possibility of occult neurological disease, the responsible practitioner needs to consider the following.

1. Steps to confirm or exclude the neurological diagnosis:
  - (a) The HCP treating LUTS should refer for a formal specialist opinion. Direct referral is preferable, for reliable and prompt assessment.
  - (b) The consensus panel does not recommend the use of MRI scanning or other imaging modality from the LUTS clinic. This is best arranged from the neurology clinic, in consultation between the neurology and neuroradiology services, because it is crucial that the correct part of the neuraxis is scanned and the appropriate settings are used.
  - (c) The referral should be made immediately, without waiting for the results of urodynamic testing (due to the potential delay). If urodynamics have already been done, the results can be included in the referral. Subsequent urodynamic tests can be forwarded when available.
  - (d) Neurological consultation and investigation following referral may not necessarily attain a confirmatory diagnosis; urological follow up is nonetheless appropriate, and re-referral to neurology may be needed in the event of subsequent change in symptoms or apparent deterioration.
2. Adaptations of the urological assessment pathway:
  - (a) The role of urodynamic testing should be re-evaluated; if not already done, they may be delayed pending receipt of the neurological evaluation, to decide how the test should be run. In this situation, it is appropriate that the test is directly overseen by the urologist.
  - (b) Definitive LUTS management should be delayed until the result of neurological assessment is available. If the neurological finding is positive, the patient should be moved to a neuro-urological care pathway for example.<sup>1,29</sup> If negative, standard LUTS pathways can be followed, but this should be reconsidered if new symptoms subsequently emerge.

### 3.4 | Additional considerations

In several situations, factors affecting lower urinary tract function may be suggested by features in the medical history or physical examination:

1. Functional neurological disorder (FND)<sup>30</sup> is suggested by symptoms such as limb weakness and nonepileptic attacks, particularly in women with chronic idiopathic urinary retention. FNDs may be accompanied by psychological comorbidities such as affective disorders (eg, depression and anxiety) and other functional syndromes, such as fibromyalgia or irritable bowel syndrome. Screening tools are available for evaluating psychological/psychiatric morbidities in adults.<sup>30</sup>
2. Centrally active medications may cause urinary retention (eg, opioids, antipsychotics, antidepressant agents, anticholinergic respiratory agents, alpha-adrenoceptor agonists and benzodiazepines<sup>31</sup>) or enuresis (eg, choline esterase inhibitors (such as rivastigmine or, donepezil) and antipsychotics<sup>32</sup>).
3. Scrutiny of medical history and current medication, to consider conditions that may already be diagnosed in the patient, but whose implication for LUTS has not been recognized. Potentially relevant conditions include (list not complete):
  - (a) Previous pelvic or retroperitoneal surgery (in case of damage to peripheral lower urinary tract nerves). This may make the patient reliant on abdominal straining for bladder emptying.
  - (b) Delayed second stage of labor (pudendal nerve damage).
  - (c) Previous traumatic brain injury.
  - (d) Previous spine hyperextension without fracture.
  - (e) Neuropathies for example vitamin B<sub>12</sub> deficiency, diabetic neuropathy (but not uncomplicated diabetes mellitus), systemic lupus erythematosus, Sjogren's syndrome, amyloid, myasthenia gravis, or Guillain Barre syndrome. Severe peripheral neuropathies can cause gait disturbance with sensory ataxia.
  - (f) Herpes zoster infection of sacral dermatomes with shingles (this is very rare).
  - (g) Active genital herpes affecting sacral levels.

If any of these is identified, they should be considered in case they represent a contributory factor underlying LUTS. If they appear to be causative:

- The possibility of occult neurological disease is reduced, and the priority of neurological assessment should be reviewed accordingly.
- The urological assessment should be designed to reflect the complexity of the LUTS mechanisms.

#### 4 | CONCLUSIONS

There is a large catalog of neurological diseases, but relatively few affect urinary tract function early in their

course. MS, MSA, PD, NPH, some types of dementia or specific spinal cord pathologies are particularly relevant. Thus, an HCP seeing a patient with LUTS should remain alert to features indicating the possibility of an underlying neurological condition. If suspected, specialist input should be sought before requesting diagnostic imaging, and the LUTS management pathway should be adapted.

## Abstract

**Aim:** This consensus statement synthesizes evidence to guide healthcare professionals on promoting consistent, cohesive and achievable bladder training for people with overactive bladder/urgency urinary incontinence and bowel training for those with urgency fecal incontinence.

**Methods:** The Consensus Statement on Bladder and Bowel Training was developed by a sub-group of the International Continence Society Nursing Committee and an expert panel, who formed a virtual Consultation Group. Review of published research, expert opinion articles, policy statements, and voluntary professional group information identified existing recommendations, from which statements were formulated and organized. A modified Delphi process was used to reach consensus on each statement, involving three rounds of virtual consultation. Consultation Group members indicated agreement/disagreement with each statement. Statements, or changes, were accepted when consensus was reached, defined as agreement by 80% of the Consultation Group.

**Results:** No universal definition of bladder training or bowel training was found, therefore a consensus definition was developed and agreed for each. Limited high quality studies of bladder training were identified and no studies investigating the use or effectiveness of bowel training for urgency fecal incontinence in adults. Broad-ranging evidence suggests both types of training should include four elements, personalized to individual need and situation: information and education; a prescribed voiding/evacuation regimen based on individually identified patterns of bladder or bowel functioning; progression of voiding/evacuation regimen; ongoing support and reinforcement.

**Conclusions:** These consensus statements will support healthcare practitioners to design and deliver consistent bladder and bowel training. Improved evidence on mechanisms and effectiveness is needed to inform practice.

## KEYWORDS

behavior therapy, bladder training, bowel dysfunction, bowel training, urinary incontinence

## 1 | INTRODUCTION

Clinical guidelines across the world recognize bladder training<sup>1-4</sup> as a first line intervention for lower urinary tract symptoms, including urgency urinary incontinence and bowel training as a first line intervention for urgency fecal incontinence in adults.<sup>5,6</sup> Healthcare practitioners involved in promoting continence and managing bladder/bowel dysfunction recommend these interventions regularly in practice. Bladder and bowel training are considered to be safe forms of therapy<sup>1,3,7,8</sup> and may be implemented in a variety of care settings including community-based clinics, home care, and rehabilitation and aging care institutions based on patient ability and motivation and symptom-reports, without the need for extensive or invasive diagnostic investigations.<sup>2,3</sup> Evidence for effectiveness of bladder training suggests it may be helpful for treatment of urinary incontinence<sup>2,3,9</sup> and that overactive bladder symptoms (urinary urgency and commonly frequency, nocturia, urgency incontinence) improve in 57% to 87% and resolve in 12% to 73% of cases.<sup>10</sup> There is currently no robust evidence on the effectiveness of bowel training for urgency fecal incontinence although observational studies have examined effects of individual parts of a bowel training program (ie, diet advice, methylcellulose fiber) on urgency fecal incontinence<sup>11</sup> and differences in anorectal manometry and endoanal ultrasound measures in women with urgency versus passive fecal incontinence.<sup>12</sup> In practice, protocols vary considerably<sup>13</sup> and published reports provide only limited descriptions of the actual intervention content and delivery methods used.<sup>14,15</sup> Therefore, healthcare practitioners may find it challenging to access information on how to support people with these types of bladder or bowel dysfunction and effectively implement bladder training or bowel training programs.

## 2 | AIM

This statement synthesizes evidence from a range of sources to offer practical guidance to promote consistent, cohesive and achievable bladder training for people with overactive bladder syndrome/urgency urinary incontinence or bowel training for those with urgency fecal incontinence or defecation urgency.

## 3 | METHOD OF STATEMENT DEVELOPMENT

The Consensus Statement was developed by a Project Working Group, a sub-group of the ICS Nursing

Committee and a virtual Consultation Group. The ICS Nursing Committee was the overseeing steering group. The five members of the Project Working Group (JB, DB, JO, KH, SE) conducted a narrative review of published research evidence, expert opinion articles, clinical guidelines, policy statements, and information from voluntary professional groups. The information used was gathered from a broad range of sources to identify existing or previous practice recommendations from initiatives at local and national levels, incorporating qualitative as well as quantitative work. Structured searches for relevant research were conducted in PubMed, CINAHL, EMBASE, Cochrane Library, using Cochrane Incontinence Group topic search terms including: urinary incontinence, bladder instability/irritability/hyperreflexia, overactive bladder, behavioral intervention and bladder (re)training. Due to the challenge of identifying studies when a low yield was expected, the search for bowel training was conducted by a biomedical librarian. Search terms included ((anal or anorectal\* or bowel\* or fecal\* or fecal\* or rectal\* or stool\*) adj4 (continen\* or incontinen\*\*)).mp., (bowel and (habit\* or management or program\* or training or re-training)).mp. Given the anticipated low number of returns, there were no date limits applied, but searches were limited to adults and articles published in English. Searches for guidelines included relevant societies such as the European Urological Association, American Urological Association, Wound, Ostomy and Continence Nurses Society, American Society of Colon and Rectal Surgeons, American Gastroenterological Association, NICE Guidance, and the International Continence Society. The most recent International Consultation on Incontinence 6th Edition<sup>2,5</sup> was consulted. Other sources were identified in gray literature using search engines such as Google, Opengrey and relevant charity/voluntary organization websites. Documents and materials used in practice by members of the Nursing Committee were also collated.

One member of the Project Working Group (JB) took the role of reading, sifting and formulating the evidence into statements, which the other members of the Project Working Group refined to construct the first version of the consensus statements to be sent to the virtual Consultation Group. The organization of the statements was modeled according to steps of the nursing process<sup>16,17</sup>: assessment, planning, intervention and evaluation (See Appendixes A and B). A similar process is used as a healthcare approach by other types of healthcare practitioners. The statements are derived from the best available evidence, including expert opinion at the time they were produced, recognizing that levels and types of evidence vary.

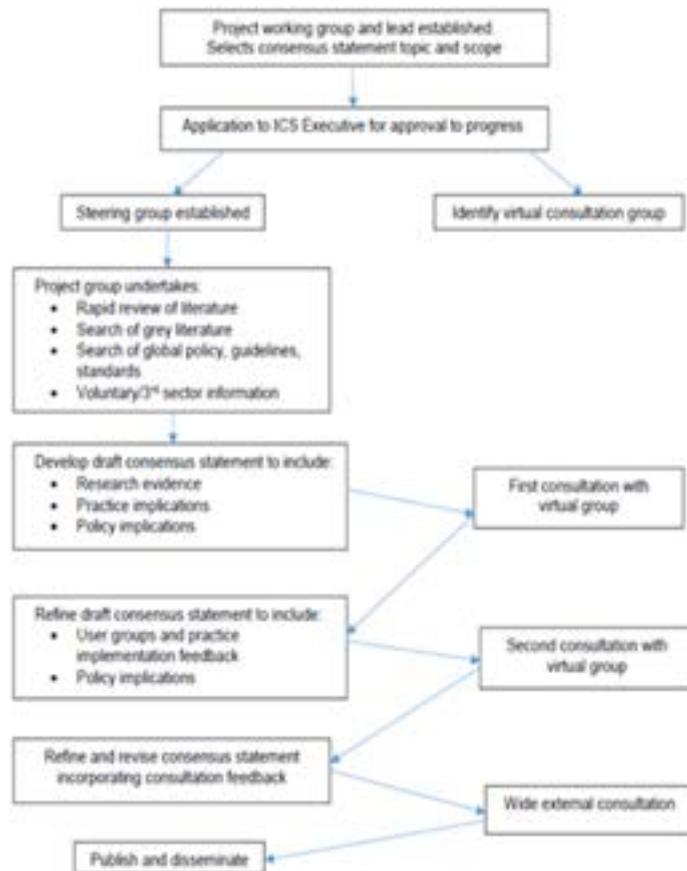

The procedure used to reach consensus about each statement was based on the Delphi method and is outlined in the flowchart below (See Figure 1). In brief, 20 nurse members of ICS were recruited by the ICS office staff to serve as the virtual Consultation Group. The Consultation Group submitted curriculum vitae that were reviewed to support their expertise on the topic. The Consultation Group reviewed the statements developed by the Project Working Group and emailed suggested changes to the ICS office staff. Staff removed information identifying the person proposing the change, before forwarding the information to the Project Working Group. The Project Working Group incorporated the suggested changes to the statements into the document that was returned to the Consultation Group by the ICS staff. The Consultation Group emailed their votes for agreeing or disagreeing with statements or changes to the ICS office staff. This procedure was repeated three times. Statements or changes were accepted when consensus was

reached, defined as agreement by 80% of the Consultation Group. For information, a glossary of the standardized ICS definitions used in constructing these consensus statements is provided as a Supporting Information file.

## 4 | CONSENSUS STATEMENT ON BLADDER TRAINING

### 4.1 | Definition of bladder training

Bladder training is a broad term, encompassing bladder retraining, bladder discipline, bladder re-education and bladder drill.<sup>2</sup> There is currently no universally agreed definition of bladder training for adults, although the 2016 International Consultation on Incontinence describes bladder training (Chap 12, p.86) as ‘a program of patient education, along with a scheduled voiding regimen with gradually adjusted voiding intervals. Specific

**FIGURE 1** Consensus statement development flowchart

goals are to correct faulty habit patterns of frequent urination, improve control over bladder urgency, prolong voiding intervals, increase bladder capacity, reduce incontinent episodes and restore patient confidence in controlling bladder function'.<sup>2</sup> Bladder training is considered to be a form of behavior modification, (defined by the International Continence Society (ICS) as 'the analysis and alteration of the relationship between the patient's symptoms and his or her environment for the treatment of maladaptive voiding patterns, which may be achieved by modification of the behavior and/or environment of the patient'<sup>18</sup>). However recent bladder training developments have placed increasing emphasis on the importance of cognitive and psychological aspects that target beliefs and perceptions to impact behavior.<sup>19</sup>

Based on the literature reviewed for the purposes of this Consensus Statement the following definition of bladder training was developed:

*Bladder training is an intervention that actively supports a motivated person, without significant cognitive or physical impairment, with an overactive bladder or urgency urinary incontinence, to make lifestyle and behavioral changes to regain bladder control through education, progressively increasing voiding intervals, use of urgency suppression techniques and positive reinforcement of effort and success.*

## 5 | HOW BLADDER TRAINING WORKS

The mechanism of action of bladder training is not fully understood.<sup>2</sup> It arose from the theoretical premise that abnormal voiding habits could be altered by modifying an individual's behavior. The purpose of bladder training is to restore a normal voiding pattern by progressively lengthening the interval between voids. People with bladder dysfunction are taught to void at regular intervals throughout the day and to otherwise suppress the urge to void using strategies such as distraction and relaxation.<sup>14</sup> It is hypothesized that by repeatedly suppressing the urge to void, the person's functional bladder capacity will increase and this, in turn, will lead to a reduction in urinary frequency and the urge to void.<sup>2,19</sup> Urgency suppression techniques help the person achieve bladder control by diverting their attention away from the urgency sensation using competing mental activities. Relaxation techniques aim to reduce anxiety and feelings of panic. It is hypothesized that deep breathing reduces the intensity of

the urgency sensation and relaxes the detrusor muscle.<sup>19</sup> Together these urge suppression techniques are thought to enable improved cortical bladder control by inhibition of involuntary detrusor contractions; improved urethral closure during bladder filling and control of afferent sensations.

To perform bladder training, patients need to have the mental and physical capacity to (a) identify the urge to void; (b) understand how the bladder functions, (c) rapidly contract their pelvic floor muscles; and/or (d) apply distraction techniques to suppress the urge to void and (e) defer voiding.<sup>2,14</sup> Thus, education and coaching are key components of the intervention. Additionally, since positive outcomes rely on active client participation, motivation and the cognitive/physical ability to adhere to a progressive schedule are also essential.<sup>20</sup>

Bladder training differs from scheduled voiding programs, such as timed voiding or prompted voiding in so far as it includes cognitive and psychological components.<sup>21,22</sup> It is thought that bladder training, through operant learning techniques, improves cortical control over the lower urinary tract.<sup>23,24</sup> Operant learning is brought about by the positive feedback created by successful urge suppression and longer voiding intervals and conscious recognition by the person of their improved bladder control. However, based on the idea that frequency is a habit that becomes a precursor to urgency and drives it, the role of emotion in the development of urgency is increasingly becoming the target of intervention.<sup>25</sup> The roles of other cognitive contributors, including self-monitoring, education/information, positive reinforcement, follow up, as well as health behavioral change theories are recognized, but have yet to be fully explored in light of bladder training theories.

The Consensus Statement on Bladder Training is presented in Table 1, however, the full document, which includes supporting evidence for each statement, as well as suggestions on demonstrating its use in practice, is provided as Appendix A.

## 6 | CONSENSUS STATEMENT ON BOWEL TRAINING

### 6.1 | Definition of bowel training

The term bowel training encompasses bowel retraining and bowel re-education, a form of behavior modification designed to restore bowel continence by changing a person's behavior and/or environment.<sup>18</sup> There is currently no universally agreed definition of bowel training so based on the literature reviewed for this Consensus

**TABLE 1** Consensus statement on bladder training**Consensus statement on bladder training****Assessment**

- Adults with urinary incontinence or other lower urinary tract dysfunction are assessed by a healthcare practitioner for lifestyle, risk factors and quality of life to ensure the type of bladder dysfunction is identified:
  - a. urinary incontinence (UI) – urgency UI, mixed UI
  - b. overactive bladder (OAB) or other storage lower urinary tract symptoms

and that the person:

- is suitable for bladder training and potentially will benefit.
- has the functional ability to use the toilet either independently or with assistance
- is cognitively able to participate
- is motivated to undertake and adhere to a personalized bladder training program
- has realistic expectations of treatment
- has ability to voluntarily contract pelvic floor muscles

**Planning**

- The person's goals for bladder training are established with the healthcare practitioner. For example, a reduction in the frequency and severity of symptoms, the ability to sleep at night without going to the toilet, the ability to go out and socialize, reduced carer impact, etc.
- The practitioner develops or structures the person's bladder training program in collaboration with them, taking into account their personal goals and the following factors, before commencing the program:
  - the frequency of voiding and voiding intervals
  - duration of bladder training the person will practice before attempting to increase the voiding interval
  - whether the person prefers a standardized bladder training schedule or one that is individually tailored
  - how long the person will attempt to suppress the urge to void when urgency is experienced (eg, 5, 10, 15 or 30 min, or until urgency subsides)
  - the duration of the full bladder training program in weeks
  - the indicators of improvement and readiness to progress (eg, reduction in number of incontinence episodes, urge reduction, demonstrated commitment to the schedule)
  - the types of urgency suppression techniques the person will use
  - the method the person will use to self-monitor their progress, for example bladder diaries, measured voided volumes

**Intervention**

- The healthcare practitioner ensures the bladder training program is structured and supervised.
- The bladder training program duration will vary according to the person's progress and goals but should be at least 6 wk.
- Healthcare practitioners should review clients on a regular basis and adjust the mode and frequency of contact according to their professional judgment and the person's goals and preferences. The degree of reinforcement (coaching) patients require will vary.
- Follow-up support to maintain effects of bladder training should be provided, in accordance with the person's goals and preferences.
- The healthcare practitioner provides adults undertaking bladder training with verbal and written information and education on:
  - a. what constitutes a healthy bladder, including its function, anatomy and potential susceptibility to dysfunction
  - b. what happens to the bladder in overactive bladder syndrome/urinary incontinence
  - c. their individual bladder function and patterns, including anticipatory/'just in case' voiding habits and incontinence episodes (based on bladder diary)
  - d. effects of current medication, diet, fluids and caffeine on bladder function
  - e. how to self-monitor symptoms and interpret their bladder diary
  - f. purpose of bladder training
  - g. how bladder training works
  - h. the rise and de-escalation of the sensation of urgency, sometimes known as the 'urge wave'<sup>26</sup>
  - i. the staged approach to bladder training
  - j. the need for active involvement, commitment and ongoing motivation
  - k. psychological strategies to support success
    1. realistic expectations about the efforts required and the potential challenges
  - m. expected outcomes

(Continues)

- An initial bladder training program and voiding intervals are agreed and implemented based on the person's baseline voiding diary information and individual goals.
- Bladder training is usually implemented during waking hours only
- Voiding intervals are set in accordance with the person's preference for a standardized bladder drill or individually tailored bladder training schedule:
  - a. If **standardized** a fixed (or pre-determined) voiding schedule of half-hourly or hourly voids is implemented for an agreed time period. Once achieved, this schedule is increased by a pre-determined duration of 5, 10, 15 or 30 min at each progression point.
  - b. If **tailored**, individualised voiding intervals are implemented based on the person's average voiding interval calculated from their voiding diary. Progression time to prolong voiding intervals is negotiated on an individual basis, for example increase by 5, 10, 15, 30 min per week.
- The health care practitioner regularly reviews the bladder training program with the person to determine specific voiding interval progression in line with their goals. Voiding diary data and self-report inform this process.
- New continence skills are developed in the form of personalized urge suppression strategies.
- Urge suppression or deferment involves:
  - a. **relaxation**—the person is instructed to stop, sit down if possible, relax their whole body, in particular their abdomen and focus on slow, controlled breathing.
  - b. **pelvic floor muscle contraction**—the person completes 5-8 fast pelvic floor muscle contractions, without increasing their intra-abdominal pressure.
  - c. **distraction techniques**—mental activities that demand cognitive attention and concentration are used to distract the person from their sensation of urgency and desire to void.
  - d. The individual should decide what will work for them. Examples include counting backwards from 100 in 7's, identifying different girl's names through the alphabet, singing out loud, word searches/crossword puzzles, digital games, reading, making lists.
  - e. Use of **self-affirming statements** such as 'I can control my bladder' and 'I don't have to go now'
  - f. **applying perineal pressure**—sit on a hard surface, rolled towel or stimulate foot sensation using toe curls and heel pressure until the urgency subsides.
- Urgency sensation may subside within 1-2 min.
- When urgency is controlled, and if voiding is permitted according to the bladder training program, the person is encouraged to walk to the toilet at a normal pace.
- The healthcare practitioner positively reinforces the person's bladder control skills and improved and/or prolonged bladder control.
- Individuals are actively encouraged and supported to:
  - a. self-monitor their:
    - relaxation capability and capacity to control their response to urgency and fear of incontinence episodes
    - duration of urge suppression
    - intensity of urgency sensations
    - number of incontinence episodes
    - reduction in negative voiding habits such as 'just in case' or anticipatory voiding
    - progress toward achieving a normal bladder pattern
  - b. self-determine their:
    - progression time, for example increasing urge suppression/voiding delay time
    - decisions about when to increase their urge suppression/voiding delay time.
  - c. self-affirm their:
    - Use of personally meaningful self-coping statements such as 'I don't have to go now; I can wait'; 'I am in control of my bladder'

#### Evaluation

- Regular contact between the person and the healthcare practitioner is made during the bladder training program to review progress, assess adherence, provide positive reinforcement and adjust voiding program/intervals.
- At the end of the bladder training program a range of person-focused outcomes are assessed. These may include:
  - perceptions of bladder condition and improvement
  - influence of bladder on daily activities
  - satisfaction with bladder training
  - tolerability of bladder training and adherence
  - frequency and severity of urgency and incontinence episodes
  - improvements in lower urinary tract symptoms
  - voiding interval changes
  - lifestyle changes
  - changes in quality of life
  - change in body-worn absorbent product use

**TABLE 2** Consensus statement on bowel training**Consensus statement on bowel training****Assessment**

- Healthcare practitioners conduct an assessment of the person's bowel symptoms to ensure the cause and type of bowel dysfunction is identified before recommending a bowel training program
- Current lifestyle and risk factors for bowel dysfunction (eg, aggravating foods, medication side effects) are assessed.
- Underlying physiological abnormalities are excluded before recommending a bowel training program
- The person's suitability to undertake bowel training is assessed including:
  - potential for benefit
  - functional ability to use the toilet/toilet aid
  - cognitive capacity
  - motivation to undertake and adhere to a personalized bowel training program
  - expectations of treatment
  - ability to voluntarily contract pelvic floor muscles

**Planning**

- The person's goals for bowel training are established with the healthcare practitioner, for example: a reduction in the frequency and severity of symptoms, the ability to go out and socialize, reduced carer burden such as laundering soiled clothing and linens, increased socialization and travel, decreased cost of absorbent products, etc.
- The practitioner develops or structures the person's bowel training program in collaboration with them, taking into account the following factors before commencing the program:
  - frequency of defaecation
  - duration of the full bowel training program in weeks/months
  - indicators of improvement
  - types of urgency suppression techniques the person will use (where appropriate)
  - methods to normalize and regulate stool consistency
  - method the person will use to self-monitor their progress, for example bowel diaries
  - lifestyle changes

**Intervention**

- The healthcare practitioner ensures the bowel training program is structured and supervised. The program duration will vary according to the person's progress and goals.
- The healthcare practitioner provides adults undertaking bowel training with verbal and written information and education on:
  - normal bowel function
  - how fecal incontinence occurs
  - factors affecting bowel functioning including diet and dietary fiber, fluids, smoking, exercise, psychological/emotional status and environment
  - medication and laxatives
  - purpose of bowel training and how it works
  - the need for active involvement, commitment and ongoing motivation by the person
  - psychological strategies to support success
  - use of containment products during bowel training
  - realistic expectations about the efforts required and the potential challenges
  - expected outcomes
- The person's bowel diary (minimum 5-7 d) is interpreted jointly by the person and the healthcare practitioner to identify individual bowel function and patterns and align with agreed goals.
- The healthcare practitioner offers the person a bowel training program that includes information about:
  - optimal time of day for defaecation
  - frequency of defaecation attempts, for example, daily, alternate days, three times per week
  - optimal type and amount of food intake
  - optimal type and amount of fluid intake
  - individual advice on smoking cessation
  - use of drugs, dietary fiber, or rectal irrigation for fecal incontinence; antidiarrheal drugs or stool bulking agents may be used to establish and maintain a normal stool consistency and frequency; laxatives, suppositories, enemas or transanal irrigation may be used to completely empty the rectum to avoid leakage

(Continues)

- An external anal sphincter (EAS) and pelvic floor muscle exercise program, tailored to the lifestyle and needs of the person is agreed with the healthcare practitioner. This will include specific exercises aimed at improving strength, speed and endurance of the external anal sphincter and pelvic floor muscle contraction and relaxation.
- Concerns/anxieties affecting the person's psychological/emotional state are actively screened for and managed.
- The healthcare practitioner ensures the person can use effective defaecation techniques:
  - correct positioning on the toilet—may involve use of footstools and leaning forward to increase hip flexion, straighten the anorectal angle, and ensure stability of sitting position.
  - allowing sufficient time to fully empty bowel
  - ensuring privacy and no interruptions
  - attention to privacy and comfort measures for example toilet temperature, noise and odor reduction
- The healthcare practitioner encourages the person to develop individualized urge suppression strategies:
- When the person feels the urge to defecate they are encouraged to suppress the urge using the techniques below until the sensation is reduced sufficiently to allow them to get to a toilet without rushing. Once they are in the toilet they are encouraged to wait for a minute or so before actually sitting on the toilet to open their bowels.
- They gradually increase the amount of time they wait before they use the toilet.
- Urge suppression or deferment involves:
  - a. **relaxation**—the person is advised to stop, relax their whole body, in particular their abdomen and focus on slow, controlled breathing.
  - b. **external anal sphincter and pelvic floor muscle contraction**— the person completes 5-8 fast contractions, without increasing their intra-abdominal pressure.
  - c. **distraction techniques**—mental activities that demand cognitive attention and concentration will distract the person from their sensation of urgency and desire to evacuate. The individual should decide what will work for them (different techniques may be used at different times). Examples include: counting backwards from 100 in 7's (or 5's for older adults), identifying girl's names through the alphabet, singing out loud, word searches/crossword puzzles, digital games, reading, making lists.
  - d. **applying perineal pressure**—sit on a hard surface, rolled towel
- Bowel urgency sensation may subside within 1-2 min. When urgency is controlled, encourage the person to walk to the toilet at a normal pace.
- The healthcare practitioner positively reinforces the person's continence skills and improved and/or prolonged bowel control.
- Individuals are actively encouraged and supported to:
  - a. self-monitor their:
    - perceived capability to relax—to stop what they are doing, take slow, deep breaths, relax their body especially their abdomen and not rush to the toilet until the urgency sensation has diminished
    - duration of urge suppression
    - intensity of urgency sensations
    - number of fecal incontinence episodes
    - reduction in negative defecation habits such as prolonged or frequent toilet use
    - progress toward achieving a normal bowel pattern
    - lifestyle changes
  - b. self-determine their:
    - progression time for example increased urge suppression/delay time
    - decisions about when to increase duration of their urge suppression/delay time.
  - c. self-affirm their:
    - use of personally meaningful self-coping statements such as 'I don't have to go now; I can wait'; 'I am in control of my bowel'

#### Evaluation

- Regular contact between the person and the healthcare practitioner is made during the bowel training program to review progress, assess adherence, provide positive reinforcement and adjust schedules.
- At the end of the bowel training program a range of person-focused outcomes are assessed. These may include:
  - a. perceptions of bowel condition and any improvements/changes
  - b. satisfaction with bowel training
  - c. tolerability of bowel training processes and adherence to recommended program
  - d. frequency and severity of bowel symptoms including urgency and incontinence episodes,
  - e. defecation intervals
  - f. lifestyle changes
  - g. quality of life
  - h. change in absorbent product use (eg, decrease in number)

Statement the following definition of bowel training was developed:

*Bowel training is an intervention that actively enables a motivated person, without significant cognitive or physical impairment, with urgency fecal incontinence or defecation urgency to make lifestyle and behavioral changes to regain a controlled response to urgency and a satisfactory pattern of defecation through education, progressively increasing intervals between defecations, use of urgency suppression techniques, and positive reinforcement of effort and success.*

## 7 | HOW BOWEL TRAINING WORKS

Similar to bladder training the mechanism of bowel training is poorly understood and robust evidence on approaches to bowel training and effectiveness of intervention is urgently needed.<sup>2</sup> There are physical and psychological elements in a bowel training program that aim to establish predictable, regular patterns of bowel elimination, using personalized education and support to adhere to routines.<sup>2</sup> The functional integrity of the external anal sphincter is a key focus because the external anal sphincter is a continuation of the striated puborectalis muscle and therefore it is voluntarily controlled and can be trained. Pelvic floor muscle exercises to strengthen the external anal sphincter, improve contraction speed, endurance and sphincter coordination are an important component of bowel training<sup>27</sup>; however, there is no evidence on the most effective protocol to achieve improvements or sustain the effects.<sup>7</sup>

The psychological components of bowel training aim to reduce anxiety and panic associated with sudden onset bowel urgency, to enable the person to develop and maintain a sense of control, which will allow them to reach a toilet before any leakage occurring.<sup>28</sup> These include general anxiety reduction techniques (including stopping, focusing, deep breathing and positive self-talk). Establishing a routine for defaecation and ensuring the bowel is fully emptied are important parts of the program, as they will increase the predictability of bowel activity and therefore reduce associated anxiety.<sup>27</sup> As with bladder training, patients undertaking bowel training need to have the mental and physical capacity to (a) identify the urge to defecate; (b) understand how their bowel functions, (c) rapidly contract their pelvic floor muscles; and/or (d) apply relaxation and distraction

techniques to suppress the urge to defecate and (e) long intervals between defecations.<sup>2</sup> Thus, education and coaching are key components of the intervention. Individual motivation to participate, as well as the cognitive and physical ability to adhere to a progressive training schedule, are considered as essential to a positive outcome for bowel training as they are for bladder training.<sup>20</sup>

The Consensus Statement on Bowel Training is presented in Table 2, however, the full document, which includes supporting evidence for each statement as well as suggestions on demonstrating its use in practice, is provided as Appendix B.

## 8 | POTENTIAL USE

The Consensus Statement on Bladder and Bowel Training can be used by nurses and other healthcare professionals in developing and implementing a plan of care for promoting continence with adults. The document offers expert consensus to fill a gap in current knowledge with the aim of supporting bladder and bowel continence nursing care and improving patient outcomes. The document highlights the sparse evidence base for bladder and bowel training, and it is hoped that it will stimulate research to provide further evidence to inform its content and improve its applicability and effectiveness.

## ACKNOWLEDGMENTS

On behalf of the ICS Nursing Committee the Chairs would like to thank the members of the Project Working Group and the members of the Consultation Group for their contributions to this Consensus Statement: Project Working Group: Sharon Eustice; Kathleen Hunter; Joan Ostaszkiwicz. Consultation Group: Alison Bardsley; Nikki Cotterill; Joanne Dean; Veerle Decalf; Tamara Dickinson; Sandra Engberg; Veronika Geng; Veronica Haggar; Amy Hunter; Lisa Krabbenhof; Yuan-Mei Liao; Katherine Moore; Angela Rantell; Joanne Robinson; Alyson Sweeney; Janie Thompson; Susanne Vahr; Mary Wilde; Debbie Yarde.

## APPENDIX A: CONSENSUS STATEMENT ON BLADDER TRAINING

## Consensus Statement on Bladder Training

Statement	Supporting evidence	Demonstrating in practice
<p>Assessment</p> <p>➤ Adults with urinary incontinence or other lower urinary tract dysfunction are assessed by a healthcare practitioner for lifestyle, risk factors and quality of life to ensure the type of bladder dysfunction is identified:</p> <ul style="list-style-type: none"> <li>○ urinary incontinence (UI) – urgency UI, mixed UI</li> <li>○ overactive bladder (OAB) or other storage lower urinary tract symptoms</li> </ul> <p>and that the person:</p> <ul style="list-style-type: none"> <li>■ is suitable for bladder training and potentially will benefit.</li> <li>■ has the functional ability to use the toilet either independently or with assistance</li> <li>■ is cognitively able to participate</li> <li>■ is motivated to undertake and adhere to a personalised bladder training programme</li> <li>■ has realistic expectations of treatment</li> <li>■ has ability to voluntarily contract pelvic floor muscles</li> </ul>	<ul style="list-style-type: none"> <li>• Bladder training may be an effective first-line behavioural therapy for adults<sup>29</sup> (including older adults<sup>30</sup>) with urgency UI/mixed UI: OAB symptoms resolved 12%-73%; OAB symptoms improved 57%-87%<sup>10</sup></li> <li>• Understanding of bladder function, the purpose of bladder training and the need to progressively increase the voiding interval are essential for bladder training to be effective<sup>31</sup></li> <li>• Active participation is essential to modify behaviour and develop central control over the bladder<sup>32</sup></li> <li>• Individual beliefs and expectations are fundamental to a person's behaviour and indicates their likely participation and adherence<sup>33</sup></li> </ul>	<p>A complete assessment includes:</p> <ul style="list-style-type: none"> <li>• Documented comprehensive individual assessment including lifestyle factors, (eg, obesity, smoking, fluid and caffeine intake, etc)</li> <li>• Voiding diary (minimum 72 h) including measured volumes</li> <li>• Diagnosed lower urinary tract disorder based on signs and symptoms or a urodynamic diagnosis</li> <li>• Individual expectations of bladder training and lifestyle changes are documented.</li> </ul>
<p>Planning</p> <p>➤ The person's goals for bladder training are established with the healthcare practitioner. For example, a reduction in the frequency and severity of symptoms, the ability to sleep at night without going to the toilet; the ability to go out and socialise, reduced carer impact, etc.</p> <p>➤ The practitioner develops or structures the person's bladder training programme in collaboration with them, taking into account their personal goals and the following factors, before commencing the programme:</p> <ul style="list-style-type: none"> <li>■ the frequency of voiding and voiding intervals</li> <li>■ duration of bladder training the person will practice before attempting to increase the voiding interval</li> <li>■ whether the person prefers a standardised bladder training schedule or one that is individually tailored</li> <li>■ how long the person will attempt to suppress the urge to void when urgency is experienced (eg, 5, 10, 15 or 30 min, or until urgency subsides)</li> </ul>	<ul style="list-style-type: none"> <li>• It is important for healthcare practitioners to assist individuals to set specific goals that are personal, and realistic<sup>21</sup> Personal goals for bladder training may be different to goals set within the programme for symptom improvement, but both are important for effective planning and are part of the evaluation<sup>34</sup></li> <li>• Jointly agreeing on personal and programme goals supports engagement with the bladder training programme.<sup>14</sup> Working towards a specific goal improves motivation and performance<sup>34,35</sup></li> <li>• Daytime voiding intervals of 2.5 to 4 h are recommended<sup>30,36</sup></li> </ul>	<ul style="list-style-type: none"> <li>• Personal goals and specific progression criteria are documented in the bladder training plan.</li> <li>• Review dates and end of bladder training programme dates are specified</li> </ul>

- the duration of the full bladder training programme in weeks
- the indicators of improvement and readiness to progress (eg, reduction in number of incontinence episodes, urge reduction, demonstrated commitment to the schedule)
- the types of urgency suppression techniques the person will use
- the method the person will use to self-monitor their progress for example bladder diaries, measured voided volumes

#### Intervention

- The health care practitioner ensures the bladder training programme is structured and supervised. The bladder training programme duration will vary according to the person's progress and goals but should be at least 6 wk.
  - Healthcare practitioners should review clients on a regular basis and adjust the mode and frequency of contact according to their professional judgement and the person's goals and preferences. The degree of reinforcement (coaching) patients require will vary.
  - Follow-up support to maintain effects of bladder training should be provided, in accordance with the person's goals and preferences.
  - The health care practitioner provides adults undertaking bladder training with verbal and written information and education on:
    - a. what constitutes a healthy bladder, including its function, anatomy and potential susceptibility to dysfunction
    - b. what happens to the bladder in overactive bladder syndrome/urinary incontinence
    - c. their individual bladder function and patterns, including anticipatory/'just in case' voiding habits and incontinence episodes (based on bladder diary)
    - d. effects of current medication, diet and fluids on bladder function
    - e. how to self-monitor symptoms and interpret their bladder diary
    - f. purpose of bladder training
    - g. how bladder training works
    - h. the rise and de-escalation of the sensation of urgency, sometimes known as the 'urge wave'<sup>26</sup>
    - i. the staged approach to bladder training
- Regular practice of skills to maintain continence is essential to maintain performance<sup>26</sup>
  - Intensive supervision by a healthcare practitioner improves the likelihood of positive outcomes<sup>2,24</sup>
  - Successful bladder training is structured and involves frequent patient contact<sup>22,24</sup>
  - Clinical guidelines, based on limited evidence recommend a 6-wk minimum bladder training programme duration<sup>3,4</sup>
  - Follow up is essential.<sup>1</sup> Effectiveness of bladder training may diminish after the programme has ceased.
  - Education is central to all behavioural therapy<sup>15,22</sup> and forms the first phase of all bladder training programmes<sup>22</sup>
  - Understanding the differences between their own bladder function and normal bladder function enables a person to identify where they can change their behaviour<sup>37</sup>
  - Understanding the purpose and content of bladder training allows a person to actively engage<sup>22,38,39</sup>
- A documented bladder training plan, including mode and frequency of contact between person and healthcare practitioner
  - Personal goals and specific progression documented in the bladder training plan.
  - Contact appointments are agreed
1. Details of verbal education and written information provided are recorded in bladder training plan, with time frames and methods for providing information.

(Continues)

- j. the need for active involvement, commitment and ongoing motivation
  - k. psychological strategies to support success
  - l. realistic expectations about the efforts required and the potential challenges
  - m. expected outcomes
- An initial bladder training programme and voiding intervals are agreed and implemented based on the person's baseline voiding diary information and individual goals.
  - Bladder training is usually implemented during waking hours only
  - Voiding intervals are set in accordance with the person's preference for a standardised bladder drill or individually tailored bladder training schedule:
    - a. If **standardised** a fixed (or pre-determined) voiding schedule of half-hourly or hourly voids is implemented for an agreed time period. Once achieved, this schedule is increased by a pre-determined duration of 5, 10, 15 or 30 min at each progression point.
    - b. If **tailored**, individualised voiding intervals are implemented based on the person's average voiding interval calculated from their voiding diary. Progression time to prolong voiding intervals is negotiated on an individual basis for example increase by 5, 10, 15, 30 min per week.
  - The health care practitioner regularly reviews the bladder training programme with the person to determine specific voiding interval progression in line with their goals. Voiding diary data and self-report inform this process.
  - New continence skills are developed in the form of personalised urge suppression strategies.
  - Urge suppression or deferment involves:
    - a. relaxation—the person is instructed to stop, sit down if possible, relax their whole body, in particular their abdomen and focus on slow, controlled breathing.
    - b. pelvic floor muscle contraction—the person completes 5-8 fast pelvic floor muscle contractions, without increasing their intra-abdominal pressure.
- Educating patients to resist urgency sensations and postpone voiding using a scheduled voiding programme is believed to result in an increased functional bladder capacity and reduced urgency, and ultimately reduces voiding frequency<sup>24,30</sup>
  - At this point in time, evidence about bladder training is limited to daytime. In general, bladder training is not performed during sleeping hours as it may interrupt the quality and duration of a person's sleep.
  - No evidence is available on how to select the most effective voiding programme – individually tailored or standardised. Limited evidence suggests both approaches are effective<sup>9,40</sup>
  - Successful and sustained increases in voiding intervals may build and embed new voiding habits but evidence is lacking on psychological and physiological effects
  - Positive reinforcement of progress towards goal attainment is a fundamental part of bladder training.<sup>15</sup> Frequent patient contact is essential to achieve this.<sup>24</sup>
- Agreed voiding programme is documented in bladder training plan.
  - The person is provided with a copy of their bladder training plan
  - Documented assessment of progress towards attaining bladder training goals
  - Voiding diaries are completed during bladder training.
1. Education about urge suppression strategies and person's selected techniques is documented in bladder training plan
- Bladder training uses techniques to enable urgency to be resisted, voiding postponed, voiding intervals to be prolonged, functional bladder capacity increased and frequency and urgency reduced as a result.<sup>19</sup>
  - Urgency may induce feelings of anxiety or panic, which affects ability to concentrate.<sup>21,32</sup> Hyperventilation and contraction of abdominal muscles are associated with anxiety and panic and raise intra-abdominal pressure.<sup>21</sup> The role of cognition and emotion in suppressing the urge to void is not well established, however deep

- c. distraction techniques— mental activities that demand cognitive attention and concentration are used to distract the person from their sensation of urgency and desire to void.
- d. The individual should decide what will work for them. Examples include: counting backwards from 100 in 7's, identifying different girl's names through the alphabet, singing out loud, word searches/crossword puzzles, digital games, reading, making lists.
- e. Use of self-affirming statements such as 'I can control my bladder' and 'I don't have to go now'
- f. apply perineal pressure—sit on a hard surface, rolled towel or stimulate foot sensation using toe curls and heel pressure until the urgency subsides.
- Urgency sensation may subside within 1-2 min.
- When urgency is controlled, and if voiding is permitted according to the bladder training programme, the person is encouraged to walk to the toilet at a normal pace.
- The health care practitioner positively reinforces the person's bladder control skills and improved and/or prolonged bladder control. Individuals are actively encouraged and supported to
- a. self-monitor their:
- relaxation capability and capacity to control their response to urgency and fear of incontinence episodes
  - duration of urge suppression
  - intensity of urgency sensations
  - number of incontinence episodes
  - reduction in negative voiding habits such as 'just in case' or anticipatory voiding
  - progress toward achieving a normal bladder pattern
- b. self-determine their:
- progression time for example increasing urge suppression/voiding delay time
  - decisions about when to increase their urge suppression/voiding delay time.
- breathing is hypothesised to induce subsidence of bladder urgency sensation and relaxation of detrusor<sup>21</sup>
- Rushing to the toilet raises intra-abdominal pressure and exposes the individual to visual cues that can trigger incontinence<sup>21</sup>
  - Rapid pelvic floor muscle contractions can inhibit detrusor contraction and diminish urgency<sup>26</sup>
  - Attention is diverted away from the sensation of urgency when concentrating on competing mental activities, which allows the urgency to subside temporarily giving the person time to walk to the bathroom at a normal pace<sup>21</sup>
  - Learning to 'stop & squeeze'<sup>41</sup> and experiencing success positively reinforces the chosen urge suppression technique.
  - Well-designed controlled trials of urge suppression have shown mean frequency of weekly urinary incontinence episode reductions of 50%-80% in women<sup>30,42,43</sup>
  - The MOTIVE trial<sup>44</sup> showed urge suppression techniques were as effective as antimuscarinics in men without bladder outlet obstruction who continue to have OAB symptoms with alpha-blocker therapy.
1. Operant learning through experiencing positive effects of bladder training builds confidence in individual ability to control bladder<sup>45</sup>
- Self-monitoring refers to monitoring of specific physiologic parameters or symptoms of a health condition<sup>46</sup>
  - Two components of self-monitoring include:
    - *awareness* of bodily symptoms, sensation, daily activities, voiding habits and cognitive processes
    - *measurement* including reading and recording results eg using a bladder diary
  - Together these inform understanding and provide information for action by the individual, in consultation with health care practitioners<sup>32</sup>
  - Supporting an individual's autonomy and competence development fosters motivation towards bladder training, ongoing engagement and adherence<sup>35</sup>
  - Conscious awareness of automatic thoughts through examining them can enable them to be self-managed. Techniques can be learned to change incontinence-related cognitions,
- Record of progress is documented.
  - Use of written bladder training programme adherence records, agreed by person and health care practitioner.

(Continues)

## c. self-affirm their:

- Use of personally meaningful self-coping statements such as 'I don't have to go now; I can wait'; 'I am in control of my bladder'

emotions and behaviours from negative to positive<sup>32</sup>

- Use of positive self-coping statements (verbally out loud is better) can interrupt automatic thoughts and act as a counter directive for example 'I can wait 2-3 min to go to the bathroom or 'I can conquer this feeling, I do not have to go now' rather than 'I can't wait, I have to go now'<sup>31</sup>

## Evaluation

Regular contact between the person and the healthcare practitioner is made during the bladder training programme to review progress, assess adherence, provide positive reinforcement and adjust voiding programme/intervals. At the end of the bladder training programme a range of person-focused outcomes are assessed. These may include:

1. perceptions of bladder condition and improvement
1. influence of bladder on daily activities
2. satisfaction with bladder training
3. tolerability of bladder training and adherence
4. frequency and severity of urgency and incontinence episodes
5. improvements in lower urinary tract symptoms
6. voiding interval changes
7. lifestyle changes
8. changes in quality of life
9. change in body-worn absorbent product use

- Frequent patient contact is a fundamental component of successful bladder training<sup>18</sup> and the most intensive supervision by a healthcare practitioner as is possible is recommended.<sup>2,3</sup>
- Feedback and reinforcement of overall changes from start of training programme confirms effectiveness and motivates continued adherence to maintain progress made<sup>23,24,40</sup>

- Voiding diaries completed and repeated during the bladder training programme<sup>30</sup>
- Use of validated, standardised symptom and quality of life tools, to ensure robust measurement and ability to compare outcomes in different populations, study settings etc.
- Measures are recorded before and after the bladder training programme.
- Goals are reviewed and level of achieving them is periodically evaluated

**APPENDIX B: CONSENSUS STATEMENT ON BOWEL TRAINING**

<b>Consensus statement on bowel training</b>		
<b>Statement</b>	<b>Supporting evidence</b>	<b>Demonstrating in practice</b>
<b>Assessment</b>		
<ul style="list-style-type: none"> <li>➤ Healthcare practitioners conduct an assessment of the person's bowel symptoms to ensure the cause and type of bowel dysfunction is identified prior to recommending a bowel training programme</li> <li>➤ Current lifestyle and risk factors for bowel dysfunction (eg aggravating foods, medication side effects) are assessed.</li> <li>➤ Underlying physiological abnormalities are excluded prior to recommending a bowel training programme</li> <li>➤ The person's suitability to undertake bowel training is assessed including:                             <ul style="list-style-type: none"> <li>• potential for benefit.</li> <li>• functional ability to use the toilet/ toilet aid</li> <li>• cognitive capacity</li> <li>• motivation to undertake and adhere to a personalised bowel training programme</li> <li>• expectations of treatment</li> <li>• has ability to voluntarily contract pelvic floor muscles</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Assessment is essential to establish the cause of the faecal incontinence/bowel dysfunction<sup>28</sup></li> <li>• Bowel training is any programme that includes scheduled attempts to defecate<sup>47</sup></li> <li>• Conservative management, including bowel training, is recommended when faecal incontinence is mild or moderate<sup>28</sup></li> <li>• Active participation is essential to modify behaviour and develop central control over the bowel<sup>32</sup></li> <li>• Individual beliefs and expectations are fundamental to a person's behaviour and indicates their likely participation and adherence<sup>33</sup></li> </ul>	<p>A complete assessment includes:</p> <ul style="list-style-type: none"> <li>• Documented comprehensive individual assessment including lifestyle factors</li> <li>• Diagnosed functional bowel disorder.</li> <li>• Completed bowel diary (minimum 5-7 d)</li> <li>• Individual expectations of bowel training and planned lifestyle changes documented<sup>5,48</sup></li> </ul>
<b>Planning</b>		
<ul style="list-style-type: none"> <li>➤ The person's goals for bowel training are established with the healthcare practitioner, for example, a reduction in the frequency and severity of symptoms; the ability to go out and socialise; reduced carer burden such as laundering soiled clothing and linens, decreased socialization and travel, cost of absorbent products etc.</li> <li>➤ The practitioner develops or structures the person's bowel training programme in collaboration with them, taking into account the following factors before commencing the programme:                             <ul style="list-style-type: none"> <li>• the frequency of evacuation</li> <li>• the duration of the full bowel training programme in weeks/ months</li> <li>• the indicators of improvement</li> <li>• the types of urgency suppression techniques the person will use (where appropriate)</li> <li>• methods to normalise and regulate stool consistency</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• It is important for healthcare practitioners to assist individuals to set specific goals that are personal, and realistic<sup>25</sup></li> <li>• Working towards a specific goal improves motivation and performance<sup>34,35</sup></li> </ul>	<ul style="list-style-type: none"> <li>• Personal goals and indicators of success documented in bowel training plan.</li> <li>• Review dates and end of bowel training programme dates are specified</li> </ul>

(Continues)

- the method the person will use to self-monitor their progress for example bowel diaries
- lifestyle changes are described

#### Intervention

- The healthcare practitioner ensures the bowel training programme is structured and supervised. The programme duration will vary according to the person's progress and goals.
- The healthcare practitioner provides adults undertaking bowel training with verbal and written information and education on:
  - normal bowel function
  - how faecal incontinence occurs
  - factors affecting bowel functioning including diet and dietary fibre, fluids, smoking, exercise, psychological/emotional status and environment
  - medication and laxatives.
  - purpose of bowel training and how it works
  - the need for active involvement, commitment and ongoing motivation by the person
  - psychological strategies to support success
  - use of containment products during bowel training
  - realistic expectations about the efforts required and the potential challenges
  - expected outcomes
- The person's bowel diary (minimum 5-7 d) is interpreted jointly by the person and the healthcare practitioner to identify individual bowel function and patterns and align with agreed goals.
- The healthcare practitioner offers the person a bowel training programme that includes information about:
  - optimal time of day for evacuation
  - frequency of evacuation attempts, for example, daily, alternate days, three times per week
  - optimal type and amount of food intake
  - optimal type and amount of fluid intake
  - individual advice on smoking cessation
  - use of drugs, dietary fibre, or rectal irrigation for faecal
- Regular practice of skills to maintain continence is essential to maintain performance<sup>5,39</sup>
- Intensive supervision by a healthcare practitioner improves the likelihood of positive outcomes<sup>7</sup>
  1. Education is central to all behavioural therapy<sup>15,22</sup>
  2. Understanding the differences between their own bowel function and normal bowel function enables a person to identify where they can change their behaviour<sup>28</sup>
  3. Expert opinion suggests that understanding the purpose and content of bowel training allows a person to actively engage<sup>47,49</sup>
  4. A single nurse-led education session improved post-stroke bowel function<sup>50</sup>; 4-5 nurse-led education sessions reduced faecal incontinence by more than half in one randomised controlled trial<sup>51</sup>
- Documented bowel training programme including mode and frequency of contact between person and healthcare practitioner in bowel training plan.
- Contact appointments agreed
- Details of verbal education and written information provided are recorded in bowel training plan.
- Bowel habit training is undertaken to establish regular, effective and predictable bowel evacuation patterns and adherence to a bowel routine.
- Peristaltic colon contractions increase in frequency following awakening from sleep and meals (gastro-colic reflex). The period after breakfast is the best time for scheduled defaecation<sup>47</sup> or after evening meal.
- Many foods and fluids are known to influence stool consistency and bowel patterns<sup>28</sup>
- Educating patients to resist bowel urgency sensations and postpone evacuation has not yet been subject to rigorous research<sup>5</sup>
- Randomized controlled trials show that dietary fibre supplementation decreased faecal incontinence<sup>51-53</sup> Observed effects of dietary fibre were
- An agreed bowel routine is documented in the bowel training plan
- The person is provided with a copy of their bowel training plan
- Regular bowel diaries are recorded during training programme.
- Documented review of progress towards attaining bowel training goals

- incontinence; antidiarrheal drugs or stool bulking agents may be used to establish and maintain a normal stool consistency and frequency; laxatives, suppositories, enemas or transanal irrigation may be used to empty the rectum to avoid leakage.
- An external anal sphincter (EAS) and pelvic floor muscle exercise programme, tailored to the lifestyle and needs of the person is agreed with the healthcare practitioner. This will include specific exercises aimed at improving strength, speed and endurance of the external anal sphincter and pelvic floor muscle contraction and relaxation.
  - Concerns/anxieties affecting the person's psychological/emotional state are actively screened for and managed.
  - The healthcare practitioner ensures the person can use effective evacuation techniques:
    - Correct positioning on the toilet—may involve use of footstools and leaning forward to increase hip flexion, straighten the anorectal angle, and ensure stability of sitting position.
    - Allowing sufficient time to fully empty bowel
    - Ensuring privacy and no interruptions
    - Attention to privacy and comfort measures for example toilet temperature, noise and odour reduction
  - The healthcare practitioner encourages the person to develop individualised urge suppression strategies:
  - When the person feels the urge to defecate they are encouraged to suppress the urge using the techniques below until the sensation is reduced sufficiently to allow them to get to a toilet without rushing. Once they are in the toilet they are encouraged to wait for a minute or so before actually sitting on the toilet to open their bowels.
  - They gradually increase the amount of time they wait before they use the toilet.
- reduced faecal incontinence frequency and firming of stool consistency in some studies<sup>54–56</sup>
- Observational studies show that dietary fibre supplementation decreased urgency faecal incontinence<sup>11</sup>
  - Observational studies show transanal irrigation decreased fecal incontinence<sup>5</sup>
  - Reported exercise regimens for external anal sphincter and pelvic floor muscles vary widely in terms of the type, number and intensity of exercises taught: for example maximum contraction held for increasing duration up to 10 s (for strength); submaximal contraction held for several seconds (for endurance); fast, short contractions (for speed); how many exercises per day and in what pattern and duration over which the exercises should be performed<sup>7</sup>
  - Psychological and emotional concerns are both a cause and a consequence of faecal incontinence and should be actively screened for<sup>28</sup>
  - Increased hip flexion in squatting straightens the anorectal angle and reduces strain associated with defecation<sup>57</sup>
- Bowel training uses techniques to enable urgency to be resisted and evacuation to be postponed until a suitable time and place can be reached. However, teaching people to resist bowel urgency sensations and postpone evacuation has not yet been subject to rigorous research<sup>5</sup>
  - Bowel urgency may induce feelings of anxiety or panic, which affects ability to concentrate<sup>32</sup>. Hyperventilation and contraction of abdominal muscles are associated with anxiety and panic and raise intra-abdominal pressure, thus increasing the sense of urgency to evacuate.
  - Waiting in the toilet before sitting down to evacuate their bowel
- Education about urge suppression strategies and person's selected techniques is documented in bowel training plan
  - Documented assessment of feelings (anxiety and panic) related to bowel training.

(Continues)

- Urge suppression or deferment involves:
    - a. relaxation—the person is advised to stop, relax their whole body, in particular their abdomen and focus on slow, controlled breathing.
    - b. external anal sphincter and pelvic floor muscle contraction—the person completes 5-8 fast contractions, without increasing their intra-abdominal pressure.
    - c. distraction techniques— mental activities that demand cognitive attention and concentration will distract the person from their sensation of urgency and desire to evacuate. The individual should decide what will work for them (different techniques may be used at different times).  
Examples include: counting backwards from 100 in 7's (or 5's for older adults), identifying girl's names through the alphabet, singing out loud, word searches/crossword puzzles, digital games, reading, making lists.
    - d. applying perineal pressure—sit on a hard surface, rolled towel  
Bowel urgency sensation may subside within 1-2 min.  
When urgency is controlled, encourage person to walk to the toilet at a normal pace.
  - The healthcare practitioner positively reinforces the person's continence skills and improved and/or prolonged bowel control.
  - Individuals are actively encouraged and supported to:
    - a. self-monitor their:
      - perceived capability to relax—to stop what they are doing, take slow, deep breaths, relax their body especially their abdomen and not rush to the toilet until the urgency sensation has diminished
      - duration of urge suppression
      - intensity of urgency sensations
      - number of faecal incontinence episodes
      - reduction in negative evacuation habits such as prolonged or frequent toilet use
      - progress toward achieving a normal bowel pattern
      - lifestyle changes
- reinforces the person's ability to hold off and the success of urge suppression in a safe environment.
- A study of internal anal sphincter pressure wave patterns in 72 adults showed relaxation breathing promotes more regular pressure wave patterns and may aid in reducing fecal urgency and incontinence<sup>54</sup>
  - Learning to 'stop & squeeze'<sup>41</sup> and experiencing success positively reinforces the chosen urge suppression technique and may lead to improved control of faecal urgency/incontinence
  - Explanations for bladder training effects include diverting attention away from the urgency sensation using competing mentally demanding activities.<sup>21</sup> This proposed mechanism may be equally applicable to bowel training
- Operant learning through experiencing positive effects of bowel training may build confidence in bowel control ability. Positive reinforcement of progress towards goal attainment is a fundamental part of bowel training<sup>55</sup>
  - Self-monitoring refers to monitoring of specific physiologic parameters or symptoms of a health condition.<sup>46</sup> Two components of self-monitoring include:
    - i) *awareness* of bodily symptoms, sensation, daily activities, voiding habits and cognitive processes and
    - ii) *measurement* including reading and recording results
  - Together these inform understanding and provide information for action by the individual, in consultation with health care practitioners<sup>32</sup>
  - Supporting an individual's autonomy and competence development will
  - Record of progress is documented.
  - Use of written bowel training programme records, agreed by person and health care practitioner.
  - Documented patient concerns/ anxieties that affect the patients psychological/emotional state and how they are being managed

- b. self-determine their:
    - progression time for example increased urge suppression/delay time
    - decisions about when to increase duration of their urge suppression/delay time.
  - c. self-affirm their:
    - use of personally meaningful self-coping statements such as 'I don't have to go now; I can wait'; 'I am in control of my bowel'
- foster motivation towards bowel training, ongoing engagement and adherence<sup>35</sup>
- Conscious awareness of automatic thoughts through examining them can enable them to be self-managed. Techniques can be learned to change incontinence-related cognitions, emotions and behaviours from negative to positive<sup>32</sup>
  - Use of positive self-coping statements (verbally out loud is better) can interrupt automatic thoughts and act as a counter directive for example 'I can wait 2-3 min to go to the bathroom or 'I can conquer this feeling, I do not have to go now' rather than 'I can't wait, I have to go now'<sup>11</sup>

#### Evaluation

- Regular contact between the person and the healthcare practitioner is made during the bowel training programme to review progress, assess adherence, provide positive reinforcement and adjust schedules.
- At the end of the bowel training programme a range of person-focused outcomes are assessed. These may include:
  - a. perceptions of bowel condition and any improvements/changes
  - b. satisfaction with bowel training
  - c. tolerability of bowel training processes and adherence to recommended programme
  - d. frequency and severity of bowel symptoms including urgency and incontinence episodes
  - e. evacuation intervals
  - f. lifestyle changes
  - g. quality of life
  - h. change in body-worn absorbent product use (eg, decrease in number)
- Feedback and reinforcement of overall changes from start of training programme confirms effectiveness and motivates continued adherence to maintain progress made<sup>26</sup>
- Positive reinforcement of progress towards goal attainment is a fundamental part of bowel training<sup>55</sup>
- Bowel diaries completed during the training programme.
- Use of validated, standardised symptom and quality of life tools, to ensure robust measurement and ability to compare outcomes in different populations, study settings etc.
- Measures are recorded before and after the bowel training programme.
- Goals are reviewed and level of achieving them is periodically evaluated

## Abstract

**Aims:** The prevalence of urinary incontinence (UI) in the developing world varies widely. Factors influencing prevalence rates are a key area of interest, and knowledge of these would provide appropriate planning for preventive primary and secondary health care programs. The objective of this report was to synthesize the best available evidence to determine UI prevalence rates in adult women in a population setting.

**Methods:** A comprehensive search strategy was employed to find published and unpublished studies. Databases searched included PubMed, Embase, Scopus, Web of Science, and Google Scholar. We used the standardized Joanna Briggs Institute Meta-Analysis of Statistics, Assessment, and Review Instrument to appraise the included studies.

**Results:** In total, 54 studies with 138,722 women aged 10 to 90 years were included in this meta-analysis. Prevalence of UI ranged from 2.8% in Nigeria to 57.7% in Iran. The total prevalence of UI was 25.7% (95% CI: 22.3–29.5) and the prevalence rates for stress, urgency, and mixed UI were 12.6% (95% CI: 10.3–15.4), 5.3% (95% CI: 3.4–8.3), and 9.1% (95% CI: 7.0–11.8), respectively. When we excluded the elderly population, UI prevalence only slightly changed (26.2%; 95% CI: 22.6–30.2). Prevalence rates varied considerably during different recall periods, ranging from 15.6% for UI during the last 12 months to 41.2% for UI during the last 3 months. However, the study quality and use of validated vs nonvalidated questionnaires only had a minor impact on the prevalence rates.

**Conclusions:** The prevalence, methodology, and definition of UI vary widely. A large-scale multinational study with a homogeneous methodology is

necessary to correctly calculate and compare the prevalence rates to improve health policies in the developing world.

#### KEYWORDS

developing countries, prevalence, urinary incontinence

## 1 | INTRODUCTION

Urinary incontinence (UI) is a global medical problem observed in all age groups in different countries, cultures, and ethnicities.<sup>1-3</sup> The International Urogynecological Association (IUGA)/International Continence Society (ICS) joint report on the terminology for female pelvic floor dysfunction defined UI as a “complaint of loss of urine.”<sup>4</sup> UI is a clinical condition<sup>5</sup> and not a disease itself.<sup>6</sup> UI is often underestimated and underdiagnosed in both the developed and developing world.<sup>7</sup> UI is more common in older women<sup>2</sup> and can affect up to 58% to 84% of the elderly population.<sup>5</sup> However, its general prevalence is reported to be approximately 34% in elderly women and 22% in elderly men.<sup>8</sup> A British survey showed that the prevalence of female UI may only be approximately 14%.<sup>9</sup> The prevalence rates vary in different countries because of the utilization of various definitions of UI, target populations, study characteristics, assessment tools, response rates, age groups, gender, availability of health care, and other factors.<sup>10,11</sup>

There are many definitions and assessment tools for the diagnosis of UI. This variety limits the establishment of UI prevalence rates and definition of the problem. Many women consider UI as an inevitable part of their life which can delay or even prevent the diagnosis.<sup>12</sup> Milsom et al<sup>13</sup> stated that (a) most of the people with UI do not seek help, (b) only a small portion of this population receive medication or surgery, and (c) the worldwide estimation of UI is limited due to the lack of epidemiological data from the underrepresented research populations. These statements apply especially for women living in developing countries. Parameters with an influence on the (change of) symptomatology are a key area of interest, and knowledge of these factors can be useful for primary prevention or prevention of deterioration of the condition. The association of UI with other diseases, socioeconomic status, ethnicity, and lifestyle has only been examined in a few studies.<sup>6,14</sup>

UI is associated with a number of psychological issues such as anxiety, embarrassment, fear, loss of self-esteem, worry, vulnerability, shame, depression, paranoia, and uncleanliness.<sup>15</sup> UI has been declared as a global medical problem with a considerable impact on health care systems.<sup>15,16</sup> Several studies have been conducted to determine the effect of UI on quality of life.<sup>17,18</sup>

Recent studies demonstrated that UI is also a predictor of death.<sup>19-22</sup> When compared to continent patients, UI is associated with increased mortality with a pooled nonadjusted hazard ratio of 2.22 (95% CI: 1.77-2.78). The mortality risk increases with UI severity: 1.24 (95% CI: 0.79-1.97) for light, 1.71 (95%CI: 1.26-2.31) for moderate, and 2.72 (95% CI: 1.90-3.87) for severe UI.<sup>23</sup> Therefore, health systems should be able to predict the burden and mortality of the condition in different populations to improve continence programs.

### 1.1 | Aim of the review

Based on our initial literature search, no systematic review or meta-analysis on UI in the developing world has been published so far. Our review aims to identify studies on UI in the developing world, calculate the total prevalence, the prevalence rates of SUI, UUI, and MUI, and define parameters that could influence UI prevalence rates (eg, study quality, recall periods, different questionnaires, and geographical regions).

## 2 | MATERIAL AND METHODS

The title of our analysis has been registered in [http://joannabriggs.org/research/registered\\_titles.aspx](http://joannabriggs.org/research/registered_titles.aspx)

### 2.1 | Review questions

Primary outcome measure was the UI prevalence rate in adult women living in developing countries, as published in population-based studies. The definition of developing countries followed the recommendations of the World Bank for low- or middle-income countries.<sup>24</sup> Secondary outcome measures were the establishment of prevalence rates of UI subtypes and determination of their associated risk factors.

### 2.2 | Inclusion criteria

- Participants: the quantitative component of this review only considered studies that included adult women

who live in developing countries. Only population-based studies were included.

- **Outcomes:** this review considered all related studies that included the following outcome measures: pooled prevalence and prevalence rates for different types of UI (including SUI, UUI, and MUI).
- **Types of studies:** the quantitative component of the review considered epidemiological study designs including prospective and retrospective cohort studies, case-control studies and analytical cross-sectional studies. The quantitative component of the review also considered descriptive epidemiological study designs, including descriptive cross-sectional studies.

### 2.3 | Search strategy

The search strategy aimed to identify both published and unpublished studies. A three-step search strategy was utilized in this review. Initially, a limited search of the PubMed/Medline and CINAHL databases was undertaken, followed by the analysis of the text identifying words used in the title and abstract, and of the index terms used to describe the article. A second search using all identified keywords and index terms was then undertaken across all included databases (see list below). Afterwards, the reference list of all identified reports and articles was searched for additional studies. Studies published in any language were considered suitable for this systematic review.

### 2.4 | Databases

- Stage 1: PubMed/Medline, CINAHL, Virginia Henderson Library.
- Stage 2: Medline, CINAHL, Academic Search Premier, Web of Science, DARE, PsyINFO, and ERIC.
- Grey Literature: Virginia Henderson Library, MEDNAR (which includes Google Scholar), New York Academy of Medicine Grey Literature Report, scirus.com, and Proquest Dissertations. Others resources were professional organizations relevant to the review objective to search for reports, guidelines, or unpublished research.

Initial keywords were “urinary incontinence” and “prevalence” (Supporting Information **Appendix 1**).

### 2.5 | Assessment of methodological quality

Publications with quantitative data were selected by two independent reviewers (HM and SH) for assessment of

the methodological validity before inclusion in the review using the Joanna Briggs Institute Meta-Analysis of Statistics Assessment and Review Instrument (JBI-MASStARI)<sup>25</sup> (Supporting Information **Appendix 2**). Disagreements between the reviewers were resolved by discussion or a third reviewer (HSP). Selected studies were categorized into three quality groups based on the score of each study. A total score of greater than 80% was defined as high quality, a score between 60% and 80% as medium quality and a score less than 60% as low quality.

### 2.6 | Data collection

Quantitative data extracted from papers used the standardized data extraction tool from JBI-MASStARI (Supporting Information **Appendix 3**). Extracted data included specific details about the study populations, methods, and outcomes of interest for the review question and other specific objectives.

### 2.7 | Data synthesis

Quantitative papers, whenever possible, were pooled in the statistical meta-analysis by using the JBI-MASStARI and Comprehensive Meta-Analysis (CMA) software (version 2.2; Biostat, Englewood, NJ). All results were subject to double data entry. Weighted mean differences (for continuous data) and their 95% confidence intervals (95% CI) were calculated for the analyses. Heterogeneity was assessed statistically by using the standard  $\chi^2$  test and also explored by using subgroup analysis based on the different quantitative study designs included in this review. Where statistical pooling was not possible, findings were presented in a narrative form, including tables and figures.

### 2.8 | Assessment of heterogeneity

Both fixed method and random effects models were used. Statistical heterogeneity was assessed by using the  $I^2$  value and the result of the  $\chi^2$  test. Results of the appropriate model are presented as forest plots.

## 3 | RESULTS

### 3.1 | Selection of studies

We initially identified a total of 3225 studies. We then removed duplicate articles ( $n = 38$ ) and screened the title as well as abstract of the remaining studies ( $n = 3187$ ). Articles

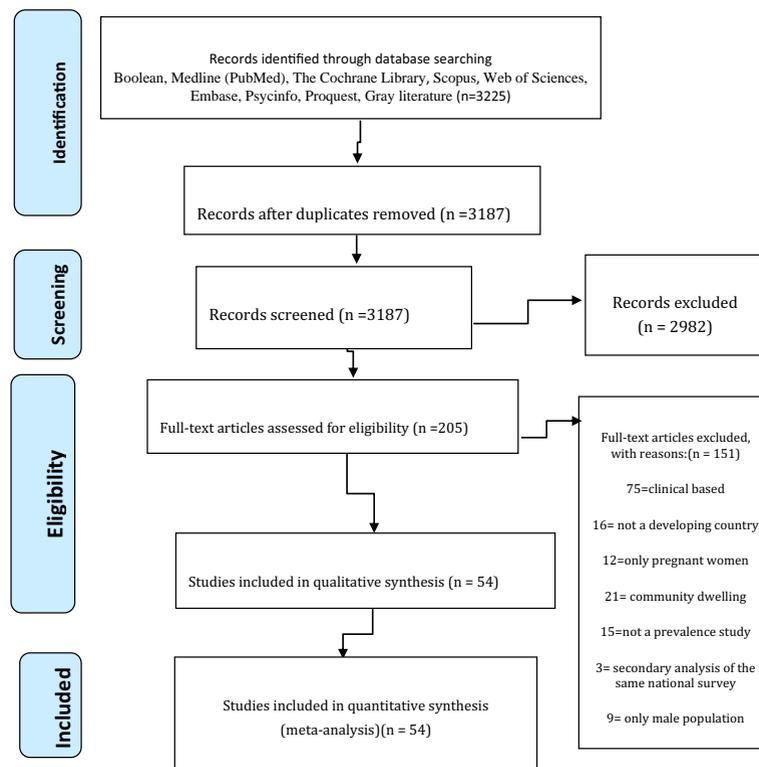

unrelated to UI were excluded, for example fecal incontinence. Studies related to other urinary problems, for example overactive bladder, urinary tract infections or male incontinence, and studies in developed countries were also excluded. Of the initially selected titles and abstracts, 2982 had to be excluded and, finally, 205 articles were retrieved for the detailed full-text review. Of these, 151 articles were excluded because they did not meet the inclusion criteria, for example prevalence studies in pregnant women. Finally, a total of 54 studies were included in the systematic review.<sup>2,6,8,9,23,26-71</sup> All studies underwent methodological quality assessment. The summary of search results and study selection is shown in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram (Figure 1). Although all studies were included in the meta-analysis, five studies only reported about the prevalence rates for UI subtypes but not about the total prevalence rate.<sup>8,54,63,66,67</sup> Therefore, not all of the 54 selected studies appeared in the forest plots for all subgroup analyses.

### 3.2 | Assessment of the methodological quality

All articles were selected for quality synthesis (Table 1). The JBI checklist for critical appraisal of systematic reviews was used for this purpose.<sup>25</sup> No article had to be excluded because of the acceptable overall quality of the included studies. The numbers of high-, medium-, and low-quality articles were 23 (42.6%), 25 (46.3%), and 6 (11.1%), respectively (Figure 2).

### 3.3 | Assessment of heterogeneity

To evaluate the level of heterogeneity,  $I^2$  statistic was calculated in the whole study and the subgroups. The  $I^2$  across all studies and considering the random effect model was 48.84. In the subgroups based of the quality of the studies,  $I^2$  was “0”, 45.17, and 55.42 for low-, medium- and high-quality studies, respectively. In the

FIGURE 2 Continued

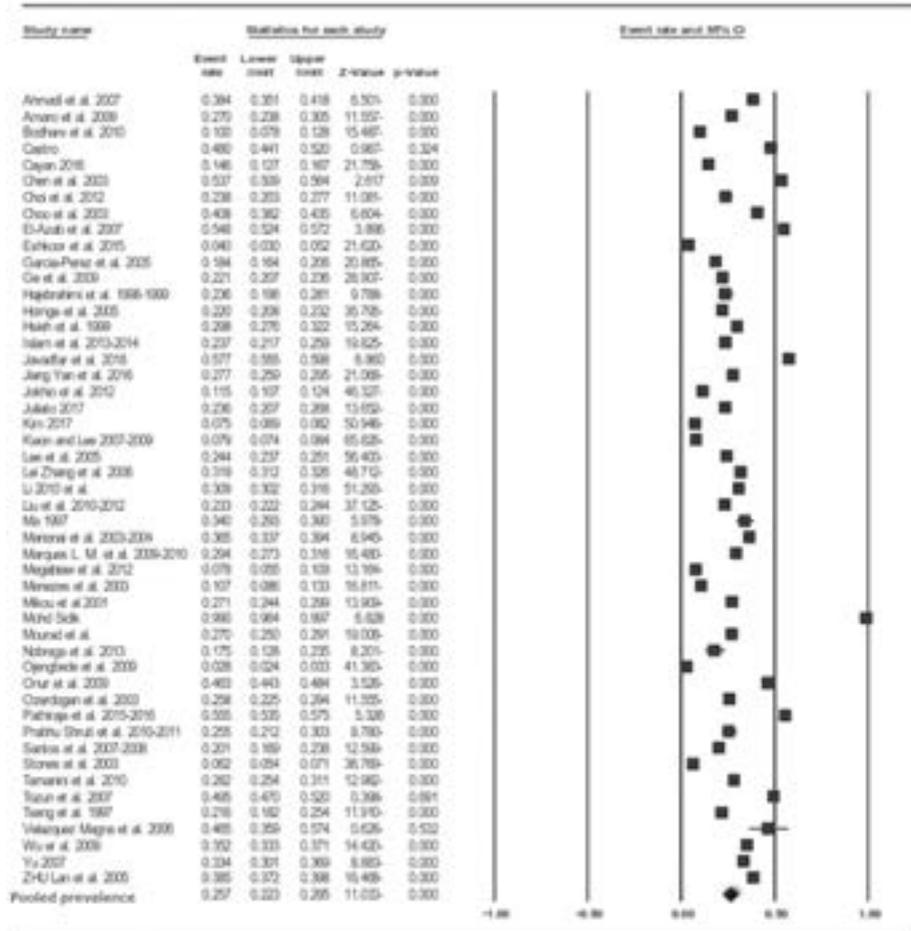

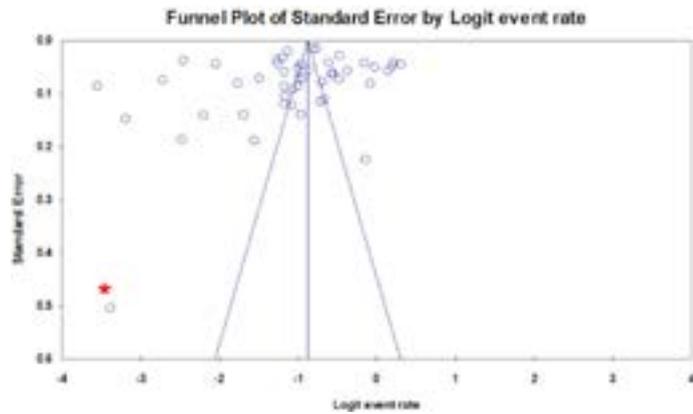

subgroups based on the definition of UI,  $I^2$  was 17.26, 47.91, 4.44, 0, 65.28, and 46.90 for UI defined as “any involuntary loss of urine”, “involuntary loss of urine in the last 4 weeks”, “involuntary loss of urine in the last 3 months”, “involuntary loss of urine in the last 6 months”, “involuntary loss of urine in the last year”, and “not identified”, respectively. The  $I^2$  was 60.55 in the studies that used a validated questionnaire and 19.48 for the studies that used nonvalidated questionnaires. Finally,

the  $I^2$  was calculated 64.70 in the “country” subgroup and 26.87 in “region” subgroup.

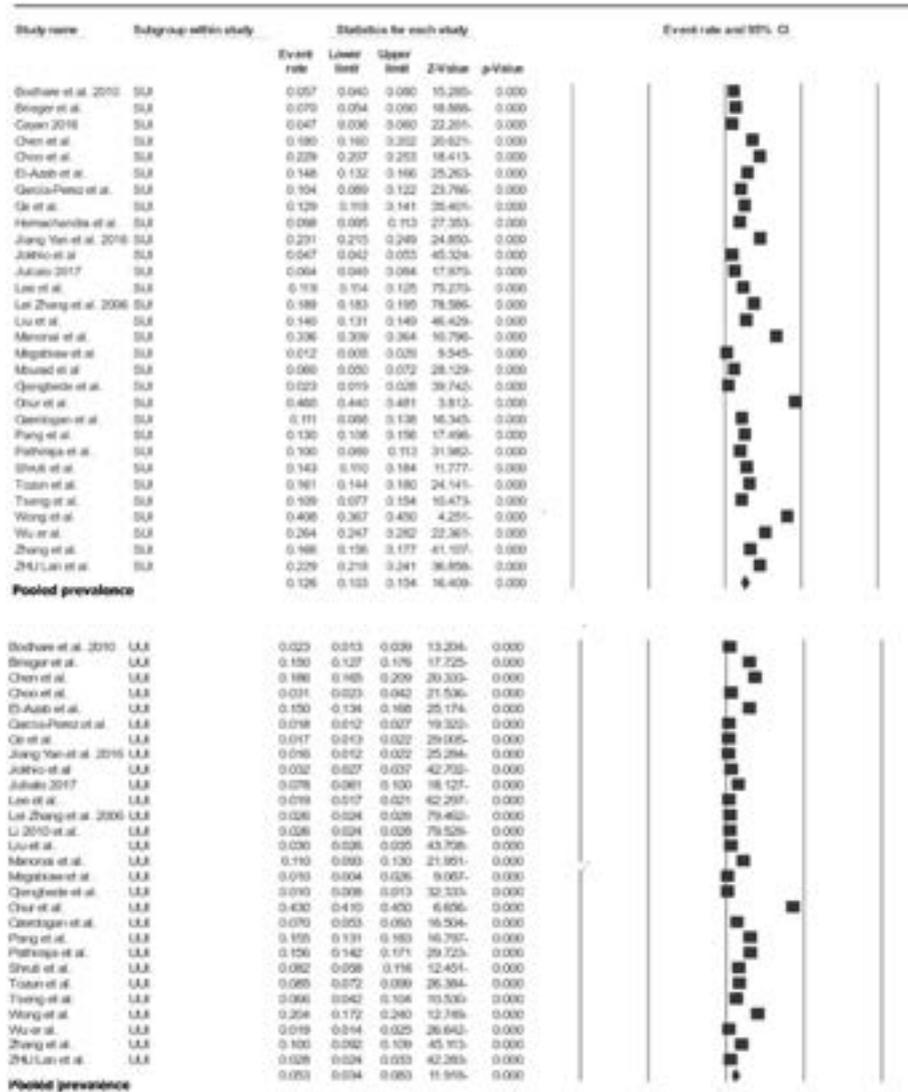

### 3.4 | Publication bias

To assess the publication bias of the selected studies, a funnel plot was drawn. It seems that the sample size of the included studies is appropriate for the purpose of

**FIGURE 3** Funnel plot analysis of 54 studies. Only one study on the left side (\*) below is totally out of distribution<sup>50</sup>

**FIGURE 4** Prevalence of urinary incontinence in the individual studies of the selected literature resulting in a pooled prevalence rate of 25.7% (95% confidence interval: 22.3-29.5) using random-effects analysis

**FIGURE 5** Prevalence rates for subtypes of urinary incontinence using random-effects analysis: stress urinary incontinence (SUI) 12.6% (95% confidence interval 10.3-15.4), urgency urinary incontinence (UUI) 5.3% (95% confidence interval 3.4-8.3) and mixed urinary incontinence (MUI) 9.1% (95% confidence interval 7.0-11.8)

our analysis but the pattern of distribution is not completely symmetric. This could have been caused by a publication bias or methodological flaw. We did not exclude any of these studies and performed subgroup analyses because only one study<sup>43</sup> was totally out of distribution (Figure 3).

### 3.5 | Prevalence of UI

The prevalence rates of the individual studies and the total prevalence of UI is shown in Figure 4. In the fixed method analysis, prevalence of UI was 29.4% (95% CI: 29.1-29.6) but  $I^2$  was more than 50% which demonstrates

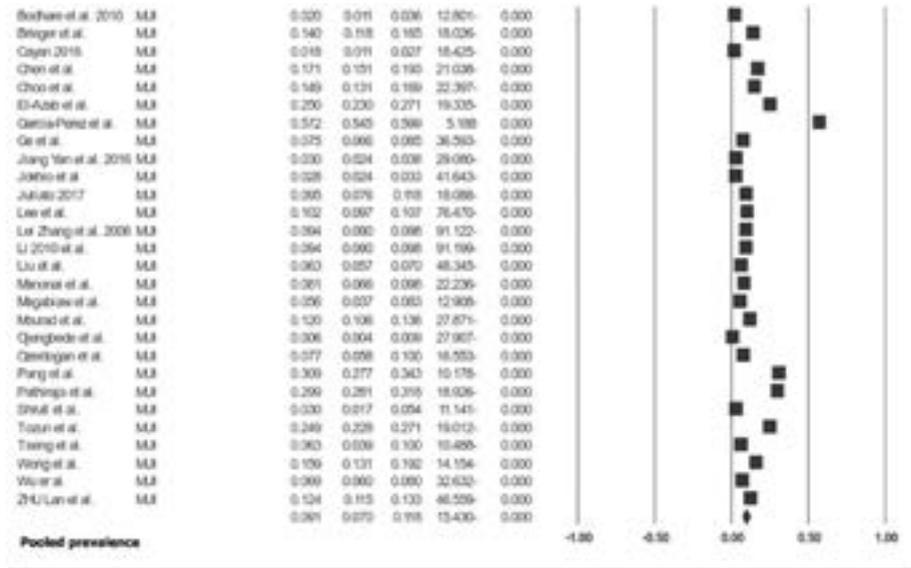

FIGURE 5 Continued

high heterogeneity of the studies. We therefore used the random effect model here and for all additional analyses that showed an overall UI prevalence of 25.7% (95% CI: 22.3-29.5). The prevalence of different UI types was 12.6% (95% CI: 10.3-15.4), 5.3% (95% CI: 3.4-8.3), and 9.1% (95% CI: 7.0-11.8) for SUI, UUI, and MUI, respectively (Figure 5).

### 3.6 | Prevalence of UI without elderly women

The prevalence of UI significantly increases with age.<sup>2</sup> However, we could not perform the age-based analysis for our patient groups because this data was unavailable in the literature. For this reason, we performed a subgroup analysis after excluding studies focussing on the elderly population in the title or text (n = 6). This analysis showed that the total UI prevalence only changed slightly to 26.2% (95%CI: 22.6-30.2; Figure 6).

### 3.7 | Prevalence of UI based on the definition of incontinence

There are several definitions for UI that may influence the prevalence. The prevalence of UI for any involuntary loss of urine independent on the time period was 25.5% (95% CI:

18.5-34.2; Figure 7). When UI was defined as involuntary loss of urine in the last 4 weeks, the prevalence rate was 33.4% (95% CI: 29.5-37.5). However, when UI was defined as involuntary loss of urine during the last 3 months, the prevalence rate was 41.2% (95% CI: 18.4-68.5), whereas the prevalence rate of any involuntary loss of urine during the last year was 15.6% (95% CI: 10.9-21.8).

### 3.8 | Prevalence of UI according to the study quality

To demonstrate the effects of the study quality on data pooling, we divided the retrieved studies according to their methodological quality. The UI prevalence was 28.2% (95% CI: 24.0-32.9), 19.4% (95% CI: 15.0-24.8), and 21.8% (95% CI: 11.1-38.3) for studies with high, medium, and low quality, respectively (Figure 8).

### 3.9 | Prevalence of UI according to the use of validated vs nonvalidated questionnaires

The methods to assess the prevalence of UI varied widely. Only approximately half of the studies (55.5%) utilized validated questionnaires (n = 30). For this reason, we analyzed the prevalence of UI according to the use of validated or

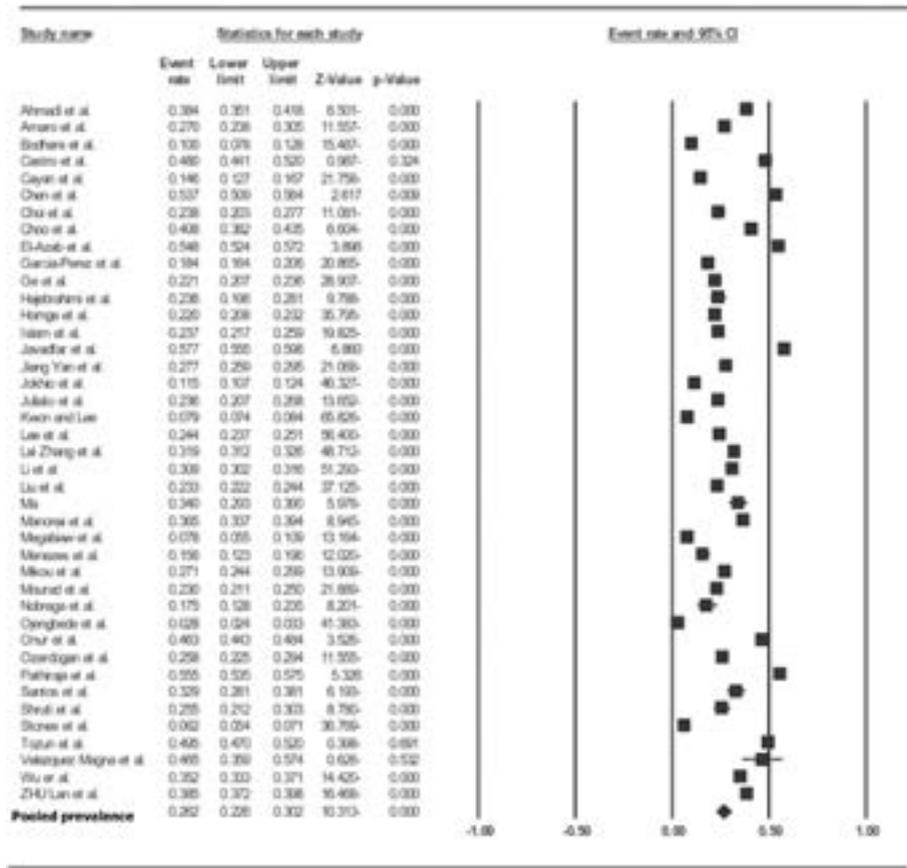

FIGURE 6 Prevalence of urinary incontinence excluding elderly women using random-effects analysis

nonvalidated questionnaires. In the studies with validated questionnaires, the prevalence rate of UI 23.5% (95% CI: 19.4-28.1). In contrast, the prevalence rate was 27.7% (95% CI: 22.6-33.4) in studies that used nonvalidated questionnaires.

### 3.10 | Prevalence of UI according to geographical region

Included studies were also analyzed according to their geographical origin (Figure 9):

- Eastern Asian and Pacific region: 25.6% (95% CI: 21.4-30.2)
- South Asia: 14.2% (95% CI: 6.1-29.8)
- Europe and Central Asia: 32.2% (95% CI: 18.9-49.15)
- Middle East and North Africa: 37.3% (95% CI: 25.8-50.5)
- Sub-Saharan region: 4.6% (95% CI: 1.7-12.3)
- Latin America: 28.8% (95% CI: 22.2-36.4).

In large population studies in individual regions or countries, the prevalence rate of UI was 18.9% (95% CI: 14.4-24.3). In contrast, the prevalence of UI was 28.8% (95% CI: 24.4-33.5) when only a small population sample was investigated. The results of all subgroup analyses are summarized in Table 2.

## 4 | DISCUSSION

Our systematic review and meta-analysis is the first comprehensive report of UI prevalence rates in the developing world. Our analysis demonstrates that approximately 26% of the adult female population in developing countries has UI. However, more accurate prevalence data is difficult to retrieve from the epidemiologic literature since striking differences exist among the studies in terms of methodology, definitions of UI and

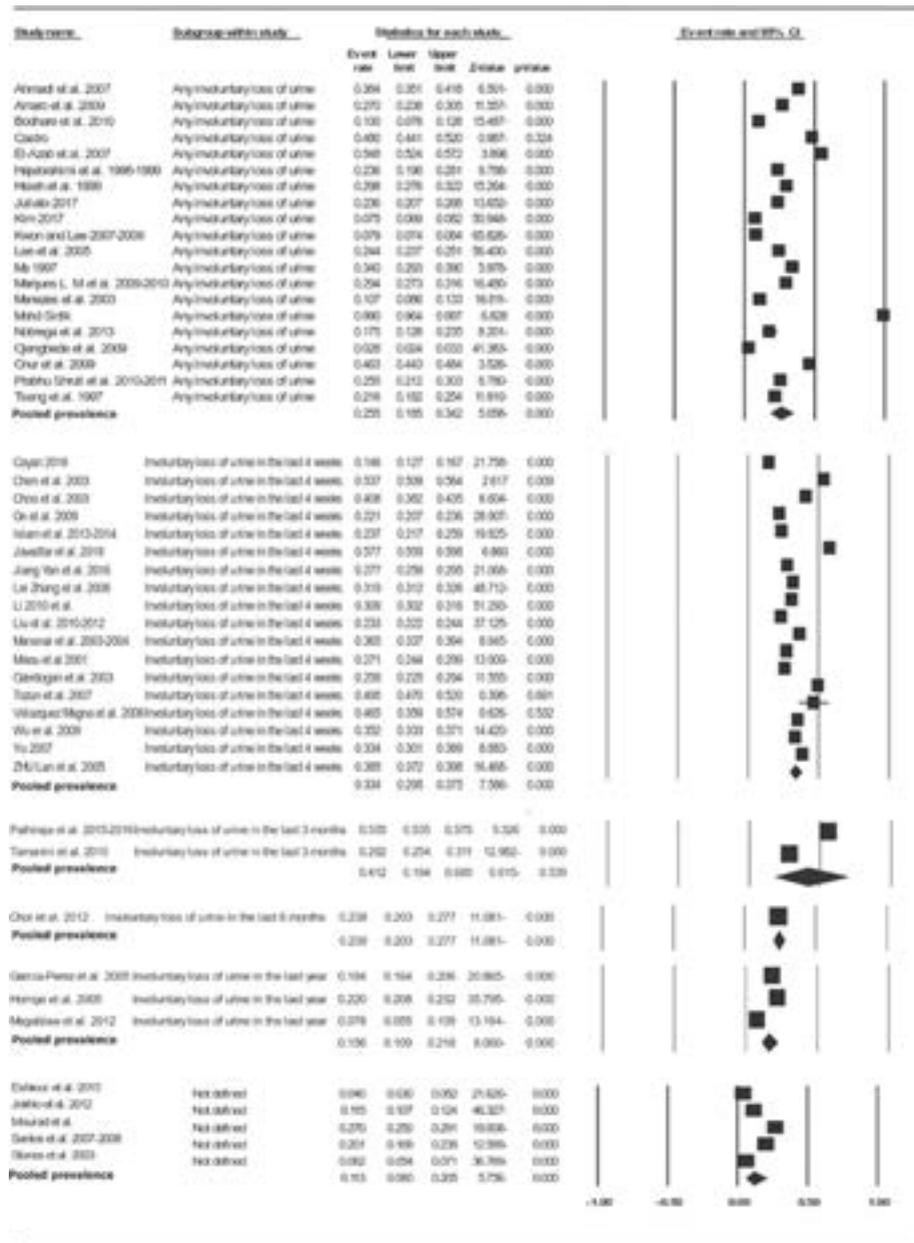

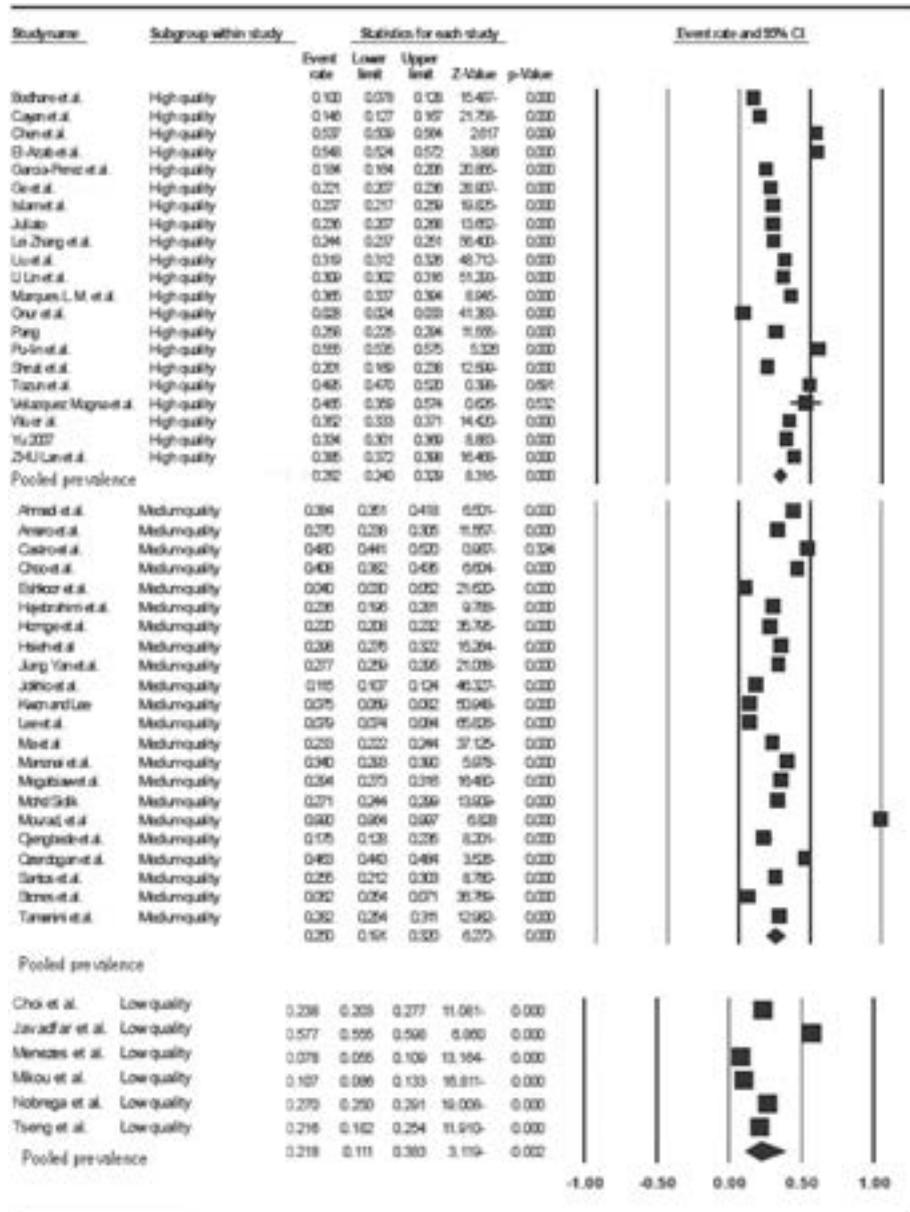

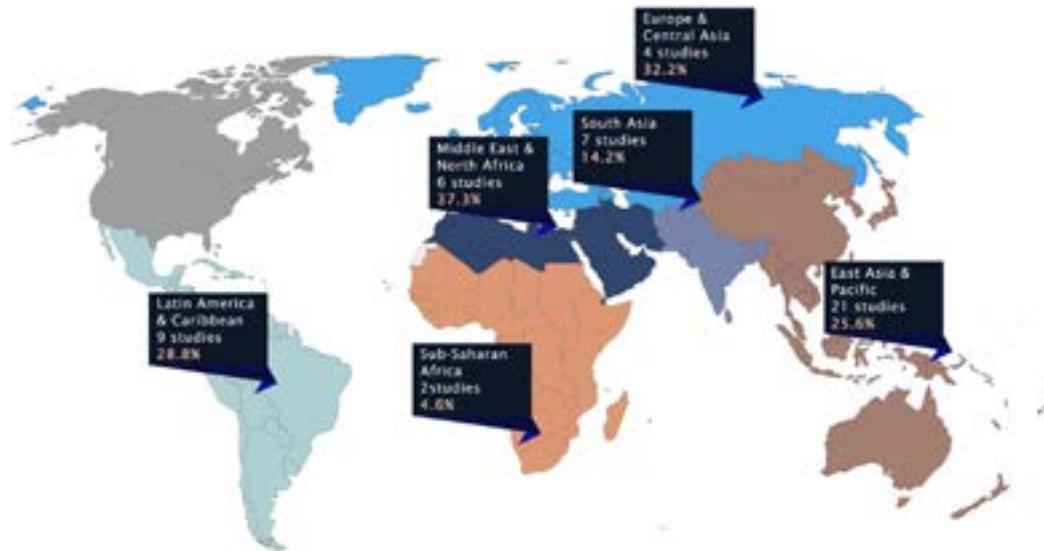

FIGURE 7 Prevalence of urinary incontinence (UI) based on its definition using random-effects analysis. Some studies defined UI as any involuntary loss of urine, whereas other studies defined incontinence as involuntary loss of urine during the last 4 weeks, 3 months, or 12 months. However, some studies did not define the recall period for UI

**FIGURE 8** Prevalence of incontinence according to the study quality using random-effects analysis. Publications with quantitative data were selected for assessment of the methodological validity before inclusion in the review by using standardized critical appraisal instruments from the Joanna Briggs Institute Meta-Analysis of Statistics Assessment and Review Instrument (JBI-MASARI) (Supporting Information Appendix 2). Selected studies were categorized into three groups based on the score of each study. A total score of less than 80% was defined as high quality, a score between 60% and 80% as medium quality and a score less than 60% as low quality

**FIGURE 9** Urinary incontinence prevalence rates based on studies in different geographical locations

populations that together limit the calculation of more accurate estimates. The heterogeneity between the studies prevented additional calculations but our results still provide some important insights into the parameters that influence the UI prevalence in the developing world.

The prevalence rate of SUI (12.6%) was higher than the prevalence rates of MUI (9.1%) or UUI (5.3%). Most strikingly, the prevalence of MUI in the developing world is almost two-fold higher than for UUI. Contradictory data appeared when comparing the prevalence rates for the recall periods of 3 months (41.2%) and 12 months (15.6%). Patients may have overestimated the frequency of UI during the shorter recall period or forgotten urinary leakage episodes during a longer recall period, especially in women with infrequent or less severe UI. In the present analysis, we did not have any time restriction of the published literature. Therefore, it is also possible that more recently published studies demonstrate a higher prevalence of UI due to greater awareness and reporting.

In our meta-analysis of 54 studies, heterogeneity in the fixed method model was high. Nevertheless, the heterogeneity in a meta-analysis of clinical trials should be small because all included studies estimate the same condition for a similar population in one region.<sup>74</sup> However, this heterogeneity is still possible due to differences in study populations, measurement methods, and possible cultural differences, especially when effects are measured by applying patient-reported outcomes.<sup>75</sup> Because of the high heterogeneity of the studies, we

performed random-effect analyses for the main results and subgroups. It is arguable whether random-effect analyses are more suitable because different studies may measure different items in epidemiological studies.<sup>76</sup> The situation is different when results are pooled from several epidemiological studies. Here different studies definitely measure different things. There is no way of controlling for all possible confounders and, therefore, substantial heterogeneity can be expected.<sup>74</sup>

In the current meta-analysis, the funnel plot was not symmetric for the selected studies and, therefore, some kind of publication bias or methodological effect is likely. Inadequate response rate can also cause an asymmetric funnel plot. In other words, we cannot see a uniform methodology and assessment tool for screening and diagnosing UI across the studies.

The difficult task in the interpretation of the meta-analysis results, despite its purely statistical tool nature, is to draw general conclusions for the real world based on analyses in the theoretical world in which all models are correct and all prerequisites are fulfilled.<sup>23</sup> The majority of the included studies were conducted in Eastern Asia and the Pacific region and only a few studies were carried out in Sub-Saharan Africa. The high number of studies in a highly populated country like China<sup>45,50-52,58,66-70,72</sup> is plausible but the high number of studies in less populated countries like Turkey<sup>28,44,47,62</sup> may influence the overall outcome of the meta-analysis. This appears to be important because ethnicity can influence the prevalence

**TABLE 2** Summary of subgroup analyses for urinary incontinence in the developing countries

Variables	Event rate	
	Random-effect analysis % (95% CI)	Fixed method model % (95% CI)
Total UI prevalence	25.7% (22.3-29.5)	29.4% (29.1-29.6)
SUI	12.6% (10.3-15.4)	17.3% (17.0-17.6)
UUI	5.3% (3.4-8.3)	7.6% (7.4-7.8)
MUI	9.1% (7.0-11.8)	12.1% (11.8-12.3)
UI prevalence without elderly women	26.2% (22.6-30.2)	29.3% (29.1-29.6)
UI prevalence based on its definition		
Any involuntary loss of urine	25.5% (18.5-34.2)	23.4% (22.9-23.8)
Involuntary loss of urine in the last 4 wk	33.4% (29.5-37.5)	32.5% (32.2-32.9)
Involuntary loss of urine in the last 3 mo	41.2% (18.4-68.5)	48.3% (46.6-50.1)
Involuntary loss of urine in the last year	15.6% (10.9-21.8)	20.7% (19.7-21.7)
UI prevalence based on study quality		
High quality	28.2% (24.0-32.9)	31.5% (31.1-31.8)
Medium quality	25.0% (19.1-32.0)	21.6% (21.2-22.0)
Low quality	21.8% (11.1-38.3)	36.3% (34.9-37.7)
UI prevalence based on questionnaire type		
Validated	23.5% (19.4-28.1)	27.7% (27.4-28.0)
Nonvalidated	27.7% (22.6-33.4)	34.0% (33.5-34.6)
UI prevalence based on geographical location		
East Asia and Pacific	25.6% (21.4-30.2)	27.5% (27.3-27.8)
South Asia	14.2% (6.1-29.8)	26.3% (25.3-27.2)
Europe and Central Asia	32.2% (18.9-49.1)	40.3% (38.9-41.6)

**TABLE 2** (Continued)

Variables	Event rate	
	Random-effect analysis % (95% CI)	Fixed method model % (95% CI)
Middle East and North Africa	37.3% (25.8-50.5)	42.8% (41.6-43.9)
Sub-Sahara	4.6% (1.7-12.3)	3.4% (2.9-3.9)
Latin America	28.8% (22.2-36.4)	29.8% (28.5-31.0)

Results of both the random-effect analysis, which were used throughout the articles, and the fixed method model are provided.

Abbreviations: MUI, mixed urinary incontinence; SUI, stress urinary incontinence; UI, urinary incontinence; UUI, urgency urinary incontinence; 95% CI, 95% confidence interval.

and type of UI.<sup>34,52</sup> The highest prevalence of UI, with more than 37% of population affected, was seen in Middle East and North Africa as well as in Europe and Central Asia, whereas the lowest prevalence rate was seen in Sub-Saharan countries. These variations in the prevalence rates of UI confirm that the region with different cultures and races influences results.<sup>1-3,77</sup> Other explanation for the geographical differences is its impact on social activities and responsibilities in different cultures and regions. Embarrassment, shame, lack of trust to the health system as well as the lack of knowledge and understanding of incontinence as a disease decrease the help seeking behavior in the patients. Thus, some patients rather hide their condition and others might consider it a natural process of aging.<sup>78</sup> Different definitions of UI complicate the calculations and produce heterogeneous data.<sup>79,80</sup> For example, the UI prevalence rate of UI ranged from 12% to 53% with a mean of 35.1% in the study of Diokno et al. In this study, the authors defined UI as urinary leakage at 6 or more days during the last 12 months.<sup>81</sup> When UI was defined as any uncontrolled loss of urine with frequency of at least twice per month, the prevalence rate ranged from 4.5% to 37%, with a mean of 18%.<sup>82</sup> These findings show that the accurate and reproducible prevalence of UI cannot be measured without using standardized definitions and validated questionnaires in well-designed high-quality studies.<sup>79</sup>

Several studies reported about the prevalence of different UI types, including SUI, UUI, and MUI. The most prevalent type of UI in the individual studies and in our meta-analysis was SUI. The prevalence ranged between 13% and 50% in younger and between 6.4% and 42.2% in older women. The number of participants included in the group with younger women ranged from 405 to 27 936 and the number of

participants included in the group with older women from 227 to 142 651.<sup>40,55,62,64,68</sup> It seems that the lower and upper limits of prevalence rates are different in first world countries where study participants were mainly evaluated by population-based or cross-sectional surveys. In contrast, data in the developing world was frequently collected by non-validated questionnaires for self-completion, postal surveys or face-to-face interviews.<sup>29,31,33,34,41,43,47,49,50,56,58,62,63,66,69,70</sup>

This was the reason why we performed a subgroup analysis to distinguish the UI prevalence rates with validated or nonvalidated questionnaires. Our subanalysis showed that UI prevalence rates with nonvalidated questionnaires are almost identical to those obtained by validated questionnaires. Therefore, we are confident that the use of non-validated questionnaires in 45% of the studies did not have a relevant impact on the overall result.

#### 4.1 | Recommendations for future research

There are still limited numbers of studies assessing the UI prevalence in developing countries. More studies are needed to draw a more accurate, valid, and homogenous picture of the problem. Furthermore, there is a need to use one internationally accepted method for assessing the prevalence of UI which includes, next to others, the same sampling strategy, definition of UI, questionnaires, and age groups. Since there is a high prevalence rate of UI in different regions of the world, additional studies can help estimating the true and accurate prevalence rates worldwide.

## 5 | CONCLUSIONS

Despite differences in the definition of UI, assessment tools, geographical regions, and ethnicities, we were able to calculate the overall prevalence of female UI in the developing world, which is approximately 26%. However, UI prevalence rates vary widely throughout the world and, therefore, prevalence rates of 2.8% or 57.7% can both be meaningful. Surprisingly, the prevalence of UI varied widely in smaller regions. We were unable to perform an age-based analysis of UI because of the lack of data in the included studies. A multinational study in the developing world with inclusion of different age groups and regions/ethnicities as well as use of identical validated questionnaires and study methodology are necessary for future research and health care policies. Our analysis may stimulate researchers and stakeholders in designing appropriate studies for determination of the exact prevalence of UI.

## ACKNOWLEDGMENTS

The researchers would like to thank the regional ethics committee and the vice-chancellor of the Research Center for Evidence Based Medicine and Research for the financial support (Grant No. IR.TBZMED.REC.1397.568). They would also like to thank the International Continence Society for their interest in and approval of the study.

## Artificial Urinary Sphincter: Executive Summary of the 2015 Consensus Conference

X. Biardeau, S. Aharony, the AUS Consensus Group,\* L. Campeau, and J. Corcos\*\*  
Department of Urology, Jewish General Hospital, McGill University, Montreal, Québec, Canada

### INTRODUCTION

The AMS800™ device, by far the most frequently implanted artificial urinary sphincter (AUS) worldwide, is considered to be the “gold-standard” when male incontinence surgical treatment is contemplated. Despite 40 years of experience, it is still a specialized procedure with a number of challenges. Here, we present the recommendations issued from the 2015 ICS AUS Consensus Group, regarding indications, management, and follow-up AMS800™ implantation or revision.

### MATERIALS AND METHODS

Under ICS auspices, an expert panel met on July 10, 2015 in Chicago, IL, in an attempt to reach a consensus on diverse issues related to the AMS800™ device. Participants have been selected on the basis of their practice in a University hospital and their number of implanted AUSs according to AMS (American Medical System Holdings Inc., Minnetonka, MN) records and/or major published articles. Listed topics were selected by a pre-meeting email brainstorming by all

participants. The co-chairs distributed topics randomly (except for one) to all participants. Each participant had to propose a statement on their topic(s) for approval by the conference after a short evidence-based presentation, when possible.

### RESULTS

A total of 25 urologists were invited to participate, 19 able to attend the conference. The present recommendations, based on the most recent and relevant data available in the literature as well as expert opinions, successively address multiple specific and problematic issues associated with the AMS800™ through a eight-chapter structure: pre-operative assessment, pre-operative challenges, implantation technique, post-operative care, trouble-shooting, outcomes, special populations, and the future of AUSs.

### Preoperative Assessment

The AUS should be offered to individuals with stress urinary incontinence (SUI) due to intrinsic sphincter deficiency (ISD),

having failed conservative management. It should be considered no earlier than 6 months after prostatectomy in patients presenting with sufficient dexterity and cognitive function to operate the device.

SUI should be evaluated and verified by careful history and physical examination. UDS should be carried out at the discretion of clinicians in cases where it will help with diagnosis or counseling and follow-up, while pre-operative endoscopic evaluation of the lower urinary tract is highly recommended prior to AUS placement.

Pre-operative teaching must deliver a full explanation of device function. Furthermore, patients must be fully informed about expected rates of mechanical failure, erosion, and infection.

#### Preoperative Challenge

Clinicians must manage bladder neck or vesico-urethral anastomotic stricture prior to AUS placement. Surgeon must treat clinically relevant bladder neck or vesico-urethral anastomotic stricture either prior to or during AUS implantation.

Radiated patients should be informed that they constitute a high-risk population with increased adverse outcomes and associated complications, including cuff erosion as well as reoperation. When AUS implantation is considered in males presenting with post-prostatectomy incontinence, the potential indication for adjuvant radiation therapy should be taken into account, and risks and benefits of cancer control versus urinary outcome need to be weighed.

Detrusor overactivity should be treated before surgery, but does not constitute a contraindication for AUS implantation.

#### Implantation Technique

Surgery for AUS implantation may be performed either in lithotomy or supine position. Surgeons should be permitted their choice of razors or clippers for pre-operative preparation of the male genitalia. A 5-min pre-operative topical antimicrobial scrub is recommended and Chlorhexidine-alcohol skin preparation should be performed.

Pre-operative prophylactic antibiotics should be administered for all AUS procedures within 60 min of the incision and all efforts should be made to ensure low bacterial counts at the time of AUS placement.

The perineal approach should be preferred for AUS cuff placement while trans-scrotal approach may represent a useful alternative in some select instances. The peri-urethral cuff placement should be favored while the trans-corporal implantation may be considered under certain circumstances.

Prosthesis may be filled with either sterile saline or contrast filling solution, at the surgeon's discretion. A 61–70 cmH<sub>2</sub>O pressure-regulating balloon should be used for most patients implanted with bulbar urethral cuff and filling volume range with empty cuff should be 22–27 cc, depending on cuff size and number of cuffs. It must be placed under the abdominal wall fascia and may be inserted into the retro-pubic space or into a space created between the abdominal musculature and the transversalis fascia. The pump should be placed in the dependent portion of the scrotum, anterior to the testicle, to ensure that patients can access it post-operatively.

At the end of the procedure, urethral injury should systematically be ruled out and proper functioning should be confirmed by device cycling. Closure should finally be done multi-layered with absorbable sutures after copious irrigation.

*Neurourology and Urodynamics* DOI 10.1002/nau

#### Post-Operative Care

A14 French urethral catheter should be left in place and removed after a brief period (usually overnight). Post-operative prescriptions should consist of oral analgesia and stool softener, if indicated by patient history, while no evidence currently supports the standard administration of post-operative antibiotics. Patients should be advised to limit physical activity during the 6-week post-operative period.

Although a virgin AUS should be activated at 4–6 weeks post-implantation, activation times after device replacement or revision may be adjusted on the basis of clinical situation and patient comfort.

Patients must be informed to forewarn healthcare professionals in the event of catheterization. They should avoid perineal pressure and be instructed to wear a *MedicAlert* type of bracelet.

Physical long-term follow-up should be ensured between 3 and 6 months post-operatively. Subsequently, yearly follow-up may be undertaken in person or by mailed questionnaire.

#### Trouble Shooting

Patients who complain of leakage problems after AUS placement may have technical issues with the device, another urodynamic factor or a combination of the two. Therefore, assessment of men with unsatisfactory outcomes after AUS requires a systematic evaluation to determine if AUS malfunction, urodynamic changes, or other influences occur.

Sub-cuff urethral atrophy is defined as progressive loss of initial continence after AUS implantation in the absence of erosion, mechanical malfunction or leak, and/or bladder-related causes of worsening urinary continence. In AUS patients presenting with recurrent or gradual worsening of incontinence, sub-cuff urethral atrophy should be considered as diagnosis of exclusion, after dismissing erosion on cysto-urethroscopy and mechanical failure by other modalities. Treatment should first take the most conservative revision approach, followed by procedures for cuff revision requiring complex surgery or additional hardware.

If AUS infection is suspected, cysto-urethroscopy should be undertaken to evaluate the urethra for cuff erosion. In gross or persistent infections, the entire device should be explanted as soon as it is clinically safe, and reimplantation should be delayed.

In case of urethral cuff exposure or erosion, the decision to remove the cuff exclusively or the device entirely will mainly depend on time since AUS implantation. The decision to perform concomitant urethroplasty should be based on the extent of urethral loss at the time of cuff explantation. Eroded cuffs should be replaced at different urethral locations or even through a trans-corporal approach, depending on local conditions.

Definitive diagnosis of mechanical AUS failure is demonstrated by decreased fluid in the system, either by intra-operative aspiration or pre-operative radiologic evidence of diminished fluid in the pressure-regulating balloon. In case of mechanical failure, whole system replacement is generally preferred at the time of AUS revision.

#### Special Populations

Inflated penile prosthesis placement after trans-corporal AUS cuff insertion should be considered a high risk and the procedure should be done in specialized, high-volume centers.

It should be noted that trans-corporal AUS could have a potentially negative impact on erectile dysfunction.

AUSs can successfully manage urinary incontinence in neurogenic bladder patients. However, it is associated with a higher numerical complication rate versus post-prostatectomy patients. Erosion is frequent in this specific population and all effort should be made to prevent its occurrence. Furthermore, long-term follow-up with bladder and upper urinary tract monitoring is essential.

Placement of indwelling urethral catheters in patients with AUSs is the most common cause of erosion and should be avoided at all costs. When catheters are absolutely required the device must be inactivated in the open position, and the smallest size urethral catheter should be used for the shortest time period (less than 48 hr). When fluid monitoring in obtunded patients is required, the device should be deactivated and an externally secured collection method, such as a condom catheter, should be attempted. In cases that require prolonged drainage (>48 hr), a supra-pubic tube should be considered, with imaging guidance.

In females, AUSs are indicated in cases of pure SUI or mixed UI in female patients if ISD is present and is the main reason for SUI. They have never been compared in this population with any technique, especially slings, and they should, therefore, be

considered as a salvage technique in bothered patients after mid-urethral sling failure in the absence of urethral mobility. AUSs in women should be contra-indicated after pelvic radiotherapy.

The retro-pubic approach is recommended over the vaginal approach because of a lower infection rate.

#### Future of AUS

The "ideal" AUS should be easily manipulated and inactivated, modify cuff pressure after implantation, be able to adapt occlusive cuff pressure in a real-time manner, have a simple and robust design, be safely implanted via a minimally invasive procedure, and be as cost effective as possible.

#### CONCLUSION

The present guidelines are issued from brainstorming by 19 urological surgeons, all considered expert in the use of the AMS800<sup>TM</sup>. The most recent and relevant data available in the literature as well as expert opinions were taken into account to reach a consensus on each of the presented statements. These recommendations will undoubtedly help urologists in their daily practice with the AMS800<sup>TM</sup>.

## Abstract

**Introduction:** Patients with nocturia have to face many hurdles before being diagnosed and treated properly. The aim of this paper is to: summarize the nocturia patient pathway, explore how nocturia is diagnosed and treated in the real world and use the Delphi method to develop a practical algorithm with a focus on what steps need to be taken before prescribing desmopressin.

**Methods:** Evidence comes from existing guidelines (Google, PubMed), International Consultation on Incontinence-Research Society (ICI-RS) 2017, prescribing information and a Delphi panel (3 rounds). The International Continence Society initiated this study, the authors represent the ICI-RS, European Association of Urology, and Society of Urodynamics, Female Pelvic Medicine and Urogenital Reconstruction (SUFU).

**Results:** Diagnostic packages: there is a consensus on history taking for all causalities, intake diary (fluid, food) and bladder diary, not for its duration. Pelvic (women) or rectal (men) examination, prostate-specific antigen, serum sodium check (SSC), renal function, endocrine screening: when judged necessary. Timing or empty stomach when SSC is not important. Therapeutic packages: the safe candidates for desmopressin can be phenotyped as no polydipsia, heart/kidney failure, severe leg edema or obstructive sleep apnea syndrome. Lifestyle interventions may be useful. Initiating desmopressin: risk management consensus on three clinical pictures.

Follow-up of desmopressin therapy: there was consensus on SSC day 3 to 7, and at 1 month. Stop therapy if SSC is <130 mmol/L regardless of symptoms. Stop if SSC is 130 to 135 mmol/L with symptoms of hyponatremia.

**Conclusion:** A summary of the nocturia patient pathway across different medical specialists is useful in the visualization and phenotyping of patients for diagnosis and therapy. By summarizing basic knowledge of desmopressin, we aim to ease its initiation and shorten the patient journey for nocturia.

Karel Everaert and Francois Hervé contributed equally to this study.

Editorial assistance was provided by Caroline Loat, PhD.

Delphi technique, desmopressin, expert opinion, guideline, interdisciplinary research, nocturia, nocturnal polyuria

**1 | INTRODUCTION**

Nocturia was defined in 2002 as a complaint that the individual has to wake at night one or more times to void.\*<sup>1</sup> It affects a high proportion of adults.<sup>2</sup> Nevertheless, for a long time, the symptom received very little specific research attention as it was considered just one of a number of lower urinary tract symptoms (LUTS) indicating overactive bladder (OAB) or benign prostatic obstruction (BPO). In recent years, however, there has been growing recognition that it is a specific symptom in its own right, with wide-ranging pathophysiology (including blood pressure changes, cardiac dysfunction, fluid shift into the lower limbs, polyuria, sleep apnea, insomnia, pharmacotherapy, and polypharmacy). Furthermore, it is associated with significant negative outcomes in terms of patient health, sleep, and quality of life. Yet there is no consensus on how to identify and manage nocturia patients for the best possible outcomes.

During the 2017 meeting of the International Consultation on Incontinence-Research Society (ICI-RS) in Bristol, a nocturia think-tank discussed how to study the gaps in our knowledge to develop a practical patient-oriented diagnostic and therapeutic algorithm for nocturia.<sup>3</sup> It was obvious that the many and varied causes of the condition are underdiagnosed and that many clinicians of different disciplines see patients with nocturia without paying specific attention to diagnosing and treating their excessive nocturnal voiding.

Nocturia guidelines are mainly hidden within broader LUTS guidelines because nocturia has historically been linked primarily to OAB and BPO, even though its main cause is nocturnal polyuria (NP).<sup>5</sup> A one-year delay between onset of LUTS symptoms and consultation of a medical professional has been reported.<sup>6</sup> Patients with nocturia are treated by healthcare providers from numerous different disciplines because nocturia is prevalent in many other conditions, such as cardiovascular disease, diabetes, and OAB. However, the specific condition of nocturia is ignored by most specialities, and only rarely does it improve with treatment of other underlying conditions. Different medical disciplines diagnose and treat nocturia or its underlying diseases

using their own guidelines and recommendations based on levels of evidence available from prior research and literature. Diagnostic and therapeutic “packages” from each discipline are helpful to visualize the approach to nocturia that is taken in clinical practice.

No single treatment can effectively treat nocturia in all contexts. However, desmopressin is the only evidence-based pharmaceutical therapy for nocturia.<sup>7</sup> Despite this, the breadth of its use in clinical practice is limited.<sup>6,8</sup> Patients with nocturia have to face many hurdles before being diagnosed properly and treated with desmopressin, instead of OAB/BPO medication.<sup>6</sup> Potential reasons for this, besides side effects, are the limited knowledge of clinicians regarding the drug and how to use it, and anxiety about safety, regardless of the evidence that with the available low-dose formulations, hyponatremia is extremely rare, even in older patients.<sup>9,10</sup> There is a clear need for a summary of the available information and a simple algorithm on how desmopressin should be used in adults with nocturia.

The aim of this paper, based on the International Continence Society’s (ICS) 2002 document,<sup>1</sup> is to:

- 1) Summarize the nocturia patient pathway.
- 2) Explore how nocturia is diagnosed and treated in the real world.
- 3) Use the Delphi method to develop a practical algorithm based on the ICS’s 2002 standardization of terminology in nocturia,<sup>1</sup> with a focus on what steps need to be taken before prescribing desmopressin.

**2 | METHODS**

An initial consultation between 12 urologists was held during the ICS 2017 meeting in Florence, with participants representing the ICS, ICI-RS, European Association of Urology (EAU), and Society of Urodynamics, Female Pelvic Medicine and Urogenital Reconstruction (SUFU). Following the meeting, a nonsystematic keyword-based literature search was performed using Google (search on “guidelines 2010-2017” + symptom/sign/disease terms [edema, hypertension, heart failure, diet, menopause, male LUTS, OAB, prolapse, renal failure, diabetes insipidus, and diabetes mellitus]). All expert panel members were also invited to add any additional important guidelines from the different

\*The nocturia definition was recently updated by the International Continence Society (see the article by Hashim et al<sup>4</sup>) as: The number of times urine is passed during the main sleep period. Having woken to pass urine for the first time, each urination must be followed by sleep or the intention to sleep. This should be quantified using a bladder diary.

medical disciplines relevant to the diagnosis and treatment of nocturia and its underlying causes. Some of these guidelines specifically target nocturia, and others aspire to target the underlying cause.

In areas where there was an absence of evidence and consistency between guidelines, the Delphi method was used to obtain an expert consensus—see Figure 1 for details. After the ICS 2017 meeting, a survey to gain views regarding the format, content, and additional panel members needed for the consensus report was distributed among nine of the urologists who agreed to participate as authors of the report, using the [www.surveymonkey.com](http://www.surveymonkey.com) platform (round 1); 75% agreement was needed to reach a consensus. As part of this round, it was decided that a broader range of experts should be included in the panel for round 2 to provide a multidisciplinary perspective. The initial Delphi panel for round 2 comprised of 20 clinicians, but 1 invitee did not respond to any of the rounds, and so the consensus was reached based on the views of the remaining 19 who participated. These 19 included 11 urologists (9 from the original group), 1 gynecologist, 1 epidemiologist/physiotherapist, 1 sleep specialist, 1 nephrologist, 1 geriatrician, 1 general practitioner, 1 neurologist, and 1 pharmacist. The Delphi panel members were asked to indicate whether they agree or disagree with statements about the diagnosis and treatment of nocturia patients. Again, 75% of the panel had to agree to achieve a consensus. If there was a criticism of the statement/question, it was reformulated for an additional subround, of which there were 2 in round 2 (Figure 1). In round 3, a different set of statements were presented to the multidisciplinary Delphi panel, and the same level of agreement was needed (ie,  $\geq 75\%$ ) for a consensus, but panel members were also asked to rate appropriateness of the statement on a scale of 1 to 9 (1-3 inappropriate; 4-6 uncertain; 7-9 appropriate). From the panel responses, a median appropriateness score was derived. As in round 2, if there was a criticism of the statement/question proposed, it was reformulated for an additional subround.

This consensus report on the diagnosis and treatment of nocturia is therefore based on real-life clinical practice, guideline/literature reviews, and where needed, an expert consensus obtained using the Delphi method.

### 3 | RESULTS

The real-life diagnostic and therapeutic pathways for nocturia patients, based on the underlying causes of nocturia,<sup>6</sup> are summarized in Figure 2. There was a consensus that we should treat bothersome nocturia but there was no consensus on whether this should be

confined to two or more voids per night, or include any level of nocturia. There was a consensus that nonbothersome nocturia, or convenient voids, should not be treated with desmopressin.

#### 3.1 | Diagnostic packages

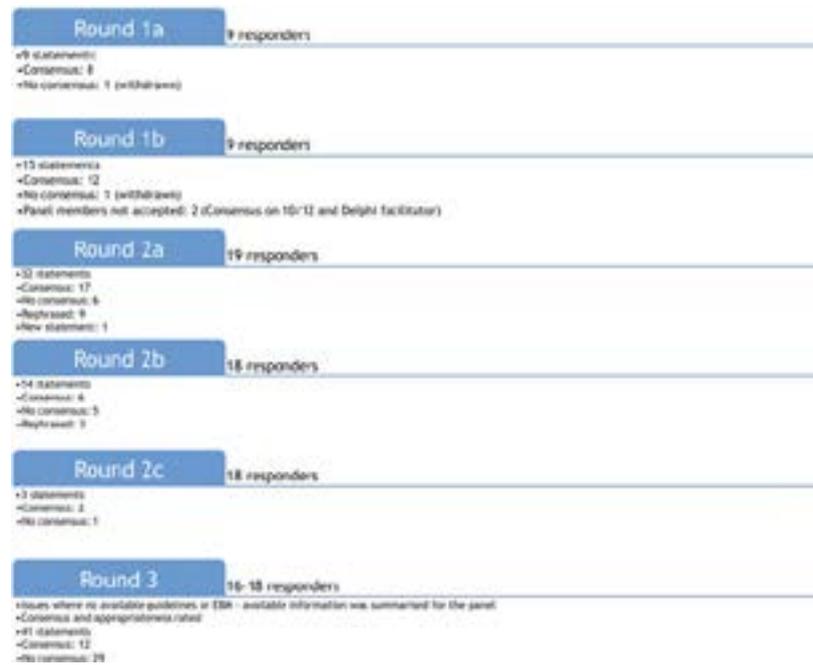

The diagnostic packages in each subdiscipline dealing with nocturia patients are summarized below with reference to guidelines, prescribing information and the Delphi consensus—see Table 1 for an overview. History-taking, physical examination, and clinical assessment including disease-specific questionnaires (DSQ) are recommended diagnostic tools. The EAU 2018 guidelines suggest the severity and bother of individual LUTS (nocturia) should be identified with a symptom score, supplemented by directed questioning if needed. Examples of nocturia-specific questionnaires are the international consultation on incontinence questionnaire—nocturia; nocturia quality of life questionnaire, and the nocturia impact diary. In line with the diagnostic considerations from each of the relevant therapeutic areas, a questionnaire has recently been developed to help to unify approaches to nocturia diagnosis.<sup>11</sup> The TANGO questionnaire is a short patient-administered screening metric designed to help the clinician assess nocturia and diagnose these different contributory mechanisms. Although some further validation is needed, the tool is available for clinical use in English and Dutch, and validation in French and Spanish is ongoing.

##### 3.1.1 | The lower urinary tract package

History-taking with or without the use of validated questionnaires is structured based on symptoms of the filling phase and the emptying phase of the bladder.<sup>4,12</sup> Physical examination focusses mainly on assessment of the prostate, vaginal examination for pelvic organ prolapse, and any urethral pathology, according to the relevant guidelines.

The 2018 EAU male LUTS guidelines<sup>4</sup> recommend to add urine analysis, serum prostate-specific antigen (PSA) test (if a diagnosis of prostate cancer will change the management), and to measure postvoid residual urine volumes.

Three-day bladder diaries, including sleep and wake up time, as well as the next morning's first void, have been recommended as giving the optimal balance between compliance and reliability.<sup>13</sup> The Delphi panel agreed (15/19) that it is necessary to demonstrate the presence of NP using a bladder diary before prescribing desmopressin. There was no consensus on the duration of

**FIGURE 1** Summary of the Delphi process [Color figure can be viewed at [wileyonlinelibrary.com](http://wileyonlinelibrary.com)]

bladder diary required, including on whether patients with cognitive impairment or impaired executive function warrant the use of a shorter duration of bladder diary. Approximately half of the panel (9/17) believe that all patients need to complete a 3-day diary; while the remainder (8/17) believe that the diary period can be shortened if the patient had his/her symptoms during the observation day. In the latter case, it would be necessary to include a question in the bladder diary regarding whether this was a typical night for LUTS, or if it was better or worse than usual, for example, to give an indication of whether the case night was indicative of the patient's condition. Even if there was an accurate questionnaire (>95% accuracy) that could predict NP, 13/18 (no consensus, 72%) would still ask patients to complete a bladder diary. This perseverance with the use of a bladder diary may reflect an underlying lack of conviction amongst the panel that such a questionnaire could feasibly be developed.

The maximum voided volume, void frequency, and the ratio of nocturnal to 24-hour urine production are the most used diary parameters to study and assess nocturia.<sup>14</sup> A maximum voided volume of 350 mL is generally considered as reduced without real evidence to support this criterion. When the nocturnal urine production exceeds the maximum voided volume, then

nocturia is predictable, with some safety margin (nocturia index of >1.3 is generally accepted as a reliable cut-off).<sup>15</sup> The frequent causes of reduced voided volumes include an OAB and residual urine (secondary to obstruction or detrusor underactivity). A residual urine measurement is, therefore, part of the initial assessment of nocturia.<sup>4</sup> When reduced voided volumes are seen, imaging, urodynamics, and occasionally cystoscopy are performed, as appropriate.

Excessive nocturnal or 24-hour urine output is diagnosed using a bladder diary. According to the ICS definition, NP is diagnosed if more than one-third (>33%) of the 24-hour urine volume is produced during the night in patients over 65 years, and after excluding patients with 24-hour polyuria (>40 mL/kg/d). In the United States, the FDA's regulatory decision-making regarding desmopressin use has been based on these definitions. In younger people (21-35 years) the cut-off for NP is >20% of 24-hour urine.<sup>1</sup> No definition of NP between these age categories has been established. The "one-third" definition in older people is the most widely used definition and has a high sensitivity but low specificity. Other definitions are available,<sup>16</sup> but the most appropriate definition of NP is still the subject of much discussion.<sup>17,18</sup> However, the definition of NP is not the scope of this document.

**FIGURE 2** Summary of the nocturia patient diagnosis and treatment pathways. Note that obesity can be indicative of excess caloric intake but is also associated with metabolic syndrome and is therefore also relevant to the cardiovascular pathway. Clinical specialities that deal with specific conditions may vary by country—for example, OSAS patients may be treated by a variety of specialists (including sleep, ear nose, and throat). BOO, bladder outlet obstruction; OAB, overactive bladder; OSAS, obstructive sleep apnea syndrome; RLS, restless legs syndrome [Color figure can be viewed at [wileyonlinelibrary.com](http://wileyonlinelibrary.com)]

The Delphi panel considered that, in women, a pelvic examination is necessary before starting desmopressin either in all cases (7/19) or in those women with daytime symptoms (8/19)—an overall consensus of 15/19 in favor of pelvic examination.

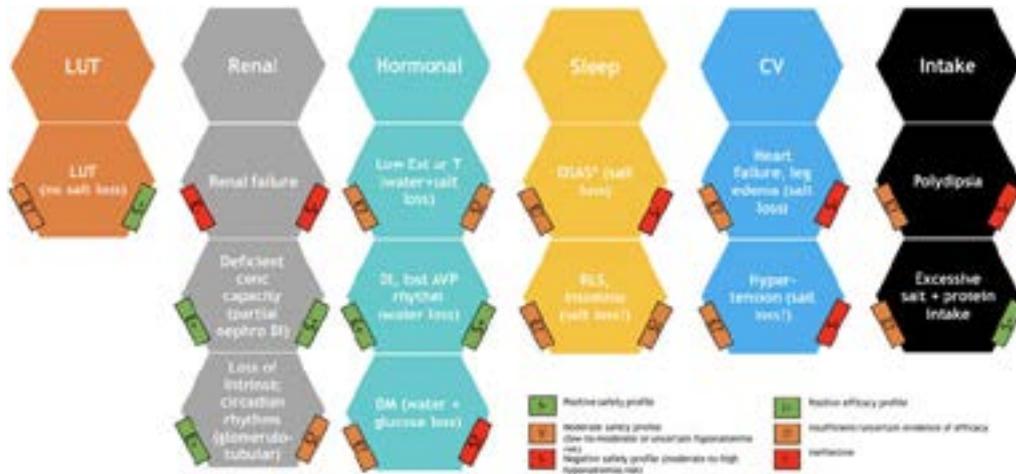

There was a consensus from the panel that a PSA check need not be standard in all older men before starting desmopressin (0/18); 7/18 answered that there is no need to check PSA and 11/18 agreed that PSA measurement is only appropriate when considered necessary for other reasons. LUTS have no relation to PSA except in advanced prostate cancer (owing to the associated bladder outlet obstruction), and NP specifically is not associated with prostate cancer.

There was a consensus that older men with nocturia should complete a DSQ (13/17, median 7.4), post-void residual (14/17, median 7.4), bladder diary is mandatory (14/17, median 8.7), and there was no consensus on the need for a digital rectal examination (10/17, median 7).

### 3.1.2 | Nephrological causes of nocturia and their diagnosis

Renal causes of polyuria include renal diseases such as nephrogenic diabetes insipidus and loss of different circadian rhythms of the kidney, for example through aging of the kidney.<sup>19,20</sup> Nephrogenic diabetes insipidus can also be caused by some medications, including lithium. Renal failure can also lead to leg edema with NP as a consequence.

When (nocturnal) polyuria is found, it is possible to diagnose the cause of the excess in urine output using renal function profiles.<sup>19</sup> These renal function profiles help in distinguishing whether the excess in urine production is due to an increase in free water clearance (vasopressin-related), osmotic diuresis (mainly salt, but can be urea [protein], glucose [diabetes], calcium [hypercalcaemia], or lithium), or a combination. However, renal function profiles are only advised after the failure of desmopressin therapy, and for research purposes. In clinical practice, elevated free water clearance is the most

**FIGURE 3** Phenotyping nocturia for uncontrolled causalities when prescribing desmopressin, based on guidelines, prescribing information or Delphi panel. \*Based on evidence and guidelines to use CPAP for sleep apnea and the high levels of ANP and nocturnal salt loss. Conc, concentration; CV, cardiovascular; DI diabetes insipidus; DM, diabetes mellitus; Est, estrogen; E, efficacy; LUT, lower urinary tract; OSAS, obstructive sleep apnea syndrome; RLS, restless legs; S, safety; T, testosterone [Color figure can be viewed at [wileyonlinelibrary.com](http://wileyonlinelibrary.com)]

frequent cause of NP throughout the lifespan and increases with age. The second most frequent etiology is an increased sodium clearance (eg, due to excess intake, leg edema, heart failure, hypertension, obstructive sleep apnea syndrome [OSAS], and medication), and this also increases with age. In summary, at first assessment, phenotyping (Figures 2 and 3) based on history taking, concomitant medication and a general physical examination help the clinician to implement lifestyle interventions and therapies such as desmopressin (assuming minimum glomerular filtration rate [GFR] of 50 mL/kg/min).

### 3.1.3 | Hormones and nocturia

Vasopressin is the main water-regulating hormone in our body. Vasopressin deficiency and vasopressin resistance of nephrogenic (receptor) origin are the main mechanisms leading to a lack of antidiuretic response within the body. The result is 24-hour polyuria and polydipsia, known as diabetes insipidus, which is a rare condition diagnosed via a bladder diary and a low morning (fasting) serum and urine osmolality. An abnormal circadian rhythm of vasopressin is the main mechanism for NP.<sup>21,22</sup> Asplund described a lack of circadian rhythm in patients with NP and nocturia in both men and women,<sup>23</sup> but plasma levels in adults without nocturia peak at around 8 pg/mL in men and 4 pg/mL in women—both with a circadian rhythm.<sup>24</sup> These levels fall and a gender difference becomes more obvious in adults, as described

by Graugaard et al,<sup>24</sup> and levels are even lower in the elderly, as described by Asplund. There is further evidence of an effect of the menstrual cycle in women,<sup>25</sup> which may also increase female sensitivity to desmopressin. If doses are given in identical strengths in men and women (not measuring the dynamic endpoint of NP), we would expect more safety concerns in women, especially elderly women. Vasopressin itself is difficult to measure as a routine test; copeptin is a by-product of vasopressin and is being explored as a biomarker of vasopressin levels.

The sex hormones are also involved in regulation of diuresis.<sup>26</sup> Deficiency in sex hormones (estrogen, testosterone) is diagnosed based on history taking and physical examination and can be confirmed with blood analysis. Some validated questionnaires are available for diagnosing menopause. Nocturia is not discussed in these guidelines.<sup>27</sup>

### 3.1.4 | Sleep and the central nervous system (CNS) as a cause of nocturia

Sleep pathology, insomnia, and sleep disruption are well-known causes of NP and nocturia,<sup>28,29</sup> and as such, they need to be diagnosed, especially as they are associated with morbidity and mortality.<sup>30–32</sup> In epidemiological studies, nocturia is associated with restless legs syndrome.<sup>33</sup> History taking and physical examination can be complemented with questionnaires including the Pittsburgh Sleep Quality Index,<sup>34</sup> which screens for both

TABLE 1 Summary of diagnostic and therapeutic packages

Diagnostic		Therapeutic			
Diagnosis	Guidelines (see the Supporting Information Materials for refs.)	Prescribing information for dDAVP	Delphi panel	Lifestyle	Pharmacological
Lower urinary tract	Nocturia within other guidelines (OAB, LUTS)	Nocturia, nocturia due to nocturnal polyuria		Bladder training (level 2 evidence)	OAB/BOO medication
History and physical examination, DSQ	+	-	Consensus	Pelvic floor training (level 2 evidence)	dDAVP
Pelvic—digital rectal examination	+	-	If judged necessary		Consider combination therapy for refractory nocturia (Delphi consensus)
PSA	+	-	If judged necessary		Botulinum toxin, sacral neuromodulation
PVR	+(weak)	-	Consensus		Prostatic and urethral surgery, prolapse correction
Kidney	Nocturia within other urological guidelines	Nocturia, nocturia due to nocturnal polyuria		Salt, protein and caloric restriction	No dDAVP if eGFR <50 (Delphi consensus)
History and physical examination, DSQ	+	-			Consider dDAVP in low/moderate renal failure
Need/use for/off questionnaire for screening NP	-	-	No consensus		Antihypertensive medication
Bladder diary	+ 3 d	+	1. Consensus on the use of a diary, no consensus on duration (50/50) 2. No consensus on the definition, NPI33 is widely used and practical but too sensitive. Use the right definition for the right population		Dialysis

Diagnostic		Therapeutic	
Diagnostic test	Guidelines (see the Supporting Information Materials for refs.)	Prescribing information for dDAVP	Delphi panel
History and physical examination and assess leg edema, DSQ	+	-	Salt restriction
BNP	+	-	Postural drainage stockings
Intake	Nocturia not mentioned	+	Fluid restriction
History and physical examination, DSQ, Intake diary	+	+	Salt, protein, and calorie restriction – balanced diet

Abbreviations: AVP, arginine vasopressin; BNP, brain natriuretic peptide; BOO, bladder outlet obstruction; CPAP, continuous positive airway pressure; dDAVP, desmopressin; DSQ, disease-specific questionnaire; FSH, follicle stimulating hormone; GFR, glomerular filtration rate; HRT, hormone replacement therapy; LH, luteinising hormone; LUTS, lower urinary tract symptoms; NP, nocturnal polyuria; NP133, nocturnal polyuria index >33%; OAB, overactive bladder syndrome; OSAS, obstructive sleep apnea syndrome; PI, prescribing information; PSA, prostate-specific antigen; PVR, post-void residual urine; RLS, restless legs syndrome.

nocturnal and diurnal symptoms related to sleep disorders. The Berlin questionnaire<sup>35</sup> and the STOP questionnaire<sup>36</sup> are screening tools for OSAS. Polysomnography is performed when a diagnosis of sleep disorders is suspected.

Parkinson's disease and restless legs syndrome are conditions characterized by a dopamine deficiency.<sup>37,38</sup> Sleep disruption and deprivation are associated with low dopamine levels in the central nervous system.<sup>39</sup> Both Parkinson's disease and restless legs syndrome are associated with NP and a reduced bladder capacity due to OAB and sphincter dysfunction.<sup>40–42</sup> However, a recent study suggested that the prevalence of NP in Parkinson's disease is no higher when compared with a control population, indicating some uncertainty in this regard.<sup>43</sup> The diagnosis of a brain- or sleep-related cause of nocturia is made clinically, and when suspected, patients need to be referred to neurologists or sleep specialists.

Evidence-based medicine<sup>6</sup> supports the need to refer and diagnose nocturia patients with suspected obstructive sleep apnea. Among the Delphi panel, there was no consensus whether suspected restless legs syndrome required a referral (9/17 [6 would treat NP simultaneously with referral]) or simply initiation of treatment for NP (8/17).

### 3.1.5 | Cardiovascular causes of nocturia

Hypertension is associated with nocturia and NP.<sup>22</sup> Nondipping hypertensive patients are a subgroup who do not exhibit a nocturnal reduction in blood pressure. There is an association between nondipping hypertension and nocturia,<sup>44</sup> and a specific association has been reported between NP and nondipping hypertension.<sup>45</sup> Children with enuresis have also been found to have higher nocturnal blood pressure than controls.<sup>46</sup> Nondipping hypertension is associated with increased morbidity.<sup>47</sup> In addition, postural hypotension with low blood pressures when standing results in higher blood pressures when supine. Diagnosis is simply made by measuring the blood pressure as part of the general clinical examination. Available guidelines in this area do not discuss nocturia.<sup>48–53</sup>

The metabolic syndrome is strongly associated with nocturia and many conditions predisposing to NP,<sup>54,55</sup> and it is an important burden for healthcare systems worldwide. The condition needs to be diagnosed when clinically suspected in patients with nocturia. Again, available guidelines in this area do not mention nocturia.<sup>56,57</sup>

Heart failure often coincides with renal failure (30%–40%) and correlates with increased mortality. This cardio-renal syndrome presents as elevated brain natriuretic peptide (BNP) with hypovolemia (normal serum

sodium) or as overfilling (hyponatremia). Both conditions coincide with an elevated creatinine, a bad estimator of GFR in these patients, and demand referral before initiation of desmopressin or timed diuretic therapy.<sup>58</sup>

Right-sided heart failure, in particular, is characterized by fluid retention and swelling of the abdomen, legs, and feet (<https://www.mayoclinic.org/diseases-conditions/heart-failure/symptoms-causes/syc-20373142>). Edema, and especially leg edema, causes NP and nocturia through resorption of fluid when supine,<sup>59,60</sup> resulting in an immediate excess in urine output and a delayed increase in ANP-related salt diuresis. Leg edema is seen with liver, heart or kidney disease or following varices of the legs, lack of physical activity or muscle paralysis. Concomitant medications that can cause edema are listed in the section below on concomitant medication. Diagnosis of edema is based on expert opinion rather than empirical evidence, and the available guideline documents for edema do not mention nocturia.<sup>48,49</sup>

As mentioned above, there was a consensus that older men with edema and nocturia should complete a DSQ (13/17), have a postvoid residual measurement (14/17), and a clinical evaluation of cardiovascular and leg edema (13/17); a bladder diary is mandatory (17/17). There was no consensus on a digital rectal examination (10/17). There was a consensus that older people with nocturia should have their blood pressure measured (13/17, median appropriateness 8). Older people with leg edema and nocturia were considered likely candidates for cardiovascular aetiological factors (13/17, median appropriateness 7), and it was agreed that clinical examination should focus on this pathophysiology (13/17, median 7).

### 3.1.6 | Fluid and food intake as a cause of nocturia

High intake of water, salt, or protein results in an increased excretion by the kidney and can result in NP and nocturia. An excess intake of osmoles leads to thirst, and increased fluid intake—a second reason for NP. An excess intake of calories results in obesity which may, even without the presence of the metabolic syndrome, result in NP due to the higher intra-abdominal pressure, mainly when supine, as a result of obstruction of the respiratory tract.<sup>61</sup> History taking, physical examination, recording of fluid and food intake on a bladder diary, and hypothetically renal function profiles can diagnose the excess of intake of sodium (salt) and ureum (protein).<sup>62,63</sup>

Dietary guidelines discuss the treatment of obesity<sup>56,64</sup> but nocturia-related recommendations are not available. The consensus panel agreed that it is appropriate (13/17, median appropriateness 7) to investigate caloric intake and physical activity through history taking and/or diaries.

### 3.1.7 | Concomitant medication leading to nocturia

Concomitant medication is often difficult to interrupt or change but might have an important impact on nocturia through increasing or decreasing diuresis, changing bladder function, or through interfering with sleep. Other factors that will influence the impact of concomitant medication are the timing of administration, mode of administration, formulation (long- vs short-acting), and so on. Most of these factors have not been well studied.<sup>3,14</sup>

For many medications, the net result on diuresis (water and osmotic diuresis) is unknown and insufficiently studied, and many medications have contradictory effects on water and osmotic diuresis. Even desmopressin, known to solely impact on free water excretion, can cause water retention resulting in renin-angiotensin-aldosterone system suppression, ANP, release and osmotic diuresis.

Another example of the contradictory effects of concomitant medication is calcium channel blockers—these increase salt excretion<sup>65</sup> to lower blood pressure, but side effects include leg edema, which can potentially worsen nocturia when the edema fluid is resorbed during the night.

Medications that typically increase diuresis are diuretics, all antihypertensive medication, progesterone, melatonin, lithium, and SECT-2-inhibitors (antidiabetic patients).<sup>6</sup> Other medications decrease diuresis, such as the older antidiabetic patients, antidepressants, antiepileptics, estrogens, testosterone, corticoids, and nonsteroidal anti-inflammatory drugs (NSAIDs).

Medications that typically cause leg edema are antidepressants (monoamine oxidase inhibitors, trazodone), antihypertensives (beta-blockers, clonidine, hydralazine, methyldopa, minoxidil and so on), antivirals (acyclovir), hormones (sex hormones), NSAIDs (celecoxib, ibuprofen), and some chemotherapeutics and cytokines.<sup>6</sup>

There is a consensus that the following conditions are a contraindication for desmopressin: congestive heart failure (16/19), polydipsia (15/19), and concomitant medication with a high risk of hyponatremia (16/19).<sup>66</sup> There was no consensus for peripheral edema (12/19), uncontrolled hypertension (13/19), uncontrolled diabetes (11/19), and oral steroids (6/19). For nasal/inhalation steroids there was a reversed consensus (0/19).

Diagnostic packages:

- Consensus on history taking or questionnaires for all causalities.
- Pelvic (women) or rectal (men) examination when judged necessary.
- Blood pressure and edema check is necessary.

- Consensus for bladder diary, but not for its duration (3 days suggested).
- Consensus for diaries on sleep, intake (fluid and food), and physical activity.
- Consensus for postvoid residual measurements.
- PSA, serum sodium check (SSC), renal/heart function, and endocrine screening when judged necessary.
- Timing or empty stomach when SSC performed is not important.

## 3.2 | Therapeutic packages

Lifestyle interventions targeted towards the aetiology of nocturia may be useful in some patients (Figure 4).

### 3.2.1 | Lower urinary tract therapy

There is level two evidence that treating dysfunctions of the bladder and the prostate (eg, OAB and BPO) with lifestyle interventions such as bladder training and pelvic floor training, or evening exercise (eg, walking the dog), as well as medication or surgery, improve nocturia.<sup>6</sup>

There was a consensus from the panel that combination therapy should be considered for nocturia that is refractory to initial treatment (18/19).

### 3.2.2 | Nephrological causes of nocturia and their therapy

Lifestyle interventions aim to prevent rather than treat renal disorders, for example by avoiding obesity, hypertension, and diabetes. Salt, protein, and caloric restriction are advised in patients with renal failure but there is no evidence of its effect on nocturia. Desmopressin can have some effect in partial nephrogenic diabetes insipidus but is not the primary choice in patients with severe renal failure as the risk of hyponatremia is much higher (Table 3). For those undergoing an investigation of renal function, there was a consensus that desmopressin should not be prescribed if eGFR is <50, and that higher limits are dependent on local prescribing information. In patients with low to moderate renal failure, as is seen in most of the older population, a loss of circadian rhythms in diuresis is found and these patients are potentially good candidates for desmopressin therapy.

### 3.2.3 | Hormones and nocturia therapy

In the 2002 standardization document,<sup>1</sup> low estrogen and menopause are recognized as a cause of nocturia, and androgen deprivation is also associated with LUTS and nocturia. There is no evidence-based medicine to demonstrate that hormonal substitution in

**FIGURE 4** Lifestyle interventions in nocturia according to pathophysiology. DM, diabetes mellitus [Color figure can be viewed at [wileyonlinelibrary.com](http://wileyonlinelibrary.com)]

postmenopausal women is an effective treatment of nocturia (ICI-RS 2017).<sup>26</sup> The 2015 NICE guidelines (<https://www.nice.org.uk/guidance/ng23>) state that there is a good evidence that hormonal substitution is helpful for vasomotor symptoms (hot flushes) and for vaginal atrophy and its consequences, but do not mention nocturia.

There was a consensus that menopause-related nocturia and hot flushes should be treated with lifestyle interventions and hormone replacement therapy (17/18). These approaches were not considered useful when

menopause is asymptomatic, except for nocturia (5/18). Desmopressin should not be given during the first treatment consultation in the presence of menopausal symptoms (1/18 if menopausal symptoms), but when there is nocturia without menopausal symptoms, there was nearly a consensus that desmopressin can be given (13/18 [74%]).

Patients with NP due to a blunted increase in AVP secretion at night, leading to an increase in free water clearance, are good candidates for desmopressin therapy.<sup>67</sup> Patients with 24-hour polyuria due to central diabetes insipidus (in which production of AVP is compromised) are also effectively treated with desmopressin,<sup>68</sup> which is in these cases a type of hormone replacement therapy.

**3.2.4 | Sleep and the CNS in nocturia therapy**

There is level 1a evidence for the use of CPAP in patients with OSAS. There is only low level 2 or lower level evidence that sleep aids, treatment of low dopamine and treatment of restless legs syndrome have an impact on nocturia (ICI-RS 2015).<sup>42</sup>

There was a lack of consensus from the panel regarding the treatment of patients with insomnia, nocturia, NP, and a diagnosis of RLS. There was no consensus (10/17) whether patients with insomnia and NP should be treated for insomnia and with desmopressin at the same time (median appropriateness was 7). There was no consensus on treating RLS, insomnia,

**TABLE 2** Prescribing information for different desmopressin formulations indicated for nocturia, which is likely to influence clinician judgments

	<b>Desmopressin 0.2 mg, tablets</b>	<b>Nasal spray 0.83-1.66 µg/ 0.1 mL (Noctiva)</b>	<b>Sublingual wafers 25-50 µg, (Nocturna)</b>
Age for baseline sodium checks and follow up	65	65	65
Fluid restriction	Restrict	Moderation advised (do not drink large amounts close to bedtime)	Restrict 1 h before to 8 h after administration
GFR (lower limit for prescribing)	50 or 60 <sup>a</sup>	50	50-60 <sup>a</sup>
Sodium checks after baseline (≥65 y)	3 d + after uptitration	Within 7 d + after uptitration	4-8 d + 1 mo or 4-8 d, 1 mo, every 3 to 6 months, depending on clinical need
Cardiovascular contraindication	Cardiac insufficiency or conditions requiring diuretics	NYHA class II or higher CHF Diuretic use	Heart failure, edema
Frail elderly	Not mentioned	Not mentioned	Contraindicated

CHF, congestive heart failure; GFR, glomerular filtration rate; NYHA, New York Heart Association  
<sup>a</sup>Moderate to severe renal failure or <50-60 mL/min depending on the formula used and cut-off used.

**TABLE 3** Consensus summary of risk management for hyponatremia when considering desmopressin administration

Risk management	Standard vigilance to hyponatremia symptoms	Standard vigilance to hyponatremia symptoms + serum sodium check (SSC)	Contraindication
	< 65 y	65 y or older	Frail older people
	Baseline sodium > 135	Baseline sodium 130-135	Baseline sodium below 130
	eGFR > 50-60	eGFR 50-60	eGFR <50
	No concomitant medication that can cause hyponatremia	Concomitant medication weakly or moderately related to hyponatremia	Concomitant medication strongly related to hyponatremia
	No leg edema	Low to moderate leg edema	Important leg oedema
	No heart failure	Heart failure (NYHA class I)	Heart failure (NYHA class II or higher)
	No diabetes mellitus or hypertension	Controlled diabetes mellitus or hypertension	Uncontrolled diabetes mellitus or hypertension
		Need for a higher dose, up-titration	Psychogenic polydipsia (>3 L/d)
		Higher risk in women	Higher risk in women
Formulation	Any desmopressin formulation	Low dose desmopressin	Treat condition if possible and wait with desmopressin
SSC	No consensus on SSC	Consensus on SSC	-

insomnia with RLS, or NP with RLS and insomnia in any combination.

In patients with insomnia, nocturia, and NP without a diagnosis of RLS, there was a consensus to treat NP (14/17) but this was split across treatment of NP per se (8/17), referral to a sleep clinic (3/17), or both (6/17). Reasons for this lack of agreement across the panel on the appropriate steps may relate to a lack of evidence on which to base treatment of insomnia with nocturia/NP, or perhaps to the range of specialisms in the group with inconsistent views on the role of other disciplines, e.g., for example, sleep medicine.

### 3.2.5 | Cardiovascular causes of nocturia and their therapy

There is ample evidence that treating heart conditions, increasing physical activity, salt restriction, losing weight, and preventing edema treats nocturia.<sup>6</sup>

Desmopressin for nocturia is contraindicated in patients with mild (class II) to severe (class IV) congestive heart failure (New York Heart Association Class II to IV) or uncontrolled hypertension, and should be used with caution (eg, monitoring of volume status) in patients with New York Heart Association Class I mild congestive heart failure because of the risk of fluid overload and electrolyte abnormalities. Patients with heart failure may also be at increased risk for low sodium concentrations.<sup>69</sup>

In people with moderate cardiac failure, there was a consensus that this condition should be treated before any attempt to address nocturia specifically (16/17, median 9). Use of desmopressin in such cases is completely inappropriate (16/17, median 2). There was no consensus concerning the use of daytime furosemide (4/17, median appropriateness 5).

In older people with NP, nocturia, and hypertension, there was no consensus as to whether hypertension should be treated first (11/18, median appropriateness 7). Treatment of NP first was considered inappropriate by 8/17 (median 4). The treatment of hypertension and NP simultaneously also had no consensus (5/17 inappropriate, 6/17 uncertain, and 6/17 appropriate; median appropriateness 5). The Delphi panel did not consider it useful to change antihypertensive drugs or their timing (other than diuretics) (8/17, median 6) to address nocturia.

In patients with varicose veins but no cardiac failure, there was no consensus on treating veins first (9/18, median 6) nor on using desmopressin first (10/17 inappropriate, 3/17 uncertain, and 4/17 appropriate; median 4).

### 3.2.6 | Intake as a target of nocturia therapy

Limiting excess fluid intake and changing the type of fluid is advised in most LUTS guidelines.<sup>70</sup> Less is known about the effect of diet and weight loss.<sup>6</sup> Weight loss will decrease hyperfiltration and diuresis. Low protein intake

will decrease salt and ureum output and osmotic diuresis. Salt restriction might decrease osmotic diuresis. Low carbohydrate intake will not change diuresis directly. Low fat intake will not directly affect diuresis. During most diets, an increase in water intake is advised, increasing water diuresis. In conclusion, from a theoretical, nonevidence-based viewpoint, a protein-rich and fat/carbohydrate-restricted diet might increase urine output as well as reduce it in the longer-term via weight loss. A well-balanced calorie-restricted diet seems the most logical approach to avoid high excretion of ureum and salt in patients with nocturia. In general, guidelines suggest caloric restriction and summarize that a high protein intake results in more efficient weight loss.<sup>56,57</sup>

There was no consensus from the Delphi panel on appropriate therapeutic options for patients with high BMI and nocturia (including losing weight [no consensus 9/18, median appropriateness 6]; weight loss with desmopressin [5/18, median 5]; desmopressin alone [6/18, median 5]; and adapting diet when there is a high osmotic load [6/18, median 5]).

Therapeutic packages:

- There is only good evidence for desmopressin and for CPAP.
- For all other therapies, the evidence is moderate (furosemide, OAB-BPH medication) or weak for most causalities.
- The safe candidates for desmopressin can be phenotyped as no polydipsia, heart/kidney failure, severe leg edema, or OSAS.

### 3.3 | Initiating desmopressin treatment

NP due to reduced nocturnal vasopressin is the primary target for desmopressin. Salt-related NP is associated with other causes such as sleep apnea (the primary target for CPAP), edema, obesity, hypertension, heart failure, and high salt intake. There is level 1a evidence that desmopressin and CPAP treat nocturia.<sup>4,7</sup> A summary of the prescribing information for available desmopressin formulations for nocturia from the United States, Australia, and Europe is given in Table 2.

The panel agreed that bothersome nocturia should be treated (17/19); however, there was no consensus regarding what level of severity warrants treatment ( $\geq 2$  voids/night [5/19], or any nocturia [12/19]). It was agreed that nonbothersome nocturia or convenience voids (ie, secondary to waking for a different reason) should not be treated with desmopressin (1 and 0/19).

There was no consensus among the Delphi panel as to an appropriate age limit above which serum sodium

should be checked before desmopressin treatment. This was also true for renal function (eGFR). This lack of consensus is likely affected by differences in prescribing information and recommendations between countries. However, there was a consensus that any age limit should not be treated too stringently, and patients who are near the limit may also be checked before treatment (17/19).

The Delphi consensus was that patients with a baseline serum sodium of  $\leq 130$  mmol/L should not be prescribed desmopressin (18/19), with the panel split between a cut-off of  $>130$  mmol/L (6/19) and  $>135$  mmol/L (12/19) for treatment. Again, the panel's views on this issue might be influenced by regional regulatory rules and prescribing information.

Dilutional hyponatremia takes several days of positive water balance to build up. To decrease by 5 mmol/L a positive water balance of 2 L is needed. There was a consensus (15/17) that SSCs can be performed at any time of day and are not affected by whether or not the stomach is empty (although note that polydipsia is a contraindication of the drug). There is sufficient literature to support that a sodium check can be done at any time of the day.<sup>71</sup>

The following conditions are agreed to be contraindications for desmopressin use: congestive heart failure (16/19), polydipsia (15/19), and concomitant medication with a high risk of hyponatremia (16/19). Concomitant medication with low risk for hyponatremia (5/19), peripheral edema (12/19), uncontrolled hypertension (13/19) or diabetes (11/19), oral steroids (6/19), and nasal steroids (0/16) did not reach consensus.

The panel agreed that women are more prone to hyponatremia and that this should have implications for desmopressin therapy and its follow-up (16/19). There is a consensus that some form of fluid restriction is needed by patients prescribed desmopressin (18/19)—either following thirst (14/19) or strict fluid restriction (4/19).

With earlier formulations of desmopressin (0.2 mg tablets), hyponatremia was seen mainly in older populations, leading to a restriction in use to those below 65 years of age. Lowering the dose to provide an antidiuretic effect of 6 to 8 hours was the logical way to treat the older (especially female) population. Low dose therapy is not a well-defined term but is today the best way to describe the newer formulations in the market, which have both been tested in an older population. Low dose therapy is advisable in older (but not frail) patients and serum sodium monitoring is needed; such monitoring can be individualized depending on patient-specific factors (eg, age, concomitant medication) and comorbidities (16/19). Frail older patients with bothersome nocturia and comorbidities or other risk factors should first be treated for other issues and comorbidities and then, if still required, desmopressin should be initiated with careful monitoring (15/18).

Young healthy patients can be treated with any licensed desmopressin formulation (15/18).

Initiating desmopressin:

- Risk management consensus on classification into three clinical pictures: (1) standard vigilance to symptoms of hyponatremia, (2) SSC, and (3) contraindications.
- Decision-based on age, renal function, heart failure, frailness, edema, baseline serum sodium, drinking habits, and medication.
- Low-dose formulations preferred in patients needing SSC.

### 3.4 | Follow-up of desmopressin therapy

Critical to the appropriate use of desmopressin and its analogs is an established schema for monitoring of sodium homeostasis in the acute and chronic phase of therapy. Contingent on stable dosing and otherwise unchanging comorbidities is the realization that shifts in fluid ingestion may potentiate the risk of hyponatremia in an otherwise stable patient. Therefore, an informed and the engaged patient is critical to desmopressin safety. In addition, acute alterations in concomitant comorbidities should be assessed for their potential to impact sodium levels.

There are various approaches to sodium monitoring in the literature. Before starting therapy, baseline sodium levels must be obtained in patients at risk for hyponatremia. Bioavailability and formulation delivery appear to have an impact on desmopressin half-life and the area under the curve (indicative of drug exposure), both of which impact the risk of hyponatremia.<sup>17</sup> There is some evidence from analysis of a merged database<sup>17</sup> that a sodium monitoring plan should begin with a baseline sodium  $\geq 135$  mmol/L with additional SSC at week 1 and month 1 after initiation of desmopressin in patients who are at increased risk (eg, due to older age, or concomitant medications). This conclusion is based on the fact that most clinically significant cases of hyponatremia were seen within 2 to 3 weeks of treatment initiation. A noteworthy observation is that time to return to normal after cessation of treatment was a median of 17 days (range 8-28).

As the optimal monitoring schedule is often debated, the Delphi panel was consulted. When baseline serum sodium levels were judged necessary, there was a consensus that serum sodium should be checked on a fixed schedule, beginning within 7 days of desmopressin initiation, but with no consensus

regarding exactly when in the first week this should occur (Day 3 [7/19] or Day 5-7 [9/19]). Weekly blood samples were not deemed necessary (1/18); 4/18 preferred 2-weekly and 13/18 (or 72%; no consensus) agreed that samples should be taken at the discretion of the physician. There was a consensus to perform an SSC as judged by the clinician at 1 month (17/18). Beyond 1 year, there is no consensus on follow up required—10/18 agree that monitoring should be performed when the patient's medical condition (eg, hospitalization, fever) or concomitant medication changes; 8/18 agreed with annual checks.

In young healthy patients, there was no consensus on SSC needed—the majority believed no checks were necessary (11/18), assuming no underlying medical conditions.

There was a consensus that some form of fluid restriction should be advised for all patients (only 1/18 found it unnecessary)—the consensus was split between advising patients to follow their own thirst (14/18) and strict fluid restriction (4/18).

If the response to desmopressin is insufficient at a low dose, there was a consensus that dose should be up-titrated (18/19), depending upon the frailty of the patient (11/19). An SSC should be carried out before up-titration, depending on the patient (17/19). If the dose is up-titrated and further sodium checks are appropriate (15/19), these should be carried out within 7 days.

If hyponatremia is found after initiating desmopressin therapy, there is a consensus (15/19) that treatment should be discontinued when an SSC is below 130 regardless of the presence of symptoms. If sodium check is between 130 and 135 and the patient is asymptomatic, treatment need not be discontinued (only 1/19 would stop the therapy), but further checks (8/19) or drug-free intervals (3/19) or lowering the dose (7/19) should be performed. See Figure 5 for a summary.

Follow-up of desmopressin therapy:

- If SSCs are necessary, follow-up on day 3 to 7 and 1 month.
- Further checks at clinician discretion.
- Stop therapy if serum sodium is  $< 130$  mmol/L regardless of hyponatremia symptoms, and if serum sodium is 130 to 135 mmol/L with symptoms.

### 3.5 | Patient-oriented nocturia care path

Based on existing guidelines, evidenced-based medicine, and the Delphi panel, we developed a patient-oriented

multidisciplinary diagnostic and therapeutic algorithm for bothersome nocturia, aiming for a more holistic approach to nocturia from a multidisciplinary angle (Figure 6). The aim of this algorithm is to ease the work of clinicians and shorten the time to treatment.

#### 4 | DISCUSSION

Diagnostic and treatment packages (Figure 2) are helpful in the visualization of the pathway of nocturia patients. We believe they could be a useful educational tool for training of healthcare professionals to improve patient care for nocturia, to limit the hurdles a patient has to get over to receive appropriate care and decrease the time to treatment.

The lifestyle interventions that are recommended in all LUTS guidelines are a good case in point. There is a growing interest globally in lifestyle interventions as a possible treatment for LUTS and, therefore, also for nocturia. The International Consultation on Incontinence summarized the need for research on conservative management of incontinence,<sup>72</sup> and the possible lifestyle interventions that can be relevant in nocturia are weight loss, diet change, fluid intake modification, and exercise. Of these, weight loss and fluid management have a fair amount of scientific data to support their impact. Weight loss (Level 1 evidence) is mentioned as a first-line treatment to reduce the prevalence of urinary incontinence with a Grade A recommendation. Restricted

fluid intake, which could decrease the voiding frequency, urgency, and volume is mentioned with a Grade B recommendation. For nocturia specifically, no such high levels of evidence exist, with the exception of fluid restriction (Level 1b). In contrast, expert opinion supports weight loss, diet, foods, salt restriction, and protein restriction in the therapy of nocturia.<sup>6</sup> This shows an important scientific knowledge gap in our understanding of approaches to the reduction of LUTS and nocturia.

There are a number of strategies to manage the risk associated with desmopressin therapy (namely hyponatremia risk). In young healthy people with nocturia, it is advised that any desmopressin formulation can be used, and dose can be up- or down-titrated when needed. In older people, the factors summarized in Table 3 should be checked, and a low dose formulation should be used or the patient should be excluded from desmopressin therapy. It is safer to start with a lower dose and to lower the threshold to perform SSC in women compared with men as women have a higher sensitivity to desmopressin and are more prone to hyponatremia. This gender difference in antidiuretic response has been found in animal studies<sup>73</sup> and in clinical studies.<sup>74,75</sup> In female rats, it was shown that this gender difference is explained by a significantly higher expression of the V2 receptor in females.<sup>73</sup> It was suggested that this was caused by escape from X-chromosome inactivation by the X-linked V2R gene, causing increased V2R dosage in females.<sup>76</sup>

**FIGURE 5** Follow-up after desmopressin prescription when serum sodium checks wanted or needed. Symptoms of hyponatremia include: nausea and vomiting, headache, confusion, loss of energy, drowsiness, and fatigue, restlessness and irritability, muscle weakness, spasms or cramps, seizures, and coma. FU, follow up; SSC, serum sodium check [Color figure can be viewed at wileyonlinelibrary.com]

High-risk medications for hyponatremia are thiazide diuretics, lithium, valproate, and carbamazepine<sup>66</sup> and use of these should be considered as a contraindication for desmopressin therapy. Low-to-moderate risk medications for hyponatremia are loop diuretics, antidepressants, ACE-inhibitors, and angiotensin-II-receptor blockers. These can be used concomitantly with desmopressin after consideration of the other factors from Table 3; concomitant use necessitates follow-up and sodium monitoring. Based on studies with loop diuretics,<sup>6</sup> it is wise not to start both medications at the same time, but to allow an interval of 2 to 3 weeks between their initiation to help the kidney in resetting its salt gradient before administering the second drug.

Since it is important to consider the frail elderly as distinct from other older persons for the purpose of desmopressin therapy, a definition of what is meant by frailty would be helpful. Perhaps the combination of a clinical frailty scale and a Timed Up and Go test (to assess a person's mobility using static and dynamic balance) would capture enough about frailty for most clinicians. The modified frailty index is an 11 item frailty index described for noncancer gynecological patients which captures enough information to detect adverse outcomes and this might be useful.<sup>77</sup> There is also the G8 survey, which captures "frailty."<sup>78</sup> Regarding comorbid conditions, a Charleston comorbidity index would be of use, although it is somewhat limited in older people by a lack of variability.

In the consideration of heart failure and its diagnosis in nocturia patients, heart failure should be suspected when there is a history of heart disease, when edema and/or weight gain with rapid onset is found and/or a patient complains of exertional dyspnea or orthopnea. A normal serum BNP concentration rules out uncontrolled heart failure. It is clear that when this condition is suspected, even in mild form, clinicians should be careful with prescribing desmopressin and it is better to refer the patient to a cardiologist and await instructions.

The monitoring of serum sodium in nocturia patients treated with desmopressin lacks sufficient evidence to produce good guidelines. As hyponatremia is rare in well-selected patients with the currently available low-dose formulations, producing strong evidence for a safety

protocol will be difficult. It is likely that complex statistical studies on merged databases may be a promising strategy for the future and could help to produce a personalized medicine algorithm for serum sodium monitoring after desmopressin initiation. In the meantime, clinicians should err on the side of caution, even if it means more SSC.

From a clinical scientific perspective, when looking at Table 2, it would be interesting to demonstrate the actual plasma levels of desmopressin following the use of the three different formulations, as this explains better the rationale for the dose differentiation. We would suggest focussing on pharmacodynamic studies combined with pharmacokinetic studies to evaluate the strength and duration of the antidiuretic effect, and the effect on serum sodium levels. These studies would ideally be performed in nocturia patients during an overnight evaluation, as performed by Goessaert et al.<sup>79</sup>

It is clear from this Delphi panel experience that items which suffer from a lack of evidence in the literature are difficult to form a consensus on with a multidisciplinary panel. This demonstrates the need for more studies on some of the smallest steps in the care path of nocturia patients. However, the performance of studies that are crucial to our understanding, but do not attract funding from the pharmaceutical industry (eg, effects of lifestyle interventions), will be challenging, as will be the study of low-frequency events and patient risk factors. There is also a difficulty in reaching consensus in relation to diagnostic tests such as serum PSA or clinical prolapse evaluation as the guidelines in these areas originated from urological or gynecological organizations (and indirectly from studies on urological and gynecological patients), whereas the Delphi panel is multidisciplinary and clearly votes from this broader perspective. Our algorithm needs more research mainly in relation to the causalities of the cardiovascular system and intake-related aetiologies. Even in urogynecology, many questions remain unanswered such as the efficacy of medication in nocturia patients with a reduced bladder capacity. For sleep disorders, little research has been done on restless legs syndrome and insomnia as a cause of nocturia. Finally, there is a need to study nocturia based on this multicausal origin, as well as from a diagnostic and a therapeutic angle. Development of a

**FIGURE 6** A patient-oriented multidisciplinary diagnostic and therapeutic algorithm for nocturia. \*If desmopressin, consider Figure 3 and Table 3 before initiating, and consider Figure 5 for follow-up. BD, bladder diary; BNP, brain-derived natriuretic peptide; BOO, bladder outlet obstruction; BPS, bladder pain syndrome; Con Med, concomitant medication; CPAP, continuous positive airway pressure; CV, cardiovascular; DI, diabetes insipidus; DM, diabetes mellitus; DSQ, disease-specific questionnaires; DVT, deep venous thrombosis; ECG, electrocardiogram; GFR, glomerular filtration rate; HRT, hormone replacement therapy; LUT(S), lower urinary tract (symptoms); MS, multiple sclerosis; OAB, overactive bladder; OSAS, obstructive sleep apnoea syndrome; PSA, prostate-specific antigen; PSG, polysomnography; PVR, post void residual; RLS, restless legs syndrome. ■ consensus, ■ consensus "when judged necessary by the clinician," "combinations possible" [Color figure can be viewed at [wileyonlinelibrary.com](http://wileyonlinelibrary.com)]

standalone evidence-based nocturia guideline will probably originate from a multidisciplinary organization, and in the future, we envisage that the nocturia care path will move away from the disciplines of urology and gynecology towards less narrowly focused specialisms such as internal medicine, geriatrics, and general practice.

## 5 | CONCLUSION

A summary of the nocturia patient pathway across different medical specialisms is useful in the visualization and phenotyping of patients for diagnosis and therapy. It also highlights that nocturia is in general not a urological symptom, but predominantly a symptom of a wide variety of causalities, many of which are easy to screen for with history taking, questionnaires, and physical examination. By providing some basic knowledge of desmopressin, its contraindications, safety concerns and follow-up here, we aim to ease its initiation for clinicians and to shorten the patient journey for nocturia.

## ACKNOWLEDGMENT

We would like to thank all the Delphi panel Members: Paul Abrams: Bristol Urological Institute, University of Bristol, Bristol, UK; Marco Blanker: University of Groningen, Department of General Practice, Groningen, The Netherlands; Donald Bliwise: Department of Neurology, Program in Sleep, Aging and Chronobiology, Emory University School of Medicine, Atlanta, Georgia; Ruud Bosch: Urology Department, UMC Utrecht, Utrecht, The Netherlands; Wendy Bower: Department of Medicine and Community Care, University of Melbourne, Melbourne, Australia; Chris Chapple: Department of Urology, Sheffield Teaching Hospitals NHS Foundation Trust, University of Sheffield, Sheffield, UK; Roger Dmochowski: Urology Department, Vanderbilt University Medical Center, Nashville, Tennessee; Marcus Drake: Bristol Urological Institute, University of Bristol, Bristol, UK; Karel Everaert: Urology Department, Ghent University Hospital, Ghent, Belgium; Hashim Hashim: Bristol Urological Institute, University of Bristol, Bristol, UK; Francois Hervé: Urology Department, Ghent University Hospital, Ghent, Belgium; Kristian Juul: Ferring Pharmaceuticals A/S, Copenhagen, Denmark; Sherif Mourad: Urology Department, Ain Shams University, Cairo, Egypt; Jalesh Panicker: Department of Uro-Neurology, The National Hospital for Neurology and Neurosurgery, UCL Institute of Neurology, London, UK; Dudley Robinson: Urogynaecology Department, Kings College Hospital, London, UK; Johan Vande Walle: Department of Paediatric Nephrology, Uro-nephrology Center, Ghent University Hospital, Ghent, Belgium; Philip Van Kerrebroeck: Urology

Female genital mutilation/cutting (FGM/C)—also known as Female Genital Cutting or Mutilation—is defined as the partial or total removal of the female external genitalia for non-therapeutic reasons. This White Paper, prepared under the auspices of the International Continence Society (ICS), is intended by the ICS as a statement promoting the abandonment of this practice. The ICS also supports the respectful and evidence-based care or treatment of women and girls already affected by FGM/C, in keeping with the World Health Organization (WHO) Guidelines on the Management of Health Complications from Female Genital Mutilation.<sup>1</sup> Our members specialize in pelvic floor disorders from perspectives within a range of specialties; we encounter and treat women living with FGM/C and its consequences—particularly incontinence, infections, voiding dysfunction, sexual dysfunction, chronic pelvic pain, and obstetric trauma. Understanding the ethical, sociocultural, medical and surgical factors surrounding FGM/C is central to caring for women and girls with a history of FGM/C. The ICS voices herein state strong opposition to FGM/C. We encourage members to apply their skills to improve prevention strategies and the management of those affected.

### KEYWORDS

circumcision, complications, cutting, defibulation, female genital mutilation, public health

## 1 | INTRODUCTION

Female Genital Mutilation (FGM/C), in its official World Health Organization Definition, “comprises all procedures that involve the partial or total removal of external genitalia or other injury to the female genital organs for non-medical

reasons.”<sup>1</sup> FGM/C is distinguished from female genital cosmetic surgery by consensual and other factors, as discussed below. This paper specifically addresses non-consensual procedures, which are for the most part performed on minors. There are no health benefits to FGM/C. FGM/C violates basic human rights. In addition there are significant immediate and long-term risks associated with FGM/C including obstetric, neonatal, urologic, gynecologic, infectious, sexual, and psychological health consequences as outlined below. FGM/C is a deeply ingrained sociocultural practice in many countries. The practice is seen within a range

Institutions: The writing was performed at all of the above institutions as well as Albany Medical Center.

Funding: None.

of cultures and ethnicities, and within Muslim, Animist, and Christian societies. However, it predates the Islamic and Christian religions and mention is absent from both the Koran and the Bible. Explanations for the practice may include safeguarding virginity, aesthetics, prevention of rape, ensuring fidelity—and therefore social acceptance, family honor and marriageability—and establishing ethnic identity.<sup>1</sup>

The ICS position is that:

1. FGM/C should be prevented and progressively eradicated.
2. Healthcare professionals should not perform FGM/C, as medicalization<sup>1</sup> of the practice does not prevent many of the complications. Healthcare professionals should be trusted promoters of prevention/abandonment of the practice and care of already affected women and girls.
3. FGM/C complications should be screened, recognized, treated, and recorded appropriately and ultimately prevented.

**1.1 | Status of FGM/C**

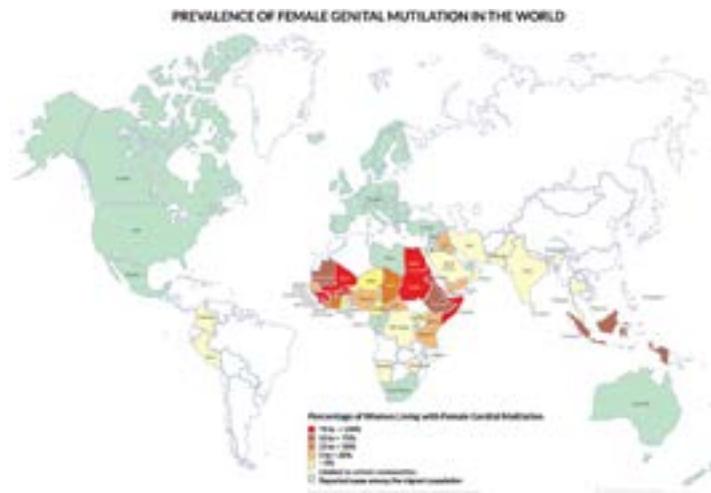

FGM/C is in fact illegal in many countries (Figure 1). However, FGM/C is still practiced in approximately 30 countries around the world,<sup>2</sup> including many where outlawed.<sup>3</sup> An estimated 200 million women have undergone FGM/C to date.<sup>3</sup> A 2013 UNICEF report estimated another 30 million girls are at risk in the coming decade.<sup>3</sup> The vast majority of FGM/C occurs in children prior to the age of 15.<sup>3</sup> Cultural factors continuing the practice of FGM/C are not simple to change and will be explored below.

The WHO classification distinguishes four basic types of FGM/C with subclassifications (See Figure 2). These

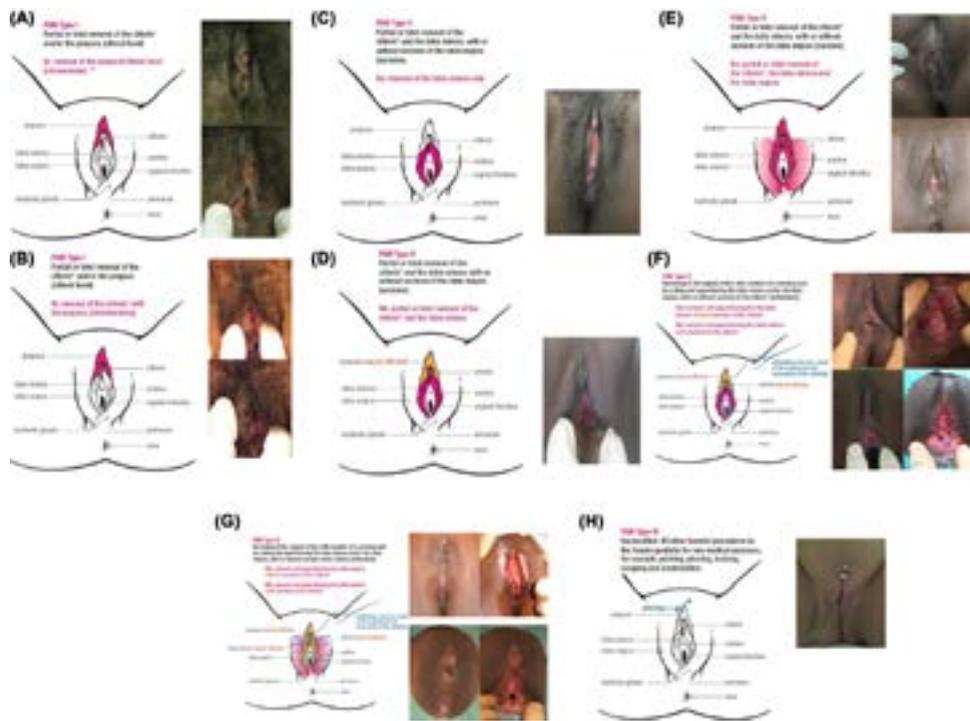

comprise a wide range of practices from the excision of the labia with or without the external part of the clitoris, with or without covering/narrowing the introitus, to performing genital piercing, pricking or stretching. Research shows that women can accurately answer whether they have undergone FGM/C; therefore, simple surveys can provide reasonable estimates of prevalence.<sup>4,5</sup> For the most part, women who have undergone FGM/C cannot correctly identify specifically what was done to them; this is not at all surprising as in many countries the majority of girls are cut before age five. Accurate classification requires examination by a trained observer (a visual reference and learning tool describing the WHO classification, including a video, has been published<sup>6</sup>). Proper classification, recording, and coding may have value clinically to individuals living with FGM/C as well as in research efforts to understand risks associated with the condition, optimal treatments, and in communication for academic and clinical endeavors. Classification is important for epidemiological and statistical purposes, for example, to study changing trends of the practice and the quality of care provided to patients. For example, following campaigns aimed at abandoning FGM/C, there is evidence that FGM/C may be performed at an earlier age and/or in a milder form.<sup>3,7</sup>

**1.2 | FGM/C should be prevented and ultimately eradicated**

It is the position of the ICS that FGM/C should be prevented and thereby eradicated. There are no studies showing any medical benefit to any form of FGM/C. FGM/C causes

significant immediate and long term complications. Most importantly, FGM/C is a violation of basic human rights.

### 1.2.1 | FGM/C violates human rights

As the WHO Guidelines state, “FGM/C violates a series of well-established human rights principles, including the principles of equality and non-discrimination on the basis of sex, the right to life when the procedure results in death, and the right to freedom from torture or cruel, inhuman or degrading treatment or punishment, as well as the rights of the child.” Many other international human rights organizations have called for an end to the practice, including the United Nations Populations Fund (UNFPA)/United Nations International Children’s Emergency Fund (UNICEF),<sup>8</sup> the United Nations Convention on the Elimination of all Forms of Discrimination Against Women (CEDAW), the United Nations Convention on the Rights of the Child (CRC), and the Protocol on the Rights of Women in Africa (“the Maputo Protocol”), and the Pan African Parliament (PAP)<sup>9</sup> among others.<sup>10</sup>

### 1.2.2 | Immediate morbidity and mortality of FGM/C

There are no reliable estimates of the morbidity and mortality attributable to FGM/C. Only a portion of the most serious complications ever reach medical attention. Nevertheless, given that the procedures are performed forcibly on young girls who are generally unaware of what will happen, and (the vast majority of the time) without the benefit of anesthesia, it is reasonable to assume that nearly all suffer pain and psychological trauma and that all are at risk of serious adverse events. Most subjects will experience bleeding. In many this will be physically and/or emotionally significant; hemorrhage and death can occur.<sup>11</sup> In a large majority of countries traditional practitioners without medical training do the cutting, typically using crude instruments (Figure 3). The lack of sterile environment and proper antiseptics leads to a risk of tissue infection, sepsis, and even death from infection. Tetanus is a particular risk given the circumstances and the lack of uniform national vaccination programs. Urinary tract infections also occur. There can be inadvertent injury to the urethra or even the

**FIGURE 3** Representative instruments used for typical FGM/C. Courtesy Charlemagne Ouedraogo

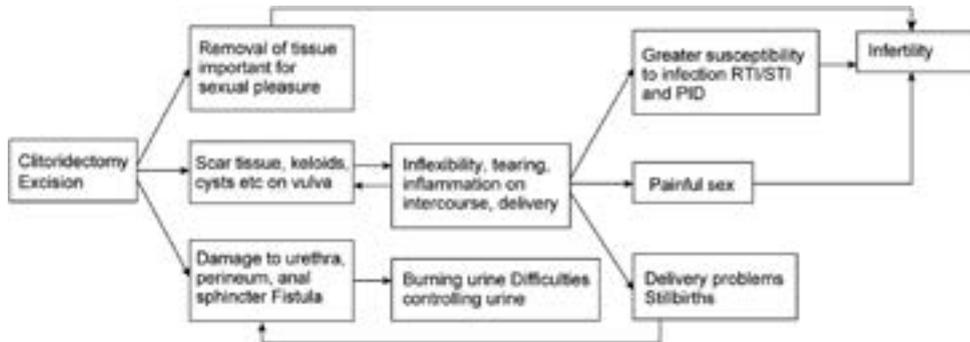

rectum. Swelling and pain can produce acute urinary retention. Although unquantified, these risks are potentially serious and substantial. They are not offset by any type of benefit.

**1.2.3 | Long-term consequences of FGM/C**

Damage caused by FGM/C can have a domino effect leading to many long-term consequences as presented in Figure 4. In 2005, a systematic review regarding the health consequences of FGM/C was published, noting difficulty in study design and capturing the data.<sup>12</sup> Observation itself is complex in limited health delivery systems; reporting may not be accurate (observers or subjects may not identify the FGM/C type correctly); sampling bias is present on multiple levels (incidence of complications, time of data collection, difficulty in finding comparison groups); and confounders abound (FGM/C effect vs poor medical care). Regardless, ICS specialists should be familiar with the spectrum of possible complications following FGM/C, and be prepared to screen, diagnose, record, code and manage them. The WHO has

published a detailed handbook “Care of Girls and Women Living with Female Genital Mutilation” (<http://www.who.int/reproductivehealth/publications/health-care-girls-women-living-with-FGM/en/>) which covers each of these topics as well as the general approach to these patients.

1. Obstetric and Neonatal complications: FGM/C, particularly type III, includes an increased rate of adverse obstetric<sup>13</sup> and neonatal<sup>14</sup> outcomes including hemorrhage, obstructed labor, perineal tears and stillbirth.<sup>15</sup> FGM/C may contribute to the obstetric factors leading to fistula. A 2006 multicenter study by the WHO showed increased relative risks for: cesarean delivery (RR 1.31), postpartum hemorrhage (RR 1.69), extended maternal hospital stay (RR 1.98), infant resuscitation (RR 1.66), and stillbirth or early neonatal death (RR1.55).<sup>16</sup> A secondary analysis of such data showed that women with FGM/C had an increased risk of C-section performed for unclear indications, probably due to a lack of training of providers in performing defibulation or in managing FGM/C.<sup>17</sup> A large systematic review and meta-analysis written in the USA and Europe in 2014<sup>14</sup> as well as a prior review from 2005<sup>12</sup> corroborated these findings. Several studies performed on obstetric outcome after FGM/C in high income countries show that with trained and appropriate management, such risks can be significantly reduced and controlled.<sup>18–20</sup> Educational material on deinfibulation has been published and is available online.<sup>21</sup> A great concern in managing a pregnant woman with FGM/C, particularly Type II and III, is perineal tearing. More recent studies and secondary analysis of the 2006 WHO paper showed that the high rate of C-section in FGM/C seems related to inappropriate indications for the C-section. This probably relates to unfamiliarity of providers concerning defibulation during/outside pregnancy or in labor and a low threshold for Cesarean for women with FGM/C. One study showed that there was no

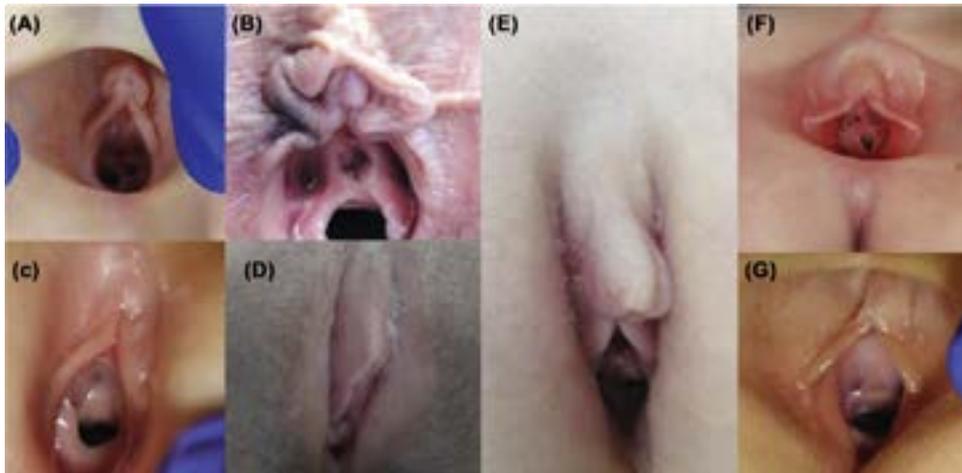

**FIGURE 4** Conceptual framework for long term consequences of FGM/C. Reproduced from Morison L, Scherf C, Ekpo G, Paine K, West B, Coleman R, Walraven G. The long-term reproductive health consequences of female genital cutting in rural Gambia: a community-based survey. *Tropical Medicine and International Health* 2001 6(8) 643–653

difference in the incidence of strong medical indications for C-section between women with and without FGM/C. However, C-sections were performed more often on women with FGM/C lacking a clear medical indication in relation to various maternal factors or arrest disorders.<sup>16</sup> Another study found that episiotomies were protective against anal sphincter tears and post-partum hemorrhage after Type III FGM/C, however in this study it is unclear if an associated defibulation was also performed.<sup>22</sup> Routine episiotomy is not currently recommended for women with FGM/C in the 2016 WHO guidelines,<sup>1</sup> however a lower threshold for episiotomy is recommended in this group.<sup>23</sup>

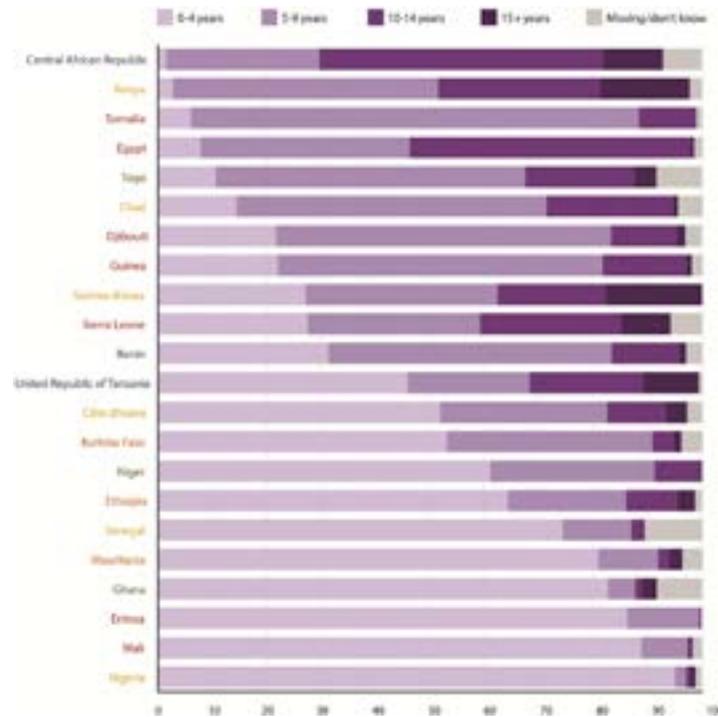

2. Urinary tract complications: Lower urinary tract complications are of special concern to ICS members and are prevalent following FGM/C.<sup>24</sup> Damage to the urethra at the time of FGM/C is common due to its intimate relation to the clitoris and labia<sup>25</sup> (Figures 5 and 6)—the cephalad apex of the clitoral hood is only 12 mm from the urethral orifice at age 0-3 and 17 mm at age 4-8.<sup>26</sup> Urethral injuries result in scarring/stricture/stenosis and subsequent lower urinary tract dysfunction. Unfortunately, good data on urinary complications is lacking. ICS membership could contribute in research initiatives. A 2005 systematic review reported significant prevalence of dysuria (58-64%), urinary retention (12-70%), urinary tract infection including recurrent UTI (2-38%), incontinence (6%) and unspecified urinary symptoms (15-25%).<sup>12</sup> Another group recruited 251 patients specifically to investigate lower urinary tract symptoms (LUTS). They found at least one LUT symptom was present in 38.8% of women. Nocturia was reported in 38.6%, intermittency in

23.5%, and incomplete voiding in 22.7%, with all three reported in 11.6% of the women. Women with a history of Type II and Type III FGM/C had a significantly higher risk of reporting all 3 LUTS than those with Type I.<sup>27</sup>

3. Infections: Infection is common in the short term after FGM/C.<sup>28</sup> A Tetanus is a serious potential risk and can even cause death after FGM/C in regions where no vaccination/immunoglobulins are available. In the long term, as noted above, girls and women may be at increased risk of urinary tract infections after FGM/C. However, other serious infections including HIV are also possible long-term sequelae as described in a 2013 systematic review.<sup>29</sup> More infections were identified in those with Type III FGM/C.<sup>29</sup>
4. Mental health problems: Women living with FGM/C suffer from psychiatric disorders significantly more commonly than their peers without this history.<sup>30</sup> A small study of Senegalese women who had undergone FGM/C found that over 90% of women recalled their cutting as “appalling and extremely traumatizing” with 30% developing posttraumatic stress disorder and another 47% suffering from other psychiatric disorders.<sup>31</sup> Appreciation of the potential psychiatric sequelae is vital to the approach to many women with FGM/C. However, it is also important for ICS specialists to consider that many women are capable of coping with the impediments and may regard the ritual as “normal” or even enhancing their gender identity or body image rather than a sickness. The experience and memories of FGM/C as well as coping strategies can differ according to the age, conditions, type and consequences of the practice. Diversity in interpreting

**FIGURE 5** Observed clitoral anatomy in the pediatric population. events and the level of remembrance is crucial for experiencing psychopathology.<sup>32</sup> Migration and a different sociocultural setting can make women more aware of their FGM/C; a woman previously well adapted to her experience may then feel stigmatized, socially excluded or ashamed.<sup>33</sup> To avoid contributing to these feelings, ICS specialists will benefit women with FGM/C by approaching care in a neutral manner. Appropriate therapy interventions should be considered for those who are experiencing symptoms consistent with anxiety disorders, depression or post-traumatic stress disorder (PTSD).

5. Sexual Dysfunction:<sup>34</sup> There are many research gaps regarding sexual function after FGM/C, especially with regards to type of FGM/C and the specific effects of clitoral involvement.<sup>35</sup> A systematic review of sexual consequences of FGM/C representing 12 671 women reported that those with a history of FGM/C were 52% more likely to have dyspareunia and greater than twice as likely to lack desire versus women without a history of FGM/C.<sup>36</sup> Some forms of FGM/C involve excision of the glans or the glans and part of the body of the clitoris. However, the remaining tumescent sexual structures (the body or part of the body; the crura of the clitoris and the vestibular bulbs and the corpus spongiosum of the urethra) are not involved by the cutting. Because of this, women may still

experience sexual pleasure and orgasm, provided other physical or psychological effects do not interfere.<sup>37</sup> The presence and severity of sexual dysfunction can vary greatly and depends on the specific tissues involved, eventual complications, and on biopsychosocial factors that have to be addressed to treat sexual dysfunction after FGM/C. Dyspareunia among women with FGM/C type III can often be treated with defibulation. Clitoral pain and dyspareunia due to post-traumatic neuromas, cysts, adhesions/synechia or obstetric trauma can be approached surgically. Pelvic floor muscle dysfunction can be treated with pelvic floor physical therapy. Culturally sensitive sexual health counseling (including education on anatomy and the sexual response) is recommended for both those living with FGM/C and their partners.

6. Other Gynecologic Problems: Dysmenorrhea can result from obstructed drainage. Infertility can result from ascending genital infection. Chronic vulvar pain can be a long-term outcome of FGM/C.
7. Effects of FGM/C on Men: FGM/C can also affect men negatively within a marriage, and thereby becomes an issue pertaining to them.<sup>38-40</sup> A Sudanese study of married men ( $n = 59$ ) found that most expressed difficulty with vaginal

penetration, wounds or infections on the penis, and psychosexual problems.<sup>39</sup> The majority perceived their wives' suffering as their own problem, and most stated they would have preferred to be married to "uncut" women. According to UNICEF, 67% of women in 29 countries and 63% of men in 18 countries, all aged 15-49 and who are aware of FGM/C believe it should stop.<sup>41</sup> Wahlberg and Johnsdotter demonstrated that most Somali immigrants, including those newly arrived, opposed all forms of FGM/C with increased opposition over time after migration.<sup>42</sup> O'Neill surveyed immigrants in three European countries and found that most men and women reported that FGM/C affected their sex lives in a negative way.<sup>43</sup>

### 1.3 | Healthcare professionals should not perform FGM/C

The ICS stands firmly against all forms of FGM/C as defined at the outset—those non-consensual procedures mostly performed on minors (and less commonly unconsenting adults). This extends to medicalization<sup>1</sup> of FGM/C where such procedures may be performed by professionals with varying degrees of surgical training, with clean instruments and in safer settings. While it is probable that medicalization can reduce some FGM/C complications such as acute infection, it does not prevent the long-term complications. Most importantly, healthcare professionals should be the trusted promoters of prevention/abandonment of the practice and of sexual and reproductive health literacy as well as the healthcare of women and girls already affected by FGM/C.

The aim of the paper does not extend to address the complex and sometimes controversial issues surrounding adult women who request various forms of genital surgery, including reinfibulation and female genital cosmetic surgery. Several researchers are addressing these topics from a legal, medical, social and ethical perspective. Conflicts between the important principle of autonomy and concerns about coercion or social pressure are not easily resolved. The long-term consequences of such surgery are not easily identified and become more nuanced when taken in a sociocultural context. Male circumcision and the concept of "genital autonomy" in intersex conditions are similarly complex issues—the ICS recognizes these as important discussions but beyond the scope of this work.

### 1.4 | FGM/C complications should be screened and recognized, treated appropriately and ultimately prevented

#### 1.4.1 | Screening for FGM/C

The first step in management is to screen and recognize the FGM/C and its eventual complications. In a study in Eastern

Sudan, only 7% of midwives could identify the four types of FGM/C correctly, whereas 81% had practiced the procedure, and in Alexandria, only 7% of nurses could identify the types; in both studies there was little knowledge among these practitioners regarding the medical consequences of the procedure and the majority planned to continue the practice.<sup>44,45</sup> Similar findings have been reported in diaspora countries; therefore, it behooves ICS members to be aware of the condition and to be prepared to identify and care for these patients.<sup>46</sup> As mentioned above, women who have experienced FGM/C may not know what unaltered anatomy looks like, what type of FGM/C they have personally experienced, and the current symptoms may be so remote from the FGM/C that they do not associate the cause and effect.<sup>47</sup>

#### 1.4.2 | Treatment of FGM/C

The WHO Handbook "Care of Girls and Women Living with Female Genital Mutilation" (<http://www.who.int/reproductivehealth/publications/health-care-girls-women-living-with-FGM/en/>) provides excellent advice to the clinician managing FGM/C patients. However, there is a relative paucity of information in many areas. A primary role for the ICS lies in improving training of its members and in sharing research and expertise, workforce, and resources to improve the care of women with FGM/C. We envision:

- Working with providers in high prevalence areas and diaspora countries to design prospective clinical trials that will inform future care.
- Supporting high quality training for front-line ob-gyn, urologists, pediatricians, general practitioners, infectious disease specialists and surgeons in managing complications of FGM/C, offering defibulation and reconstructive techniques.
- Sharing knowledge through regional meetings and via on-line educational resources.
- For those who wish to submit educational material for ICS online content are invited to submit according to the Standard Operating Procedures for format: <https://www.ics.org/committees/education/icsops>

#### 1.4.3 | Prevention of FGM/C

We need to understand the socio-cultural milieu that supports the practice of FGM/C if we are to prevent it. The most effective and durable change will arise from within the practicing societies rather than being imposed upon them. FGM/C stems from long-standing socio-cultural mores; therefore, efforts toward eradication must align

with cultural factors perpetuating the practice. The updated 2013 UNICEF statistical overview emphasizes the challenging dynamics of cultural change, noting according to social science research it “is difficult for individual families to stop the practice on their own. There is a social obligation to conform to the practice and a widespread belief that if they do not, they are likely to pay a price that could include social exclusion, criticism, ridicule, stigma or the inability to find their daughters suitable marriage partners.”<sup>53</sup> According to Mpofu and colleagues, the practice of FGM/C is deeply embedded in social and cultural traditions dating back generations. Over time, interventions have failed to understand the complexities surrounding the practice.<sup>48</sup> “Most campaigns against FGM/C have come about from a viewpoint of outrage, disgust and condemnation, and therefore are seen as a direct and aggressive attack on a people’s core values, beliefs and traditions which have been a part of their very existence for generations<sup>49–51</sup>” and can lead to further stigmatization of girls and women who have already undergone FGM/C. “FGM/C is said to enhance marriageability, fertility, and to promote purity or virginity of a woman,<sup>52–54</sup> and is also said to “. . . temper female sexual urges thereby preserving a girl’s virginity for marriage.”<sup>50,55</sup> “. . .The belief in the protection of female virtue goes hand in hand with upholding family status and dignity! When one is [circumcised], it is a symbol of entry into womanhood and marks that one fully belongs to a community.” Marriage and reproduction are essential to the long term economic and social security of most women, and FGM/C is regarded in many communities as a normal and acceptable part of raising the girl child.

Programs aimed at preventing FGM/C and its consequences must therefore:

- Be strongly based on facts and evidence as opposed to aversion and disgust
- Evolve from cultural understanding within the society rather than being imposed from outside.
- Avoid stigmatizing the girls and women who have already undergone FGM/C.

The evidence discussed above regarding the effects of FGM/C on men and the changing attitudes of many immigrants are promising, as they may allow strategies to lift the social obligation of FGM/C, once proper dialogue between genders and within community hierarchies can occur. UNICEF<sup>3</sup> has been developing programs in consultation with communities. These participatory programs have a greater impact as individuals within the community state publicly they will not practice FGM/C, and they then educate others. According to WHO, however, programs that educate women and girls about

their bodies and their rights are very rare.<sup>56</sup> According to UN estimates, most young people lack access to education about their bodies and the impact of FGM/C.<sup>57</sup> WHO recommends that to have the most responsible impact, preventing unintended alienation and retraumatization, educational interventions should be evidence-informed and scientifically accurate, non-prejudicial, non-judgmental, sensitive and respectful, non-stereotypical, and when involving adolescents, geared toward their evolving capacities. A culturally integrated educational approach will favor these goals. Mpofu highlights select programs that emphasize the healthy portions of the coming-of-age rituals associated with FGM/C, teaching girls about the responsibilities associated with adult and married life, while omitting the FGM/C itself.

The fundamental question at hand remains: how can FGM/C be most effectively prevented? Although in decline, it remains distressingly prevalent. The Pan African Parliament (PAP) has recently joined the U.N. Population Fund (UNFPA) in an action plan to ban FGM/C for the whole continent. This is a promising legal and cultural statement on the part of the Parliament. The initiative includes legislation, community mobilization, advocacy, and recruitment of men to speak out against FGM/C.<sup>9</sup> There is some evidence that changing hearts and minds at the community level will ultimately be the most effective strategy.<sup>58</sup>

Looking more closely at specific countries country will highlight the complexity of changing the practice of FGM/C. The prevalence in Kenya decreased from 41% in 1984 to 11% in 2014 (however, these numbers differ from those in Mpofu’s study). In 2001, the Kenyan government outlawed the practice, passing the Children’s Act.<sup>59</sup> Further, in 2011 it passed the Prohibition of Female Genital Mutilation Act. Lastly, successful public education campaigns have led to relief of social pressures—for example, young men have had an impact by publicly declaring their preference to marry a woman who has not undergone FGM/C.<sup>60</sup> In 1990 Burkina Faso formed the Committee to Fight the Practice of Excision (Comité National de lutte contre la Pratique De l’excision, CNLPE). In November 1996 a penal code was adopted forbidding female genital mutilation, threatening imprisonment of 6 months to 3 years and large fine for all forms of FGM/C. In addition, special emphasis is placed on education of the girl so that in adulthood, she does not seek FGM/C for her daughters. The CNLPE instituted campaigns of sensitization regarding FGM/C; policemen were trained to intervene in keeping with the law; the subject of FGM/C became part of scholastic programs; and women who had endured complications linked to FGM/C were treated free of charge in certain health initiatives identified by CNLPE, in line with WHO Guidelines. A free telephone line called “SOS Excision” (SOS Female genital cutting), was set up to

gather real-time information on the acts of mutilation. According to UNICEF<sup>xi</sup>, the prevalence of FGM/C in Burkina Faso declined from 89% in 1980 to 58% in 2010 (however, not unlike Kenya, according to internal statistics, the prevalence of FGM/C may remain significant: 76 % [EDSBF-MICS IV 2010]).<sup>61</sup> The persistent high prevalence, although decreasing and lower than some surrounding countries, is likely multifactorial—including the low level of population education (30% literacy), the persistence of traditional practices impacting the health of women overall (eg, beliefs impacting nutrition during pregnancy), and inadequate funding for the permanent implementation of the national strategy against FGM/C. The continued high incidence of FGM/C in Burkina Faso, Kenya, and other countries also calls into view the complexity of criminalization. It is possible that this strategy may have a diminished effect by driving the practice underground instead of into the light. It is certain that work across health care disciplines in cooperation with government and non-government organizations engaging community leadership will be required for optimal results.

Medical professionals can help prevent FGM/C by providing healthy, non-judgmental messages in every interaction. For example:

- offer health education on FGM/C during pregnancy (preparing for the issue to arise if the future child is a girl),
- primary doctors must build trusting relationships, including the father or other important family elders and exploring the beliefs of the family,
- pediatricians must discuss this issue with parents over time,
- doctors can provide safeguarding/protection measures according to the local laws in case of real and immediate risks.

## 2 | CONCLUSION

FGM/C is relevant to all who practice pelvic medicine, as understanding the unique health issues significantly impacts care for this population. The ICS position on FGM/C is that it should never be performed in any form on a girl or non-consenting woman. ICS members can educate themselves and others on the practice. Those with significant experience in caring for women with FGM/C can offer information, health education, reconstructive and rehabilitative services to women and girls with a history of FGM/C experiencing urogynecological, infectious, obstetric, sexual and functional pelvic floor consequences. A respectful, neutral, non-judgmental, non-stigmatizing and trained approach should be the tone of the individual patient interaction.

The International Continence Society is uniquely positioned to promote the care for women and girls living with FGM/C. Although a smaller percentage of our members have significant experience in managing patients with FGM/C, as a multidisciplinary, international society, we have significant reach with educational needs around the world. We can lend our expertise to many of the preventative and cure needs such as obstetric trauma, urogynecological and psychosexual consequences. Our expertise in education, research methodology, complex reconstructive surgery, nursing, physiotherapy, psychosexual issues can be of great value. We will start by providing educational opportunities to our members so that they can develop appropriate sociocultural, rehabilitative (including physiotherapy), medical and surgical knowledge of the topic.

ICS and its Members will lend support and act to:

### 1) Educate:

- Support the work of practitioners treating high volumes of patients with FGM/C throughout the world through assistance in creating, presenting, filming and distributing educational material (See [www.ics.org/tv](http://www.ics.org/tv), <https://www.ics.org/committees/education/icssops>).
- Educate health care workers, patients, and communities regarding FGM/C—raising awareness, exploring medical, ethical and cultural issues, consequences of FGM/C, and management.
- Work within communities to engage women and men regarding the medical risks of FGM/C and to lift the myths perpetuating this practice.

### 2) Research:

- Lend our expertise to define the benefits and risks of post-FGM/C intervention, and to further characterize the health consequences.
- Support and/or conduct studies to define optimal care of those with FGM/C.

### 3) Provide Care:

- Provide neutral, clear, non-alienating information to women and girls who have experienced FGM/C regarding its meaning to her individual situation, and options for care.
- To provide holistic care always, high quality reconstructive surgery where appropriate, and to support colleagues in high prevalence areas of the world when opportunities arise.

### 4) Advocate:

- Partner with affected women and girls and other associations regarding FGM/C.
- Promote government support for medical care of women who have had FGM/C, including culturally fluent psychological care.
- Work within communities to promote the healthy coming-of-age rituals associated with FGM/C while removing the permanently damaging risks associated with FGM/C.

## CONFLICTS OF INTEREST

## SACRAL NEUROMODULATION CONSENSUS STATEMENT

### INTRODUCTION

***Sacral neuromodulation (SNM) is an accepted therapy for refractory urinary urgency and frequency, urgency urinary incontinence (UI), non-obstructive urinary retention (NOR), and fecal incontinence (FI).***

- These indications for SNM are approved by the FDA in the United States. In other parts of the world there are some other approved indications for various pelvic floor conditions.
- A need was identified for a comprehensive document reflecting best practices across indications related to SNM

***A panel of experts from the fields of urology, gynecology, and colorectal surgery was convened to determine best practices for use of this therapy.***

- Eight urologists, three colorectal surgeons and two urogynecologists, covering a wide breadth of geographic and specialty interest representation, met for two days in Chicago, Illinois, USA on January 19-20, 2017 to discuss best practices for neuromodulation. Suggestions for statements were submitted in advance and specific topics were assigned to committee members. Committee members prepared each assigned topic and presented supporting data to the group at which time each topic was discussed in depth. Best practice statements were formulated based on available data and expert opinion and then each member prepared a discussion section for each particular topic which reflected the current literature and expert opinion. Another urologist was added to the group during the initial writing process. After multiple rounds of editing within the group the highlights of the statements were presented at the ICS meeting in Florence, Italy in September 2017. This document was then circulated to multiple external reviewers after which final edits were made and approved by the group.
- The meeting and editing expenses were supported by the ICS. Funding to support this project was based on an unrestricted society-initiated grant made by Medtronic to the ICS.
- As many of the recommendations herein are based on expert panel consensus, the recommendations in this document, while meant to aid clinical decision-making, do not pre-empt physician judgment in individual cases.

***The statements and recommendations included in this document pertain to SNM in its present form (Interstim, Medtronic) They may or may not have relevance for future SNM products or therapies which become available for clinical use.***

- At the time this document was created, the only sacral neuromodulation device commercially available was the Medtronic Interstim (Minneapolis, MN). Thus, the data and statements discussed pertain to this device. However, it is clear that other sacral neuromodulation devices will be available in the near future. Accordingly, many of the concepts contained within this document will likely apply to newer devices as well.

- The panel used the International Consultation on Urological Diseases (ICUD) method when determining levels of evidence and grades of recommendation. Table 1 summarizes the criteria used for determining levels of evidence and grades of recommendation.<sup>1</sup>

## **DEFINITIONS**

***SNM: a technique that electrically stimulates a sacral spinal nerve root to modulate a neural pathway with the aim of treating bladder and/or bowel dysfunction.***

- The term neuromodulation vs. neurostimulation was preferred by the committee since SNM, through electrically stimulating nerves, effectively functions by modulating the lower urinary tract or bowels.

***Neurogenic lower urinary tract dysfunction (NLUTD): includes all bladder/urinary sphincter dysfunction related to any relevant neurological disease***

***Peripheral nerve evaluation (PNE) lead: a monopolar, temporary lead which is always removed after an SNM test period and is not designed for long-term therapy.***

***Staged (tined) lead: a quadripolar lead which is designed for potential long-term use after a successful test period.***

## **BACKGROUND**

***SNM is not indicated as a first line therapy for either urinary or bowel disorders.***

- Typically, conservative measures (behavioral, physical therapy) and medical treatment are recommended prior to treatment with SNM.

***In the absence of a comparative study with recommended doses of onabotulinum toxin A (BTX-A) and contemporary SNM tined leads, no recommendations can be made as to whether BTX-A or SNM should be used over the other for the management of refractory overactive bladder (OAB).***

- *The Rosetta trial is a prospective randomized trial that compared SNM to Botulinum toxin.<sup>2</sup> It showed a slight short-term advantage to Botulinum toxin, however, it did not utilize currently recommended doses of Botulinum toxin (200u as opposed to the recommend 100u dose) or the currently available SNM lead technology and thus no conclusions can be drawn relative to contemporary practice.*

***SNM is a minimally invasive technique with good long-term outcomes. SNM can be offered to patients with OAB with or without incontinence who fail to respond to or are intolerant of conservative and medical therapies. (Level of Evidence: I; Grade of Recommendation: A)***

### **OAB Without Incontinence**

The initial SNM prospective, randomized, 12 center study enrolled 51 patients for severe urgency-frequency syndrome. This group reflects the present definition of OAB “dry” (urinary urgency and frequency without urinary urgency incontinence). Subjects who demonstrated a satisfactory response to PNE were randomly assigned either to immediate treatment or implant following a 6-month delay (control group). At 6 months, voiding diary results demonstrated statistically significant

4

improvements in the immediate implant group in comparison to the control group with respect to the number of daily voids, volume per void and degree of urgency.<sup>3</sup> At 2 years follow-up, 29 urgency-frequency patients showed significant reduction in the number of voids per day, with 56% of patients showing 50% or greater reduction in the average voids per day, including 32% who returned to a normal range of 4 to 7 voids per day.<sup>4</sup>

#### **OAB With Incontinence**

The initial prospective, randomized, multicenter trial included 34 patients with severe urgency incontinence (OAB “wet”) who underwent immediate implantation of SNM after a positive trial test and 42 patients (delayed group) who received standard medical therapy (SMT) for 6 months and then were offered implantation. At 6 months, the number of daily incontinence episodes, severity of episodes and absorbent pads or diapers replaced daily due to incontinence were significantly reduced in the early stimulation compared to the delayed group. In the early stimulation group, 16 patients (47%) were completely dry and an additional 10 (29%) demonstrated a greater than 50% reduction in incontinence episodes 6 months after implantation. Efficacy appeared to be sustained for 18 months. Surgical revision was required in 32.5% of patients.<sup>5</sup>

In this cohort, the long-term efficacy of SNM for refractory urinary urge incontinence remained high. At 3 years, leaking was significantly reduced, with 59% of patients reporting 50% or greater reduction in leaks per day and 46% of patients reporting that they were completely dry.<sup>2</sup> As compared to baseline, the group of 96 implanted patients demonstrated significant reductions in urge incontinence symptoms at an average of 30.8 (range 12-60) months with respect to the number of urge incontinence episodes per day, severity of leaking, and the number of absorbent pads/diapers replaced per day due to incontinence. About 10% of patients underwent device explant due to lack of efficacy, pain or bowel dysfunction but no permanent injuries associated with the devices or therapy were reported.<sup>3</sup> Others demonstrate that after 3 years, 59% of urinary urgency incontinent patients showed greater than 50% reduction in leaking episodes per day with 46% of patients being completely dry.<sup>2</sup> A single center study with median long-term follow-up of 50.7 months showed a success rate of 84.8% for urgency UI. Overall 39% of patients needed revision of the SNM neuromodulation implant.<sup>6</sup> SNM showed superior subjective and objective results compared to pharmacologic–SMT treatment for OAB, at 6 months. SNM is shown to be a safe and effective treatment for OAB patients.<sup>7</sup> Ultimately, a 2009 Cochrane review concluded that implantable neurostimulators have benefits for some patients with OAB symptoms, retention without organic obstruction, and in those for whom other methods of treatment have failed.

***SNM is an effective treatment for Fowler’s Syndrome, voiding dysfunction and NOR. (Level of Evidence: I; Grade of Recommendation: A)***

#### **Non-Obstructive Urinary Retention (NOR)**

The initial SNM prospective, randomized, 12 center study enrolled 177 patients for NOR. All patients had PNE and 38.4% eventually received the implant. Of the 68 patients who qualified for implantation 37 were randomly assigned to an immediate treatment and 31 to a 6-month delayed implant (control group). At 1.5-year follow-up 70% of 42 implanted patients (immediate or late) showed greater than 50% reduction in volume per catheterization.<sup>2</sup> Further publication of 18-month follow-up showed that of the patients treated with implants 69% eliminated catheterization at 6 months and an additional 14% had a 50% or greater reduction in volume per catheterization. Therefore, successful results were achieved in 83% of the implant group with retention compared to 9% of the control group at 6 months.

5

Temporary inactivation of SNM therapy resulted in a significant increase in residual volumes but effectiveness of SNM was sustained through 18 months after implantation.<sup>8</sup> Extension of this study with 5-year follow-up showed significant reduction in the mean volume per catheterization and the mean number of catheterizations. The clinical success rate of 71% was observed at 5 years after implantation.<sup>9</sup> In another single center study, out of 60 women implanted there was a spontaneous voiding rate of 72% over a mean follow-up of 4 years. After surgery, of the 43 women who voided, 13 required the continued use of clean intermittent self-catheterization up to twice a day, but this was less than before surgery. Women with abnormal EMG did better, with 76% of patients experiencing restoration of voiding.<sup>10</sup> Another study confirmed that the presence of Fowler's syndrome is a positive predictive factor for SNM in female urinary retention.<sup>11</sup> Several single center studies reported good long-term outcomes between 73%<sup>12</sup> and 87%.<sup>5</sup>

### **SACRAL NEUROMODULATION FOR INTERSTITIAL CYSTITIS/BLADDER PAIN SYNDROME**

***There is limited evidence supporting the role of SNM for patients with interstitial cystitis (IC)/bladder pain syndrome (BPS).***

***SNM is an option for IC/BPS non-responsive to conservative therapies after appropriate assessment. (Level of Evidence: III; Grade of Recommendation: C)***

IC/BPS is a condition characterized by bladder, urethral and pelvic pain along with urinary frequency, urgency and nocturia.<sup>13</sup> SNM may be considered for patients with IC/BPS who do not sufficiently respond to first, second or third-line treatments. However, SNM has approval for pelvic pain conditions in only a few countries, and is not approved specifically for IC in any nation. There is limited evidence supporting the role of SNM for patients with IC/BPS - typically small observational case series all reporting different criteria for success. Based on these small observational studies, the success rate for SNM for IC/BPS using intention to treat analysis was 48% to 72%.<sup>14,15,16,17,18,19</sup>

Based on the available limited evidence, SNM may be an option for IC/BPS non-responsive to conservative therapies after appropriate assessment and multidisciplinary team review. The AUA IC/BPS Guidelines lists SNM as a 4<sup>th</sup> line therapy.<sup>20</sup>

***There is a lack of evidence supporting SNM as a treatment option for patients with non-IC/BPS chronic pelvic pain. (Level of Evidence: III; Grade of Recommendation: C)***

Chronic pelvic pain is defined as "chronic or persistent pain perceived in structures related to the pelvis of either men or women. It is often associated with negative cognitive, behavioral, sexual and emotional consequences as well as with symptoms suggestive of lower urinary tract, sexual, bowel, pelvic floor or gynecological dysfunction. Pain must have been continuous or recurrent for at least 6 months".<sup>21</sup>

There is minimal evidence reporting the efficacy of SNM for chronic pelvic pain.<sup>22</sup> Based on available evidence, SNM cannot be recommended as a treatment option for patients with non-IC/BPS chronic pelvic pain. However, pelvic pain is not necessarily a contraindication in patients with concomitant voiding symptoms such as frequency and urgency, if those voiding symptoms improve during the trial period and the patient endorses an associated improvement in quality of life.

## **SACRAL NEUROMODULATION (SNM) FOR NEUROGENIC LOWER URINARY TRACT DYSFUNCTION (NLUTD)**

***SNM is an option for symptom control in patients with NLUTD who are at low risk of upper urinary tract deterioration. (Level of Evidence: III, Grade of Recommendation: C)***

SNM for NLUTD is of growing interest, although it is still as an “off-label” indication. There have been many reports of good outcomes in NLUTD but with a lack of standardized criteria in terms of patient selection, success definition, etc. Most of the evidence is focused on incomplete SCI and multiple sclerosis (MS) but patients with cerebrovascular accident, brain trauma, cerebral palsy, and Parkinson’s disease have been implanted as well with similar outcomes as in patients with non-neurogenic indications.<sup>23,24</sup>

SNM has been utilized in the treatment of detrusor overactivity (DO), NOR, detrusor sphincter dyssynergia (DSD) and FI due to incomplete SCI. Although there are no clinical or urodynamic criteria to select ideal candidates for SNM in SCI, in one study ASIA D (incomplete injury with some preservation of motor function below the lesion) and E (normal sensory and motor functions below the injury level) lesions and sensation of bladder filling were associated with higher success rate during the test trial.<sup>25</sup> We recommend that in SCI patients, SNM should be limited to ASIA D and E patients with preserved bladder filling sensation.<sup>33</sup>

The success rate of SNM in patients with upper motor neuron injury may be higher than in patients with lower motor neuron injury since the former preserves afferent integrity and contractility of the detrusor. One study demonstrated an improvement in bladder emptying with SNM in patients with acontractile or hypocontractile bladder, but the mechanism of action is unclear.<sup>26</sup>

In patients with MS, SNM has demonstrated good results treating DO and NOR due to DSD but a low success rate in treatment of NOR has been reported in those with an acontractile or hypocontractile bladder.<sup>27</sup> Patients with MS being considered for SNM should have stable disease without an expected requirement for frequent or routine magnetic resonance imaging (MRI); patients with rapidly progressive MS typically should not have SNM systems implanted.

The most recent studies in SNM for NLUTD utilize longer periods of the test trial than for patients with idiopathic dysfunctions.<sup>28</sup> Longer test periods might be more appropriate for more complex conditions such as NOR<sup>29</sup> as well as NLUTD.

Since SNM is used after all other therapies have failed and prior to more invasive procedures, a 50% improvement during the trial period is adequate to define success. Most studies define success with the same parameters as in non-neurogenic patients, such as reduction of urinary frequency, urgency incontinence episodes, number of catheterizations, volume per catheterization and FI episodes.

## **NEED FOR URODYNAMIC TESTING PRIOR TO SNM**

***There is a lack of evidence to suggest that urodynamic testing can predict SNM outcomes. (Level of Evidence III, Grade of Recommendation C).***

Patient characteristics such as age, sex, comorbidities, duration and severity of symptoms, and results of examination and testing such as cystoscopy, imaging and urodynamic studies (UDS) have shown insignificant value in predicting which patients will respond to a trial of SNM. Indeed, in some parts of

the world, UDS are commonly performed prior to SNM trial, whereas in other areas, they are not, without an obvious difference in outcomes.

With regard to clinical studies, while some case series<sup>30</sup> have shown that older patients and longer duration of symptoms are less likely to respond, others<sup>31,32</sup> have contradicted this. One study suggested that combining traditional urodynamics and ambulatory monitoring might have additional predictive value<sup>33</sup> over conventional studies alone. None appear to be more sensitive, specific, or cost effective for the prediction of response to SNM as the screening trial, consisting of a PNE or a staged lead implant.<sup>34,35,36</sup> There is however a single recent prospective study showing that children with bowel and bladder dysfunction who had detrusor overactivity on videourodynamic testing had significantly greater improvement in symptoms with 2 stage SNM implant.<sup>37</sup>

***The trial phase of SNM is the single most valuable tool for predicting the potential therapeutic success of SNM for urinary indications. (Level of Evidence II, Grade of Recommendation B).***

Several large, multicenter trials have shown that the PNE<sup>4</sup> and the staged trial<sup>6</sup> predict which patients are likely to respond, and also which will likely have long term benefit from the therapy.<sup>1,8,9,39</sup> A unique advantage of SNM is this inherent ability to predict which patients are likely to benefit with its own specific trial. **UDS is unlikely to add significant diagnostic benefit in the evaluation of routine idiopathic OAB.**<sup>38</sup>

The index patient suffering from refractory OAB is female, has no neurologic disease, has not had prior pelvic surgery, and has no or minimal SUI. On physical exam there is no significant pelvic organ prolapse or urinary residual. She has failed first and second line options, and has significant bothersome symptoms. In this scenario, the panel agreed that there is scant evidence that the result of a UDS is likely to change the third line therapy options or outcomes. Patients with neurologic disease, an unclear degree of SUI or bladder emptying symptoms, significant prolapse, male patients, and prior pelvic surgeries including outlet reduction procedures (e.g. transurethral resection of prostate) and slings are more likely to benefit from UDS to aid in the correct differential diagnosis.

***Pressure flow study or Video UDS may be valuable in the diagnosis of NOR. (Expert Opinion).***

Urodynamics is particularly helpful to rule out obstruction when considering the diagnosis of NOR or incomplete bladder evacuation.<sup>39,40</sup> Another study showed that SNM treatment response in male patients with impaired bladder emptying can be predicted with a bladder outlet obstruction (BOO)-contractility nomogram.<sup>41</sup> In this study of 18 men, the authors found that only 20% of patients below the 10th percentile of contractility, but 86% of men between the 10 and 25th percentiles of the Maastricht-Hannover nomogram were treated successfully with SNM. All successfully treated patients voided without needing self-catheterization. Other studies have shown that EMG study of the external urethral sphincter may be helpful in defining Fowlers syndrome.<sup>42</sup> In females, the combination of video imaging and real time urodynamic data has been determined to be the best method of defining BOO.<sup>43</sup> Video studies in men may also be useful in determining the level of obstruction, for example benign prostatic hypertrophy vs. pseudodyssynergia.<sup>44</sup>

***In cases where SNM has been tried and failed, UDS may be considered to further define the underlying disorder. (Expert Opinion)***

Considering that the PNE or staged lead placement have the best predictive value for determining which patients will benefit from long term treatment with SNM, patients who fail screening, or those who have declining efficacy over time may benefit the most from initial or repeat urodynamic assessment, which may reveal bladder pathologies not amenable to SNM and direct another therapeutic course.

**FECAL INCONTINENCE (FI)**

***SNM should be considered as a second line treatment option for bothersome FI in patients who have failed conservative measures. (Level of Evidence: 2, Grade of Recommendation: B)***

Conservative medical measures are the first line treatment for FI, however, SNM should be considered as the second line of treatment in most patients with FI.<sup>45,46,47</sup> Physicians should consider SNM if the patient has failed medical measures, as SNM has been shown to be superior to best medical management in a randomized trial.<sup>13</sup> Results of pooled analysis has suggested that 79% of patients with permanent implant for chronic stimulation experience  $\geq 50\%$  improvement in incontinence episodes in the short-term, while 84% achieve this endpoint with 3 years of follow-up.<sup>48</sup> Comparative studies are scarce. One study compared 23 patients randomized to SNM vs. 17 randomized to percutaneous tibial nerve stimulation.<sup>49,50</sup> Though short-term outcomes were acceptable in both groups, the design of the study did not allow statistical comparison between groups. One study compared 15 patients treated with SNM to 15 historical controls treated with the artificial bowel sphincter. Postoperative incontinence scores were slightly better with the artificial sphincter, though constipation scores were worse.<sup>51</sup> Importantly, both the artificial bowel sphincter and the magnetic sphincter, another recent option for FI, are currently unavailable. There are no comparative studies of SNM vs. sphincteroplasty, the major competing procedure for FI.

***An anal sphincter muscle defect is not a contraindication for SNM. (Level of Evidence: 3, Grade of Recommendation: C)***

There is a large and growing body of evidence that a defect of the internal or external sphincter is not a contraindication for SNM for FI.<sup>50,52,53,54,55,56,57,58,59,60,61</sup> Though clinical success has been reported in patients with sphincter defects up to 180 degrees,<sup>13,57,62</sup> most would agree that the size of the defect does not matter and should not affect decision making.<sup>50,54</sup> This is likely because the proposed mechanism of action relies more on sensory nerve fibers and bowel motility than on muscular contraction.<sup>63,64</sup> Given the extent of the available evidence stating that a sphincter defect does not impact the success of SNM, some authors have advocated using preoperative ultrasound only in selected patients with FI.<sup>65</sup>

In a patient who is a good candidate for a sphincter reconstruction, typically in a younger woman with relatively recent obstetric injury, it is appropriate to have a full discussion of risks and benefits of a sphincteroplasty vs. SNM. Though there is no evidence to compare the outcomes of these two techniques, many young women with new onset obstetric sphincter defect may be good candidates for sphincter muscle repair.

Other factors such as pudendal neuropathy and the presence of a prior sphincter repair do not predict the outcome for SNM and should not be among the factors considered when deciding which patients to test for SNM.<sup>45,65</sup>

***Patients who have FI after Low Anterior Resection for rectal cancer may be a candidate for SNM test lead implantation if conservative treatment fails. (Level of Evidence: 3, Grade of Recommendation: D)***

As treatment for rectal cancer has evolved and sphincter preservation strategies have emerged, many of these patients are cured of their disease, but as many as 50-90% will suffer at least some degree of bowel dysfunction.<sup>66</sup> Many patients will suffer from debilitating low anterior resection syndrome (LARS), a constellation of fecal urgency, clustering of bowel movements, and FI. As these patients have altered anatomy after resection of the rectum, it is unclear how much benefit SNM may play in achieving relief of symptoms. Two separate studies were conducted on the utility of SNS in LARS.<sup>67,68,69</sup> Success was noted in 47-100% of patients subjected to a test implantation and QOL was generally improved.<sup>67</sup> The difficulty in interpreting this data is that the patient groups are heterogeneous. Some, but not all, of the patients had radiation for rectal cancer, and the rectal resections were done for different disease processes such as cancer or Crohn's disease. Additionally, LARS is a constellation of symptoms with many dimensions such as bowel movement clustering, urgency, and incontinence. Though most studies report on improvement in continence, further research should use a more comprehensive scoring system such as the LARS score<sup>70</sup> to determine which elements of the overall syndrome are improved by SNM. Though it is reasonable to consider SNM test stimulation in the clinical setting of LARS, conservative treatment such as medical bowel management and lifestyle modification should be attempted first.

***SNM is the preferred therapy in an appropriate patient with combined urinary and bowel symptoms. (Level of Evidence: III, Grade of Recommendation: C)***

**Combined Urinary and Bowel Symptoms**

Early studies of 14 patients with FI and associated urinary disturbances showed encouraging results with permanent SNM implant.<sup>71</sup> A study of 24 female patients with combined FI and UI showed improvement in both symptoms after SNM implant in 31.8% of patients with a mean follow-up of 28 months. SNM may be beneficial in selected patients with FI and UI.<sup>72</sup> A recent study showed improvement of bowel dysfunction in patients implanted with SNM for urinary urgency incontinence. There was significant improvement in mean urinary and bowel symptom scores, though only urinary quality of life (QOL) scores improved.<sup>73</sup>

SNM for combined urinary and fecal incontinence has been also explored in children with a positive response. Based on prospective clinical data and patient-reported measures, 29 patients showed between 55% and 91% improvement in both bowel and bladder dysfunction.<sup>74</sup>

SNM should be considered for combined urinary and FI after the work-up for both conditions has been completed.

## **OTHER BOWEL CONDITIONS**

***SNM for constipation should only be considered for patients who have had symptoms for more than one year and have failed conservative treatment, as results of clinical studies have been disappointing. There should be no mechanically correctable cause. (Level of Evidence: 4, Grade of Recommendation: D)***

Reported outcomes of SNM in patients with constipation have been mixed,<sup>75,76,77,78,79,80</sup> thus this remains an area of considerable debate. Success rates with test lead implantation have been reported at 42-100%, and extended testing periods of 2-3 weeks are often necessary.<sup>81</sup> Contradictory studies have emerged, suggesting much lower rates of clinical success. A study by Graf et al<sup>82</sup> indicated that only 11% of patients were improved at 24 months. A double-blind randomized trial of SNM vs. Sham indicated that only 28% of SNM patients met the criteria for device implantation and there was no benefit of this therapy over sham treatment.<sup>83</sup> Additionally, this therapy is not approved by the US Food and Drug Administration, and is not universally covered by insurers in Europe. Best evidence suggests that all less invasive medical and surgical measures should likely be taken prior to proceeding with SNM in these patients.

## **NEED FOR BOWEL TESTING PRIOR TO SNM**

***A 2-3-week bowel diary is necessary prior to SNM test for bowel dysfunction. Anorectal physiology testing (manometry, anorectal sensation, volume tolerance, compliance) can be considered to help define the elements of dysfunction and guide management. (Level of Evidence: 4, Grade of Recommendation: C)***

It is difficult to identify from the literature the optimal work-up prior to SNM in bowel indications. Some clinicians even consider the PNE test itself as a part of the pre-SNM work-up in FI patients, as there is no known physiologic predictor of success of SNM in these patients.<sup>84</sup>

However before embarking on an SNM trial, common bowel investigations are typically done to identify those patients for whom such a test could be of greatest potential benefit.<sup>85</sup> Typically, the patient proposed for SNM test has chronic, severe FI which is defined as more than “one leak per week, over a 3 to 4-week period, lasting for more than 6 months” and that has failed conservative measures. A 2-3-week bowel diary is the most important document prior to SNM test for bowel dysfunction. The following is recorded and will be compared with a similar diary done during the test phase: leaks (minor and major), normal evacuated stools, time to defer as a mean by day, and medications taken. The Bristol stool chart is useful to characterize the bowel habits and to allow exclusion of patients with diarrhea from SNM since a normalized stool pattern has not been reached.

Additional investigations **may** include the following:

- Anorectal physiology testing (manometry, anorectal sensation, rectal volume tolerance and compliance) can be considered to help define the elements of dysfunction and guide management. It is usually done before surgical decision-making, as part of the FI work-up and plays a role to guide pelvic floor retraining.
- Endoanal ultrasound is the recommended tool to assess the anal sphincter complex and to identify any sphincter defects. It would guide the discussion to proceed for repair vs. SNM trial according to the different aspects of the defect.

- Dynamic defecography, either standard or MRI, is nowadays also a test to consider prior to SNM trial.<sup>86</sup> This exam allows for identification of any posterior pelvic floor disorder including high-grade rectal intussusception, which can be clinically difficult to identify and a potential cause of FI. In such a case, many clinicians would first correct the rectal prolapse followed by an SNM trial if FI persists.
- Neurophysiology testing may be performed in some neurologic conditions, but is not part of the usual investigations.
- A/P and lateral views of the sacrum could exclude some abnormalities/malformations making the needle and electrode placement difficult for instance in the case of sacral agenesis associated with anorectal malformations.

### **SNM FOR THE PEDIATRIC POPULATION**

***SNM may be considered in children who have failed an extended period of behavioral modification, biofeedback, and pharmacologic therapy and should be considered before irreversible surgery.***

***Safety and effectiveness have not been established for pediatric indications. (Level of Evidence: III, Grade of Recommendation: C)***

***Anatomical differences and somatic growth make implantation technically more challenging (Level of Evidence: IV, Grade of Recommendation: D)***

SNM has been reported to be effective in children in several single center pilot studies. In one, a total of 23 patients, ranging from 6 to 15 years old with presenting symptoms of dysfunctional voiding, enuresis, incontinence, urinary tract infections, bladder pain, urinary retention, urgency, frequency, constipation and/or fecal soiling were followed for a mean of 13.3 months after SNM. The overall patient satisfaction rate was 64%, while that of the caregiver was 67%. Explantation rate was 10%.<sup>87</sup> Another study with 30 children with refractory bowel and bladder dysfunction showed significant improvements.<sup>37</sup>

There are only two prospective randomized trials utilizing SNM in children. The first study of 42 children with incontinence due to neurogenic LUTD showed subjective improvement in about half of children undergoing SNM, including improved bowel function in 9 children, resolution of urinary tract infections in 5 children, and improved bladder sensation in 6 children.<sup>88</sup> The other randomized study of 33 patients (24 boys) with mostly neurogenic LUTS and with a mean age of 12.2 years compared SNM to standard conservative treatment. Incontinence was mixed urinary and fecal in 19 cases, urinary only in 9 and fecal only in 5. Overall positive response rate was more than 75% for urinary and bowel dysfunction.<sup>89</sup>

A study with longer follow-up (average 3.2 years) in consecutive children with UI, constipation, frequency and/or urgency, and nocturnal enuresis from a single center showed that nearly all children (99 of 105) experienced improvement of at least 1 symptom. Reoperations occurred in 56% of children, mainly for device malfunction. Explantation was performed in 35%, mainly for complete symptom resolution.<sup>90</sup> Of note, certain health preventive measures are of greater importance in children, mainly reduced radiation exposure. Also, anatomical differences and somatic growth must be considered with SNM implantation in the pediatric population.

## **CONTRAINDICATIONS FOR SNM IMPLANTATION**

***Absolute contraindications for SNM includes: Inadequate clinical response to a therapeutic trial, inability to operate the device with lack of supportive caregivers who could otherwise offer assistance, and pregnant patients (Level of Evidence: IV, Grade of Recommendation: C).***

***Relative contraindications for SNM includes: patients with severe or rapidly progressive neurologic disease, patients with established complete SCI, patients with known anticipated need for MRI of body parts below the head and patients with abnormal sacral anatomy (Level of Evidence: III, Grade of Recommendation: C).***

The manufacturer of the currently most widely available system (InterStim II) has approved the safety of the current device for 1.5 Tesla MRI of the head. See manufacturer’s website for further detail.<sup>91</sup> Recent studies have shown that the risk of heating is low for clinical lumbar and pelvic MRI at 1.5-Tesla, both in an intact SNM system and with a fractured lead.<sup>92</sup>

In pregnant women, no negative effects of SNS on the fetus, mother or device have been reported. However, further studies are needed to conclude if it is a safe practice to implant or to leave a device activated in a pregnant woman.<sup>93,94</sup> Indeed, a recent review that included 16 Cesarean and 9 vaginal deliveries, comprising 25 pregnancies with SNM devices in situ (8 with device left on during gestation, 18 with device deactivated, typically between 3-12 weeks gestation) reported that post-delivery SNM dysfunction was present in 32%, with 3 after vaginal delivery and 5 after c-section. Ultimately, the authors suggested that “within the current limited evidence, the decision regarding SNM activation or deactivation should be individualized [in pregnancy].”<sup>93</sup> Until more data is available, for example from a patient registry, the panel recommends not implanting a SNM device in a pregnant woman and deactivating the device when a patient already on SNM therapy becomes pregnant.

## **TIPS FOR INTRODUCTION OF SNM TO PATIENTS**

***SNM therapy should be discussed with all patients as part of their bowel or bladder control treatment pathway. (Level of Evidence: IV, Grade of Recommendation: C)***

***Surgeons should review the need for life-long follow-up, eventual battery replacement, complications, and expected symptom improvement. (Level of Evidence: IV, Grade of Recommendation: C)***

SNM is classified as a 3<sup>rd</sup> line option for treating OAB symptoms,<sup>95</sup> and as a 2<sup>nd</sup> line therapy for FI. Medications and non-invasive interventions comprise first line therapy. It is known that many patients will not respond to initial therapies and will potentially be offered neuromodulation as an option. There is no documented ‘best practice’ for introducing SNM to patients, however at least one study showed that group-education visits made patients more informed and prepared for the test phase, which translated into improved patient-reported outcomes compared to those undergoing standard preoperative counseling, despite voiding diary outcomes being no different between the groups.<sup>96</sup> As no reliable predictor for patient response to more conservative therapies exists, it is our recommendation that all patients be informed of this therapy as early as possible in the treatment pathway. Similarly, for FI, where limited therapies exist beyond pelvic-floor therapy and modification of stool consistency, patients should be alerted that SNM therapy exists.<sup>97</sup> Patients with dual bladder and bowel disorders stand to benefit with respect to both symptoms,<sup>73</sup> which may direct the clinician

to educate the patient about SNM almost at the first encounter. This is discussed in further detail elsewhere in this consensus statement.

As patients are introduced to SNM it is important to review the limitations and implications of the therapy. Currently, the InterStim II device is labeled for an expected battery life of 3-5 years, though some have shown longer periods with lower energy settings.<sup>5</sup> Long-term follow-up, the need for battery replacement, possible revision of the lead or programming changes are all important aspects of SNM therapy,<sup>98</sup> and should be communicated to the patient, in particular given that a recent study using contemporary technology found a 32% rate of surgical intervention at 3 years following implantation.<sup>31</sup> Furthermore, while symptom improvement can be dramatic in some patients, the target response of >50% improvement both objectively and subjectively as the implant threshold indicates this is not a cure in most patients. Expectations for the patient are important and should be balanced against the known response to trial and long-term implant success.

### **PREOPERATIVE COUNSELING - ADVERSE EVENTS**

***Preoperative counseling prior to SNM should include a discussion of risks including implant site pain, infection, paresthesia, leg pain, and/or need for reprogramming or for device revision. (Level of Evidence: 3, Grade of Recommendation: C)***

Though SNM is a relatively safe surgical procedure, adverse events do occur. The most complete report on adverse events comes from the North American Multi-Center trial, as investigators were required to report all adverse events. The most common adverse events were implant site pain (32.5%), paresthesia (19.2%), implant site infection (10%), leg pain (5.8%) or buttock pain (5.0%).<sup>99</sup> The 5-year clinical data on implants for bowel indications from Hull et al<sup>16</sup> suggest that preoperative counseling and long-term follow-up are necessary, as 24.4% required revision or replacement by 5 years, and 19% were permanently explanted by 5 years. Close follow-up with programming parameter optimization, may increase clinical efficacy, while decreasing paresthesias and leg pain.<sup>100</sup>

In a recent multicenter trial, the infectious complication rate was 3.3%.<sup>101</sup> It may be helpful to distinguish between early (<1 month after implantation) vs. late (>1 month after implantation) infections. Wexner et al<sup>102</sup> reported that in colorectal patients, 5/7 early device infections resolved with antibiotics, while all 4 late infections required device explantation. As testing strategies evolve over time, there is increasing interest in the percutaneous office approach to testing, as at least one publication suggested an overall infection incidence of 0% in patients tested via office PNE vs. 10.5% in patients who received a staged approach in the operating room (OR).<sup>103</sup>

### **RATIONALE for PNE vs STAGED PROCEDURE**

***Both PNE and staged trial play a role in SNM. The advantages and disadvantages of each must be taken into consideration when selecting the approach. (Level of Evidence: II, Grade of Recommendation: C)***

One of the unique aspects of SNM is that patients are allowed to undergo a trial period to evaluate whether the therapy is efficacious and provides adequate symptom relief.

Both PNE and the staged trial play a role in SNM. The advantages and disadvantages of each must be taken into consideration when selecting the approach.<sup>2,6,104,105</sup> An ideal candidate for PNE is one who

is comfortable undergoing a procedure under local anesthesia (LA) and who is able to tolerate the potential, mild discomfort related to the procedure. Patients with heightened levels of anxiety or a low pain threshold may benefit from a staged procedure in the OR under monitored anesthesia care (MAC) sedation /local or general anesthesia (GA).<sup>106</sup>

***PNE is less invasive, less costly and can provide reliable sensory responses. (Level of Evidence: III, Grade of Recommendation: C)***

***This form of test stimulation may be required by insurance carriers and may also act as a bridge to therapy acceptance. However, PNE lead migration can be problematic, and there may be limitations in pediatric populations and patients with NLUTD. (Level of Evidence: II, Grade of Recommendation: C)***

Overall, the PNE approach is less invasive, less costly if performed in an office setting, and can provide reliable sensory as well as motor responses.<sup>107</sup> As it is generally performed in the office setting, it may also be more convenient for the patient as it has the potential to avoid one trip to the OR. This advantage would reduce the risks associated with anesthesia and hospital admission by having only one procedure in the hospital vs. two. Additionally, this form of test stimulation may be required by insurance carriers as well as acting as a bridge to accepting therapy. However, there are issues with PNE lead migration, and it may have limitations in a pediatric population and patients with neurogenic voiding dysfunction.<sup>93</sup>

***Staged implant is superior to PNE with regards to conversion rates to chronic therapeutic stimulation in OAB and FI. (Level of Evidence: II, Grade of Recommendation: B)***

***This approach also has the advantage of a longer trial period.***

***However, this approach may be more costly, may require two trips to the OR and may be associated with a greater rate of adverse events.***

The advantage of the staged implant is that there is a longer trial period, and the lead that is being tested is the lead the patient will use long-term. The patient is also allowed to trial multiple programs to achieve optimal outcomes. The conversion to permanent implant is consistently higher in the staged vs. the PNE at rates of 80% vs. 44-52%, respectively.<sup>2,93,94,103,108</sup> Now with the use of fluoroscopy at the time of PNE lead placement, the PNE conversion rate may be higher, however there is no current data to support this supposition.

***More data is needed to identify ideal candidates for PNE vs. staged implant. Reliable predictors of test stimulation success are currently lacking in both bladder and bowel dysfunction. (Level of Evidence: III, Grade of Recommendation: D)***

***For patients with FI who have continent periods of >5-7days punctuated by intermittent episodes of FI, a staged implant may be preferable to ensure an adequate trial period. (Level of Evidence: IV, Grade of Recommendation: D)***

***Since NLUTD is a complex condition and given the lower rate of positive tests using PNE, a staged procedure should be considered for the majority of NLUTD patients. (Level of Evidence: III, Grade of Recommendation: D)***

In patients with underlying neurological conditions, since NLUTD is a complex condition and given the lower rate of positive tests using PNE, a staged procedure should be considered for the majority of NLUTD patients. The majority of studies recently published in this area reported exclusively on the use of tined lead electrodes for the test trial in NLUTD patients.<sup>36</sup> Even though these studies do not report comparative results between the two techniques it has been demonstrated that PNE testing has disadvantages compared to the staged procedure such as lead migration 11-18%,<sup>2</sup> lower rate of positive tests 46% vs 88%<sup>109</sup> (9) and different responses between temporal and definitive lead – up to 20%.

## **SCREENING FOR SUCCESS DURING THE TEST PERIOD**

***Patients who achieve  $\geq 50\%$  improvement in one or more of their bothersome urinary or bowel parameters during PNE or Stage 1 test period may be offered a full system implantation.***

For both PNE and stage 1 trials, both objective and subjective measures of improvement should be assessed. Success during the SNM trial is defined as at least 50% improvement in one or more of the bothersome parameters.<sup>9</sup> Patients who achieve this benchmark should be offered full implantation.

PNE duration is typically 7 days for bladder indications. As the PNE leads are not anchored with tines, there has historically been concern regarding lead migration causing an inconclusive trial; thus, PNE trials are typically not done for more than about 7 days. However, some implanters do utilize longer PNE trials with little ill effect (in particular European implanters for bowel indications).

***PNE test stimulation period is typically 7 days for bladder and 10-21 days for bowel indications. (Level of Evidence: III, Grade of Recommendation: 3)***

PNE duration for urinary urgency/frequency and urgency incontinence is typically 7 days. This can be extended in cases of NOR. The period for SNM trial recommended by the manufacturer is two-weeks for bowel indications. It has been strictly applied in the US with a 10-14 day trial in the major published studies.<sup>16</sup> However, in Europe this is considered too short a duration as stated in the published consensus statement based on a Delphi process in 2015.<sup>54</sup> Assuming the lead remains viable without significant migration, a 3-week trial period has been chosen as an empirical compromise.<sup>110</sup>

Thus, for bowel indications, it is suggested that SNM test duration last from 10 days to 4 weeks, allowing for testing of various stimulation programs, which may be beneficial when a satisfactory result is not immediately achieved.<sup>111</sup> Ultimately, the goal of any trial (whether PNE or staged), is to provide an adequate duration to determine whether at least a 50% improvement in symptoms has been achieved.

***Stage 1 test period duration is typically 2-3 weeks.***

***Stage 1 testing can be attempted if PNE is inconclusive, particularly if a longer test period is required for screening.***

***A repeat stage 1 test may be performed at the physician's discretion.***

Stage 1 duration is typically 2-3 weeks. There are some experts who do utilize up to four weeks, in part to avoid any possible placebo effect, or in instances when it is unclear if the patient has met the 50% improvement criterion, or for patients with incomplete emptying.<sup>112</sup> Kessler and colleagues followed a series of 44 patients who underwent prolonged tined lead testing for a median of 30 days,

with 70% proceeding to full implantation. The complication rate was 5% during the prolonged tined lead testing, but none of these were attributable to the extended testing itself.<sup>113</sup>

Patients should be encouraged to adjust the stimulation settings during their test period to optimize the trial.<sup>2</sup> If PNE testing is inconclusive, it is reasonable to consider a Stage 1 trial, in particular if a longer duration of testing is required. Stage 1 trials are typically not repeated, but can be attempted at the physician's discretion in select circumstances.

### **REMOVAL OF SCREENING LEAD**

***PNE electrode(s) removal preferably occurs in the clinician's office, but may be removed by patient/family at home.***

***Stage 1 tined leads can be removed under local anesthetic (in the office or OR) with or without sedation to ensure patient comfort during removal of all components.***

There are no published studies regarding removal of the PNE lead at home by the patient versus in the office by the clinician. Removal at home is convenient for patients, especially those who travel a great distance to their clinician's facility; however, removal in the office allows for both confirmation that the lead was removed intact, as well as an opportunity to review outcomes of the trial (though this could also be done via phone in conjunction with home lead removal). The panel agrees that removal of a PNE lead can likely be safely performed in either setting

Stage 1 tined leads should be removed by a physician.<sup>114</sup> These can be removed under local anesthetic in the office or the OR setting, with or without sedation, as needed to ensure patient comfort.

### **PREVENTION OF SURGICAL SITE INFECTION (SSI)**

***A perioperative antibiotic aimed at coverage of skin flora should be given intravenously within 60 minutes of incision for both bowel and bladder indications.***

***The specific antibiotic of choice should be guided by the local antibiogram and the patient's allergy profile. (Level of Evidence: IV, Grade of Recommendation D)***

The most significant complication after SNM device implantation is wound infection. Reported wound infection rates range from 2–11% and are most commonly caused by *Staphylococcus aureus*.<sup>115</sup> A recent large multicenter trial reported a wound infection rate of 3.3%.<sup>116</sup>

No defined perioperative or postoperative antibiotic protocol is uniformly agreed upon for neurostimulator implantation; instead, this decision should be guided by the local antibiogram and surgeon discretion. For the staged procedure, preoperative intravenous antibiotics should be given within 60 minutes prior to the incision and aseptic techniques should be closely followed.

The AUA Best Practice Statement for perioperative antibiotic prophylaxis recommends the use of a first-generation cephalosporin for open surgical procedures that do not involve entry into the urinary tract and does not recommend prolonged antibiotic usage, since there is no evidence to support it.<sup>101</sup> Prostheses implantation surgeries are recommended to receive prophylaxis with an aminoglycoside plus a first-/second-generation cephalosporin or vancomycin. It is debatable how to categorize the SNM procedure because it is an open surgical procedure not entering the urinary tract as well as an implanted procedure.

In a study done by Haraway et al,<sup>104</sup> the use of cefazolin as the preoperative antibiotic was the only significant risk factor for subsequent infection and explanation of the SNM device. Indeed, cefazolin was less effective than vancomycin with or without gentamicin in preventing infection in this study, likely due to resistant organisms.

Antibiotic recommendations for bowel and bladder indications are similar. The European consensus statement for sacral nerve stimulation for FI and constipation recommends a single dose of prophylactic antibiotics before both the tined lead and the IPG implantation procedures, and suggests that routine postoperative antibiotics are not required.<sup>54</sup>

Chlorhexidine-based skin prep is commonly used for perioperative cleansing of the patient's back and upper buttocks, but this varies between clinicians. Care should be taken in preparation of the buttocks and anus. If the implanter chooses to visualize the anus during test stimulation to observe the anal sphincter contraction, it should be covered with a separate plastic drape until visualization is required during surgery.

Other investigators suggest minimizing the risk of SSI with a preoperative shower with antiseptic, as well as allowing the dressing to remain in place for 48 hours postoperatively following stage 2 procedures.<sup>117</sup>

## **IDEAL ANESTHESIA**

***No data suggest superiority of local anesthesia (LA) with IV sedation vs. general anesthesia (GA) for a successful staged neuromodulation trial.***

***Muscle relaxants with GA and regional anesthesia causing neuromuscular blockade must be avoided.***

***LA is preferred for PNE, and LA with IV sedation for IPG implant. GA may be considered.***

There are two current methods for trialing SNM to screen for efficacy.

The first is the PNE, which is generally done in the office under LA. There is the option to perform the PNE in an ambulatory surgical center (ASC) or even in the hospital and provide monitored anesthesia care (MAC) or GA. The second method is the staged approach, which is typically done in an ASC or hospital setting under MAC or GA. When SNM was first approved, this involved a PNE screening trial, and if the patient was determined to be a success, they then underwent implant of the long-term device. This required a large cut-down to the posterior aspect of the sacrum and was routinely performed under GA with high success rates. This suggests that the use of GA does not negatively impact the success of SNM.

In general, LA is considered to be safer than MAC, which is itself considered safer than GA. There is no current data that suggests any type of anesthesia is superior over another in terms of outcomes for SNM. As one of the parameters for determining a successful implant is appropriate motor response (bellows and great toe flexion), the use of a paralytic agent should be avoided if using GA. ***(Level of Evidence: V, Grade of Recommendation: C)***

LA is preferred for PNE if patients are able to tolerate it, and LA with IV sedation (MAC) for tined lead and IPG implant. GA may be considered under certain circumstances according to physician discretion,

however there is no evidence that the choice of anesthesia impacts outcomes (**Level of Evidence: II, Grade of Recommendation: B**).<sup>9,97</sup>

## **IMPLANT TECHNIQUE**

***The clinician should strive to achieve appropriate motor and/or sensory responses on all 4 contacts at stimulus amplitudes of <2 volts. (Level of Evidence: II, Grade of Recommendation: B)***

The concept of “Optimal Lead Placement” derives from the notion that while the overall success of SNM is excellent,<sup>118</sup> there is a potential for an individual patient to experience an incomplete benefit, or a “false negative” response due to technique and imprecise lead positioning<sup>2</sup>. Although it remains to be proven scientifically, logically it is hard to dispute that the quality of the interface between the neuromodulation device and the nervous system is of general importance to the therapeutic outcome of SNM. The current 3023 tined lead is an electrode array, consisting of four equally spaced contacts in a flexible assembly. By taking readily reproducible steps to steer the lead into position it is often possible to follow the course of the sacral nerve target, and achieve similar motor and sensory responses at each individual contact.<sup>119,120,121</sup> Some have demonstrated more accurate placement with the curved lead.<sup>121</sup> These electrode contacts may then be employed singly or in combination to achieve neuromodulation for clinical benefit.

The closer the lead is to the intended target, the lesser is the amount of energy that will be required to obtain a neuromodulation response. On one level, effective programming at lower thresholds is more efficient, and is likely to result in longer lasting battery life and less frequent need for replacement thus increasing the cost efficacy of the therapy and reducing risks related to re-operation.<sup>122,123</sup> On another, electrode placement near the nerve means that the chance of stimulation of unwanted tissues (ie, the piriformis muscle), which may trigger uncomfortable stimulation or paresthesias, will be minimized. In turn, the need for reprogramming or re-operation to resolve uncomfortable stimulation should be lessened.

***Leads that require higher thresholds or offer responses at fewer than 4 contacts can be successful. (Level of Evidence: II, Grade of Recommendation: B)***

Sub-optimal lead placement can be therapeutically beneficial. Initial techniques for chronic lead placement were performed in a “blind” fashion, guided only by anatomical landmarks, without the routine use of fluoroscopy.<sup>4</sup> The depth of lead placement, lead direction, and even the final sacral level of placement was not standardized. Many subsequent series have shown excellent symptom benefit before the concept of lead optimization was widely suggested. However, it is unknown if the overall degree of symptom relief could potentially have been greater, and the rate of screen failure, re-operation, or eventual therapy abandonment might have been reduced within these study populations, had lead optimization been a standard.<sup>124,125</sup> Another unknown is whether the demands for precise lead placement may differ for various indications. An example of this concept is the notion that the target for lead placement for the indication of FI seems to be more robust, with a relatively large neuromodulation target (S3 or S4), while placement for urinary frequency and urgency without urge incontinence, and with a component of pelvic pain, may require hitting a narrower target (S3 or pudendal lead placement).

***S3 is the preferred target for SNM. Bellows and toe dorsiflexion are the motor responses consistent with S3 placement. Thresholds for bellows should be lower than for toe. Leads placed in S4 may be appropriate in some cases. S2 should be avoided due to the risk of aberrant sensation and motor response in the leg. (Level of Evidence: 3, Grade of Recommendation: C)***

From the initial studies on SNM, S3 is the preferred target for SNM. A typical S3-mediated response is a contraction of the pelvic floor along with plantar flexion of the first and second toes, whereas S4 stimulation does not produce any toe response.<sup>126</sup> There is individual variation in composition of the sacral roots. A direct ventral sacral root electrical stimulation study measuring bladder contraction by means of intravesical pressure showed that in 100% of the patients, bladder pressure increase was measured upon stimulation of the S3 anterior sacral root, but also in 60%, upon stimulation of S4, 40% on S2 and around 15% at S5. There is an individual difference in distribution of bladder efferent fibers.<sup>127</sup> It is unknown if the distribution of motor nerves activated directly by neurostimulation is similar to the distribution of the rootlets stimulated for the indirect neuromodulation effect.

In a retrospective study on patients with FI however, there was no difference in success rate upon S3 or S4 stimulation during a 3-week PNE test.<sup>128</sup> These findings are also supported by reports of accidentally or deliberately implanted leads in S4.

S2 stimulation produces outward rotation of the leg and sensation running down the leg.<sup>116</sup> These effects may bother the patient, and S2 stimulation should therefore be avoided.

***The clinician should consider both sensory and motor responses important for success. (Level of Evidence: IV, Grade of Recommendation: C)***

The most readily quantifiable responses are motor (bellows and toe) with the patient under sedation. It is easier to obtain sensory responses than motor during a PNE, when the patient may not be able to relax and is fully conscious.<sup>116,129</sup> A purported mechanism of action of SNM is sensory afferent neuromodulation, so the sensory side of the response may be meaningful. Indeed, given that sensory responses are used when reprogramming, having appropriate sensory responses during initial placement may help guide successful reprogramming and eliminate the need for revisions.

***Motor responses alone may be utilized in patients who undergo GA. (Level of Evidence: IV, Grade of Recommendation: C)***

With patients under heavy sedation or GA, sensory responses are unlikely to be elicited. The pattern of motor responses can be helpful in predicting where paresthesias will be felt. For example, all bellows and no toe, or toe only at a significantly higher threshold than bellows, is likely to be associated with anal sensation, while bellows followed by toe response immediately or at slightly higher thresholds is more likely to be associated with genital sensation. Toe movement at a lower threshold than bellows is likely to be associated with uncomfortable sensation down the leg.

***Sensation down the leg or in the buttock and discomfort in the anal, perianal, or genital areas should be avoided. (Level of Evidence: II, Grade of Recommendation: B)***

Although sub-sensory thresholds are potentially associated with good patient outcomes, generally patients tend to do better when the stimulation is comfortable. One of the most common adverse events of SNM is uncomfortable stimulation.<sup>105</sup> Most patients find stimulation in the buttocks or down the leg less comfortable, than in the anal, perineal, or genital areas.<sup>116</sup>

Patients are more likely to require reprogramming when stimulation is uncomfortable.<sup>105</sup> It is unclear whether anal, perineal, or genital sensations are associated with higher success in individual patients or between patient groups depending on diagnosis, ie, FI vs. urinary frequency with or without a component of pelvic pain.

***Standard frequency and pulse width settings of 10-20 Hz should be used. (Level of Evidence: II, Grade of Recommendation: B)***

***Other frequencies and pulse widths can be used during troubleshooting procedures. (Level of Evidence: IV, Grade of Recommendation: D)***

There are no studies which show definitive advantages of specific programming settings over others for a condition or indication. Low frequency stimulation of 10-20 Hz, with pulse width between 180-210  $\mu$ s, has been associated with therapeutic success for all the indications approved for SNM. These settings should be used initially. If patient comfort or therapeutic efficacy is not achieved, it is reasonable to experiment with alternative programming, though consistent success is anecdotal.

## **ROLE OF FLUOROSCOPY**

***Fluoroscopy is recommended for staged lead positioning to control depth of foramen puncture and optimize placement of the lead. (Level of Evidence IV, Grade of Recommendation D)***

***Fluoroscopy may be used for PNE to confirm proper lead placement. Alternatively, use of bony landmarks to determine lead placement is acceptable if fluoroscopy is not available. (Level of Evidence III, Grade of Recommendation C)***

Fluoroscopy is a key element underlying quality tined lead placement, allowing the surgeon to control both depth of puncture and the placement of the lead. In many countries, labeling of the therapy indicates that fluoroscopy must be used for tined lead placement. Fluoroscopy may also be used during PNE, but not all clinicians do this during their office procedures.

Siegel and colleagues first described fluoroscopic lead placement in 1992.<sup>130</sup> Their description is still useful today, and very much in keeping with the modern technique; however, they described an open surgical procedure, which contrasts with the modern, minimally-invasive approach to tined lead placement. The role of fluoroscopy has become even more crucial following conversion to the minimally-invasive placement technique, as it allows for consistent, reproducible and optimal positioning of the lead in the foramen, as well as confirming curvature along the path of the S3 nerve, plausibly avoiding multiple punctures, minimizing bleeding, infection risk, post-operative pain and surgical time.

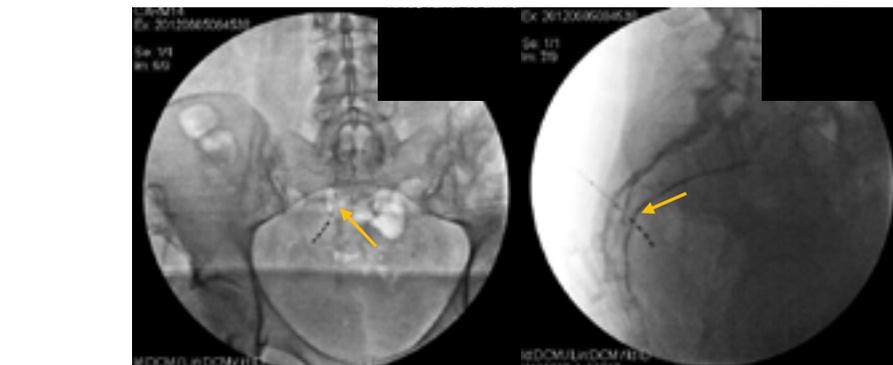

- **Active lateral fluoroscopy should be used during final tined lead deployment.**
- **The distal end of the lead introducer should be placed only 1/2 to 2/3 through the sacral bone table.**
- **The motor and sensory responses and the stimulus amplitude at which they occur, along with AP and lateral x-ray images associated with final deployment, should be recorded in the medical record.**
- **Radiographic appearance consistent with ideal lead placement entails:**

- In the lateral view, the lead parallels the fusion plane between third and fourth sacral segments, enters above the hillock, and curves caudally. Distal lead contacts appear to be spaced more closely together than proximal contacts.
- In the AP view, the lead starts close to the medial edge of the foramen, and curves out mediolaterally. Proximal contacts appear to be spaced more closely together than distal contacts.
- The curved stylet may be able to increase the number of responding contacts at lower stimulus amplitudes. (Level of Evidence IV, Grade of Recommendation C)

There remains debate regarding optimal lead placement, and no prospective studies exist to correlate clinical response (in bowel or bladder conditions) with lead positioning. Jairam et al<sup>131</sup> from Masstricht retrospectively reviewed lead placement in 189 patients, and found no correlation between the position of the tined lead in the Stage 1 trial, with regard to depth, angle, and deflection, and the number of active electrodes, and the likelihood of a successful trial in either the OAB group or the NOR group. Nonetheless, expert consensus dictates that placement close to the nerve may reduce voltage used and improve programming options and long-term battery life.

**Figure 1a: A/P image demonstrating medial placement in the S3 foramen (arrow)**

**Figure 1b: Lateral image demonstrating 3 contacts below the sacral plate**

### **IPG PLACEMENT**

***IPG buttock placement in the lateral upper quadrant is preferred but abdominal placement may be required in some cases. (Level of Evidence: 3, Grade of Recommendation: C)***

***IPG should be placed above the muscle layer, no deeper than 2.5 cm (1 in). (Level of Evidence: 3, Grade of Recommendation: C)***

When SNM was first introduced, the IPG was placed in the anterior abdominal wall. This required repositioning of the patient during surgery and prolonged the procedure, and, of note, the lead extension required for this type of placement is no longer manufactured. Buttock placement of the IPG was described by Scheepens et al<sup>132</sup> in 2001. This technique simplified the procedure and reduced

22

operative time in all 39 trial patients by approximately 1 hour, given that no repositioning of the patient was required during surgery. Pain was reduced and there were no infections.<sup>121</sup> It is, however, difficult to assess the true advantage of buttock vs. abdominal placement, since no direct randomized trials have been published. In some patients with very limited fat, an abdominal placement might be utilized.

Because of the distance limitation of the wireless communication with the programmer, the IPG should be placed no deeper than 2.5 cm (1 in). [Product information data]

## **POST PROCEDURAL PATIENT RESTRICTIONS**

***PNE test stimulation is associated with a risk of lead migration. Limited physical activity during the trial is advised to reduce this risk. (Level of Evidence: 3, Grade of Recommendation: C)***

***Risk of lead infection is greater with Stage 1 testing than with PNE. Operative dressings should not be removed during the test period, unless permitted by the surgeon. (Level of Evidence: 3, Grade of Recommendation: C)***

***Following Stage 1 and Stage 2 procedures, patients should be encouraged to minimize vigorous activity for several weeks to allow the tined lead to scar in place and prevent lead migration. (Level of Evidence: 3, Grade of Recommendation: C)***

Besides the manufacturer's recommendations (Manual InterStim 3889, 3058, etc.) very limited data has been published regarding specific post procedural patient restrictions. However, the two main risks to the implants are infection and dislodgement.

For test stimulation with temporary leads, which are only secured by external dressing and not by internal fixation like the tined lead, secure fixation with splash-resistant, transparent dressing allowing for washing and showering after disconnection of the external pulse generator is advised.<sup>133</sup> Patients should be instructed to avoid strenuous physical activities, which result in tension on the electrode.

For test stimulation with a tined lead, the risk of dislodgement appears to be less;<sup>134</sup> however, the risk of infection becomes more relevant. In a retrospective review of 669 SNM procedures, one group did find substantial decreases in infection rates after instituting an at-home chlorhexidine washing protocol.<sup>135</sup> The removal of the dressing throughout the test period should, however, still be avoided unless the physician has concern upon inspection of the dressing for infection or bleeding. There is no consensus on the use or efficacy of continued antibiotics during the trial period.

In one study<sup>136</sup> of 235 patients, lead migration occurred 1 subject when using a tined lead. In another study, with 2 years follow-up after tined lead implantation, there was a 10% rate of lead migration following tined lead implantation.<sup>137</sup> Regardless, after implantation, vigorous activity and excessive bending or twisting at the waist should be avoided for sufficient time to allow scarring and fixation of the implanted device.

## **POST-OPERATIVE AND FOLLOW-UP CARE**

***Routine follow up should include a clinical examination, symptom evaluation, system check of the stimulation device and confirmation that it is functioning. (Level of Evidence: III, Grade of Recommendation: C)***

***In patients with urinary retention, a post-void residual should be assessed.***

***Suggested routine follow up consultations during the first year should occur at 1, 6 and 12 months postoperatively, then annually thereafter. (Level of Evidence: IV, Grade of Recommendation: D)***

***Follow up consultations on demand should also be available. (Level of Evidence: IV, Grade of Recommendation: C)***

The purpose of post-operative follow-up care is to confirm adequate functioning of the therapy and to address potential complications/side effects. Different patterns of follow up visits have been described.<sup>100</sup>

It is recommended that the initial follow-up visits and subsequent follow-up visits should be spaced at least 1 month apart because full evaluation of setting changes may not be meaningful if the interval is less.<sup>138</sup> Based on the experience that a proportion of patients requires reprogramming in the early phase of follow-up, more than one follow-up visit in the first year is recommended.<sup>100,139</sup>

Subsequent yearly follow-up visits are advised by international expert groups,<sup>100,125</sup> but no consensus on the timing and interval of follow-up was determined on recent systematic review.<sup>54</sup> Follow up visits are uniformly recommended when problems occur.<sup>54,100,125</sup> A clinical evaluation of the efficacy of SNM (eg, bowel and bladder diaries, scoring of the severity of symptoms, measurement of the impact of symptoms on QOL) and evaluation of the correct functioning of the neurostimulation device (eg, stimulation settings, impedances and side effects) are considered minimum requirements of follow-up.<sup>100</sup>

***Radiological imaging of the tined lead is advised at final implantation, which allows for comparison and evaluation of lead migration in case of dysfunction or unexpected loss of efficacy. (Level of Evidence: 3, Grade of Recommendation: C)***

Whether postoperative radiological imaging after temporary lead insertion may be helpful to confirm the position remains controversial.<sup>54</sup> Intraoperative fluoroscopic monitoring/documentation during the implantation phase and/or postoperative documentation of the implanted hardware is recommended to document positioning of the electrode in the sacral foramen. Post-implantation radiological imaging at routine follow up is not required, unless there is loss of efficacy potentially due to electrode dislodgement or breakage.<sup>140</sup>

## **SUCCESSFUL OUTCOME—BLADDER AND BOWEL**

***A patient who is satisfied with the treatment is considered to have a successful treatment outcome. (Level of Evidence: III, Grade of Recommendation: C)***

For SNM, the most commonly used criterion for successful test stimulation is an improvement in the patient's bothersome symptoms of  $\geq 50\%$  during the period of observation monitored by bladder or bowel diaries.<sup>54,100</sup> Some data suggest that greater improvement during test stimulation may predict better long-term outcomes.<sup>141,142,143</sup> Regardless, the symptom improvement should be associated with concomitant patient satisfaction before pursuing full implantation.

***For patients with voiding dysfunction or NLUTD, further evaluations may be necessary to ensure long-term safety of the urologic tract. (Level of Evidence: III, Grade of Recommendation: C)***

24

Of note, in patients with voiding dysfunction in the setting of NLUTD, further evaluation may be necessary to ensure the long-term safety of the upper urinary tract. The clinical evaluation of patients' LUT symptoms often includes a bladder diary, uroflowmetry followed by measurement of post-void residual urine volume in spontaneous voiders, urinalysis, renal-bladder ultrasonography, assessment of renal function, quality-of-life measurements and sometimes urodynamic investigations and/or cystoscopy.<sup>144</sup> UDS, with or without fluoroscopy, can at times be essential in these patients as a means to assess detrusor and bladder outlet function and give fundamental information about detrusor pressure and thus the risk factor for upper tract damage.<sup>145</sup> Additional interventions, ranging from oral medication or intradetrusor BTX-A injections, to augmentation cystoplasty or even urinary diversion, may be required and are not contraindicated in the setting of SNM.

### **SNM INFECTION**

***Explantation of the IPG and lead and debridement of the infected tissue is recommended in instances of SNM infection. The wound should be irrigated and a course of oral antibiotics can be considered. (Level of Evidence: III, Grade of Recommendation: C)***

Infection rate of SNM is low at 2-11% for urinary indications,<sup>2</sup> as well as for FI.<sup>102</sup> In one large investigational trial of SNM for FI, in which patients were followed for an average of 28 months (range 2.2-69.5), 10.8% of subjects reported infection with SNM implant. One infection spontaneously resolved and five were successfully treated with antibiotics. Seven infections (5.8%) required surgical intervention, with infections in six patients requiring full permanent device explanation.<sup>102</sup>

A study of staged SNM implantation revealed lead infection in 12% and IPG infection in 11%. The only significant difference in clinical/surgical characteristics between infected and non-infected patients was a longer operative time for Stage 2 in infected patients.<sup>146</sup> A prolonged first stage implant trial with permanent quadripolar electrode has shown colonization in 13/34 electrode extension leads with the mean stage 1 SNM evaluation period of 52.3 (27–116) days but this was not associated with an increased risk of wound infection. The most frequent colonization was with *Staphylococcus epidermidis*, *Staphylococcus capitis*, *Peptostreptococcus* spp., *Enterococcus faecalis* and *Micrococcus luteus*.<sup>101</sup> In the urinary literature, one study demonstrated that Cefazolin alone was less effective in preventing infection compared with the other antibiotic regimens, with 88% of infections that required explantation stemming from *Staphylococcus aureus* species resistant to cephalosporins.<sup>104</sup>

There are no specific published reports regarding treatment of SNM device infections. Based on common general surgical principle, guidelines and expert opinion the infected device must be removed in its entirety, the wound irrigated/drained and oral/systemic antibiotic therapy started. The choice of the antibiotic should depend on local institutional guidelines. In very rare instances, removal of only one component of SNM implant may be contemplated with adequate antibiotic coverage. The choice to close the wound primarily or allow it to heal by secondary intention should be decided on a case by case basis. Other techniques to combat infection can be considered.<sup>147</sup>

***A 3-month waiting period prior to reimplantation is advised and use of the contralateral side for the IPG pocket should be considered. (Level of Evidence: IV, Grade of Recommendation: D)***

There is no reliable data regarding the waiting period for reimplantation after removal of the infected device. The recommendation of a 3-month waiting time is based on expert opinion.

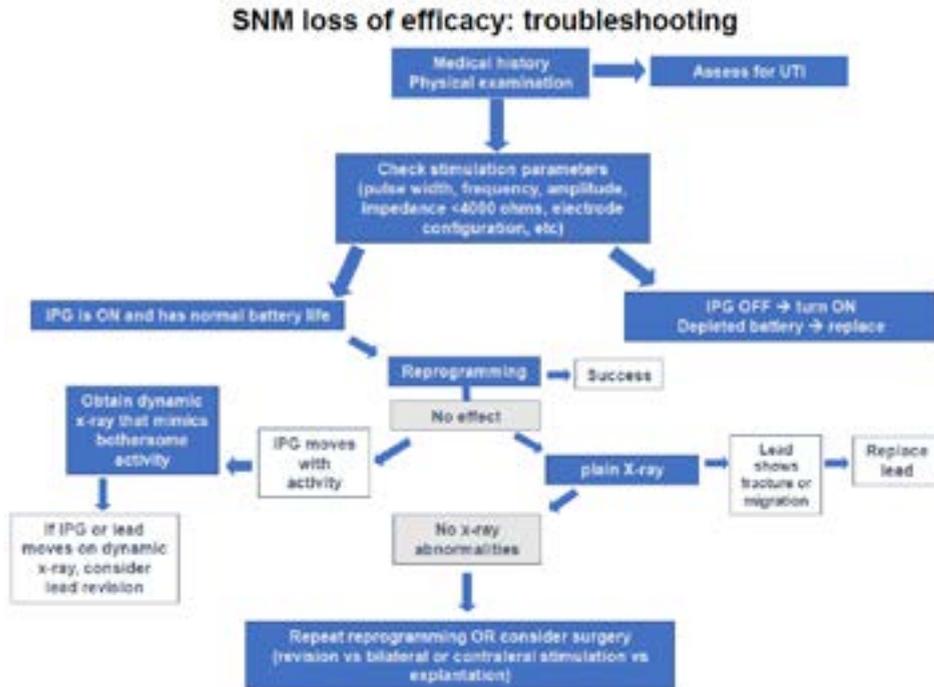

## **TROUBLESHOOTING DEVICE MALFUNCTION – LOSS OF EFFICACY & PAINFUL STIMULATION**

***Patients with declining efficacy or painful stimulation should undergo device assessment. Turning off the device will differentiate painful stimulation vs. local pain at site of IPG. Changing program voltage or lead configuration may correct painful stimulation prior to attempting lead revision. (Level of evidence III, Grade of Recommendation C)***

After permanent implantation, patients should be followed considering their primary reason for implant and clinical effect obtained at the time of their trial. Common complaints include discomfort at the site of the IPG, painful stimulation, recurrence of symptoms, absent stimulation, and stimulation in non-target areas.<sup>5,148</sup>

Such complications can be related either to the device, implantation technique, or parameters of stimulation. The most recent prospective, controlled data with 3 year follow-up is now available,<sup>31</sup> reporting a global device-related adverse event rate of 16%. Concerning the IPG, 47% of patients in the series reported adverse events, of which 91% were resolved at the time of analysis. These included an undesirable change in stimulation (49/272, 18%), implant site pain (34/272, 13%) and lack of efficacy (16/272, 6%). Loss of efficacy may develop either due to failure of the therapy to achieve significant clinical improvement of symptoms (> 50%) or due to a depleted battery.

Little has been published regarding the troubleshooting of sacral neuromodulation systems since the description by the Cleveland Clinic in 2005. As such, the following algorithm is recommended:

When a patient presents with a side-effect which may be related to stimulation, such as declining efficacy, painful stimulation, or aberrant neurological stimulation, the first action by the clinician should be to turn off the IPG. Should symptoms disappear, the IPG may be turned back on and reprogrammed, trying to avoid return of the presenting symptom. Pain related to stimulation should disappear when turning off the IPG and reprogramming, which may include decreasing voltage, decreasing frequency and/or changing the lead configuration. This can be done by the physician, or by a physician assistant or dedicated nurse if they are adequately trained in programming as well as clinical analysis of patient complaints. If pain persists after the IPG is turned off, the pain is may be due to the position of the IPG itself and IPG repositioning may be required, or it may be unrelated to the device. At minimum, other etiologies should be considered.

***Device programming should be performed by experienced clinicians targeting comfortable low sensory thresholds to the perineum. (Level of Evidence IV, Grade of Recommendation C)***

Follow-up of patients undergoing permanent SNM depends somewhat on the local health care system. As most of the adverse events require the clinician to analyze symptoms and then try to correlate those symptoms with any device malfunction, office evaluation (rather than a telemedicine visit) is usually required.

***Patients given a complement of programs should try a new program for at least 1 week, unless it is not tolerable secondary to unpleasant stimulation or severe worsening of symptoms. (Level of Evidence IV, Grade of Recommendation C)***

Since voiding and bowel disorders are not always constant over time, any new program should be tested for at least one week unless the patient experiences side effects from the new program. In a recent prospective trial<sup>118</sup> 22% of patients needed reprogramming due to an undesirable change in stimulation, decrease in therapeutic efficacy, or pain, within 5 years of implantation.

***If reprogramming does not improve the patient's symptoms, radiographic imaging should be performed to assess for lead breakage or migration. (Level of Evidence IV, Grade of Recommendation C)***

X-ray images can reveal lead fractures or migration of system components that subsequently necessitate replacement of the system. Moreover, impedances > 4000 ohms are also diagnostic of a lead fracture or microfracture (which may not be visible on imaging) and likely requires lead replacement, although evidence from a large retrospective series shows many abnormal impedances can be programmed around to salvage a lead.<sup>98</sup>

### **WHEN TO STOP SNM TESTING/THERAPY**

***SNM testing or therapy should be discontinued if the patient no longer wishes to proceed, or if in the judgment of the clinician, further testing/lead revision will not lead to symptom improvement. (Level of Evidence: III, Grade of Recommendation: C)***

The only documented predictor for treatment success is the response to a trial of stimulation. Since implanted patients may experience declining efficacy over time,<sup>39</sup> therapy may need to be altered. As outlined elsewhere in this text, patients may elect to undergo device interrogation, re-programming, or surgical revision when symptoms are not well controlled with SNM. If at any time the patient does not desire to continue with SNM, or would prefer to transition to other 3<sup>rd</sup> line treatments, then therapy should be discontinued. Furthermore, once a patient has exhausted the possible revisions and alterations of therapy (lead location and side, programming options) and the clinician determines that no further benefit can be expected, then SNM should be discontinued.

### **DEPLETED IMPLANTABLE PULSE GENERATOR (IPG)**

***Exchange of IPG should occur when end of service is confirmed and the patient has maintained a successful response to SNM prior to battery depletion.***

***Check the impedance of the lead and, if indicated, replace the lead when exchanging the IPG. (Level of Evidence: III; Grade of Recommendation: C)***

Patients with a depleted IPG battery (end of service) will usually present with loss of SNM stimulation and/or loss of efficacy of SNM. Occasionally, increased stimulation may be experienced. When patients present with a depleted IPG battery, confirm end of service by running a battery check with a physician programmer. Exchange the IPG when the end of service is confirmed and the patient has maintained a successful response to SNM prior to battery depletion. Check the impedance of the lead and, if indicated, replace the lead when exchanging the IPG.

## **NON-FUNCTIONING SYSTEM**

***When patients present with a non-functioning system, confirm impedances by checking all combinations with a physician programmer. If all of the combinations are non-functional, then the IPG should be turned off to conserve battery life and the lead replaced. The lead should also be replaced if there is a therapy-limiting number of programming options. (Level of Evidence: III; Grade of Recommendation: C)***

Patients with a non-functioning lead will usually present with loss of SNM stimulation and/or loss of efficacy of SNM. When patients present with a non-functioning lead, confirm by an impedance check all combinations with a physician programmer. At least one functioning lead electrode is required for a lead to operate unipolar and two functioning leads for bipolar stimulation. If all of the combinations are non-functional, the IPG should be turned off and the lead replaced.

When assessing the lead with the physician programmer, run an impedance check at 2.0 volts to deliver sufficient energy for a complete check and assess all the seven possible circuit combinations. A non-functioning combination will return a reading above 4,000 ohms or 0 ohms. If all of the combinations are non-functional, the IPG should be turned off and the lead replaced (consider a trial of unipolar stimulation if only one electrode is functioning). If not all of the combinations are non-functional then, by a process of elimination, the non-functioning electrode(s) can be identified and not used in future programming. Many devices with non-functional electrodes can be salvaged and used to provide continued therapy after programming around the broken lead.<sup>98</sup>

Before replacing a non-functioning lead, the clinician should discuss the implications of lead removal, including the risk of retained fragments. Confirmation of the lead site should be sought, in the form of a sacral X-ray if the prior operative reports or intraoperative films are not available. It is recommended that the lead be removed through the pre-sacral incision. When removing the lead through the pre-sacral incision, use gentle traction in a straight-line direction with respect to the lead tines. If too much resistance is encountered during lead removal, further dissection through lumbosacral fascia and pre-sacral periosteum may be required. The prevalence of lead breakage during lead removal is 1-3.6%.<sup>103,149,150</sup> Of note, some anecdotally report successful lead removal through the buttock incision using gentle traction on the lead. Nonetheless, leads left in for prolonged periods of time may be more challenging to remove this way and strong consideration should be given to midline removal.

## **RESIDUAL LEAD FRAGMENTS FOLLOWING LEAD REMOVAL**

***Patients with residual lead fragments should be advised of the presence, nature and safety of the residual fragments. Current evidence suggests it may be safe for residual lead fragments to remain long-term. (Level of Evidence: III, Grade of Recommendation: C)***

Patients with residual lead fragments should be advised of the presence, nature and safety of the residual fragments. This should include providing patients with information regarding composition, size and location of residual lead fragments. Although not reported for SNM, migration, infection, and injury to surrounding structures from residual lead fragments are theoretical risks. Current evidence suggests it is generally safe, for residual lead fragments to remain *in situ* long-term, including in patients undergoing MRI.<sup>85</sup>

## **BILATERAL AND PUDENDAL LEADS**

***During PNE testing, bilateral temporary lead placement is recommended to reduce the risk of test failure due to lead migration. (Level of Evidence: III, Grade of Recommendation: C)***

***There is no published evidence that bilateral tined lead placement is more efficacious than unilateral placement. (Level of Evidence: 3, Grade of Recommendation: C)***

For PNE test, a non-tined electrode is used. The currently available version is a thin wire without any anchoring system and is prone to migration. The risk of migration is related to the duration of the test and thus only a few days of reliable stimulation are possible. Placing bilateral PNE leads increases the possibility of a correctly placed lead, and increases the possibility of a successful test. Tined leads are more expensive than non-tined, and it may be difficult in some countries due to insurance to place bilateral tined leads for testing. In a retrospective study of 55 patients with unilateral tined leads and 69 with bilateral tined leads, 76% of patients with bilateral leads went on to full implantation, versus only 58% of those trialed with a unilateral lead. It should be noted that in patients with bilateral leads, both leads were consecutively stimulated—not simultaneously.<sup>151</sup>

Theoretically, bilateral stimulation may be more efficacious than unilateral. This hypothesis is supported by animal experiments which demonstrate that with bilateral stimulation more nerve fibers can be stimulated enhancing the neuromodulatory effects.<sup>152</sup> However, in a prospective randomized trial on 25 patients, no beneficial effect was found with bilateral PNE lead stimulation compared to unilateral stimulation.<sup>153</sup> In patients with loss of efficacy, adding a contralateral PNE lead to achieve bilateral stimulation resulted in a significant decrease in the number of voids and pads per day. However, no benefit was found between bilateral or contralateral stimulation.<sup>154</sup> In FI, a study exploring the benefit of bilateral over unilateral sacral neuromodulation had to be discontinued prematurely after an interim analysis of 20 patients demonstrated no additional benefit in symptom score, quality-of-life score, or findings on anorectal manometry.

***Placement of pudendal leads can be considered as an alternative option if SNM fails after sacral lead positioning and programming has been optimized, especially if the IPG is already in place or if the patient is refractory to other minimally-invasive treatments. (Level of Evidence: III, Grade of Recommendation: Grade C)***

The currently available system for SNM can be used off-label for pudendal stimulation. However no long-term data are yet available. A retrospective study in a mixed patient group including OAB wet/dry, NOR and painful bladder syndrome showed successful responses upon pudendal stimulation in 93% of patients failing SNM.<sup>155</sup> In two prospective studies, patients (OAB wet/dry; painful bladder) were implanted with leads at both S3 and close to the pudendal nerve. Of the patients responding successfully to the test, 78% subjectively favored the pudendal lead for chronic stimulation; however, it should be noted that the pudendal leads were placed with EMG guidance, while the sacral leads were not.<sup>156,157</sup>

## **MRI CONSENSUS STATEMENT**

***For current devices, manufacturer labeling should be followed for MRI imaging of the head or extremities. (Level of evidence: Grade IV, Grade D)***

MRI imaging is used to diagnose and monitor an increasing number of conditions. There are three magnetic fields during MRI that can react with implanted neuromodulation devices including mechanical force and torque induced by a static magnetic field, induced voltages and current on leads by a pulsed gradient field, and current induced into the generator body by the radiofrequency magnetic field.<sup>158,159,160</sup> These forces could potentially result in local tissue injury or damage to the implanted devices. Until the development of MR conditional neuromodulation systems, it is necessary to consider explanation of entire systems in order to perform MRI, exposing the patient to loss of therapy benefit, additional surgical risks, and costs.

According to the manufacturer's labeling (2012 manufacturer's instructions for use [IFU]), non-clinical testing has demonstrated that InterStim Therapy systems have been found to be MR Conditional. If a patient is implanted with an InterStim II Model 3058 Neurostimulator or an eligible serial number of an InterStim Model 3023 Neurostimulator (when implanted as a system including a neurostimulator, lead, and extension as applicable), MRI examinations of the head only may be safely performed under the following conditions:

- 1.5-Tesla (T) horizontal closed bore
- Maximum spatial gradient of 19 T/m (1900 gauss/cm)
- RF transmit/receive head coil only (no RF transmit body coil)
- Gradient slew rate limited to 200 T/m/s
- Normal operating mode (Scanning frequency of approximately 64 MHz only)
- If possible, do not sedate the patient
- Model 3058 and eligible Model 3023 Neurostimulators: Turn the neurostimulator off
- Eligible Model 3023 Neurostimulators only: Disable the magnet switch

According to the manufacturer, scanning under different conditions may result in severe patient injury or device malfunction, and is currently not recommended by FDA labelling. As a matter of course, implant surgeons and radiologists should recognize these guidelines.

***There appears to be an increasing body of evidence that axial MRI imaging can be performed safely with present devices under certain circumstances. (Level of Evidence: II, Grade of Recommendation: B)***

Two separate studies have shown that MRI studies of the extremities other than the head and body MRI scanning including the lumbar spine and pelvis can be performed safely with earlier and current InterStim devices. Elkelini<sup>147</sup> as well as Chermanski<sup>161</sup> reported the results from individual small series of patients studied without event using the interstim I device, using 1.5 and 0.6 Tesla machines. In one case, a generator (IPG) was found to be damaged after study due to leaving the magnet switch on, and both studies recommended setting the amplitude to zero and turning the magnet switch off.

In an ex vivo phantom model simulator study of the contemporary InterStim II device,<sup>162</sup> there was no significant heating, defined as an increase in temperature of >1°C, found using an intact system or with a 5cm distal lead fragment meant to simulate a retained lead fragment after partial extraction. Significant heating was found when a full-length lead, not connected to an IPG, was evaluated. Based on these findings, a prospective in vivo study was performed<sup>163</sup> wherein a pelvic or lumbosacral MRI was performed on a series of eleven patients with their devices in situ, and turned off (no magnet switches as part of these devices). No serious adverse events were reported during the MRI study and there were no changes in the devices after, though two patients did report a sensation of warmth at the IPG site during the scan, which resolved afterward. A caveat is that the patients were studied on

31

the same MRI machine used to study the phantom model, and they were not willing to generalize to other machines and specific locations.

***Alternative forms of imaging should be considered carefully before device removal for MRI imaging. (Level of Evidence: IV, Grade of Recommendation: D)***

Although it appears that less restrictive use of MRI may be safe in certain clinical settings, it is recommended that implanting physicians and radiologists follow the manufacturer's guidelines at the present time. Thoughtful discussion and planning with radiologists may be helpful in obtaining MRI imaging of extremities that are geographically separate from the pelvis, using the principles outlined in the manufacturers' IFU for study of the head only. It remains prudent to consider imaging modalities that can serve as a substitute for MRI whenever appropriate; indeed, a study by Lloyd et al suggests that up to 24% of patients who undergo SNM device removal for MRI ultimately do not go on to receive an MRI study, and that only 56% of MRIs lead to a change in clinical management, emphasizing that it is of paramount importance to confirm the necessity of MRI before removing a functional SNM device.<sup>164</sup> Clearly, full body MRI conditional safety will be a highly valuable feature if and when it becomes available with future systems and devices.

## **FUTURE RESEARCH**

***Future research, including newer technologies, mechanisms for patient-response driven programming, and techniques for optimal lead placement, is needed.***

***This research will be aided by a better understanding of the mechanism of action of SNM***

***Attention should also be directed toward the development of better composite measures of therapy outcomes.***

This consensus statement highlights the complex nature of neuromodulation therapy. Broadly, we have a low level of evidence for many of our recommendations. Patient selection is based on symptoms, not biochemical or functional testing. Pelvic floor, urinary and bowel studies have not reliably predicted the best candidates for SNM, nor have patient symptoms.<sup>165</sup> One study has shown an association of treatment satisfaction with pudendal nerve terminal motor latency in FI<sup>128</sup> and another suggests that strong toe responses at as many electrodes as possible intraoperatively may reduce the risk of future lead revision,<sup>166</sup> but only response to a trial of stimulation can currently predict response to treatment. This opens the door to newer technologies which incorporate the lead trial into long-term therapy, possibly with a one-step implant if costs can be contained. The current IPG (InterStim, Medtronic) is costly which is the reasoning behind a staged-implant approach. Other perceived weaknesses of this device, including lead fracture, battery life, clinician-dependent programming, and MRI compatibility, need to be addressed, as does the long-term effect of SNM on bladder and bowel physiology.

Surgical technique has not changed much since the introduction of the tined-electrode, which eliminated the need to suture directly to the periosteum. There remains debate regarding how precisely the lead must be positioned. Some studies suggest that only one active electrode is needed for a clinical response<sup>114</sup>, though most advocate for 4-electrodes targeted at low voltages.<sup>167</sup> CT guidance has been used for those with complex anatomical findings,<sup>168</sup> while others have shown intra-operative EMG to be of help.<sup>169</sup> Nevertheless, further outcomes-based research is needed to clarify the best method for placing the lead. ***(Level of Evidence: III, Grade of Recommendation: C)***

32

Furthermore, there are no specific programming recommendations besides the 4-program settings and patient selection based on perceived symptom improvement. More novel approaches may incorporate a patient's "vote" for a program or a setting based on bowel/bladder diaries kept in real time. There are already available smart-phone applications for patients to track their symptoms which may be utilized in device programming.<sup>170</sup>

Economic modeling suggests that SNM becomes cost-effective relative to intradetrusor botulinum toxin injections for idiopathic OAB after about 5 years of treatment.<sup>171</sup> At 10 years, models suggest that SNM is also cost-effective relative to oral medical therapy for OAB.<sup>172</sup> There is little data on SNM cost-effectiveness relative to other treatments for urinary retention and fecal incontinence. Such studies would need to incorporate patient reported outcome measures to best characterize therapeutic benefit versus the cost of therapy.

**BACKGROUND:** The clinical role of LASER for vulvar and vaginal treatments in gynecology and female urology is controversial.

**AIMS:** In this best practice document, we propose recommendations for the use of LASER for gynecologic and urologic conditions such as vulvovaginal atrophy, urinary incontinence, vulvodinia, and lichen sclerosus based on a thorough literature review.

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

**MATERIALS & METHODS:** This project was developed between January and September 2018. The development of this document followed the ICS White Paper Standard Operating Procedures.

**RESULTS:** Most of the available studies are limited by their design; for example they lack a control group, patients are not randomized, follow up is short term, series are small, LASER is not compared with standard treatments, and studies are industry sponsored. Due to these limitations, the level of evidence for the use of LASER in the treatment of these conditions remains low and does not allow for definitive recommendations for its use in routine clinical practice. Histological evidence is commonly reported as proof of tissue regeneration following LASER treatment. However, the histological changes noted can also be consistent with reparative changes after a thermal injury rather than necessarily representing regeneration or restoration of function. The use of LASER in women with vulvodynia or lichen sclerosus should not be recommended in routine clinical practice. There is no biological plausibility or safety data on its use on this population of women.

**DISCUSSION:** The available clinical studies do not present convincing data regarding the efficacy of LASER for the treatment of vaginal atrophy or urinary incontinence. Also, while short-term complications seem to be uncommon, data concerning long-term outcomes are lacking.

**CONCLUSION:** At this point, LASER is not recommended for routine treatment of the aforementioned conditions unless part of well-designed clinical trials or with special arrangements for clinical governance, consent, and audit.

#### KEYWORDS

genitourinary syndrome of menopause, ICS, ISSVD, LASER, lichen sclerosus, urinary incontinence, vulvovaginal atrophy, vaginal laxity

## 1 | INTRODUCTION

“Light Amplification by Stimulated Emission of Radiation” (LASER) has been widely used in gynecology and urology for more than 40 years. It is well established in the management of HPV-related genital lesions, prostate vaporization, and lithotripsy.<sup>1,2</sup> More recently the use of trans-vaginal or vulvar LASER has escalated to be used as a panacea for several urological and gynecological conditions, such as: lichen sclerosus, vulvodynia, “vaginal laxity”, overactive bladder, and pelvic organ prolapse.

Limited ex-vivo studies have suggested that LASER has the potential to modify tissue characteristics. Clinically it has already been adopted for tissue remodeling of non-mucosal scars and wrinkles with relative success. These findings have led to the concept that LASER technology could be used in the treatment of vaginal atrophy<sup>3</sup> and has already been utilized and marketed as a “treatment” or therapy for vaginal “rejuvenation” and “Designer LASER Vaginoplasty” by the aesthetics industry.

Several published studies have suggested that fractional microablative CO<sub>2</sub> and Er:Yag LASER effectively treat not only atrophic vaginal mucosa (2014)(3), but also improve urinary incontinence (2015).<sup>4</sup> From the initial studies, the jump to aggressive marketing and widespread adoption of the LASER technology was quick. However, the studies failed to provide definitive evidence of its safety and effectiveness. Flaws of these studies include short follow-up time, absence of control groups, lack of standardized outcome measures, and the involvement of industry sponsorship.

Vaginal atrophy related to hypoestrogenism is recognized as a prevalent and significant cause of morbidity in the postmenopausal population.<sup>5</sup> In 2014 it was integrated into the broader definition of “genitourinary syndrome of menopause” (GSM).<sup>6</sup> GSM classifies an extensive list of signs and symptoms common to the natural process of female menopause as a syndrome. This umbrella term also carries the risk of classifying true disease (ie, lichen sclerosus) as GSM.<sup>7</sup>

Despite the lack of a true functional or anatomical definition, the use of the term “vaginal laxity” has become more widespread.<sup>8</sup> The term has been defined by the International Urogynecological Association (IUGA) and the International Continence Society as a feeling of vaginal looseness,<sup>9</sup> a woman’s subjective sensation of vaginal “looseness.” “Vaginal rejuvenation” with LASER is targeted to women with “vaginal laxity” as a procedure to improve the sensation of laxity and thus enhance sexual function in those with decreased vaginal sensation.<sup>10</sup>

In 2007 the American College of Obstetrics and Gynecology (ACOG) included “vaginal rejuvenation” and “designer vaginoplasty” in a list of procedures that were “not medically indicated” due to a “lack of evidence confirming safety and effectiveness.”<sup>11</sup> However the US Food and Drug Administration (FDA) licenced the CO<sub>2</sub> LASER systems for “incision, excision, ablation, vaporization, and coagulation of body soft tissues and was used by specialities such as aesthetics (...), otolaryngology (...), gynecology, neurosurgery, and genitourinary surgery” in 2010.<sup>12</sup> Other LASER manufacturers requested FDA approval in 2014, with similar licence terms approved.<sup>13</sup> Er:YAG LASERs were licensed for dermatologic uses: coagulation, vaporization, ablation, or cutting of skin in dermatology and plastic/aesthetic surgery (2011).<sup>14</sup> The Nd:YAG had a similar approval in 2014.<sup>15</sup>

Treatment of vaginal atrophy and other gynecological disorders with LASER devices gained popularity and was marketed for this purpose. In response to this surge, ACOG issued a warning in 2016 clarifying that the FDA had not approved the use of these devices for the treatment of vulvovaginal atrophy.<sup>16</sup> Despite this announcement, claims that the devices had received FDA approval for such conditions were circulated.<sup>17,18</sup>

Several authors<sup>19,20</sup> and groups, such as the International Society for the Study of Vulvovaginal Disease (ISSVD)<sup>10</sup> and the Society of Obstetricians and Gynecologists of Canada (SOGC),<sup>21</sup> have raised concerns about the lack of evidence sustaining the use of LASER technologies for these gynecological indications. Finally, on the July 30th, 2018, the FDA issued a warning that the effectiveness and safety of energy-based devices (LASER and radiofrequency) for urinary incontinence, vaginal “rejuvenation” or cosmetic vaginal procedures has not been established.<sup>22</sup>

The executive council of the International Society for the Study of Vulvovaginal Disease (ISSVD) and the board of trustees of the International Continence Society (ICS) acknowledge the need to establish scientifically based recommendations on the new uses of LASER in their fields. This best practice document has therefore been developed to provide guidance on the use of LASER for the treatment of gynecological and urogynecological conditions and to educate providers about the weaknesses of the available data.

## 2 | MATERIAL AND METHODS

The ISSVD and the ICS identified and invited members to develop this project; participants were assigned a specific topic to be thoroughly researched and summarized in order to produce recommendations. The project was developed between January and September 2018. The development of this document followed the ICS White Paper Standard Operating Procedures.<sup>23</sup>

Literature searches were performed using Pubmed, Google Scholar, Ovid, Cochrane, and Embase to identify relevant papers. Search results were limited to papers written in English and published prior to June 2018.

Search strings for each topic were:

1. Vaginal atrophy/“rejuvenation”:
  - a. “genitourinary syndrome of menopause,” “vulvovaginal atrophy,” “atrophic vaginitis,” “vaginal atrophy,” “vaginal rejuvenation,” “menopause” and “LASER.”
2. Urinary incontinence and/or pelvic organ prolapse:
  - a. “urinary incontinence,” “incontinence,” “prolapse,” “POP,” “pelvic organ prolapse,” “cystocele,” “rectocele,” “hysterocele,” and “LASER.”
3. Vaginal laxity:
  - a. “vaginal tightening,” “vaginal laxity syndrome,” and “LASER.”
4. Vulvodynia:
  - a. “vulvodynia,” “vestibulodynia,” and “LASER.”
5. Lichen sclerosus:
  - a. “lichen sclerosus” and “LASER.”
6. Other possible uses of LASER:
  - a. “bleaching,” “whitening,” “brightening” “labiaplasty,” “labioplasty,” “nymphoplasty” and “LASER.”

Evidence was graded according to the Center of Evidence Based-Medicine’s “Levels of Evidence for Therapeutic Studies” and recommendations according to the American Society of Plastic Surgeons’ “Grade Practice Recommendations.”<sup>24</sup>

After discussion and consensus among all participants, the final version of the text was approved by the Executive Council of the ISSVD and the Board of Trustees of the ICS.

## 3 | BASIC SCIENCE EVIDENCE

### 3.1 | Proposed mechanism of action of LASER on skin and vaginal tissue

Human skin is comprised of three layers: the epidermis, the dermis, and the subcutaneous fat.<sup>25</sup> Currently, the hypothesized mechanism by which the LASER rejuvenates the vaginal mucosal epithelium has been developed based on the effects of LASER on epidermal skin epithelium. The LASER is believed to induce controlled injury to the epithelial layer of the skin, which stimulates tissue repair and remodeling.<sup>26</sup>

Wound repair in skin epithelium is a well-defined process characterized by inflammation, proliferation leading to tissue restoration, and tissue remodeling.<sup>27</sup> LASER is believed to normalize the cycle of collagenesis and collagenolysis<sup>28–30</sup> by inducing break down of disorganized collagen fibrils,<sup>31</sup> creating more organized collagen bundles, and decreasing collagen bundle thickness and density.<sup>32</sup>

Similar to skin, the vaginal wall is composed of three histologically unique layers. The most superficial layer of the vaginal mucosa is made up of stratified squamous epithelium but, unlike the skin epidermis, is devoid of keratinocytes and is therefore non-keratinized. Also unlike skin, vaginal tissue undergoes a number of discrete histologic changes during menopause. Thinning of the vaginal epithelium, reduced vaginal blood flow, diminished lubrication, increased pH, and a change in the vaginal microbiome, as well as decreased elasticity of the vaginal wall can occur.<sup>33</sup>

Neocollagenesis and restoration of the trabecular architecture of collagen is the proposed basis for vaginal rejuvenation with CO<sub>2</sub> LASER treatment. Investigators have hypothesized that the molecular and histologic changes demonstrated in the skin in response to LASER treatment can be recreated in the vaginal wall. However, given the differences in anatomy as well as histologic changes in response to hormone balance, such as those seen during menopause, it is unclear whether the effects of the LASER on skin could be expected for the vaginal wall.

In 2011, Gaspar et al<sup>34</sup> demonstrated that vaginal fractional CO<sub>2</sub> LASER treatment increased the thickness of the vaginal epithelium and increased the fibrillary component of the extracellular matrix. In 2015, Salvatore et al<sup>35</sup> described fibrillogenesis and neocollagenesis of vaginal tissue following vaginal LASER treatment in postmenopausal women. Zerbinati et al<sup>36</sup> in 2015 carried out a similar study and examined the tissue of postmenopausal patients with severe symptoms of GSM following CO<sub>2</sub> LASER treatment. They concluded that the histological changes seen support the theory that the LASER stimulates fibroblasts to produce collagen. It is unclear, however, if these histologic changes following LASER treatment can be directly correlated with improvement of clinical symptoms, as no control group was used (discussed in section 3.2).

Current published literature on the specific use of LASER in the vagina for the treatment of GSM is limited in the basic science results as well as clinical outcomes and the potential correlation to the histology findings (level of evidence 3b/4, grade of recommendation C). Thus, clinical conclusions drawn from these studies are highly speculative (Table 1).

### 3.2 | Histological effects

There is little known about the histology of the vaginal mucosa after LASER therapy for vaginal rejuvenation or functional remodeling. What is reported is based on small studies of patients over a short period of time.

Salvatore et al<sup>37</sup> described a single case, with a post-treatment biopsy performed 1 hour after the CO<sub>2</sub> fractional LASER treatment. The biopsy showed superficial epithelial desquamation. In comparison, animal skin burn studies report signs of injury to include desquamation. Desquamation therefore cannot be interpreted as beneficial remodeling.<sup>38</sup>

In a prospective study from the same group,<sup>35</sup> the authors compared treated vaginal mucosa with mucosa out of the field of therapy from the same patient. They noted neovascularization, neocollagenesis, and restoration of the trabecular architecture of collagen in the treated mucosa, which was interpreted as remodeling changes. These biopsies however were taken at the time of the LASER procedure, which would have provided insufficient time for remodeling to occur. In comparison, skin studies have shown changes of wound healing in the first few days after LASER therapy, while restorative changes ensue weeks later.<sup>39</sup> The histology images in the paper mentioned show denuding of the epithelium and different degrees of tissue coagulation, which are consistent with thermal injury.

Zerbinati et al<sup>36</sup> biopsied five patients before vaginal treatment, and at 1 and 2 months after treatment, which would allow early changes to be appreciated. At 1 and 2 months, changes were similar, noting thickened epithelium with superficial shedding, increased dermal papilla with elongated capillaries, giving the epidermal-dermal junction an undulating pattern, increased glycogen in the epithelial cells, and an increase in fibroblast activity. Increased collagen and ground substance have also been described in existing studies.<sup>35,36</sup> The illustrations in Zerbinati's paper show epidermal thickening with acanthosis, and some show parakeratosis and increase in dermal chronic inflammatory cells.<sup>36</sup> These changes are consistent with repair, as might be seen in lichen simplex chronicus, and alone do not indicate functional remodeling.

Histology changes to the vaginal mucosa following intravaginal LASER therapy have also been compared to a healing vaginal wound at the 2-month time point. A lack of significant capillary density and the increase in cellularity of connective tissue is consistent with this. It has not been confirmed if these changes are favorable for functional

**TABLE 1** The use of LASER in the vagina for the treatment of atrophy/rejuvenation

	Level of evidence	Grade of recommendation
The mechanism of action of LASER on vaginal tissue in normal or diseased states is not known and cannot be used to justify treatment results	3b/4	C

**TABLE 2** The histology of vaginal LASER “rejuvenation”

	Level of evidence	Grade of recommendation
The histological changes present after LASER therapy are consistent with reparative changes after a thermal injury. They do not necessarily represent restoration of function, and cannot be used to justify treatment results.	4	C

remodeling or if they would be sustained at the 6 and 12 month marks.<sup>21</sup>

Interpretation of available studies overall is limited by the lack of long-term follow-up, and hence complications such as scarring may not have been detected.<sup>40</sup> In addition, in a review of the literature on LASER therapy for treating GSM, the authors noted that in one pilot study, the maturation index (a ratio obtained by performing a random cell count of the three major cell types shed from the vaginal squamous epithelium: parabasal, intermediate, and superficial cells) was not considered.<sup>3,40</sup>

In summary, the histology of vaginal LASER “rejuvenation” is not well studied. Only small series have been published, with short follow-up. The changes present after therapy are consistent with reparative changes after a thermal injury. Whether they represent restoration of function has not yet been demonstrated by the histology. Further study is needed (level of evidence 4, grade of recommendation C). Further study is needed (Table 2).

### 3.3 | Impact on the vaginal microbiome

In postmenopausal women, lactobacilli concentration and diversity tend to be lower, while there is a higher diversity of other species.<sup>41–43</sup> These changes have been correlated to the severity of vulvovaginal atrophy symptoms with normalization using hormonal replacement therapy (HRT) associated with symptom improvement.<sup>44</sup> Based on the limited and controversial evidence demonstrating that vaginal LASER improves sexual health, vaginal glycogen, and vaginal epithelial thickness, its impact on the vaginal microbiome was evaluated in two studies.

Athanasiou et al<sup>46</sup> enrolled 53 women with at least one moderate or severe symptom of GSM. The methodology is insufficient as it assumes that one symptom can be used as a surrogate of an entire syndrome<sup>45</sup> and does not describe which scale of severity was used.

Following vaginal LASER treatment, the authors report a significant decrease in vaginal pH, but only one third reached a pH lower than 4.5. This decrease was accompanied by an

**TABLE 3** Impact on the vaginal microbiome

	Level of evidence	Grade of recommendation
LASER cannot be recommended as a means to improve the vaginal microbiome.	2b	B
The use of CO <sub>2</sub> LASER does not negatively impact the vaginal microbiome.	2b	B

increase in the number of lactobacilli although the techniques used to estimate the lactobacilli population are known to produce an inaccurate estimation. Interestingly, with an inclusion criteria of vaginal pH in the range 4.5–5 at baseline, nearly half of the women had normal vaginal flora according to Nugent and Ison-Hay scores. Following treatment and at the end of the study, this increased to approximately 90%. Colonization by *Candida* was very low (1.9%) and remained stable. The vaginal maturation index improved, but no changes regarding the presence of leukocytes in the vagina were noted.

Becorpi et al<sup>47</sup> studied the vaginal microbiome in 20 breast cancer survivors treated with two sessions of CO<sub>2</sub> LASER. The study reported an almost unchanged microbiome following treatment. The authors suggested that any possible benefits would be derived from a possible anti-inflammatory effect.

While LASER cannot be recommended as a means to improve the vaginal microbiome, it does not seem to have a deleterious effect on it (level of evidence 2b, grade of recommendation B) (Table 3).

## 4 | “GENITOURINARY SYNDROME OF MENOPAUSE” AND VAGINAL ATROPHY

GSM and vulvovaginal atrophy (VVA) are commonly seen in women after menopause. Nearly 50% of postmenopausal women report a vaginal symptom.<sup>48</sup> These symptoms have a significant impact on the quality of life, interfering with the ability to be intimate, and enjoy sexual intercourse in 60–70% of sexually active postmenopausal women.<sup>49,50</sup> However, many women consider their symptoms to be a natural part of aging. A survey of American women with a median age of 58 years revealed that 81% did not think VVA was a medical condition, of whom 71% had never sought treatment.<sup>5</sup>

A total of 24<sup>51–74</sup> clinical studies were identified that investigated transvaginal LASER in women with GSM/VVA. Two studies appeared to include the same study population (separate analyses).<sup>55,67</sup> The vast majority of the studies used

either Er:YAG or fractional, micro ablative CO<sub>2</sub> LASER. Some studies used ablative Er:YAG LASER.<sup>62</sup> All studies but four were prospective or retrospective case series without a control group. There was one randomized placebo/estriol controlled study<sup>74</sup> (level of evidence 2b) and three prospective, non-randomized studies using estradiol gel (or lubricant) as the comparative arm (level of evidence 3b).<sup>51,53,69</sup>

The clinical outcomes measured were inconsistent throughout the studies. Both subjective non-validated outcome measures and validated clinical outcomes scores were used to assess symptoms, quality of life impact, and general health. Samples taken varied from vaginal punch biopsy after treatment in one study,<sup>75</sup> to cytology, and pH evaluation<sup>66</sup> in others. Most studies had a follow up period of less than 12 months, although three studies presented 18-24 month follow up data. In addition, conflicts of interest were not always clearly specified and adverse events were rarely specifically outlined.

LASER treatment for women with a history of breast cancer and vaginal atrophy was investigated in one paper. In this group of women hormonal treatment is either contraindicated or patients are reluctant to take low dose topical estrogens for symptoms of GSM. This limited study drew similar conclusions to those reached for other women and was hindered by similar study design flaws.<sup>70,71,76</sup>

Recent developments for the use of LASER in women with GSM/VVA include an international multicenter observational study aiming to evaluate 1500 women treated with vaginal Er:YAG LASER.<sup>77</sup> There is also an ongoing randomized study comparing the effects of CO<sub>2</sub> LASER to vaginal estrogen treatment. This study aims to enrol nearly 200 patients and is expected to finish by the end of 2018.<sup>78</sup> However there is still a need for a prospective randomized controlled trial with a placebo or sham control arm to understand the differences. For example a recent meta-analysis demonstrated that 67.7% of the treatment effect for female sexual dysfunction is accounted for by placebo.<sup>79</sup>

The available studies on the use of LASER to treat vaginal atrophy have overall not provided sufficient evidence of efficacy and long term safety (level of evidence 2b/3b, grade of recommendation C) (Table 4).

**TABLE 4** “Genitourinary syndrome of menopause” and vaginal atrophy

	Level of evidence	Grade of recommendation
There is currently not enough scientific data demonstrating efficacy and safety of LASER for treating vulvovaginal atrophy.	2b/3b	C

## 5 | STRESS URINARY INCONTINENCE AND/OR PELVIC ORGAN PROLAPSE

Some evidence on the role of vaginal LASER exists for its use in urinary incontinence and pelvic organ prolapse.<sup>4,34,77,80–86</sup> The data on its use in stress urinary incontinence comprises mainly short-term observational studies. Participants varied from 19 to 205 women. Treatment response was usually assessed with validated questionnaires and showed favorable outcomes in terms of improvement of symptoms, but only one study followed patients for 24 months. None of the studies had a control or placebo group.<sup>4,34,80–83</sup>

There is minimal published data on the use of LASER in treating female pelvic organ prolapse. Its use has been described in women with grade II (prolapse to the hymen) to IV (maximum descent) cystoceles and follow up at 12 months has demonstrated an improvement in prolapse grade, with some patients sustaining the effect at 36 months.<sup>86</sup>

While the use of LASER to treat stress urinary incontinence and/or pelvic organ prolapse may seem appealing, the lack of good quality evidence in the form of multi-center randomized placebo-controlled trials is concerning.

Use of LASER may lead to serious adverse events such as vaginal burns, scarring, dyspareunia, and chronic pain. Although reports of adverse events in the literature is minimal, the sample sizes are small hence minimal reassurance can be taken from this.<sup>87</sup> The histological effects of LASER to the vaginal wall remain unclear leaving further questions regarding the effect of LASER therapy on surgical dissection and outcomes in women who may eventually require reconstructive pelvic or anti-incontinence surgery.

A recent review article looking at the evidence relating to the risks and benefits of intravaginal LASER technology in the management of stress urinary incontinence confirmed that despite the short-term observational studies of small patient numbers demonstrating improvements, there is still insufficient evidence to offer it as an effective modality for the treatment of stress urinary incontinence over alternative managements, such as pelvic floor physiotherapy, incontinence pessaries, or continence surgery.<sup>21</sup> Similarly there is insufficient evidence to offer intravaginal LASER therapy for vaginal prolapse (level of evidence 4, recommendation grade D) (Table 5).

## 6 | VAGINAL LAXITY SYNDROME

Vaginal laxity as a subjective patient complaint has been described by IUGA and ICS as a feeling of vaginal looseness.<sup>9</sup> Its anatomical definition, quality of life impact and treatment are poorly understood<sup>88</sup> and not widely recognized. “Vaginal laxity syndrome” (VLS) or even

**TABLE 5** Stress urinary incontinence and/or pelvic organ prolapse

	Level of evidence	Grade of recommendation
There is limited evidence supporting the use of LASER for stress urinary incontinence	4	D
There is limited data concerning the safety of LASER for stress urinary incontinence	4	D
The evidence supporting the use of LASER for pelvic organ prolapse is limited	4	D
The data concerning the safety of LASER for pelvic organ prolapse is limited	4	D

“vaginal hyperlaxity syndrome” are concepts and marketing terminology with a lack of a standardized definition.

Some believe that VLS is an evolution of the aesthetic designation of “vaginal rejuvenation.”<sup>89</sup> It is described as a disorder derived from the excessive laxity of the vaginal walls, leading to a sensation of looseness, diminished sensation of penile friction, and may be associated with urinary incontinence (urgency or stress).<sup>61</sup> VLS is considered a consequence of aging and related to having had vaginal deliveries. The term VLS and therefore its therapy, vaginal rejuvenation, is not endorsed or formally defined by the leading gynecological societies.<sup>11</sup> However, management of the symptoms have evolved from techniques involving sutures and the adaptation of traditional urogynecological procedures to the use of LASER<sup>61,90</sup> and radiofrequency procedures.<sup>91–99</sup>

In 2011, there was an attempt to restore the *rugae* of the vagina in postmenopausal women (“vaginal rugation rejuvenation”), by vaporization of the vaginal wall in order to create parallel grooves. The procedure was performed in women with a sensation of a loose or smooth vagina. In a small observational trial (10 patients in each arm), there was an apparent improvement of sexual function and no complications. The design and small sample size did not allow the authors to draw conclusions from the study.<sup>90</sup>

In 2014, Lee evaluated two different protocols (15 patients in each arm), using Er:YAG LASER. Women in both groups were evaluated 2 months after the procedure. There were no complications or adverse effects, although mild heating of the vagina and ecchymosis were reported. There was an objective (perineometer) and subjective improvement for 70% of the subjects with 76.6% of their partners reporting an improvement in sexual function. No validated scales were used for evaluation of the sexual function. A histological improvement was also suggested, but no analysis was shown in Ref.<sup>61</sup>

**TABLE 6** “Vaginal Laxity Syndrome”

	Level of evidence	Grade of recommendation
There are no data supporting the recommendation of performing “vaginal rugation rejuvenation” or showing its safety	4	D
Er:YAG LASER for vaginal looseness or laxity has not been shown to be safe or efficacious	4	D

In total, two small studies on the use of LASER in vaginal relaxation syndrome comprising 51 women showed non-validated patient-reported improvements in sexual experience after LASER treatment but follow up was short term.<sup>84,85</sup> We could not find any study in the literature evaluating the role of CO<sub>2</sub> LASER for vaginal tightening specifically. Several studies have arisen using radiofrequency. The available data, in comparison to that for LASER use, are more robust and sustained by studies with a better design. So far, there has been no comparison between the different types of energy. There are no data supporting the recommendation of performing “vaginal rugation rejuvenation” or showing its safety (level of evidence 4, grade of recommendation D) (Table 6).

## 7 | VULVODYNIA

Vulvodynia is a chronic, complex pain disorder of multifactorial aetiology that can be difficult to manage. It is common, affecting more than 4-16% of women and can occur at any age, including postmenopausal women, particularly among those who remain sexually active.<sup>100,101</sup>

In 2015, the ISSVD, the International Society for the Study of Sexual Health of Women (ISSWSH) and the International Pelvic Pain Society (IPPS) adopted new terminology for vulvar pain and vulvodynia.<sup>102</sup> It is classified according to the site of pain (generalized or localized), the need of a stimulus (provoked, not provoked [spontaneous], or mixed), and the onset (primary or secondary). Treatment is difficult, and rapid resolution is unusual even with proper treatment. Decrease in pain may take weeks to months and may not be complete. No single treatment is successful in all women.<sup>103</sup> The vulvodynia treatment algorithm includes vulvar skin care guidelines, topical, oral, and injectable medications, pudendal nerve block, biofeedback, physical therapy, dietary modifications, cognitive behavioral therapy, sexual counseling and surgery, as well as alternative therapies such as acupuncture and hypnotherapy.<sup>104</sup>

Few studies have been conducted evaluating the usefulness of LASER therapy in the treatment of vulvodynia.<sup>59,105,106</sup>

A retrospective study indicated less pain with sexual intercourse among 24 of 37 women treated with LASER pulse therapy for vestibulodynia. However, 35% of the patients in the study required a vestibulectomy to control the symptoms.<sup>105</sup>

In 2016, in a study involving 70 patients who underwent fractional micro-ablative CO<sub>2</sub> LASER treatment for vestibular pain plus vestibulodynia ( $n = 37$ ) or menopausal patients (age > 50 years) who presented with vulvar pain secondary to GSM/VVA ( $n = 33$ ), showed statistically significant improvement of dyspareunia and pain scores, with gradual improvement over each time point persisting through 4-month follow-up. Average overall vestibular health index score (a non-validated score, that intends to assess vestibular atrophy) improved significantly in the two groups after each of the three individual treatments. There was no statistically significant difference in outcomes between the two study groups.<sup>59</sup>

More recently, a placebo-controlled, double-blinded, randomized clinical trial involving 34 women aged 19-46 years old using low-level LASER therapy (LLLT) versus placebo showed *Clinical Pain Report* improvement in 78% in the LLLT group and 44% in the placebo group. Nevertheless, other measurable parameters (Q-tip test, intercourse pain on the Visual Analog Scale, and tampon tests before and after treatment, severity of discomfort in daily activities and/or in daily pain intensity) did not show a difference between groups. Although none of the patients reported side effects during the study, recurrence of pain was evidenced in 33% of the LLLT group.<sup>106</sup>

Interestingly, LASER (pulse or scan), used to treat vulvar mucosa disease (warts or vulvar HSIL) has been shown to be a possible cause of chronic vulvar pain.<sup>107</sup>

The few available studies concerning the treatment of vulvodynia with LASER have not proven it to be efficacious or safe, therefore its use should not be considered in these patients (level of evidence 2b, grade of recommendation B) (Table 7).

**TABLE 7** Vulvodynia

	Level of evidence	Grade of recommendation
LASER therapy cannot be recommended as a means to improve pain in vulvodynia.	2b	B
The use of low-level LASER does not negatively impact symptoms in vestibulodynia.	2b	B

## 8 | LICHEN SCLEROSUS

Lichen sclerosus (LS) is a complex chronic inflammatory autoimmune dermatosis that can be found in patients of any age and race.<sup>108</sup> It is 10 times more common in females.<sup>109</sup> The incidence rate is around 10 per 100 000 woman-years, rising to over 30 per 100 000 woman-years in women older than 55.<sup>110</sup> The main symptoms are itching, burning, and dyspareunia, with impact on health-related quality of life.<sup>111</sup>

Vulvar LS (VLS) clinical aspects can vary significantly. Differentiated (dVIN), the HPV-independent pathway to vulvar carcinoma, must be suspected and biopsied promptly in treatment-resistant cases, and in the presence of erosion or hyperkeratotic plaques in a field of VLS.<sup>112</sup> The risk of vulvar cancer in VLS is estimated to be 2-5%, with higher risk in older women and with longer duration of disease.<sup>110,113,114</sup> Long term therapy, however, seems to be protective.<sup>115,116</sup> Current guidelines recommend the use of super-potent topical corticosteroids as first-line. Both the risk of cancer and the need of long term follow up must be taken into account when new treatment options are presented for LS, given the proven efficacy of topical corticosteroids.<sup>117-120</sup>

In 1991 a Canadian study reported seven women with LS refractory to topical testosterone who became asymptomatic following LASER ablation (600-900 W/cm<sup>2</sup> depth of tissue destruction 2 mm under general anesthesia). No biopsy after treatment was performed to confirm histological changes.<sup>121</sup> Similar results and depth of tissue vaporization was described by Kartamaa and Reitamo<sup>122</sup> in two patients with VLS. The aim to "remove the epithelium and papillary dermis involved in LS" for resolution of symptoms was reported in another two cases study in the absence of post treatment biopsies.<sup>123</sup>

In a recent case series,<sup>124</sup> five women underwent fractional CO<sub>2</sub> LASER treatment for hyperkeratotic VLS not responding to topical clobetasol. After 1-3 treatments with CO<sub>2</sub> LASER, energy 140-170 MJ and treatment depth 150 µm, symptoms had complete resolution in three, partial in one, and one was asymptomatic before treatment. Median follow up was 9 months (range 6-48). Re-epithelialization occurred in 3-4 weeks in all cases. Hyperkeratosis recurred after 6-8 months. In all patients, maintenance treatment was clobetasol. The objective to ablate the improper function of dermal epidermal zone, creating a new zone with proper function, is not supported by the published data.

All the papers considered are studies with very small series of patients, who did not undergo randomization, with short follow-up time. Neither visual acuity scale (VAS) for symptoms, nor details of pre/post treatment vulvar lesions were reported. The lack of description of the corticosteroid regimen utilized is another common weakness in the reported studies that prevent correct analysis of CO<sub>2</sub> LASER-treated patients and interpretation of its true efficacy. Furthermore, injuries (mechanical, chemical, burning, etc.) can be a cause

**TABLE 8** Lichen sclerosus

	Level of evidence	Grade of recommendation
There are no data supporting the use of CO <sub>2</sub> LASER in VLS	4	C
There are no data concerning the long term safety of the use of CO <sub>2</sub> LASER in VLS treatment	4	C

of isomorphic or Koerber phenomenon in LS patients.<sup>125</sup> Currently, there is no evidence that fractional LASER is exempt from this risk in LS patients. Up to now the description of CO<sub>2</sub> LASER as a safe and effective therapy for recalcitrant VLS has no evidence within the literature data (level of evidence 4, grade of recommendation C) (Table 8).

**9 | OTHER POSSIBLE USES OF LASER (VULVAR BLEACHING/WHITENING/BRIGHTENING, LABIAPLASTY)**

While the labia tend to be more pigmented than the surrounding structures, some women have the desire to whiten it. It can represent up to 6.8% of the patients consulting a gynecological aesthetical unit.<sup>126</sup> This procedure, using LASER, is commonly offered, but there are no studies showing its efficacy or safety. We could only find reference to it in one study, but LASER was done in combination with other procedures, such as labiaplasty, augmentation of the labia *majora*, *mons pubis* liposuction, or vaginal tightening.<sup>127</sup> Of note, even the use of LASER for hair removal has been related to serious urogynecological complications, such as labial adhesion with cryptomenorhea, and acute urinary retention.<sup>128</sup> In one survey, 85.9% of physicians stated that there is no medical indication for the performance of such procedures.<sup>129</sup>

Labiaplasty is one of the most performed female cosmetic genital procedures worldwide. There are several techniques described, some with the use of LASER. Despite the misleading anatomical description, the procedure coined “Designer LASER Vaginoplasty” is also a form of labiaplasty.<sup>130</sup> Of note, this procedure has been considered unethical by the American College of Obstetricians and Gynecologists, due to the lack of supporting evidence.<sup>11</sup>

In 2006, the use of Nd:YAG LASER for the treatment of hypertrophy of the labia *minora* was reported. In a series of 55 women (including 4 children 10-15 years old), of whom 11 (20%) lacked the authors’ established criteria of hypertrophy of the labia *minora* (>2 cm of width), there were no intraoperative complications, dehiscence occurred in 5.4%, and there was no pain after 7 days. Satisfaction rates were very high (>90%).<sup>131</sup> In another series, comprising 231

**TABLE 9** Other possible uses of LASER (vulvar bleaching/whitening /brightening, labiaplasty)

	Level of evidence	Grade of recommendation
There is no medical indication for the use of LASER for vulvar bleaching	4	C
There are no data concerning the safety of the use of LASER for vulvar bleaching	4	C
Nd:YAG and CO <sub>2</sub> LASER appear to be safe options for labiaplasty	3b	C
There is no data supporting the use of LASER labiaplasty to enhance sexual function	4	C

women who underwent reduction of the labia *minora* using CO<sub>2</sub> LASER to make a lambda shaped incision, a 100% satisfaction rate was reported, along with a low complication rate (11 wound dehiscence, 3 hematomas, 1 acute bleed requiring return to the operating room); however, there is no reference to the duration of follow up.<sup>132</sup> More recently, in a study involving 112 women aged 15-62 years old using CO<sub>2</sub> LASER, improvement in overall satisfaction and comfort during intercourse were reported. The rate of complications and the duration of follow-up were not mentioned.<sup>133</sup>

None of the studies have included a control group. In at least two of the studies children were enrolled. In at least one study, women did not meet the (controversial) study definition of hypertrophy of the labia *minora*. There appears to be no sufficient good quality data showing the safety of or justification of the use of LASER for cosmetic indications.

There is no universally accepted definition of hypertrophy of the labia *minora*; some authors have described it as a width superior to 4 or 5 cm, or protruding beyond the labia *majora*.<sup>133</sup> There is no correlation between the size of the labia *minora* and the ability to feel sexual pleasure or orgasm.<sup>134</sup> Brodie et al evaluated normal adolescents and pointed that there can be significant variance in the size of labia *minora*, according to being stretched or non-stretched (1-13 mm), that asymmetry is common (>50% of adolescent women), and that the mean width of labia *minora* was 10 mm (3-70 mm) (unstretched) and 20.5 mm (5-62 mm) (stretched) <sup>135</sup>. If those definitions were applied to adolescents, a significant number would be considered “abnormal”!

There appears to be no sufficient good quality data showing the safety of or justification of the use of LASER for gynecological cosmetic indications in general (level of evidence 4, grade of recommendation C). It appears, however, to be safe for labiaplasty (level of evidence 3b grade of recommendation C) (Table 9).

## 10 | CONCLUSIONS

Advances in science, including medicine, are often questioned. However, as science evolves, we must remain committed to maintaining a high ethical standard. The four pillars of ethics—autonomy, beneficence, non-maleficence, and justice<sup>134</sup>—must guide medicine in both clinical practice and research.

The lack of quality studies regarding the use of trans-vaginal and vulvar LASER for gynecology and urology raises the question of whether such therapy provides beneficence and absence of maleficence; its use also hinders the patient's autonomy and choice. In order to give truly informed consent, there is need for clear and definitive information. Many questions remain unanswered from the safety profile of the therapies, comparison to current treatments, and long-term effects on tissues. Interestingly, the majority of LASER research carried out so far has been industry-funded, leading to significant risk of bias. There is an attraction to this office procedure which is profitable to the individual provider, however this should not drive un-guided practice.

Controversial applications regarding the use of LASER that have been promoted recently without rigid scientific validation, regulation, or oversight include the reconstructive therapy for “vaginal rejuvenation,” and design LASER vaginoplasty.<sup>130</sup> The deceptive marketing of unproven treatments may not only cause injuries but may also keep patients from accessing appropriate and recognized therapies. It is imperative that providers protect patients from potential unknown harm due to the understudied clinical application of LASER technology and protect themselves from potentially indefensible lawsuits.

While there is potential for utilization of LASER to treat some proposed clinical conditions, most commonly vaginal atrophy and stress urinary incontinence, the scientific evidence remains exploratory. The existing literature is almost all post-marketing, in the setting of daily practice, rather than within controlled clinical trials. As with other innovations this is unacceptable, as safety must be proven before reaching the consumer. LASER has been available for use and disseminated among clinicians before sufficient data regarding quality, safety, and efficacy were provided.<sup>135</sup> Use of this technology prior to rigorous scientific examination may end in adversity, as has been demonstrated by previous technologies such as vaginal mesh for prolapse repair and power tissue morcellation.<sup>136</sup>

Although LASER technology seems promising for select indications, long-term efficacy and safety data are lacking. In order to elucidate its optimal clinical application, LASER therapy must be evaluated in rigorous, well-designed studies that are of appropriate time scale, randomized and sham-controlled, to evaluate safety and efficacy. Therefore, despite its appeal to clinicians and women, assumptions cannot yet be made regarding the durability of this treatment nor its long-term effects, either positive or negative to date. Until further literature emerges, this technology should be considered experimental and

remain within the domain of clinical trials or with special arrangements for clinical governance, consent, and audit.

## 11 | RECOMMENDATIONS

Based on the available scientific evidence, with no supporting long term follow-up data, the use of LASER should, at present, not be recommended for the treatment of vaginal atrophy, vulvodynia, or lichen sclerosis. The data for the role of LASER for stress urinary incontinence and vaginal laxity are inadequate to draw any conclusions or safe practice recommendations. Therefore based on the available scientific evidence and on the lack of long term follow-up, the use of LASER should, so far, not be recommended for the treatment of vaginal atrophy, vulvodynia, lichen sclerosis, stress urinary incontinence, vaginal prolapse, or vaginal laxity.

## KEYWORDS

International Continence Society, lower urinary tract function, standardisation, terminology

## 1 | INTRODUCTION

This report presents definitions of the symptoms, signs, urodynamic observations, and conditions associated with detrusor underactivity (DU) and the potentially associated lower urinary tract symptom complex of the underactive bladder (UAB), relating to DU in all patients groups from children to the elderly. It is important to emphasize that in the past the use of the term UAB has been used in a non standardized and imprecise fashion.

Detrusor underactivity (DU) may be an aspect of (or contributor to) lower urinary tract symptoms (LUTS),

especially in later life. While DU is a urodynamic definition describing the detrusor voiding contraction, the clinical component of the definition—reduced urinary flow rate and/or an increased post-void residual (PVR)—have often and imprecisely been described as “underactive bladder” (UAB).<sup>1,2</sup> In contrast to overactive bladder (OAB) and detrusor overactivity (DO), UAB and DU have remained largely unrecognized and poorly researched.<sup>1,2</sup> There is a paucity of data regarding the pathogenesis and treatment of DU, and the definitions of DU and UAB remain imprecise, with a variety of definitions and diagnostic criteria found within contemporary literature.<sup>1,2</sup> This lack of uniformity creates difficulties in characterizing UAB, in researching its effect on patient quality of life, and in evaluating possible treatments.

John Heesakkers led the peer-review process as the Associate Editor responsible for the paper.

The symptoms associated with UAB are common<sup>3</sup> and likely to impact on quality of life.<sup>4</sup> In the absence of a specific consensus-based definition of UAB, the true burden cannot be fully appreciated, nor can appropriately robust clinical trials be conducted.<sup>1-4</sup> In this report, we discuss a new definition for UAB that could be used as a platform for future discussion and research.

Although DU is an increasingly recognized urodynamic observation contributing to LUTS in both men and women, there has been a lack of research into all aspects of this dysfunction, and as yet, no effective treatments exist. DU can be diagnosed only on the basis of an invasive urodynamic study. An international consensus group met at the International Consultation on Incontinence-Research Society (ICI-RS) and International Continence Society (ICS) annual meetings in 2014 and again at these meetings in 2015 to consider the feasibility of developing a working definition of a symptom complex associated with DU. Drawing an analogy to detrusor overactivity (urodynamic observation) and overactive bladder (clinical diagnosis based on a symptom complex), the aim of this document is to help identify affected patients of all ages and to facilitate further clinical and epidemiological research.

## 2 | METHODS

The definitions restate or update those presented in previous International Continence Society Standardisation of Terminology reports.<sup>5-14</sup>

As far as possible, the definitions are descriptive of observations, without implying underlying assumptions that may later prove to be incorrect or incomplete. By following this principle, the ICS aims to facilitate comparison of results and enable effective communication by investigators who use urodynamic methods.

This document was developed according to the published methodology of the ICS Standardization Steering Committee.<sup>5</sup> The group commissioned for this report developed an outline of proposed content and revised this in the light of a workshop held at the 4th International Neuro-Urology Meeting in Zurich, Switzerland in August 2015. The subsequent text was reviewed by the working group before a final draft was discussed at a workshop during the ICS meeting in Montreal in October 2015.

## 3 | DEFINITIONS

LUTS are defined from the individual's perspective who is usually, but not necessarily, a patient within the healthcare system. Symptoms are either volunteered by, or elicited from, the individual or may be described by the individual's caregiver.

LUTS are divided into three groups: storage, voiding, and post micturition symptoms.

LUTS are not disease specific. The symptoms of hesitancy, straining to void, and a slow urinary stream can be characteristic of both bladder outflow obstruction (BOO) and detrusor underactivity (DU).

**Storage Symptoms** are experienced during the storage phase of the micturition cycle.

- **Increased daytime frequency** is the complaint by the patient who considers that he/she voids too often by day.
- **Nocturia** is the complaint that the individual has to wake at night one or more times to void.
- **Urgency** is the complaint of a sudden compelling desire to pass urine which is difficult to defer.

**Voiding Symptoms** are experienced during the voiding phase. Since UAB is a disorder of emptying these seem to be the predominant ones but voiding symptoms may also be associated with storage symptoms in case of incomplete bladder emptying.

- **Slow stream** is reported by the individual as his or her perception of reduced urine flow, usually compared to previous performance or in comparison to others.
- **Intermittent stream (intermittency)** is the term used when the individual describes urine flow which stops and starts, on one or more occasions, during micturition.
- **Hesitancy** is the term used when an individual describes difficulty in initiating micturition resulting in a delay in the onset of voiding after the individual is ready to pass urine.
- **Straining** to void describes the muscular effort used to either initiate, maintain, or improve the urinary stream.
- **Feeling of incomplete emptying of the bladder** during voiding
- **Terminal dribble** is the term used when an individual describes a prolonged final part of micturition, when the flow has slowed to a trickle/dribble.

**Post Micturition Symptoms** are experienced immediately after micturition.

- **Feeling of incomplete emptying** is a self-explanatory term for a feeling experienced by the individual after passing urine.
- **Post micturition dribble** is the term used when an individual describes the involuntary loss of urine immediately after he or she has finished passing urine, usually after leaving the toilet in men, or after rising from the toilet in women.

### Symptom syndromes suggestive of lower urinary tract dysfunction

In clinical practice, empirical diagnoses are often used as the basis for initial management after assessing the individual's lower urinary tract symptoms, physical findings and the results of urinalysis and other indicated investigations.

- Urgency, with or without urgency incontinence, usually with frequency and nocturia, can be described as the overactive bladder syndrome, urge syndrome, or urgency-frequency syndrome.  
These symptom combinations are suggestive of urodynamically demonstrable detrusor overactivity but can be due to other forms of urethro-vesical dysfunction. These terms can be used if there is no proven infection or other obvious pathology.
- **Lower urinary tract symptoms suggestive of bladder outlet obstruction** is a term used when a man complains predominately of voiding symptoms in the absence of infection or obvious pathology other than possible causes of outlet obstruction
- **Underactive bladder** is characterized by a slow urinary stream, hesitancy and straining to void,<sup>a</sup> with or without a feeling of incomplete bladder emptying sometimes with storage symptoms.<sup>b</sup> (NEW)

## 4 URODYNAMIC OBSERVATIONS AND CONDITIONS

In the context of urodynamics we would affirm the ICS standardisation report definitions:

### Detrusor function during voiding

#### - Normal detrusor function

Normal voiding is achieved by a voluntarily initiated continuous detrusor contraction that leads to complete bladder emptying within a normal time span, and in the absence of BOO. For a given detrusor contraction, the magnitude of the recorded pressure rise will depend on the degree of outlet resistance.<sup>c</sup>

- **Abnormal detrusor activity** can be subdivided:

- **Detrusor underactivity** is defined as a contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span<sup>d</sup>.
- **Acontractile detrusor** is one that cannot be demonstrated to contract during urodynamic studies.

- **Post void residual (PVR)** is defined as the volume of urine left in the bladder at the end of micturition.<sup>e</sup>

**Abnormal detrusor activity** in the voiding phase does not exclude the presence of **detrusor overactivity** in the storage phase. This may then be described as, for example, storage phase detrusor overactivity combined with voiding phase detrusor underactivity.

## 5 | CONCLUSIONS

DU is diagnosed urodynamically and has a pressure/flow-based ICS definition, however, it is not feasible to utilize urodynamics outside a secondary care centre. DU is characterized by an absent or low-pressure, and/or poorly-sustained detrusor contraction in combination with low urinary flow. In contrast, UAB has no ICS definition but we would propose UAB as the clinical syndrome that includes DU. Because UAB is largely undefined in the literature, there is, in our view, the need for a new symptomatic definition.

For the sake of symptom quantification in much-needed research moving forward, it appears that a crystallized definition of UAB would be of definite value. In properly defining UAB, it will be important to consider the entire symptom complex, describing the sensation of incomplete or impaired voiding that may include hesitancy, straining to void, incomplete bladder emptying, slow or prolonged stream, or intermittent stream, without implying any specific urodynamic/functional findings or causative physiology.

Properly defined, UAB could be to DU as OAB is to DO, where treatment according to a symptom-based diagnosis would be possible if the diagnosis was sufficiently robust. Patient choice, practical, and cost reasons often necessitate treatment without a pressure/flow-based diagnosis

We propose that this definition should now be tested to check its validity. In particular the factors to be considered are the influence of gender, age, and origin (neurogenic versus non-neurogenic), combining the interpretation of symptoms along with bladder diaries, flow rates, PVR volumes, and urodynamic data. It is hoped that this suggested definition may be used as a springboard for future UAB research and discussion, in terms of both qualitative research to look for characteristic symptoms, and quantitative research in urodynamically-defined DU patients.

OY is a researcher and/or a speaker for Astellas, Ferring, Pfizer, Hisamitsu and Asahikasei. AW is a consultant/advisor to Avadel, Allergan, Axonics, Valencia, Urovant, and Medtronic. VN is a researcher for Allergan, Astellas, and Medtronic.

## ENDNOTES

<sup>a</sup> FOOTNOTE a) Underactive bladder occurs in association with diverse pathophysiologies and based on current knowledge there is no single distinguishing symptom.

<sup>b</sup> FOOTNOTE b) Storage symptoms are varied and may be highly prevalent, including nocturia, increased daytime frequency, reduced sensation of filling and incontinence. Underlying mechanisms of storage symptoms are diverse, and are often related to a significant post voiding residual urine volume.

<sup>c</sup> FOOTNOTE c) In women voiding symptoms are usually less likely to be caused by anatomical bladder outlet obstruction, therefore, detrusor underactivity and functional causes of outlet dysfunction are more likely (such as dysfunctional voiding).

<sup>d</sup> FOOTNOTE d) A urodynamic study is essential to differentiate between Bladder outlet Obstruction and Detrusor Underactivity. A normal detrusor contraction will be recorded as: high pressure if there is high outlet resistance, normal pressure if there is normal outlet resistance or low pressure if urethral resistance is low.

<sup>e</sup> FOOTNOTE e) If after repeated free uroflowmetry no residual urine is demonstrated, then the finding of residual urine during urodynamic studies should be considered an artefact, due to the circumstances of the test.

## 5. ICS EDUCATION MODULES

An ICS Education Module is an endorsed, evidence based, standardised module designed to teach best practice in the clinical or basic science of urinary, bowel and pelvic floor disorders. The module represents the gold standard of education for the ICS and is proposed and planned according to ICS Standard Operating Procedure.

The module includes a 3-part format:

- Official ICS-consensus PowerPoint available for download
- A studio-quality video (hosted on the ICS website) and
- A peer-reviewed published article published in NAU

These modules represent the highest level in the ICS educational mission: ICS seeks to develop and distribute high quality global health educational modules; define standards and competencies in health education; and address the needs of students, educators, and trainees as they seek to gain the skills and knowledge necessary to become healthcare leaders. All ICS modules are created to be used by educators around the world who can download the ICS module and present this to their students/colleagues. It is also expected that when an ICS speaker is invited to speak at an educational course or guest lecture the educational modules are used to provide the standardised educational content. The outcome of these modules is that educators around the world, and ICS faculty, can download the ICS module and present this to their students/colleagues. Additionally, if people are unable to attend a course on the topic the video can serve as an excellent educational tool.

**All of the modules can be found on ICS TV: [www.ics.org/tv](http://www.ics.org/tv)**

If one clicks on the module one will see the text below the video- click 'show more' and this will include the PPT slide and publication.

**ICS Education Module Standard Operating Procedure (SOP)**

ICS Education Modules are created according to SOP:

[www.ics.org/education/icsstandardoperatingprocedures/videosops/icseducation3partmodule](http://www.ics.org/education/icsstandardoperatingprocedures/videosops/icseducation3partmodule)

# ICS Teaching Module: Ambulatory Urodynamic Monitoring

A Digesu, C Gargasole, C Hendricken, M Gore, E Kociancic, V Khullar & P Rosier

**ICS**

International Continence Society  
Teaching Module

1

## ICS teaching module

- To assist clinicians in performing and Interpreting AUM
- This teaching module should be used together with the manuscript: 'ICS teaching module: Ambulatory Urodynamic Monitoring (AUM)'
- This manuscript includes the best available evidence but also contains experts' opinions reported as "eo" if reliable evidence is unavailable
- This module can, only in its complete form, freely be used for teaching purposes

# Introduction

- A summary of the published literature on the role of AUM in clinical and research practice.
- Indications
- Technique and Protocol for AUM
- Troubleshooting
- Interpretation of AUM traces
- Advantages and disadvantages of AUM compared to laboratory cystometry (routine saline urodynamics)

# Philosophy & Pathophysiology

- AUM has been recognized by the ICS as a useful tool to investigate LUTS in patients with inconclusive urodynamics diagnoses (19% to 44%)

## Philosophy & Pathophysiology

### ADVANTAGES

- Natural (orthograde) filling of the bladder
- Less embarrassing test since the patients are fully dressed
- The pressure are recorded for several hours (3-4)
- The patients able to leave the urodynamic room
- Increased diagnostic accuracy in the detection of DO

## Philosophy & Pathophysiology

### DISADVANTAGES

- Time-consuming test
- It requires trained and dedicated personnel
- It requires specialized equipment
- A high rate of abnormal detrusor contractions using AUM in asymptomatic controls

## Catheters

- Catheter-mounted microtip transducers:
  - silicone-covered braided metal makes them very flexible
  - low stiffness and the circumferential configuration
  - allow greater patient's mobility
  - low incidence of artifacts<sup>(eo)</sup>
- Fluid-filled catheters: possible but use not yet proven
- Air - charged catheters: possible but use not yet proven

## Single use Catheters

- The use of single use catheters would be ideal as:
  - it would reduce the costs
  - save the time needed to reprocess/clean the multi-use electronic microtip transducers catheters
- Although recent studies have shown promising results in performing AUM with water filled catheters (for Pves/Pabd) scientific evidence is still lacking

## Pressure sensor systems

- Tiny airtight capsules inserted into the bladder and rectum which then communicate with a portable recorder attached to the body to reduce artifacts
- The clinical use has not been proven & validated yet

## Recording systems

- Gaeltec Devices
  - the oldest systems using electronic catheters-mounted microtip transducers
  - large recorder box which is very awkward to carry around
  - Lack of a patient event-marker capability to capture the patient sensation data and timing for urgency, voids, accidents, etc.

## Recording systems

- Goby, Laborie Medical or Luna, MMS:
  - Newer systems
  - Small remote control attachment to capture data
  - Compatible with water, air and microtip catheters

## Patient preparation

- Information leaflets explaining the test are posted to patients prior to the appointment
- Comfortably full bladder
- A uroflow and a urine analysis are performed
- AUM test can be performed if there are no signs of urine infections (nitrites and leucocytes)
- Wearing comfortable clothes (preferably gown for women)
- Empty bowel if possible

## Technique

- Similar to laboratory cystometry
- Catheters are inserted into the bladder and the rectum
- Sufficient catheter length into bladder/rectum
- Catheters should be securely taped adjacent to the anus and external urethral meatus to reduce the risk of catheter's falling out as well as to reduce artifacts
- Transducers set to zero
- The patient can then dress and the catheters can be connected to the AUM recording system

## Zero setting: water filled catheters

- Transducers must be set to zero at the atmospheric pressure
- Two three-way taps can be attached to the vesical and rectal transducers
- 10 ml syringe is used to flush fluid through the tubing system to eliminate bubbles from the transducers and catheters
- Transducers and the open end of the three-way tap must be at the same horizontal level of the symphysis pubis after having excluded the syringe by closing the tap where the syringe is attached

## Zero setting: Air-charged & microtip transducers catheters

- Set zero prior to recording
- Before or after insertion into the bladder & rectum
- Not necessarily at the atmospheric pressure

## Technique

- Prior to commence recording the patient is asked to cough to check the intravesical, abdominal and subtracted detrusor pressures
- AUM can be started if there is a similar increase of the intravesical and abdominal pressures and the subtracted detrusor pressure does not change
- Any problem must be rectified!

## Technique

- Before the patient leaves the urodynamic room it is mandatory to ensure that the patient:

1. Understands and is able to follow instructions
2. Records on a diary all the urinary symptoms reported during AUM test

Since symptoms are compared against the pressures recorded, an accurate recording of symptoms and the times when they occur is essential for the final AUM diagnosis

## Technique: recording urine leakage

- Method has not yet been standardized
- This may be recorded by:
  - An electronic pad
  - A remote control with event marker button
  - Completing a urinary symptom diary
  - All the above

## Instructions to the patient

- To record episodes of urgency, incontinence, pain, voluntary voids, time and volume of fluid intake, feeling of catheter displacement, any provocative maneuvers (running, washing hands, coughing etc)
- How to use the event buttons on the AUM device
- To drink about 200-400 ml/hour or a fluid load up to 1 litre drunk over 30 minutes (unless a fluid load is contraindicated the AUM time would take longer <sup>60</sup>)

## Instructions to the patient

- To return to the urodynamic room:
  - Every hour to check the system is recording the pressures correctly and subtraction is accurate
  - If need to void
  - If one of the catheter falls out (if a diagnosis has not be revealed the pressure transducers would need to be re-inserted, re-zeroed and the test will be re-started thus the length of the test will be altered from the suggested standard)
  - If the patient needs to defecate the catheter would need to be removed and reinserted accordingly

## Quality control assessment

To ensure a good quality control it is important to check the signal quality by:

- Setting each transducer to zero prior to commencing to record the pressures or during the test if needed;
- Ensure that the intravesical/abdominal pressures are similar by asking the patient to cough prior to commencing the test and every hour
- Asking the patient to cough before and after each void when pressure flow studies are recorded (LE 2a)

## Quality control assessment

- Ensure that all the catheters are securely taped on the patient's thigh, the catheter's length is reduced to the shortest length possible to avoid accidental displacement during the test
- If filled fluid catheters are used, ensure that there is no air in the system that may affect the quality control
- Provide information to patients advising to attend the appointment with an empty bowel if possible

## Analysis and interpretation of AUM trace

- Assessment of the quality of data (signal) recorded:
  - Is the trace “active”?
  - Is the baseline static or highly variable?
  - Are the cough tests regularly present?
  - Is the subtraction adequate?
- At the end of the test, hourly or if any problem arises, to reduce the risk of missing or uninterpretable data
- The use of a detailed patient diary or event markers on the newer AUM systems is strongly recommended to improve the analysis of events occurring during AUM <sup>(14 eo)</sup>

## Contraindications

- Poor patient mobility
- Cognitive impairment
- Inability to follow instructions
- Severe constipation
- Active urinary tract infection
- Medical conditions which limit patient’s participation (clinician’s discretion)

## Recommendations

- AUM is most sensitive for the detection or exclusion of detrusor overactivity compared to laboratory cystometry (LE 2a<sup>16</sup>)
- AUM is valuable when all other diagnostic tests have failed to detect the underlying cause of LUTS and/or LUTS do not correlate to laboratory cystometry diagnosis (LE 2a)
- Stress urinary incontinence is better detected by laboratory cystometry than AUM <sup>(15)</sup> (LE1B)
- UTI must be excluded prior to commencing the test

## Scientific Evidence

- No scientific evidence demonstrating that routine antibiotic cover before and after the test is needed
- Post procedure broad spectrum antibiotic cover may be considered in patients with:
  - Diabetes
  - Recurrent urinary tract infections
  - High post micturition residual<sup>eo</sup>
- Although there is no scientific evidence supporting the use of routine bowel evacuation agents before AUM test (as they can cause rectal activity and/or abdominal discomfort) an impacted bowel should be avoided
- To date there is no clear LE about AUM role in the assessment of neurogenic LUTS

## Conclusions

- AUM is a valuable and effective second line test where laboratory cystometry has failed to give a satisfactory diagnosis (LE2a)
- AUM improves the outcome of continence surgery by unmasking preoperative underlying DO (<sup>100</sup>, unpublished data)
- AUM is a more time consuming test than laboratory cystometry
- AUM requires expertise as well as specialised equipment
- To make the most of its diagnostic capability and to avoid over diagnosis of DO, a detailed record of urinary symptoms during the test is always recommended

## ICS Teaching Module: Ambulatory Urodynamic Monitoring

G. Alessandro Digesu,<sup>1\*</sup> Clara Gargasole,<sup>1</sup> Caroline Hendricken,<sup>1</sup> Michelle Gore,<sup>1</sup> Ervin Kocjancic,<sup>2</sup> Vik Khullar,<sup>1</sup> and Peter F. Rosier<sup>3</sup>

<sup>1</sup>Department of Urogynaecology, Imperial College Healthcare NHS Trust, London, United Kingdom

<sup>2</sup>Department of Urology, University of Illinois at Chicago, Chicago, Illinois

<sup>3</sup>University Medical Centre Utrecht—Urology, The Netherlands

**Aim:** To present the ICS Teaching Module on ambulatory urodynamics monitoring (AUM). **Methods:** This teaching module has been developed by the ICS Urodynamics Committee to assist ICS members in their routine clinical practice. A detailed literature search on studies published on the clinical role of AUM as well as expert opinions have been considered. A slide set on AUM has been developed, approved by all members of the ICS Urodynamics Committee and is available to the ICS membership on the ICS website. The final approved teaching module has been presented at the ICS Annual Scientific Meeting in Brazil 2014. **Results:** The scientific evidence on the clinical role of AUM in patients with lower urinary tract symptoms is summarized. The catheters and recording systems used, the patient preparation for the test, the technique, the instructions to the patient, the analysis, interpretation, and quality control assessment of AUM trace as well as the contraindications for AUM are described. **Conclusions:** The clinical role of AUM is still controversial. The scientific evidence on the usefulness of AUM is still limited but the ICS Urodynamics Committee recommends its use as a second line diagnostic tool when office laboratory urodynamics have failed to achieve a diagnosis. AUM has been showed to be more sensitive than laboratory urodynamics in diagnosing detrusor overactivity but the level of evidence for this measurement is not high. This manuscript summarizes the evidence and provides practice recommendations on AUM for teaching purposes in the framework of an ICS teaching module. *NeuroUrol. Urodynam.* 36:364–367, 2017.

**Key words:** ambulatory urodynamics; ICS teaching module; inconclusive urodynamics; lower urinary tract symptoms

### INTRODUCTION

Ambulatory Urodynamic Monitoring (AUM) has been mentioned in International Continence Society (ICS) standards.<sup>1–2</sup> AUM may be considered a useful tool to investigate lower urinary tract dysfunction (LUTD) in patients with lower urinary tract symptoms (LUTS) and inconclusive results on laboratory urodynamic testing.<sup>3,4</sup> The clinical sensitivity and specificity of AUM are not very well established and the specific technical demands and the technical reliability are deliberated.<sup>1–2,5</sup> To date there is no clear consensus about the role of AUM in the assessment of LUTD.<sup>6,7</sup> Although the here above mentioned standards suggest some practical aspects, they do not cover all issues arising with clinical testing. The ICS Urodynamics Committee presents the teaching module “Ambulatory Urodynamic Monitoring” to serve as a standard education of Good Urodynamic Practice for everyone involved in indicating, performing, and analyzing urodynamic testing in general and more specifically, performing AUM. The teaching module consists of a PowerPoint presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base for the ICS PowerPoint presentation, which is available via <http://www.icsoffice.org/eLearning>. The presentation explains testing requirements, clinical workup, and analysis. The presentation and this manuscript are based on the highest-level available published evidence, graded according to the modification of the Oxford Center for Evidence-Based Medicine levels of evidence as also used by the 5th International Consultation on Incontinence. Where evidence is unavailable, experts’ opinion has been used and the sentence is marked as “eo” (experts’ opinion). The aim of this ICS Teaching Module is to provide a summary of the published literature on the role of AUM in clinical research practice, including indications. Furthermore the technique and

a practice protocol for AUM including troubleshooting and interpretation are presented.

### Evidence and Philosophy of AUM

Conventional urodynamics is the standard clinical tool to investigate LUTD.<sup>2,8</sup> However, it has been reported that it can fail to precisely demonstrate the cause of (storage) LUTS in 19–44% of the cases.<sup>2–4</sup> This may be due to the shorter duration of the test, thus abnormalities are not detected before the end of recording. Lack of correlation between abnormalities detected and symptoms reported by patients may also play a role since it is well known that in LUTD, signs and symptoms are neither very specific nor sensitive towards the dysfunction.<sup>9</sup> When conventional urodynamics is inconclusive, AUM may be helpful in diagnosing the cause of the symptoms and guiding more appropriate management of patients. In particular, AUM has been observed to have an increased detection of detrusor overactivity.<sup>10–16</sup> However, the fact that AUM shows abnormalities, especially detrusor overactivity, in healthy volunteers may also be considered a sign of lesser specificity, apart from the fact that a person’s perception of LUT function may be “false negative.”<sup>17–20</sup> There is single center expert retrospective evidence that stress urinary incontinence became detectable during AUM with a leakage

Prof. Christopher Chapple led the peer-review process as the Associate Editor responsible for the paper.

detector<sup>15</sup> (LE3). The sensitivity and or specificity of AUM towards voiding dysfunction or abnormalities is at present unknown.

AUM is performed in a similar way to conventional cystometry but differs in some specific elements: it uses natural (orthograde) filling of the bladder (the patients are usually asked to drink extra) and testing lasts for approximately 2–4 hr. Patients are fully dressed after the initiation of the test and are able to leave the urodynamic room, which may reduce embarrassment.<sup>11,12</sup> Disadvantages of AUM may be that the test and analysis are time-consuming and require specialized equipment with trained and dedicated personnel.

#### Catheters

The majority of the reported studies on AUM have used catheter-mounted microtip transducers since they allow greater patient mobility and have a lesser incidence of movement artifacts.<sup>(60)</sup> Although it is possible to measure pressures during AUM with fluid-filled lines, with intravesical capsules or with air filled catheters, the evidence of their usefulness has still to be proven.<sup>10</sup>

#### Recording Systems

The oldest systems (Gaeltec Devices Ltd, Isle of Skye, Scotland) are mostly known for their catheters, made of flexible silicone-covered braided metal, with mounted electronic microtip transducers. The main disadvantage of this system is the large recorder box which has been awkward to carry around. The newer systems (i.e., Goby, Laborie Medical, Canada or Luna, Medical Measurement Systems, Mississauga, Canada) have a smaller remote control attachment that also allows data capturing of the important physiological events. These newer systems can also accommodate water filled, air filled, and electronic (microtip) options. (Comparative) evidence about the clinical or technical reliability of each system or combination is lacking.

#### Patient Preparation

The patient is asked to come to the department with an empty bowel if possible, with a comfortably full bladder and wearing comfortable (not too tight) clothes. If the rectum is loaded with feces at the start this may need to be sorted prior to commencement to prevent “fecal urgency” during the test. Active urinary tract infection must be excluded prior to commencing the test. There is no scientific evidence demonstrating that routine antibiotics before and or after the test are needed nor evidence supporting the use of routine bowel evacuation agents before AUM. Furthermore, laxatives can cause rectal activity and/or abdominal discomfort and therefore hinder the representativeness of the test.<sup>60</sup>

To record episodes of urgency, incontinence, pain, start and end of voluntary voids, time and volume of fluid intake, feeling of catheter displacement as well as any provocative manoeuvres (running, washing hands, coughing, sneezing etc) a remote control might be useful. Information leaflets explaining the test should be made available for patients prior to their appointment to explain what the test involves and how they can cooperate with the test. Preferably a uroflow and post void residual urine test are performed before AUM is started. If there are no signs of urinary tract infection the AUM test can be performed.

#### Technique

Before the test is started it is mandatory to ensure that the patient understands and is able to follow some important

instructions (described more in detail in the following section) and will be able to record on a diary all the (LUT) signs and symptoms perceived during the AUM test. Since symptoms are compared against the pressures recorded, an accurate recording of symptoms and the times when they occur is essential for the final AUM diagnosis.<sup>21–23</sup>

Similar to conventional cystometry the catheters are inserted into the bladder and the rectal canal. Air-filled or microtip transducers catheters need to be zeroed prior to insertion at the atmospheric pressure by having the open end of three-way taps, attached to the catheters, at the level of the symphysis pubis. Via these three-way taps some gentle fluid flush can eliminate entrapped air and debris from the catheters and can also check them for leaks. Sufficient catheter length should be inserted into the bladder/rectum and the catheters must be securely taped adjacent to the anus and external urethral meatus to reduce the risk of catheters falling out as well as to reduce movement artifacts. The patient can then dress and the catheters can be connected to the AUM recording system.

Prior to commencing recording the patient is asked to cough to check the intravesical, abdominal, and subtracted detrusor pressures. If there is a prompt and steep increase of the vesical and abdominal pressures during cough and the subtracted detrusor pressure does not change then the test can be started. Otherwise any problem must be rectified.

The method of recording urine leakage has not yet been standardized. An electronic pad and/or the patient using a remote control and pressing an event marker button and/or completing a urinary symptom diary are possibilities. No evidence exists for any of the methods being more specific, predictive, or reliable.

#### Instructions to the Patient and AUM Test

As stated above, during AUM the bladder filling is accomplished with the patient's own urine production instead of filling the bladder through a catheter. The test may last from 2 to 4 hr. Patients should receive instructions prior to leaving the urodynamic room (See Table I) in an easy to understand manner. In order to maximize AUM diagnostic power, the use of a detailed patient diary is strongly recommended to improve the analysis of events occurring during AUM.<sup>14,60</sup> However the availability of event markers on the newer AUM systems may replace the use of the diary allowing more freedom, ease, and flexibility for the patient.

Usually patients are instructed to drink extra during the test, to be able to record some storage to voiding cycles in a reasonable amount of time. Forced diuresis may unmask/provoke detrusor overactivity, however voiding an equivalent of 4 L/24 hr may be an unusual challenge for the LUT.<sup>20</sup>

The patient instruction includes advice to return to the urodynamic office in case of problems. If a catheter is displaced or evacuated, or the system is malfunctioning, the trace, the recorded pressures, subtractions, and quality of the trace the test duration may need to be reviewed. If a diagnosis has not been revealed, in case of malfunction and test prolongation the pressure transducers would need to be re-zeroed, re-inserted, and the test re-started.

#### Quality Control Assessment

There is risk of losing signal quality associated with AUM. Therefore, there are a number of additional precautions to consider while performing AUM compared to conventional cystometry. Obviously it is relevant to ensure that all the catheters are securely taped adjacent to the meatus and the

**TABLE I. Outline of Patient Instructions for Ambulatory Urodynamic Test**  
**How to you use the event buttons on the AUM device**

---

Drink about 200–400 ml per hour or a fluid load up to 1L drunk over 30 min.  
 If a fluid load is contraindicated the AUM time would take longer.<sup>eo</sup>  
 Register urgency, incontinence, pain, start and end of voluntary voids, time and volume of fluid intake.  
 Register activity and maneuvers that (usually tends to) provoke symptoms like example drinking, running, lifting weight, washing hands, coughing, sneezing etc.  
 Return to the urodynamic room every hour to allow to check the system is recording the pressures correctly.  
 Return to the urodynamic room whenever you need to void.  
 This may allow recording up to three pressure flow studies during the whole study.<sup>eo</sup>  
 Return to the urodynamic room when a catheter (or both) falls out, or is expelled during voiding (or defecation).

---

anus. The catheter's length should be fixed to the lower abdomen (stay inside the pants) and the rest of the length to the monitor box should be as short as possible and secured underneath the clothes to further avoid accidental displacement during the test.

To ensure good quality control it is important to check the signal quality by setting each transducer to zero prior to commencing to record the pressures and to ensure that the intravesical and abdominal pressures are similar by asking the patient to cough. Thus it can be checked that the subtracted detrusor pressure is within the normal range prior to commencing the test and this may be checked every hour to make sure that the pressures are correctly recorded and that the catheters are not displaced. The instructions should also preferably ask the patient to cough before and after each void when pressure flow studies are recorded (LE 2a).

#### Analysis and Interpretation of AUM Trace

The first step in the analysis of an AUM trace is the assessment of the quality of data (signal) recorded and to judge whether the trace appears "active" with clearly visible coughs and pressure variations due to the movement of the patient. A dead (flat) signal in one or both of the pressures indicates a problem and depending on the duration the test may not be evaluable. If both pressures have been recorded for a sufficient amount of time, the detrusor pressure should be evaluated. Evaluation of detrusor pressure is possible for the period that the movement and cough responses have been "balanced," without causing significant positive or negative deflections in this pressure; though inevitably rectal activity may play a role in (negative) deflections of detrusor "pressure" and these must be recognized.

Analysis and interpretation of the trace should be performed immediately following the test to allow discussion of the findings and management options with the patient, thus avoiding unnecessary repeat visits.<sup>eo</sup>

#### Contraindications for AUM

Poor patient mobility, cognitive impairment, or inability to follow instructions are relative contraindications for AUM. Severe constipation and active urinary tract infection may need to be treated before the test.

#### CONCLUSIONS

AUM may be performed when conventional urodynamic tests have failed to detect any underlying cause of LUTS and/or may be useful when conventional cystometry diagnosis does not explain the symptoms. AUM is a more time consuming test than conventional cystometry and requires expertise as well as specialized equipment. In order to make the most of its

diagnostic capability a standardized workup and systematic analysis by a skilled physician is mandatory. Analysis should be built on an as reliable as possible measurement including a detailed record of lower urinary tract signs and symptoms. For this reason, it is also very relevant to ensure patient cooperation. We have presented an evidence based teaching module to support good clinical practice regarding AUM with recommended elements of standardization for the physician as well as for the instructions to the patient.

## ICS teaching module

- This teaching module should be used together with the manuscript:
- 'ICS teaching module: Analysis of Voiding; Pressure Flow Analysis' published in: Neurourology and Urodynamics
- The manuscript provides the scientific background and the evidence base of pressure flow analysis as well as the references.
- This teaching module contains expert opinion recommendations to compensate for lacking evidence where necessary. Expert opinions are marked with 'eo' in the title of the slide.
- Reference to this presentation and teaching module:
- Neurorol Urodynam 2014 ##### (33) ###
- This teaching module contains 25 slides and can, only in its complete form, freely be used for teaching purposes.

ICS Teaching Module

2

## Normal lower urinary tract function

- Bladder filling begins (Storage LUT function -phase)
- Nervous system maintains relaxed detrusor
  - and ensures low intravesical pressure
- Distension activates muscle stretch receptors
  - Perception (proprioception) of fullness develops
- Cortical determination of desire to void
- Voiding (Voiding LUT function -phase)
  - Until bladder emptied
- Bladder filling, again

## Normal voiding

- Voiding is desired (and socially acceptable)
- Pelvic floor relaxes by will..
  - ...subsequently and autonomically the..:
- ...urethral sphincter relaxes and (antagonistic) detrusor-dome contracts;
- Detrusor pressure forces the (relaxed) bladder neck, the urethra and pelvic floor to open;
- Urine flow begins;
- Detrusor contraction ends;
- Urethral sphincter and pelvic floor contraction resume.

## Control of lower urinary tract function

- Central control and influence
  - Cognition
  - Social
  - Emotional
- Central & peripheral pathways
  - Afferent (sensory)
    - Somatic
    - Autonomic/visceral
  - Efferent (motor)
    - Somatic
    - Autonomic/visceral
- While testing: (sub-) conscious central influence may (in comparison to storage phase) play a larger role in voiding function.<sup>60</sup>

## General principles of urodynamic testing\*

### Well informed patient

- Appropriate environment
  - Physical (warm, least uncomfortable position...)
  - Emotional (adequate draping, private...)
- Antiseptic procedure
  - Urinary tract infection as a result of urodynamic testing should be prevented
    - (Not 'corrected' with prophylactic antibiotics)

\* See also: Basic module 'cystometry'

## Voiding: pressure flow test(s)

- Because the pressure flow test may be more influenced through the patient's emotion:
  - Ask patient (after voiding):
    - 'Was this voiding -almost- as usual?'
    - 'Was the bladder 'uncomfortably' full?'
  - You have:<sup>\*</sup>
    - Indicated on cystometry: first sensation of filling
    - Indicated on cystometry: normal desire to void
    - Indicated on cystometry: strong desire to void > end of filling AND
    - Indicated on cystometry: permission to void
      - The 'permission to void' separates the storage and voiding (LUT) phases!
  - Compare with free (without catheter) flow!

<sup>\*</sup> see also: basic module 'cystometry'

## Voiding: pressure flow test(s)

- Negative influence on voiding:
  - Uncomfortably large intravesical volume at the start of voiding<sup>eo</sup>
  - Very unrepresentative urgency at the start of voiding<sup>eo</sup>
  - Extreme inhibition of overactive detrusor contractions before the start of voiding<sup>eo</sup>
  - Rectal catheter hindering pelvic muscle relaxation

## Voiding: Pressure flow test(s)

- Be aware that the transurethral catheter:
  - Causes (some) passive effect
    - May be obstructive (esp. when stricture exists)
    - May 'stent' kinking urethra in female
  - Causes active effect (hinders normal behaviour)
    - alters voiding sensation
      - Anaesthetic (lidocaine) gel
    - (fear for) pain during voiding
  - May -partially- slip out

## Set up for the test

- (ICS-) Good urodynamic practice:
  - See also ICS module: Cystometry
- Ensure balanced intravesical and intra abdominal (intra rectal) pressure recording.
- Couch (pressures balance) check before and after voiding.
- Ensure correction of flow curve for the systematic delay between (recorded) flow and pressure.
  - depending on the meatus to flowmeter distance
  - before a pressure flow analysis is done

## Set up for the test

- Best possible (= most comfortable for patient), position during voiding.
- Flowmeter as close as possible to the meatus.
  - Minimize time delay between flow at meatus and entering flowmeter
- No hindering of stream between funnel and beaker or spinning disk.
  - (e.g. No (long) tube between funnel and beaker or disk.)
- Use thin transurethral catheter.
- Use thin rectal catheter.
- Tape catheters alongside meatus / anus.

## Mechanics of voiding

- Detrusor pressure (cmH<sub>2</sub>O) generates flow (ml/s)
  - Intravesical pressure minus intra-abdominal pressure
- Urethra (normally) functions as a tube...
  - with passive distension (until Q<sub>max</sub>)
  - and passive collapse (after Q<sub>max</sub>)
- Flow (Q<sub>max</sub>) is limited by the 'flow controlling zone' (FCZ)
  - The FCZ is the virtual (! by definition) point in the urethra that gives the highest resistance to flow
  - Increased resistance drives detrusor to higher pressures to generate flow
- Urethral catheter (8F) causes ±10cm H<sub>2</sub>O increase of detrusor pressure
  - (Systematic) increase of measured outlet obstruction.
  - Should be corrected for if suprapubic catheter is used.

# Mechanics of voiding: phases

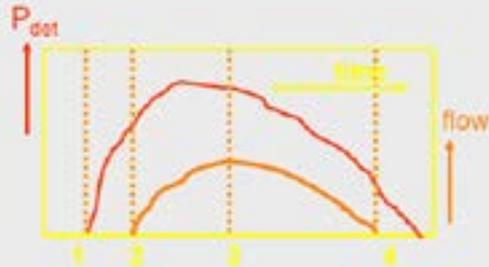

Start of pressure flow = end of storage: Indicated by 'permission to void'.

After voluntary pelvic floor relaxation after

- Permission to void \*

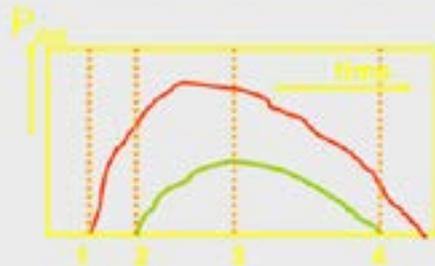

The voiding reflex starts and:

- Detrusor pressure rises (1)
- Outlet relaxes and becomes distended
  - Passive distensible...
- 'Detrusor opening pressure' when flow starts (2)
- 'Maximum flow' when distension is maximal (3)
  - Limited by FCZ
- Steady state /balanced forces until...
- Outlet collapses
  - ... collapsible tube
- 'Closing pressure' (end of flow) (4)

# Voiding phases

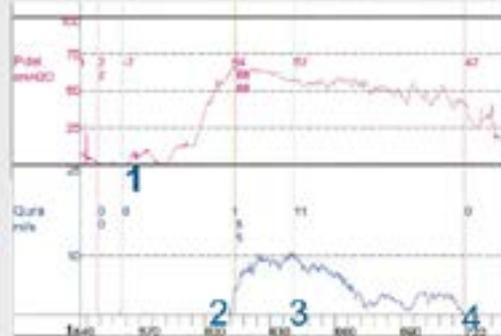

- start of voiding = detrusor pressure rise (see graph): 1 >>
- >> distension of outlet = opening pressure>start of flow: 2 >>
- >> maximum flow = beginning of 'steady state outlet'\*: 3 >>
- >> end of flow = collapse of outlet: closing pressure: 4

\* During a normal voiding there exist a balance between the forces outside and inside the bladder outlet (urethra) between 3 and 4.

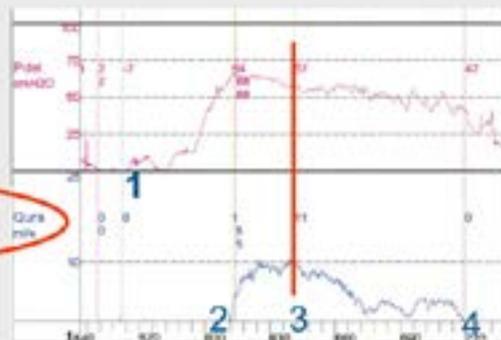

## ICS terms

- Pre -micturition pressure (1)
- Opening detrusor pressure (2)
- Opening time
- Maximum detrusor pressure
- Maximum flow (3)
- Detrusor pressure at maximum flow (3)
- Closing detrusor pressure (4)
- Minimum voiding detrusor pressure
- Flow delay time

## ICS terms

- Pre -micturition pressure (1)
  - Opening detrusor pressure (2)
  - Opening time
  - Maximum detrusor pressure
  - Maximum flow (3)
  - Detrusor pressure at maximum flow (3)
  - Closing detrusor pressure (4)
  - Minimum voiding detrusor pressure
  - Flow delay time
- Detrusor pressure at maximum flow ( $P_{detQmax}$ ) and maximum flow ( $Q_{max}$ ) are, in combination, the most relevant for the analysis of LUT voiding function

## Provisional ICS method for definition of obstruction

- Easy way to grade pressure-flow result\*:
- On the basis of:
  - Detrusor pressure at maximum flow (PdetQmax) and maximum flow (Qmax)

- calculate  $P_{det}Q_{max} - 2 \times Q_{max}$  (#)

- (pressure at maximum flow minus 2 times maximum flow rate)
- use cmH2O for pressure & ml/s for flow rate

# Provisional ICS method for definition of OBS.

\* See also ICS modules: Pressure flow testing: Advanced analysis

## Provisional ICS method for definition of obstruction

- p-ICS method is 'clinically calibrated' for elderly male patients with an enlarged prostate
  - if p-ICSmethod < 20: No BOO
  - if p-ICSmethod >40: BOO
  - if p-ICSmethod 20 to 40: Equivocal/ intermediate
- Might be interpreted for male patients with an enlarged prostate as\*: (eo)
  - No BOO: des-obstruction will not change the voiding very much
  - BOO: des-obstruction will likely be effective to improve voiding
  - Equivocal: the result of 'des-obstruction' is not predictable (50% chance of symptomatic improvement)

\* this does not take filling phase abnormalities into account

## Quality control

- Before:
  - Is the patient adequately informed and instructed?
  - Is anything changed after the indication for UDI testing was settled?
- During:
  - Are sterile catheters and filling medium used?
  - Are antiseptic procedures applied?
  - Is the patient clothed/covered as much as possible?
  - Is the patient comfortably positioned?
  - (Especially if male:) Preferred position for voiding?
  - Has everyone who is unnecessary left the site of testing?
- After:
  - Is the patient instructed to drink  $\pm$  0,5-1liter immediately after the test?

## Quality control (p/Q analysis)

- Ask the patient:
  - Was this voiding more or less as usual / as at home?
    - If not: clinical urodynamic diagnosis may be irrelevant
      - E.g: Not being able to void does frequently (but not always) not represent the real function and is therefore situative during UDI
- Observe the tracings (of the entire cystometry)
  - Are the pressures in the physiological range
  - Are the intravesical and intra abdominal pressures reacting synchronous on patients' movements and coughing (balanced pressures), also after the voiding?
  - Is permission to void adequately marked /indicated?

## Quality control (continued)

- **Observe pressure and flow:**
    - Is the time lag (meatus to flowmeter) adequately corrected?
      - May be a standard time correction per institute
    - Are flowrate artefacts visible/correctable/corrected?
    - Are pressure artefacts visible/correctable/corrected?
      - (compare cough-pressure-test before and after voiding)
    - Is post void residual urine measured?
    - Is it possible to make an adequate, complete and relevant diagnosis of lower urinary tract voiding function?
    - If not: repeat the test
  - Is a pressure-flow plot analysis needed? \*
    - Quantification of BOO may be less reliable with (severe) underactive contraction
    - Is a physiologically plausible pressure-flow 'loop' recognizable?
    - Can the lower pressure border be recognised?
    - Did automated analysis produce plausible and valid results?
- \* See ICS modules: Pressure flow testing; Advanced analysis

## Clinical Quality

- **Patients unable to void because of the test situation:**
  - Might be not unexpected ('shy voiders / shy bladder/ paruresis')
    - Allow more time; ensure absolute privacy; dim the lights
    - Allow something (cold water) to drink
    - (Sound of ) running tap-water
  - Some contraction is seen but no, or very little voiding:
    - not acontractility, not representative, BOO impossible to 'calibrate'\*
  - No contraction is observed and no voiding:
    - If patient is usually able to void:
      - not definite acontractility; not representative\*
- \*patients tend to start straining; usually not productive and not representative!
- Formal pressure flow analysis and diagnosis (outlet or contractility) of voiding (other than 'shy') is impossible now.

## Clinical Quality: Pressure flow analysis

- For (elderly) men (with a larger prostate):
  - Pressure flow (relation and) analysis is straightforward
  - Clinically applicable limits for (grading of outlet properties) exist
- For young men, women and children: (eo)
  - Basic principles of voiding and p/Q analysis are known and applicable
  - Universally agreed clinical grading of outlet properties does not exist
- Dynamic outlet obstruction /dysfunctional voiding: (eo)
  - No (standard) grading of outlet dynamics is available
  - No urodynamic (pressure flow relation) criteria
- Neurogenic dyssynergia or neurogenic dynamic outlet obstruction: (eo)
  - No (standard) grading is available
  - No urodynamic (pressure flow relation) criteria
    - However (detrusor) Leak Point Pressure is relevant

## Pressure flow analysis: concluding

- Flow relates to pressure and is determined (or limited) by outlet properties
  - Representative voiding and clinically relevant pressure flow analysis depends on good urodynamic practice and properly ascertained patient cooperation
  - A very unrepresentative voiding and -or significant underactive detrusor contraction limit the validity of the pressure flow analysis
- Pressure flow starts: after permission to void
- Bladder outlet obstruction can be graded by:
  - p-ICS-method =  $P_{det} Q_{max} - 2 \times Q_{max}$

<sup>5</sup>University of Pennsylvania Health System - Division of Urology, Philadelphia, Pennsylvania

**Aims:** To present the evidence background for an ICS teaching module for the urodynamic analysis of voiding.

**Methods:** Literature analysis and expert opinion are combined to collate an outline and explanation of a preferred and good urodynamic practice. **Result:** Patient's preparation, pathophysiology, technique and principles of pressure flow analysis are summarized in this manuscript. **Conclusions:** This manuscript serves as scientific background for a slides set, made available on the ICS website to teach the basic and practical elements of pressure flow analysis. *NeuroUrol. Urodynam.* 35:36–38, 2016. © 2014 Wiley Periodicals, Inc.

**Key words:** bladder outlet obstruction; diagnosis; pressure flow analysis; review; teaching module; underactive detrusor; voiding

### INTRODUCTION

The ICS Urodynamics Committee presents the teaching module Analysis of Voiding; Pressure Flow Analysis-basic module to serve as a standard education of Good Urodynamic Practice for everyone involved in indicating, performing, and analyzing urodynamic testing in general and more specifically, performing analysis of voiding. The teaching module consists of a presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base, for the ICS Power Point presentation; available via <http://www.icsoffice.org/eLearning/>. The presentation explains normal physiology, testing requirements, pressure flow analysis methods, and introduces the nomograms. The presentation and this manuscript uses experts opinion where evidence is, especially for the clinical practice aspects, unavailable and is marked with:<sup>eo</sup> (experts' opinion).

### PREPARATION OF THE PATIENT

Urodynamic testing requires an optimally informed patient, after adequate relevant medical history, systematic symptoms analysis, laboratory, and clinical (neuro-gyneco-urological) exam and, preferably, at least one, not-catheterized (free) flowmetry with post-void residual determination.<sup>1–3</sup> Pressure flow analysis is the element of urodynamic testing to diagnose voiding dysfunction. Although voiding is, plausibly, negatively influenced by the shift of the autonomic system to sympatral dominance in the situation of mental stress, there is not very much evidence, that voiding in laboratory circumstances is unacceptably unrepresentative.<sup>eo</sup> Some indirect evidence exists that differences between office and home are not large in (elderly) male,<sup>4,5</sup> as long as the bladder is not uncomfortably full.<sup>6</sup> Perceivably, it is patient friendly to ensure adequate draping, normal seating (or standing, if preferred by the –male patient) and maximum possible privacy during voiding as well as quiet, relaxing circumstances with as little number as possible persons involved during urodynamic testing.<sup>eo</sup>

Infection prophylaxis necessitates sterile catheterization but for this short time catheterization in the noncompromised

patient prophylactic antibiotics is unnecessary.<sup>7,eo</sup> Laxatives are also unnecessary and might cause unwanted bowel (over) activity and fecal urgency during the test, but is advantageous to ask the patient to arrive with an empty bowel if possible.<sup>eo</sup> If high incidences of urinary tract infections after urodynamic testing are observed in a given practice, the first step should be that the procedures are changed so that strict antisepsis is followed.<sup>eo</sup> Thin (6–8F) double lumen or micro tip with lumen catheters for intravesical filling and pressure recording are advised<sup>2</sup> with adequate fixation alongside the meatus over the penis or a labium.

### PATHOPHYSIOLOGY

Voiding is an autonomic reflex that is, in the normal situation, initiated through voluntary and conscious pelvic floor relaxation. The detrusor dome, when parasympatically activated delivers the energy to void. The bladder outlet or bladderneck (or autonomic sphincter) relaxes as a result of inhibition of sympathetic input and allows emptying. The normal outlet controls the flow by passive distension and through its visco-elasticity. The outlet collapses when the intravesical pressure is too low to overcome the forces that close the outlet.<sup>8</sup> Typically, reduced patency of the bladder outlet through an enlarged prostate or a urethral stricture, is limiting the (maximum) flowrate and driving the detrusor muscle to higher power contraction, thus higher intravesical pressures, during voiding.

Christopher Chapple led the peer-review process as the Associate Editor responsible for the paper.

Clinical nomograms to quantify pressure flow analysis results in a standard manner are available for symptomatic elderly male with an enlarged prostate.<sup>9-11</sup> All of those methods give very consistent results.<sup>12,13</sup> Women (and young men) voiding dynamics differs from elderly men because there is no prostate to act as a stable nozzle and pressure flow nomograms are more difficult to construct. Time based pressure and flow graphs allow judgement of the voiding; post processing with pressure and flow on an X-Y graph is possible on all contemporary urodynamic equipment, and allows precise appreciation of bladder outlet obstruction (BOO) and outlet dynamics throughout voiding. Nevertheless, good quality and plausibility control as well as an evaluation of clinical representativity are necessary.<sup>2</sup>

## TECHNIQUE AND INTERPRETATION

### Technique

Pressure flow starts after permission to void and hesitancy can be recognized if that permission is precisely marked. More important, permission to void indicates the end of storage phase and differentiates between detrusor overactivity (DO) and detrusor voiding contraction; DO to be diagnosed only in the storage phase.

Pressure flow analysis relies on the simultaneous recording of pressures and flow. Pressures in the storage phase are interpreted as pattern; DO or reduced compliance, and there is no evidence that the absolute pressures play a role. In pressure flow analysis however, the absolute pressures, referred to atmospheric pressure, are relevant for the clinical interpretation with the nomograms (v.i.).

There is no specific evidence for the preferred position during pressure flow testing. Plausibly women shall perform best while comfortably sitting, however, many women never really sit on the toilet, or are used to squat.<sup>14,15</sup> Sitting uncomfortably and voiding in a manner that does not adequately represent the usual way of voiding may likely occur on a videourodynamic equipment, because of the restrictions of the equipment. More in general: in the semi recumbent, supine, or gynecological position, voiding can hardly be as usual, however, direct comparative evidence is lacking.<sup>60</sup> As in adults, position is of influence for storage phase results, but the relevance of voiding position seems not studied in children and is not mentioned in the standard.<sup>16,17</sup> Free flow in men is, in group-wise comparisons, influenced by position, however, individuals might have a preferred position and the possibility to allow the patient preferred position seems relevant.<sup>18-20</sup> To include the lag-time from meatus to flow recording is necessary in any way,<sup>21</sup> but a very short meatus to flowmeter distance is beneficial.<sup>60</sup>

If the patient's position is changed during the test, external pressure transducers (if used) must be adjusted to the height of the symphysis pubis again.

### Interpretation

Analysis of bladder outlet obstruction is done on the second, passive phase of micturition, usually from the moment maximum of flow when detrusor and outlet act in a steady state and are in balance.<sup>9,10</sup> Before maximum flow, pelvic floor relaxation and outlet distension dynamics are predominant, but after maximum flow, the true passive outlet resistance is obtained. Pressure at maximum flow in combination with corresponding maximum flow gives a clinically relevant grading of bladder outlet obstruction when used in a formula.<sup>11</sup>

This grading number is presented, and subsequently adopted, as the ICS-obstruction number.<sup>22,23</sup>

Likewise, maximum of detrusor contraction (or contractility) can be calculated with the ICS contraction number.<sup>22</sup> Detrusor contraction power during voiding can also be calculated throughout the entire voiding<sup>24</sup> and relates to bladder outlet obstruction and affectivity of voiding.<sup>25</sup> Both analysis methods give similar results.<sup>26</sup>

Analysis of female micturition is less standardized but follows the principles as mentioned here above. There is usually more flowrate and pressure variation during the time of one female voiding. Most women however, empty with high peak flowrates and because high flowrate rules out static outlet obstruction, outlet dynamics is the cause of variation here. Relatively high detrusor pressure during voiding is also in women regarded as a sign of (static) bladder outlet obstruction.<sup>27</sup> This is captured in a nomogram that integrates maximum of (not catheterized) free flowrate with a minimum cut-off pressure, to be observed during voiding cystometry or with observations during radiography.<sup>28,29</sup> Although frequently used, in variations of application, this nomogram has never been ICS-standard. Pressure at maximum flow is at present accepted as the most relevant parameter.<sup>30</sup>

Pressure flow voiding can occur in a manner that does not represent the patients' usual behaviour. Comparison with free flowmetry and asking the patients' opinion in this regard are valuable.<sup>60</sup>

Artefacts arise when the (intravesical pressure recording) catheter is slipping out during voiding. This can be suspected already from the pressure recording during voiding and also from the pressures response on cough testing after voiding.<sup>2</sup> All artefacts that are known from uroflowmetry are to be expected, and should be controlled for, also in pressure flow cystometry.<sup>2,31</sup>

Very low pressure-voiding, inability to void, or to inability to initiate a full voiding reflex as usual, limits the applicability of pressure flow analysis. Especially in shy voiders, it can become a problem to objectively diagnose the bladder outlet properties, or the real ability of the detrusor muscle to generate sufficient pressure. However, if (little) fluid leaves the bladder during a weak or incomplete voiding reflex, serious bladder outlet obstruction is relatively unlikely when this happens with low pressure, although the level of uncertainty of this diagnosis is high.

## CONCLUSIONS

Pressure flow analysis is the golden standard for the analysis of voiding. For male patients, precise and clinically relevant limits for bladder outlet obstruction are available. For female and children, the limits are less precisely defined however, on the basis of what can be expected from normal lower urinary tract physiology, closely linked to the methods and nomograms that are calibrated for male patients. Strict adherence to antisepsis and a patient-centred approach before, during and after testing limits unwanted effects and enhances representativity. Adherence to good urodynamic practice standards, with adequate reference to atmospheric pressure ensures optimal quality of analysis and diagnosis. This ICS educational module provides the background for the basic education of the analysis of voiding in patient with lower urinary tract symptoms.

# Best Practices: Basic Care in Indwelling Urinary Catheter Management

January 2016

Mary H. Wilde, PhD, RN

Professor, School of Nursing, University of Rochester, USA  
Member of the ICS Nurses' Committee

ICS

International Continence Society  
Teaching Module

## Objectives

- Our purpose is to educate continence nurses to improve patient care and health outcomes globally.

At the conclusion of this presentation, readers should be able to:

- 1. Describe best practices for basic care of people using indwelling urinary catheters.
- 2. Understand the differences and similarities in shorter-term care in acute settings as compared with long-term care in the community.

## Prevalence of catheter use

### Prevalence in the USA:

- Acute care, 15-25%; 5% nursing homes (Gould et al. HCPAC, 2009)
- Long term catheter users overall estimate is 153,818.
  - 9% home care ;33% hospice (National Home and Hospice Study, 2007 [cdc.gov/pub/Health/Statistics/NCHS/Datasets/NHHS/2007](http://cdc.gov/pub/Health/Statistics/NCHS/Datasets/NHHS/2007))
  - 34% in home care were long-term users (Wilde et al. 2010)
  - Spinal cord injury– 23% of those discharged from rehabilitation, but some use an intermittent catheter later. (Cameron et al., 2010)

### Prevalence in England:

- England & Wales, 19 hospitals 1997 cited by Scottish Nurses Association, 26.3% in acute care, range 12-40% depending on specialty (Glynn et al. 1997)
- England, survey in acute care, 18%, varied by specialty, more in ICU. HPA survey on HCAI and antimicrobial use across acute hospitals in England (2011)
- England, 0.07% community study of 827,595 over two years (0.05%  $\geq$  75 yrs old) (Kohler-Ochmore & Fenley 1996)

## Indications for short-term catheter use

- Urinary retention or bladder outlet obstruction
- Improving comfort for end-of-life care if needed
- Critically-ill and need for accurate measurements of I&O (e.g., hourly monitoring)
- Selected surgical procedures (GU surgery/colorectal surgery)
- Assist in healing open sacral or perineal wound in the incontinent patient
- Intraoperative monitoring of urinary output during surgery or large volumes of fluid or diuretics anticipated
- Prolonged immobilization (e.g., potentially unstable thoracic or lumbar spine, multiple traumatic injuries such as pelvic fractures)

<http://nursingworld.org/CAMI/1-1-04> (based on USA CDC guidelines, Gould et al. 2009)

## Indications for long-term catheter use

- Intractable **urinary retention** for those who cannot manage an intermittent catheter (and no caregiver to do it)
- **Bladder outlet obstruction**, not surgically treated
- Improving comfort for **end-of-life care** if needed
- **Alternatives to consider**: toileting schedule (when no retention), intermittent catheter, condom/sheath catheter (for cooperative males without obstructed urine or persistent retention )

(USA CDC guidelines, Gould et al. 2009)

## Short & long-term catheter use defined:

- **Short term**- less than 1 months' expected use
  - Can be longer, failing trial without catheter
- **Long term**- over 1 months use but often extends over many years.
  - "Indefinite use" would be more accurate term, but no agreement on terminology.
- Both "catheter types" and "catheter use" for expected time of catheterization are called short and long-term, causing confusion. (Cottenden et al. 2013)

## Short term catheter types

- Short term use—less than 14 days' expected use
  - **Latex or plastic**, but caution related to latex allergy.
  - **Coated catheters** (silver alloy, nitrofurazone or minocycline/rifampicin) for up to two weeks
    - Can decrease bacteriuria but do not prevent symptomatic UTI & evidence is weak.
    - Can be uncomfortable and are more expensive. (Lam et al., 2014)
- **Long term catheter types** also can be used. (Cottenden et al., 2013).

## Long term catheter types

- Can be used for 28 days and up to 12 weeks, dependent on local policy.
  - **Latex coated poly-tetrafluoro-ethylene (PTFE or Teflon)**
  - **Silicone** elastomer-coated latex or 100% silicone (harder surface but wider lumen). Balloon water can evaporate quicker in pure silicone catheters. Take care to prevent traction as erosion of penis has occurred with silicone.
  - **Hydrogel** polymer-coated latex (softer which can be of benefit) Hydrogel less likely to form suprapubic catheter "deflation cuff". (Parkin, 2002; Jahn et al. 2012; Cottenden et al. 2013)

## Catheter sizes

**Catheter sizes** (Fr= French which is the same as Charrière or Ch) **Use the smallest size** that permits flow and to prevent potential trauma to urethra and sphincter.

- 12-16 Fr for men and 12-14 Fr for women.
- Children: 5-6 Fr for newborns ; 5-10 Fr toddlers to children to age 12

**Balloons** 5-10 mL. (30mL only for postoperative bleeding), 2.5-5mL for children

(WOCN, Indwelling Urinary Catheters, Best Practices for Clinicians, 2009; Cottenden et al. 2013)

ICS Teaching Module

## Catheter insertion

- Long term catheters often changed every 4 weeks. People with frequent blockage can need it every 2-3 weeks or more often. Can extend to 6-8 weeks if no problems.
- Observe several changes for “catheter life pattern.” (Getliffe, 1994)
- Good lighting, and help of another if spasticity in legs.
- Use sterile gloves.
- Lubricate catheter well, especially for males.
- **For Males:**
  - Insert all the way to Y (bifurcation) to prevent catheter being inflated within the urethra.
  - If resistance is felt, encourage deep breaths and distraction.
- **For females:** Urethra can be short, especially in older women.
  - Insert 1” further than point of urine flow.
  - Fill balloon all the way to 10mL.

(ANA CAUTI prevention, 2015 <http://nursingworld.org/ANA-CAUTI-Prevention-100>; Wilde & Feng, 2013)

ICS Teaching Module

## Catheter securement

- Nurses often recommend but not use it:
  - Of 82 nurses (8 continence specialists), 98% recommended but only 4% used it. (Siegel, 2006);
  - 18% secured in acute care in one day point-prevalence study (N= 8 of 44) (Appah et al. 2015)
- Securement could **prevent dislodgement and urethral/bladder neck trauma**
  - **Adhesive**—good for those likely to dislodge but irritating to skin
  - **Non-adhesive**—prevent constricting circulation (Wilde & Feng, 2013)

## Securement examples

• Non-adhering

Adhering

Holster

## General catheter care

- **Hand hygiene** before and after catheter care. In home, teach family.
- If **breaks in the closed system** (e.g., disconnection, cracked tubing), **replace** the catheter and tubing.
- Perform **perineal hygiene** at a minimum daily, per facility protocol/procedure and as needed. Soap and water is all that is needed most often.
- Use **fecal containment device** when appropriate for **fecal incontinence**.

ANA CAUTI prevention, 2015 <http://nursingworld.org/ANA-CAUTI-Prevention-Tool>

ICS Teaching Module

## Drainage bags

- **Closed drainage essential in acute care, short term use.**
  - It is the only proven method of decreasing UTI. (Kunin & McCormack, 1966)
- **Types:**
  - Overnight (2000-4000mL)
  - Leg bags (270-1000 mL.)
  - Belly bag (with normal bladder pressure) (WOCN, 2009)
- **Prevent kinks/twists in tubing:** Blocked urine flow can contribute to damage to the kidneys (Feneley et al. 2015)
- **Keep bag at least 12" below the level of the bladder and off the floor to prevent suction of the catheter eyes on the bladder mucosa.** (Glahn et al. 1988)

ICS Teaching Module

## Care for drainage bags

- Empty the drainage bag regularly using a **separate, clean collecting container for each patient**; avoid splashing, and prevent contact of the drainage spout. <http://nursingworld.org/ANA-CAUTI-Prevention-Tool>
- Empty when **1/3 to 1/2 full**.
- For long-term catheter users, replace drainage bags weekly.
- No evidence that connecting a catheter to a leg bag continuously & then hooking up an overnight bag is beneficial. (Cottenden et al. 2013)

## Cleaning & reuse of drainage bags

- **Systematic review revealed need for research in this area.**
  - Conflicting guidelines and research virtually lacking since 1990s. (Wilde, Fader et al. 2013)
- In a U.S. study of 202 long-term catheter users, most switched between leg and night bag
  - 54% cleaned leg bags & 59% night bags. (Wilde, McDonald, et al. 2013)
  - Rehabilitation nurses have used mild bleach (1 part household bleach to 10 parts water). (Dille & Kirchoff, 1993; Dille et al. 1993)
- In home care **in the past**: vinegar was recommended (1 part vinegar to 4 parts water) (Wilde, 1986)

## Irrigation (also called flushing or washouts)

- **Irrigation not recommended.** Sometimes used in hospitals to remove blood clots post operatively.
- In one U.S. study of 202 long term catheter users , 42% irrigated and 18% once or more a day.
  - Solutions were saline (76%) and sterile water (23%).
  - Surprising, 9% used plain tap water, which could have bacteria or other impurities in it.
  - 4% used Renacidin --not readily available in the US and made fresh in a pharmacy. (Wilde, McDonald et al. 2013)

## Irrigation sachets

- Irrigation sachets (**Suby G and Suby R**, called catheter maintenance solutions) are available in the United Kingdom, and in some other countries, **to dissolve encrustations if change is not appropriate.** These solutions are not available in every country.
  - **Saline or sterile water is not effective in breaking up encrustations.**
  - Research in Canada testing saline, no irrigation and Suby G showed no difference in decreasing time to change but underpowered. (Moore et al., 2009)
  - There is a desperate need for irrigation solutions which are **effective, easily obtained and used, inexpensive, and safe.**

## Symptoms CAUTI- short term catheter users

- In acute care diagnosis of CAUTI, catheter in place 2> days:
- 1. At least **one symptom below with no other recognized cause**:
  - fever (>38.0°C) • suprapubic tenderness • costovertebral angle pain or tenderness • urinary urgency • urinary frequency • dysuria
- 2. **AND urine culture with no more than two microorganism  $\geq 10^5$  CFU/m**
  - <http://www.cdc.gov/nhsn/pdfs/pscManual/7pscCAUTIcurrent.pdf>
- **Differential diagnosis not simple** to identify source of infection
  - Fever-- without other possible source, comorbidities confound
  - Bacteriuria (Lo et al., 2014)

## Symptoms CAUTI--long term catheters

- **Urine Changes:**
    - Color – Discolored, cloudy, dark, blood stained
    - Odor – Foul smelling, change in smell from usual
    - Sediment (grit) – Increased amount
  - **Temperature** – Fever, chills
  - **Pain and/or pressure** in bladder area or back (Burning possible, not common)
- Early, mild symptoms of autonomic dysreflexia (e.g., goosebumps, headaches, sweats) mainly in people with spinal cord injury
- General Symptoms** Blahs!, feeling sick
- Functioning or mental changes – weakness, spasticity, change in the level of alertness (Wilde, McDonald et al., 2013)

## CAUTI prevention

- Do not insert indwelling catheter if bladder management is possible any other way, e.g., condom catheter (sheath, external) or intermittent catheter (including caregiver performing or assisting).
- Remove catheter as soon as possible.
- Track CAUTI rate systematically:  

$$\frac{\text{Events of symptomatic UTI}}{\text{Catheter days' use (number of persons X days catheter used)}} \times 1000$$
- Encourage staff and celebrate when CAUTI rate & usage of catheters decreases.
- In acute care, a daily order for catheter continued use is recommended.
- In community, assess regularly whether indwelling is still needed.
- Checkout this important document from the USA, American Nurses' Association: ANA CAUTI prevention, 2015 <http://nursingworld.org/ANA-CAUTI-Prevention-tool>

## **Abbreviations**

ADL	Activities of daily living
APACHE II	Acute Physiology and Chronic Health Evaluation II
ASA	American Society of Anesthesiologists
ASB	Asymptomatic bacteriuria
BUN	Blood urea nitrogen
CAUTI	Catheter-associated urinary tract infection
CDC	Centers for Disease Control and Prevention
CFU	Colony-forming units
CI	Confidence interval
CIC	Clean intermittent catheterization
CICU	Coronary intensive care unit
COPD	Chronic obstructive pulmonary disease
ED	Emergency department
F/U	Follow-up
GRADE	Grading of Recommendations Assessment, Development, and Evaluation system
Hb	Hemoglobin concentration
HICPAC	Healthcare Infection Control Practices Advisory Committee
H/O	History of
HPF	High power field
HR	Hazard ratio
ICU	Intensive care unit
IDR	Incidence-density ratio
LOS	Length of stay
MDR	Multi-drug resistant
MICU	Medical intensive care unit
NHSN	National Healthcare Safety Network
NIH	National Institutes of Health
NS	Not significant
OBS	Observational controlled study
OR	Odds ratio
P	P value
PACU	Post-anesthesia care unit
PVC	Polyvinyl chloride

RCT	Randomized controlled trial
RD	Risk difference
RH	Relative hazard
RR	Relative risk
SAPS II	Simplified Acute Physiology Score II
SICU	Surgical intensive care unit
SR	Systematic review
SUTI	Symptomatic urinary tract infection
TMP/SMX	Trimethoprim/sulfamethoxazole
TURP	Transurethral resection of prostate
UTI	Urinary tract infection
VAS	Visual analog scale
WMD	Weighted mean difference

## **I. Executive Summary**

This guideline updates and expands the original Centers for Disease Control and Prevention (CDC) Guideline for Prevention of Catheter-associated Urinary Tract Infections (CAUTI) published in 1981. Several developments necessitated revision of the 1981 guideline, including new research and technological advancements for preventing CAUTI, increasing need to address patients in non-acute care settings and patients requiring long-term urinary catheterization, and greater emphasis on prevention initiatives as well as better defined goals and metrics for outcomes and process measures. In addition to updating the previous guideline, this revised guideline reviews the available evidence on CAUTI prevention for patients requiring chronic indwelling catheters and individuals who can be managed with alternative methods of urinary drainage (e.g., intermittent catheterization). The revised guideline also includes specific recommendations for implementation, performance measurement, and surveillance. Although the general principles of CAUTI prevention have not changed from the previous version, the revised guideline provides clarification and more specific guidance based on a defined, systematic review of the literature through July 2007. For areas where knowledge gaps exist, recommendations for further research are listed. Finally, the revised guideline outlines high-priority recommendations for CAUTI prevention in order to offer guidance for implementation.

This document is intended for use by infection prevention staff, healthcare epidemiologists, healthcare administrators, nurses, other healthcare providers, and persons responsible for developing, implementing, and evaluating infection prevention and control programs for healthcare settings across the continuum of care. The guideline can also be used as a resource for societies or organizations that wish to develop more detailed implementation guidance for prevention of CAUTI.

Our goal was to develop a guideline based on a targeted systematic review of the best available evidence, with explicit links between the evidence and recommendations. To accomplish this, we used an adapted GRADE system approach for evaluating quality of evidence and determining strength of recommendations. The methodology, structure, and components of this guideline are approved by HICPAC and will be used for subsequent guidelines issued by HICPAC. A more detailed description of our approach is available in the [Methods](#) section.

To evaluate the evidence on preventing CAUTI, we examined data addressing three key questions and related subquestions:

1. Who should receive urinary catheters?
  - A. When is urinary catheterization necessary?
  - B. What are the risk factors for CAUTI?
  - C. What populations are at highest risk of mortality related to urinary catheters?
2. For those who may require urinary catheters, what are the best practices?
 

Specifically, what are the risks and benefits associated with:

  - A. Different approaches to catheterization?
  - B. Different catheters or collecting systems?
  - C. Different catheter management techniques?
  - D. Different systems interventions (i.e., quality improvement programs)?
3. What are the best practices for preventing CAUTI associated with obstructed urinary catheters?

Evidence addressing the key questions was used to formulate recommendations, and explicit links between the evidence and recommendations are available in the [Evidence Review](#) in the body of the guideline and [Evidence Tables](#) and [GRADE Tables](#) in the [Appendices](#). **It is important to note that Category I recommendations are all considered strong recommendations and should be equally implemented**; it is only the *quality* of the evidence underlying the recommendation that distinguishes between levels A and B. Category IC recommendations are required by state or federal regulation and may have any level of supporting evidence.

The categorization scheme used in this guideline is presented in Table 1 in the [Summary of Recommendations](#) and described further in the [Methods section](#).

The [Summary of Recommendations](#) is organized as follows: 1) recommendations for who should receive indwelling urinary catheters (or, for certain populations, alternatives to indwelling catheters); 2) recommendations for catheter insertion; 3) recommendations for catheter maintenance; 4) quality improvement programs to achieve appropriate placement, care, and removal of catheters; 5) administrative infrastructure required; and 6) surveillance strategies.

The [Implementation and Audit](#) section includes a prioritization of recommendations (i.e., high-priority recommendations that are essential for every healthcare facility), organized by modules, in order to provide facilities more guidance on implementation of these guidelines. A list of recommended performance measures that can potentially be used for internal reporting purposes is also included.

Areas in need of further research identified during the evidence review are outlined in the [Recommendations for Further Research](#). This section includes guidance for specific methodological approaches that should be used in future studies.

Readers who wish to examine the primary evidence underlying the recommendations are referred to the [Evidence Review](#) in the body of the guideline, and the [Evidence Tables](#) and [GRADE Tables](#) in the [Appendices](#). The [Evidence Review](#) includes narrative summaries of the data presented in the [Evidence Tables](#) and [GRADE Tables](#). The [Evidence Tables](#) include all study-level data used in the guideline, and the [GRADE Tables](#) assess the overall quality of evidence for each question. The [Appendices](#) also contain a clearly delineated search strategy that will be used for periodic updates to ensure that the guideline remains a timely resource as new information becomes available.

## II. Summary of Recommendations

Category IA	A strong recommendation supported by high to moderate quality† evidence suggesting net clinical benefits or harms
Category IB	A strong recommendation supported by low quality evidence suggesting net clinical benefits or harms or an accepted practice (e.g., aseptic technique) supported by low to very low quality evidence
Category IC	A strong recommendation required by state or federal regulation.
Category II	A weak recommendation supported by any quality evidence suggesting a trade off between clinical benefits and harms
No recommendation/ unresolved issue	Unresolved issue for which there is low to very low quality evidence with uncertain trade offs between benefits and harms

\* Please refer to Methods (p.32) for implications of Category designations

†Please refer to Methods (p. 29-30) for process used to grade quality of evidence

### I. Appropriate Urinary Catheter Use

- A. Insert catheters only for appropriate indications (see Table 2 for guidance), and leave in place only as long as needed. **(Category IB)** (Key Questions 1B and 2C)
1. Minimize urinary catheter use and duration of use in all patients, particularly those at higher risk for CAUTI or mortality from catheterization such as women, the elderly, and patients with impaired immunity. **(Category IB)** (Key Questions 1B and 1C)
  2. Avoid use of urinary catheters in patients and nursing home residents for management of incontinence. **(Category IB)** (Key Question 1A)
    - a. Further research is needed on periodic (e.g., nighttime) use of external catheters (e.g., condom catheters) in incontinent patients or residents and the use of catheters to prevent skin breakdown. **(No recommendation/unresolved issue)** (Key Question 1A)
  3. Use urinary catheters in operative patients only as necessary, rather than routinely. **(Category IB)** (Key Question 1A)
  4. For operative patients who have an indication for an indwelling catheter, remove the catheter as soon as possible postoperatively, preferably within 24 hours, unless there are appropriate indications for continued use. **(Category IB)** (Key Questions 2A and 2C)

<b>Table 2.</b>
<b>A. Examples of Appropriate Indications for Indwelling Urethral Catheter Use</b> <sup>1-4</sup>
Patient has acute urinary retention or bladder outlet obstruction
Need for accurate measurements of urinary output in critically ill patients
Perioperative use for selected surgical procedures: <ul style="list-style-type: none"> <li>• Patients undergoing urologic surgery or other surgery on contiguous structures of the genitourinary tract</li> <li>• Anticipated prolonged duration of surgery (catheters inserted for this reason should be removed in PACU)</li> <li>• Patients anticipated to receive large-volume infusions or diuretics during surgery</li> <li>• Need for intraoperative monitoring of urinary output</li> </ul>
To assist in healing of open sacral or perineal wounds in incontinent patients
Patient requires prolonged immobilization (e.g., potentially unstable thoracic or lumbar spine, multiple traumatic injuries such as pelvic fractures)
To improve comfort for end of life care if needed
<b>B. Examples of Inappropriate Uses of Indwelling Catheters</b>
As a substitute for nursing care of the patient or resident with incontinence
As a means of obtaining urine for culture or other diagnostic tests when the patient can voluntarily void
For prolonged postoperative duration without appropriate indications (e.g., structural repair of urethra or contiguous structures, prolonged effect of epidural anaesthesia, etc.)

Note: These indications are based primarily on expert consensus.

- B. Consider using alternatives to indwelling urethral catheterization in selected patients when appropriate.
1. Consider using external catheters as an alternative to indwelling urethral catheters in cooperative male patients without urinary retention or bladder outlet obstruction. **(Category II)** (Key Question 2A)
  2. Consider alternatives to chronic indwelling catheters, such as intermittent catheterization, in spinal cord injury patients. **(Category II)** (Key Question 1A)
  3. Intermittent catheterization is preferable to indwelling urethral or suprapubic catheters in patients with bladder emptying dysfunction. **(Category II)** (Key Question 2A)
  4. Consider intermittent catheterization in children with myelomeningocele and neurogenic bladder to reduce the risk of urinary tract deterioration. **(Category II)** (Key Question 1A)
  5. Further research is needed on the benefit of using a urethral stent as an alternative to an indwelling catheter in selected patients with bladder outlet obstruction. **(No recommendation/unresolved issue)** (Key Question 1A)
  6. Further research is needed on the risks and benefits of suprapubic catheters as an alternative to indwelling urethral catheters in selected patients requiring short- or long-term catheterization, particularly with respect to complications related to catheter insertion or the catheter site. **(No recommendation/unresolved issue)** (Key Question 2A)

## II. Proper Techniques for Urinary Catheter Insertion

- A. Perform hand hygiene immediately before and after insertion or any manipulation of the catheter device or site. **(Category IB)** (Key Question 2D)
- B. Ensure that only properly trained persons (e.g., hospital personnel, family members, or patients themselves) who know the correct technique of aseptic catheter insertion and maintenance are given this responsibility. **(Category IB)** (Key Question 1B)
- C. In the acute care hospital setting, insert urinary catheters using aseptic technique and sterile equipment. **(Category IB)**
  - 1. Use sterile gloves, drape, sponges, an appropriate antiseptic or sterile solution for periurethral cleaning, and a single-use packet of lubricant jelly for insertion. **(Category IB)**
  - 2. Routine use of antiseptic lubricants is not necessary. **(Category II)** (Key Question 2C)
  - 3. Further research is needed on the use of antiseptic solutions vs. sterile water or saline for periurethral cleaning prior to catheter insertion. **(No recommendation/unresolved issue)** (Key Question 2C)
- D. In the non-acute care setting, clean (i.e., non-sterile) technique for intermittent catheterization is an acceptable and more practical alternative to sterile technique for patients requiring chronic intermittent catheterization. **(Category IA)** (Key Question 2A)
  - 1. Further research is needed on optimal cleaning and storage methods for catheters used for clean intermittent catheterization. **(No recommendation/unresolved issue)** (Key Question 2C)
- E. Properly secure indwelling catheters after insertion to prevent movement and urethral traction. **(Category IB)**
- F. Unless otherwise clinically indicated, consider using the smallest bore catheter possible, consistent with good drainage, to minimize bladder neck and urethral trauma. **(Category II)**
- G. If intermittent catheterization is used, perform it at regular intervals to prevent bladder overdistension. **(Category IB)** (Key Question 2A)
- H. Consider using a portable ultrasound device to assess urine volume in patients undergoing intermittent catheterization to assess urine volume and reduce unnecessary catheter insertions. **(Category II)** (Key Question 2C)
  - 1. If ultrasound bladder scanners are used, ensure that indications for use are clearly stated, nursing staff are trained in their use, and equipment is adequately cleaned and disinfected in between patients. **(Category IB)**

### III. Proper Techniques for Urinary Catheter Maintenance

- A. Following aseptic insertion of the urinary catheter, maintain a closed drainage system **(Category IB)** (Key Question 1B and 2B)
  - 1. If breaks in aseptic technique, disconnection, or leakage occur, replace the catheter and collecting system using aseptic technique and sterile equipment. **(Category IB)**
  - 2. Consider using urinary catheter systems with preconnected, sealed catheter-tubing junctions. **(Category II)** (Key Question 2B)
- B. Maintain unobstructed urine flow. **(Category IB)** (Key Questions 1B and 2D)
  - 1. Keep the catheter and collecting tube free from kinking. **(Category IB)**
  - 2. Keep the collecting bag below the level of the bladder at all times. Do not rest the bag on the floor. **(Category IB)**
  - 3. Empty the collecting bag regularly using a separate, clean collecting container for each patient; avoid splashing, and prevent contact of the drainage spigot with the nonsterile collecting container. **(Category IB)**
- C. Use Standard Precautions, including the use of gloves and gown as appropriate, during any manipulation of the catheter or collecting system. **(Category IB)**
- D. Complex urinary drainage systems (utilizing mechanisms for reducing bacterial entry such as antiseptic-release cartridges in the drain port) are not necessary for routine use. **(Category II)** (Key Question 2B)
- E. Changing indwelling catheters or drainage bags at routine, fixed intervals is not recommended. Rather, it is suggested to change catheters and drainage bags based on clinical indications such as infection, obstruction, or when the closed system is compromised. **(Category II)** (Key Question 2C)
- F. Unless clinical indications exist (e.g., in patients with bacteriuria upon catheter removal post urologic surgery), do not use systemic antimicrobials routinely to prevent CAUTI in patients requiring either short or long-term catheterization. **(Category IB)** (Key Question 2C)
  - 1. Further research is needed on the use of urinary antiseptics (e.g., methenamine) to prevent UTI in patients requiring short-term catheterization. **(No recommendation/unresolved issue)** (Key Question 2C)
- G. Do not clean the periurethral area with antiseptics to prevent CAUTI while the catheter is in place. Routine hygiene (e.g., cleansing of the meatal surface during daily bathing or showering) is appropriate. **(Category IB)** (Key Question 2C)
- H. Unless obstruction is anticipated (e.g., as might occur with bleeding after prostatic or bladder surgery) bladder irrigation is not recommended. **(Category II)** (Key Question 2C)

1. If obstruction is anticipated, closed continuous irrigation is suggested to prevent obstruction. **(Category II)**
- I. Routine irrigation of the bladder with antimicrobials is not recommended. **(Category II)** (Key Question 2C)
- J. Routine instillation of antiseptic or antimicrobial solutions into urinary drainage bags is not recommended. **(Category II)** (Key Question 2C)
- K. Clamping indwelling catheters prior to removal is not necessary. **(Category II)** (Key Question 2C)
- L. Further research is needed on the use of bacterial interference (i.e., bladder inoculation with a nonpathogenic bacterial strain) to prevent UTI in patients requiring chronic urinary catheterization. **(No recommendation/unresolved issue)** (Key Question 2C)

#### *Catheter Materials*

- M. If the CAUTI rate is not decreasing after implementing a comprehensive strategy to reduce rates of CAUTI, consider using antimicrobial/antiseptic-impregnated catheters. The comprehensive strategy should include, at a minimum, the high priority recommendations for urinary catheter use, aseptic insertion, and maintenance (see Section III. Implementation and Audit). **(Category IB)** (Key Question 2B)
  1. Further research is needed on the effect of antimicrobial/antiseptic-impregnated catheters in reducing the risk of symptomatic UTI, their inclusion among the primary interventions, and the patient populations most likely to benefit from these catheters. **(No recommendation/unresolved issue)** (Key Question 2B)
- N. Hydrophilic catheters might be preferable to standard catheters for patients requiring intermittent catheterization. **(Category II)** (Key Question 2B)
- O. Silicone might be preferable to other catheter materials to reduce the risk of encrustation in long-term catheterized patients who have frequent obstruction. **(Category II)** (Key Question 3)
- P. Further research is needed to clarify the benefit of catheter valves in reducing the risk of CAUTI and other urinary complications. **(No recommendation/unresolved issue)** (Key Question 2B)

#### *Management of Obstruction*

- Q. If obstruction occurs and it is likely that the catheter material is contributing to obstruction, change the catheter. **(Category IB)**
- R. Further research is needed on the benefit of irrigating the catheter with acidifying solutions or use of oral urease inhibitors in long-term catheterized patients who have frequent catheter obstruction. **(No recommendation/unresolved issue)** (Key Question 3)

- S. Further research is needed on the use of a portable ultrasound device to evaluate for obstruction in patients with indwelling catheters and low urine output. **(No recommendation/unresolved issue)** (Key Question 2C)
- T. Further research is needed on the use of methenamine to prevent encrustation in patients requiring chronic indwelling catheters who are at high risk for obstruction. **(No recommendation/unresolved issue)** (Key Question 2C)

#### *Specimen Collection*

- U. Obtain urine samples aseptically. **(Category IB)**
  - 1. If a small volume of fresh urine is needed for examination (i.e., urinalysis or culture), aspirate the urine from the needleless sampling port with a sterile syringe/cannula adapter after cleansing the port with a disinfectant. **(Category IB)**
  - 2. Obtain large volumes of urine for special analyses (not culture) aseptically from the drainage bag. **(Category IB)**

#### *Spatial Separation of Catheterized Patients*

- V. Further research is needed on the benefit of spatial separation of patients with urinary catheters to prevent transmission of pathogens colonizing urinary drainage systems. **(No recommendation/unresolved issue)** (Key Question 2D)

### **IV. Quality Improvement Programs**

- A. Implement quality improvement (QI) programs or strategies to enhance appropriate use of indwelling catheters and to reduce the risk of CAUTI based on a facility risk assessment. **(Category IB)** (Key Question 2D)

The purposes of QI programs should be: 1) to assure appropriate utilization of catheters 2) to identify and remove catheters that are no longer needed (e.g., daily review of their continued need) and 3) to ensure adherence to hand hygiene and proper care of catheters. Examples of programs that have been demonstrated to be effective include:

- 1. A system of alerts or reminders to identify all patients with urinary catheters and assess the need for continued catheterization
- 2. Guidelines and protocols for nurse-directed removal of unnecessary urinary catheters
- 3. Education and performance feedback regarding appropriate use, hand hygiene, and catheter care
- 4. Guidelines and algorithms for appropriate peri-operative catheter management, such as:

- a. Procedure-specific guidelines for catheter placement and postoperative catheter removal
- b. Protocols for management of postoperative urinary retention, such as nurse-directed use of intermittent catheterization and use of bladder ultrasound scanners

## V. Administrative Infrastructure

### A. Provision of guidelines

- 1. Provide and implement evidence-based guidelines that address catheter use, insertion, and maintenance. **(Category IB)**
  - a. Consider monitoring adherence to facility-based criteria for acceptable indications for indwelling urinary catheter use. **(Category II)**

### B. Education and Training

- 1. Ensure that healthcare personnel and others who take care of catheters are given periodic in-service training regarding techniques and procedures for urinary catheter insertion, maintenance, and removal. Provide education about CAUTI, other complications of urinary catheterization, and alternatives to indwelling catheters. **(Category IB)**
- 2. When feasible, consider providing performance feedback to these personnel on what proportion of catheters they have placed meet facility-based criteria and other aspects related to catheter care and maintenance. **(Category II)**

### C. Supplies

- 1. Ensure that supplies necessary for aseptic technique for catheter insertion are readily available. **(Category IB)**

### D. System of documentation

- 1. Consider implementing a system for documenting the following in the patient record: indications for catheter insertion, date and time of catheter insertion, individual who inserted catheter, and date and time of catheter removal. **(Category II)**
  - a. Ensuring that documentation is accessible in the patient record and recorded in a standard format for data collection and quality improvement purposes is suggested. Electronic documentation that is searchable is preferable. **(Category II)**

### E. Surveillance resources

- 1. If surveillance for CAUTI is performed, ensure that there are sufficient trained personnel and technology resources to support surveillance for urinary catheter use and outcomes. **(Category IB)**

## VI. Surveillance

- A. Consider surveillance for CAUTI when indicated by facility-based risk assessment. **(Category II)**
1. Identify the patient groups or units on which to conduct surveillance based on frequency of catheter use and potential risk of CAUTI.
- B. Use standardized methodology for performing CAUTI surveillance. **(Category IB)**
1. Examples of metrics that should be used for CAUTI surveillance include:
    - a. Number of CAUTI per 1000 catheter-days
    - b. Number of bloodstream infections secondary to CAUTI per 1000 catheter-days
    - c. Catheter utilization ratio: (urinary catheter days/patient days) x 100
  2. Use CDC/NHSN criteria for identifying patients who have symptomatic UTI (SUTI) (numerator data) (see NHSN Patient Safety Manual: <http://www.cdc.gov/nhsn/library.html>).
  3. For more information on metrics, please see the U.S. Department of Health & Human Services (HHS) Action Plan to Prevent Healthcare-Associated Infections: <http://www.hhs.gov/ohs/initiatives/hai/infection.html>.
- C. Routine screening of catheterized patients for asymptomatic bacteriuria (ASB) is not recommended. **(Category II)** (Key Question 2D)
- D. When performing surveillance for CAUTI, consider providing regular (e.g., quarterly) feedback of unit-specific CAUTI rates to nursing staff and other appropriate clinical care staff. **(Category II)** (Key Question 2D)

### **III. Implementation and Audit**

#### **Prioritization of Recommendations**

In this section, the recommendations considered essential for *all* healthcare facilities caring for patients requiring urinary catheterization are organized into modules in order to provide more guidance to facilities on implementation of these guidelines. The high-priority recommendations were chosen by a consensus of experts based on strength of recommendation as well as on the likely impact of the strategy in preventing CAUTI. The administrative functions and infrastructure listed above in the summary of recommendations are necessary to accomplish the high priority recommendations and are therefore critical to the success of a prevention program. In addition, quality improvement programs should be implemented as an active approach to accomplishing these recommendations and when process and outcome measure goals are not being met based on internal reporting.

#### **Priority Recommendations for Appropriate Urinary Catheter Use (Module 1)**

- Insert catheters only for appropriate indications (see Table 2), and leave in place only as long as needed. **(Category IB)**
  - Avoid use of urinary catheters in patients and nursing home residents for management of incontinence. **(Category IB)**
  - For operative patients who have an indication for an indwelling catheter, remove the catheter as soon as possible postoperatively, preferably within 24 hours, unless there are appropriate indications for continued use. **(Category IB)**

#### **Priority Recommendations for Aseptic Insertion of Urinary Catheters (Module 2)**

- Ensure that only properly trained persons (e.g., hospital personnel, family members, or patients themselves) who know the correct technique of aseptic catheter insertion and maintenance are given this responsibility. **(Category IB)**
- In the acute care hospital setting, insert catheters using aseptic technique and sterile equipment. **(Category IB)**

#### **Priority Recommendations for Proper Urinary Catheter Maintenance (Module 3)**

- Following aseptic insertion of the urinary catheter, maintain a closed drainage system **(Category IB)**
- Maintain unobstructed urine flow. **(Category IB)**

#### **Performance Measures**

- A. Internal Reporting. Consider reporting both process and outcome measures to senior administrative, medical, and nursing leadership and clinicians who care for patients at risk for CAUTI. **(Category II)**
  1. Examples of process measures:
    - a) Compliance with educational program: Calculate percent of personnel who have proper training:
      - Numerator: number of personnel who insert urinary catheters and who have proper training
      - Denominator: number of personnel who insert urinary catheters
      - Standardization factor: 100 (i.e., multiply by 100 so that measure is expressed as a percentage)

- b) Compliance with documentation of catheter insertion and removal dates: Conduct random audits of selected units and calculate compliance rate:
    - Numerator: number of patients on unit with catheters with proper documentation of insertion and removal dates
    - Denominator: number of patients on the unit with a catheter in place at some point during admission
    - Standardization factor: 100 (i.e., multiply by 100 so that measure is expressed as a percentage)
  - c) Compliance with documentation of indication for catheter placement: Conduct random audits of selected units and calculate compliance rate
    - Numerator: number of patients on unit with catheters with proper documentation of indication
    - Denominator: number of patients on the unit with catheter in place
    - Standardization factor: 100 (i.e., multiply by 100 so that measure is expressed as a percentage)
2. Recommended outcome measures:
- a) Rates of CAUTI: Use NHSN definitions (see <http://www.cdc.gov/nhsn/library.html>). Measurement of rates allows an individual facility to gauge the longitudinal impact of implementation of prevention strategies:
    - Numerator: number of CAUTIs in each location monitored
    - Denominator: total number of urinary catheter-days for all patients that have an indwelling urinary catheter in each location monitored
    - Standardization factor: Multiply by 1000 so that the measure is expressed as cases per 1000 catheter-days
  - b) Rate of bloodstream infections secondary to CAUTI: Use NHSN definitions for laboratory-confirmed bloodstream infection, available at <http://www.cdc.gov/nhsn/library.html>.
    - Numerator: number of episodes of bloodstream infections secondary to CAUTI
    - Denominator: total number of urinary catheter-days for all patients that have an indwelling urinary catheter in each location monitored
    - Standardization factor: Multiply by 1000 so that the measure is expressed as cases per 1000 catheter-days
- B. External Reporting. Current NHSN definitions for CAUTI were developed for monitoring of rates within a facility; however, reporting of CAUTI rates for facility-to-facility comparison might be requested by state requirements and external quality initiatives.

## **IV. Recommendations for Further Research**

Our literature review revealed that many of the studies addressing strategies to prevent CAUTI were not of sufficient quality to allow firm conclusions regarding the benefit of certain interventions. Future studies of CAUTI prevention should:

- 1) Be primary analytic research (i.e. systematic reviews, meta-analyses, interventional studies, and observational studies [cohort, case-control, analytic cross-sectional studies])
- 2) Evaluate clinically relevant outcomes (e.g., SUTI, bloodstream infections secondary to CAUTI)
- 3) Adjust for confounders as needed using multivariable analyses
- 4) Stratify outcomes by patient populations at risk for CAUTI
- 5) Ensure adequate statistical power to detect differences

The following is a compilation of recommendations for further research:

1. Catheter materials
  - a. Antimicrobial and antiseptic-impregnated catheters
    - i. Effect of catheters on reducing the risk of SUTI and other clinically significant outcomes
    - ii. Patient populations most likely to benefit
    - iii. Incidence of antimicrobial resistance in urinary pathogens
    - iv. Role of bacterial biofilms in the pathogenesis of CAUTI
  - b. Standard catheters
    - i. Optimal materials for reducing the risk of CAUTI and other urethral complications
2. Appropriate urinary catheter use
  - a. Incontinent patients
    - i. Risks and benefits of periodic (e.g., nighttime) use of external catheters
    - ii. Risk of local complications (e.g., skin maceration, phimosis) with the use of external catheters
    - iii. Appropriate use of urinary catheters to manage sacral or perineal wounds
  - b. Appropriate indications for continued use in postoperative patients and associated risks
3. Antiseptics
  - a. Use of antiseptic vs. sterile solutions for periurethral cleaning prior to catheter insertion
  - b. Use of antiseptics (e.g., methenamine) to prevent CAUTI
4. Alternatives to indwelling urethral catheters and bag drainage
  - a. Risks and benefits of suprapubic catheters as an alternative to chronic indwelling urethral catheters
  - b. Use of a urethral stent as an alternative to an indwelling catheter in selected patients with bladder outlet obstruction
  - c. Use of catheter valves in reducing the risk of CAUTI and other urinary complications
  - d. Other alternative methods of urinary drainage

5. Optimal methods for preventing encrustation in long-term catheterized patients who have frequent obstruction
  - a. Optimal catheter materials
  - b. Irrigation with acidifying solutions or oral urease inhibitors
  - c. Use of methenamine
  
6. Other prevention measures
  - a. Use of portable ultrasound in patients with low-urine output to reduce unnecessary catheter insertions or irrigations (in catheterized patients)
  - b. Use of new prevention strategies such as bacterial interference in patients requiring chronic catheterization
  - c. Optimal cleaning and storage procedures (e.g., wet vs. dry storage) for catheters used for clean intermittent catheterization
  
7. Prevention of transmission
  - a. Spatial separation of patients with urinary catheters (in the absence of epidemic spread or frequent cross-infection) to prevent transmission of pathogens colonizing urinary drainage systems

## **V. Background**

Urinary tract infections are the most common type of healthcare-associated infection, accounting for more than 30% of infections reported by acute care hospitals.<sup>19</sup> Virtually all healthcare-associated UTIs are caused by instrumentation of the urinary tract. Catheter-associated urinary tract infection (CAUTI) has been associated with increased morbidity, mortality, hospital cost, and length of stay.<sup>6-9</sup> In addition, bacteriuria commonly leads to unnecessary antimicrobial use, and urinary drainage systems are often reservoirs for multidrug-resistant bacteria and a source of transmission to other patients.<sup>10,11</sup>

### **Definitions**

An indwelling urinary catheter is a drainage tube that is inserted into the urinary bladder through the urethra, is left in place, and is connected to a closed collection system. Alternative methods of urinary drainage may be employed in some patients. Intermittent (“in-and-out”) catheterization involves brief insertion of a catheter into the bladder through the urethra to drain urine at intervals. An external catheter is a urine containment device that fits over or adheres to the genitalia and is attached to a urinary drainage bag. The most commonly used external catheter is a soft flexible sheath that fits over the penis (“condom” catheter). A suprapubic catheter is surgically inserted into the bladder through an incision above the pubis.

Although UTIs associated with alternative urinary drainage systems are considered device-associated, CAUTI rates reported to the National Healthcare Safety Network (NHSN) only refer to those associated with indwelling urinary catheters. NHSN has recently revised the UTI surveillance definition criteria. Among the changes are removal of the asymptomatic bacteriuria (ASB) criterion and refinement of the criteria for defining symptomatic UTI (SUTI). The time period for follow-up surveillance after catheter removal also has been shortened from 7 days to 48 hours to align with other device-associated infections. The new UTI criteria, which took effect in January 2009, can be found in the NHSN Patient Safety Manual (<http://www.cdc.gov/nhsn/library.html>).

The limitations and heterogeneity of definitions of CAUTI used in various studies present major challenges in appraising the quality of evidence in the CAUTI literature. Study investigators have used numerous different definitions for CAUTI outcomes, ranging from simple bacteriuria at a range of concentrations to, less commonly, symptomatic infection defined by combinations of bacteriuria and various signs and symptoms. Furthermore, most studies that used CDC/NHSN definitions for CAUTI did not distinguish between SUTI and ASB in their analyses.<sup>30</sup> The heterogeneity of definitions used for CAUTI may reduce the quality of evidence for a given intervention and often precludes meta-analyses.

The clinical significance of ASB in catheterized patients is undefined. Approximately 75% to 90% of patients with ASB do not develop a systemic inflammatory response or other signs or symptoms to suggest infection.<sup>6,31</sup> Monitoring and treatment of ASB is also not an effective prevention measure for SUTI, as most cases of SUTI are not preceded by bacteriuria for more than a day.<sup>25</sup> Treatment of ASB has not been shown to be clinically beneficial and is associated with the selection of antimicrobial-resistant organisms.

## Epidemiology

Between 15% and 25% of hospitalized patients may receive short-term indwelling urinary catheters.<sup>12,13</sup> In many cases, catheters are placed for inappropriate indications, and healthcare providers are often unaware that their patients have catheters, leading to prolonged, unnecessary use.<sup>14-16</sup> In acute care hospitals reporting to NHSN in 2006, pooled mean urinary catheter utilization ratios in ICU and non-ICU areas ranged from 0.23-0.91 urinary catheter-days/patient-days.<sup>17</sup> While the numbers of units reporting were small, the highest ratios were in trauma ICUs and the lowest in inpatient medical/surgical wards. The overall prevalence of long-term indwelling urethral catheterization use is unknown. The prevalence of urinary catheter use in residents in long-term care facilities in the United States is on the order of 5%, representing approximately 50,000 residents with catheters at any given time.<sup>18</sup> This number appears to be declining over time, likely because of federally mandated nursing home quality measures. However, the high prevalence of urinary catheters in patients transferred to skilled nursing facilities suggests that acute care hospitals should focus more efforts on removing unnecessary catheters prior to transfer.<sup>18</sup>

Reported rates of UTI among patients with urinary catheters vary substantially. National data from NHSN acute care hospitals in 2006 showed a range of pooled mean CAUTI rates of 3.1-7.5 infections per 1000 catheter-days.<sup>17</sup> The highest rates were in burn ICUs, followed by inpatient medical wards and neurosurgical ICUs, although these sites also had the fewest numbers of locations reporting. The lowest rates were in medical/surgical ICUs.

Although morbidity and mortality from CAUTI is considered to be relatively low compared to other HAIs, the high prevalence of urinary catheter use leads to a large cumulative burden of infections with resulting infectious complications and deaths. An estimate of annual incidence of HAIs and mortality in 2002, based on a broad survey of US hospitals, found that urinary tract infections made up the highest number of infections (> 560,000) compared to other HAIs, and attributable deaths from UTI were estimated to be over 13,000 (mortality rate 2.3%).<sup>19</sup> And while fewer than 5% of bacteriuric cases develop bacteremia,<sup>6</sup> CAUTI is the leading cause of secondary nosocomial bloodstream infections; about 17% of hospital-acquired bacteremias are from a urinary source, with an associated mortality of approximately 10%.<sup>20</sup> In the nursing home setting, bacteremias are most commonly caused by UTIs, the majority of which are catheter-related.<sup>21</sup>

An estimated 17% to 69% of CAUTI may be preventable with recommended infection control measures, which means that up to 380,000 infections and 9000 deaths related to CAUTI per year could be prevented.<sup>22</sup>

## Pathogenesis and Microbiology

The source of microorganisms causing CAUTI can be endogenous, typically via meatal, rectal, or vaginal colonization, or exogenous, such as via contaminated hands of healthcare personnel or equipment. Microbial pathogens can enter the urinary tract either by the extraluminal route, via migration along the outside of the catheter in the periurethral mucous sheath, or by the intraluminal route, via movement along the internal lumen of the catheter from a contaminated collection bag or catheter-drainage tube junction. The relative contribution of each route in the pathogenesis of CAUTI is not well known. The marked reduction in risk of bacteriuria with the introduction of the sterile, closed urinary drainage system in the 1960s<sup>23</sup> suggests the importance of the intraluminal route. However, even with the closed drainage system,

bacteriuria inevitably occurs over time either via breaks in the sterile system or via the extraluminal route.<sup>24</sup> The daily risk of bacteriuria with catheterization is 3% to 10%,<sup>25,26</sup> approaching 100% after 30 days, which is considered the delineation between short and long-term catheterization.<sup>27</sup>

Formation of biofilms by urinary pathogens on the surface of the catheter and drainage system occurs universally with prolonged duration of catheterization.<sup>28</sup> Over time, the urinary catheter becomes colonized with microorganisms living in a sessile state within the biofilm, rendering them resistant to antimicrobials and host defenses and virtually impossible to eradicate without removing the catheter. The role of bacteria within biofilms in the pathogenesis of CAUTI is unknown and is an area requiring further research.

The most frequent pathogens associated with CAUTI (combining both ASB and SUTI) in hospitals reporting to NHSN between 2006-2007 were *Escherichia coli* (21.4%) and *Candida* spp (21.0%), followed by *Enterococcus* spp (14.9%), *Pseudomonas aeruginosa* (10.0%), *Klebsiella pneumoniae* (7.7%), and *Enterobacter* spp (4.1%). A smaller proportion was caused by other gram-negative bacteria and *Staphylococcus* spp.<sup>5</sup>

Antimicrobial resistance among urinary pathogens is an ever increasing problem. About a quarter of *E. coli* isolates and one third of *P. aeruginosa* isolates from CAUTI cases were fluoroquinolone-resistant. Resistance of gram-negative pathogens to other agents, including third-generation cephalosporins and carbapenems, was also substantial.<sup>5</sup> The proportion of organisms that were multidrug-resistant, defined by non-susceptibility to all agents in 4 classes, was 4% of *P. aeruginosa*, 9% of *K. pneumoniae*, and 21% of *Acinetobacter baumannii*.<sup>29</sup>

## **VI. Scope and Purpose**

This guideline updates and expands the original CDC Guideline for Prevention of CAUTI published in 1981. The revised guideline addresses the prevention of CAUTI for patients in need of either short- or long-term (i.e., > 30 days) urinary catheterization in any type of healthcare facility and evaluates evidence for alternative methods of urinary drainage, including intermittent catheterization, external catheters, and suprapubic catheters. The guideline also includes specific recommendations for implementation, performance measurement, and surveillance. Recommendations for further research are also provided to address the knowledge gaps in CAUTI prevention identified during the literature review.

To evaluate the evidence on preventing CAUTI, we examined data addressing three key questions and related subquestions:

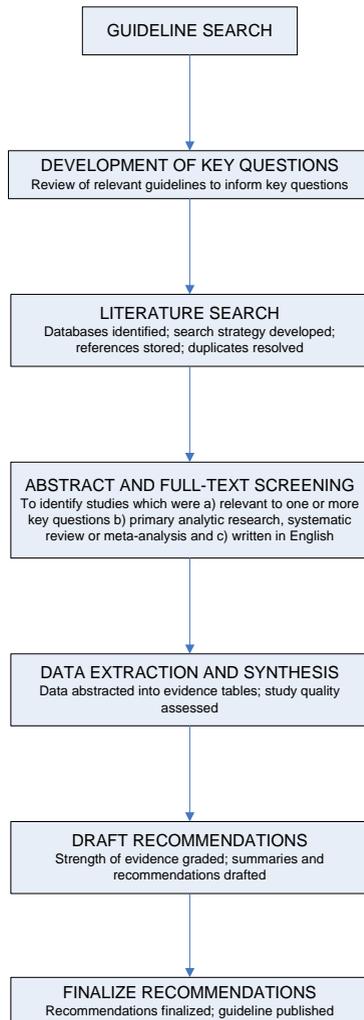

1. Who should receive urinary catheters?
  - A. When is urinary catheterization necessary?
  - B. What are the risk factors for CAUTI?
  - C. What populations are at highest risk of mortality from catheters?
2. For those who may require urinary catheters, what are the best practices? Specifically, what are the risks and benefits associated with:
  - A. Different approaches to catheterization?
  - B. Different catheters or collecting systems?
  - C. Different catheter management techniques?
  - D. Different systems interventions (i.e., quality improvement programs)?
3. What are the best practices for preventing UTI associated with obstructed urinary catheters?

This document is intended for use by infection prevention staff, healthcare epidemiologists, healthcare administrators, nurses, other healthcare providers, and persons responsible for developing, implementing, and evaluating infection prevention and control programs for healthcare settings across the continuum of care. The guideline can also be used as a resource for societies or organizations that wish to develop more detailed implementation guidance for prevention of CAUTI.

## VII. Methods

This guideline was based on a targeted systematic review of the best available evidence on CAUTI prevention. We used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach<sup>32-34</sup> to provide explicit links between the available evidence and the resulting recommendations. Our guideline development process is outlined in *Figure 1*.

**Figure 1. The Guideline Development Process**

## Development of Key Questions

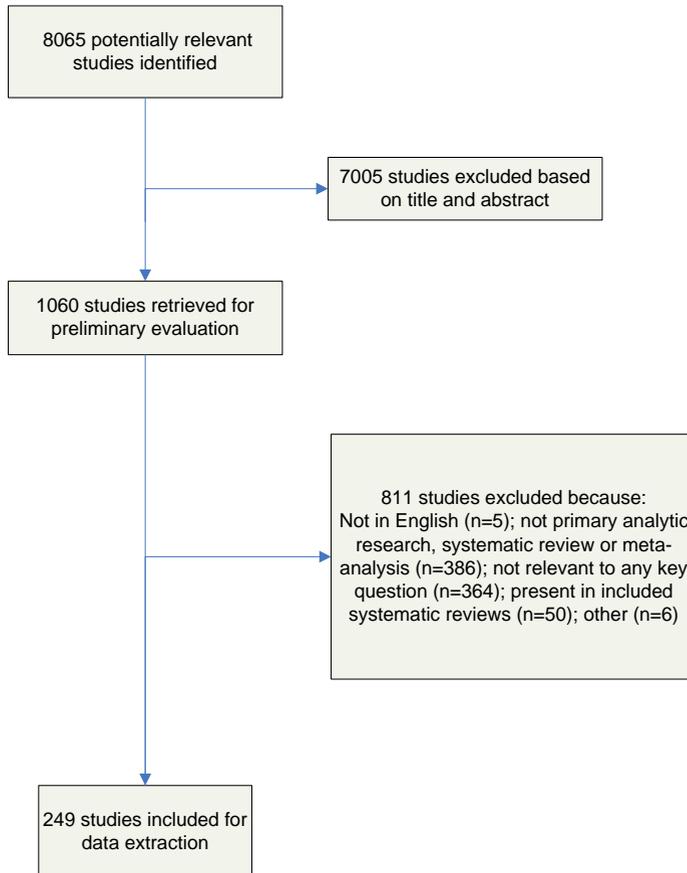

We first conducted an electronic search of the National Guideline Clearinghouse® (Agency for Healthcare Research and Quality), Medline® (National Library of Medicine) using the Ovid® Platform (Ovid Technologies, Wolters Kluwer, New York, NY), the Cochrane® Health Technology Assessment Database (Cochrane Collaboration, Oxford, UK), the NIH Consensus Development Program, and the United States Preventive Services Task Force database for existing national and international guidelines relevant to CAUTI. The strategy used for the guideline search and the search results can be found in [Appendix 1A](#). A preliminary list of key questions was developed from a review of the relevant guidelines identified in the search.<sup>1,35,36</sup> Key questions were finalized after vetting them with a panel of content experts and HICPAC members.

## Literature Search

Following the development of the key questions, search terms were developed for identifying literature relevant to the key questions. For the purposes of quality assurance, we compared these terms to those used in relevant seminal studies and guidelines. These search terms were then incorporated into search strategies for the relevant electronic databases. Searches were performed in Medline® (National Library of Medicine) using the Ovid® Platform (Ovid Technologies, Wolters Kluwer, New York, NY), EMBASE® (Elsevier BV, Amsterdam, Netherlands), CINAHL® (Ebsco Publishing, Ipswich, MA) and Cochrane® (Cochrane Collaboration, Oxford, UK) (all databases were searched in July 2007), and the resulting references were imported into a reference manager, where duplicates were resolved. For Cochrane reviews ultimately included in our guideline, we checked for updates in July 2008. The detailed search strategy used for identifying primary literature and the results of the search can be found in [Appendix 1B](#).

## Study Selection

Titles and abstracts from references were screened by a single author (C.V.G, R.K.A., or D.A.P.) and the full text articles were retrieved if they were 1) relevant to one or more key questions, 2) primary analytic research, systematic reviews or meta-analyses, and 3) written in English. Likewise, the full-text articles were screened by a single author (C.V.G. or D.A.P.) using the same criteria, and included studies underwent a second review for inclusion by another author (R.K.A.). Disagreements were resolved by the remaining authors. The results of this process are depicted in *Figure 2*.

**Figure 2: Results of the Study Selection Process**

## Data Extraction and Synthesis

Data on the study author, year, design, objective, population, setting, sample size, power, follow-up, and definitions and results of clinically relevant outcomes were extracted into evidence tables ([Appendix 2](#)). Three evidence tables were developed, each of which represented one of our key questions. Studies were extracted into the most relevant evidence table. Then, studies were organized by the common themes that emerged within each evidence table. Data were extracted by one author (R.K.A.) and cross-checked by another (C.V.G.). Disagreements were resolved by the remaining authors. Data and analyses were extracted as originally presented in the included studies. Meta-analyses were performed only where their use was deemed critical to a recommendation, and only in circumstances where multiple studies with sufficiently homogenous populations, interventions, and outcomes could be analyzed. Systematic reviews were included in our review. To avoid duplication of data, we excluded primary studies if they were also included in a systematic review captured by our search. The only exception to this was if the primary study also addressed a relevant question that was outside the scope of the included systematic review. Before exclusion, data from the primary studies that we originally captured were abstracted into the evidence tables and reviewed. We also excluded systematic reviews that analyzed primary studies that were fully captured in a more recent systematic review. The only exception to this was if the older systematic review also addressed a relevant question that was outside the scope of the newer systematic review. To ensure that all relevant studies were captured in the search, the bibliography was vetted by a panel of clinical experts.

## Grading of Evidence

First, the quality of each study was assessed using scales adapted from existing methodology checklists, and scores were recorded in the evidence tables. [Appendix 3](#) includes the sets of questions we used to assess the quality of each of the major study designs. Next, the quality of the evidence base was assessed using methods adapted from the GRADE Working Group.<sup>32</sup> Briefly, GRADE tables were developed for each of the interventions or questions addressed within the evidence tables. Included in the GRADE tables were the intervention of interest, any outcomes listed in the evidence tables that were judged to be clinically important, the quantity and type of evidence for each outcome, the relevant findings, and the GRADE of evidence for each outcome, as well as an overall GRADE of the evidence base for the given intervention or question. The initial GRADE of evidence for each outcome was deemed high if the evidence base included a randomized controlled trial (RCT) or a systematic review of RCTs, low if the evidence base included only observational studies, or very low if the evidence base consisted only of uncontrolled studies. The initial GRADE could then be modified by eight criteria.<sup>34</sup> Criteria which could decrease the GRADE of an evidence base included quality, consistency, directness, precision, and publication bias. Criteria that could increase the GRADE included a large magnitude of effect, a dose-response gradient, or inclusion of unmeasured confounders that would increase the magnitude of effect ([Table 3](#)). GRADE definitions are as follows:

1. High - further research is very unlikely to change confidence in the estimate of effect
2. Moderate - further research is likely to affect confidence in the estimate of effect and may change the estimate
3. Low - further research is very likely to affect confidence in the estimate of effect and is likely to change the estimate
4. Very low - any estimate of effect is very uncertain

After determining the GRADE of the evidence base for each outcome of a given intervention or question, we calculated the overall GRADE of the evidence base for that intervention or question. The overall GRADE was based on the lowest GRADE for the outcomes deemed critical to making a recommendation.

**Table 3. Rating the Quality of Evidence Using the GRADE Approach**

Type of Evidence	Initial Grade	Criteria to Decrease Grade	Criteria to Increase Grade	Overall Quality Grade
RCT	High	<u>Quality</u> Serious (-1 grade) or very serious (-2 grades) limitation to study quality	<u>Strong association</u> Strong (+1 grade) or very strong evidence of association (+2 grades)	High Moderate
Observational study	Low	<u>Consistency</u> Important inconsistency (-1 grade)	<u>Dose-response</u> Evidence of a dose-response gradient (+1 grade)	Low
Any other evidence (e.g., expert opinion)	Very low	<u>Directness</u> Some (-1 grade) or major (-2 grades) uncertainty about directness <u>Precision</u> Imprecise or sparse data (-1 grade) <u>Publication bias</u> High risk of bias (-1 grade)	<u>Unmeasured Confounders</u> Inclusion of unmeasured confounders increases the magnitude of effect (+1 grade)	Very low

## Formulating Recommendations

Narrative evidence summaries were then drafted by the working group using the evidence and GRADE tables. One summary was written for each theme that emerged under each key question. The working group then used the narrative evidence summaries to develop guideline recommendations. Factors determining the strength of a recommendation included 1) the values and preferences used to determine which outcomes were "critical," 2) the harms and benefits that result from weighing the "critical" outcomes, and 3) the overall GRADE of the evidence base for the given intervention or question (Table 4).<sup>33</sup> If weighing the "critical outcomes" for a given intervention or question resulted in a "net benefit" or a "net harm," then a "Category I Recommendation" was formulated to strongly recommend for or against the given intervention respectively. If weighing the "critical outcomes" for a given intervention or question resulted in a "trade off" between benefits and harms, then a "Category II Recommendation" was formulated to recommend that providers or institutions consider the intervention when deemed appropriate. If weighing the "critical outcomes" for a given intervention or question resulted in

an "uncertain trade off" between benefits and harms, then a "No Recommendation" was formulated to reflect this uncertainty.

<b>HICPAC Recommendation</b>	<b>Weighing Benefits and Harms for Critical Outcomes</b>	<b>Quality of Evidence</b>
STRONG (I)	Interventions with net benefits or net harms	IA – High to Moderate IB – Low or Very Low (Accepted Practice) IC – High to Very Low (Regulatory)
WEAK (II)	Interventions with trade offs between benefits and harms	High to Very Low
No recommendation/ unresolved issue	Uncertain trade offs between benefits and harms	Low to Very Low

For Category I recommendations, levels A and B represent the quality of the evidence underlying the recommendation, with A representing high to moderate quality evidence and B representing low quality evidence or, in the case of an established standard (e.g., aseptic technique, education and training), very low quality to no evidence based on our literature review. For IB recommendations, although there may be low to very low quality or even no available evidence directly supporting the benefits of the intervention, the theoretical benefits are clear, and the theoretical risks are marginal. Level C represents practices required by state or federal regulation, regardless of the quality of evidence. It is important to note that the strength of a Category IA recommendation is equivalent to that of a Category IB or IC recommendation; it is only the quality of the evidence underlying the IA recommendation that makes it different from a IB.

In some instances, multiple recommendations emerged from a single narrative evidence summary. The new HICPAC categorization scheme for recommendations is provided in [Table 1](#), which is reproduced below.

Category IA	A strong recommendation supported by high to moderate quality evidence suggesting net clinical benefits or harms
Category IB	A strong recommendation supported by low quality evidence suggesting net clinical benefits or harms or an accepted practice (e.g., aseptic technique) supported by low to very low quality evidence
Category IC	A strong recommendation required by state or federal regulation.
Category II	A weak recommendation supported by any quality evidence suggesting a trade off between clinical benefits and harms
No recommendation/ unresolved issue	Unresolved issue for which there is low to very low quality evidence with uncertain trade offs between benefits and harms

Category I recommendations are defined as strong recommendations with the following implications:

1. For patients: Most people in the patient's situation would want the recommended course of action and only a small proportion would not; request discussion if the intervention is not offered.
2. For clinicians: Most patients should receive the recommended course of action.
3. For policymakers: The recommendation may be adopted as a policy.

Category II recommendations are defined as weak recommendations with the following implications:

1. For patients: Most people in the patient's situation would want the recommended course of action, but many would not.
2. For clinicians: Different choices will be appropriate for different patients, and clinicians must help each patient to arrive at a management decision consistent with her or his values and preferences.
3. For policymakers: Policy making will require substantial debate and involvement of many stakeholders.

It should be noted that Category II recommendations are discretionary for the individual institution and are not intended to be enforced.

The wording of each recommendation was carefully selected to reflect the recommendation's strength. In most cases, we used the active voice when writing Category I recommendations - the strong recommendations. Phrases like "do" or "do not" and verbs without auxiliaries or conditionals were used to convey certainty. We used a more passive voice when writing Category II recommendations - the weak recommendations. Words like "consider" and phrases like "is preferable," "is suggested," "is not suggested," or "is not recommended" were chosen to reflect the lesser certainty of the Category II recommendations. Rather than a simple statement of fact, each recommendation is actionable, describing precisely a proposed action to take.

The category "No recommendation/unresolved issue" was most commonly applied to situations where either 1) the overall quality of the evidence base for a given intervention was low to very low and there was no consensus on the benefit of the intervention or 2) there was no published evidence on outcomes deemed critical to weighing the risks and benefits of a given intervention. If the latter was the case, those critical outcomes will be noted at the end of the relevant evidence summary.

Our evidence-based recommendations were cross-checked with those from guidelines identified in our original systematic search. Recommendations from previous guidelines for topics not directly addressed by our systematic review of the evidence were included in our "Summary of Recommendations" if they were deemed critical to the target users of this guideline. Unlike recommendations informed by our literature search, these recommendations are not linked to a key question. These recommendations were agreed upon by expert consensus and are designated either IB if they represent a strong recommendation based on accepted practices (e.g., aseptic technique) or II if they are a suggestion based on a probable net benefit despite limited evidence.

All recommendations were approved by HICPAC. Recommendations focused only on efficacy, effectiveness, and safety. The optimal use of these guidelines should include a consideration of the costs relevant to the local setting of guideline users.

## **Reviewing and Finalizing the Guideline**

After a draft of the tables, narrative summaries, and recommendations was completed, the working group shared the draft with the expert panel for in-depth review. While the expert panel was reviewing this draft, the working group completed the remaining sections of the guideline, including the executive summary, background, scope and purpose, methods, summary of recommendations, and recommendations for guideline implementation, audit, and further research. The working group then made revisions to the draft based on feedback from members of the expert panel and presented the entire draft guideline to HICPAC for review. The guideline was then posted on the Federal Register for public comment. After a period of public comment, the guideline was revised accordingly, and the changes were reviewed and voted on by HICPAC. The final guideline was cleared internally by CDC and published and posted on the HICPAC website.

### **Updating the Guideline**

Future revisions to this guideline will be dictated by new research and technological advancements for preventing CAUTI and will occur at the request of HICPAC.

## **VIII. Evidence Review**

### **Q1. Who should receive urinary catheters?**

To answer this question, we focused on three subquestions: A) When is urinary catheterization necessary? B) What are the risk factors for CAUTI? and C) What populations are at highest risk of mortality from urinary catheters?

#### **Q1A. When is urinary catheterization necessary?**

The available data examined five main populations. In all populations, we considered CAUTI outcomes as well as other outcomes we deemed critical to weighing the risks and benefits of catheterization. The evidence for this question consists of 1 systematic review,<sup>37</sup> 9 RCTs,<sup>38-46</sup> and 12 observational studies.<sup>47-58</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 1A.

For *operative patients*, low-quality evidence suggested a benefit of avoiding urinary catheterization.<sup>37-44,47-49</sup> This was based on a decreased risk of bacteriuria/unspecified UTI, no effect on bladder injury, and increased risk of urinary retention in patients without catheters. Urinary retention in patients without catheters was specifically seen following urogenital surgeries. The most common surgeries studied were urogenital, gynecological, laparoscopic, and orthopedic surgeries. Our search did not reveal data on the impact of catheterization on peri-operative hemodynamic management.

For *incontinent patients*, low-quality evidence suggested a benefit of avoiding urinary catheterization.<sup>45,50-52</sup> This was based on a decreased risk of both SUTI and bacteriuria/unspecified UTI in male nursing home residents without urinary catheters compared to those with continuous condom catheters. We found no difference in the risk of UTI between having a condom catheter only at night and having no catheter. Our search did not reveal data on the impact of catheterization on skin breakdown.

For *patients with bladder outlet obstruction*, very low-quality evidence suggested a benefit of a urethral stent over an indwelling catheter.<sup>53</sup> This was based on a reduced risk of bacteriuria in those receiving a urethral stent. Our search did not reveal data on the impact of catheterization versus stent placement on urinary complications.

For *patients with spinal cord injury*, very low-quality evidence suggested a benefit of avoiding indwelling urinary catheters.<sup>54,56</sup> This was based on a decreased risk of SUTI and bacteriuria in those without indwelling catheters (including patients managed with spontaneous voiding, clean intermittent catheterization [CIC], and external striated sphincterotomy with condom catheter drainage), as well as a lower risk of urinary complications, including hematuria, stones, and urethral injury (fistula, erosion, stricture).

For *children with myelomeningocele and neurogenic bladder*, very low-quality evidence suggested a benefit of CIC compared to urinary diversion or self voiding.<sup>46,57,58</sup> This was based on a decreased risk of bacteriuria/unspecified UTI in patients receiving CIC compared to urinary diversion, and a lower risk of urinary tract deterioration (defined by febrile urinary tract infection, vesicoureteral reflux, hydronephrosis, or increases in BUN or serum creatinine) compared to self-voiding and in those receiving CIC early (< 1 year of age) versus late (> 3 years of age).

### **Evidence Review Table 1A. When is urinary catheterization necessary?**

1A.1. Use urinary catheters in operative patients only as necessary, rather than routinely. **(Category IB)**

1A.2. Avoid use of urinary catheters in patients and nursing home residents for management of incontinence. **(Category IB)**

1A.2.a. Further research is needed on periodic (e.g., nighttime) use of external catheters in incontinent patients or residents and the use of catheters to prevent skin breakdown. **(No recommendation/unresolved issue)**

1A.3. Further research is needed on the benefit of using a urethral stent as an alternative to an indwelling catheter in selected patients with bladder outlet obstruction. **(No recommendation/unresolved issue)**

1A.4. Consider alternatives to chronic indwelling catheters, such as intermittent catheterization, in spinal cord injury patients. **(Category II)**

1A.5. Consider intermittent catheterization in children with myelomeningocele and neurogenic bladder to reduce the risk of urinary tract deterioration. **(Category II)**

### **Q1B. What are the risk factors for CAUTI?**

To answer this question, we reviewed the quality of evidence for those risk factors examined in more than one study. We considered the critical outcomes for decision-making to be SUTI and bacteriuria. The evidence for this question consists of 11 RCTs<sup>59-69</sup> and 37 observational studies.<sup>9,50,54,70-103</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 1B.

For *SUTI*,<sup>50,54,61,62,74,75,79,83,102,103</sup> low-quality evidence suggested that female sex, older age, prolonged catheterization, impaired immunity, and lack of antimicrobial exposure are risk factors. Very low quality evidence suggested that catheter blockage and low albumin level are also risk factors. For *bacteriuria*,<sup>9,59-61,63-68,72,73,76-78,82,84-86,89-94,96-100</sup> multiple risk factors were identified; there was high quality evidence for prolonged catheterization and moderate quality evidence for female sex, positive meatal cultures, and lack of antimicrobial exposure. Low-quality evidence also implicated the following risk factors for bacteriuria: older age, disconnection of the drainage system, diabetes, renal dysfunction, higher severity of illness, impaired immunity, placement of the catheter outside of the operating room, lower professional training of the person inserting the catheter, incontinence, and being on an orthopaedic or neurology service. Our search did not reveal data on adverse events and antimicrobial resistance associated with antimicrobial use, although one observational study found that the protective effect of antimicrobials lasted only for the first four days of catheterization, and that antimicrobial exposure led to changes in the epidemiology of bacterial flora in the urine.

**Evidence Review Table 1B. What are the risk factors for CAUTI?**

1B.1. Following aseptic insertion of the urinary catheter, maintain a closed drainage system. **(Category IB)<sup>a</sup>**

1B.2. Insert catheters only for appropriate indications, and leave in place only as long as needed. **(Category IB)<sup>b</sup>**

1B.3. Minimize urinary catheter use and duration of use in all patients, particularly those at higher risk for CAUTI such as women, the elderly, and patients with impaired immunity. **(Category IB)**

1B.4. Ensure that only properly trained persons (e.g., hospital personnel, family members, or patients themselves) who know the correct technique of aseptic catheter insertion and maintenance are given this responsibility. **(Category IB)**

1B.5. Maintain unobstructed urine flow. **(Category IB)<sup>c</sup>**

<sup>a</sup> More data are available under Question 2B.

<sup>b</sup> More data are available under Question 2C.

<sup>c</sup> More data are available under Question 2D.

**Q1C. What populations are at highest risk of mortality from urinary catheters?**

To answer this question, we reviewed the quality of evidence for those risk factors examined in more than one study. The evidence for this question consists of 2 observational studies.<sup>7,74</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 1C.

Low-quality evidence suggested that older age, higher severity of illness, and being on an internal medicine service compared to a surgical service were independent risk factors for mortality in patients with indwelling urinary catheters. Both studies evaluating these risk factors found the highest risk of mortality in patients over 70 years of age. Low-quality evidence also suggested that CAUTI was a risk factor for mortality in patients with catheters.

**Evidence Review Table 1C. What populations are at highest risk of mortality from catheters?**

1C.1. Minimize urinary catheter use and duration in all patients, particularly those who may be at higher risk for mortality due to catheterization, such as the elderly and patients with severe illness. **(Category IB)**

**Q2. For those who may require urinary catheters, what are the best practices?**

To answer this question, we focused on four subquestions: A) What are the risks and benefits associated with different approaches to catheterization?, B) What are the risks and benefits associated with different types of catheters or collecting systems?, C) What are the risks and benefits associated with different catheter management techniques, and D) What are the risks and benefits associated with different systems interventions?

### **Q2A. What are the risks and benefits associated with different approaches to catheterization?**

The available data examined the following comparisons of different catheterization approaches:

- 1) External versus indwelling urethral
- 2) Intermittent versus indwelling urethral
- 3) Intermittent versus suprapubic
- 4) Suprapubic versus indwelling urethral
- 5) Clean intermittent versus sterile intermittent

For all comparisons, we considered SUTI, bacteriuria/unspecified UTI, or combinations of these outcomes depending on availability, as well as other outcomes critical to weighing the risks and benefits of different catheterization approaches. The evidence for this question consists of 6 systematic reviews,<sup>37,104-108</sup> 16 RCTs,<sup>62,63,109-122</sup> and 18 observational studies.<sup>54,73,81,84,123-136</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 2A

#### *Q2A.1. External versus indwelling urethral*

Low-quality evidence suggested a benefit of using external catheters over indwelling urethral catheters in male patients who require a urinary collection device but do not have an indication for an indwelling catheter such as urinary retention or bladder outlet obstruction.<sup>81,109,123</sup> This was based on a decreased risk of a composite outcome of SUTI, bacteriuria, or death as well as increased patient satisfaction with condom catheters. Differences were most pronounced in men without dementia. Statistically significant differences were not found or reported for the individual CAUTI outcomes or death. Our search did not reveal data on differences in local complications such as skin maceration or phimosis.

#### *Q2A.2. Intermittent versus indwelling urethral*

Low-quality evidence suggested a benefit of using intermittent catheterization over indwelling urethral catheters in selected populations.<sup>84,104-106,110-114,124-126,135,136</sup> This was based on a decreased risk of SUTI and bacteriuria/unspecified UTI but an increased risk of urinary retention in postoperative patients with intermittent catheterization. In one study, urinary retention and bladder distension were avoided by performing catheterization at regular intervals (every 6-8 hrs) until return of voiding. Studies of patients with neurogenic bladder most consistently found a decreased risk of CAUTI with intermittent catheterization. Studies in operative patients whose catheters were removed within 24 hrs of surgery found no differences in bacteriuria with intermittent vs. indwelling catheterization, while studies where catheters were left in for longer durations had mixed results. Our search did not reveal data on differences in patient satisfaction.

#### *Q2A.3. Intermittent versus suprapubic*

Very low-quality evidence suggested a benefit of intermittent over suprapubic catheterization in selected populations<sup>115,116,134-136</sup> based on increased patient acceptability and decreased risk of urinary complications (bladder calculi, vesicoureteral reflux, and upper tract abnormalities). Although we found a decreased risk of bacteriuria/unspecified UTI with suprapubic catheterization, there were no differences in SUTI. The populations studied included women undergoing gynecologic surgery and spinal cord injury patients.

*Q2A.4. Suprapubic versus indwelling urethral*

Low-quality evidence suggested a benefit of suprapubic catheters over indwelling urethral catheters in selected populations.<sup>37,62,104,107,108,128-133,135,136</sup> This was based on a decreased risk of bacteriuria/unspecified UTI, recatheterization, and urethral stricture, and increased patient comfort and satisfaction. However, there were no differences in SUTI and an increased risk of longer duration of catheterization with suprapubic catheters. Studies involved primarily postoperative and spinal cord injury patients. Our search did not reveal data on differences in complications related to catheter insertion or the catheter site.

*Q2A.5. Clean intermittent versus sterile intermittent*

Moderate-quality evidence suggested no benefit of using sterile over clean technique for intermittent catheterization.<sup>63,73,105,117-122</sup> No differences were found in the risk of SUTI or bacteriuria/unspecified UTI. Study populations included nursing home residents and adults and children with neurogenic bladder/spinal cord injury.

**Evidence Review Table 2A. What are the risks and benefits associated with different approaches to catheterization?**

2A.1. Consider using external catheters as an alternative to indwelling urethral catheters in cooperative male patients without urinary retention or bladder outlet obstruction. **(Category II)**

2A.2. Intermittent catheterization is preferable to indwelling urethral or suprapubic catheters in patients with bladder emptying dysfunction. **(Category II)**

2A.3. If intermittent catheterization is used, perform it at regular intervals to prevent bladder overdistension. **(Category IB)**

2A.4. For operative patients who have an indication for an indwelling catheter, remove the catheter as soon as possible postoperatively, preferably within 24 hours, unless there are appropriate indications for continued use. **(Category IB)\***

2A.5. Further research is needed on the risks and benefits of suprapubic catheters as an alternative to indwelling urethral catheters in selected patients requiring short- or long-term catheterization, particularly with respect to complications related to catheter insertion or the catheter site. **(No recommendation/unresolved issue)**

2A.6. In the non-acute care setting, clean (i.e., non-sterile) technique for intermittent catheterization is an acceptable and more practical alternative to sterile technique for patients requiring chronic intermittent catheterization. **(Category IA)**

\* More data are available under Question 2C

## **Q2B. What are the risks and benefits associated with different catheters or collecting systems?**

The available data examined the following comparisons between different types of catheters and drainage systems:

1. Antimicrobial/antiseptic catheters vs. standard catheters
  - a. Silver-coated catheters vs. standard catheters
  - b. Nitrofurazone-impregnated catheters vs. standard catheters
2. Hydrophilic catheters vs. standard catheters
3. Closed vs. open drainage systems
4. Complex vs. simple drainage systems
5. Preconnected/sealed junction catheters vs. standard catheters
6. Catheter valves vs. catheter bags

For all comparisons, we considered CAUTI outcomes as well as other outcomes critical to weighing the risks and benefits of different types of catheters or collecting systems. The evidence for this question consists of 5 systematic reviews,<sup>37,137-140</sup> 17 RCTs,<sup>64,143-158</sup> 23 observational studies,<sup>82,86,89,97,159-163, 165-178</sup> and 3 economic analyses.<sup>179,180,181</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 2B.

### *Q2B.1.a. Silver-coated catheters vs. standard catheters*

Low-quality evidence suggested a benefit of silver-coated catheters over standard latex catheters.<sup>37,82,86,137-139,143,159-163, 165,166</sup> This was based on a decreased risk of bacteriuria/unspecified UTI with silver-coated catheters and no evidence of increased urethral irritation or antimicrobial resistance in studies that reported data on microbiological outcomes. Differences were significant for silver alloy-coated catheters but not silver oxide-coated catheters. In a meta-analysis of randomized controlled trials (see [Appendix](#)), silver alloy-coated catheters reduced the risk of asymptomatic bacteriuria compared to standard latex catheters (control latex catheters were either uncoated or coated with hydrogel, Teflon®, or silicone), whereas there were no differences when compared to standard, all silicone catheters. The effect of silver alloy catheters compared to latex catheters was more pronounced when used in patients catheterized <1 week. The results were robust to inclusion or exclusion of non peer-reviewed studies. Only one observational study found a decrease in SUTI with silver alloy-coated catheters.<sup>166</sup> The setting was a burn referral center, where the control catheters were latex, and patients in the intervention group had new catheters placed on admission, whereas the control group did not. Recent observational studies in hospitalized patients found mixed results for bacteriuria/unspecified UTI.

### *Q2B.1.b. Nitrofurazone-impregnated catheters vs. standard catheters*

Low-quality evidence suggested a benefit of nitrofurazone-impregnated catheters in patients catheterized for short periods of time.<sup>137,138</sup> This was based on a decreased risk of bacteriuria and no evidence of increased antimicrobial resistance in studies that reported microbiological outcomes. Differences were significant in a meta-analysis of three studies examining nitrofurazone-impregnated catheters (only one individual study significant) when duration of catheterization was <1 week. No differences were seen when duration of catheterization was >1 week, although the meta-analysis was borderline significant.

### *Q2B.2. Hydrophilic catheters vs. standard catheters*

Very low-quality evidence suggested a benefit of hydrophilic catheters over standard non-hydrophilic catheters in specific populations undergoing clean intermittent catheterization.<sup>137,144-148,169</sup> This was based on a decreased risk of SUTI, bacteriuria, hematuria, and pain during insertion, and increased patient satisfaction. Differences in CAUTI outcomes were limited to one study of spinal cord injury patients and one study of patients receiving intravesical immunochemoprophylaxis for bladder cancer, while multiple other studies found no significant differences.

### *Q2B.3. Closed vs. open drainage systems*

Very low-quality evidence suggested a benefit of using a closed rather than open urinary drainage system.<sup>89,171</sup> This was based on a decreased risk of bacteriuria with a closed drainage system. One study also found a suggestion of a decreased risk of SUTI, bacteremia, and UTI-related mortality associated with closed drainage systems, but differences were not statistically significant. Sterile, continuously closed drainage systems became the standard of care based on an uncontrolled study published in 1966 demonstrating a dramatic reduction in the risk of infection in short-term catheterized patients with the use of a closed system.<sup>23</sup> Recent data also include the finding that disconnection of the drainage system is a risk factor for bacteriuria (Q1B).

### *Q2B.4. Complex vs. simple drainage systems*

Low-quality evidence suggested no benefit of complex closed urinary drainage systems over simple closed urinary drainage systems.<sup>150-152,154,172,176,177</sup> Although there was a decreased risk of bacteriuria with the complex systems, differences were found only in studies published before 1990, and not in more recent studies. The complex drainage systems studied included various mechanisms for reducing bacterial entry, such as antiseptic-releasing cartridges at the drain port of the urine collection bag; see evidence table for systems evaluated.

### *Q2B.5. Preconnected/sealed junction catheters vs. standard catheters*

Low-quality evidence suggested a benefit of using preconnected catheters with junction seals over catheters with unsealed junctions to reduce the risk of disconnections.<sup>64,153,156,175</sup> This was based on a decreased risk of SUTI and bacteriuria with preconnected sealed catheters. Studies that found differences had higher rates of CAUTI in the control group than studies that did not find an effect.

### *Q2B.6. Catheter valves vs. drainage bags*

Moderate-quality evidence suggested a benefit of catheter valves over drainage bags in selected patients with indwelling urinary catheters.<sup>140</sup> Catheter valves led to greater patient satisfaction but no differences in bacteriuria/unspecified UTI or pain/bladder spasms. Details regarding the setting for recruitment and follow-up of the patients in the studies were unclear, and the majority of subjects were men. Our search did not reveal data on the effect of catheter valves on bladder function, bladder/urethral trauma, or catheter blockage.

**Evidence Review Table 2B. What are the risks and benefits associated with different catheters or collecting systems?**

2B.1. If the CAUTI rate is not decreasing after implementing a comprehensive strategy to reduce rates of CAUTI, consider using antimicrobial/antiseptic-impregnated catheters. The comprehensive strategy should include, at a minimum, the high priority recommendations for urinary catheter use, aseptic insertion, and maintenance (see Section III. Implementation and Audit). **(Category IB)**

2B.1.a. Further research is needed on the effect of antimicrobial/antiseptic-impregnated catheters in reducing the risk of symptomatic UTI, their inclusion among the primary interventions, and the patient populations most likely to benefit from these catheters. **(No recommendation/unresolved issue)**

2B.2. Hydrophilic catheters might be preferable to standard catheters for patients requiring intermittent catheterization. **(Category II)**

2B.3. Following aseptic insertion of the urinary catheter, maintain a closed drainage system. **(Category IB)**

2B.4. Complex urinary drainage systems (utilizing mechanisms for reducing bacterial entry such as antiseptic-release cartridges in the drain port) are not necessary for routine use. **(Category II)**

2B.5. Urinary catheter systems with preconnected, sealed catheter-tubing junctions are suggested for use. **(Category II)**

2B.6. Further research is needed to clarify the benefit of catheter valves in reducing the risk of CAUTI and other urinary complications. **(No recommendation/unresolved issue)**

**Q2C. What are the risks and benefits associated with different catheter management techniques?**

The available data examined the following catheter management techniques:

1. Antimicrobial prophylaxis
2. Urinary antiseptics (i.e., methanamine)
3. Bladder irrigation
4. Antiseptic instillation in the drainage bag
5. Periurethral care
6. Routine catheter or bag change
7. Catheter lubricants
8. Securing devices
9. Bacterial interference
10. Catheter cleansing
11. Catheter removal strategies (clamping vs. free drainage prior to removal, postoperative duration of catheterization)
12. Assessment of urine volumes

For all comparisons, we considered CAUTI outcomes as well as other outcomes critical to weighing the risks and benefits of different catheter management techniques. The evidence for this question consists of 6 systematic reviews,<sup>37,105,106,182-184</sup> 56 RCTs,<sup>60,61,65-69,143,158,185-231</sup> 34 observational studies,<sup>83,85,88,90,96,102,133,167,178,232-258</sup> and 1 economic analysis.<sup>180</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 2C.

#### *Q2C.1. Antimicrobial prophylaxis*

Low-quality evidence suggested no benefit of antimicrobial prophylaxis in patients undergoing short-term catheterization.<sup>37,60,61,83,85,133,158,178,182,185,186,189-191,232-234</sup> This was based on heterogeneous results for SUTI and bacteriuria/unspecified UTI and no adverse events related to antimicrobials. Lack of consistency in specific factors, such as patient population, antimicrobial agents, timing of administration, and duration of follow-up, did not allow for a summary of evidence of the effect of antimicrobial prophylaxis on CAUTI in patients undergoing short term catheterization. Only two studies evaluated adverse events related to antimicrobials. Our search did not reveal data on antimicrobial resistance or *Clostridium difficile* infection.

Low-quality evidence suggested no benefit of antimicrobial prophylaxis in patients undergoing long-term catheterization (indwelling and clean intermittent catheterization).<sup>106,183,192,194,235,238</sup> This was based on a decreased risk of bacteriuria, heterogeneous results for SUTI, and no differences reported for catheter encrustation or adverse events, although data were sparse. One systematic review suggested an increase in antimicrobial resistance with antimicrobial use.

#### *Q2C.2. Urinary antiseptics*

Low-quality evidence suggested a benefit of methenamine for short-term catheterized patients.<sup>196,197</sup> This was based on a reduced risk of SUTI and bacteriuria and no differences in adverse events. Evidence was limited to two studies of patients following gynecological surgery in Norway and Sweden.

Very low-quality evidence suggested a benefit of methanamine for long-term catheterized patients.<sup>106,236-239</sup> This was based on a reduced risk of encrustation but no differences in risk of SUTI or bacteriuria. Data on encrustation was limited to one study. Studies involved primarily elderly and spinal cord injury patients with chronic indwelling catheters

#### *Q2C.3. Bladder irrigation*

Low-quality evidence suggested no benefit of bladder irrigation in patients with indwelling or intermittent catheters.<sup>66,69,199-206,240-242</sup> This was based on no differences in SUTI and heterogeneous findings for bacteriuria.

#### *Q2C.4. Antiseptic instillation in the drainage bag*

Low-quality evidence suggested no benefit of antiseptic instillation in urinary drainage bags.<sup>90,207-211,243-245</sup> This was based on no differences in SUTI and heterogeneous results for bacteriuria.

#### *Q2C.5. Periurethral care*

Low-quality evidence suggested no benefit of antiseptic meatal cleaning regimens before or during catheterization to prevent CAUTI.<sup>65,67,68,88,158,212-216,246,247</sup> This was based on no difference in the risk of bacteriuria in patients receiving periurethral care regimens compared to those not receiving them. One study found a higher risk of bacteriuria with cleaning of the urethral meatus-catheter junction (either twice daily application of povidine-iodine or once daily cleaning with a non-antiseptic solution of green soap and water) in a subgroup of women with positive meatal cultures and in patients not receiving antimicrobials. Periurethral cleaning with chlorhexidine before catheter insertion did not have an effect in two studies.

#### *Q2C.6. Routine catheter or bag change*

Low-quality evidence suggested no benefit of routine catheter or drainage bag changes to prevent CAUTI.<sup>102,217-219,248,249</sup> This was based on no difference or an increased risk of SUTI and no difference in bacteriuria with routine compared to as-needed changes or with more frequent changing intervals. One study in nursing home residents found no differences in SUTI with routine monthly catheter changes compared to changing only for obstruction or infection, but the study was underpowered to detect a difference. Another study in home care patients found an increased risk of SUTI when catheters were changed more frequently than monthly.

#### *Q2C.7. Catheter lubricants*

Very low-quality evidence suggested a benefit of using lubricants for catheter insertion.<sup>167,220-223,250-254</sup> This was based on a decreased risk of SUTI and bacteriuria with the use of a pre-lubricated catheter compared to a catheter lubricated by the patient and a decreased risk of bacteriuria with use of a lubricant versus no lubricant. Studies were heterogeneous both in the interventions and outcomes studied. Several studies comparing antiseptic lubricants to non-antiseptic lubricants found no significant differences.

#### *Q2C.8. Securing devices*

Low-quality evidence suggested no benefit of using catheter securing devices to prevent CAUTI.<sup>224</sup> This was based on no significant difference in the risk of SUTI or meatal erosion. The only study in this category looked at one particular product.

#### *Q2C.9. Bacterial interference*

Moderate-quality evidence suggested a benefit of using bacterial interference in catheterized patients.<sup>225</sup> In the one study evaluating this intervention, urinary colonization with a non-pathogenic *Escherichia coli* was associated with a decreased risk of SUTI in adults with spinal cord injury and a history of frequent CAUTI.

#### *Q2C.10. Catheter cleansing*

Very low-quality evidence suggested a benefit of wet versus dry storage procedures for catheters used in clean intermittent catheterization.<sup>255</sup> This was based on a decreased risk of SUTI with a wet storage procedure in one study of spinal cord injury patients undergoing clean intermittent catheterization compared to a dry storage procedure where the catheter was left to air dry after washing. In the wet procedure, the catheter was stored in a dilute povidone-iodine solution after washing with soap and water.

#### *Q2C.11. Catheter removal strategies*

a. Clamping vs. free drainage prior to removal

Low-quality evidence suggested no benefit of clamping versus free drainage before catheter removal.<sup>37,184</sup> This was based on no difference in risk of bacteriuria, urinary retention, or recatheterization between the two strategies. One study comparing a clamp and release strategy to free drainage over 72 hours found a greater risk of bacteriuria in the clamping group.

b. Postoperative duration of catheterization

Moderate-quality evidence suggested a benefit of shorter versus longer postoperative durations of catheterization.<sup>37,184,227,228</sup> This was based on a decreased risk of bacteriuria/unspecified UTI, decreased time to ambulation and length of stay, no differences in urinary retention and SUTI, and increased risk of recatheterization. Significant decreases in bacteriuria/unspecified UTI were found specifically for comparisons of 1 day versus 3 or 5 days of postoperative catheterization. Recatheterization risk was greater in only one study comparing immediate removal to removal 6 or 12 hours after hysterectomy.

*Q2C.12. Assessment of urine volumes*

Low-quality evidence suggested a benefit of using portable ultrasound to assess urine volume in patients undergoing intermittent catheterization.<sup>229,230</sup> This was based on fewer catheterizations but no reported differences in risk of unspecified UTI. Patients studied were adults with neurogenic bladder in inpatient rehabilitation centers. Our search did not reveal data on the use of ultrasound in catheterized patients in other settings.

**Evidence Review Table 2C. What are the risks and benefits associated with different catheter management techniques?**

2C.1. Unless clinical indications exist (e.g., in patients with bacteriuria upon catheter removal post urologic surgery), do not use systemic antimicrobials routinely as prophylaxis for UTI in patients requiring either short or long-term catheterization. **(Category IB)**

2C.2.a. Further research is needed on the use of urinary antiseptics (e.g., methanamine) to prevent UTI in patients requiring short-term catheterization. **(No recommendation/unresolved issue)**

2C.2.b. Further research is needed on the use of methanamine to prevent encrustation in patients requiring chronic indwelling catheters who are at high risk for obstruction. **(No recommendation/unresolved issue)**

2C.3.a. Unless obstruction is anticipated (e.g., as might occur with bleeding after prostatic or bladder surgery), bladder irrigation is not recommended. **(Category II)**

2C.3.b. Routine irrigation of the bladder with antimicrobials is not recommended. **(Category II)**

2C.4. Routine instillation of antiseptic or antimicrobial solutions into urinary drainage bags is not recommended. **(Category II)**

2C.5.a. Do not clean the periurethral area with antiseptics to prevent CAUTI while the catheter is in place. Routine hygiene (e.g., cleansing of the meatal surface during daily bathing) is

appropriate. **(Category IB)**  
 2C.5.b. Further research is needed on the use of antiseptic solutions vs. sterile water or saline for periurethral cleaning prior to catheter insertion. **(No recommendation/unresolved issue)**

2C.6. Changing indwelling catheters or drainage bags at routine, fixed intervals is not recommended. Rather, catheters and drainage bags should be changed based on clinical indications such as infection, obstruction, or when the closed system is compromised. **(Category II)**

2C.7.a. Use a sterile, single-use packet of lubricant jelly for catheter insertion. **(Category IB)**  
 2C.7.b. Routine use of antiseptic lubricants is not necessary. **(Category II)**

2C.8. Further research is needed on the use of bacterial interference to prevent UTI in patients requiring chronic urinary catheterization. **(No recommendation/unresolved issue)**

2C.9. Further research is needed on optimal cleaning and storage methods for catheters used for clean intermittent catheterization. **(No recommendation/unresolved issue)**

2C.10.a. Clamping indwelling catheters prior to removal is not necessary. **(Category II)**  
 2C.10.b. Insert catheters only for appropriate indications, and leave in place only as long as needed. **(Category IB)**  
 2C.10.c. For operative patients who have an indication for an indwelling catheter, remove the catheter as soon as possible postoperatively, preferably within 24 hours, unless there are appropriate indications for continued use. **(Category IB)**

2C.11.a. Consider using a portable ultrasound device to assess urine volume in patients undergoing intermittent catheterization to assess urine volume and reduce unnecessary catheter insertions. **(Category II)**  
 2C.11.b. Further research is needed on the use of a portable ultrasound device to evaluate for obstruction in patients with indwelling catheters and low urine output. **(No recommendation/unresolved issue)**

***Q2D. What are the risks and benefits associated with different systems interventions?***

The available data examined the following systems interventions:

1. Infection control/quality improvement programs (multifaceted)
2. Catheter reminders
3. Bacteriologic monitoring
4. Hand hygiene
5. Patient placement
6. Catheter team versus self-catheterization
7. Feedback
8. Nurse-directed catheter removal

We considered CAUTI outcomes, duration of catheterization, recatheterization, and transmission of pathogens when weighing the risks and benefits of different systems interventions. The evidence for this question consists of 1 RCT<sup>259</sup> and 19 observational

studies.<sup>3,25,260-276</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 2D.

#### *Q2D.1. Multifaceted infection control/quality improvement programs*

Low-quality evidence suggested a benefit of multifaceted infection control/quality improvement programs to reduce the risk of CAUTI.<sup>3,260-267</sup> This was based on a decreased risk of SUTI, bacteriuria/unspecified UTI, and duration of catheter use with implementation of such programs. Studies evaluated various multifaceted interventions. The studies with significant findings included: 1) education and performance feedback regarding compliance with catheter care, emphasizing hand hygiene, and maintaining unobstructed urine flow; 2) computerized alerts to physicians, nurse-driven protocols to remove catheters, and use of handheld bladder scanners to assess for urinary retention; 3) guidelines and education focusing on perioperative catheter management; and 4) a multifaceted infection control program including guidelines for catheter insertion and maintenance. A program using a checklist and algorithm for appropriate catheter use also suggested a decrease in unspecified UTI and catheter duration, but statistical differences were not reported.

#### *Q2D.2. Reminders*

Very low-quality evidence suggested a benefit of using urinary catheter reminders to prevent CAUTI.<sup>268-270</sup> This was based on a decreased risk of bacteriuria and duration of catheterization and no differences in recatheterization or SUTI when reminders were used. Reminders to physicians included both computerized and non-computerized alerts about the presence of urinary catheters and the need to remove unnecessary catheters.

#### *Q2D.3. Bacteriologic monitoring*

Very low-quality evidence suggested no benefit of bacteriologic monitoring to prevent CAUTI.<sup>25,271</sup> Although one study found a decreased risk of bacteriuria during a period of bacteriologic monitoring and feedback, only 2% of SUTI episodes were considered potentially preventable with the use of bacteriologic monitoring.

#### *Q2D.4. Hand hygiene*

Very low-quality evidence suggested a benefit of using alcohol hand sanitizer in reducing CAUTI. This was based on one study in a rehabilitation facility that found a decrease in unspecified UTI, although no statistical differences were reported.<sup>272</sup> A separate multifaceted study that included education and performance feedback on compliance with catheter care and hand hygiene showed a decrease in risk of SUTI.<sup>265</sup>

#### *Q2D.5. Patient placement*

Very low-quality evidence suggested a benefit of spatially separating patients to prevent transmission of urinary pathogens.<sup>273</sup> This was based on a decreased risk of transmission of urinary bacterial pathogens in nursing home residents in separate rooms compared to residents in the same rooms.

#### *Q2D.6. Catheter team versus self-catheterization*

Very low-quality evidence suggested no benefit of a catheter team to prevent CAUTI among patients requiring intermittent catheterization.<sup>274</sup> This was based on one study showing no difference in unspecified UTI between use of a catheter care team and self-catheterization for intermittent catheterization in paraplegic patients.

*Q2D.7. Feedback*

Very low-quality evidence suggested a benefit of using nursing feedback to prevent CAUTI.<sup>275</sup> This was based on a decreased risk of unspecified UTI during an intervention where nursing staff were provided with regular reports of unit-specific rates of CAUTI.

*Q2D.8. Nurse-directed catheter removal*

Very low-quality evidence suggested a benefit of a nurse-directed catheter removal program to prevent CAUTI.<sup>276</sup> This was based on a decreased risk of unspecified UTI during an intervention where criteria were developed that allowed a registered nurse to remove a catheter without a physician's order when no longer medically necessary. Of the three intensive care units where the intervention was implemented, differences were significant only in the coronary intensive care unit.

**Evidence Review Table 2D. What are the risks and benefits associated with different systems interventions?**

2D.1.a. Ensure that healthcare personnel and others who take care of catheters are given periodic in-service training stressing the correct techniques and procedures for urinary catheter insertion, maintenance, and removal. **(Category IB)**

2D.1.b. Implement quality improvement (QI) programs or strategies to enhance appropriate use of indwelling catheters and to reduce the risk of CAUTI based on a facility risk assessment. **(Category IB)**

Examples of programs that have been demonstrated to be effective include:

1. A system of alerts or reminders to identify all patients with urinary catheters and assess the need for continued catheterization
2. Guidelines and protocols for nurse-directed removal of unnecessary urinary catheters
3. Education and performance feedback regarding appropriate use, hand hygiene, and catheter care
4. Guidelines and algorithms for appropriate peri-operative catheter management, such as:
  - a. Procedure-specific guidelines for catheter placement and postoperative catheter removal
  - b. Protocols for management of postoperative urinary retention, such as nurse-directed use of intermittent catheterization and use of ultrasound bladder scanners

2D.2. Routine screening of catheterized patients for asymptomatic bacteriuria is not recommended. **(Category II)**

2D.3. Perform hand hygiene immediately before and after insertion or any manipulation of the catheter site or device. **(Category IB)**

2D.5. Maintain unobstructed urine flow. **(Category IB)**

2D.6. Further research is needed on the benefit of spatial separation of patients with urinary catheters to prevent transmission of pathogens colonizing urinary drainage systems. **(No recommendation/unresolved issue)**

2D.7. When performing surveillance for CAUTI, consider providing regular (e.g., quarterly) feedback of unit-specific CAUTI rates to nursing staff and other appropriate clinical care staff. **(Category II)**

### **Q3: What are the best practices for preventing UTI associated with obstructed urinary catheters?**

The available data examined the following practices:

1. Methods to prevent/reduce encrustations or blockage
2. Catheter materials preventing blockage

For this question, available relevant outcomes included blockage/encrustation. We did not find data on the outcomes of CAUTI. The evidence for this question consists of 1 systematic review,<sup>277</sup> 2 RCTs,<sup>278,279</sup> and 2 observational studies.<sup>280,281</sup> The findings of the evidence review and the grades for all important outcomes are shown in Evidence Review Table 3.

#### *Q3.1. Methods to prevent/reduce encrustations or blockage*

Low-quality evidence suggested a benefit of acidifying solutions or oral acetohydroxamic acid in preventing or reducing catheter encrustations and blockage in long-term catheterized patients.<sup>277,278,280,281</sup> No differences were seen with daily catheter irrigation with normal saline.

#### *Q3.2. Catheter materials preventing blockage*

Low-quality evidence suggested a benefit of silicone over latex or Teflon-coated catheters in prevention or reducing catheter encrustations in long-term catheterized patients who were prone to blockage. No differences were seen with different materials in patients considered “non-blockers.”<sup>279</sup>

#### **Evidence Review Table 3. What are the best practices for preventing UTI associated with obstructed urinary catheters?**

3.1.a. Further research is needed on the benefit of irrigating the catheter with acidifying solutions or use of oral urease inhibitors in long-term catheterized patients who have frequent catheter obstruction. **(No recommendation/unresolved issue)**

3.2.a. Silicone might be preferable to other materials to reduce the risk of encrustation in long-term catheterized patients who have frequent obstruction. **(Category II)**

# ICS teaching module: Clinical stress test for urinary incontinence

ML Guralnick, X Fritel, T Tarcan, M Espuna-Pons,  
PFWM Rosier

The ICS grants permission to use the PowerPoint slide set in educational environment with the proviso that the set remains unchanged, the ICS branding remains visible for non-commercial use. The ICS does not need prior approval for use of this slide set.

For commercial use please contact the ICS Office.

## Clinical Testing For SUI – Cough Stress Test (CST)

*International Consultation Incontinence*  
[ICS Standard Terminology 2002]:

- 'The stress test involves observation for urine loss with coughing or Valsalva manoeuvre ...
- Can be used to help make the diagnosis of SUI (objective test done in clinic) especially prior to surgical management
- Can be used as objective outcome measure when reporting treatment effects.

## No Standardization of Performance/Reporting of CST

- Variables to consider:
  - Patient position (supine/lithotomy/seated/standing)
  - Bladder volume and method of determination
  - Number of coughs
  - Method of SUI detection

## Many Reports Fail to Describe How The CST Was Done

- positioning included: supine/lithotomy, semi-lithotomy, seated, standing
- \*\* bladder volumes included "empty", "comfortably/symptomatically full", "full", 100-700ml
- \*\*\* natural fill or retrograde fill via catheter (often done during UDS)
- ^ number of coughs ranged from 1-10 or reported as "a series of coughs"
- ^^ direct visualization of incontinence or pad testing

## ICS Uniform Cough Stress Test (ICS-UCST)

Provisional (consensus)

- To standardize performance/reporting of CST to allow for easier, more consistent interpretation
- Recommendations of ICS working group based on review of more than 200 articles that have some mention of stress test
- To be done during uro-gynecological examination

### Inform patient:

- ... there are diverse causes of urinary incontinence
- ... physical effort as one of the causes will be tested
- ... through a forceful cough during the clinical examination
  - vaginal inspection
- ... not pleasant, nor elegant, but helps select the best management

## ICS-UCST Variables

(Evidence base in accompanying manuscript)

- Patient Position:
  - Supine/lithotomy
- Bladder volume:
  - 200-400mL
- Method of bladder filling:
  - Natural:
    - Patient advised to present with comfortably full bladder
    - Use ultrasound or voided volume + PVR after ICS-UCST to determine
  - Retrograde:
    - Specific volume instilled by examiner

## ICS-UCST Variables:

- Number of coughs (up to 4):
  - Patient coughs forcefully x 1
  - If no SUI, patient then coughs 3 more times
    - if SUI noted after 1 cough, additional coughs not needed
- Method of SUI detection:
  - Examiner spreads labia and directly visualizes leakage of urine per urethral meatus

## Interpretation ICS-UCST:

- ICS-UCST is **positive** when urine (fluid) is observed, leaving the meatus *coincident/simultaneous* to one or more of the coughs
- ICS-UCST is **negative** when there is no urine (fluid) lost or leakage of urine (fluid) lasts longer than the cough/delayed from the cough (cough induced detrusor overactivity)
  - Report: '... incontinence is not demonstrated during ICS-UCST.'

## Other Tests (Accessory Stress Tests):

- 'Stress tests -variants'
  - In other positions or with alternative provocation
    - *Standing / seated*
      - Generally recommended that upright CST be done if supine CST is negative in patient with complaint of SUI
    - *Strain / Valsalva*
  - Other bladder volumes:
    - *Empty (Supine Empty Stress Test, SEST)* – may help identify potential intrinsic sphincter deficiency
    - *"full bladder"* (>300mL)
- Cystometry (e.g. LPP testing):
  - Confirming or refuting (U)SUI

## Scientific Reporting

- Report proportion (%) of patients (recruited or included) with:
  - Positive ICS-UCST
  - Positive accessory tests (specify)
  - Cystometry

## Conclusion:

- ICS-Uniform Cough Stress Test is presented
  - ICS-UCST:
    - Supine/lithotomy position
    - Bladder volume 200-400mL
    - 1-4 forceful coughs
    - Incontinence seen coincident/simultaneous to the cough(s)
  - Accessory stress tests may be used when ICS-UCST negative to further clarify diagnosis
    - Not standardized

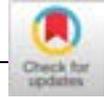

## Future

- Validity of ICS-UCST should be determined/quantified:
  - Specificity
  - Sensitivity (compare with accessory tests, UDS)
  - Predictive value towards outcome of management

**Introduction:** A cough stress test (CST) is recommended in the evaluation of the uncomplicated female patient with the complaint of stress urinary incontinence (SUI) to identify the sign of SUI, and is often used as an outcome measure following SUI treatment. However, there has been no standardization of the performance or reporting of CST. A working group of the International Continence Society (ICS) has developed an educational module, comprising a Powerpoint™ presentation and evidence base manuscript, to instruct on the performance, interpretation, and reporting of the CST in a standardized manner: the ICS-Uniform Cough Stress Test (ICS-UCST).

**Methods:** The working group performed a PUBMED literature search of articles (observational/experimental and reviews) published prior to 2017 that mentioned a CST. The evidence base examined various variables in performing a CST as well as sensitivity/specificity and positive/negative predictive values of CST.

**Results:** The variables involved in performing/interpreting an ICS-UCST include: patient positioning, degree of bladder filling, number, and forcefulness of coughs, and method of SUI detection. For the ICS-UCST it is recommended that the patient be in a supine/lithotomy position with 200–400 mL of fluid in the bladder. She coughs forcefully 1–4 times and the examiner directly visualizes the urethral meatus for the presence of leakage. Leakage of fluid from the urethral meatus coincident with/simultaneous to the cough(s) is considered a positive test.

**Conclusion:** This module provides instructions to educate a uniform CST (the ICS-UCST), with the aim of improving the clinical practice of cough stress testing in female patients with urinary incontinence.

## KEYWORDS

cough stress test, stress urinary incontinence

## 1 | INTRODUCTION

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

The cough stress test (CST) is a clinical test used in the evaluation of urinary incontinence (UI). The patient coughs

and the visualization of urine loss synchronous with the cough confirms the presence of stress urinary incontinence (SUI).<sup>1</sup> CST is used to objectively make the diagnosis of SUI<sup>2</sup> and assess the outcome of treatment for SUI.<sup>3,4</sup> Its use in the evaluation of UI (when symptoms of SUI are expressed; the SUI syndrome: SUI-S<sup>5</sup>) has been endorsed by several societies including the French College of Gynecologists and Obstetricians; International Federation of Gynecology and Obstetrics (FIGO); International Urogynecological Association (IUGA), and American College of Obstetricians and Gynecologists.<sup>2,6–8</sup> Although the European Association of Urology guideline is brief about this test, the recent American Urological Association guideline considers it a sine-qua-non for the diagnosis of SUI.<sup>9,10</sup> Based on their review, the FIGO working group recommended all patients being evaluated for SUI-S should have a CST (Grade A)<sup>8</sup> and in a research context, CST has been the most commonly used measure for evaluating the outcome of SUI surgery.<sup>3,4</sup> Despite the support for the CST, standardization of how to perform a CST does not exist. The ICS Urodynamics Committee presents the teaching module “Cough stress test in the evaluation of female urinary incontinence” to serve as a standard for educating a CST for the evaluation of female UI and/or SUI-S.

A new ICS term for the CST is introduced: ICS Uniform Cough Stress Test (ICS-UCST) because the secondary aim of this module is to uniformize, by teaching, CST for clinical routine and research. This manuscript provides the evidence base for the ICS educational PowerPoint™ presentation that accompanies this module as well as the arguments for the uniformization. The aim of this module is to educate the utilization and interpretation of the CST which will hopefully improve and facilitate the clinical diagnosis of SUI and the assessment/reporting of SUI treatment outcomes.

## 2 | METHODS

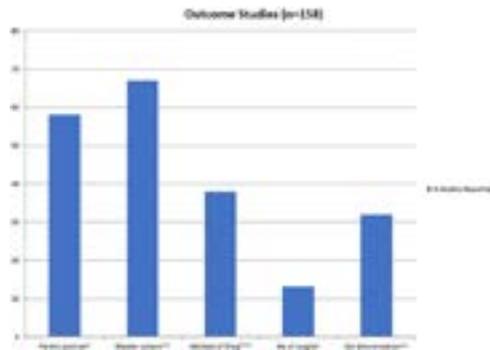

The working group for this module did an extensive literature review of more than 200 articles published prior to 2017 that mention a cough stress test, via a PUBMED online search using the terms “cough and stress test and incontinence.” These included observational/experimental studies as well as review articles. References used specifically for this manuscript are provided at the end and a full references list in an accessory file on the publisher's website.

### 2.1 | The evidence base for standardization of CST

There is general consensus that the CST in combination with the SUI-S is reliable in confirming that the pathophysiology of the UI is SUI.<sup>11–18</sup> In a review of the

literature to determine the predictive value of the clinical evaluation of SUI (history, physical exam with CST) using multichannel UDS as the comparator, it was found that for the diagnosis of genuine SUI, the CST alone had sensitivity (sens:) 57%, specificity (spec:) 71%, positive predictive value (PPV) of 55% and negative predictive value (NPV) of 73%.<sup>15</sup> However, when other UDS diagnoses (eg, mixed incontinence) were included, the PPV was 91%, indicating that CST had been demonstrating UI but not “uncomplicated SUI” in all patients. When combined with the symptoms of SUI-S, the CST had a PPV of 78–97%.<sup>15</sup> A randomized trial of UDS prior to SUI surgery observed that an office evaluation including a CST correctly identified 97% of women found to have SUI on UDS and the demonstration of SUI during UDS subsequent to a positive CST did not improve the treatment success of SUI surgery.<sup>12</sup> In a prospective study, when CST was compared to multichannel UDS and 24 h pad testing the agreement between UDS and CST was 89% ( $k = 0.51$ ), whereas agreement between UDS and 24 h pad test was only 60% ( $k = 0.08$ ) and agreement between the CST and 24 h pad test was only 67% ( $k = 0.26$ ).<sup>16</sup> Using UDS as the reference, the sens, spec, PPV and NPV of the CST were 90%, 80%, 98%, and 44% respectively. CST during single channel cystometry was compared to CST during multichannel UDS in another prospective study<sup>13</sup> that alternated the gold standard for diagnosing SUI (a cough UPP during multichannel UDS versus CST and simple CMG). No significant difference between the two methods was seen with both having sens, spec, PPV, and NPV between 80% and 87%. In a similar study, when CST with simple bladder filling was compared to CST during multichannel UDS (using CST during UDS as the gold standard),<sup>14</sup> for the diagnosis of SUI the CST with simple bladder filling had a sens 88%, spec 77%; PPV 82% and NPV 84%. It was concluded that CST with simple bladder filling is a reliable method of diagnosing SUI and can replace complex UDS which is in keeping with an assessment of AHCPR criteria for predicting SUI clinically (using UDS as the gold standard) that found that the most helpful criterion was the CST which had sens 93%; spec 56%; PPV 68% and NPV 89%.<sup>17</sup>

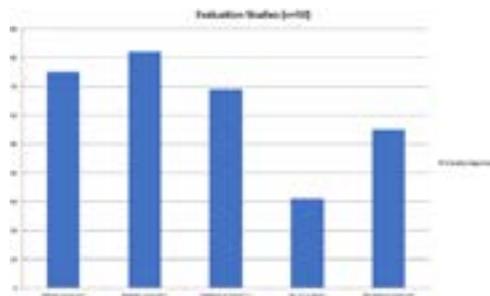

Despite the evidence supporting the use of CST there has not been any standardization of the performance or reporting of CST. In fact, in reviewing 208 studies that make mention of a CST (outcome assessment studies, test evaluation studies) we found that only 62% specified the patient positioning, 71% the bladder volume, 45% the method of filling, 17% the number of coughs and 38% the method of SUI determination (Figures 1 and 2). The lack of standardization makes every statement about the predictive value of (history and) clinical examination (and CST) on the outcome of management for UI difficult to evaluate and/or impossible to extrapolate.

**FIGURE 1** Studies assessing the outcome of a treatment intervention that mentioned using a CST (references online). \*Positioning included: supine/lithotomy, semi-lithotomy, seated, standing. \*\*Bladder volumes included “empty,” “comfortably/symptomatically full,” “full,” 100-700 mL. \*\*\*Natural fill or retrograde fill via catheter (often done during UDS). ^Number of coughs ranged from 1 to 10 or reported as “a series of coughs.” ^^Direct visualization of incontinence or pad testing

**2.2 | Educating the ICS-UCST**

From the available evidence we have selected the elements of CST: (1) preparation for the test; (2) performing the test: (a) patient positioning; (b) bladder volume; (c) number of coughs; (d) leakage detection; and (3) interpretation and reporting of the test. On the basis of our review of the evidence, we propose, to educate the elements of the CST to be performed in a standard manner, the ICS-UCST (Figure 3).

**FIGURE 2** Studies looking at the evaluation of incontinence (e.g. studies assessing clinical factors contributing to incontinence, studies evaluating the performance of UDS, that mentioned using a CST (references online). \*Positioning included: supine/lithotomy, semi-lithotomy, seated, standing. \*\*Bladder volumes included “empty,” “comfortably/symptomatically full,” “full,” 100-700 mL. \*\*\*Natural fill or retrograde fill via catheter (often done during UDS). ^Number of coughs ranged from 1 to 10 or reported as “a series of coughs.” ^^Direct visualization of incontinence or pad testing

The education of the ICS-Uniform Cough Stress Test includes the explanation of the instructions.

**The physician should:**

- Explain to the patient before or during clinical exam in lithotomy position that the ICS-UCST is one of the tests that is used to unravel the nature/origin of the urinary incontinence
- That the test may be embarrassing, however considered valuable and necessary
- Ask the patient about bladder fullness (see below)
- Be aware of the usual voided volumes (and frequency)

**The physician:**

- Has instructed the patient to be in supine/lithotomy position and is able to observe the bladder
- Considers likelihood that the present intravesical volume, during the test, is representative for this patient and between 300 and 400mL.
- Asks the patient to cough as forceful as possible and if no leakage is observed, asks to cough 3 more times, as forceful as possible

**The physician:**

- Objectively determines what the intravesical volume is or has been during the CST
- Reports that the ICS-UCST has been positive with “+” or “+/-” or negative
- Considers repeating CST (up to 4 coughs) in standing position and reports the standing accessory CST to be positive or negative
- Considers complementary or accessory evaluation to determine the pathophysiology as the cause of the UI\*

\* In a patient with UI or more specifically with SUI-S, a negative ICS-UCST and a negative accessory CST, an ICS standard pad test\*\* and/or (full) urodynamic testing may be considered to evaluate the complete lower urinary tract function, as per current practice guidelines.

**FIGURE 3** Educating the ICS-UCST

**2.2.1 | Preparation**

A cough stress test is typically performed during the physical examination of the patient in the outpatient clinic, but can be done at the time of a procedure or during urodynamic testing. The last being a urodynamic stress test and/or leak point pressure (LPP) determination. Practice and validity of (UDS-) LPP testing are not further discussed but are summarized, for example, in the ICI-consultation report.<sup>18</sup>

We believe that before the ICS-UCST the patient should be informed about the relevance and rationale for performing the test and also the potential embarrassing nature of the test. Apart from undressing the lower part of the body and some issues mentioned below, the patient does not have to prepare herself specifically for the test.

**2.2.2 | Technique**

**Patient position**

A CST can be performed in the supine, semi supine, standing, sitting, or lithotomy positions. In the supine position (using pads to measure the leakage), it was noted that only 49% of women leaked during the cough stress test (when floor and trampoline jumping were used as the comparator).<sup>19</sup> In addition, CST was negative when done in a semi-supine position in 14% of patients who complain of SUI in another study on the effects of a UDS catheter on the diagnosis of SUI.<sup>20</sup> Furthermore, it has been noted that during LPP testing (done during CMG with a catheter in place), both Valsalva LPP and CLPP are significantly lower when the patient is standing versus supine.<sup>21</sup>

However, probably the most convenient time to do a CST is when the patient is undergoing a vaginal exam in the supine/lithotomy position (legs either in stirrups or abducted in a “frog-leg” position), when one assesses vaginal anatomy and pelvic floor function. This positioning allows for relatively easy visualization of the urethral meatus for the occurrence of urine leakage.

Because of the observed potential for a false negative in the supine position, reported in some cohort studies, it has been recommended that patients undergo a CST in the upright position, especially if they had a negative test in the supine position.<sup>7,8</sup> However, having the patient stand for the CST requires more effort on the examiner's part to expose the urethral meatus for visualization of the leakage. As well, not all patients are able to stand on their own, and testing in the standing position may therefore be less relevant and/or representative in these patients. Furthermore, it is currently unknown if the pathophysiology of a patient who has a positive CST in the upright position but negative in the supine/lithotomy position is comparable to a patient who has a positive CST in the supine position.

Conclusion for the purposes of uniformized practice of the ICS-UCST, we recommend that the CST be done in the supine/lithotomy position at the time of vaginal examination (LoE 1b, GoR A). If the test is negative (ie, no leakage detected), then accessory stress testing such as repeating the test in the upright position should be considered. When reporting the results of an ICS-UCST, it can be assumed that the test was done in the supine/lithotomy position. A patient with a negative test in the supine/lithotomy position and a positive accessory stress test in the upright position should be reported as: “ICS-UCST negative, accessory (upright CST) positive.”

#### Bladder volume

A spectrum of CST bladder volumes has been used in the literature from empty to 700 mL, including a “comfortably full” or a “symptomatically full” bladder. No consensus exists regarding the bladder volume for CST and to our knowledge no one has evaluated CST at differing bladder volumes in the same patient. The effect of differing bladder volumes has been evaluated in the context of LPP testing during UDS: Valsalva LPP was lower when bladder volumes were larger and the detection of SUI on LPP testing increased with increased bladder volumes.<sup>22–25</sup> During (cystometry-) LPP testing in women with SUI-S, leakage was not detected in any patient with a bladder volume <100 mL while leakage was detected in 19% of patients with a volume of 150 mL, 58% with a volume of 200 mL and 95% with a volume of 250 mL.<sup>26</sup> It seems reasonable to extrapolate this to the CST done in the clinic: a larger bladder volume may be more likely to elicit a positive test. On the other hand, one wants to avoid overfilling the bladder and elicit results that are not

representative. Some patients may not routinely store more than 250–300 mL and it may be unrealistic for them to be filled to a larger volume. The use of a “comfortably full bladder might remedy this because one presumes that the patient's bladder volume will be close to their functional capacity but this reported sensation may be affected by anxiety level. Basing the CST volume on a percentage of the patient's bladder (maximum) capacity seems logical and this concept was used in the context of pad weight testing using a bladder filled to a volume of 50% of cystometric capacity.<sup>27</sup> It was concluded that this type of standardization reduced test retest variation in the quantifying of UI volume. However, determining cystometric capacity requires the patient undergo UDS first. Another option is to base the CST volume on a percentage of the capacity/maximum voided volume on a frequency-volume chart, or use the “usual/average voided volume” avoiding the need for urethral instrumentation/UDS. To our knowledge this has not been studied in the context of a CST and therefore requires additional evaluation. For the purposes of standardization for the ICS-UCST, we recommend that the patient has a bladder volume in the range of 200–400 mL, and to ensure that this volume is not exceptional (far too low or far too high) for this patient (LoE 2, GoR B).

How one achieves/determines the bladder volume is also up for debate. Natural bladder filling or retrograde filling with a catheter can be used. Retrograde bladder filling allows for filling to a preset amount independent of patient activity. This requires catheterization which carries a small risk for infection and a potential to irritate/injure the urethral mucosa which could affect the results.<sup>28</sup> Natural bladder filling avoids urethral instrumentation albeit with lesser control over the actual bladder volume. One may determine the patient's bladder volume at the time of CST via an ultrasound bladder scan prior to or immediately after a CST or one could do a CST then have the patient void and add the voided volume to the postvoid residual volume (via bladder scanner or catheterization) to calculate the bladder volume retroactively.

For the ICS-UCST we recommend the patient be asked about their sense of bladder fullness and the time since the last micturition to get an idea of the degree of fullness with natural filling. We propose the test be performed in a target range of bladder volumes between 200 and 400 mL with the frequency volume chart serving as a guide for usual normal desire to void. We recommend furthermore that a more precise determination of the bladder volume during the test, using one of the aforementioned methods, be reported (in mL) when reporting the results of the ICS-UCST. (eg, “ICS-UCST 380 mL positive”)

#### Number/Forcefulness of coughs

The goal of a CST is to reproduce the patient's UI or at least to determine the likelihood that SUI is a cause of the UI. The CST, therefore, should ideally reproduce the kinds of

provocative maneuvers that are experienced by the patient on a day to day basis. In addition, the test must be easy to perform and interpret (ie, it should be of minimal burden to the patient and provide clear, easy to interpret results). While it has been demonstrated that with greater exertional effort (eg, jumping), SUI will be more likely to be elicited,<sup>19,29</sup> many women do not routinely subject themselves to such exertion and furthermore, it may be unrealistic, or too risky, to expect women to do such strenuous maneuvers in the clinic. Hence, on the basis of the available evidence as well as practicality, we propose that coughing be the provocative maneuver within the ICS-UCST.

In many reports that used a CST there was no mention of the number of times the patient was asked to cough (Figures 1 and 2). There is some evidence that, during UDS, multiple coughs are more likely to elicit leakage as was demonstrated during a “1-3-5” cough test.<sup>30</sup> The patient initially coughs once and if no SUI is noted then coughs three times and again if no SUI is noted then coughs five times. The “severity” of SUI was graded based on the occurrence of SUI after fewer coughs (more severe) versus many coughs (more mild). When compared with patient-perception questionnaires (eg, ICIQ-FLUTS, King’s Health Questionnaire, UDI-6, and UIQ-7), statistically significant associations of higher grades of SUI (based on the 1-3-5 CST) with higher scores of incontinence domains on the questionnaires were noted. Others have speculated that (pelvic) muscular fatigue may have a role in SUI and its diagnosis: by having patients cough repeatedly (up to seven times), a greater than 20% decrease in MUCP was measured in almost a quarter of patients with SUI-S.<sup>31</sup>

While standardization of cough effort/force has been attempted using an audiometer as a gauge (to measure audible cough strength),<sup>32</sup> it has been suggested that it is rather difficult to achieve reliable standardization of coughing force/effort<sup>33</sup> and for the purposes of a routine office visit it is impractical. Rather, the recommendation of three coughs “as hard as possible” seems reasonable.<sup>34</sup>

Taking all of this together, we recommend that for the ICS-UCST: The patient should cough as forceful as possible. If no leakage is seen after the first cough, coughing should be repeated three more times (ie, total of four coughs) before calling the test negative (LoE 2, GoR B). If no leakage is seen after four forceful coughs, accessory stress testing (eg, greater number of coughs; upright testing; alternative provocations; ICS standard pad testing or UDS) can be performed, with no evidence based preference for any of these. We recommend this however to be reported specifically, especially for scientific purposes.

#### Determination of SUI/Interpretation

Most reports that describe the method of CST use direct visualization of incontinence that occurs simultaneous with a

cough as the definition of a positive CST.<sup>7,8,34</sup> Incontinence occurring subsequent to a cough (ie, after a brief delay) or incontinence that persists after the cough has subsided is reported to be indicative of a concurrent detrusor contraction and usually referred to as cough induced DO<sup>2</sup> or cough associated DO.<sup>35</sup>

While some have used pads to capture the incontinence, avoiding the need for direct visualization of the incontinence,<sup>29,32</sup> the lack of direct visualization of the moment of the incontinence could call into doubt whether one is dealing with actual SUI versus cough associated DO. For the ICS-UCST therefore, we recommend that a positive test requires direct visualization of the efflux of urine from the urethral meatus synchronous with the cough.

### 2.2.3 | Accessory stress tests

#### Upright CST

As previously noted, a negative CST in the supine/lithotomy position does not necessarily rule out the presence of SUI. It has therefore been recommended that a patient with the complaint of SUI who has a negative CST in the supine/lithotomy position undergo a repeat test in the upright position.<sup>7</sup> This can be done in the same fashion as the standard ICS-UCST (bladder volume of 200-400 mL), up to four forceful coughs. If the upright CST is positive and the ICS-UCST (supine/lithotomy) is negative, the patient should be reported as having ICS-UCST negative, accessory (upright CST) positive.

#### Supine empty stress test (SEST)

A positive CST performed in the supine position with an “empty” bladder (volume <100 mL) has been suggested to indicate the presence of intrinsic sphincter deficiency (ISD). In a prospective series it was noted that a positive SEST was associated with a lower MUCP (mean, 20 vs 36 cm H<sub>2</sub>O) and SEST had sens: 65-70% and spec: 67-76% for predicting ISD using low MUCP to diagnose ISD.<sup>36</sup> A positive SEST was also associated with a low LPP (40% of women with a positive SEST had a LPP of 60 cm H<sub>2</sub>O or less versus 10% with negative SEST) with sens: 93.5%, spec: 90%, PPV 96.7% and NPV 81.8% for detecting ISD using ALPP to define ISD.<sup>37</sup> The IUGA suggests that SEST could be used as a simple test to be reasonably assured that ISD is not present (without resorting to multichannel UDS)<sup>2</sup> If a SEST is done as an accessory to (or preceding) an ICS-UCST, the results of each should be specified and reported.

In a patient with UI or more specifically with SUI-S, a negative ICS-UCST and a negative accessory CST, an ICS standard pad test<sup>38</sup> and/or (full) urodynamic testing may be considered to evaluate the complete lower urinary tract function, as per current practice guidelines.

### 3 | CONCLUSION

This module has introduced and provided the evidence base for the International Continence Society-Uniform Cough Stress Test (ICS-UCST) to standardize the performance and reporting of the cough stress test used in the clinical and outcomes assessment of women with urinary incontinence.

## Background

- McGuire, 1981
  - Observations of videourodynamic studies of children with MMC and UI secondary to impaired bladder compliance
  - DLPP was found to predict the upper urinary tract deterioration (UUTD)\*
- Further applied to different etiologies of neurogenic lower urinary tract dysfunction (N-LUTD) in adults

\*McGuire McGuire EJ, Woodside JR, Borden TA. Upper urinary tract deterioration in patients with myelodysplasia and detrusor hypotonia: a followup study. J Urol 1983;129:823-6.

## The ICS definition of DLPP

- The lowest detrusor pressure at which urine leakage occurs in the absence of either a detrusor contraction or increased abdominal pressure\*

\*Abrams P, Cardozo L, Fall M, Griffiths D, Rosier P, Ulmsten U, van Kerrebroeck P, Victor A, Wein A: Standardisation Sub-committee of the International Continence Society. The standardisation of terminology of lower urinary tract function: report from the Standardisation Sub-committee of the International Continence Society. Neurourol Urodyn. 2002; 21:167-78.

## Controversies

- The exact value of DLPP to predict UUTD is debatable
- Measuring DLPP lacks standardization and carries pitfalls
- A common mistake:
  - Using DLPP in N-LUTD during detrusor contractions (neurogenic detrusor overactivity) instead of reduced bladder compliance

## The ICS Urodynamics Committee Teaching Module

- Aim
  - To standardize and improve the method of DLPP measurement in patients with N-LUTD to minimize performer- and patient dependent variations
  - To review the clinical implications
- Methods
  - Literature search, key word: Detrusor Leak Point Pressure

## Preparation and Technique: DLPP is a cystometric finding

- Should be in accordance with:
  - ICS reports on Good Urodynamic Practices (GUP) and urodynamic equipment performance\*
  - The International Children's Continence Society (ICCS) report on the standardization of terminology of LUT function\*\*

\*Schäfer W, Abrams P, Liao L, Mattiasson A, Pesce F, Spangberg A, Sterling AM, Zinner NR, von Kerckhoveck P: International Continence Society. Good urodynamic practices: uroflowmetry, filling cystometry, and pressure-flow studies. *NeuroUrol Urodyn* 2002;21:261-74.

 ICS Educational Module

## Technique I

- Standard urodynamic equipment
- Patients in supine position with empty bladder
- ICI recommends sitting position in suitable patients (grade B)\*
- No evidence for the influence of specific positioning of patients with N-LUTD on the DLPP

\*Rostor PFWM, Kuo H-C, De Gennaro M, Kaldzaki H, Hashim H, Van Meel TD, Hobson PT: Urodynamic Testing. In: 5th International Consultation on Incontinence. Paris February, 2012. Editors: Paul Abrams, Linda Cardoso, Saad Khoury, Alan Wein. 5th EDITION 2013.

 ICS Educational Module

## Technique II: Catheter

- Using progressively larger catheters increase DLPP
  - Small cystometry catheter ( $\leq 10$  F)
  - As thin as possible, 'one-catheter-systems' LoE 4\*
  - 5-8 F double lumen cystometry catheters during water cystometry
- Underestimation of DLPP when suprapubic catheter is used\*\*

\*Rosier P.F.W.M., Kuo H.C., De Gennaro M., Kakizaki H., Hashim H., Van Meel T.D., Hobson P.T. Urodynamic Testing. In 5th International Consultation on Incontinence, Paris February, 2012. Editors: Paul Abrams, Linda Cardozo, Saad Khoury, Alan Wein. 5th EDITION 2013.  
 \*\*Combs A.J., Horowitz M. A new technique for assessing detrusor leak point pressure in patients with spina bilda. J Urol 1996; 156:757-60.

 ICS Educational Module

## Technique III: Filling rate

- Not standardized in the ICS GUP
- Usually done with a rate dependent on age (from 20ml/min in children to 30-60 ml/min in adults)
  - Detrusor adaptation to volume (compliance) may be challenged in high filling rates
- Classified as physiologic and non-physiologic by ICS rather than slow-medium-rapid\*

\*Abrams P, Cardozo L, Fall M, Griffiths D, Rosier P, Ulmsten U, van Kerrebroeck P, Victor A, Wein A, Standardisation Sub-committee of the International Continence Society. The standardisation of terminology of lower urinary tract function: report from the Standardisation Sub-committee of the International Continence Society. *NeuroUrol Uroqyn.* 2002; 21:167-78.

 ICS Educational Module

## Technique III: Filling rate (cont'd)

- Day-to-day bladder capacity by using voiding or catheterization diary-volumes
- 5-10% of known or predicted capacity may be used in children\*
- Slow filling rate needed in adult neurogenic patients with a known hypocompliant bladder (EO)

\*Nevelus T, von Gontard A, Hoebeke P, Hjaltnäs K, Bauer S, Bower W, Jørgensen TM, Ridig S, Walle JV, Yeung CK, Durrhus JC. The standardization of terminology of lower urinary tract function in children and adolescents: report from the Standardisation Committee of the International Children's Continence Society. *J Urol*. 2006;176(1):314-24.

 ICS Educational Module

## Technique IV: Pump and filling

- Infusion pump devices rather than gravity-type infusion systems
  - Avoid iatrogenic bladder pressure increases
- The influence of fluid temperature on DLPP is never studied
- More accurate representation of bladder activity with natural fill (ambulatory) cystometry in children\*

\*Nevelus T, von Gontard A, Hoebeke P, et al. The standardization of terminology of lower urinary tract function in children and adolescents: Report from the standardisation committee of the International Children's Continence Society. *J Urol* 2006;176:314-24.

 ICS Educational Module

## Technique V: Detection of urinary leakage

- One person observing for leakage and another observing the recording and marking pressures
- In video-UDS, fluoroscopic visualization of contrast around the catheter may be more accurate
  - Lane TM, Shah PJ. Leak-point pressures. *BJU Int* 2000;86:942–9.

## Technique VI: When to stop?

- Cystometry may be stopped when\*;
  - Pdet exceeds 40 cmH<sub>2</sub>O
  - Maximum bladder volume at intermittent catheterization is reached
  - A detrusor contraction occurs

\*McGuire EJ, Cespedes RD, O'Connell HE. Leak-point pressures. *UroClin North Am*. 1990;23:253-62

## Technique VII: Other definitions

- End filling pressure (EFP)
  - When the cystometry is ended without leakage
- Neurogenic Detrusor Overactivity Leak Point Pressure (N-DO LPP)\*
  - If leakage occurs with an episode of neurogenic detrusor overactivity (N-DO) any time during filling cystometry
- Detrusor Overactivity Leak Point Pressure (DO LPP)\*\*
  - In non-neurogenic women with urgency

\*NDOLPP has not been defined yet, but suggested by the authors of this module

\*\*Smith AL, Jaffe WL, Wang M, Wein AJ. Detrusor overactivity leak point pressure in women with urgency incontinence. *Int Urogynecol J*. 2012;23:443-6

## Basic Pathophysiology related to DLPP

- DLPP is the pressure which overwhelms the bladder outlet resistance and causes urinary leakage
- Reflection of the resistance of the bladder outlet or external sphincter
- DLPP may estimate how much and how long the urinary tract will be exposed to high pressure in-between bladder emptying periods (with or without CIC)

## The treatment of patients with a high DLPP aims:

- Reduction of outlet resistance is proposed to improve safe bladder storage and preserve upper tracts
  - remains unproven and leads to incontinence
  
- The treatment of patients with a high DLPP who are on CIC should aim:
  - Improving bladder compliance

\*McGuire/McGuire EJ, Woodside JR, Borden TA. Upper urinary tract deterioration in patients with myelodysplasia and detrusor hypertonia: a followup study. J Urol 1983;129:823-6.

## Which cut off for DLPP?

- The absolute values of DLPP are unreliable
  - No UUT deterioration of several patients with DLPP's of >40 cmH<sub>2</sub>O in the long term follow-up\*

\*Combs AJ, Horowitz M. A new technique for assessing detrusor leak point pressure in patients with spina bifida. J Urol 1990; 156: 757-60.

Urology and Nephrology

**Is 40 cm H<sub>2</sub>O Detrusor Leak Point Pressure Cut-Off Suitable for Upper Urinary Tract Protection in Children With Myelodysplasia?**

Yalçın Yılmaz\*, Çağrı Akın, Mehmet Özen, Alihan Özer, Turan Çiçek, Mustafa Akın, Mehmet Akın, Mustafa Akın, Turan Çiçek, Mustafa Akın

- Higher sensitivity of 20 cm H<sub>2</sub>O DLPP cutoff to predict the risk group for UUT deterioration in children with MMC

DLPP	Percentage of patients with UUT deterioration (N)	P-value
>40 cm H <sub>2</sub> O	57.8 (57/98)	0.510
30-40 cm H <sub>2</sub> O	43.5 (27/62)	0.014
20-40 cm H <sub>2</sub> O	43.5 (27/62)	
<20 cm H <sub>2</sub> O	18.1 (6/33)	

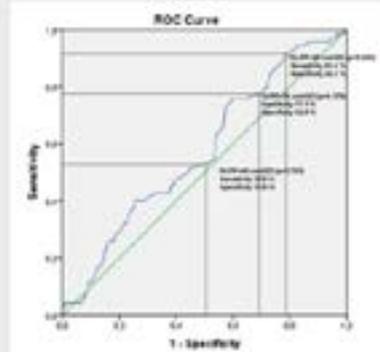

Fig. 1. UUT damage in three different DLPP cut-off values with their sensitivity and specificity is shown in ROC curve analysis.

## N- DO is also a risk factor for UUT

- Significant association with hydronephrosis in patients with N-DO >75 cmH<sub>2</sub>O\*
- The total duration of N-DO contractions\*\*
  - The only statistically significant urodynamic variable for upper tract dilatation or VUR in spinal cord lesion patients

\*Çelkan B, Demirkesen O, Durak H, Uygun N, İsmailoğlu V, Çetinel B. Which factors predict upper urinary tract deterioration in overactive neurogenic bladder dysfunction? Urology. 2005 Jul;66(1):99-104.

\*\*Linschmyer TA, Bagaria SF, Gendron B et al. The impact of urodynamic parameters on the upper tracts of spinal cord injured men who void reflexly. J Spinal Cord Med 1998; 21:15-20

## Conclusions and recommendations I

- DLPP
  - A part of cystometric evaluation of children and adults with N-LUTD to help predicting (and preventing) UUTD (Grade B/C)
- Recommendations of ICS and ICCS should be followed for cystometric equipment and for the measurement technique

## Conclusions and recommendations II

- Discrimination of high risk (for UUTD) patients on the basis of DLPP (Grade B/C)
- Not to be used as the sole parameter to decide on invasive therapies, e.g.
  - Bladder augmentation and sphincterotomy

## Conclusions and recommendations III

- Other factors to predict UUTD in N-LUTD
  - Bladder compliance
  - Volume where leakage occurs
  - Duration and amplitude of detrusor contractions
  - Volume which obtained by CIC
- Low sensitivity of traditional cutoff  $>40$  cmH<sub>2</sub>O for the prediction of UUTD

## Conclusions and recommendations IV

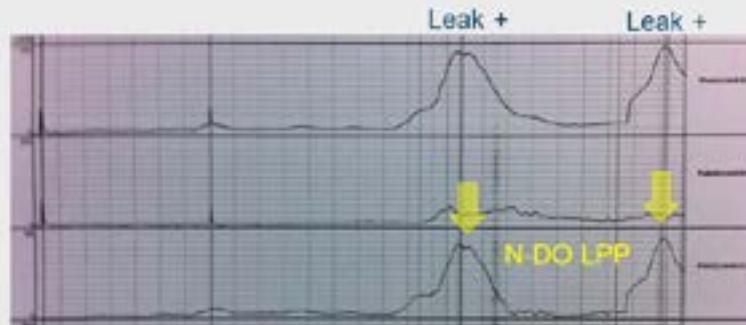

- Future research to standardize the technique and better classify DLPP cutoffs in N-LUTD
- The predictive value of LPP may differ according to underlying etiology of N-LUTD such as MMC, MS or SCI.

## Conclusions and recommendations V

- Cystometric readings should be sub-classified and differentiated according to the presence of N-DO

## Conclusions and recommendations V (cont'd)

- N-DO LPP: refers to the detrusor pressure that belongs to a spontaneous N-DO leading to leakage during cystometry

## Conclusions and recommendations VI

- EFP should be taken into consideration if the leakage does not occur during cystometry however, the clinical relevance of EFP is unclear.

Thank you

**Aims:** This manuscript serves as a scientific background review; the evidence base, for the presentation made available on ICS website to summarize current knowledge and recommendations for the measurement and use of the DLPP.

**Methods:** This review has been prepared by a Working Group of The ICS Urodynamics Committee. The methodology used included comprehensive literature review, consensus formation by the members of the Working Group, and review by members of the ICS Urodynamics Committee core panel. **Results:** DLPP has been recommended and utilized in the urodynamic evaluation of N-LUTD for many years, but it lacks standardization and there are numerous pitfalls in its measurement. EFP and LPP associated with N-DO are frequently and mistakenly reported as DLPP. The information that high DLPP predicts UUTD originates from retrospective cohort studies of a low level of evidence (LoE 3). Existing data confirm that patients with lower DLPP do better than patients with higher DLPP in terms of their upper urinary tract. However, there appears to be no reliable 'safe/no safe' cut-off for DLPP since there are other urodynamic factors that influence UUTD such as bladder compliance and more. **Conclusion:** Although higher DLPP is associated with a greater risk of UUTD, there is no reliable cut-off level to undoubtedly discriminate the risky group, including the traditional cut-off level of 40 cm H<sub>2</sub>O. Therefore, DLPP should not be used as the sole urodynamic parameter. Future research should be directed to standardization of the technique and better classification of DLPP cut-offs in N-LUTD. *NeuroUrol. Urodynam.* © 2015 Wiley Periodicals, Inc.

**Key words:** detrusor leak point pressure; neurogenic bladder; urodynamics

### INTRODUCTION

Detrusor leak-point pressure (DLPP) testing originates from observations of videourodynamic studies of children with myelomeningocele (MMC) and urinary incontinence secondary to impaired bladder compliance. McGuire retrospectively evaluated this group of children with the aim of finding predictors for upper urinary tract deterioration (UUTD).<sup>1-3</sup> This concept has been further applied to different etiologies of neurogenic lower urinary tract dysfunction (N-LUTD) in adults.<sup>4</sup> The International Continence Society (ICS) defines the DLPP as the lowest detrusor pressure at which urine leakage occurs in the absence of either a detrusor contraction or increased abdominal pressure.<sup>5</sup> The value of DLPP to predict UUTD is not known very precisely, and the measurement of DLPP lacks standardization and carries pitfalls. For example, although DLPP measurement has been recommended in neurological patients with reduced bladder compliance, some authors measure DLPP during involuntary detrusor contractions.<sup>5</sup>

The ICS Urodynamics Committee presents the teaching module "detrusor leak point pressures in patients with relevant neurological abnormalities" to serve as a standard education of good urodynamic practice for everyone involved in indicating, performing, and analyzing urodynamic testing in general and more specifically, for those caring for patients with N-LUTD. The teaching module consists of a web-casted presentation, in combination with this manuscript, which is available on the ICS website. The presentation explains testing requirements, clinical workup, and analysis. The presentation and this manuscript contain experts' opinion where evidence is

unavailable, especially for the clinical practice aspects, and is marked with: "EO" (expert's opinion).

This module reviews the value of DLPP measurement in predicting UUTD in N-LUTD in light of the existing literature. Our purpose is to standardize and improve the method of DLPP measurement in patients with N-LUTD to minimize performer- and patient-dependent variations.

### MATERIALS AND METHODS

All the requirements and instructions for the measurement of DLPP described in this section follow the ICS reports on Good Urodynamic Practices (GUP)<sup>6</sup> and urodynamic equipment performance.<sup>7</sup> The International Children's Continence Society (ICCS) report on the standardization of terminology of lower urinary tract function in children and adolescents has been taken into consideration for the measurement of DLPP in children.<sup>8</sup> DLPP is obtained during a standard cystometry and no specific other equipment or specific patient preparation is needed to determine DLPP. DLPP uses detrusor pressure;

Prof. Christopher Chapple led the peer-review process as the Associate Editor responsible for the paper.

consequently, it cannot be obtained via a single channel cystometry and, therefore, both vesical and intra-abdominal pressure must be recorded.

**Technique**

The measurement of DLPP is a part of cystometric evaluation in patients with N-LUTD. Traditionally, the patient is positioned supine and the bladder emptied. A small cystometry catheter ( $\leq 10$  F) is inserted into the urethra and standard urodynamic equipment used to measure vesical pressure via a pressure transducer with a rectal probe to monitor intra-abdominal pressure changes.<sup>9</sup>

In suitable patients, the study can also be performed in the sitting position according to ICI recommendations, because this is reported to have a higher sensitivity for the diagnosis of filling phase abnormalities (recommendation Grade B).<sup>10</sup> No evidence is available on the influence of positioning of patients with N-LUTD on the DLPP. The size of the catheter has an influence on the DLPP and it has been shown that using progressively larger catheters increases DLPP.<sup>11</sup> According to the ICI 2013, there is evidence of level 3 that, in general, flow rate during voiding is reduced with a urodynamic catheter in the urethra and that this reduction is partially caused by the size of the catheter. Use of, as thin as possible, “one-catheter systems” (dual lumen if fluid filled) for filling and pressure recording during urodynamic testing is recommended with a level of evidence 4.<sup>10</sup> This recommendation may correspond to 5–8 F double lumen cystometry catheters during water cystometry. The consequence of this recommendation is that DLPP is also done with a 5–8 F transurethral catheter. Another consequence is that when cystometry is performed via a suprapubic catheter, the DLPP will theoretically be underestimated if compared with published data, as this can also indirectly be deduced from a study where catheters were removed and reinserted during cystometry.<sup>13</sup>

A cystometry filling rate is not standardized in the ICS GUP but is usually done with a rate dependent on age (from 20 ml/min in children to 30–60 ml/min in adults).<sup>6</sup> There is some evidence that fluid temperature may not be relevant for the outcome of cystometry; however, the influence on DLPP has not been studied.<sup>14,15</sup>

Detrusor adaptation to volume (compliance) may however, be challenged if relatively high filling rates are used.<sup>9</sup> The ICS classifies infusion rates as physiologic and non-physiologic and no longer wishes to divide the filling rates as slow if  $< 10$  ml/min, medium if 10–100 ml/min, or rapid if  $> 100$  ml/min, although almost all investigations are performed using medium filling rates within a wide range.<sup>5</sup> It is advised to learn the day-to-day bladder capacity by using voiding (or catheterization) diary volumes before the study, although particularly large or small capacities might affect the desired filling rates. For this reason, we recommend a slow filling rate in adult neurogenic patients with a known hypocompliant bladder (EO).

According to the ICCS, filling rates (per minute) of 5–10% of known or predicted capacity may be used in children. Infusion pump devices rather than gravity-type infusion systems are recommended to avoid iatrogenic bladder pressure increases during filling and inaccurate interpretation by pressure transducers.<sup>9–11</sup> The ICCS also reports that the use of natural fill (ambulatory) cystometry provides a true physiological filling rate and offers a more accurate representation of bladder activity than traditional cystometry in children and may be the technique of choice in pediatric urodynamics if time and equipment are available.<sup>8</sup>

According to an expert review, urinary leakage (in the absence of fluoroscopy) is best detected by having one person

observing for leakage and another observing the recording and marking pressures using an event marker. However, the authors also stated that fluoroscopy visualization of contrast around the catheter is more accurate than observing the meatus or observing urine falling onto a sheet.<sup>9</sup>

It is suggested that the cystometry for patients with N-LUTD may be stopped when  $P_{det}$  exceeds 40 cm H<sub>2</sub>O or the maximum volume recovered at intermittent catheterization is reached or if a detrusor contraction occurs.<sup>3</sup> When cystometry ends without leakage, the end filling pressure (EFP) should be noted. If leakage occurs with an episode of neurogenic detrusor overactivity (N-DO) any time during filling cystometry, we suggest that it should be noted as N-DO LPP. A similar definition in non-neurogenic patients has recently been proposed as the “detrusor overactivity leak point pressure” in women with urgency incontinence.<sup>16</sup> The bladder volume at which leak occurs should also be noted, as it may be important for a particular patient to organize their clean intermittent self-catheterization (CIC) regimen.

**Basic Pathophysiology and Clinical Implications of DLPP in Patients With N-LUTD**

DLPP is the pressure that overwhelms bladder outlet resistance, causing urinary leakage. DLPP is a reflection of the resistance of the bladder outlet or external sphincter.<sup>1</sup> McGuire’s pioneering work has stated that patients with MMC and a LPP  $> 40$  cm were at risk of developing UUTD and this cutoff has been traditionally accepted without a high level of evidence.<sup>2</sup> It was shown in another study that reduction of outlet resistance may improve bladder storage in the long-term and may preserve the upper tracts.<sup>12</sup> Combs et al., however, reported that several of their patients with DLPPs of  $> 40$  cm H<sub>2</sub>O (followed over a long period) showed no deterioration in their upper tracts, while by contrast some individuals undergoing successful bladder augmentation required an artificial urinary sphincter, despite apparently good outlet resistance before surgery.<sup>13</sup> These authors suggested that absolute values of DLPP reported previously were unreliable because the technique lacked standardization. Another retrospective study has challenged the single cutoff level of 40 cm H<sub>2</sub>O<sup>17</sup> showing that UUT involvement rates are 18% in children with a DLPP below 20 cm H<sub>2</sub>O; 38% between 20 and 40 cm H<sub>2</sub>O; and 28% above 40 cm H<sub>2</sub>O, respectively. The authors concluded that determining the cut-off value of the DLPP as 20 cm H<sub>2</sub>O instead of 40 cm H<sub>2</sub>O showed a higher sensitivity to predict the risk group for UUT deterioration (Table 1). They also suggested that children with MMC and a DLPP between 20 and 40 cm H<sub>2</sub>O should be closely monitored, since 38.4% of children in their study had UUT deterioration at the age of 3.<sup>17</sup>

In spite of the ICS definition, DLPP is sometimes referred to as the elevation of the detrusor pressure during contractions leading to leakage. In fact, this is not DLPP but is N-DO LPP. However, the (clinical) significance of N-DO LPP versus DLPP in

**TABLE 1. UUT Involvement According to Different DLPP Cut-Off Values<sup>17</sup>**

DLPP	Percentage of patients with upper tract involvement	Sensitivity (ROC analysis)
$> 40$ cm H <sub>2</sub> O	18/64 (28.1%)	51.4%
$> 30$ cm H <sub>2</sub> O	24/88 (27.3%)	68.6%
$> 20$ cm H <sub>2</sub> O	33/102 (32.3%)	91.4%

**TABLE II. Recommendations of the ICS Teaching Module for the Measurement, Clinical Utilization, and Future Research on DLPP**

- (1) Measuring and reporting of DLPP should be a part of cystometric evaluation of children and adults with N-LUTD to help predict (and prevent) UUTD (Grade B/C)
  - a. The recommendations of the ICS and the ICSS should be followed for cystometric equipment and technique
- (2) Discrimination of high-risk (UUTD) patients is, however, not very precisely possible on the basis of DLPP (Grade B/C)
- (3) DLPP should not be used as the sole parameter to decide on invasive therapies such as bladder augmentation and sphincterotomy
  - a. UUTD in N-LUTD does not only depend on DLPP but will also depend on other factors such as bladder compliance; volume where leakage occurs; and detrusor contraction duration and amplitude, with all of these related to CIC obtained volumes. On the other hand, the resistance of the bladder outlet to the involuntary rise in detrusor pressure is another important parameter for deterioration
  - b. The traditional cut-off for DLPP of 40 cm H<sub>2</sub>O may have too low a sensitivity for the prediction of UUTD
- (4) Future research should be directed to standardization of the technique and better classification of DLPP cut-offs in N-LUTD
  - a. The predictive value of LPP may differ according to underlying etiology of N-LUTD such as MMC, MS, or SCI
  - b. Cystometric readings should be sub-classified according to the presence of neurogenic DO (overactive detrusor contractions with or without leakage)
  - c. EFP should be taken into consideration if the leakage does not occur during cystometry, however, the clinical relevance of EFP is unclear

N-LUTD has not been investigated. Frequent DO episodes with high LPP are plausibly a similar risk for future upper tract changes. The duration of the bladder contraction during an N-DO episode and DLPP >75 mmH<sub>2</sub>O is reported to have a significant association with hydronephrosis.<sup>4,18</sup> In a study with spinal cord lesion patients, the total duration of DO contractions appeared as the only statistically significant urodynamic variable that correlated with upper tract dilatation or with vesicoureteral reflux.<sup>18</sup> Although DLPP is a measure of outlet resistance, treatment of patients with a high DLPP is directed toward reducing the vesical pressures and increasing the bladder capacity. Reducing the number and amplitude of overactive detrusor contractions and improving bladder compliance, for example, with antimuscarinics, botulinum neurotoxin, or bladder augmentation is the mainstay of treatment. The clinical implication of DLPP is to help estimating how much and how long the urinary tract system will be exposed to high pressure in-between bladder emptying periods (with or without CIC) in the patient's daily life.

#### End Filling Pressure (EFP)

Another problem with the utilization of DLPP is that a significant number of patients with N-LUTD do not leak during studies. It is generally accepted that the filling phase finishes when the detrusor pressure remains over 40 cm H<sub>2</sub>O without leakage. In a recent study of 80 children with MMC and a median age of 7 years (range 2–17), the majority of children with MMC did not leak during urodynamics but bladder wall thickness as well as urinary levels of TGF- $\beta$  1, NGF, and TIMP-2 were found to be significantly increased when DLPP or EFP was greater than 40 cm H<sub>2</sub>O in this cohort.<sup>19</sup> Alternative methods, such as biomarkers, may become available to predict UUTD.

A recent study has challenged the predictive value of EFP in predicting UUTD in a cohort of children who underwent bladder neck surgery (different types of slings) without augmentation for neurogenic incontinence.<sup>20</sup> Seventeen children with sustained EFP >40 cm for more than 1 year despite anticholinergics were included in the study. During a mean follow-up of 39 months, new hydronephrosis or VUR developed in six (35%), whereas all new hydronephrosis resolved with medical treatment, as did two out of three new VUR cases. The other patient with VUR had successful suburethric injection.

The authors concluded that despite a sustained EFP >40 cm, upper tract changes developed in only 35% of patients, and resolved with medical management or minimally invasive interventions, and suggested that EFP should not be used as an independent indication for augmentation.

*Neurology and Urodynamics* DOI 10.1002/nau

#### CONCLUSION

Although the causative relationship between the pressure within the urinary tract and UUTD has been acknowledged for a long time, there are still many caveats regarding the standardization of urodynamic measurements and their predictive roles. According to the fifth International Consultation on Incontinence, DLPP in patients with N-LUTD is considered a relevant parameter with the recommendations of grade B/C.<sup>10</sup> It has been stated that DLPP is not consistently defined throughout the literature and that lack of standardization is hindering comparison of studies.

Using a single “safe-unsafe” cut-off at 40 cm H<sub>2</sub>O may not reflect clinical reality and as McGuire suggested, a clinical management approach with an “as low as” reasonably achievable detrusor pressure over the entire daily volume range is advisable.<sup>21</sup>

The clinical recommendations on the basis of this review of DLPP are summarized in Table II. Better standardization of DLPP measurements as well as better definition of urodynamic capacity where leakage occurs and of EFP as well as of leak point pressure at overactive detrusor contraction will be helpful. The bladder volume at which leakage occurs is very important in order to adapt patients to CIC. Furthermore, EFP and N-DO LPP should be separated from DLPP in urodynamic investigations, and the definition should include the difference between these terms in order to prevent any confusion. Prospective follow-up studies in patients with N-LUTD to evaluate the predictive value of these parameters for upper tract deterioration are recommended. This manuscript has summarized the practice and interpretation of DLPP from a clinical perspective.

#### ACKNOWLEDGMENT

We would like to thank the members of the ICS Urodynamics Committee core panel for establishing the teaching module and reviewing the manuscript.

Educational Module

1

## ICS Educational module

- This slide set should be used together with manuscript „ICS educational module: Electromyography in the assessment and therapy of lower urinary tract dysfunction in adults. *Neurourol Urodyn.* 2018;37: 27-32”, which provides the scientific background and the evidence base for use of EMG in urology as well as references.

 **ICS** Educational Module

2

## Principle of EMG

- Recording of the electrical activity from (striated) muscle with electrodes, to unveil function and innervation.

2 methods:

**Needle EMG > Needle electrode(s):** Inside muscle – motor unit.

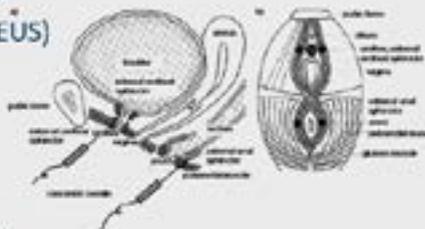

- Positive: - allows assessment of single action potentials
- Negative: - invasive
  - complex expertise in EMG required

**Surface EMG > Surface (patch) electrode(s):** On muscle – ‘whole’ muscle.

- Positive: - non-invasive, less time- and money-consuming
- Negative: - less specific, less ‘detail’
  - does not allow assessment of single action potentials

## EMG tests in adult urology

- Needle EMG of external anal sphincter (EAS)
- Needle EMG of external urethral sphincter (EUS)
  - Monopolar
  - Bipolar (concentric)
  - Wire(s)

- Surface EMG of external anal sphincter (EAS)
- Surface EMG and sacral reflexes conductivity testing
- Surface EMG and biofeedback
- Surface EMG with cystometry and pressure/flow
- *Surface EMG = ‘kinesiological EMG’: with pair (or array) of electrodes over muscle*

## Needle EMG of external anal sphincter (EAS)

### Principle:

- Recording of electrical activity of EAS
- Elements of muscle activity of the pelvic floor

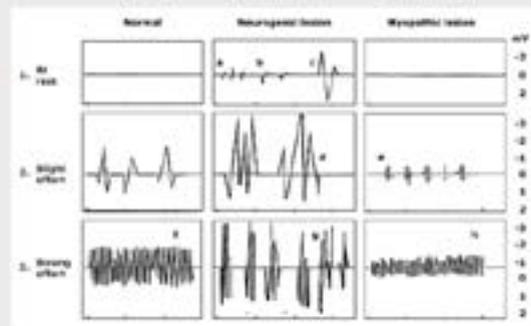

### Technique:

- Patient in lateral decubitus or lithotomy position
- EAS: Needle electrodes inserted bilaterally, approximately 0.5 cm lateral to the anus
- Assessment during maximal relaxation, during slight pelvic floor contraction, during maximal voluntary contraction and or during artificial bladder filling

## Needle EMG of external anal sphincter (EAS)

### Evidence:

- Potentially useful to detect disturbances in neuroregulation of the pelvic floor muscles in patients with
  - lower motor neuron lesion
  - demyelinating diseases
  - with Parkinson disease
  - Multiple System Atrophy

Sakakibara R, et al.: J Neurol Neurosurg Psychiatry 2000; 68: 25

# Needle EMG of external urethral sphincter (EUS)

## Principle:

- Direct recording of electrical activity of EUS

## Technique:

- Patient in lateral decubitus or lithotomy position
- Needle electrodes inserted transperineally (♂) or transvaginally (♀) or transurethrally – via catheter
- Assessment during maximal relaxation, during slight pelvic floor contraction, during maximal voluntary contraction and or during artificial bladder filling

# Needle EMG of external urethral sphincter (EUS)

## Evidence:

- Limited evidence for role in clinical setting for EUS–EMG
- Some role in Fowler's (♀ retention) syndrome
- Potentially useful in direct detection of electrical activity while bladder filling

## Surface EMG of external anal sphincter (EAS)

### Principle:

- Recording of muscle activity using surface (patch) electrodes or electrodes on cone or plug

### Technique:

- Degreasing of the perianal skin
- 2 'active' electrodes adjusted bilaterally to the muco-cutaneous line + ground electrode
- Assessment of activity rest vs. contraction

### Evidence:

- Tool to detect pelvic floor muscle activity or relaxation

## Surface EMG and Sacral reflexes conductivity testing

### Principle:

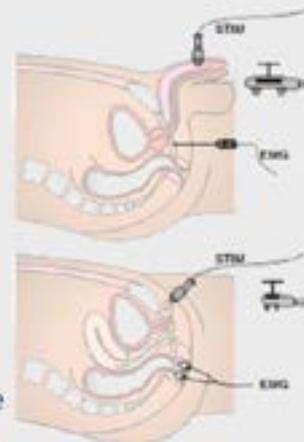

- Stimulation of the pudendal nerve to induce pelvic floor contraction to evaluate of bulbocavernosus (clitro-anal) reflex

### Technique:

- Stimulation using electrode dorsal at the base on the penis (♂) or on clitoris (♀)
- The response recorded with surface or needle electrodes from the region of anal sphincter or bulbocavernosus muscle

### Evidence:

- Absence or delay in response, suggest lower motor neuron impairment
- No relevant recent study which could support the role of this examination in the daily clinical work-up was found

## Surface EMG and biofeedback

- **Principle:**

- Detect the pelvic floor muscle activity and transform it into a visual and/or acoustic display in order convey the information to the patient

- **Technique:**

- Surface electrodes are placed close to the anal sphincter or on an anal or intravaginal plug
- Recorded signal transformed into apparent sound or visual clue
- Allows the patient to better understand the functional status of the pelvic floor

## Surface EMG and biofeedback

- **Clinical observations:**

- Baseline between contractions – inconsistent and elevating
- Resting baseline – varies widely from session to session, especially when pain exists
- Erratic tracing without artifact or noise
- Patient has symptoms of overactive PFM – obstructed urination, defecation, pain
- Return to baseline after startle or frightening – overactive PFM is slow
- 2/3 of dysfunctional muscles will have normal resting baseline

## Surface EMG and biofeedback

- **Evidence:**

- Potentially useful for conservative treatment (PFM training) of stress urinary incontinence and OAB
- Little evidence regarding the use of EMG biofeedback as tool to help relax the pelvic floor muscles during micturition in adults

Dannecker C, et al: Arch Gynecol Obstet. 2005;273(2):93-7; Wang AC, et al: Urology. 2004 Jan;63(1):61-6

## Surface EMG with cystometry

- **Principle:**

- Recording of pelvic floor muscle activity during filling of the bladder.

- **Technique:**

- Surface EMG (as on earlier slides)

- **Evidence:**

- Introduced on the basis of expert opinion/ plausibility
- No (comparative) evidence
- Surface EMG may fail to reflect urethral (continence) function

# Surface EMG with pressure flow studies

## Principle and technique:

- Identical to surface EMG

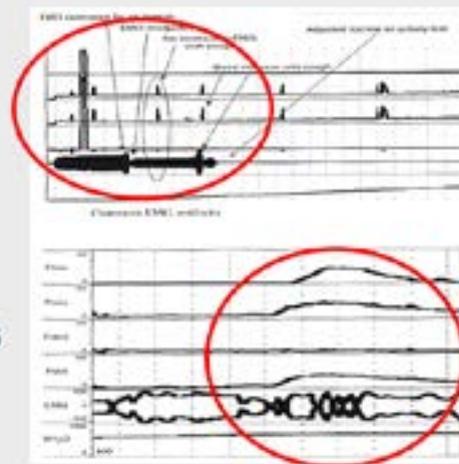

## Evidence:

- Introduced on the basis of expert opinion/ plausibility
- No (comparative) evidence
- Expert series demonstrating plausible results
- However: Large (n= 655) prospective cohort  with EMG revised:
  - Many (51%) were not interpretable (but also)...
  - ...surface EMG failed to reflect EUS relaxation.

Kirby AC et al. *Neurol Urodyn* 2011; 30: 1591-1596

# Surface EMG (adult)

- May be not interpretable
  - (technical) artefacts
- May give not plausible results
  - Not reflect relevant (EUS) activity
  - Smooth flow-rate and bizarre EMG

## sEMG with urodynamic tests (adult)

### Lacking practice standards for:

- Display: envelope; linear envelope; full wave; half wave
- Time scale
- Sampling: ... Hz; Filtering: moving average; root mean square
- Placing of active electrodes (♀ ; ♂)
- Impedance check(s) (cleaning of skin): <5 (or <10) kΩ
- Reference electrode - neutral! (Not on another muscle); trochanter; pelvic rim; sacrum
- Technical and clinical quality checks
- Analysis, interpretation and reporting

## sEMG with urodynamic tests (adult)

- Not very invasive
- Not very time and cost consuming
- Without standard
- Without certainty of relevance
- May add confusion if artefacts are not acknowledged
- May be of help in (pelvic) muscle strength and control training and learning to relax

## EMG tests in adult urology

- The concept of use of EMG methods in functional urology/urogynaecology and physiotherapy is supported by good theoretical basis
- Current value of EMG in diagnosis is however limited
- Currently EMG practice can only rarely play a decision making role in diagnostics of LUT partially due to lack of standards

A long way ahead.....

**Aim:** To present the teaching module “Electromyography in the assessment and therapy of lower urinary tract dysfunction in adults.” This teaching module embodies a presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base made available on ICS website to summarize current knowledge and recommendations.

**Methods:** This review has been prepared by a Working Group of The ICS Urodynamics Committee. The methodology used included comprehensive literature review, consensus formation by the members of the Working Group, and review by members of the ICS Urodynamics Committee core panel.

**Results:** Electromyography (EMG) is a method to record spontaneous or artificially induced electrical activity of the nerve-muscle unit or to test nerve conductivity. EMG of the anal sphincter using surface electrode is most widely used screening technique to detect detrusor-sphincter dyssynergia in urology. It is non-invasive and easy to perform. EMG methods using needle electrodes are reserved for diagnostics in well selected group of mainly neurogenic patients. These methods require expertise in the field of general EMG and are usually performed by neurologist and neuro-physiologist. The evidence in many aspects of use of EMG in urology remains sparse.

**Conclusions:** Currently EMG methods rarely play a decision making role in selecting proper treatment of lower urinary tract dysfunction. With the current efforts to improve phenotyping of these patients in order to provide individualized treatment, the role of EMG could increase.

## KEYWORDS

bio-feedback, diagnostics, electrode, electromyography, ICS teaching module, urinary incontinence

## 1 | INTRODUCTION

The role of electromyography (EMG) is to record spontaneous or artificially induced electrical activity of the nerve-muscle unit or to test nerve conductivity. It is a component of the comprehensive urodynamic evaluation, however, the current

use of this method is limited. The aim of this communication is to summarize the current evidence regarding the use of EMG in adult urology and provide some suggestions for future research which could lead to further development of this diagnostic and therapeutic method in urology. This paper was prepared by a Working Group of The ICS Urodynamics Committee. The methodology used included comprehensive literature review, consensus formation by the members of the Working Group,

Roman Zachoval led the review process.

and review by members of the ICS Urodynamics Committee core panel. Literature review was performed according to the modified PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) methodology in March 2016.<sup>1</sup> Following Medical Subject Heading (MeSH) were used for electronic search on MEDLINE database: (a) electromyography; (b) neurofeedback; (c) lower urinary tract symptoms; (d) urodynamics; (e) pelvic floor disorders. Terms (a) and (b) were subsequently crossed with (c); (d); and (e). Total 1576 publications were identified. After removing duplications (1576-355 = 1221), all articles published before 1986 (1221-302 = 919) and all articles in other than English language were excluded (919-132 = 787). We identified 81 relevant papers which served as a evidence base for preparation of this manuscript and slide set. The ICS Urodynamics Committee presents this teaching module to serve as a standard education tool for professionals involved in diagnostics and treatment of lower urinary tract dysfunctions. The teaching module consists of a ICS Power Point Presentation, available via <http://www.icsoffice.org/eLearning/> and this paper which serves as a scientific background review. The presentation and this manuscript contain experts' opinion where evidence is, especially for the clinical practice aspects, unavailable and is marked with: "eo" (expert opinion).

### 1.1 | History

EMG is the oldest and most widely used electrophysiological assessment method. The first records of EMG use involved examination of skeletal muscles and it dates back to 19th century. The first sphincter EMG was described by Beck in 1930.<sup>2</sup> The EMG of the anal sphincter was first used in clinical setting by Bailey in 1968.<sup>3</sup> He used EMG as a part of complex neuro-urological evaluation of 184 incontinent children with neurogenic bladder. He also proposed that EMG could be used in adults with neurogenic bladder. Chantrain was the first to conduct comparative studies of skeletal muscle and anal sphincter EMG.<sup>4</sup> In 1979, Mayo included EMG of the anal sphincter into the urodynamic assessment.<sup>5</sup> The future steps in the development of this diagnostic method were marked by neural conductivity studies looking at sacral reflex pathways in 1970s and finally introduction of sensory and motor evoked potentials testing which was first published in 1982.<sup>6,7</sup>

### 1.2 | Electrophysiology

An intact and functioning motor unit (MU) is the basic component required for adequate function of any muscle. MU consists of a single  $\alpha$ -motoneuron residing in the anterior horn of the spinal cord, axon nerve fiber and corresponding muscle fiber. Neurons conduct electrical impulses—action

potentials. Action potentials are waves of cell membrane depolarization which travels toward the periphery. The transmission of neural action potential to a respective muscle, which leads to its contraction, takes place at the neuromuscular junction. The action potentials are associated with changes in extracellular and intracellular currents, which could be recorded and processed for their quantitative (frequency and amplitude of action potential) and qualitative (pattern of action potential) characteristics. Simultaneous activation of multiple motor units leads to contraction of a single muscle. Voluntary contraction force is modulated by the number of recruited MU and changes in the activation frequency. The number of recruited MU and their mean discharge frequency of excitation determines the electrical activity, which could be recorded using EMG. There is a direct relationship between the EMG and the muscle force.

### 1.3 | Technical aspects of EMG

Most clinical EMG devices use a differential amplifier to enhance the display of information. This includes two or more active electrodes placed in proximity to the target muscle or muscle fibers and a common electrode placed equidistant from the active electrodes or on a neutral tissue. The differential amplifier compares the information in all electrodes and discards any information that is the same in all electrodes. This represents the background electrical noise of the body. The remaining information (the target muscle) is then amplified to reduce the influence of artifact or environmental noise on the signal.

Technical parameters of the EMG unit play crucial role in validity of the obtained information. The quality of units used in urology differs significantly. A minimal technical requirement for EMG unit for use in urology should include: Bandwidth: 30 Hz-10 kHz; Time scale: 10-100 ms; Sensitivity: 0.1-2.0 mV; 5p DIN connector; 1.5 mm touch-proof connector for common electrode; EMG processing average rectified curve, raw EMG curve, and audio EMG.

### 1.4 | Electrodes

In general electrodes are used for recording changes in the algebraic sum of motor unit action potentials, or for neural stimulation. The recording unit consists of two or more active electrode and a ground electrode. The size of the electrode determines the specificity of the recording. Larger electrodes are used to record large muscle areas such as the activity of the entire pelvic floor muscle contraction. Smaller electrodes are used to evaluate single motor units. According to their design, technical characteristics and purpose (recording vs stimulation) electrodes are divided in several groups:

Needle electrodes are inserted into the recording muscle and are designed to record single fiber action potentials or action potentials from a small number of units.

#### 1.4.1 | Coaxial needle electrode

Is the most widely used type of needle electrode used in myography performed by neurologists. It consists of the platinum wire (active electrode) which is wrapped in a steel sheet (reference/common electrode). The electrode records the differences in a single action potential between the tip of the platinum wire and the conductive sheet.

#### 1.4.2 | Bipolar needle electrode

Consists of two platinum wires embedded in the sheet and records the difference between action potentials recorded by the two active wires.

#### 1.4.3 | Monopolar needle electrodes

Measure activity recorded by a conically shaped tip of the needle which is embedded in the unconductive sheet. Compared to coaxial needles, it has a larger recording surface, and a wider pick-up field, resulting in higher amplitudes of recorded potentials. This does not allow for recording of action potential from a single muscle fiber and is therefore less specific.

#### 1.4.4 | Surface electrodes

Surface electrodes are placed on the skin overlaying the muscle of interest. This includes both external patch and internal vaginal or rectal probe electrodes. They consist of silver chloride conductive discs or bars. They have a larger reception field, which means that they display a summary of the entire muscle not single action potential. They are however, easy to use and not associated with needle insertion, therefore, despite their low sensitivity they are the most widely used electrodes in urodynamic evaluation.

#### 1.4.5 | Stimulation electrodes

Their principal use is to provoke action potential remotely, which is then picked up by the recording electrode for the purpose of assessing the nerve conductivity and neuromuscular transmission. They could be designed as both needle or surface electrodes of different shapes according to the type of use (clip electrodes, band electrodes).

## 2 | EMG METHODS USED IN UROLOGY

### 2.1 | Needle EMG of anal sphincter

#### 2.1.1 | Principle

External anal sphincter is the component of the pelvic floor which is easiest to identify and target using a needle electrode. Due to close anatomical location and shared innervation, it's activity could implicate the activity of other anatomical structures of the pelvic floor. It is therefore used as a tool for indirect evaluation of the urethral closing mechanism.

#### 2.1.2 | Technique

With the patient in the lateral decubitus or lithotomy position, under digital rectal control, needle electrodes are inserted bilaterally, approximately 0.5 cm lateral to the anus. The depth of insertion is 3-8 cm, depending on patient's constitution.

First, we assess the EMG during maximal relaxation, than during slight pelvic floor muscle contraction or during slow artificial bladder filling. Subsequently we assess the sphincter activity during maximal voluntary contraction of the anal sphincter. To obtain reproducible results it is necessary to record at least 10-20 single action potentials in every phase of the assessment.<sup>8</sup> This assessment is challenging for the patient, time consuming, requiring skills, and expertise.

#### 2.1.3 | Evidence

Anal sphincter EMG using needle electrodes allows the physician to detect disturbances in neuroregulation of the pelvic floor muscles, which could be due to spinal cord injury, lower motor neuron lesion, demyelinating diseases, and Parkinson disease. It could indirectly detect detrusor-sphincter dyssynergia (*eo*).

However, no systematic study or meta-analysis has been published during last two decades with the topic of the use of needle EMG of the anal sphincter in urology. Currently, only limited evidence based on single center expert opinion is available (*eo*).

### 2.2 | Needle EMG of urethral sphincter

#### 2.2.1 | Principle

Direct detection of the activity of the striated external urethral sphincter.

### 2.2.2 | Technique

In male patients the needles are inserted into the perineum 0.5 cm lateral to the midline at the point of projection of the urethral bulb. The needle tip is directed toward the apex of the prostate and the depth of insertion is controlled by digital rectal examination (DRE) and by acoustic and visual evidence of activity recorded by the EMG equipment. In female patients the electrodes are inserted transvaginal, after the bladder neck is identified with help of a urethral Foley catheter. The recording technique is identical to that of the anal sphincter.

### 2.2.3 | Evidence

Allows direct recording of the urethral sphincter, however, due to its invasive nature and technical difficulty is used only used in a limited number of carefully selected cases, most often in research studies.<sup>9</sup> Basic work describing the use of needle EMG of the urethral sphincter can be dated back to 1984.<sup>10</sup> More recently Mahajan confirmed the superiority of needle urethral sphincter electrodes compared to surface electrodes.<sup>11</sup> However, only limited evidence based on single center expert opinion is available.

## 2.3 | EMG of anal sphincter using surface electrodes

### 2.3.1 | Principle

Non-invasive detection of activity of the entire pelvic floor muscles which is routinely used in urology in course of uroflowmetry or invasive urodynamics.

### 2.3.2 | Technique

Surface patch electrodes are attached adjacent to the mucocutaneous line of anus bilaterally. The impedance of the skin is reduced using careful degreasing. In some cases a careful epidermis abrasion is required. Excessive hair and adipose tissue around the anal sphincter decrease accuracy of the EMG reading. The electrode wires need to be positioned away from the urine stream. Practitioners are also cautioned not to place the electrodes too lateral in which case the gluteus muscles are being recorded. The common electrode can be placed on the thigh or trochanter. The proper attachment of the electrodes is subsequently tested by recording increased activity during the voluntary pelvic floor contractions.

### 2.3.3 | Evidence

Evidence for using EMG diagnosis of anal sphincter dysfunction using surface electrodes in adults remains weak. This modality is used for screening purposes to detect detrusor-

sphincter dyssynergia in patients with neurogenic bladder and impaired pelvic floor muscle relaxation in patients with dysfunctional voiding. Recently it has been documented that anal sphincter EMG using surface electrodes did not document pelvic floor muscle relaxation during voiding in the majority of a large cohort of patients, suggesting the low sensitivity of this evaluation.<sup>12</sup> However, in pediatric urology literature evidence has been published in support of the beneficial role of simultaneous uroflowmetry and EMG to detect dysfunctional voiding. The argument is that abnormal voiding pattern, that is, staccato and interrupted/fractionated voiding observed on uroflowmetry alone, can lead to overdiagnosis of dysfunctional voiding or detrusor underactivity and that adding simultaneous EMG could significantly improve the diagnostic accuracy.<sup>13</sup> In addition, evidence of usefulness of EMG lag time has been reported in children. EMG lag time is a uroflow/EMG measurement of the time interval between the moment that relaxation of the pelvic floor EMG takes place and the moment urine flow begins. When the lag time is short it is supportive of the diagnosis of detrusor overactivity, while prolongation supports the diagnosis of primary bladder neck dysfunction, especially when they appear in combination with certain LUTS and uroflow patterns.<sup>14</sup> These data should stimulate future studies exploring the role of simultaneous uroflow and EMG in adults.

## 2.4 | Sacral reflex conductivity testing

### 2.4.1 | Principle

Stimulation of the pudendal nerve to induce pelvic floor muscle contraction. The presence or absence of response of pelvic floor muscles is evaluated together with recording for latency interval between the stimulus and the response. The goal is to assess the peripheral limb of the micturition reflex.

### 2.4.2 | Technique

Neurostimulation is performed with surface electrodes attached at the dorsal aspect close to the base of the penis in men and to small labia in women. The response could be recorded by both surface or needle electrodes from the region of anal sphincter or bulbocavernous muscle.

### 2.4.3 | Evidence

This modality is potentially useful for evaluation of bulbocavernosus and anorectal reflexes.

Absence or delay in response, suggest lower motor neuron impairment. No relevant recent study which could support the role of this examination in daily clinical work-up was found.

## 2.5 | EMG biofeedback

### 2.5.1 | Principle

Detect the pelvic floor muscle activity and transform it into a visual and/or acoustic display in order to convey the information to the patient. This is subsequently used for biofeedback training.

### 2.5.2 | Technique

Surface electrodes are placed close to the anal sphincter (as described above) or inside the vaginal or rectal canal. The recording signal is transformed into sound or visual clue and used to guide the patient to better understand the functional status of the pelvic floor muscles.

### 2.5.3 | Evidence

This technique is widely used in conservative treatment of incontinence. Acoustic or visual clues help patients to improved awareness of their pelvic floor muscles and to improve their ability to selectively contract the appropriate group of muscles. EMG biofeedback seems to be effective in the conservative treatment of stress urinary incontinence as well as overactive bladder.<sup>15,16</sup> However, there is only limited number of well designed randomized controlled studies to support this observation.

On the other hand, in dysfunctional voiders, EMG biofeedback is used as a tool to help relax the pelvic floor muscles during micturition. While being a well established method in the treatment of voiding dysfunctions in the pediatric population, where combination of acoustic and visual biofeedback plays an important role, evidence in adults is lacking.<sup>17,18(eo)</sup>.

## 2.6 | Patients perspective

Electromyography does not require any specific patient preparation. Patients must be properly instructed that insertion of EMG needles is associated with a certain degree of pain. Surface EMG is non-invasive and painless. However, the patient must be informed that hair removal, skin defatting and, in some cases, epidermis abrasion is required before placing electrodes. In all cases, but especially for EMG used for biofeedback, patients should be physically and mentally capable of following instructions given by the health care professional (eg, contraction or relaxation of the pelvic floor muscles).

## 2.7 | Standards for reporting EMG data

The “Standards for Reporting EMG Data” endorsed by the International Society of Electrophysiology and Kinesiology have

been written by Dr. Roberto Merletti.<sup>19</sup> This document summarizes technical information that has to be included for each type of electrode, necessary data on detection mode, amplification, rectification of signal and its computer processing. In addition it provides guidelines on EMG amplitude and frequency processing, normalization, EMG processing for estimation of muscle fiber conduction velocity and EMG crosstalk. Every medical professional using EMG, especially in research, should follow these guidelines.

## 2.8 | Suggestions for future research

There is a clear lack of evidence in many aspects of the use of EMG in urology. High quality trials are required especially in following topics:

1. EMG pattern of the pelvic floor muscle under physiological and pathological conditions.
2. Role of the EMG in the comprehensive urodynamic evaluation.
3. Role of EMG in the phenotypisation of the patients suffering from LUTS.
4. Role of the pelvic floor muscle EMG as a biofeedback tool in LUT dysfunctions.
5. Role of audio monitoring during EMG in adults.
6. Role of simultaneous uroflowmetry and EMG in detection of voiding dysfunctions, detrusor overactivity, and detrusor underactivity in adults.

## 3 | CONCLUSIONS

The concept of the use of electrophysiological methods in urology is supported by good theoretical basis. However, the evidence supporting the value of EMG techniques in diagnostics is limited. With the current efforts to improve phenotyping of these patients in order to provide individualized treatment, the role of EMG could increase. In contrary evidence in support of EMG biofeedback exists and should be considered an integral part of conservative treatment of incontinence, OAB, and dysfunctional voiding.

# Filling Cystometry

Carlos D'Ancona, Mario João Gomes, Peter F.W.M. Rosier

## Cystometry - Definition

- Transurethral or suprapubic continuous fluid filling of the bladder, and measurement of vesical and abdominal pressures .....
- ...Cystometry ends with 'permission to void' or with incontinence (involuntary loss) of the (total) bladder content.

## Cystometry: Aims

- To diagnose lower urinary tract reservoir function and find an explanation for the patients' complaints
- To evaluate lower urinary tract reservoir function for research purposes

## Cystometry (clinical relevance)

- Demonstrate the reservoir function of the bladder relevant to the symptoms and signs that the patient perceives

### What should be known before starting?

- Patient's perceived (LUT-) symptoms and signs
  - Symptoms questionnaire (preferable)
  - Voiding diary ('usual' volumes voided)
    - 'Predict' -estimated- cystometric capacity
  - Free uroflowmetry
  - Post void residual urine

## ICS Standard:

- Fluid filled: saline solution
- External pressure transducers
- Reference = pressure at the level of the symphysis
- Patient in standing position
- Fill until strong desire to void
- Medium fill-rate (e.g. 10% of expected capacity /minute)
- Indicate end of cystometry on trace
  - Stopping of the pump (and /or)
  - 'Permission to void'

## Solution infused

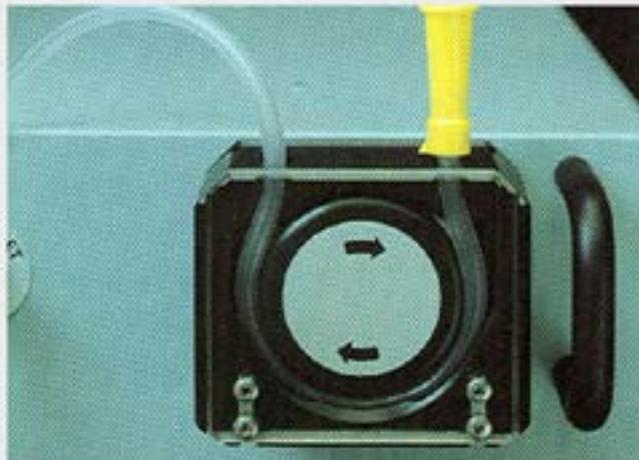

- Saline solution
  - Or contrast
- Temperature
  - Room temperature

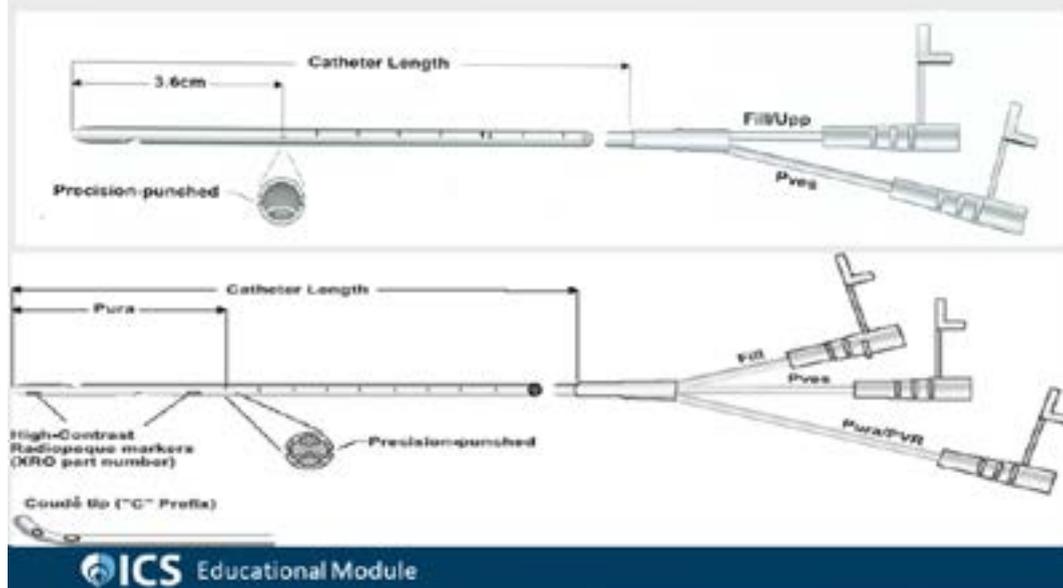

## Patient position during cystometry

- Sitting (standing) position is more provocative for abnormal detrusor activity (ex. overactivity) than the supine position. At some point in the test, filling might desirably take place with the patient standing.
- Patients unable to sit or stand → supine position.

## Infusion Pump

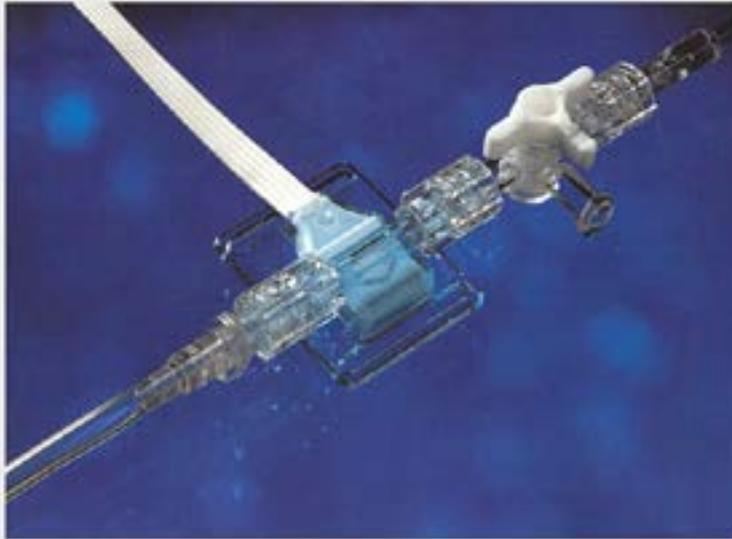

## Urethral Catheter

## Insert catheters

- Usually lithotomy position
- Sterile catheters
  - Vesical: double lumen (or separate)
    - 6-7F
  - Rectal: catheter with a punctured balloon
- Fix the catheters adjacent to the meatus
- Patient in comfortable position
- Cover the patient - ex. with a towel

## Transducer

 ICS Educational Module

## Position of the Transducer

- External transducer measured at the level of the symphysis pubis
- Equals: Base of the bladder
- Intra rectal and intravesical pressures are assumed to be measured at identical levels

 ICS Educational Module

## Filling cystometry

- Initial resting pressure
  - Supine 5 -20cmH<sub>2</sub>O
  - Sitting 15-40cmH<sub>2</sub>O
  - Standing 30-50cmH<sub>2</sub>O

Hogan S. NeuroUrol & Urodyn 2012, 31: 1104-117

## Bladder sensation - classification

- **Normal bladder sensation**
  - can be judged by three defined points noted during filling cystometry and evaluated in relation to the bladder volume at that moment and in relation to the patient's symptomatic complaints.
- **First sensation of bladder filling**
  - is the feeling the patient has, during filling cystometry, when he/she first becomes aware of the bladder filling.
  - To be separated from the sensation that the catheterisation has caused, that means it disappears after a few minutes.
- **First desire to void**
  - is defined as the feeling, that would lead the patient to pass urine at the next convenient moment, but voiding can be delayed if necessary.
- **Strong desire to void**
  - is defined, as a persistent desire to void without the fear of leakage.
- **Urgency**
  - during filling cystometry, is a sudden compelling desire to void.

- **Increased bladder sensation**
  - is defined, as an early first sensation of bladder filling (or an early desire to void) and/or an early strong desire to void, which occurs at low bladder volume and which persists.
- **Reduced bladder sensation**
  - is defined, as diminished sensation through out bladder filling.
- **Absent bladder sensation**
  - means that, during filling cystometry, the individual has no bladder sensation.
- **Non-specific bladder sensations,**
  - during filling cystometry, may make the individual aware of bladder filling, for example, abdominal fullness or vegetative symptoms.
- **Bladder pain,**
  - is a self explanatory term and is an abnormal finding.
  - Pain may increase with volume, or not, which should be reported.

## Filling cystometry - information

- Cystometric capacity (mL)
  - Infused weight and pump-speed helpful during the test
  - And include diuresis (capacity: voided volume + PVR) after the test.
  - Measure PVR after pressure flow via the catheter
- Bladder sensations (mL)
  - Electronic buttons during cystometry do not include diuresis; correct after the test if needed

## Bladder filling sensation

- Is a subjective parameter
  - *Depending on interaction /communication with the patient*
- Normal bladder sensation (rule of thumb) of cap.
 

• First sensation	+/- 175-250mL	33%
• First desire to void	+/- 272-450mL	66%
• Strong desire to void	+/- 429-700mL	100%

## Bladder capacity

- Cystometric capacity – bladder volume at the end of filling phase
  - Commonly there is no reason to fill more than 800mL e.g. in the absence of sensation and/or contraction
- Maximum cystometric capacity – patient can no longer delay micturition
  - Overfilling hinders subsequent representative voiding
- Maximum anesthetic capacity – volume of bladder without urinary leakage

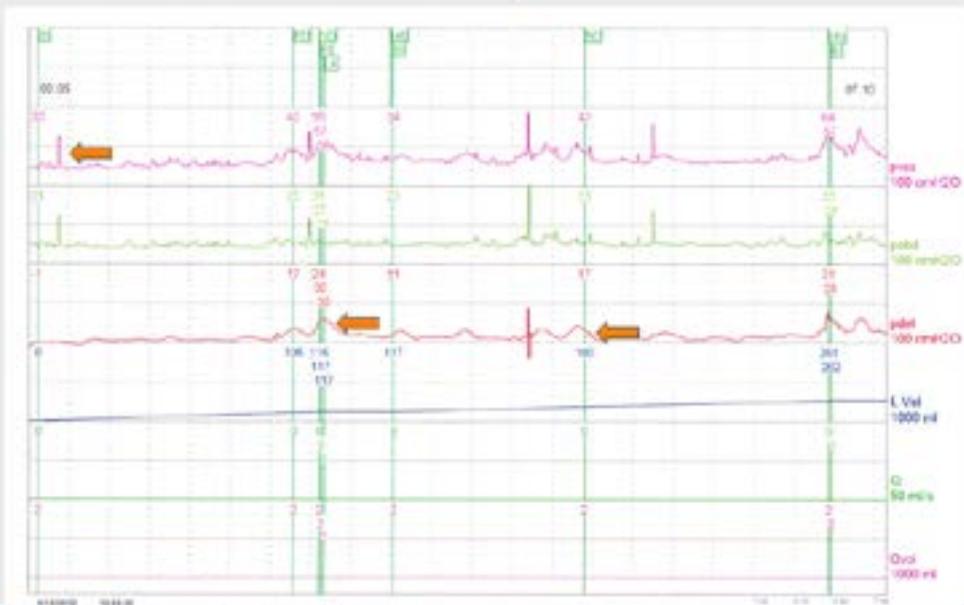

## Detrusor function

- Normal detrusor function – little or no changes in pressure
  - Detrusor overactivity – ANY amplitude of detrusor pressure raise before permission to void:
    - Neurogenic; when relevant neurological abnormalities are present
    - Idiopathic
- Cystometry patterns do not discriminate Neurogenicity: History and clinical exam**

Abrams P. Urology. 2003, 61: 37-49

**ICS** Educational Module

## Detrusor overactivity

**ICS** Educational Module

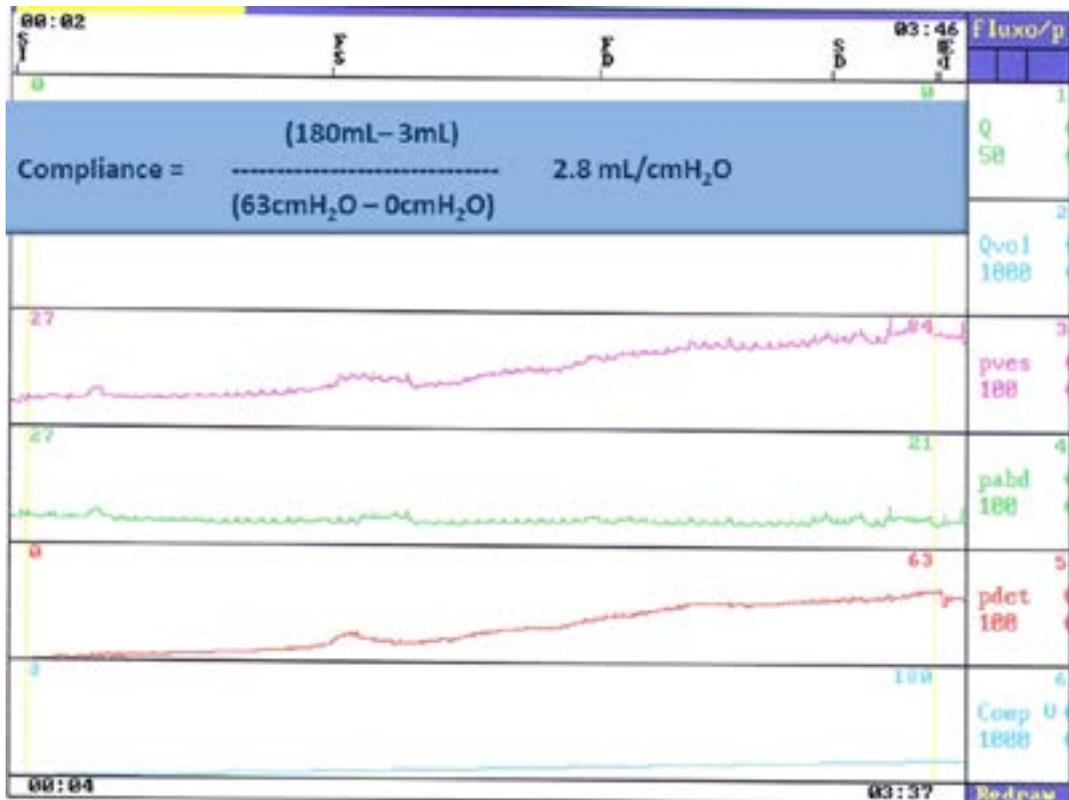

# Bladder Compliance

- Good compliance is large volume and low pressure

$$C = \frac{(V1 - V0)}{(P1 - P0)}$$

Abrams P. Urology. 2003, 61: 37-49

ICS Educational Module

## Bladder Compliance – Normal Values

- Not well defined
- (Neurogenic) LUT dysfunction:
  - (low) values 13 – 40 mL/cmH<sub>2</sub>O, upper tract risk
- Normal >40 mL/cmH<sub>2</sub>O
- Low <30 mL/cmH<sub>2</sub>O
  - Relation with sensation, volume and leak point

## Filling cystometry

# Cystometry

- Patient should be relaxed and trustful
- Technically adequate
- Observe the pressures 'as an engineer'
- Perform the test as representative for the usual situation as possible
- Systematically report all observations

Thank You

## Correspondence

Carlos Arturo Levi D'Ancona, Division of Urology, University of Campinas School of Medicine, Campinas, Sao Paulo, Brazil.  
Email: cdancona@uol.com.br

**Aims:** To summarize the evidence background for education of good urodynamic practice, especially cystometry.

**Methods:** A search was done in PubMed for the last 5 years of publications selecting only clinical studies, utilizing the following keywords: cystometry 133 articles and filling cystometry 53 articles.

**Results:** The evidence with regard to clinical setting and cystometry technique, as well as for catheters and transducers type, infused solution and patient position is presented with recommendations. Also the practice of determining bladder filling sensation and capacity and the basis of detrusor storage function diagnosis is educated.

**Conclusions:** This manuscript provides the evidence background for the practice of cystometry.

## KEYWORDS

cystometry, urodynamics

## 1 | INTRODUCTION

Cystometry is the method by which the storage function of the lower urinary tract (LUT) is measured during the filling of the bladder.<sup>1,3</sup> The aim of urodynamics is to find an objective, pathophysiological, explanation for the patient's LUT symptoms and to answer the clinical (or research) question.<sup>3-5</sup> Cystometry is an important part of invasive urodynamics as it evaluates the storage function of the bladder. Invasive urodynamics, that is, cystometry requires insertion of catheters and technical instrumentation and also depends on cooperation of the patient. Urodynamics is a replication of the LUT physiology in a laboratory situation and the interpretation should be made with specific attention to representativeness, technical details, as well as clinical relevance. Cystometry is the golden standard for LUT storage function assessment.<sup>1-5</sup>

The ICS Urodynamics Committee presents this teaching module "Cystometry" as standard education of Good Urodynamic Practice<sup>2,3</sup> for everyone involved with indicating,

performing, and analyzing urodynamic testing. The teaching module consists of a presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base, for the ICS PowerPoint presentation; available via <http://www.icsoffice.org/eLearning/.....> The presentation explains normal physiology, testing requirements, practice of testing, and analysis methods.

### 1.1 | Clinical setting

Cystometry is part of invasive urodynamic investigation and contemporary guidelines recommend that a LUT symptom questionnaire, a voiding diary, clinical examination, and laboratory urine exam preceded invasive testing. Usually uroflowmetry and a post void residual urine (PVR) are also recommended before further testing. The voiding diary informs about the range of the volume of micturition and the frequency of voiding. Uroflowmetry and PVR are recommended for clinical reasons but also relevant to evaluate the representativeness of pressure flow analysis (not further discussed here). For the practice of cystometry however, PVR is also informative to be aware of the "hidden" capacity of the bladder, not visible on the voiding diary.

Dr. Alan Wein led the peer-review process as the Associate Editor responsible for the paper.

Voided volumes (including PVR) provide a clue to the urodynamic capacity that can be expected. Cystometry should result in a diagnosis of detrusor (muscle volume-adaptation) function and bladder compliance as well as diagnoses of bladder filling sensation and cystometric (bladder) capacity.<sup>1</sup> Clinical stress-testing during examination can demonstrate urine loss however cystometry allows stress (urinary incontinence) testing while intravesical volume and pressures are monitored, allowing to control for detrusor activity.<sup>6,7</sup> All this information gives the urodynamic diagnosis of storage phase function and is basis for management of patients with symptoms and signs of LUTD.<sup>5</sup> The cystometry starts (after insertion of the catheters) when the infusion begins and ends when the infusion stops under the command of the patient and/or decision of the urodynamicist.<sup>1-3</sup> Cystometry may also end with loss (incontinence) of total bladder volume.

## 1.2 | Technique of cystometry

Catheterization is performed trans-urethral however, can also be done via the suprapubic route. ICS standard requires fluid filled catheters connected to an external pressure transducer. Simultaneous recording of abdominal pressure (Pabd) is also standard and can be obtained with the use of a catheter in the rectum and connected to a pressure transducer.<sup>1-3</sup>

The external transducers are positioned at the level of the upper border of symphysis pubic and zeroed at atmospheric pressure before connecting to the catheters, or via a tree-way stopcock while connected.<sup>3</sup> Air bubbles in the connecting tubes and catheters cause dampening of the pressure transmission and should be removed from the system before insertion and measuring.

Before and during the exam, it is necessary to verify that both pressures are registering by asking the patient to cough.<sup>3</sup> The amplitude of pves and pabd should be similar. The vital signs of respiration, talking of the patient, and movement should be visible in pves and pabd throughout the entire cystometry as a sign of pressure registering quality.<sup>2,8,9</sup> Rectal contractions may occur during cystometry and should not be misinterpreted as detrusor overactivity in the pdet trace.<sup>9</sup> On the other hand classification of intensity and frequency of rectal contractions may be of relevance.<sup>10</sup>

## 1.3 | Types of catheters

A double lumen catheter, as thin as possible (usually 7-8F), is ICS good urodynamic practices standard. A double lumen catheter requires an infusion pump on the filling lumen. Using a double lumen catheter allows a smooth transition from storage to voiding and permits the exam to be repeated without reinsertion of a filling catheter.

A double lumen catheter may be considered too expensive in some health care systems and in that case a 6F catheter is

inserted together with a filling catheter (usually 8-10F) that is removed at the end of the filling to avoid excess obstruction during voiding. Abdominal pressure, surrounding the bladder in the lower pelvis, is measured with a, preferably punctured, balloon filled with a small amount of fluid to prevent clogging of the catheter by rectal content, but may also be an open fluid filled tube without balloon.<sup>2,3</sup> Vaginal placing or via a stoma are alternatives when the rectum is closed. Although this is—especially stoma placement—less reliable.

The size of the abdominal pressure catheter is preferably similar to that of the Pves so that the same sensitiveness to transfer the pressure is present.

## 1.4 | Pressure transducer

Electronic external transducer, connected to the tubing via a pressure dome is the most frequently used in ICS standard urodynamic evaluation and all pressure parameters are based on this system. New microtip or air filled transducers have the advantage of no air bubbles in the fluid system or obstruction of measuring holes, but the results obtained with these systems are not entirely identical.<sup>11</sup> New studies should elucidate the magnitude of the differences and uncover practical methods to calibrate the clinical results with the alternative systems with the available reference values obtained with fluid filled systems.

## 1.5 | Solution infused

Saline solution is the commonly used fluid for bladder filling. When videourodynamics is performed, a contrast solution is added. Body temperature fluid and room temperature fluid do not differently affect bladder sensory thresholds and do not unequally provoke DO or LUT irritation<sup>12,13</sup> but forced diuresis (without external filling) does lead to a higher incidence of DO.<sup>14</sup>

The infusion rate is, by ICS good urodynamic practices, divided into Physiological filling rate—less than predicted maximum; calculated with body weight in kg divided by four expressed in mL/min; Non-physiologic filling rate; defined as filling rate greater than the predicted maximum filling rate.<sup>1</sup> A fill rate of 10% of anticipated capacity, based on voiding diary and PVR, per minute may be an acceptable rule of thumb to select the (non-physiologic) fill rate.<sup>1-3</sup>

## 1.6 | Patient position

The ICS standard position during cystometry is sitting upright or standing in all patients able to do. The initial resting pressures, if zeroed to the ICS reference, are 15-40 cmH<sub>2</sub>O (sitting) or 30-50 cmH<sub>2</sub>O (standing), both for the vesical as well as intrarectal pressure. In the supine position, the vesical pressure will be 5-20 cmH<sub>2</sub>O and the intrarectal pressure in an individual, usually somewhat higher as a consequence of this

position.<sup>15</sup> By consequence the subtracted detrusor pressures are around zero. Small differences (< + or – 10 cmH<sub>2</sub>O) can be considered to be a result from differences in catheter tip position of both catheters inside the body and are therefore acceptable.

### 1.6.1 | Bladder sensation

During the exam verbal communication is maintained with the patient so he/she can give information about the bladder sensation. This is a subjective parameter. ICS has defined three points to be evaluated: First sensation of bladder filling—is the feeling the patient has, during filling cystometry, when he/she first becomes aware of the bladder filling. First desire to void—defined as the feeling, during filling cystometry, that would lead the patient to pass urine at the next convenient moment, but voiding can be delayed if necessary. Strong desire to void—is defined, during filling cystometry, as a persistent desire to void without the fear of leakage.<sup>1,3</sup> These definitions should be put in practice as follows: First Sensation should be separated from the sensations that the catheterization has caused, that usually diminishes after the first minutes; The patient is asked “Tell me when you become aware that the bladder is not empty anymore.” Normal desire is (if no or little chronic post void residual exists) usually roughly associated with “average” FVC-BD volumes and can be asked as: “Tell me when you have the sensation that normally tells you go to the toilet, without any hurry. Strong desire is “the moment that you, without any pain, will not likely postpone the voiding any more, and or will visit the nearest restroom, eg. while shopping.” Correlating the results of cystometry volume and sensations with FVC-BD may provide background information regarding day to day sensory findings and bladder volumes. Sensation volumes are “normally” occurring at respectively  $\pm 30$  and 60% of capacity, and are also associated with the dysfunction.<sup>16,17</sup> Bladder sensation can be classified with the terms normal, absent, reduced, and increased sensations. Sensation is considered increased when the sensations, as described above, occur early, at relatively small volumes.<sup>1</sup> Bladder sensation can also be atypical, usually in patients with neurological abnormalities (not further discussed in this module).

### 1.6.2 | Bladder capacity during filling cystometry

Bladder capacity during filling cystometry is characterized by cystometric capacity and maximum cystometric capacity. Usually reported is capacity at strong desire which may be interpreted as maximum cystometric capacity that should be around 500 mL in women<sup>16,17</sup> and somewhat less in elderly men.<sup>8</sup> Filling of more than 800 mL is seldom useful.

Maximum anesthetic capacity; the volume to which the bladder can be filled under deep general or spinal anesthetic,

without urinary leakage, is rarely reported in scientific literature but may be of relevance in (ketamine) interstitial cystitis.

Cystometry is apart from urinary tract infection and urethral lesion not associated with excessive risks. In persons with a spinal cord lesion, however, autonomic dysreflexia may occur; immediate emptying of the bladder is the remedy (further discussed in specific ICS module). After cystoplasty or myectomy of the detrusor there is an increased risk of rupture of reservoir and especially in these patients (but not exclusively) the bladder should not be filled far beyond the usual volumes.<sup>18,19</sup>

### 1.6.3 | Detrusor function

Detrusor function can be normal or overactive.<sup>1</sup> Normal detrusor function—allows bladder filling with little or no change in pressure. Detrusor overactivity—is characterized by phasic detrusor pressure increments, which may be spontaneous or provoked. Examples of provocative maneuvers: non-physiological fast, for example, 100 mL/min bladder filling, change of position, stress test, and washing hands.

Detrusor overactivity should be classified as neurogenic or idiopathic. Detrusor overactivity is a urodynamic diagnosis and clinical symptoms may be urgency, urgency and incontinence, or overactive bladder syndrome.<sup>1,7</sup> When detrusor overactivity is observed in a patient with a relevant neurologic abnormality (should be diagnosed based on history and clinical examination) the detrusor overactivity is neurogenic.

### 1.6.4 | Bladder compliance

Bladder compliance represents the relationship between change in bladder volume and change in detrusor pressure and shows the capacity of the detrusor to relax and to stretch to accommodate to volume increment. Also reduced compliance may result in frequent voiding.

The module “cystometry advanced” discusses abnormalities of sensation and or detrusor function abnormalities.

## 2 | CONCLUSION

The evidence with regard to clinical setting and cystometry technique, as well as for catheters and transducers type, infused solution, and patient position is presented with recommendations. Also the practice of determining bladder filling sensation and capacity and the basis of detrusor storage function diagnosis is educated and provides the evidence background for the practice of cystometry shown in the ICS teaching module slides-set and presentation.

# ICS Teaching Module: Measurement of Post-Void Residual Urine

A D Asimakopoulos, C De Nunzio, E Kocjancic, A  
Tubaro, P Rosier & E Finazzi-Agro

 **ICS** International Continence Society  
Education Module

1

## Definitions

 **ICS** Education Module

2

## PVR

*“The amount of residual urine in the bladder after a voluntary void”*

Kaplan SA et al. J Urol. 2008 Jul;180(1):47-54.

Increased in pts with:

1. BOO (BPH, poor sphincter relaxation, urethral/meatal stricture or bladder stones)
2. Detrusor underactivity
3. Bladder diverticulum
4. Large volume vesicourethral reflux → “pseudoresidual”

## PVR and BOO

### Limits

- I. Can be due to detrusor underactivity
- II. 1/3 of male patients with BPH and bladder outlet obstruction do NOT present PVR

*More useful if used in combination with uroflowmetry or other parameters.*

*Belal M, Abrams P: J Urol 2006*

## PVR

- *Threshold values delineating what constitutes an abnormal PVR are poorly defined.*
- *Most urologists agree that volumes of 50-100 mL constitute the lower threshold to define an abnormal PVR.*

*Abrams PH et al . Br Med J 1978; 2: 1258*

## Measurement

## PVR measurement

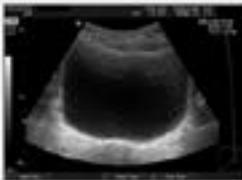

- Urethral catheterization has been accepted as the gold standard for PVR measurements, but this may cause discomfort for patients and carries a risk of urinary tract infection and trauma.

Schaeffer AJ, et al. J Urol 1983;130:1096–9.

- Non-invasive ultrasound bladder volume measurement has been used as an alternative to urethral catheterization, as a good compromise between accuracy and patients safety/comfort.

Griffiths CJ, et al. J Urol 1986;136:808-812

## PVR measurement by US

Ultrasound bladder volume estimation can be performed in two ways:

1. By a real-time ultrasound to directly visualize the bladder.

Griffiths CJ, et al. J Urol 1986;136:808-812

2. By using a portable bladder scanner to calculate the volume automatically without directly visualizing the bladder.

Hartnell GG et al, Br J Radiol 60 (1987), pp. 1063–1065.

## PVR measurement

### Bladder scanner advantages:

1. easy to use;
2. requires only basic training;
3. can be carried out on the ward.

Reliability? (Better with additional real-time pre-scan imaging?)

Park YH: Neurourol Urodyn 2011; 30:335–8.

## Significance

## Significance of PVR

### PVR and acute or chronic urinary retention

Chronic urinary retention has been widely accepted as corresponding to a PVR of more than 300 mL (nevertheless variable definitions).

Abrams PH, et al. Br Med J 1978; 2: 1258.

(Chronic) PVR does not seem to be a strong predictor of acute urinary retention (AUR).

Roehrborn CG, et al. J Urol, suppl., 2005; 173: 443, abstract 1638.

## Significance of PVR BOO

- *It is commonly thought that the increase in PVR indicates the severity of BOO.*
- *However, abnormal measurements of free uroflowmetry or PVR can detect only voiding dysfunction without indicating BOO specifically.*
- *Nevertheless, PVR measurements are used as parameter of efficacy for medical and surgical treatments of BPO.*

Kaplan SA, et al. Eur Urol. 2007 Jun;51(6):1717-23. Epub 2007 Jan 16.

## Significance of PVR

### PVR and clinical progression of BPO

- *High PVR is associated with an increased risk of LUTS deterioration and should thus be reconsidered in practice as a predictor of BPO progression.*
- *According to the EAU guidelines on the Management of Male Lower Urinary Tract Symptoms (LUTS), incl. Benign Prostatic Obstruction (BPO) , very large PVRs may herald progression of disease and may indicate bladder dysfunction and predict a less favourable response to treatment.*

Oelke M, et al EAU Guidelines on the Management of Male LUTS, incl. BPO

## Significance of PVR

### PVR and clinical progression of BPO

- *However, residual urine is not a contraindication to watchful waiting or medical therapy and no level of residual urine mandates invasive therapy and no PVR "cut-point" is yet established for decision-making.*

Oelke M, et al EAU Guidelines on the Management of Male LUTS, incl. BPO

## Significance of PVR

### PVR and Antimuscarinics in men

- It is common belief that antimuscarinics should not be used in men with BOO for a potential of AUR.
- Some placebo controlled clinical trial data suggest that antimuscarinics (alone or in combination with an alpha-blocker) do not increase the risk of AUR and do not produce a clinically significant increase of PVR in men, even in presence of BPO.

Roehrborn CG, et al. Urology. 2008 Nov;72(5):1061-7; discussion 1067.

Athanasopoulos A, et al. Eur Urol. 2011 Jul;60(1):94-105.

*However, patients with significant PVR were excluded from these studies and the safety of antimuscarinics in men remains to be confirmed.*

## Significance of PVR

### PVR and bacteriuria

Large PVRs may be associated with UTIs, especially in persons at risk (children, patients with spinal cord injury or diabetes).

Kelly CE. Rev Urol. 2004;6 Suppl 1:S32-7.

*Other studies, however, demonstrated that elevated PVR is not correlated to bacteriuria, incontinence, immobility, impaired cognition, or neurological disease.*

## Significance of PVR

### PVR and Chronic kidney disease (CKD)

- Very large PVRs (>300 mL) may be associated with an increased risk of upper urinary tract dilation and renal insufficiency.

Kelly CE. Rev Urol. 2004;6 Suppl 1:S32-7.

- A PVR >100 mL has been associated with CKD, even if other studies do not suggest this association.

## Significance of PVR

### PVR and Female incontinence

Measurement of PVR is recommended in the management of female urinary incontinence.

Thüroff JW, et al. EAU guidelines on urinary incontinence. Eur Urol. 2011 Mar;59(3):387-400.

PVR should be measured during the assessment of women complaining of overactive bladder symptoms to exclude voiding dysfunction and anticholinergic medication should be used if PVR is low.

Milleman M, et al. J Urol. 2004 Nov;172(5 Pt 1):1911-4

## Significance of PVR PVR and Children

Assessment of PVR is mandatory in a variety of pediatric patients, such as those with voiding LUTS, UTIs, vesicoureteral reflux, posterior urethral valves or neural tube defects.

Kelly CE. Rev Urol. 2004;6 Suppl 1:S32-7.

## Recommendations and evidence summary

## PVR

### Actual recommendations

- The interval between voiding and PVR measurement should be as short as possible (eo). It is advisable to ask the patients if the voiding was similar to a typical micturition in his/her daily life (eo).
- Use preferably noninvasive ultrasound bladder volume measurement instead of urethral catheterization (LE 3).
- Measurement of PVR is recommended at the management of female urinary incontinence (LE 3).
- Assessment of PVR is considered mandatory in a variety of pediatric patients (LE 3).

## PVR

### Evidence summary

- Unrepresentative results may be obtained when voiding has to occur in unfamiliar surroundings or on command with an only partially filled or an overfilled bladder (eo).
- Portable bladder scanner may present some advantages over real-time ultrasound, especially if equipped with an additional real-time pre-scan imaging (LE 3).
- There is no universally accepted definition of a significant residual urine volume. For clinical practice, PVR <30 mL can be considered insignificant, while residual volumes persistently >50 mL could be regarded as relevant (eo).

## PVR

### Evidence summary

- Large PVR (>200–300 mL) often indicates LUTD and may predispose to unsatisfactory treatment results if invasive BOO treatment is undertaken (LE 3). Nevertheless, no level of residual urine, of itself, mandates invasive therapy and no PVR threshold is yet established for decision-making (LE 3).

## PVR

### Evidence summary

- PVR cannot be used as a robust predictor of acute urinary retention (LE 3).
- PVR can detect only voiding dysfunction without indicating BOO specifically (LE 2-3).

## PVR

### Evidence summary

- PVR is not increased significantly in patients treated with antimuscarinic drugs (LE 2). However, consider that patients with significant PVR were excluded from studies published up to now.
- PVR may be associated with UTI, especially in subjects at risk, such as children or patients with spinal cord injury or diabetes (LE 3). This association among adults is far from clear (LE 3).
- Large PVR may be associated with chronic kidney diseases (LE 3).

## PVR

### Conclusions

- Measurement of PVR is recommended in guidelines and recommendations on the management of LUTS and urinary incontinence.
- Increased PVR values may be associated with an increased risk of UTI, risk of upper urinary tract deterioration and renal failure, risk of progression in men with BPO, risk of AUR following antimuscarinic treatment and risk of poor outcome following surgery of BPO.
- Up to now, most of the ominous features associated with PVR are not evidence-based.

## Measurement of Post-Void Residual Urine

**Aims:** To present the teaching module "Measurement of Post-void residual urine." **Methods:** This module has been prepared by a Working Group of the ICS Urodynamics Committee. The methodology used included comprehensive literature review, consensus formation by the members of the Working Group, and review by members of the ICS Urodynamics Committee core panel. **Results:** In this ICS teaching module the evidence for and relevance of PVR measurement in patients with lower urinary tract dysfunction (LUTD) is summarized; in short: The interval between voiding and post-void residual (PVR) measurement should be of short duration and ultrasound bladder volume measurement is preferred to urethral catheterization. There is no universally accepted definition of a significant residual urine volume. Large PVR (>200–300 ml) may indicate marked bladder dysfunction and may predispose to unsatisfactory treatment results if for example, invasive treatment for bladder outlet obstruction (BOO) is undertaken. PVR does not seem to be a strong predictor of acute urinary retention and does not indicate presence of BOO specifically. Although the evidence base is limited, guidelines on assessment of LUTS generally include PVR measurement. **Conclusion:** Measurement of PVR is recommended in guidelines and recommendations on the management of LUTS and urinary incontinence, but the level of evidence for this measurement is not high. This manuscript summarizes the evidence and provides practice recommendations for teaching purposes in the framework of an ICS teaching module. *Neurourol. Urodynam.* 35:55–57, 2016. © 2014 Wiley Periodicals, Inc.

**Key words:** bladder outlet obstruction; measurement; post-void residual urine; urinary incontinence; urinary tract infections; urodynamics

### INTRODUCTION

The incomplete evacuation of the bladder leads to post-void residual urine (PVR). PVR is defined as the volume (ml) of urine left in the bladder at the end of micturition.<sup>1</sup>

The ICS Urodynamics Committee presents the teaching module "Measurement of post-void residual urine" to serve as a standard education of Good Urodynamic Practice for everyone involved in indicating, performing, and analyzing urodynamic testing in general and more specifically, performing analysis of voiding. The teaching module consists of a PowerPoint presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base for the ICS PowerPoint presentation is available via <http://www.icsoffice.org/eLearning/> or via the QR code on this page. The presentation explains testing requirements, clinical workup and analysis. The presentation and this manuscript are based on the highest-level available published evidence; evidence has been graded according to the modification of the Oxford Center for Evidence-Based Medicine levels of evidence used by the 5th International Consultation on Incontinence.<sup>2</sup> Where evidence is unavailable, experts' opinion has been used and the sentence is marked as "eo" (experts' opinion).

### PATHOPHYSIOLOGY

PVR is very frequently the consequence of lower urinary tract dysfunction (LUTD), with bladder outlet obstruction (BOO) and underactive or acontractile detrusor as its most prevalent

examples. However, anatomical abnormalities for example, bladder diverticulum or large volume vesicourethral reflux may also cause PVR (in the latter case due to very early refilling of the bladder by the refluxed urine).<sup>3</sup> BOO may be a consequence of prostate enlargement (BPE), urethral or meatal stricture, or incomplete or interrupted sphincter relaxation. Rarely a bladder stone or tumor is the cause of PVR.<sup>3</sup> Underactive detrusor contraction can result from neurogenic, myogenic or psychogenic causes or be an effect or side effect of pharmacotherapy.<sup>3</sup> In any individual, especially in the elderly, or the neurologically affected, the pathophysiology of PVR may be multifactorial.<sup>3</sup> Furthermore, threshold values delineating what constitutes an abnormal PVR are poorly defined.<sup>4–7</sup>

### PREPARATION

PVR is measured after a flowmetry. However PVR can also be measured after visiting a normal toilet. No evidence exists about the reliability of PVR measurements in the last

Christopher Chapple led the peer-review process as the Associate Editor responsible for the paper.

Potential conflicts of interest: Nothing to disclose.

mentioned situation. No specific patient preparation is needed. It may be reasonable to ask the patient if the voiding was similar to a typical micturition in his/her daily life.

#### TECHNIQUE

Ideally, the interval between voiding and PVR measurement is of short duration. Furthermore, unrepresentative results may be obtained when voiding has to occur in unfamiliar surroundings or on command with a partially filled or overfilled bladder. Although transurethral catheterization has been accepted as the gold standard for PVR measurements, this may cause discomfort for patients and carries a risk of urinary tract infection and trauma.<sup>8</sup> To overcome these limitations, non-invasive ultrasound bladder volume measurement has been used as an alternative to urethral catheterization since it represents a good compromise between accuracy and patients' safety/comfort.<sup>9–11,31</sup> Traditionally, ultrasound bladder volume estimation can be performed in two ways; either by using real-time ultrasound to directly visualize the bladder<sup>9–10</sup> or by using a portable bladder scanner to calculate the volume automatically without directly visualizing the bladder.<sup>11</sup> Portable bladder scanners have many advantages over real-time ultrasound. They are easy to use, require only basic training, and can be used on the ward, freeing up precious radiology department resources. Furthermore, a bladder scanner may reduce catheterizations; minimize the threat of urethral injuries and causes less patient discomfort. Recently, in an aim to improve accuracy, a portable ultrasound bladder scanner equipped with an additional real-time pre-scan imaging (RPI) has been introduced. It seems to be able to enhance accuracy, as it can provide examiners with pre-localization of the central target point as well as information on the shape of the bladder prior to actual scanning, reducing the variability of the measured values.<sup>12</sup>

#### INTERPRETATION

##### PVR and Acute or Chronic Urinary Retention

Chronic post-void residual has been widely accepted as corresponding to a consistent PVR of more than 300 ml,<sup>4</sup> however, some investigators have defined it as more than 400 ml,<sup>13</sup> as 100–500 ml<sup>14</sup> or have given it no definite number at all.<sup>15</sup> On the other hand, (chronic) PVR does not seem to be a strong predictor of acute urinary retention (AUR).<sup>16</sup>

##### BOO

It is commonly thought that the increase in residual urine indicates the severity of BOO. However, abnormal measurements of free uroflowmetry or PVR can detect only a voiding dysfunction without indicating BOO specifically. Detrusor underactivity may be the only cause of a large PVR. Nevertheless, PVR measurements are used as parameter of efficacy for medical and surgical treatments for BPO.<sup>17–18</sup>

##### PVR and Clinical Progression Of BPO

High volume PVR is associated with an increased risk of LUTS deterioration and considered a predictor of BPO progression.<sup>19–20</sup> In the EAU Guidelines on the Management of Male Lower Urinary Tract Symptoms (LUTS), incl. Benign Prostatic Obstruction (BPO),<sup>21</sup> it is paraphrased that very large PVRs may herald progression of disease. However, expert

opinion prevails that very large PVR volumes (>200–300ml) may indicate detrusor underactivity and predict a less favorable response to treatment. PVR as such is not considered a stringent contraindication for watchful waiting or medical therapy. The use of PVR measurements is considered optional in men with uncomplicated LUTS undergoing noninvasive therapy. No level of residual urine, of itself, mandates invasive therapy<sup>21</sup> and no PVR “cut-point” is yet established for decision-making.

##### PVR and Antimuscarinics in Men

Some recent placebo controlled clinical trial data suggest that anti-muscarinics (alone or in combination with tamsulosin) do not increase the risk of AUR and do not produce a clinically significant increase of PVR<sup>22–23</sup> in men, even in the presence of BPO. However, patients with significant PVR were excluded from these studies and the safety of anti-muscarinics in men with BPO remains to be confirmed in long-term trials.

##### Bacteriuria

Large and/or persistent PVRs may be associated with urinary tract infections (UTI), especially in persons at risk, such as children or patients with spinal cord injury or diabetes.<sup>24</sup> Although this association is confirmed in a pediatric population<sup>24</sup> and in patients with neurogenic dysfunction,<sup>25</sup> other studies concluded that PVR does not correlate with bacteriuria, incontinence, immobility, impaired cognition, or neurological disease.<sup>26–27</sup>

##### Chronic Kidney Disease (CKD)

Very large PVRs (>300 ml) may increase the risk of upper urinary tract dilation and renal insufficiency.<sup>24</sup> A PVR > 100 ml has been associated with CKD in elderly men with LUTS;<sup>28</sup> however, other studies do not show a significant correlation between PVR and CKD.<sup>29</sup>

##### Female Incontinence

It is currently recommended that PVR should be measured during the assessment of women with signs and symptoms of urinary incontinence and/or overactive bladder syndrome to exclude voiding dysfunction.<sup>5</sup> Although the available evidence is still limited, antimuscarinic or anticholinergic medication should generally be considered if PVR is low.<sup>30</sup> Measurement of PVR is recommended in the management of female urinary incontinence.<sup>31</sup>

##### Children

Assessment of PVR is mandatory in a variety of pediatric patients, such as those with voiding LUTS, UTIs, vesicoureteral reflux, posterior urethral valves or neural tube defects.<sup>24</sup>

#### ACTUAL RECOMMENDATIONS

- The interval between voiding and PVR measurement should be as short as possible (eo). It is advisable to ask the patients if the voiding was similar to a typical micturition in his/her daily life (eo).
- Preferably use non-invasive ultrasound bladder volume measurement instead of urethral catheterization (LE 3).
- Measurement of PVR is recommended in the management of female urinary incontinence (LE 3).

- Assessment of PVR is considered mandatory in a variety of pediatric patients (LE 3).

#### EVIDENCE SUMMARY

- Unrepresentative results may be obtained when voiding has to occur in unfamiliar surroundings or on command with an only partially filled or an overfilled bladder (eo).
- A portable bladder scanner may present some advantages over real-time ultrasound (LE 3), especially if equipped with additional real-time pre-scan imaging (LE 3).
- There is no universally accepted definition of a significant residual urine volume. For clinical practice, PVR <30 ml can be considered insignificant, while residual volumes persistently >50 ml could be regarded as important (eo).
- Large PVR (>200–300 ml) often indicates LUTD and may predispose to unsatisfactory treatment results if invasive BOO treatment is undertaken (LE 3). Nevertheless, no level of residual urine, of itself, mandates invasive therapy and no PVR threshold is yet established for decision-making (LE 3).
- PVR cannot be used as a robust predictor of acute urinary retention (LE 3).
- PVR can detect only voiding dysfunction without indicating BOO specifically (LE 2–3).
- There is no evidence that PVR increases significantly in patients treated with anti-muscarinic drugs (LE 2). However, consider that patients with significant PVR were excluded from studies published up to now.
- PVR may be associated with UTI, especially in persons at risk, such as children or patients with neurogenic dysfunction (LE 3). This association among adults is far from clear (LE 3).
- Large PVR may be associated with chronic kidney diseases (LE 3).

#### CONCLUSIONS

Measurement of PVR is recommended in guidelines and recommendations on the management of LUTS and urinary incontinence. However, there is still lack of evidence on the precise associations of PVR with most of the lower urinary tract dysfunctions and, consequently, most of the ominous features associated with PVR are not evidence-based. We have reviewed the evidence and provided recommendations for ICS standard teaching purposes.

# ICS Teaching Module: Pad Weight Testing in the Evaluation of Urinary Incontinence

J Krhut, A Martan, P Rosier, P Smith, L Valansky, R Zachoval, & P Zvara

**ICS**

International Continence Society  
Teaching Module

1

## Aims of the pad weight testing

- Qualitative assessment (continent vs incontinent)
- Quantitative assessment (how much)

2

## Principle of the pad weight testing

- weight of the pads before and after test
- weight gain in g = urine loss in mls

## Duration of the pad weight test

### Short term tests

- 20 min – 2 hrs
- qualitative assessment

### Long term tests

- 12 hrs – 72 hrs
- quantitative assessment

## ICS pad weight test

- Only 1 hour pad weight test is standardized<sup>1</sup>

- 0 - 15 min: drinking of 500 ml sodium-free liquid, resting
- 15 - 45 min: walking, including stairs climbing to one flight up and down
- 45 - 60 min: standing up from sitting (10 times)  
coughing vigorously (10 times)  
running on the spot (1 min)  
bending to pick up small object from the floor (5 times)  
washing hands in running water (1min)

<sup>1</sup>Seventh report on the standardisation of terminology of lower urinary tract function: lower urinary tract rehabilitation techniques. International Continence Society Committee on Standardisation of Terminology. Scand J Urol Nephrol, 26:99, 1992

## Preparation of the patient

### Short term tests

- without retrograde filling
- with retrograde filling<sup>1</sup>  
(200-300 ml)  
(50-75% of the bladder capacity)

### Long term tests

- without retrograde filling

## Performing the pad weight test

### Short term tests

- set of standardized activities

### Long term tests

- normal daily activity

The same technique for both men and women is usually used

## Cut-off values

### Short term tests

- weight gain  $> 1g^1$

### Long term tests

- weight gain  $> 4g/24hrs^1$

<sup>1</sup>Staskin D, Kelleher C, Bosch R, Coyne K, Cotterill N, Emmanuel A, Yoshida M, Kopp Z: Initial assessment of urinary and faecal incontinence in adult male and female patients. In: Incontinence. Ed.: Abrams P, Cardozo L, Khoury S, Wein A. 4th Ed. Health Publ Ltd, Paris 2009, pp 333-412

## Quantification of the incontinence severity using the pad weight test

	<i>1-hour test</i>	<i>24-hour test</i>
<i>Mild incontinence</i>	< 10 mL	< 20 mL
<i>Moderate incontinence</i>	11-50 mL	21-74 mL
<i>Severe incontinence</i>	>50 mL	>75 mL

O'Sullivan R, Karantanis E, Stevermuer TL, et al : Definition of mild, moderate and severe incontinence on the 24-hour pad test. BJOG 2004; 111: 859-862

## Is leak of 1 mL significant?

1 mL of fluid = 25 drops

## Is leak of 1 mL of fluid significant?

- 1 mL of fluid leaked into the pad
- 1 mL of fluid leaked into the cloth

## Is leak of 5 mL of fluid significant?

- 5 mL of fluid absorbed by pad
- 5 mL of fluid leaked into the clothing

## Sensitivity and specificity

### Short term tests

- sensitivity: 34-83%<sup>1,2</sup>
- specificity: 65-89%<sup>2</sup>

### Long term tests

- sensitivity: no sufficient data
- specificity: no sufficient data

<sup>1</sup>Wu, WCY, Sheu, B. C., Liu, H. H.: Twenty-minute pad test: comparison of infusion of 250 ml of water with strong-desire amount in the bladder in women with stress urinary incontinence. *Eur J Obstet Gynecol Reprod Biol*, **110**: 121, 2008

<sup>2</sup>Costantini, F., Lazzeri, M., Bini, V. et al.: Sensitivity and specificity of one-hour pad test as a predictive value for female urinary incontinence. *Urol Int*, **81**: 153, 2008

## Limitations

- lack of standardization
- results of the long term tests may be influenced by:
  - fluid intake
  - increased voiding frequency
  - sweating
  - vaginal discharge (up to 7g/24 hrs)<sup>1</sup>
  - patient compliance
- no value in determining incontinence etiology
- weak correlation with the degree of patient's bother

<sup>1</sup>Kanantonis E, O'Sullivan R, Moore KH: The 24 hour pad test in continent women: and men: normal values and cyclical alterations. *BJOG* 2002; **110**: 567-571

## Clinical conclusions

- pad-test can provide additional information about degree of patient's incontinence
- easy to perform, inexpensive, risk-free
- could be influenced by many factors, therefore

Outcomes should be interpreted in context of other diagnostic instruments

## Recommendation for clinical use of the pad weight test

- detailed instruction and patient motivation are crucial
- use short term test for qualitative evaluation of incontinence
- if retrograde filling is to be used, bladder should be filled to 50-75% of bladder capacity
- use long term test for quantitative evaluation of incontinence
- interpret test results in conjunction with other relevant assessments (self-assessment, questionnaires, physical examination, etc.)
- pad weight test result doesn't always correlate with patient's bother

**Aim:** To present the teaching module “Pad Weight Testing in the Evaluation of Urinary Incontinence.” This teaching module embodies a presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base made available on ICS website to summarize current knowledge and recommendations. **Methods:** This review has been prepared by a Working Group of The ICS Urodynamics Committee. The methodology used included comprehensive literature review, consensus formation by the members of the Working Group, and review by members of the ICS Urodynamics Committee core panel. **Results:** The pad test is a non-invasive diagnostic tool for urinary incontinence. It is an easy to perform, inexpensive test with utilization in both the daily patient care and clinical research. Despite it is clear value in initial diagnosis, selection of treatment, and follow-up evaluation, only less than 10% of urologists perform the test routinely. A number of testing protocols with varying lengths of recording time exist, however, only a 1-hr pad test has been standardized. One-hour pad tests are most suitable in establishing initial diagnosis, the 24-hr test serves most often for evaluation of treatment outcomes, and longer pad tests are used in clinical studies. **Conclusions:** The pad test is clearly underutilized. Well-designed studies providing level one evidence are lacking. Numerous variations in how the test is performed by individual urologists make the evaluation of published literature difficult. Future research goals should include randomized studies leading to establishment of optimal protocols of testing for clinical research and daily care. *NeuroUrol. Urodynam. 33:507–510, 2014.*

**Key words:** diagnostics; ICS teaching module; urinary incontinence; urodynamics; pad weight test

### INTRODUCTION

Pad testing is a non-invasive method of detecting and quantifying severity of urine leakage. The 4th International Consultation on Incontinence defined pad testing as “an optional test for evaluation of urinary incontinence.”<sup>1</sup> Diverse testing durations have been reported in the literature and only for the 1-hr pad test a specific test protocol has been standardized.<sup>2,3</sup> Although it is generally believed that longer tests are more reproducible, evidence on the accuracy of different methods of pad testing is inconsistent. A 24-hr test is more reproducible than a 1-hr test, but longer testing requires more preparation and a greater commitment on the part of the patient. Twenty-four-hour testing is reported to be adequate in routine clinical settings while 48- to 72-hr testing is deemed necessary for clinical research.<sup>2,4</sup>

### MATERIALS AND METHODS

This review has been prepared by a Working Group of The ICS Urodynamics Committee. The methodology used included comprehensive literature review, consensus formation by the members of the Working Group, and review by members of the ICS Urodynamics Committee core panel.

The ICS Urodynamics Committee presents the teaching module “Pad Weight Testing in the Evaluation of Urinary

Incontinence” to serve as a standard education of Good Urodynamic Practice for everyone involved in indicating, performing and analyzing urodynamic testing in general and more specifically, performing analysis of voiding. The teaching module consists of a presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base, for the ICS Power Point presentation; available via <http://www.icsoffice.org/eLearning/> or via the QR code on this page. The presentation explains, testing requirements, clinical workup and analysis. The presentation and this manuscript contain experts’ opinion where evidence is, especially for the clinical practice aspects, unavailable and is marked” with: “eo” (experts opinion).

Heinz Koelbl led the peer-review process as the Associate Editor responsible for the paper.

Conflict of interest: none.

## RESULTS

### Preparation

- (1) **Test selection:** The type of pad test selected is based on goals. A 1-hr test is usually administered during initial evaluation to select treatment and estimate prognosis for cure (*eo*). Twenty-four-hour or longer testing is necessary for quantifying the degree of urine leakage (*eo*).
- (2) **Instruction:** Detailed instruction is critical in order to elicit the full compliance of patients.
- (3) **Filling the bladder to a set starting volume:** The short duration pad test (1-hr or less) may be performed using an instilled starting bladder volume. Usually, the bladder is filled through a urethral catheter (or during cystoscopy). Most reported studies used 150–300 ml, some recommend a volume equivalent to 50–75% of the functional bladder capacity.<sup>5,6</sup> Filling to the first desire to void or sensation of fullness has also been reported.<sup>7</sup> Although studies have documented that this modification improves the quantitative value of the test, the consensus on the ideal starting volume is lacking.<sup>3</sup>

### Technique

The test is administered in a same manner to both male and female patients (*eo*).

**One-hour pad test.** The testing protocol has been standardized by International Continence Society (ICS-pad test):

- the test is started by putting one pre-weighted pad without patient voiding,
- patient drinks 500 ml of sodium-free liquid in <15 min—then sits or rests,
- patient walks for 30 min, including climbing one flight of stairs (up and down),
- patient performs the following activities: standing up from sitting (10×), coughing vigorously (10×), running on the spot for 1 min, bending to pick up an object from the floor (5×), and washing hands in running water for 1 min (this activity program may be modified according to the patient's physical fitness),
- the total amount of urine leaked is determined by weighing the pad.

If a moderately full bladder cannot be maintained through the hour (if the patient must void), the test has to be started again.

**Twenty-four-hour pad test.**

- the test should be started with an empty bladder,
- normal daily activities should be followed and recorded in a voiding diary so that the same schedule will be observed during follow-up re-testing (*eo*),
- to avoid urine loss through leakage or evaporation the pads should be worn inside waterproof underpants and exchanged every 4–6 hr during daytime,
- pads should be weighed immediately. If weighing is performed at the clinic, pads must be stored in airtight bag.

### Interpretation

The upper limit of weight increase for the 1-hr test in continent women is 1.4 g (equivalent to 1.4 ml) and 1.3–4.4 g for 24-hr test. These values may increase in situations of increased perspiration.<sup>8</sup> In the analysis of 1-hr pad test, an

increase of 1–10 g is classified as representing mild incontinence, 11–50 g moderate and >50 g severe incontinence. The values for 24-hr pad test are classified as follows: Mild (4–20 g/24 hr), moderate (21–74 g/24 hr), and severe (>75 g/24 hr) incontinence.<sup>9</sup>

A weight gain of less than 1.4 g during 1-hr test or 4.4 g for 24-hr test could be a result of sweating or vaginal discharge. If the findings are inconclusive, oral phenazopyridine which colors the urine orange could be used.<sup>10</sup> Listed cut-off values are based on studies performed in female patients. The values specific to males have not been yet determined.

The outcomes of studies which attempted to correlate the volume of leakage to the etiology (stress, urge, and mixed incontinence) showed significant variability, suggesting that the pad test is not appropriate for separating the types of incontinence based on their etiology.<sup>11,12</sup> Ryhammer et al. compared weight gain between two groups of randomly selected women, 79 of whom reported continence and 38 reported incontinence. They found no difference in the outcome of 24-hr pad test, suggesting that pad test should not be used as a screening tool.<sup>13</sup> The sensitivity and specificity of the 1-hr pad test reported in the literature varies significantly.<sup>14</sup> The 1-hr pad test was shown to have a high positive predictive value, however the false positive results can occur in more than 50% of cases.<sup>15</sup>

### Recommendations

-in the initial patient work-up, an objective measure of incontinence loss volume such as the pad test may help in treatment selection (e.g., male sling vs. artificial sphincter in the treatment of the post-prostatectomy incontinence) (Table I).<sup>16</sup>

-estimation of treatment prognosis (patients with high volume incontinence may experience lower cure rates) (*eo*),

-objective measure of treatment outcome for anti-incontinence procedures,

-the volume of leakage does not always correlate with the degree of bother (e.g., 2 g of urine leakage, which is roughly equivalent to 40 drops, produces a large spot on the clothing), therefore pad tests should be always interpreted in conjunction with history, clinical examination and self-assessment questionnaires (*eo*),

-future research goals should include determination of the optimal technique and duration of testing for both clinical and research purposes with the ultimate goal of developing an appropriate individualized testing protocol for patients and their varying circumstances (*eo*).

**One-hour pad test.**

-the 1-hr pad test, using the ICS standardized protocol is appropriate in routine evaluation of patients during initial work up,

TABLE I. Basic Characteristics and Degree of Accuracy of Individual Types of Pad Tests

	Short-term tests (qualitative assessment)	Long-term tests (quantitative assessment)
Bladder filling	No artificial filling or retrograde filling	No artificial filling
Physical activity during test	Standardized activities	Normal daily activities
Evaluation	Weight gain >1 g	Weight gain >4 g/24 hr
Sensitivity	34–83% <sup>22</sup>	Insufficient data
Specificity	65–89% <sup>22</sup>	Insufficient data

-if either the patient or physician have doubts about the accuracy of the initial test, evaluation should be extended by an additional hour or repeated,  
 -the test should always be interpreted in conjunction with standard self-assessment questionnaires including the both-er index,  
 -performing the test with a known start volume might increase the accuracy, but the data supporting this assumption is inconclusive and there is no consensus on what the volume should be (eo).

#### Twenty-four-hour pad test.

-it is more reproducible than 1-hr test,  
 -highly dependent on patient compliance and therefore not suitable for all patients (eo),  
 -detailed instruction and patient motivation are important, the test results depend on fluid intake, physical activity levels, hormonal status, sexual activity, and environmental factors (temperature, humidity),  
 -the protocol should be personalized based on patient's physical status (eo),  
 -the physical activity and detailed voiding diary should be recorded so that a similar protocol is followed during the initial and all follow-up (eo).

### DISCUSSION

Pad weighing as a diagnostic method for incontinence was first described by James et al. in 1971.<sup>17</sup> In 1981, Sutherst et al. were the first to publicize the use of the pad test with a prescribed set of activities and exercises.<sup>18</sup> Since then, a number of published studies used various forms of the pad testing protocols. Pad testing is easy and inexpensive, yet recent surveys of the Society for Urodynamics and Female Urology members showed that only 4.5–8% of the members perform the pad test routinely in their practice.<sup>19</sup> A number of studies have documented that the longer the testing, the better the correlation between the test results and the degree of incontinence. However, 24- to 72-hr pad tests are cumbersome and require high levels of patient compliance.<sup>15,20</sup> Test outcomes are affected by many factors and therefore have to be interpreted in combination with other methods of evaluation. Caution has to be exercised especially in giving too much weight to a negative 1-hr pad test (eo). Repeated short term testing is recommended especially in cases where the test result does not correlate with subjective assessment provided by the patient.<sup>21</sup> Good correlation has been reported by Abdel-Fattah et al.<sup>22</sup> between the self-assessment questionnaires and the 1-hr pad test. The King's Health Questionnaire showed a 96% sensitivity and 93% specificity of a 1-hr pad test in identifying incontinent patients.<sup>22</sup> The good correlation between self-assessment questionnaires and 1-hr pad test, but not the 24-hr pad test supports the value in standardization. Good correlation with the 24-hr pad test and the International Consultation on Incontinence Questionnaire—Short Form (ICIQ-SF) has been documented.<sup>23</sup> The biggest cost associated with the pad testing is the office visit, therefore home pad tests using the mail has been proposed.<sup>24</sup> Longer testing protocols could potentially increase the sensitivity and specificity, however, they require selection of highly motivated patients. The type of pad, leak, and evaporation could affect the outcome, therefore pad should be exchanged every 4–6 hr during the 24-hr and longer pad testing.<sup>25</sup>

### CONCLUSIONS

The pad test is non-invasive and easy to perform, yet factors such as embarrassment and behavioral changes to reduce

*Neurourology and Urodynamics* DOI 10.1002/nau

incontinence severity (inactivity, fluid restriction) could affect the outcome significantly. The 1-hr pad test as standardized by ICS is currently the only tool with a set protocol, and we recommend using the original protocol. In the case that artificial bladder filling is used, the bladder should be filled to 50–75% of its functional capacity prior to the initiation of the test. The 24-hr test is sufficient in daily clinical practice. Performing this test in conjunction with a voiding diary, or simply recording fluid intake and frequency of incontinence episodes, will significantly increase its utility. A standard protocol for 24- to 72-hr pad testing does not exist at the present time, and we believe establishing one would be very helpful. Prescribing specific physical activity over 24–72 hr is problematic, therefore we recommend instructing the patient to follow a normal daily routine. Despite the above limitations, the pad test provides objective assessment of involuntary urine loss. Its optimal utility depends upon understanding the impact of these limitations for diagnostic and prognostic use. The correlations of specific testing protocols with subjective and objective measures must be performed so that the most appropriate testing protocol may be employed according to circumstance. We believe that standardization of testing is an important first step in improving the utilization of this simple and inexpensive testing method.

## ICS Teaching Module: Artefacts in Urodynamic Pressure Traces (Basic Module)

Andrew Gammie,<sup>1\*</sup> Carlos D'Ancona,<sup>2</sup> Hann-Chorng Kuo,<sup>3</sup> and Peter F.W. Rosier<sup>4</sup>

<sup>1</sup>Bristol Urological Institute, Southmead Hospital, Bristol, United Kingdom

<sup>2</sup>University of Campinas–, UNICAMP, Sao Paulo, Brazil

<sup>3</sup>Department of Urology, Buddhist Tzu Chi General Hospital and Tzu Chi University, Hualien, Taiwan

<sup>4</sup>University Medical Centre–Urology, Utrecht, the Netherlands

**Aims:** To present the ICS Teaching Module on artefacts in urodynamics pressure traces. **Methods:** Slides from three urodynamics centres were assembled. Descriptions and labels were agreed by the authors and the module presented at the ICS Annual Scientific Meeting in Brazil 2014. **Results:** Ten artefacts that should be recognized while using water-filled urodynamic systems are presented and remedial action described. **Conclusions:** This manuscript serves as scientific background for the slide set made available on the ICS website. By following the guidelines in this teaching module, good quality urodynamics can be more readily achieved. *Neurourol. Urodynam.* 36:35–36, 2017.

**Key words:** artefacts; pressure measurement; quality

### INTRODUCTION

The International Continence Society (ICS) Urodynamics Committee presents the first teaching module of Artefacts in Urodynamic Pressure Traces as a resource to enhance good urodynamic practice.

An artefact is understood to be 'Something ...that is not naturally present but occurs as a result of ...the procedure.'<sup>1</sup> When artefacts arise during the test, they should be removed or can sometimes be compensated for, thus improving the quality of urodynamic results. If artefacts have not been corrected during the test they should be recognized during post-test evaluation. This module presents the artefacts that this working group has considered to be the most prevalent when water-filled urodynamic systems are used. They are described as patterns on the urodynamic traces, and all are recognizable and correctable during the test. Some artefacts may, however, necessitate repetition of the test.

We present ten artefact patterns with an explanation of their causes and a description of the remedies. Further understanding of the prevalence and nature of artefacts can be found in Hogan et al.,<sup>2</sup> and a full presentation of Good Urodynamic Practices is found in Schaefer et al.<sup>3</sup> These underline that signal quality is only assured through using adequate equipment, with careful installation of the whole system and with skilled and alert staff performing the test. The teaching module referred to here consists of this manuscript and a slide presentation available at [www.ics.org/tv?play=3364](http://www.ics.org/tv?play=3364). An advanced module will also be made available dealing with less common artefacts, along with those found in other types of pressure measurement systems.

### CONTENTS

The ten artefacts described in this module are:

- Movement/tube knock
- Patient position change
- Expelled vesical catheter
- Expelled rectal catheter
- Flushed catheter
- Line open to syringe

© 2015 Wiley Periodicals, Inc.

- Empty bladder (poor response)
- Empty rectal catheter
- Poor cough response
- Poor response to live signal

The descriptions below are all with reference to water-filled pressure measurement systems, although some of these artefacts do occur in other types of system. Each artefact has the observed effect, underlying cause and recommended remedy described.

### ARTEFACT DESCRIPTIONS, CAUSES AND REMEDIES

#### Movement/Tube Knock

**Effect observed.** High frequency, short duration pressure spikes visible in  $p_{ves}$ ,  $p_{abd}$ , or both, with spikes always visible in  $p_{det}$ .

**Cause of artefact.** Knocking of one or both tubes. In the example, the knock is first on the  $p_{ves}$  line, then on the  $p_{abd}$  line.

**Remedial action.** Ensure tubes are away from the cause of the knock. Ignore these spikes when analysing the trace.

#### Patient Position Change

**Effect observed.** A lasting change in  $p_{ves}$  and  $p_{abd}$  of equal magnitude on both, usually between 8 and 35  $\text{cmH}_2\text{O}$ .<sup>2</sup> It is often accompanied by noisy signals as the lines are knocked.

**Cause of artefact.** A change in patient position. In the example, the patient has begun supine, stood up, then sat down on the

DOI 10.1002/nau.22881

commode at a position below the level of the transducer. The level of the transducers was then adjusted to the level of the symphysis pubis.

**Remedial action.** Ensure the transducers are moved to the level of the symphysis pubis after any patient position change. Transmission of pressure should also be checked after patient movement.

#### Expelled Vesical Catheter

**Effect observed.** A sudden drop in  $p_{ves}$ , usually to well below zero, with no response to transmission checks.

**Cause of artefact.** The vesical catheter is expelled from the patient, normally by the pressure of voiding.

**Remedial action.** Recatheterise and repeat the test, if the urodynamic question has not been answered.

#### Expelled Rectal Catheter

**Effect observed.** A sudden drop in  $p_{abd}$ , usually to well below zero.

**Cause of artefact.** The abdominal catheter is expelled from the patient, normally by the pressure of valsalva or straining.

**Remedial action.** Recatheterise and repeat the test, if the urodynamic question has not been answered

#### Flushed Catheter

**Effect observed.** An abrupt large increase in a single pressure trace, maintained for some seconds, followed by a sudden normalisation of pressure.<sup>2</sup>

**Cause of artefact.** Water is pushed through the transducer dome in order to remove air from the catheter and tubing.

**Remedial action.** Check for good pressure transmission after the flush. Ignore the high pressure generated when analysing trace.

#### Line Open to Syringe

**Effect observed.** Repeated flushes of the line do not restore a good response to a cough signal.

**Cause of artefact.** The syringe inadvertently remains connected to the water line, and acts as a damper on the signal. Since an air bubble is not the problem, flushing fails to resolve it.

**Remedial action.** Set the taps correctly, so the syringe is not connected to dome. Repeat the cough test for good pressure transmission.

#### Empty Bladder (Poor Response)

**Effect observed.** Response of the intravesical catheter to a pressure transmission test is poor when bladder volume is low.

**Cause of artefact.** When the bladder is empty, the catheter may touch the bladder wall, so pressure changes within the lumen cannot be registered.

**Remedial action.** Fill the bladder slightly (e.g. 50 ml) and test the pressure transmission again.

#### Empty Rectal Catheter

**Effect observed.** Deterioration in abdominal pressure transmission, with or without a change in pressure, during filling or voiding.

**Cause of artefact.** Reduction of water in the rectal balloon. The balloon fails to connect effectively with the rectal wall as a result.

**Remedial action.** Refill balloon and test for good pressure transmission

#### Poor Cough Response

**Effect observed.** One cough spike is visibly smaller than the other, despite a cough affecting  $p_{ves}$  and  $p_{abd}$  equally.

**Cause of artefact.** Usually an air bubble in the water-filled line, reducing the transmission of pressure from patient to transducer.

**Remedial action.** Flush the line through with water, pushing the air bubble from the tube. The next cough should be registered equally on both traces. If not, flushing should be repeated.

#### Poor Response to Live Signal

**Effect.** Live signal is observed on one trace (in this case  $p_{ves}$ ) and on  $p_{det}$ , despite a previous cough test being satisfactory.

**Cause.** Usually an air bubble in the water-filled line, reducing the transmission of pressure from patient to transducer, in this case in the abdominal line. It could also be the pump or patient causing noise on the affected line.

**Remedy.** Check that there is no interference on the affected line by visual inspection and stopping the pump. If it is still present, flush the line through with water (not visible on this trace), pushing the air bubble from the tube.

#### CONCLUSIONS

Poor quality urodynamic testing may easily result in inadequate or wrong diagnosis. Maintaining good quality of pressure transmission, recording, and display, and being able to interpret the traces correctly are therefore critical for patient benefit. Recognising artefacts in the pressure signals and dealing with them appropriately is an essential component of maintaining this quality. By following the guidelines in this teaching module, good quality urodynamics can be more readily achieved.

# Self-Management of Indwelling Urinary Catheters

## February 2016

Mary H. Wilde, PhD, RN

Professor, School of Nursing, University of  
Rochester, USA

Member of the ICS Nurses' Committee

**ICS**

International Continence Society  
Teaching Module

## Objectives

- Our purpose is to educate continence nurses **to improve patient care and health outcomes globally.**

At the conclusion of this presentation, readers should be able to:

1. Examine **evidence in research** related to self-management in long-term urinary catheter users.
2. Describe **best practices for promoting self-management** in people using indwelling urinary catheters.
3. Use **theoretical concepts** related to catheter self-management.

**ICS** Teaching Module

## Indications for long-term catheter use

- Intractable urinary retention for those who cannot manage an intermittent catheter (and no caregiver to do it)
- Bladder outlet obstruction, not surgically treated
- Improving comfort for end-of-life care if needed
- Alternatives to consider: toileting schedule (when no retention), intermittent catheter, condom/sheath catheter (for cooperative males without obstructed urine or persistent retention )

(USA CDC guidelines, Gould et al. 2009)

## Long-term catheter use defined:

- Long term- over 1 months use but often extends over many years.
  - “Indefinite use” would be more accurate term, but no agreement on terminology.
- Both “catheter types” and “catheter use” for expected time of catheterization are called short and long-term, causing confusion. (Cottenden et al. 2013)

## Little research in urinary catheter self-management

- Self-management research is common in chronic conditions – **but not with people with catheters**
- LT catheter users **learn by trial and error**, lack support groups.
- Catheters are **stigma**; can indicate decline in health.
- People with catheters often **told to drink**, but not how much, nor how to manage.

NIH/NIH R01 NR01553 & R21 NR012753

ICS Teaching Module

## My research developed inductively-- most in talking with patients

- **7 previous studies with indwelling catheters**
  - Experience of using a catheter
  - Descriptive studies to identify catheter problems
  - How UTI, blockage, fluids, urine flow were related
  - What catheter users do to prevent/address problems
- **2 studies with intermittent catheter users, expanding theoretical framework to this population. (next power-point presentation)**

NIH/NIH R01 NR01553 & R21 NR012753

ICS Teaching Module

## Catheter management problems

- Prevent **CAUTI**
- Avoid **leakage** (bypassing of urine)
- Minimize **catheter blockage** (& frequent changes)
- Prevent **accidental dislodgment** (catheter falling out or being pulled out)

NSH/NSNR RD1 FRD1303 & R23 NR012763

 ICS Teaching Module

## Quality of life disruption with indwelling catheters

- **Daily routines** of catheter users and their families. “It’s ok when it’s working right.” (Wilde, 2002)
  - Background to foreground with a problem: “Psshtt. You’re really soaked. It ruins the day. It ruins whatever you’re drivin’ in.” (p. 10, Wilde, 2003)
  - Troubleshooting in evening and weekend hours, causes excess health care expenses.
- **Choice of SP or urethral**: sexual activity can be more positive with SP, but not always (Chappel et al., 2014)
- **Some developed self-reliance; others not so positive** (Fowler et al. 2014)

NSH/NSNR RD1 FRD1303

## Educational Booklet--Basic Catheter Self-Management--Fluids

- **Stay Aware.** stay aware of your body and how you feel.
- **Drink more water** than any other beverage! Limit caffeine.
- **Drink Consistently.** Optimal and consistent level all day to help prevent catheter blockage.
- **Your Body Needs Fluids.** Most people need 2000 to 3000 cc of fluid a day. For instance a 150 pound person would need 2045 cc which is equivalent to about 8½ glasses per day. More fluids are needed for hot weather or when exercising. My fluid goal is \_\_\_\_\_.
- **Pay attention** to the color of your urine. It should be light yellow all day long.

NH/PCNR R01 NR01553

 ICS Teaching Module

## Basic Catheter Self-management- Prevent dislodgement

- **Notice Changes** in what you feel.
- **Notice Catheter Position** when you move and teach others.
- **Check for kinks and twists** by feeling with your hand.
- **Ask for Help.**

NH/PCNR R01 NR01553

 ICS Teaching Module

## Tips from Catheter Users

**“Drink the water and go!”**

“I didn’t know amounts of intake and output.”

“I am paying attention to the color and quantity of the urine.”

“Now I drink more when I am out of the house.”

“I measure intake and caffeine and notice the color of urine, and sediment in the tubing. I am really being aware.”

“I check the position of the catheter when getting in and out of bed.”

“I think about how to best secure the catheter during activities

NE-PENK R01 NR03553

ICS Teaching Module **“If you don't feel right, act on it quickly!”**

## Quick Guide to Problems and Action Strategies

Problem	Action Strategies	See Page Number
Decreased/Inconsistent fluid intake	Increase fluid intake	7
UTI	Increase fluid intake	7
	Recognize early symptoms of UTI and acting on it	8
Catheter blocks	Increase fluid intake	7
	Promote catheter changes at best intervals	11
Adjustment to living with a catheter	Approaches for living with a catheter	9
Not sure of the best schedule for catheter changes	Promote catheter changes at best intervals	11
Kinks, twists, or tugs on catheter	Prevent kinks, twists, or tugs on catheter	13
Too much caffeine	Decrease caffeine	14
Catheter leaks	Decrease catheter leakage	15
	Empty urine bag	16
Urine bag odor	Clean urine drainage bag	17
Changes with sex	Make adjustments for sexual activity	18
Autonomic Dysreflexia (for people with spinal cord injury)	Recognize early symptoms of Autonomic Dysreflexia	19

NE-PENK R01 NR03553

ICS Teaching Module

## Increase fluid intake

- "I am more conscious of what I drink. I am adamant about drinking 6 glasses of water."
- Low fluid intake might be associated with blockage and urinary tract infection (UTI).

Paying Attention	Things You Can Do
Notice whether you are getting enough fluids throughout the day.	Drink 2000-3000 cc. fluids per day. If you like the water cold, keep several bottles in the fridge and refill them everyday. To add flavor to water, try 2 oz of cranberry or apple juice to 8-10oz of water. Keep glasses of water scattered in the house. Secure a jug of water to your wheelchair. You may want to drink around meal times and before bed. Have a caregiver remind you to drink water.
Notice changes in color or odor of urine.	If color gets dark or urine has foul smell, increase water.
If you are on fluid restriction, make sure that you stay within the restricted range.	Record occasionally to check that you are staying within range.
Be aware of changes in activities, such as stress and illness, I & O.	Use a journal to increase awareness of how activity affects fluid intake.

ICS Teaching Module

## Symptoms CAUTI--long term catheters

### Urine Changes:

- Color – Discolored, cloudy, dark, blood stained
- Odor – Foul smelling, change in smell from usual
- Sediment (grit) – Increased amount

**Temperature** – Fever, chills

**Pain and/or pressure** in bladder area or back (Burning possible, not common)

**Autonomic dysreflexia** Early, mild symptoms of autonomic dysreflexia (e.g., goosebumps, headaches, sweats) mainly in people with spinal cord injury.

(See next slide for details.)

**General Symptoms** Blahs!, feeling sick

- Functioning or mental changes – weakness, spasticity, change in the level of alertness (Wilde, McDonald et al., 2013)

ICS Teaching Module

## Autonomic dysreflexia (AD)

- AD is a syndrome related to a reflex of imbalanced discharges at the level of the spinal cord injury above or at Thoracic 6.
- It can lead to **severe high blood pressure and a life threatening situation if not addressed quickly.**
- It is most often caused by a blocked or poorly functioning catheter or an overly full bag.
- Constipation or pressure ulcers can also cause AD.

ICS Teaching Module

## Results

- CAUTI and dislodgement outcomes did not differ by group.
- Blockage was significantly lower in the intervention group, but the result did not last the full 12 months.
- Rates showed both groups improved.
- The intervention group had more ED visits & hospitalizations for CAUTI and also higher self-reported CAUTI severity scores. Not powered for ED events. (Wilde, McMahon, et al. 2015)

NH & NHNR RD1 NPO1553

ICS Teaching Module

## Conclusion

- Both groups improved over time--Self-monitoring r/t calendar (unintentional intervention).
- Unclear whether decreases in UTI, blockage, and dislodgement rates were related to the intervention.
- Symptom identification, severity of UTIs, & getting care early could be r/t higher hospitalization for CAUTI in the intervention group.

NIH/ONR R01 NR01553

25

## Implications

- Recommend additional nurse support over time to sustain intervention.
- Value in optimal/consistent fluid intake.
- Catheter calendar, a minimal intervention, could be easily implemented.
- Dissemination for education and research (indwelling and intermittent catheter studies). Contract with University of Rochester email Mary Wilde:  
mary\_wilde@urmc.rochester.edu

NIH/ONR R01 NR01553

<sup>2</sup>Visiting Nurse Service of New York, Center for Home Care Policy and Research

### Abstract

**Aims**—The aims were to characterize a sample of 202 adult community-living long-term indwelling urinary catheter users, to describe self-care practices and catheter problems, and to explore relationships among demographics, catheter practices, and problems.

**Background**—Long-term urinary catheter users have not been well studied, and persons using the device indefinitely for persistent urinary retention are likely to have different patterns of catheter practices and problems.

**Design**—The study was a cross-sectional descriptive and exploratory analysis.

**Methods**—Home interviews were conducted with catheter users who provided information by self-reported recall over the previous two months. Data were analyzed by descriptive statistics and tests of association between demographics, catheter practices, and catheter problems.

**Results**—The sample was widely diverse in age (19–96 years), race, and medical diagnosis. Urethral catheters were used slightly more often (56%) than suprapubic (44%), for a mean of 6 yrs. (SD 7 yrs.). Many persons were highly disabled, with 60% having difficulty in bathing, dressing, toileting, and getting out of the bed; 19% also required assistance in eating. A high percentage of catheter problems were reported with: 43% experiencing leakage (bypassing of urine), 31% having had a urinary tract infection, 24% blockage of the catheter, 23% catheter-associated pain, and 12% accidental dislodgment of the catheter. Treatments of catheter-related problems contributed to additional health care utilization including extra nurse or clinic visits, trips to the emergency department, or hospitalization. Symptoms of catheter associated urinary tract infections were most often related to changes in the color or character of urine or generalized symptoms.

**Conclusions**—Catheter related problems contribute to excess morbidity and health care utilization and costs.

**Relevance to clinical practice**—More research is needed in how to minimize catheter associated problems in long-term catheter users. Information from this study could help inform the development of interventions in this population.

## Keywords

urinary catheterization; nursing; urinary tract infection; urinary retention; complications; self-care

## Introduction and Background

Living with an indwelling urinary catheter presents numerous challenges that must be addressed on a daily bases. Nevertheless, it can be indicated for persons unable to use any other bladder management method, including people with persistent urinary retention who lack sufficient cognition or hand dexterity for self-catheterizations and no one to do it for them. Also a catheter can be an option to improve quality of life in selected cases of severe incontinence or when a disability makes it difficult to use the bathroom (Cottenden et al., 2009). The majority of long-term catheter users have a neurogenic bladder dysfunction related to a disability, such as spinal cord injury (SCI) or multiple sclerosis (MS) (Wilde & Dougherty 2006, Wilde et al. 2010). While catheter problems are well known—recurrent and persistent blockage, catheter-related urinary tract infection (CAUTI), accidental dislodgment, and leakage of urine (bypassing)—data on the frequency and severity of these problems are limited. Information on catheter management, such as drainage bag replacement and/or cleaning and caregiver assistance, is even less well known. Moreover, community dwelling study samples are often small (<45) in persons with long-term use, (Wilde & Carrigan 2003, Wilde & Dougherty 2006, Wilde & Brasch 2008, Wilde et al. 2010), thus making it difficult to characterize the population and their needs.

This is a report of a cross-sectional analysis of data from 202 persons with long-term indwelling urinary catheters (urethral or suprapubic [SP]). The purpose of this analysis is to describe catheter care practices and catheter-related problems to inform clinicians and researchers. Having information from a large sample will help fill a gap in the literature in which small samples have been the norm.

## Methods

### Design

This analysis is based on baseline data collected for a single blinded randomized trial of an educational program in urinary catheter self-management with long-term catheter users. This analysis is based on data derived through a one-time home interview of 202 study participants, prior to randomization, conducted by trained interviewers from June 2009 through June 2011. The aims of this analysis were to:

1. Characterize the sample of 202 community-dwelling long-term adult indwelling urinary catheter users who had catheter problems in the past 6–12 months or those new to a catheter within the past year.
2. Depict how persons with catheters take care of the device on a day to day basis, including others who help in this care.
3. Describe the prevalence and incidence of self-reported catheter-related problems over a two month period.
4. Explore relationships among demographics, catheter practices, and catheter problems

**Setting and sample**—The study was conducted at two sites—the University of Rochester, NY (Utica to Buffalo region) and at the Visiting Nurse Service of New York (VNSNY) in New York City and parts of Nassau and Westchester Counties —with separate

*J Clin Nurs.* Author manuscript; available in PMC 2014 February 06.

teams conducting the study activities using the same procedures and tools. To be eligible for the study, participants had to: (1) be 18 years of age or older; (2) expect to use an indwelling urethral or SP catheter for at least one year; (3) report having a catheter-associated problem (UTI in the last year, or blockage or dislodgement in the last six months) OR report using a catheter for less than one year (4) complete study measurements alone or with the help of a family member; and (5) communicate in English. Despite the need in the parent study to include only persons who would benefit the most from the intervention, only 3.6% of those screened were excluded for criteria #3 above. Individuals were excluded if they had a terminal illness. Institutional approval was obtained and synchronized for human subject's ethics at both sites.

### Data Collection

**Measures**—Two instruments were used for this cross sectional analysis: 1) *Demographics and Catheter Care Questionnaire (DMC)* and 2) *Catheter Problems Questionnaire (CPQ)*. Both instruments were developed by the Principal Investigator (PI) for research in similar populations (Wilde & Dougherty 2006, Wilde & Brasch 2008) and modified for this study. For the *DMC*, 50 items measured demographics and catheter-related variables to describe the sample, and included: 1) person/family--age, race/ethnicity, type/presence of caregivers (e.g., relative or paid person), education, employment, insurance; 2) chronic conditions--diagnosis, list of medications, and functional ability through the Katz score (Katz, Ford, Moskowitz, Jackson, & Jaffee 1963) and 3) catheter related-- catheter type (e.g., silicone or latex coated), interval for catheter changes, and bag care. The content validity scores were found to be acceptable in previous studies using the same instrument (Wilde & Dougherty 2006, Wilde & Brasch 2008).

Catheter related problems (e.g., UTI, blockage [encrustation within the catheter]) were measured using the *CPQ*. Content validity scores for a previous study (Wilde & Brasch 2008) indicated that the items were acceptable. *CPQ* was modified to include additional information related to CAUTIs, i.e., severity and symptoms. Frequency of catheter related problems was asked, and for CAUTI and blockage of the catheter, associated treatments were solicited. Information was recorded for up to six CAUTI events and up to 12 blockage events (as blockages were sometimes frequent).

**Procedures**—Study participants at the Rochester site were recruited through provider referral from clinics, home care agencies and private urological offices. In New York City, a database was used to identify people with catheters. Potential participants at both sites were screened for eligibility and interest by telephone call. At intake, participants provided informed consent, and subsequent to enrollment—but prior to random assignment-- home interviews were conducted. An electronic data collection system, Questionnaire Development System (QDS), was used to collect and manage data. Participants received an honorarium of \$20 for the interview.

### Data Analysis

Prior to analysis, data were verified, cleaned and checked for consistency with a full range of logic checks. Decisions about how to code missing data and outliers (Yang, Xie, & Ngee Goh 2011) were made by the team, with input from the statistician. Data were analyzed descriptively for central tendency (mean, median), dispersion (SD, range), and distribution (skew, kurtosis). Specific emphasis was on describing prevalence and incidence of major catheter problems of CAUTI, blockage, and dislodgment of the catheter. Associations were explored (*t*-tests or Pearsons' *r* for interval level data and Chi Sq. or odds ratios and confidence intervals (CI) for categorical data) among variables believed to contribute to

these catheter-related problems. Analyses were performed using IBM Statistical Program for Social Sciences (SPSS) 19 and SAS 9.2.

## Results

### Demographics

The sample was diverse by age, race, and medical diagnosis. The male to female ratio was roughly equivalent at 51 and 49% respectively. Ages ranged from 19 to 96 with a mean and median age of 61, SD of 17.4 years. The race identified most often by participants was white (57%), followed by Black (30%), Asian (2%), American Indian or Alaskan Native (2%), biracial (2%), and unknown (9%). Eleven percent of the sample was Hispanic. Diversity was also demonstrated by the marital status selections, with approximately 34% of participants reporting never having been married, over 19% separated or divorced, 18% widowed, 27% married and 2% common law married or living with a life partner. A single diagnosis believed to affect bladder function was identified for each person and we labeled them as “primary” in Table 1, categorizing by the order in the table. Many persons had other diagnoses affecting the bladder, and these were labeled “secondary.” Spinal cord injury (SCI) and multiple sclerosis (MS) were the most common medical diagnoses, with 40% and 23% respectively.

Medications included 26 different classes, and many persons took more than one medicine in a single category, for instance heart medicine was taken by 44%, but of these patients over half took more than one cardiac medicine. Eleven percent were on antibiotics and 4% on urinary antiseptics. Other bladder medicines included: anticholinergics (20%), antispasmodic/ antimuscarinics (3%), alpha blocker (5%), and muscle relaxants (39%). Frequent medicines were for MS (13%), anticonvulsants (30%), upper gastrointestinal ([GI] 33%), laxatives (34%), psychological/depression (44%), diuretics (24%), diabetes (17%), hypertension (25%), respiratory (19%). Pain medicine was taken by many, including NSAIDs/aspirin (38%), Tylenol (26%), and narcotics (34%). Smaller numbers took medicine for cancer (8%), sleep (5%), or steroids (5%). Eighty-four percent reported taking at least one vitamin or mineral, most typically a multivitamin, calcium or vitamin D.

The majority of participants lived with another person, generally family (55%); only 8% lived with paid caregivers, and 37% lived alone. Employment rates were minimal with only 11 persons working, six of them full time. Most individuals had some type of public insurance and 48% reported having private insurance. Education levels of the subjects varied greatly with 16% not completing high school, 27% with high school or GED, 19% with some college, and 38% with a college degree, including 12% with a graduate degree.

Activities of daily living (ADL)--in bathing, dressing, toileting, getting out of bed, and eating---were evaluated by the Katz scale, with item responses calculated as 1 point for independent and 2 points for needs assistance. The range was 5–10 for the total scale, with a higher score indicating less functional ability; the mean was 7.75 (SD1.9) and mode was 9. Twenty-four percent reported that they were independent in all activities, 24% needed assistance with 1–3 ADLs, 35% needed assistance with 4 ADLs and 17% needed help with all 5 ADLs.

### Catheter Care Practices

**Catheter characteristics**—The length of time of catheter use varied considerably from 1 to 470 months (39 yrs.). The mean was 72.5 months or 6 yrs. (SD 85.4months, 7yrs.). Median use was 3.25 yrs. Urethral catheters were used more often than SP, with 112 (56%) and 89(44%), respectively; one person had both types (Table 2). Fifty-eight of those with SP

had used urethral catheters in the past; whereas, only two currently using a urethral catheter had tried a SP catheter. In the past, 35% had used an intermittent catheter, 16% an external condom catheter, 29% had used Crede, and 83% had used absorbent products.

Catheter sizes and the amount of water in the balloon varied. Catheter sizes ranged from 12–30 Fr. with a mean of 18.5 (SD 3.2), and in general urethral catheters were significantly smaller (mean 17.1 Fr., SD2.1) than SP catheters (mean 20Fr., SD 3.5;  $t$  test  $-7.29$ ;  $df$  182;  $P < 0.01$ ). Balloon size varied from 5–30 mL with 70% being 5–10mL; the water within the balloon was reported as 2–50mL, with the majority (55%) using 5–10mL. Some people (8%) did not know the size of the catheter and 23% did not know the balloon size or amount of water instilled. (See Table 2 for details.)

**Drainage bag use**—Most persons (58%) used both leg and overnight (night) bags, switching between them. Some individuals used just one type, with leg bags used alone by 17% and night bags used alone by 23%. Three persons used other collection methods: one a belly bag, one connected tubing to empty the bladder directly from the catheter, and another used a plastic cover over the end and emptied the catheter (without a clamp). Only four persons (2%) used a leg bag continuously, connecting it to the night bag later in the day. The majority switched between leg and night bag, and most also cleaned them (leg bags by 54% and night bags by 59%). Solutions for cleaning bags and the frequency for replacing and cleaning the bags are in Table 3.

**Catheter changes**—Catheter changes were performed by professionals (nurses, physicians) in homes, clinics and offices (Table 4). Unscheduled changes were reported in the previous two months by 37% ( $n=74$ ), with 3 who said this occurred weekly, 15 said several times a month, 12 monthly, and 43 once in two months. Catheter users changed it themselves 8% ( $n=16$ ) of the time for routine changes and 10% ( $n=20$ ) for unscheduled; likewise spouses/family members did so 8% ( $n=14$ ) of the time for routine changes and 10% ( $n=19$ ) for unscheduled. For regularly scheduled changes, out of 12 males who did this, 2 changed urethral and 10 SP; out of 4 females, all changed urethral catheters. For unscheduled changes, out of 14 males who changed their own catheter, 2 had urethral and 12 had SP; out of 6 females, five had urethral catheters, and one had SP. Physicians or home attendants also changed or assisted with catheter changes, for routine changes for 4 persons and unscheduled for 9. Noteworthy is that in the previous two months, 3.5% had used the emergency department (ED) for routine changes, and 31% among those who reported unscheduled changes. Significant differences were found for routine changes in the ED by study sites, with 6 in the NYC site and 1 in Rochester (Chi Sq. 7.0;  $df=1$ ;  $P=.008$ .) However, the unscheduled changes in the ED were not significantly different, with 52 in NYC and 11 in Rochester. (Chi Sq. 2.6;  $df=1$ ;  $P=.106$ .)

**Catheter irrigations**—Irrigating the catheter, which is not a recommended practice (Cottenden et al. 2009, Gould et al. 2009), was done by 42%. Of those who irrigated, 18% did so daily or more often, 13% did it one or more times a week, 43% did it one or more times a month, and 25% once in two months, and persons who irrigated daily were more likely to have had blockage (Chi-Sq. 13.50,  $df=1$ ,  $P=.019$ ). Preventive irrigations were done by 37%, for urine flow problems by 34%, and both preventively and for problems by 39%. Those who irrigated for prevention and problems were more likely to also have had blockage, (Chi-Sq. 13.57,  $df=1$ ,  $P=.001$ ). Solutions for irrigation included: saline 76%, sterile water 23%, tap water 9%, and Renacidin™ (an acidic solution for instillation) 4%. Irrigating the catheter was significantly related to blockage (Chi-Sq. 15.94,  $df=1$ ,  $P < .001$ ) but the pattern of irrigation and blockage vs. CAUTI varied by the individual. Out of 83 who irrigated, 14 had both blockage and CAUTI, 17 had only blockage, 18 had only CAUTI, 32 had no blockage or CAUTI, and 2 did not know.

## Catheter Problems

Prevalence and incidence of self-reported catheter related problems for the previous two months are described in Table 5, including means, SDs, and rates per 1000 catheter use days for CAUTI, blockage, and dislodgement. CAUTI was defined as a urinary infection treated with an antibiotic. Self-reported prevalence of CAUTI was 31% (63/202). In 63 persons, there were 75 episodes reported, with 54 persons having 1 event, seven having 2, one having 3 and one having 4. Blockage in the previous two months was reported by 48 persons (24% prevalence) and frequency of the event was reported by 47 of 48 persons: from 1–2 times in 31 persons, 3–4 times in 9, 7–9 times in 4, and 20 or more times in 3. Frequencies and other details are reported in Table 5 of leakage (bypassing), sediment, kinks/twists, bladder spasms, and autonomic dysreflexia (AD), a painful syndrome caused by injury to central nerves.

### Relationships among demographics, catheter practices, and complications—

No significant associations were found related to CAUTI in the past two months (Yes/No) for catheter size, type of catheter (urethral or SP), leakage, kinks/twists or dislodgement of the catheter. Younger persons were more likely to have reported CAUTI, with a mean age of 57.5 years (SD 16.3) as compared with 63 years (SD 17.6) for those who did not ( $t$  test= 2.11,  $df$  199,  $P$ = .0036) and to have used the catheter for a longer period of time (Pearson's  $r$ = -.157,  $P$ = 0.026). Catheter size and length of time using a catheter were not significantly correlated with the number of CAUTIs.

All chi-square tests of associations were not significant for CAUTI or blockage (Yes/No) for catheter management issues related to caregivers who assist with catheter care (e.g., spouse, family, paid helpers); frequency of bag changes (night and/or leg bag); or cleaning the bag.

Blockage was significantly related to CAUTI, with the odds of having a CAUTI were 2.29 times as great (95% CI= 1.17, 4.48) among those with blockages compared with those reporting no blockages. Out of 47 persons reporting frequency of blockage at least once in two months, 22 had at least one UTI (46%); in contrast, out of 152 persons with no blockage, 41 reported UTI (27%).

**Treatments—**Treatments associated with excess healthcare utilization for UTI or blockage, such as extra nurse home visits or hospital visits, are listed in Table 6. All persons reporting UTI had associated treatments, 96% of those with blockage had excess treatments, and only one person out of 88 with either UTI or blockage had no excess treatments. Some treatments required additional family or patient time or use of extra supplies. For example, in those with blockage, the catheter position was adjusted by 19% in relation to blockages, and irrigation was done for blockages by 49%. Doubtless some of the irrigations also were done by the catheter users or caregivers in the home, not nurses. In the previous two months, 17 study participants reported they were hospitalized for UTI for a total of 165 days. The mean number of days hospitalized was 9.71 (SD 7.41), and if including all of those who had UTI but were not hospitalized, the mean days per hospitalization was 2.62 (SD 5.75).

**Symptoms of UTI—**Questions of frequency and severity of UTI symptoms were asked. Symptoms associated with 75 episodes of UTI were asked, with yes or no to each symptom (Table 7). The most frequent symptoms were related to a change in the color (#1) or character of the urine (odor #2; sediment #5). Generalized symptoms also were reported often (malaise #3, bladder spasm #4). Severity of UTI symptoms were reported also for 74 events in two months. On a scale of 1–10 with 1 being very mild and 10 being the most severe UTI you can imagine, a score of 1–4 was reported 22% of the time, a score of 5–7 was reported 43% of the time, and a score of 8–10 was reported 35% of the time.

*J Clin Nurs.* Author manuscript; available in PMC 2014 February 06.

**Leaking/sediment**—Of the 86 persons (43%) who reported leaking (bypassing of urine), 8% indicated it was not a problem, 31% a small problem, 29% a moderate problem, and 32% a large problem. Sediment was noticed by 127 (63%), of these 41% saying it was a small amount (hardly noticeable); 34% a moderate amount (can be seen in tubing and bag if looking for it); and 25% a large amount (very easy to see in tubing and bag. In the previous two months, presence of sediment was associated with blockage (Chi-Sq. 13.93, df=1,  $P < .001$ ) but not CAUTI (Chi-Sq. .48, df=1,  $P=0.49$ ).

**Pain**—Catheter related pain was reported by almost a quarter of the sample ( $n=46$ , 23%), and of those with catheter pain it was attributed to positioning (e.g., sitting on it) by 46%, bladder spasms 46%, some catheter changes 30%, and every catheter change 26%. Fifteen percent said that the pain bothered them very little, 46% said somewhat, and 39% said a great deal. Three percent ( $n=6$ ) said they have catheter pain all the time. In addition, AD can be painful, and this was experienced by 41 persons (20%) at some time, most within the past two months (Table 5). Primarily those with AD had SCI (38 of 41).

**Difficult insertions/removals**—Twenty-four individuals (12%) reported having difficulty with the insertion of their catheter in the previous 2 month and 11 (5%) persons had difficulty during removal. While 31 of 35 people said this difficulty had occurred just once or twice in the past two months (mean 1.7, SD 1.1), four persons had experienced it between 3 and 6 times. For those reporting any difficulty, the level of difficulty for the most difficult insertion or removal experienced (defined as difficult or challenging for the patient) was assessed with a visual analogue scale from 1–10, with 1 being just a little more difficult than usual and 10 being a very challenging situation. The difficulty mean score was 6.9 (SD 3.0), and more than half (54%) were rated from 8–10.

When asked if the catheter interfered with daily life, 29% said not at all, 26% said very little, 29% said somewhat and 16% said it interfered a great deal. However, in further analyses, the catheter significantly interfered “a great deal” in persons with blockage (14 of 31; Chi Sq. 9.53, df 3,  $P=0.023$ ) and those with difficult catheter changes (11 of 32; Chi Sq. 8.65, df 3,  $P=0.034$ ).

## Discussion

Although the majority of the persons enrolled in this study were recruited from a home care agency in New York City (75%), the sample is believed to be a good representation of this population because recruitment also took place through clinics and private offices in the Rochester site. Only 3.6% of the persons recruited were not eligible because of not having any major catheter problems, which is consistent with another study in this population in which not one of the 43 persons were problem free during the eight months’ study (Wilde et al. 2010). The sample was older than in some previous studies, with a mean of 61 yrs. as compared with a mean of 49yrs. in two recent studies (Wilde et al. 2010, Wilde & Brasch 2008) with similar populations that had more persons with SCI. The current sample, with a total of 87% recruited through home care agencies, may reflect a more vulnerable population than in earlier studies. Multiple secondary diagnoses and co-morbidities were reported as well as a wide range of medications. Often large studies with catheter users involve retrospective chart audits related to a single medical diagnosis, most often SCI, aimed at finding out about urinary health or catheter management strategies over time (Cameron et al. 2010, El-Masri, Chong, Kyriakider, & Wang 2011).

### Catheter Practices and Care

This is the first known large study (N=202) providing great detail on catheter management practices and problems. Many people lacked knowledge about their catheters, such as the balloon size (47persons/23%) and a few gave us information that was questionable for accuracy, such as catheter sizes of 15 and 17Fr, which are not known to exist. Also, 34% said the catheter was all latex; it is possible that some did not know it might have a Teflon™ coating, as this is a commonly used coating over latex and only one person indicated this type. It was of concern that 29 persons said the balloon was size 30 mL since this is only recommended for postoperative bleeding. The 8 persons who said their 30mL balloons were inflated part way might also be mistaken, but if they were correct, inflating between 16–29 mL could contribute to asymmetry of the balloon and possible erosion into the bladder mucosal lining (Cottenden et al. 2009). Patients and their caregivers need to know more about the proper size of catheters and balloons so that the sizes can be decreased if increased for a specific reason, such as bleeding.

It was not surprising that most people received help with managing their catheters (Table 2), given the large number of people with neurological disorders and the high mean Katz score of 7.8, which indicates a high level of disability. The level of disability is similar to the score of 7.6 (Wilde & Dougherty 2006) cited in a study of 30 catheter users, and in another study with 43 individuals, 44% required assistance from another to dress the upper body, and 91% were in wheelchairs (Wilde et al. 2010).

**Drainage bag replacement and cleaning**—There was much variation in how often the drainage bag was replaced by a brand new one and/or cleaned, but the reason for the frequency was not asked. Logically, the percentage of persons cleaning the leg bag increased as the number of days between replacements extended. However, some people replaced the bag infrequently (e.g., within 22–30 days or >30 days) and not all cleaned the bag between replacements (Table 3). It was unanticipated that so few used a bleach solution to clean since it is the only product recommended for cleaning drainage bags (Gould et al. 2009); however, bleach is caustic and it can damage clothing and irritate the skin or eyes. Nor was vinegar used much, and this had been the standard in home settings in the past (Wilde 1986, Wilde 1991). A lack of research in this area, as well as whether supplies are reimbursed, puts catheter users in a position to make their own decisions about cleaning and reuse of bags. Somewhat surprising was that only 2% indicated they kept the leg bag attached all the time, adding a night bag to it for continuous evening drainage. This practice is recommended at the VNSNY and it is commonly recommended in the United Kingdom due to a belief that this keeps the catheter less disturbed and more of a closed system. (Jones, Brooks, Foxley, & Dunkin 2007, Royal College of Nurses (England 2008). In contrast to our sample, in the U.K., leg and night bags are routinely changed every seven days or more often if needed, i.e., appear dirty or have an odor. (Personal communication, M. Fader, August 2011).

**Catheter changes**—This is the first time detailed information about who changes catheters was reported and that catheter users and family members sometimes changed it (Table 4). People in home settings with chronic illnesses often manage complex technology, even as complicated as total parenteral nutrition. Yet catheter changes are not always simple, particularly in men. However, significantly more males routinely changed their catheters more often than females, and SP catheters were significantly more often changed than urethral for unplanned changes. Providing careful teaching for those changing their own catheters is essential to prevent traumatic insertions, especially when taking into consideration the proportion of people who experienced difficult insertions (12%) and removals (5%). Home care nurses changed the great majority of catheters, understandably

since the majority of the sample came through home care agencies. Thus, it was particularly surprising that unscheduled changes were often done in the emergency department (31% of the time) and more often in NYC than in the Rochester site. Also ED visits for routine changes (3.5%) contribute to substantial costs that could be reduced through planning and use of home care agencies. The homebound restrictions in Medicare might have contributed to this as people who are able to get out, hold a job, etc. are not eligible for home care services under Medicare. Further research in reasons for catheter related ED use is warranted.

### Catheter Problems

Even though this is a selected group of patients who experienced catheter related problems in the past year or were relatively new to catheter use, this analysis related to data from a two month period confirms the widespread prevalence of catheter related problems. The current report on nine catheter related problems, frequency of occurrence, and their associated professional treatments is the first with this level of detail. In just two months prior to study enrollment, 31% reported having had a CAUTI, blockage of the catheter was reported by 24%, dislodgement by 12%, leakage by 43%, and pain by 23%. Though the rates of CAUTI was 6.2/1000 catheter days (95% CI= 4.8, 7.6), lower than the 8.4/1000 days reported in a study of 43 long-term catheter users over a six month period (Wilde et al. 2010), it is much higher than the rate of 1.7/1000 days reported through a home care benchmarking project which includes short and long-term catheter users (MAHC 2011). In comparison with other research, (Maki & Tambyah 2001, Wilde et al. 2010) catheter size and gender were not associated with CAUTI.

The rates for blockage and dislodgment are the first known to be published. This report affirms the relationship of blockage and CAUTI reported in previous samples of 24 (Wilde & Carrigan 2003) and 30 (Wilde & Dougherty 2006). Research is needed to explicate the relationship between CAUTI and blockage, such as bladder mucosal bleeding from distension related to poor urine flow (Pearman 1984) or bladder stones.

**Symptoms of CAUTI**—In a recent report of a study in 43 community dwelling adults, the most frequently reported symptoms of CAUTI were urinary sediment, foul odor, general malaise and changes in the color of the urine. (Wilde et al. 2010) In three other studies, foul urine odor was a common symptom (Wilde 1986, Wilde & Dougherty 2006, Wilde & Brasch 2008) though other symptoms varied. These symptoms were confirmed in the current study with the top five being: changes in urine color and odor, malaise, weakness, and sediment. While there are individual differences, this population did not report as often the typical symptoms of UTI in the general public (i.e., burning, urgency, and fever). Of concern, in a study of patients with intermittent urinary catheters, accuracy in predicting UTIs based on their symptoms was not well validated (Massa, 2009). Although cloudy urine was the most accurately reported symptom of UTI, the researchers concluded that most patients were better at identifying when they did not have a UTI, rather than when it was present. This study underlines the need for further symptom research in long-term catheterized patients. Without better knowledge in this area, it is not known whether symptom awareness alone can prevent episodes of symptomatic CAUTI. Thus for patients to seek early treatment, they must know what symptoms to watch for and in particular which ones are their own valid symptoms. This could benefit their health and reduce excess healthcare utilization, especially if ED visits and/or hospitalization can be avoided.

### Limitations

All data are self-reported, and thus we expect some errors. Also there were limitations in sampling because the majority was recruited through one large home care agency and there

*J Clin Nurs.* Author manuscript; available in PMC 2014 February 06.

were differences in recruitment processes (referral versus database). Persons more bothered by catheter problems might have been more willing to join the study, contributing to selection bias. Some information from study participants might have been inaccurate, for instance catheter sizes of 15 and 17Fr. described above. However, we have confidence in the accuracy of our self-reported data. In a comparison of self-report to chart accuracy in a small sample of a similar population of catheter related problems, congruence was reported as 97% (Wilde et al. 2010).

## Conclusion and Relevance to Clinical Practice

This report characterizes a diverse sample of the population of long-term indwelling urinary catheter users in a way not reported before, providing detailed information about demographics, catheter care practices, and numerous catheter related problems and associated healthcare utilization. The widespread report of catheter problems is of concern because the timeframe was just two months, this population is likely to need an indwelling catheter indefinitely, and many of these problems negatively impact personal health and associated healthcare expenditures. Gaps in research include optimal frequency for replacement and methods of cleaning urinary drainage bags, increasing the predictive value of CAUTI symptoms, decreasing excess ED use (especially for catheter changes), and best practices for educating caregivers (family and paid carers). To better portray this vulnerable population, prospective longitudinal research is needed with long-term catheter users having a range of diagnoses. Also, for surveillance, CAUTI rates for short and long-term users should be distinguished.

Implications for practice involve providing complete information about the catheter to those who use the device, using the appropriate catheter balloon size and water inflation, and consideration of criteria for teaching catheter changes to patients and caregivers. Moreover, since disability levels can change over time, such as in those with MS, monitoring catheter self-care capability over time could proactively identify people whose caregivers need to learn more about catheter management.

Many of the catheter-related problems reported in this study could be prevented or minimized with more attention to catheter management, early identification of problems, and more evidence-based catheter practices. Therefore, information from this study is critical to researchers who wish to plan interventions to address the persistent catheter related problems that affect large proportions of long-term indwelling urinary catheter users.

## Acknowledgments

We wish to thank persons who assisted in this study with: data collection, Yessica Terrero, Christopher Clinton, Laura Edlitz, JoAnn Moda, Manny Schwimmer, Paula Wilson, and Maria Viterbo-Verna; information technology, Brian Harrington, Michael Fisher, Annette Curtis, Sridevi Sridharan, Timothy Peng, Richard Dumpson; nursing consultation, Paula Wilson, Seon Lewis-Holman, Yanick Martelly; medical consultation, Bob Mayer; data and safety monitoring, Susan Fisher, Christopher Murtaugh; and administrative guidance Penny H. Feldman, Pamela Sawdey.

Funding for this study was through the United States National Institute of Nursing Research, National Institutes of Health #R01 NR0155.

**Abstract**

**Background**—People using long-term indwelling urinary catheters experience multiple recurrent catheter problems. Self-management approaches are needed to avoid catheter-related problems.

**Objectives**—The aim was to determine effectiveness of a self-management intervention in prevention of adverse outcomes (catheter-related urinary tract infection, blockage, and accidental dislodgement). Healthcare treatment associated with the adverse outcomes and catheter-related quality of life was also studied.

**Method**—A randomized clinical trial was conducted. The intervention involved learning catheter-related self-monitoring and self-management skills during home visits by a study nurse (twice during the first month and at four months—with a phone call at two months). The control group received usual care. Data were collected during an initial face-to-face home interview followed by bimonthly phone interviews. A total of 202 adult long-term urinary catheter users participated. Participants were randomized to treatment or control groups following collection of baseline data. Generalized estimating equations (GEE) were used for the analysis of treatment effect.

**Results**—In the intervention group, there was a significant decrease in reported blockage in the first six months ( $p = .02$ ), but the effect did not persist. There were no significant effects for catheter-related urinary tract infection or dislodgment. Comparison of baseline rates of adverse outcomes with subsequent periods suggested that both groups improved over 12 months.

**Discussion**—A simple-to-use catheter problems calendar and the bimonthly interviews might have functioned as a modest self-monitoring intervention for persons in the control group. A simplified intervention using a self-monitoring calendar is suggested—with optimal and consistent fluid intake likely to add value.

**Keywords**

---

Indwelling urethral or suprapubic catheters are used by individuals with chronic urinary retention who are unable to perform intermittent-catheterization because of poor hand dexterity, no caregiver assistance, difficulty in using the bathroom, or in select cases of incontinence. While many catheter users have spinal cord injury (SCI) or multiple sclerosis (MS), the population also includes those with other neurological disorders, diabetes, or disease/injury to the bladder region. Unfortunately, indwelling urinary catheters are seldom trouble free (Cottenden et al., 2013; Wilde, McDonald et al., 2013). Data collected in a longitudinal study of 43 long-term catheter users indicated that recurrent problems affect the great majority. Prevalence rates during eight months of catheter use were 70% for catheter-associated urinary tract infection (CAUTI) with a rate of 8.4/1000 catheter days; 74% for

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

blockage; and 33% for catheter expulsion or dislodgement (Wilde, et al., 2010). For a two-month period prior to the beginning of this randomized clinical trial (RCT), catheter problems were reported as: 31% for CAUTI, 24% blockage, and 12% dislodgment (Wilde, McDonald et al., 2013).

These complications are distressing to patients/families (Wilde & Cameron, 2003; Wilde, 2003) and contribute to increased healthcare expenses, such as additional clinic, home care, or emergency department visits or hospitalization (Wilde, McDonald et al., 2013).

Interventions to address prevention of CAUTI in long-term catheter users such as the use of silver coated or antimicrobial coatings on the catheter (Parker et al., 2009) installations to the drainage bag (Thompson et al., 1984), or special cleaning of the urinary meatus (Burke, Jacobson, Garibaldi, Conti, & Alling, 1983) have not been successful. Although research in self-management of chronic conditions in diabetes (Coyle, Francis, & Chapman, 2013), stroke (Lennon, McKenna, & Jones, 2013), and asthma (van Gaalen et al., 2013) has grown, no self-management clinical trials have been found in catheter users (Cottenden et al., 2013; Niël-Weise, van den Broek, Peterhans, da Silva, & Silva, 2012).

The research clinical trial (RCT) for the current report was developed inductively through six previous studies conducted primarily by the first author (MHW). These studies included research with 30 individuals who kept a urinary diary and were interviewed twice to determine what their self-care practices were (Wilde & Dougherty, 2006). A concept analysis was next conducted of self-monitoring, delineating key attributes and how it fit within self-management literature (Wilde & Garvin, 2007). Then a pilot study teaching self-monitoring of urine flow in long-term catheter users was conducted. The results of the pilot study indicated that optimal fluid intake and preventing dislodgment were the most useful self-management components reported by study participants. Importantly, CAUTI decreased in the six months during the single group pilot (Wilde & Brasch, 2008a). Taken together, the theoretical model for the current study proposed that the intervention would affect catheter self-management indirectly through self-efficacy, and directly; and that higher levels of awareness, monitoring, and behaviors related to catheter care would improve outcomes (Figure 1; Wilde, Zhang et al., 2013).

The aim of the study was to determine the effect of the self-management intervention on health outcomes compared to the usual care control. It was hypothesized that the self-management group would: (a) have fewer episodes of UTI (and severity), blockage, and dislodgement of the catheter; (b) have decreased unplanned catheter-related healthcare utilization, including hospitalizations, emergency department visits, and fewer nurse home/or clinic visits; and (c) report higher catheter-related quality of life.

## Methods

### Design

The study was a randomized, single-blinded experimental design with repeated measures every two months over a 12-month period. The design called for 101 individuals to receive the self-management intervention and 101 to receive usual care (catheter-related care provided by home care nurses, clinics, or private providers).

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

### Inclusion/Exclusion Criteria

Eligible participants were adults age 18 and over. Inclusion criteria were: (a) expect to use an indwelling urethral or suprapubic catheter for at least one year, and will be in the study region for at least four months; (b) can complete study measurements alone or with the help of a caregiver; (c) speak English; and (d) have access to a telephone for data collection. Because we wanted to target only individuals who might benefit from this study and, thus, better determine effectiveness, our participants also must have had a catheter problem of CAUTI within the last year, or blockage or dislodgement within the last six months, or be new to a catheter within the last year. Individuals were excluded for terminal illness or cognitive impairments. Children under 18 were not included because they might not have the capacity for self-care, which includes directing others.

### Setting and Recruitment

Participants consisted of community-dwelling individuals recruited in two distinct regions by two study sites: (a) a university in a large northeastern U.S. state, and (b) a home care agency which conducts research in a large metropolitan area in the same state. For the university site, participants were recruited through nurses or physicians in home care agencies, medical center clinics, hospitals, and private medical offices (e.g., urology). Screening for eligibility and interest in participation was conducted by phone by the first author (MHW) or the project coordinator after contact information was received from providers who had permission to do so from potential participants. Some catheter users contacted the researchers themselves. In the home care agency, their database was used to identify potential participants with a catheter for telephone call screenings and recruitment by trained study interviewers. Using data from the agency's U.S. Outcome and Assessment Information Set (OASIS) for home care, catheter users were screened and excluded if they had a poor prognosis/life expectancy, cognitive impairment, confused, severe speech impairment, behavior problems, diagnosis indicating dementia, or had been previously interviewed (in another study or declined). Data were collected from June 2009-June 2012 in the homes of community-dwelling individuals and through telephone contacts over 12 months of participation.

### Sample Size and Power Calculations

Power calculations were performed to determine a sample size for an adequately powered study to detect clinically meaningful effects across multiple outcomes. For each of the primary outcomes, *a priori* range of clinically meaningful effect sizes was determined based on previous research. All calculations employed a significance level of .05 and 80% power. Power analyses were performed with SAS 9.1 using Monte Carlo simulation resampling techniques for general estimating equation (GEE) analysis (Gastañaga, McLaren, & Delfino, 2006; Yuan & Hayashi, 2003). The analysis indicated that a sample of 220 (160 completers) would provide sufficient power to detect medium effect sizes (15% to 30% differences between groups) for the primary health status outcomes. However, health care utilization measures, such as hospitalizations and ED visits, require larger samples due to their relatively rare frequency of occurrence.

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

### **Ethics/Human Subjects**

The study was approved at each site by their respective bodies for protection of human subjects. A coordinated approach assured that the same processes were used, including the same consent form with stamps and contact information from both sites. A Data Safety Monitoring Board was formed and convened annually to assess interim results and potential adverse events.

### **Randomization and Blinding**

Randomization was conducted by the main study statistician who directed the processes with the study coordinators at each site—each of whom subsequently enrolled participants at their own site and allocated them to treatment or usual care after completion of the baseline home visit (HV) interview. Participants were stratified by site to balance the large number of study subjects in the large metropolitan area (75% of participants), as compared with the university site (25% of participants) which was a combination of urban, suburban, and rural areas. Block randomization with random block sizes of 4, 6, or 8 was carried out independently at the two sites to balance the two treatment groups. For each site, a sequence of random assignments was generated by the study statistician and sealed in sequentially numbered envelopes by the study coordinator. The participants were sequentially assigned the treatment after completing the consent and initial HV interview; then, the study nurse called those allocated to the intervention and made arrangements for the first nurse contact in the home. Study investigators, data gathering teams, and statisticians were blinded to allocation status until the final analyses were completed.

### **The Urinary Catheter Self-Management Intervention**

The intervention designed to improve self-management in people with long-term, indwelling urinary catheters was based on self-efficacy theory (Bandura, 1997). Sources of urinary catheter self-efficacy were targeted in the nurse home visit interventions—specifically mastery experiences—vicarious observation, verbal persuasion, and knowledge about physiological status.

Each of the two study sites followed identical intervention protocols, which consisted of three home visits and one telephone call by a trained registered nurse to deliver the intervention. Two home visits took place in the first month and a third (booster) visit occurred at four months. During the first home visit, participants were taught to conduct self-monitoring using a three-day urinary diary to record observations and measurements of fluid intake and output (I & O), urine characteristics, and sensations of flow. This was to teach awareness of urine flow, basic self-monitoring skills, and to increase their level of mastery, thus, contributing to increased catheter related self-efficacy. During the second home visit, about a week later, self-management skills were taught first by reviewing the information from the urinary diary, calculating the intake and output averages and comparing these to an optimal volume (30ml/kg body weight), and identifying the individual's catheter-related problems. Anything notable about I & O, the color/character of urine, or of urinary sensations, was discussed and implications for self-management pointed out.

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

An educational booklet which had been piloted and viewed as very helpful (Wilde, Zhang, et al., 2013) was then provided and discussed, which focused on basic catheter self-management skills related to: (a) maintaining optimal and consistent fluid intake; and (b) preventing catheter dislodgement—which were the key components of the intervention. In the presence of certain bacteria which cause urea in the urine to split, sodium, magnesium, and calcium will precipitate from the urine—often at about a pH of 6.8, causing sediment and encrustation. However, researchers found that urine pH could increase to as high as 9 or 10, and the catheter might not block if fluid intake is increased to dilute the concentration of minerals (Khan, Housami, Melotti, Timoney, & Stickler, 2010). This is our foundation for the fluid intake requirements, which we set at 30ml/kg body weight (Gray & Krissovic, 2003).

Other modules of the booklet were reviewed briefly or in-depth, depending on interest or need. These were: recognizing early symptoms of CAUTI; living with the catheter; promoting optimal catheter change intervals; decreasing caffeine; decreasing leakage; emptying and cleaning the drainage bag; making adjustments for sex; and recognizing early symptoms of autonomic dysreflexia (for people with spinal cord injury/disease). Goals, if any, were written in the educational booklet. A motivational bookmark with quotes and pictures was reviewed to help encourage participants to be attentive to urine flow.

Two weeks later, the study nurses called to answer questions and, if needed, helped the participants revise goals or plans. At four months, a third home visit served as a booster of the intervention to further refine or modify goals/plans as the catheter user desired. Family or caregivers were encouraged to be present, but the intervention was delivered to the catheter user.

**Intervention compliance and fidelity**—Two study nurses (one at each site), who were trained together at the beginning of the project, delivered all the intervention components. Multiple strategies were used to establish and sustain the fidelity and integrity of the intervention. These involved: (a) standardization of the intervention and training, including use of a detailed training manual that incorporated Bandura's self-efficacy concepts (Bandura, 1997); (b) randomly selected fidelity assessments of 10% of the interventions—half by audiotape and half in-person home observations; (c) at least monthly conference calls; (d) training study nurses together; (e) tracking study nurse activities and responsiveness of the participants; (f) assessment of participant skills at the end of the study; and (g) inclusion of fidelity assessment in the analysis plan. The results of the audiotape and in person fidelity assessment indicated that competence and adherence to the intervention parameters were highly scored with most means between 4–5 (5 was the highest possible score). Also, because there was little variability in the proportion of the intervention participants who received the intervention contacts (i.e., 98% for HV1, 95% for HV2, 93% TC at two weeks, and 91% HV3 at four months), we decided it was not necessary to adjust for fidelity in the main outcomes analysis. All participants, regardless of group allocation, continued to receive usual nursing and medical care.

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

### Usual Care

Participants randomized to the control group received usual care.

### Measures

Measures were developed for this study based on previous research of the first-author's team (Wilde & Brasch, 2008a; Wilde & Dougherty, 2006). Instrumentation was modeled on the Stanford Chronic Disease Self-Management programs (<http://patienteducation.stanford.edu/>). Participants in both groups were administered identical data collection instruments. At baseline, self-report was used for data collection related to the two-month timeframe prior to the study (for evaluating equivalence of the groups), and every two months for 12 months thereafter through telephone call interviews. To improve accuracy of recall, all participants were asked to maintain an ongoing catheter calendar over the 12 months of the study, using letter symbols for problems: CAUTI (U), blockage (B), and dislodgement (D). Treatments were identified as antibiotic (A), extra nurse home visit (HV), extra office visit (O), hospitalization (H), and emergency department visit (ED). For missed interviews, data were collected for the primary outcomes at the next scheduled interview—if the study participant had kept track of problems in their catheter calendar. This occurred only nine times.

### Outcomes

Primary outcomes consisted of catheter-related complications of CAUTI, blockage, and dislodgement. CAUTI was defined as a urinary tract infection that was treated with an antibiotic prescribed by the person's healthcare provider. Blockage was defined as an occurrence in which the urine would not flow through the catheter due to an obstruction of the catheter tube. Blockage was distinguished from kinks or twists that are external to the catheter tube. Dislodgement occurred when the catheter fell out or became displaced accidentally due to traction (i.e., pulling on it). Catheter-related quality of life was also a primary outcome using our previously developed measure with a five-point Likert scale from 1 = *strongly agree* to 5 = *strongly disagree*; higher scores reflect better quality of life (Wilde, Brasch, Getliffe, McMahon et al., 2010).

Excess healthcare expenditures (treatments) related to catheter problems were also primary outcomes; these included extra nurse or clinic visits, hospitalizations, rehabilitation, and emergency department visits. Additional information was asked about each episode of CAUTI regarding the perceived severity of the infection (on a scale of 1–10, with 1 = *very mild* and 10 = *most severe imaginable*), and the number of days hospitalized or in rehabilitation specifically related to the CAUTI.

### Data Analysis

Standard data cleaning procedures were applied to screen for errors and potential univariate and multivariate outliers. These procedures led to the removal of blockage data (percentages/month, counts, treatments) for one participant due to inconsistent and contradictory responses. All other data were used; several outliers for blockage were

adjusted by windsorizing to 9 as the maximum number of events in a two-month period for testing group differences.

Intention-to-treat analysis was used. Data were analyzed with SAS 9.3 (SAS Institute Inc., Cary, NC, USA). Generalized linear models were utilized with an identity link function for continuous outcomes (CAUTI severity and QOL) and a logit link function for binary outcomes. Randomization achieved comparability on demographic characteristics of participants and aspects of catheter use (Tables 1 and 2) in treatment and usual care groups. The groups were similar on key outcome variables during the two months prior to the study, except for catheter blockage ( $p < .05$ ) and days hospitalized ( $p < .01$ ) (Table 2). Thus, we fitted each of the models with and without controlling for baseline information on the outcome variable. First, data for the first six months were modeled; then, data from the entire 12 month period of the study were modeled.

**First six months**—We let “group” be the indicator of treatment assignment (0 = *usual care*; 1 = *treatment*), and  $y_{it}$  be the outcome for the  $i^{\text{th}}$  subject at month  $t$ . Three models were developed for each outcome over the first six months of the study: a group differences model, a model for interaction of group and time; and a model controlling for baseline and time. The group differences model is

$$\mu_{it} = E(y_{it}) = f(\beta_0 + \beta_1 * \text{group}) \quad (1)$$

where  $f$  is the appropriate link function, the intercept  $\beta_0$  is the  $y$ -intercept in the usual care group when  $f$  is an identity function and mean log odds for the usual care group when  $f$  is the logit link,  $\beta_1$  is the treatment effect, and the “\*” symbol denotes multiplication. The interaction model, controlling for baseline and time is

$$\mu_{it} = E(y_{it}) = f(\beta_0 + \beta_1 * \text{group} + \beta_2 * y_{i0} + \beta_3 * \text{month} + \beta_4 * \text{group} * \text{month}). \quad (2)$$

When the interactions in Equation 2 were not significant, we further modeled the data controlling for baseline and time, with

$$\mu_{it} = E(y_{it}) = f(\beta_0 + \beta_1 * \text{group} + \beta_2 * y_{i0} + \beta_3 * \text{month}). \quad (3)$$

In the models given in Equations 1 and 3, inference about  $\beta_1$  provides information about the treatment effect, either as difference in outcome (CAUTI severity, quality of life) or difference in log odds of the outcome (binary outcomes) as a function of group (Equation 1) or group, baseline, and time in months (Equation 3).

**Complete 12 month outcomes**—We applied the same group difference model in Equation 1 to the 12-month data (i.e.,  $t = 2, 4, 6, 8, 10$  and 12). For the models controlling for baseline and time (Equations 2 and 3), an indicator variable “second” was added to allow modeling differences between the first and second six months of the study (scored 0 when  $t = 2, 4, 6$  months and 1 when  $t = 8, 10, 12$  months). An interaction term between

“second” and “group” was added to the models described in Equations 2 and 3 to detect possible treatment effects between the first and last six months of the study, shown as

$$\mu_{it} = E(y_{it}) = f(\beta_0 + \beta_1 * \text{group} + \beta_2 * y_{it} + \beta_3 * \text{month} + \beta_4 * \text{second} + \beta_5 * \text{group} * \text{second}) \quad (4)$$

and

$$\mu_{it} = E(y_{it}) = f(\beta_0 + \beta_1 * \text{group} + \beta_2 * y_{it} + \beta_3 * \text{month} + \beta_4 * \text{second}). \quad (5)$$

To deal with the dependency among the repeated measures, generalized estimating equations (GEE) with a first order autoregressive structure for the working correlation were utilized. We chose to use GEE because of the complexity and difficulty in modeling the correlations among the repeated measures—especially for discrete outcomes. As a semiparametric approach, GEE has the advantage that the inference is robust to the misspecification of the working correlation matrix—in the sense that estimates are consistent even when the working correlation departs from the true correlations among repeated measures (Diggle, Heagerty, Liang, & Zeger, 2002). Nominal *p*-values of .05 for two-tailed tests were used.

## Results

### Sample Description

Baseline characteristics of participants are displayed in Table 1. Ages ranged from 19–96 years (*Mdn* = 61). The range in duration of catheter use was 1 to 470 months (39 years). Self-reported diagnoses involved SCI (40%), MS (23%), diabetes (12%), stroke (2%), prostate (10%), spina bifida (1%), neurogenic bladder not otherwise reported (8%), Parkinson’s disease (2%), and other (3%). Indications for indwelling catheter use were: immobility or difficulty moving around (58%), incontinence (57%), neurogenic bladder (54%), obstructed urine (32%), healing wounds (11%), and other reasons (11%). More than one indication could be listed. Additional detailed information about the participants at baseline is available in Wilde, McDonald et al. (2013).

Table 2 lists catheter-related health status, healthcare related to CAUTI, healthcare related to blockage, and quality of life at baseline by treatment group. Following randomization, groups appeared equivalent except that, during the two months prior to the study, the percentage of participants who had catheter dislodgement and the number of days hospitalized for a catheter-related CAUTI were higher in the control group.

Attrition was similar in both groups (Figure 2). There were more deaths in the experimental group than the control group (10 vs. 7). More participants whose catheters were removed were in the control group, mostly late in the study (3 vs. 10). Three persons withdrew from each arm of the study.

## Treatment Effects

Table 3 lists treatment effects for primary outcomes for models depicted in Equation 3 (short term effects during the first six months of the study, controlling for baseline value and time) and Equation 5 (longer-term effects, controlling for baseline value, time, and first vs. second half of study). Complete statistical results are available from the authors (MHW).

**First six months**—Without controlling for any covariates, the overall short-term effect of the intervention relative to the control condition was assessed over the first six months (Equation 1). During the first six months, patients in the experimental group were less likely to report catheter blockage ( $p < .05$ ) and fewer blockage-related nurse visits ( $p < .05$ ), but they reported experiencing more severe CAUTI ( $p < .001$ ) and significantly more CAUTI-related emergency room visits ( $p < .05$ ), in terms of the percentage reporting such events. As shown in Table 3, we obtained similar conclusions controlling for the outcome variables at baseline (such as CAUTI) as well as time (Equation 3).

**Complete 12 month outcomes**—Without controlling for any covariates, the overall long-term effect of the intervention compared to the control condition was assessed over the whole 12-month period (Equation 1, with  $t = 2, 4, 6, 8, 10, 12$ ). However, the overall difference in blockage between the two groups was not significant over this longer period. The experimental group continued to report significantly higher CAUTI severity scores ( $p < .01$ ) and CAUTI-related emergency room visits (percentage reporting these events [ $p < .001$ ] and frequencies of events [ $p < .01$ ], as well as more hospitalizations for CAUTI (percentage [ $p < .01$ ], frequencies [ $p < .01$ ], and days hospitalized [ $p < .05$ ]; Table 3; Table 4 [days hospitalized]).

Additional statistical tests of treatment effect controlling for baseline outcomes, time, and study period (“second”) were conducted (Equation 4, not shown in a table.). The experimental group tended to report more CAUTI compared to the control group in the second half ( $\hat{\beta}_1 = 0.04$ ; 95% CI [0.03, 1.30],  $p = .04$ ), and no difference between the two groups during the first half year. The experimental group reported higher CAUTI severity than the control group in the first half year ( $\hat{\beta}_1 = -2.84$ ; 95% CI [-4.62, -0.97],  $p < .0001$ ), but no difference between the two groups during the second half. This indicates that the experimental group’s CAUTI severity scores decreased relative to the control group from the first to the second half of the year. Blockages were fewer in the experimental group (by percentage) compared with the control group in the first half of the year ( $\hat{\beta}_1 = 1.17$ , 95% CI [0.38, 1.97],  $p < .05$ ), but not in the second half of the year.

For other outcomes, the interaction was not significant, and was therefore removed. Treatment effect was estimated controlling for baseline outcomes and time. The experimental group had higher hospitalization for CAUTI ( $p < .01$ ) and emergency room visits ( $p < .001$ ; Table 3). Catheter-related quality of life did not differ significantly by group (Table 3).

## Rates Comparisons

Table 4 provides detailed information about rates of blockage, CAUTI, dislodgement, and hospitalizations within groups over the course of the study and between groups. See Table 4 for a figure displaying the percentage of persons who reported experiencing catheter adverse outcomes of blockage, CAUTI, or dislodgement by group over time.

**Catheter-related health status**—Comparison of between- and within-groups rates per 1000 catheter days from baseline provided further details about changes in the primary outcomes over the first six months, second six months, and full study of 12 months. Blockage rates were significantly lower in the experimental group during the first six months ( $p < .01$ ) and for the full study ( $p = .03$ ), but there were no differences during the second half of the study ( $p = .31$ ). Blockage improved significantly within each group at each assessment time from baseline.

For CAUTI, there were significant rate differences favoring the control group during the second half of the study ( $p = .01$ ), but no differences for the first half ( $p = .55$ ) or the full study ( $p = .16$ ). Compared with baseline rate estimates, the experimental group had significant decreases in CAUTI rates during the first half of the study ( $p = .02$ ), and for the overall full study time period of 12 months ( $p = .05$ ). The control group had a significant decrease in CAUTI during the second half of the study ( $p = .02$ ).

For dislodgement, rates decreased steadily in both groups by six months and 12 months, and there were no significant group differences. Dislodgement rates were lower in the experimental group at baseline, and larger decreases in dislodgement took place over time in the control group. During the second half of the study, the experimental group rate was slightly better than the control, but not significantly so ( $p = .06$ ).

**Hospitalization rates**—Hospitalizations were significantly higher in the experimental group for most time points (Table 4). While the hospitalization rates favored the control group, rates decreased in both groups compared with their respective rates at baseline. Slight increases in rates were found during the second six months in the experimental group, compared with the first six months, but control group rates continued to decrease during the second six months. With further analysis at the individual level, we found that one person (in the experimental group) was hospitalized six times during the study, and five of these occurred in the second six months of the study. All others hospitalized in either group were hospitalized either once or twice during the study.

## Discussion

### Key Findings

Four Cochrane reviews concluded that there was an astounding lack of evidence to guide practice in long-term catheter use (Cottenden et al., 2013). Almost all intervention research in the past has focused on applications such as silver or antibiotic coatings (Johnson, Kuskowski, & Wilt, 2006) to the catheter, special cleaning of the urinary meatus (Burke, Jacobson, Garibaldi, Conti, & Alling, 1983), or drainage bag additives (Washington, 2001). None have proven effective in long-term catheter users. We believe this study is a unique

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

contribution because it is the first known study of its kind using a randomized clinical trial with an inductively derived, theory-based behavioral intervention (Wilde, 2002; Wilde & Brasch, 2008b; Wilde and Dougherty, 2006; Wilde & Garvin, 2007) to assess whether teaching catheter users self-management skills could decrease short-term, catheter-related problems, and whether improvements could be sustained over 12 months.

The GEE analyses indicated that there was a significant group difference in the first six months only for the blockage outcome—favoring the experimental group. Several interactions suggested that effects of the intervention were stronger for the first six months than the long-term effects over 12 months. Comparisons of rates for the first six months, second six months, and full study of 12 months—as well as the changes in rates from baseline—provided additional information suggesting that both groups improved over time. The line graphs (see Supplemental Digital Content) also indicate a general downward trend for both groups over the 12-month study.

The decreases in rates for CAUTI and blockage are believed to be clinically meaningful in both groups. In a recent report from the Agency on Healthcare Research and Quality (2013, p. 26), decreases in CAUTI in hospitalized persons went down in two months from 2.56 to 2.39/1000 catheter days—a relative reduction of 6.3%. The rate decreased even further at 14 months to 2.14/1000 catheter days—a 16.1% relative reduction in 14 months. These changes reflected that “progress has been made” toward national goals. CAUTI rates in community-dwelling persons can be as high as 8.4/1000 catheter days (Wilde, Brasch, Getliffe, Brown et al., 2010). In our study in the experimental group, the baseline CAUTI rate of 6.93/1000 catheter days decreased to 4.89 (a 29% relative reduction) and in the control group from 5.5/1000 catheter days to 4.12 (a 25% relative reduction; see Table 4).

Blockage prevalence is often cited as about 50% (Getliffe, 2003), but our previous research reflects a wide range of 74% over eight months in 43 persons (Wilde, Brasch, Getliffe, Brown et al., 2010) to 24% in our cross-sectional analysis—before random assignment at baseline in the current study (Wilde, McDonald et al., 2013). Importantly, there is no agreement of whether blockage is a one-time occurrence or a persistent pattern, and this might explain the wide range in blockage prevalence. Because our study tested group differences in this randomized trial, the blockage rates reported should be viewed with caution because blockage outliers were adjusted statistically to a maximum of 9 in a two-month time period. Prior to our study, there were no known reports of dislodgement rates. Therefore, we recommend that in future research, rates per 1000 catheter days should be calculated for blockage and dislodgement, as well as CAUTI.

Although blockage decreased significantly in the first six months in the experimental group—as compared with the control group—it is not known whether this was truly of benefit since the control group also improved and started with more blockages. In addition, since this effect did not last over the full 12 months, and the three nurse home visits took place in months one and four, there might be a benefit in expanding the intervention dose over time.

One major issue remains: whether the self-management intervention contributed to more hospitalizations, whether the experimental group was sicker and more prone to severe

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

CAUTIs requiring hospitalization, or whether this group simply noticed signs of CAUTI and acted on them more quickly. A priori, we had identified hospitalization as an indicator of CAUTI severity. Nevertheless, we had hypothesized that the intervention participants would contact care providers earlier and, thus, avoid some of the hospitalizations. However, if the experimental group were to have been more prone to serious CAUTIs—as severity scores suggested—then seeking early care—even if it included hospitalization—might have kept them from more serious consequences, such as long hospitalizations, sepsis, or death. There is no way to know this.

In a recent analysis addressing reasons for rehospitalization, chronic disease and vulnerability in patients' conditions seem to play a big role. Also, morbidity and mortality appeared to be inversely related, meaning sicker patients were treated more often at a hospital and extending their lives. Thus, hospitalization is not necessarily an indicator of poor quality in care (American Hospital Association, 2011). As with the other primary outcomes, we found a pattern of both groups improving over time in relation to hospitalization. That is, rates in hospitalization (times hospitalized and days hospitalized) decreased in both groups, and there were larger decreases in the first six months of the study (see Supplemental Digital Content).

The experimental and control groups both appeared to have improved during the study. Simple self-monitoring through use of the catheter calendar for bimonthly data collection by study participants in both groups could have contributed to fewer catheter problems overall. Essentially, it is possible that study participants in both groups became more aware of catheter problems due to the calendar, and were reminded of their catheter through the phone call interviews every two months. This could have contributed to changes in self-management behaviors, such as increasing fluids for early CAUTI symptoms. Teaching people with indwelling urinary catheters to keep track of key catheter problems (self-monitoring) in a simple notation calendar could be easy and practical to implement in practice. Because blockage decreased significantly in the first six months of the study, in the intervention group, there could be added value in teaching about optimal and consistent fluid intake.

Research implications include replication with additional nurse contacts over time, simplifying the intervention to focus on optimal fluid intake and preventing dislodgement, and using a simple catheter calendar as a self-monitoring intervention. Testing in a multisite RCT using data collection forms embedded in the home care patient records could eliminate self-reported data for outcomes. Evidence-based policies will lag until more randomized trials—or other forms of scientifically sound research—are conducted in this understudied and vulnerable population that use indwelling catheters for long-term bladder management.

### Limitations

Self-reported data were used because standardized health records were not available. The catheter calendar was used to minimize self-report error. In addition, recall during the pilot study was excellent using bimonthly telephone interviews (Wilde & Brasch, 2008a). Agreement between self-reported catheter problems (CAUTI, blockage, dislodgement) and chart data was high in another study (97%; Wilde, Brasch, Getliffe, Brown et al., 2010).

*Nurs Res.* Author manuscript; available in PMC 2016 January 01.

Use of a medical diagnosis with antibiotic treatment for defining CAUTI could include some inaccurate diagnoses because some providers could have treated asymptomatic bacteriuria. Because bacteriuria is universal in this population after 30 days, colony counts would be useless. It was not possible to review multiple sources of data in multiple agencies to determine symptoms which might have been used for treatment decision making. Moreover, symptoms vary among individuals and over time. Thus, the decision for treating symptomatic CAUTI is complex, and it requires clinical judgment of the provider.

Attrition was similar in both groups. It was addressed regularly by the team during monthly meetings. Each of the 17 deaths that occurred during the study was evaluated. At the large home care agency site, charts were audited to determine whether there was any person whose death might have been related to the study. In one or two instances, details about comorbidities were discussed with the urologist on the team. The data safety monitoring board (DSMB) met annually with the lead investigators, statistician, urologist, and an outside researcher to review information about each death. The DSMB conclusion was that no deaths were related to the study, and that comorbidities contributed to each event.

### Conclusions

Adults with a variety of health conditions are challenged with managing urinary catheter self-care to avoid complications and enhance quality of life. In a one-year RCT setting, participants receiving a self-monitoring, self-management intervention had less catheter blockage during the first six months. No other differences between treatment and control groups were noted. Participants in experimental and control groups improved over 12 months, compared with baseline. The simple-to-use catheter problems calendar and bimonthly interviews used for data collection may have served as a modest intervention in both groups.

### Abstract

A long-term indwelling urinary catheter intervention was tested in a randomized trial that is described in this article. The perceived value of the intervention to the catheter users, one of the study's specific aims, was assessed at the end of their 12-month participation and is reported here. Study participants' responses, our findings, and implications for home healthcare are discussed.

### Introduction and Purpose of the Study

There is limited evidence to guide long-term urinary catheter users for self-management. They ordinarily are not in support groups of any sort and might not know others using such a device, yet many use an indwelling urinary catheter (suprapubic or urethral) for years (Wilde et al., 2013) or indefinitely. Those with intractable urinary retention who are unable to perform intermittent catheterization or have no one to do it are sometimes without other options. This type of urinary retention is most often caused by a neurologically based injury or disease, such as a spinal cord injury, multiple sclerosis, diabetes, or by obstructive prostate disease (Cottenden et al., 2013). In our experience, individuals with long-term catheters often learn about self-managing through piecemeal instruction from healthcare providers and by trial and error.

This report describes a new intervention to teach self-management to community-living long-term indwelling urinary catheter users and their perceived value of the intervention.

Understanding how the study participants responded provides information that could be useful in dissemination and/or changes in the research.

## Background and Literature Review

Although policies and procedures are well developed for patients with indwelling urinary catheters in home care and in clinics, an emphasis on self-management is not the norm. Self-management is a form of collaborative care with a healthcare provider (nurse or physician) in which the patient learns to pay attention to bodily symptoms, makes observations and recordings (e.g., diaries), and determines how behavioral changes they are making affect the condition. Self-management research is often conducted with people having chronic conditions, such as arthritis (Ackerman et al., 2013), diabetes (Rothman et al., 2008), or asthma (Kaptein et al., 2010), but self-management research has not been done in indwelling urinary catheter users.

The National Home and Hospice Care Study conducted in 2000 by U.S. National Center for Health Statistics estimated that there are 148,400 urinary catheter users in the United States, for a prevalence of 0.05% in the adult population in community settings (CDC, 2013a). A more recent National Home and Hospice Care Survey in 2007 reported catheter prevalence in home care (excluding hospice) at 9% ( $n = 4683$ ) (CDC, 2013b) or 135,000 people with catheters of the 1.5 million home care patients in 2007 (<http://www.cdc.gov/nchs/fastats/homehealthcare.htm>). However, it is not known how many of them have long-term catheters nor whether they use indwelling or nonindwelling catheters (Lisa Dwyer, National Center for Health Statistics, personal communication, June 20, 2013).

Persistent catheter-related problems are common in long-term catheter users. In one recent study of 43 people over an 8-month period, 74% experienced blockage of the catheter from encrustations, 70% had catheter-associated urinary tract infection (CAUTI), 79% had leakage of urine (bypassing), and 33% had accidental dislodgement (Wilde et al., 2010). In a larger study with 202 long-term indwelling urinary catheter users, catheter problems were recorded by recall for the previous 2-month period, and in this short period of time, 31% had experienced CAUTI, 24% had blockage, 12% had accidental dislodgement, 43% had leakage of urine, and 23% had catheter-associated pain (Wilde et al., 2013).

Most research in the past has focused on improving the catheter itself through: coatings, such as silver or antibiotic (Johnson et al., 2006), catheter materials like silicone (Schumm & Lam, 2008), instillations into the drainage bag (Washington, 2001), and special care to the urinary meatus (Burke et al., 1983), but none have proven effective in preventing blockage or CAUTI (Parker et al., 2009). Other interventions, commonly believed to be of value, such as smaller catheter size, cranberry juice consumption (Jepson & Craig, 2008), and acidic instillations or irrigations, have not been tested in randomized controlled trials in people with catheters (Moore et al., 2009). Closed drainage, which has been shown to significantly reduce the rate of CAUTI, is the only critical innovation in the last 40 years to prove beneficial (Stickler & Feneley, 2010). However, many persons with catheters open them daily to switch from leg to night bags or to clean the bags between uses. In the aforementioned larger study of 202 long-term catheter users, 58% used both leg and overnight bags, and a majority cleaned their bags, using water, soap and water, or a solution of water with bleach or vinegar (Wilde et al., 2013). Cleaning with a diluted bleach solution was shown in a seminal study to increase bag life to 1 month; however, rates of CAUTI remained unchanged (Dille et al., 1993). Consumption of a citrated drink (water with lemon juice) or additional fluids was tested in one study, and results are promising that either can decrease catheter blockage (Khan et al., 2010), but trials have not been done. Thus, evidence-based self-management strategies for persons using indwelling urinary catheters remain in a preliminary stage.

*Home Healthc Nurse.* Author manuscript; available in PMC 2014 October 01.

A first step for catheter users to prevent or minimize catheter-related problems (e.g., CAUTI, blockage, or accidental dislodgement) is to become aware of what to notice and how to self-monitor urine flow. Strategies can then be selected for self-managing the catheter based on this knowledge to address problems early to prevent more serious complications, such as an insidious CAUTI requiring intravenous antibiotics and hospitalization.

### Study Description

A research study was conducted, building on the prior investigations. A new catheter self-management educational intervention was piloted (Wilde & Brasch, 2008a, 2008b) and tested for effectiveness in a randomized clinical trial in long-term indwelling urinary catheter users. The 4-year study was conducted in one northeastern U.S. state, including a large city and a mix of urban/suburban and rural areas. Two hundred and two adult persons with long-term indwelling catheters (56% urethral and 44% suprapubic) who were expecting to use catheters indefinitely, or at least for a year, were enrolled in the study for 12 months. Equal numbers of 101 were assigned to the intervention group or the control group. One hundred seventy-five study participants (87%) were recruited through home care agencies (one large city agency enrolled 152 persons); the rest were referred through a combination of clinics or private urological offices. Approximately equal numbers of men and women were enrolled, aged 19 to 96 years (mean 61, SD 17.4), with racial and ethnic diversity (White 57%, Black 30%, other races 13%).

The self-management intervention was theoretically based on Bandura's self-efficacy theory (Bandura, 1997). Self-efficacy is the confidence to perform a specific behavior and, in this study, optimal and consistent levels of fluid intake and preventing accidental dislodgment were the key behaviors targeted. Study participants were taught to pay attention to urine flow, self-monitor bodily changes, and choose appropriate self-management behaviors. The theoretical concepts of awareness, self-monitoring, and self-management (Wilde & Garvin, 2007) were central to the intervention, and Stanford's Chronic Disease Self-management program (Lorig et al., 2001) provided the overall model (Figure 1). The intervention was designed to enhance self-management of urine flow in the intervention group. The control group received only their usual care.

Study outcomes were: (a) catheter-related complications (CAUTI, catheter blockage, and accidental dislodgement), (b) complications' associated costs, and (c) quality of life. To measure study outcomes, data were collected from both groups about catheter-related problems for a year, once face to face in their homes when enrolled and then in six follow-up bimonthly telephone interviews with trained interviewers.

The intervention group was visited by a study nurse in their home three times, for a total of three home visits. Two of them occurred in the first month. The first home visit was to teach about self-monitoring using a urinary diary, and the second home visit was to use this information to plan for improved self-management and to introduce an educational booklet. This was followed by one phone call 2 weeks later to identify any additional issues and to reinforce the teaching. The third home visit was a "booster" of the intervention at 4 months to further refine teaching.

Specifically, study participants were taught to increase their awareness of sensations of urine flow and to learn how these change with daily activities or catheter-related problems. Problem areas were identified in conjunction with information from the 3-day urinary diary (intake and output and open-ended journal). After learning about basic catheter self-management (Table 1 from the Paying Attention Educational Booklet), all were taught to pay attention to fluid intake and catheter position to prevent dislodgement. Then the study

*Home Healthc Nurse.* Author manuscript; available in PMC 2014 October 01.

nurse reviewed all sections of the educational booklet, focusing on areas of individual interest (Table 2 and Figure 2). The study nurse filled out forms after each encounter, which were similar to a care plan, to remind her of the participant's catheter problems and interests or goals. Whenever possible, measurable goals were set and written into the educational booklet.

Below is a report of one of the specific aims of this study, to describe the perceived value of the self-management intervention received by the intervention group. A full report of the main outcomes for this research will be published elsewhere.

## Perceived Value of the Catheter Self-Management Program

### Methods

Study participants who received the catheter self-management intervention were contacted by phone by one of the two study coordinators within a month of their year-long study participation to assess their perceived value of the intervention. Not everyone was able to be reached or was not able to be interviewed; therefore, out of the 74 persons who completed the intervention arm of the study, 60 brief telephone interviews were conducted. Study participants were asked several quantitative questions about helpfulness of each component of the intervention, using a modification of items previously piloted (Wilde & Brasch, 2008a, 2008b), on a scale of 1 to 10, with 1 being not helpful at all and 10 being very helpful. Study participants were also asked five open-ended questions, allowing for comments to be shared, related: (a) goals, (b) changes to behavior, (c) impact on self-management, (d) helpfulness of the program, and (e) suggestions for improving the program. The interviewers took brief notes to obtain the comments data, which were entered into a spreadsheet and SPSS.

### Data Analysis

Quantitative items were analyzed descriptively for means and standard deviations. For the comments data, a descriptive analysis was conducted using simple coding by two researchers, the principal investigator and a doctoral student. Coded comments were then organized into tables before writing a descriptive summary of responses for each item. Both coders agreed on the final codes, the organization of data, and the summary.

### Results

Based on the scores, the study nurse visits and the intake and output part of the urinary diary were the most favored elements of the intervention (Table 3). A large majority of the persons rated each component of the intervention (i.e., intake and output, journal, educational booklet, study nurse encounters, and learning self-management) between 8 and 10 on the 10-point scale. The means (SD) for each component ranged from 7.25 (2.40) to 8.33 (3.15). The open-ended journal, which was identified in the study nurses' process recordings (not reported in this article) as being used by only 2% of the intervention sample, was valued less with the lowest mean score 7.25 (3.15).

Out of the 60 persons interviewed, goals were recalled by 21 persons (35%), not set by 36 (60%), and 3 (5%) did not remember. Responses to whether they were doing anything differently with the catheter because of the study were: 25 (42%) said no, 18 (30%) said yes somewhat, and 17 (28%) said yes greatly. 43 (71%) had suggestions for improving the program and 17 (29%) did not.

*Home Healthc Nurse.* Author manuscript; available in PMC 2014 October 01.

### Goals Set During the Study

Fifteen persons had goals related to hygiene or preventing urinary tract infections (UTI), specifically cleaning near the catheter, drinking adequate fluids, and preventing UTI. Self-monitoring goals by 14 persons involved noticing changes in the urine, such as watching for sediment or urine color, or in paying attention to the catheter to maintain an appropriate position, or prevent dislodgment, kinks/twists, or leaks. Two persons also stated they wanted to stay healthy urologically.

### Changes to Behavior

Study participants who had said they were doing things differently because of the study were asked to describe in what ways. Some reported changes that were similar to the goals they cited. Self-monitoring of the catheter was identified by nine persons related to repositioning the catheter to prevent leakage and twists, or checking the catheter position in relation to the bag or body; or watching for changes in the urine, sediment, or color. Eight said they paid attention more often to urine output or to avoid letting the bag get too full. Nine said they have increased their fluid intake and two said they keep better track of fluids. Eleven were focused more on the catheter itself, such as knowing the exact amount of water in the balloon, about irrigation or cleaning the bag, changing the catheter more often, and in managing the catheter when traveling by using a larger bag at home and smaller one for travelling, or knowing the locations of available bathrooms. Two stated they knew better when to call the provider for catheter problems. One worked on bowel management more and one stays away from caffeine. One reported fewer UTIs.

### Impact on Self-Management

Participants also were asked how the study affected their catheter self-management. Six said they were more aware in relation to: cleaning the catheter, noticing urine color, emptying the bag to prevent urine buildup, and knowing where bathrooms were. Six reported having fewer UTIs, and two had less sediment, blockage, or mucus. One individual had more catheter comfort and was pain-free. Five people spoke of being more knowledgeable about and supported with the catheter, or knew when to call the provider. A few recognized patterns of problems, such as burning sensations and kinks. One noted being hospitalized four times recently (but we are not sure what that meant).

### Helpfulness of the Program

The comments related to whether learning self-management was helpful or not were aimed at understanding more about the value of the catheter self-management intervention. Comments from 17 individuals were primarily about catheter-related knowledge gained, skills acquisition (including enhanced awareness of their bodily symptoms related to the catheter), and feeling cared for by the study nurse making home visits. There were just four negative comments: three who did not learn anything new and one who did not think program helped. Also three persons said they do not self-manage, but one said it was helpful to know.

### Suggestions for Improving the Self-Management Program

Many suggestions and comments were received also, including more use of Web sites, combining the urinary diary forms (i.e., intake and output forms with the journal), managing pain, and sketches of instructions. Several asked for better designed catheters and equipment.

*Home Healthc Nurse.* Author manuscript; available in PMC 2014 October 01.

## Discussion

For the quantitative assessment of intervention components, there was a possible small ceiling effect with higher percentages reporting 10 (very helpful) for the study nurse encounters and intake and output, by 41% and 32% of the sample respectively. The open-ended journal was not used by most study participants (2%) and this was the case also during the pilot study (Wilde & Brasch, 2008a, 2008b), and thus it should probably be eliminated from future tests of this intervention.

The information solicited about goals at the end of this 12-month intervention with 60 individuals is in stark contrast to the information collected by the study nurses in their process forms in which 82 persons set initial goals (81% of 101 in the self-management intervention group), and over 70% said they met their goals during the phone call in month 2 or the home visit in month 4. Perhaps goal setting was not a high priority or there was insufficient recall at 12 months, when so much time had passed after the intervention visits. However, those persons who did set goals used language to reflect the key components taught in the intervention, such as goals about fluid intake, preventing UTI, and noticing changes in urine or in the position of the catheter.

Intervention participants showed that they understood key study concepts because they described activities that demonstrated awareness, self-monitoring, and self-management related to fluid intake, preventing CAUTI, and proper positioning of the catheter. Some seemed to have an emotional connection with the study nurse, saying they felt “cared for” by her. A few said that no one else has talked with them like this about the catheter and in such depth, and this made them feel valued as persons. Responses also illustrated individual variation in how much the self-management intervention was liked and for what reasons.

## Implications for Practice

Long-term indwelling catheter users can be taught to pay attention to urine flow. Specifically they should know how much fluid intake is right for them and what types of fluids should be monitored (e.g., caffeine). By noticing catheter-related changes—such as the color or character of the urine, catheter position, or kinks/twists in the tubing—and by responding quickly, catheter-related problems might be avoided or minimized. In this study, catheter users’ comments indicated how they valued and learned from the self-management intervention. Home care nurses are in an important and unique position to partner with their patients with catheters and their families to improve care and quality of life.

## Conclusion

This may be the first self-management intervention in long-term indwelling urinary catheter users. Knowing how the study participants responded to the intervention is critical in determining its dissemination and overall research value. In summary, research participants seemed to like the intervention, were able to identify what they should pay attention to, and told us what they were doing differently related to their catheter. These new behaviors should be beneficial in their catheter-related health. Although this intervention is not ready yet for full dissemination—due to ongoing analysis and writing reports of the main study results—many of the components, such as the urinary diary (I and O), the basic self-management tips in Table 1, and the sample educational page on identifying UTI, could be useful for home care nurses teaching catheter self-management to long-term indwelling urinary catheter users.

## Acknowledgments

Recognize early symptoms of urinary tract infections (UTI) and act on it

- Early recognition might prevent serious problems, such as severe UTI requiring hospitalization.
- Quote from catheter user: "I think about how much I am drinking. It has become a way of life. The study made me more aware and I changed bad habits. A couple of times, I did not do what I was supposed to do and had a UTI."

Paying Attention	Things You Can Do
<p>Signs of UTI:</p> <p>Urine Changes:                      Color—discolored, cloudy, dark, blood stained                      Odor—foul smelling, change in smell from usual                      Sediment (grit)—increased amount</p> <p>Pain and/or pressure in bladder area or back (burning possible, not common)</p> <p>Temperature—fever chills, sweaty/clammy                      General Symptoms—blahs!, feeling sick</p> <p>Functioning or mental changes—weakness, spasticity, change in the level of alertness</p> <p>Early, mild symptoms of autonomic dysreflexia (e.g., goosebumps, headaches, sweats) mainly in people with spinal cord injury</p>	<p><i>"Stay on top of it psychologically."</i></p> <p>Be sure you know when and how to contact your physician or nurse if you suspect that you are getting a UTI.</p> <p>Increase fluid intake especially water.</p> <p>Record in journal when you have a difficult catheter insertion and notice if a UTI develops afterward.</p> <p>Keep urine bag below bladder level. The tubing should be above the bag.</p> <p>Ask your healthcare provider about whether cranberry tablets or juice might help you.</p> <p><i>"If something doesn't feel right, act on it quickly."</i></p> 

**Figure 2.** Sample of educational module (Note: the quotes are from previous study participants (Wilde & Brasch, 2008a, 2008b).<sup>1</sup> UTI = urinary tract infection.

**Table 1**

## Basic Catheter Self-Management

- 
- **Stay aware.** Having a catheter requires that you *stay aware of your body* and how you feel.
- 
- **Drink more water** than any other beverage! Limit coffee, and consider substituting tea and decaffeinated beverages.
  - **Drink consistently.** Fluid intake needs to be at a good *level for your weight* and you need to drink in a *consistent* way to help prevent catheter blockage.
  - **Your body needs fluids.** Most people need 2,000 to 3,000 cc of fluid a day. For instance, a 150-lb person would need 2,550 cc that is equivalent to about 10.5 glasses per day. More fluids are needed for hot weather or when exercising. My fluid goal is \_\_\_\_\_.
  - **Pay attention** to the *color* of your urine. It should be light yellow all day long. The color of urine can be used a quick way to know whether you are drinking enough during the day.
  - **Notice changes.** If the urine color changes, notice if you are doing something different, such as drinking less water or more caffeinated beverages or are using a diuretic medicine or water pill, such as furosemide or chlorothiazide.
  - **Notice catheter position.** Notice where the catheter is after each change in your position and reposition it if needed. If you have others who help you, teach them to do this.
  - **Check for kinks and twists** in the catheter by feeling with your hand from where the catheter leaves your body all the way to the drainage bag.
  - **Ask for help.** If you need assistance with the catheter, learn to ask for help.
-

**Table 2**

Quick Guide to Catheter Problems (from the Paying Attention Educational Booklet)

<b>Problem</b>	<b>Action Strategies</b>
Decreased/inconsistent fluid intake	Increase fluid intake
Urinary tract infection	Increase fluid intake Recognize early symptoms of urinary tract infection and act on it
Catheter blocks	Increase fluid intake Promote catheter changes at best intervals
Adjustment to living with a catheter	Approaches for living with a catheter
Not sure of the best schedule for catheter changes	Promote catheter changes at best intervals
Kinks, twists, or tugs on catheter	Prevent kinks, twists, or tugs on catheter
Too much caffeine	Decrease caffeine
Catheter leaks	Decrease catheter leakage Empty urine bag
Urine bag odor	Clean urine drainage bag
Changes with sex	Make adjustments for sexual activity

Table 3

## Helpfulness of the Self-Management Program Components

On a scale of 1-10, With 1 Being Almost No Help, and 10 Meaning It Was a Very Big Help	n	M	SDs	1-4	5-7	8-10
1. Intake and output	56	8.04	2.40	11%	12%	77%
2. Catheter journal	56	7.25	3.15	20%	14%	66%
3. Educational booklet	57	7.72	2.79	12%	19%	68%
4. Study nurse's home visits and TC	58	8.33	2.53	10%	12%	78%

# Self-Management of Intermittent Urinary Catheters

## February 2016

Mary H. Wilde, PhD, RN

Professor, School of Nursing, University of  
Rochester, USA

Member of the ICS Nurses' Committee

**ICS**

International Continence Society  
Teaching Module

## Objectives

- Our purpose is to educate continence nurses to improve patient care and health outcomes globally.

At the conclusion of this presentation, readers should be able to:

1. Describe an approach to intermittent catheter self-management using a **web-based application** (related to a recent research study).
2. **Evaluate its usefulness** in promoting self-management in clinical practice and/or further research.

# Study: A Web-Based Self-Management Intervention for Intermittent Urinary Catheter Users

NIH/NINR funding: R21 NR012763

Wilde, M.H. (PI), Fairbanks, E., Parshall, R., Zhang, F., Miner, S., Thayer, D., Harrington, B., Brasch, J., Schneiderman, D., McMahon, J. M. (Co-I).

 ICS Teaching Module

## Intermittent catheter problems

- Psychological concerns, including stigma. (Shaw et al., 2008).
- Worries about CAUTIs
- Inconvenience in everyday activities
  - Inaccessible bathrooms-too small, lacking in privacy, and/or unclean (Wilde et al., 2011)
- Inadequate insurance, choice catheters/supplies
- Catheter type varies by individual; some find lubricated catheters hard to manage.

(Kelly et al., 2014; Wilde, et al., 2011)

NIH/NINR R21 NR012763

 ICS Teaching Module

## Aims and Goals of new online self-management intervention for people with spinal cord injury (SCI) using CIC)

- Feasibility (acceptability and usability)
- Preliminary effectiveness of the intervention
- Develop and test new measures of CIC self-efficacy and self-management
- Goals :
  - Learn more about own patterns with CIC
  - Obtain support and information for self-management
  - Sustain CIC over time

NBI/NBNI R21 NR012763

 ICS Teaching Module

## Design

- Interventional study – teaching awareness, self-monitoring, self-management
- Web resources—catheter products; educational booklet
- Online urinary diary: I&O, observation of self-cathing
- 3 phone calls with study nurses
- Pretesting group of 4 people with SCI to refine intervention.
- Discussion forums with peer leaders

NBI/NBNI R21 NR012763

 ICS Teaching Module

## Sample at baseline N=29

- SCI- 45% complete, 45% incomplete, 10% other SC disease
- 48% female
- Age 44 (SD 13) years; median 47 years
- Use of CIC- 16 years (range 1-39, SD 16 years; n=28)
- Diverse by race and ethnicity: 72% white, 14% black, 3% Asian, 10% more than one race; 3% Hispanic
- ADL - Katz score = 5.97 (SD 1.6), range 5-10; lower scores indicate more independent function.
  - 28/29 chair-fast but wheel independently
  - 1 used assistive device and/or person

**Weekly Pattern**

To better plan for catheter and fluid intake requirements, it might be helpful to think about your typical week. If you wish, use the box to describe your typical week Monday through Friday, or use the box to describe your typical week Saturday through Sunday, because daily patterns often change on the weekend.

I use every afternoon 0-F, so my mornings are at home and afternoons are out.  
My time to drink is more in the early morning and later in the evening when I get home so I do not have to cath as often when out.  
Weekends vary a lot, and I sometimes don't drink enough when out.

darker than usual maybe from too much coffee.
I will try to drink more water.

NIH/NIHR R23 2763

**Add/Edit I/O Entry**

### Journal Entry

Record what you noticed. Then what is going on or what you did about it. Consider the following which might affect fluid intake and urine output:

1. Do you feel less well today than usual?
2. Is this an unusual fluid intake or urine output?
3. Were your activities different from normal?
4. On a new medicine?
5. Describe sensations in the bladder area or abdomen on scale of 1-10.
6. Urine leakage or "accident" and what you could do to prevent it in the future.

Date/Time	Notice	Action

## Feasibility evaluation

- Several people withdrew or were lost to follow up early. 26 of 30 had nurse consultations for the intervention.
- Websites (recruitment and intervention sites) worked well, little difficulty navigating.
- Forums used by 10 of 26 but rated positively. Most posts r/t travel, insurance, mediations, treatments for SCI.
- Liked intervention: educational materials, urinary diary, nurse consultations, and discussion forums.

NIH/NIDDK R21 NR012763

## Results

- Frequency catheterizing 4-6 times a day increased slightly, 69-77% (NS)
- Self-management of the intermittent catheter increased significantly (P= .032)
- Self-efficacy and quality of life scores improved (NS).
- CAUTI, leakage and pain decreased (NS.)
- Measures performed adequately-- need further development in larger sample with more power.
- Increases in fluid intake biggest self-management change.

NHGREN R21 NR032703

 ICS Teaching Module

## One person said:

- "I'm probably more conscious of my intake of fluids than anything because I was one that was really slacking on taking fluids and I needed to- I needed to do something about it and I just sort of was lazy...[and] after the 2nd time we talked [with the study nurse] I really cranked up my intake of water because I was not a water drinker. And now I'm probably drinking probably 36 ounces of water a day. And I've cut out carbonated drinks."

NHGREN R21 NR032703

 ICS Teaching Module

## Conclusion and Implications

- Multi-site larger study in SCI units
- Newly injured and experienced people with CIC; plus others
- Compare web-urinary diary with paper and pencil
- Cohort enrollments for forum of about 10 people
- More information for logins, actions taken etc.
- Evaluation of this web-based approach will require more use of it, and for evidence of its value, more research.
- Dissemination for education and research (indwelling and intermittent catheter studies). Contract with University of Rochester email Mary Wilde: Mary\_wilde@urmc.rochester.edu

NH&NHR & R21 NR012763

## General Clinical Practice

# A Web-Based Self-Management Intervention for Intermittent Catheter Users

Mary H. Wilde, Eileen Fairbanks, Robert Parshall, Feng Zhang, Sarah Miner, Deborah Thayer, Brian Harrington, Judith Brasch, Dan Schneiderman, and James M. McMahon

Spinal cord injury (SCI) affects the bladder's storage and emptying, often contributing to persistent urinary retention (National Spinal Cord Injury Statistical Center, 2014). Intermittent catheterization (IC), by which the bladder is drained several times a day, is the preferred bladder management method (Cottenden et al., 2013). While the exact frequency of IC is individualized, people with full retention are ordinarily taught to catheterize four to five times a day or every four to six hours (Cottenden et al., 2013). Learning to manage this procedure takes time, with rehabilitation lengths of stay shorter in recent years (Christopher & Dana Reeve Foundation, 2015; National Spinal Cord Injury Statistical

© 2015 Society of Urologic Nurses and Associates

Wilde, M.H., Fairbanks, E., Parshall, R., Zhang, F., Miner, S., Thayer, D., ... McMahon, J.M. (2015). A Web-based self-management intervention for intermittent catheter users. *Urologic Nursing*, 35(3), 127-133, 138. doi:10.7257/1052-816X.2015.35.3.127

A new Web-based self-management intervention was developed for persons with spinal cord injury who use intermittent urinary catheters. Included are a description of the components, examples from the educational book, and multiple screen shots of the online urinary diary.

**Key Words:** Self-management, spinal cord injury, Internet, intervention research.

Center, 2014), individuals with SCI must develop skill in the method at the same time they are adjusting to this major life-changing event.

Research reports suggest there are many problems associated with living with IC that can influence the acceptance and continued use of it, including managing the frequency and technique of

the procedure (Logan, Shaw, Webber, Samuel, & Broome, 2008; Shaw, Logan, Webber, Broome, & Samuel, 2008; van Achterberg, Holleman, Cobussen-Boekhorst, Arts, & Heesakkers, 2008), impact on sex (Shaw et al., 2008), inconvenience of catheterizing (Wilde, Brasch, & Zhang, 2011), urinary tract infection (Wilde et al., 2011; Woodbury, Hayes, & Askes, 2008),

**Dan Schneiderman** is a Senior Analyst/Programmer, University of Rochester, School of Nursing, Rochester, NY.

**James M. McMahon, PhD**, is an Associate Professor, University of Rochester, School of Nursing, Rochester, NY.

**Statement of Disclosure:** Dr. Wilde is a consultant for NovaBay Pharmaceutical. No other authors have conflicts of interest.

**Authors' Note:** We gratefully acknowledge our two research consultants on the study: Eun-Ok Im, PhD, RN, and Wonshik Choe, PhD, University of Pennsylvania; and our nurse consultant Karen Genet, MS, RN, who assisted us in recruitment and improvements in the educational materials.

Funding was provided by the National Institute of Nursing Research; National Institutes of Health (U.S.) #R21 NR012763; the University of Rochester, School of Nursing; and the Leary Fund.

urine leakage, inaccessible bathrooms, and a lack of optimal catheter supplies (Al-Jadid, Al-Asmari, & Al-Moutaery, 2004; Wilde et al., 2011). Thus, managing IC issues can be a daily struggle (Kelly, Spencer, & Barrett, 2014; Logan et al., 2008; Shaw et al., 2008).

Moreover, not being well prepared to incorporate catheterizing into everyday life can lead to the use of a long-term indwelling urinary catheter or non-adherence to optimal IC frequency, which can adversely affect the bladder and kidneys (El-Masri, Chong, Kyriakides, & Wang, 2011). People with SCI, who are often injured while young, need to learn to live with IC as a part of their normal routines. Bladder self-management is integral to engaging in and maintaining social and employment opportunities. Restriction in travel due to urine leakage can interfere with quality of life (Brillhart, 2004) and full employment. Sadly, about 65% of adults with SCI are not employed (Webman, 2010). Therefore, people using IC need excellent self-management skills, such as learning how to 1) adhere to their IC regime; 2) self-monitor fluid intake to prevent leakage while maintain optimal hydration; 3) notice early symptoms of UTI; 4) perform IC in a variety of situations with good technique; 5) choose most advantageous catheters, supplies, and lubrication; and 6) adapt to social needs (Wilde et al., 2011).

Web-based interventions, which are currently expanding, are likely to continue to be developed and disseminated after testing and proven feasible. All activities in this study were approved by our university department for the protection of human subjects. The sample was diverse by race and ethnicity, and was composed of almost equal numbers of males and females, ranging in age from 22 to 79 years ( $M = 44$ ,  $SD = 13.1$ ,  $Md = 47$ ). The research findings will be reported elsewhere in two other articles related to 1) the development of the web-based intervention (under peer review),

**Table 1.**  
**Basic Intermittent Catheter Self-Management**

• Stay aware. Using an intermittent catheter requires that you stay aware of your body and how you feel.
• Drink more water than any other beverage! Limit coffee, and consider substituting tea and decaffeinated beverages.
• Balance fluids with cathing volumes. You may find it helpful to do a two to three-day intake and output diary to know how much you are drinking. While it will vary by individual, drinking more than about 2 liters could cause over-distention of the bladder, but it depends on the type of fluids. Over-distention is a major contributor to urinary tract infection (UTI). You do not need to focus on the amount taken each day as long as your volumes for catheterization do not go over 500 mL. If your volumes are consistently over 500 mL, then you should either drink less or catheterize more frequently.
• Pay attention to the color of your urine. It should be light yellow to yellow all day long. The color of urine can be a quick way to know whether you are drinking enough or too much during the day. If the urine color changes, notice if you are doing something different, such as drinking more caffeinated beverages or taking a diuretic medicine or water pill, such as furosemide (Lasix®) or chlorothalidate sodium (Diuril®).
• Notice how often you are catheterizing. Most people need to do this four to five times a day, approximately every four to six hours. If you do not do it often enough, you are more susceptible to UTIs or leakage of urine. You should have less than 500 cc. in each catheterization.
• Pay attention to how fluids affect your activities, the time between intermittent catheterization (IC), and how the amount and what you drank contribute to urine leakage and accidents.
• Consider other catheters. You can try other types of catheters if you wish. Not one catheter will work with all people. Contact your physician after you have considered options.
• Prepare for getting out. You may need to learn different positions for cathing or where the bathrooms are. You might need to assemble your own IC kit.
• Ask for help. If you need assistance with IC or bathroom access, ask for help.

and 2) testing its feasibility/usability, with a full description of the sample and procedures (in progress, not submitted yet).

#### **Purpose**

A new Web-based intervention for people using intermittent urinary catheterization to empty the bladder periodically throughout the day is a part of a single-group trial funded by the National Institutes of Research/National Institute of Nursing Research to evaluate feasibility of a new web-based approach in 34 individuals with SCI who use IC. This report is expected to provide urological practitioners with

information about IC self-management using web-based materials and processes, including use of the tables and figures. However, the authors maintain copyright of the figures and tables, and therefore, the content should not be modified or used without permission of the first author.

#### **Intervention Website**

The intervention website includes content on a number of pages: a Home Page, Continence Product Advisor, Commercial Products, Educational Materials, Personal Data, Forum, Contact Us, Help, and Logout. The Home Page is a welcome/introductory page

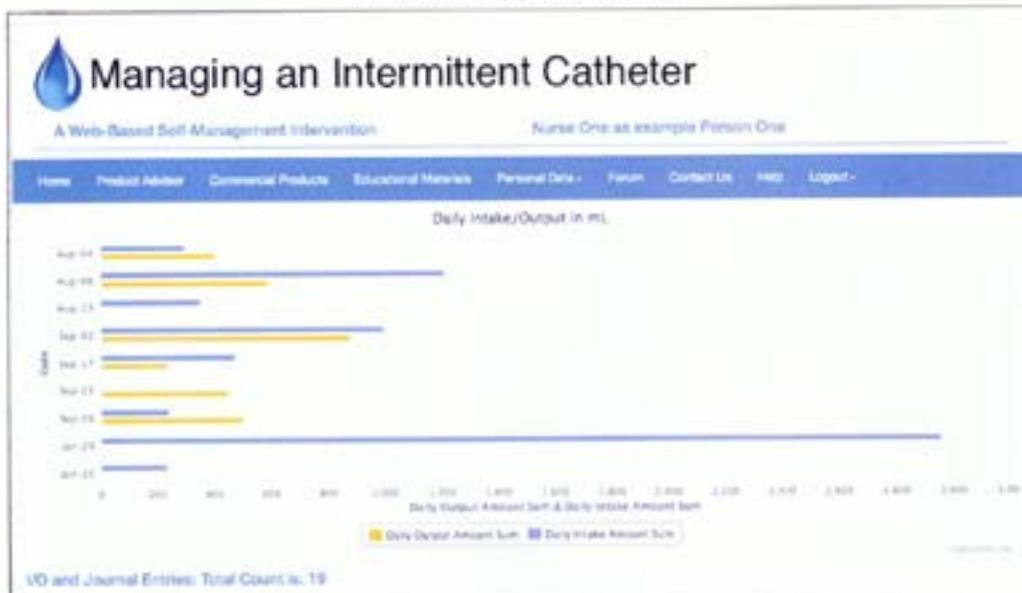

Figure 3.  
Journal Page

Source: Copyright © University of Rochester School of Nursing. Used with permission.

- Manage painful catheterizations.
- Decrease caffeine.
- Am I dehydrated? (Urine Color Chart).

The Personal Data page (viewed only by the study participant and the study nurses) is the most interactive section of the intervention website and involves links to four webpages: goals and catheterization frequency, intake and output (I&O) entries, journal, and an overview with summary tables and graphs (see Figures 1 to 5). The *goals and catheterization frequency* (see Figure 1) has a textbox for writing, revising, and deleting goals, and places to select a date and frequency of catheterization for that date. The *I&O entries* (see Figure 2) include options for entering volumes and characteristics. For fluid intake, options are mL/cc, ounces, cup, pint, or quart; type of fluids (such as water, milk, juice, beer, soda); and if the fluid was caffeinated or not (with a table listing the amount of caffeine). For urine output, the amounts are in mL/cc

Figure 4.  
Intake and Output in a Bar Graph

Figure 5.  
Daily Amounts in Tables and Line Graphs

Source: Copyright © University of Rochester School of Nursing. Used with permission.

or ounces, and characteristics can be selected, such as mucus, blood clots, or urine color (using a simplified color chart with options that include clear, light yellow, yellow, and amber). Leakage can be monitored as *none*, *small*, *medium*, or *large amounts*. Amounts for both I&O are automatically calculated to mL, and thus, are not dependent on the metric used for data entry.

The *Journal* page (see Figure 3) includes a place for the date, two sections for “what was noticed” and another for “what was going on or done about it,” and questions/statements to facilitate writing journal entries. The prompts are based on questions used in the previous indwelling catheter study by the

research team (Wilde & Brasch, 2008), with modifications for IC:

- Do you feel less well today than usual?
- Is this an unusual fluid intake or urine output?
- Were your activities different from normal?
- On a new medicine?
- Describe sensations in the bladder area or abdomen on scale of 1 to 10.
- Urine leakage or “accident” and what you could do to prevent it in the future.

Lastly, the Personal Data section includes an Overview page, which is composed of tables and graphs of all cumulative data. These are *intake and output in a bar graph* (see Figure 4) with a blue color for intake and light

yellow for output, showing amounts/day; a table with daily totals of intake and output; and catheterization information with *daily amounts in tables and line graphs* (see Figure 5) showing patterns and trends. These overview visuals show differences among dates and can depict discrepancies between intake and output. In addition, because this overview displays all entries chronologically, the catheter user or study nurse can more readily see patterns between notes in the journal and the entries for I&O. This level of linking detail is believed to facilitate better self-management skills. For instance one might discover reasons for not adhering to their IC planned frequency on

**Table 2.**  
**Balance Fluids with Activity: Optimal Fluid Intake**

While you need fluids for health, drinking too much can cause over-distention of the bladder, and this can contribute to urinary tract infection (UTI).

Quote: "As long as the urine looks clear and clean, I'm not worried about it."

Paying Attention	Things You Can Do
<p>Notice whether you are getting enough fluids – but not too much – throughout the day.</p> <p>Become aware of whether different types of fluids make you need to cath more frequently or with more urgency.</p> 	<p>If you find you are not drinking enough, by cathing volume, you can try some of the suggestions below to increase your fluids.</p> <p>If you like the water cold, keep several bottles in the fridge and refill them with fresh water every day.</p> <p>To add flavor to water, try 2 ounces of cranberry or apple juice to 8 to 10 ounces of water. You may also try adding a little lime or lemon juice.</p> <p>Keep fresh glasses of water throughout the house.</p> <p>Secure a jug or bottle of water to your wheelchair.</p> <p>Use a rigid straw so you don't have to suck hard.</p> <p>You may want to drink around meal times and before bed.</p> <p>Have a caregiver remind you to drink water.</p>
<p>Notice changes in color of urine every time you catheterize.</p>	<p>Color should remain light yellow to yellow all day. (See the color chart at the end of the booklet.)</p> <p>If color gets dark or urine has foul smell, increase water.</p>
<p>If you are on fluid restriction, make sure you stay within restricted range.</p>	<p>Record fluid intake occasionally to check that you are staying within range.</p>
<p>Be aware of changes in daily activities, such as stress, illness, or travel.</p>	<p>Use a journal to increase awareness of how activity affects fluid intake. If you choose to restrict fluids for a while to prevent leakage, it could take up to 24 hours to balance your intake again. Noticing the color and amount in cathing will tell you when you are back on track.</p>

weekends by reviewing how their activity and fluid intake varied during the week as compared with the weekend.

#### Study Nurse Consultations

The study nurse made two phone consultations about a week apart. The first contact was to teach the initial three-day self-monitoring, explaining how to use the online diary formats, including use of the personal database for storing I&O information/graphs and journal notes. The second contact was to discuss the results of the self-monitoring period; reviewing I&O data, graphs, identifying what the person noticed about how intake

affected output, activities, urine leakage, and suggesting self-management activities to prevent problems. While the entire educational booklet was reviewed, special emphasis was on issues related to balancing fluids with activity (see Table 2) and adherence to appropriate IC intervals (see Table 3). Participants were informed that they could email the study nurse with questions. The third consultation phone call was made at three months to identify additional issues and to guide the person in further self-management activities.

#### Peer-Led Online Forum Discussions

Online forums became avail-

able when three or four people were enrolled. Topics in the Discussion Forum were open-ended, allowing study participants and peer leaders to start new topics (threads) or post to already developed topics. Peer leaders guided the discussion assisted by the study nurses or principal investigator. A urologist and a urology nurse were available to answer more complex clinical questions, which were then posted by the principal investigator.

#### Mobile Phone Modification

In addition to our National Institutes of Health funding, we were fortunate to have received a substantial gift for our research

**Table 3.**  
**Balance Fluids with Activity: Promote Your Best Intermittent Catheterization (IC) Intervals**

IC should be done on the average every four to six hours, and the amount of urine should be less than 500 mL (cc). Cathing too often is irritating to the urethra, but not cathing often enough contributes to a urinary tract infection (UTI).

Quote: "I've met a lot of people who say, 'Oh, I don't want to drink a lot because I'm always worried.' I do the same thing, but I try to find certain times of the day where I can hydrate my body."

Paying Attention	Things You Can Do
<p>Become aware of your own cathing pattern. Pay careful attention to urine color and how you feel.</p> 	<p>Pay attention to cathing intervals (times of day and number of hours in between) and amounts for three days to see what your usual pattern is. If you think you might not be adhering to your best intervals, keep track of it for a few days to be sure you are on track.</p>
<p>Become aware of reasons for urine "accidents" so you can prevent them in the future. (See page on leakage.)</p>	<p>Consider whether you waited too long and your bladder was too full, you drank too much in a short time, or the bathroom was inaccessible. Sometimes more urine is produced during the night related to your position, the legs being up, and that the kidneys function better when lying down. For women, monthly hormone changes can also affect this.</p>
<p>Notice when and what you drink in the evening.</p>	<p>Withhold fluids in the evening to prevent a need to cath at night. However, some people need to wake at night to stay dry. If you avoid caffeine, you are less likely to need to void. (See page on caffeine.)</p>

Source: Copyright © Mary H. Wilde et al. Used with permission. Content should not be modified or used without permission of the first author.

from a local donor. The team decided to use these funds to develop a modification in the program for mobile phone use. This decision was based on suggestions from four pretesting study participants who tried out the website in the first six months of the study.

### Conclusion

This web-based intervention is the first known of its kind for intermittent catheter users. The intervention included a new and unique web-based interactive urinary diary, which was modified for mobile phone use, three study nurse phone call contacts, and peer-led discussion forums. The intervention will be evaluated for feasibility and usability at the conclusion of the pilot study, which is currently in progress with 30 individuals with SCI. Depending on the feasibility

assessment, further research is likely to test the efficacy of the intervention in a larger sample of people using long-term intermittent urinary catheters, with the eventual goal of wide-spread dissemination in a permanent website. ■

 Education Module

## Cystometry: outline

## Background

- Lower urinary tract dysfunction in children is encountered frequently (20-30%) in clinical practice. Some need to be evaluated by urodynamic studies following a careful history & physical examination
- The aim of urodynamic testing is to reproduce symptoms, to identify the underlying causes for symptoms, and to quantify underlying pathophysiological processes
- This section follows the guideline from ICS & ICCS on Good Urodynamic Practice

Oracle – “Pee”  
1000-2000 B. C.

<http://www.ics.org/>

## Cystometry

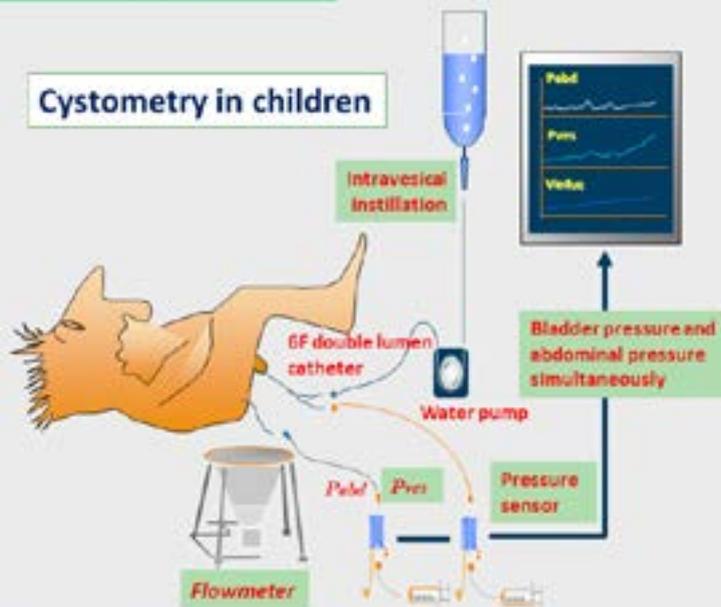

- When undertaken, cystometry is the core evaluation of pediatric urodynamic study (PUDS) in the evaluation of LUTD/LUTS
- It measures the pressure-volume relationship of the bladder during the filling
- In this module, its techniques and recording parameters will be introduced in details
- Pressure flow study & video-urodynamic studies will not be covered in this section

## Cystometry in Children

- Indicated from birth and onwards  
*primarily*
- to monitor compliance and thereby avoid potential damage to kidney function

## Cystometry: setting

ICS Education Module

## Conventional Cystometry

- 1: 6-F transurethral double lumen catheter**  
To monitor vesical pressure and for filling
- 2: 8-F (optionally balloon) catheter in rectum**  
To register abdominal pressure
- 3: Levelling the transducers both to pubic level**  
Filling rate usually 5-10% of expected bladder capacity
- 4: Electronic subtraction of abdominal pressure from vesical pressure = detrusor pressure**

ICS Education Module

## Indications

1. Suspicion of, or overt neuropathic voiding dysfunction, LUT obstruction, DSD. etc
2. Profound non-neuropathic detrusor-sphincter dysfunction (ie., dilating ureter(s), high grade vesicoureteral reflux, valve bladder syndrome)
3. Significant PVR with no apparent reason
4. Congenital malformations of the lower urinary tract (ie., exstrophy, epispadias, ureterocele, multiple bladder diverticula)

## Indications and preparation

5. The procedure is assumed to effect treatment strategies & for evaluating the treatment response or follow up
6. It is undertaken after history taking, physical examination, voiding diaries & uroflow patch EMG recordings. If these measures do not answer the questions related to causes, nor provide management schemes for LUTD

### Preparation

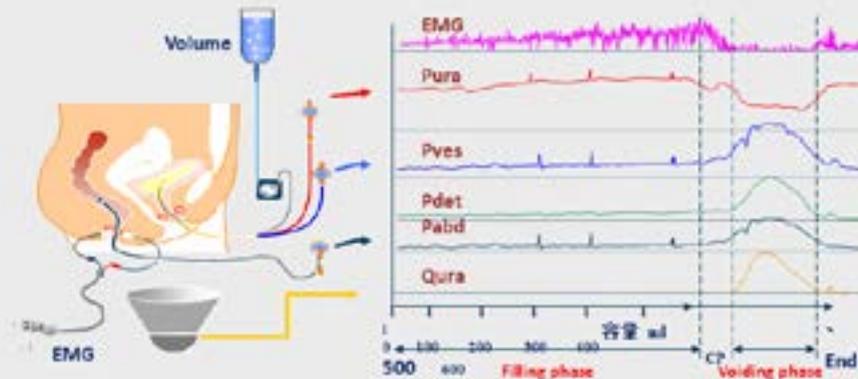

- Empty the rectum. Enema Glycerini is recommended. Severe constipation may need cleaning enema
- Drink sufficient quantities of water in order to have a full bladder for an initial uroflowmetry

Cleaning enema

## Technique: insert catheters

- Double-lumen catheter for Pves, or triple lumen catheter for Pves & Pura recording (3rd channel for filling); rectal balloon catheter for Pabd recording

ICS Education Module

## Technique: place surface electrodes

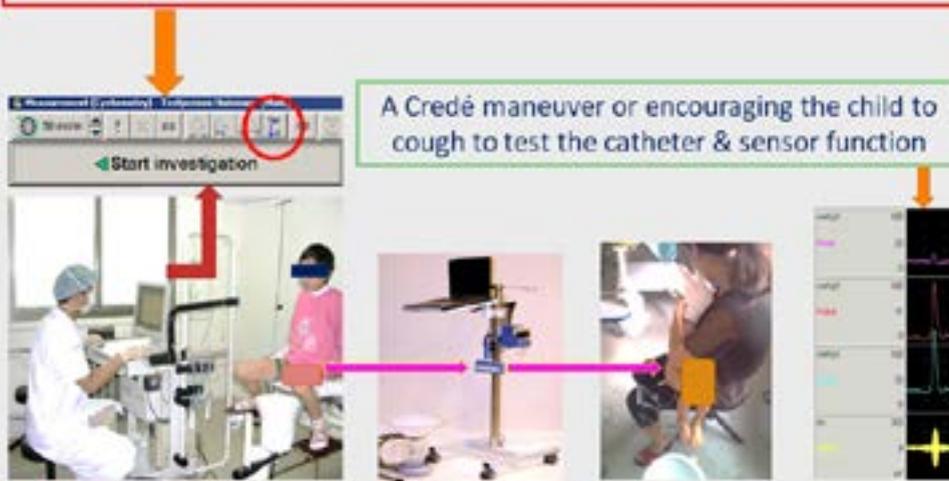

- Surface electrodes are positioned symmetrically left & right from the external anal sphincter, to record the reactivity of pelvic floor muscles

ICS Education Module

## Technique: position and zeroing the pressure

Upright or supine position – babies may be held in mother's arm. Before filling the bladder, the vesical pressure channel must be zeroed to the atmosphere with the transducer placed at the level of the pubis

ICS Education Module

## Cooperation: during filling

- To build the lab so it looks like a kindergarten, and e.g. animation wall with TV
- Employ dedicated & knowledgeable staff able to give children an explanation of the procedure and aim of the urodynamic study. If possible, engage the infants to cooperate
- Have a well cleansed rectum
- After inserting the catheter in the bladder, if the child is still agitated, engage parents to help to keep him/her calm

Animation wall

To avoid cry

Start until calm

ICS Education Module

## Cooperation: during filling

- The urodynamic evaluation approach should start with as minimally tests as possible, ending up with the invasive investigations, if needed
- Toys, eating or drinking, reading, allow mother to be present, during the examination
- Apply 1% lidocaine jelly or other topical anesthetic solution instilled into the urethra to aid in catheter passage
- Administer sedative if necessary but not an anesthetic, & document if child is very fearful

toys

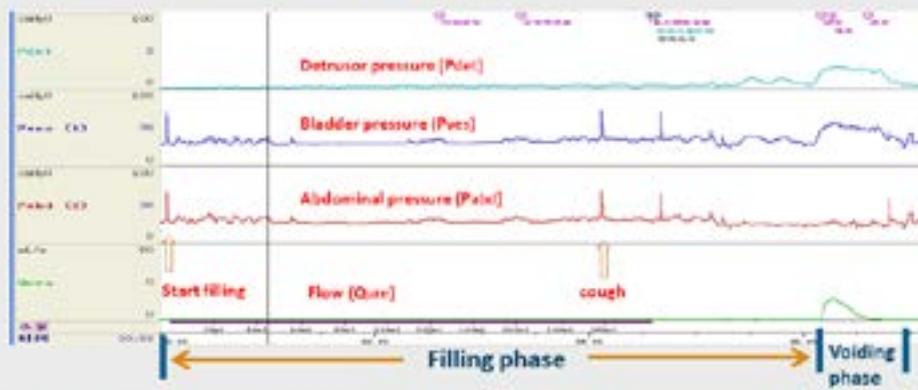

Drinking

Mother with child

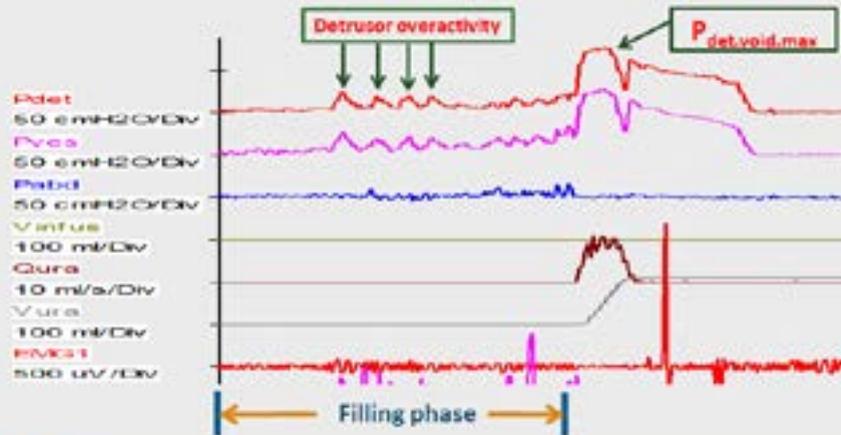

## Interpretation: filling pressure

- $P_{det}$  increases initially ( $< 5 \text{ cm H}_2\text{O}$ ) immediately at the start of filling, & incrementally with further filling of the bladder, it reaches a maximum just before the urge to void (normally,  $< 15 \text{ cmH}_2\text{O}$ ).

## Interpretation: detrusor overactivity

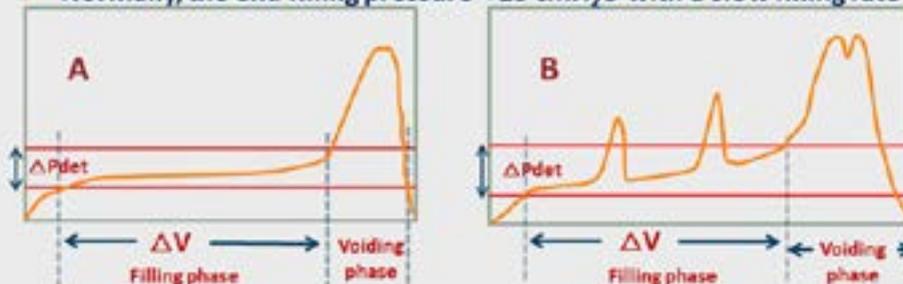

- Detrusor overactivity indicates a detrusor contraction that occurs during the filling phase **before expected bladder capacity is reached &**, which may occur in 10% of normal children. While in children with VUR, it may be seen in more than half of the infants

ICS Education Module

## Interpretation: detrusor compliance ( $\Delta C$ )

- $\Delta C = \Delta V / \Delta P_{det}$  – measures the visco-elastic properties of the bladder  $\Delta C < 10 \text{ ml/cmH}_2\text{O}$  indicates decreased bladder compliance, which may due to decreased bladder capacity or increased  $P_{det}$  or both
- Normally, the end filling pressure  $< 15 \text{ cmH}_2\text{O}$  with a slow filling rate

A: The non-linear portions - the beginning & end of the V/ $P_{det}$  diagram do not contribute to compliance. B:  $\Delta V / \Delta P_{det}$  essentially captures the angle of the line describing the incremental increase in resting pressure

ICS Education Module

## Interpretation: estimated bladder capacity based on age

Bladder capacity (BC), post-void residual (PVR), maximum detrusor pressure during voiding ( $P_{max, det, void}$ ) in the literatures

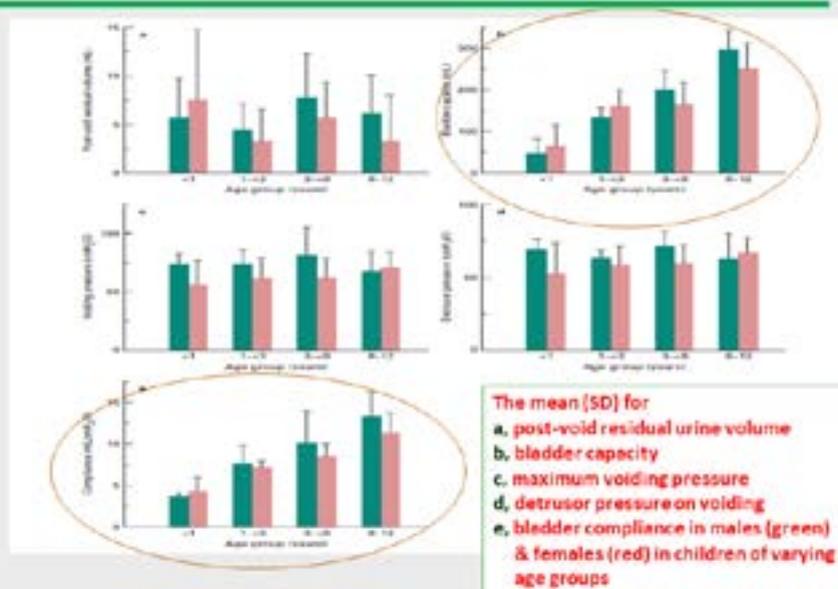

Age	BC (ml)	PVR (ml)	$P_{max, det, void}$ (cmH <sub>2</sub> O)
<b>Neonatal</b>			
Premature Infant (<0.5~7w)	13.2 ± 4.9	1.5 ± 1.0	—
Term Infant (<4w)	22.6 ± 7.8	1.4 ± 1.1	—
Term Infant (1w)	24.6 ± 10.9	1.4 ± 1.1	—
Term Infant (2w)	23.6 ± 8.7	1.2 ± 1.0	—
<b>Infant</b>			
3 month	53 ± 13	5.7 ± 4.5	50~75
12 month	70 ± 30	7.1 ± 6.3	41~66
24 month	79 ± 31	6.6 ± 7.0	38~60
36 month	128 ± 72	3.3 ± 5.3	38~55

Expected capacity (ml) = 30 + (age in years × 30) in a child > 1 year of age;

Expected capacity (ml) = 38 + 2.5 × age (months) for infants < 1 year old

ICS Education Module

## Interpretation: bladder capacity, compliance

From Wen, et al. British Journal of Urology 1998 81, 468-73

ICS Education Module

## Interpretation: estimate sensation of filling

- Evaluating sensation of filling depends on both verbal or non-verbal signs, such as movement of the feet, awakening from sleep, a sudden cry. Bladder filling should be stopped when the filling pressure exceeds 40 cm H<sub>2</sub>O
- In older children, ask them to hold & not void at their first sensation to void, especially if expected or known maximum bladder capacity has not been reached
- For newborn & infants < 1year, it is difficult to identify the sensation of bladder filling; however, it is easy to generate urination during the cystometry in these children

Verbal  
communication

ICS Education Module

## Conclusions

- Cystometry with an initial 'free' uroflowmetry is a useful tool to evaluate the LUT function in children
- It should be considered as one procedure, but not the only one, to clarify the diagnosis & to make therapeutic decisions as well as for follow up
- To understand the findings at cystometry, normal voiding parameters as well as following ICS & ICCS recommendations are the basis of successful testing

ICS Education Module

# ICS educational module: Cystometry in children

 Email: wenjg@hotmail.com

**Aims:** To introduce the standard procedure of cystometry and interpretation of the results in children.

**Methods:** The literature on cystometry in children in PubMed for the last 20 years was reviewed. The updated knowledge regarding indication, preparation, technique, and interpretation of cystometry in children were summarized.

**Results:** Filling cystometry is the core content of a paediatric urodynamic study. In this section, the technique for performing cystometry is introduced in details. Emphasis is placed on correctly setting up the equipment according to ICS and ICCS guidelines, using appropriate terminology, providing indications for its performance with specific considerations for children, and proper interpretation of results.

**Conclusions:** Cystometry can be used in children including newborn to evaluate lower urinary tract dysfunction.

## KEYWORDS

children, cystometry, procedure, urodynamics

## 1 | INTRODUCTION

The International Continence Society (ICS) and International Children Continence Society (ICCS) define filling cystometry as the urodynamic procedure by which the pressure-volume relationship of the bladder is measured. Filling cystometry is done to provide information on storage function (detrusor activity, sensation, compliance, and cystometric capacity). Filling cystometry in children is usually performed in combination with perineal EMG skin electrodes to add information regarding pelvic floor striated muscle activity.<sup>1-4</sup> On rare occasions needle electrodes are inserted into the pelvic floor musculature to precisely define denervation in patients with neurogenic bladder dysfunction.

The ICS educational module consists of an oral presentation in combination with this manuscript, the latter serving as a scientific background review; the evidence gathered for the ICS PowerPoint presentation is available via <http://www.icsoffice.org>. The presentation explains when and how to do a filling cystometry and how to analyze the results in children.

Filling cystometry is the core content of a paediatric urodynamic study. In this section, the technique for performing cystometry will be discussed in detail. Emphasis will be placed on correctly setting up the equipment according to ICS and ICCS guidelines,<sup>2-4</sup> using appropriate terminology, providing indications for its performance with specific considerations for children, and proper interpretation of results.<sup>5</sup> Other elements of a urodynamic investigation, for example, pressure flow study or video-urodynamic study will be covered in specific educational modules.

## 2 | INDICATIONS AND PREPARATION

Filling cystometry is indicated when history and clinical examination raises a suspicion of either anatomic and/or neurologic lower urinary tract dysfunction involving primarily the storage phase, or there is a question that cannot be answered by less invasive testing. Additionally, filling cystometry is relevant when anatomical or functional bladder

outflow obstruction (voiding phase) (eg, valve bladder syndrome, detrusor-sphincter dyssynergia associated with neuropathic bladder), or congenital anomalies of the bladder (exstrophy, ureteroceles, multiple bladder diverticula) may be causing symptoms and signs of dysfunction that may need further delineation.<sup>6</sup> When a urodynamic investigation is ordered the patient and/or his/her parents should fully understand the reason(s) for the test. It is assumed results of the investigation will define pathophysiology and influence treatment strategies. When constipation exists, it should be managed according to set guidelines before cystometry is undertaken. Having an empty rectum before the urodynamic study is advantageous as this allows for accurate monitoring of abdominal pressure and hence detrusor pressure.

Apart from a comprehensive history and complete physical examination, a voiding (or catheterization) diary, uroflowmetry, and post-void residual volume, as measured by ultrasonography, are to be conducted before ordering this invasive urodynamic study. In children, more than one uroflowmetry is strongly suggested to establish with certainty the necessity of an invasive study.<sup>1,2</sup> The child is advised to arrive at the urodynamics suite with a full bladder if possible and the examination starts with a free uroflowmetry. This is best accomplished by adequate but not excessive hydration beforehand and/or appropriate timing of a previous void so the bladder is relatively full at the time the child arrives at the urodynamics facility.

The (parents and) child should be instructed that all lower urinary tract modulating medications be taken either at a set time before the study or stopped at a sufficient interval to minimize their effect. Depending on the reason for the study, it should be however decided individually whether to continue or to stop medication (eg, in follow up evaluation). For children who are anxious or fearful beyond consolation, administration of a sedative (not anesthetics) may be considered but its timing and dose should be documented.

### 3 | TECHNIQUE

Current guidelines recommend multichannel fluid filled pressure recordings for filling cystometry as the standard in children. This educational module combines ICCS and ICS standards, into practical protocol elements to perform cystometry.

As the documents related to the tip-transducer or air-charged catheter used in pediatric urodynamic studies are limited and the pressures measured using air-charged catheters, microtip catheters are not readily comparable with fluid-filled systems, also in pediatric urodynamic studies fluid-filled systems are considered the ICS standard.

#### *Inserting the catheter and placement of surface EMG electrodes*

- (1) A transurethral catheter is used to measure the pressure within the bladder. A 6 Fr double-lumen catheter that allows both filling and recording of pressure is recommended. The catheter is inserted after applying lubricating gel. No evidence exists regarding how well this gel acts as an anesthetic in children. In some facilities, a suprapubic double lumen catheter is inserted following administration of a short anesthetic the day before the test.
- (2) The transurethral urodynamic catheter can be used to empty the bladder before starting the cystometry; if a relatively large volume is measured ultrasonographically or expected, it may be helpful to empty the residual by aspirating the bladder via the urodynamic catheter.
- (3) A completely fluid filled open 8-Fr. feeding tube or a small air-free fluid filled balloon catheter is inserted into the rectum to record abdominal pressure.
- (4) Both transurethral and rectal catheters should be secured with tape adjacent to their respective skin openings. After insertion, the catheters are attached, via connecting tubes, to the external pressure transducers and leveled to the height of the pubic symphysis.
- (5) After cleaning the skin two surface EMG electrodes are positioned symmetrically, left, and right from the external anal sphincter, to record reactivity of pelvic floor muscles. No specific evidence regarding skin preparation to reduce impedance or electrode placement is available.<sup>2</sup> A third reference electrode should be placed at an electrically neutral position; preferably over a bony prominence and not an abdominal or leg muscle.

#### *Position and zeroing the pressure*

- (6) Filling cystometry is preferably best performed in a seated position; however, lying supine or an infant held in mother's arm is also acceptable.
- (7) Before filling the bladder, the bladder pressure channel must be zeroed to atmospheric pressure with the transducer situated at the level of the symphysis pubis, irrespective of the position of the child.
- (8) Testing the catheter and sensor: Initial resting pressure should roughly represent the weight of the abdominal contents (below the diaphragm, in centimeter "water"-column) above the pelvic floor, for example, 15-25 cm H<sub>2</sub>O. The fluid filled transurethral catheter requires some fluid in the bladder to allow for a degree of "unfolding" in order to obtain an accurate initial resting pressure. Furthermore, when using gel to insert the catheter, it should be flushed away from the pressure measuring side holes. When the child is upright the initial subtracted detrusor pressure should be close to zero. To further test catheter and sensor function in

infants the lower abdomen is gently pressed (Credé) whereas older children are encouraged to cough. The abdominal pressure rise should have a response peak similar to bladder pressure so detrusor pressure remains about zero.

- (9) Even though children usually move and/or talk during the investigation, causing pressure variations that may serve as a quality control measure during the test, regular cough “tests,” or Credé maneuvers in infants, should be promoted throughout filling to continuously check the catheters’ ability to accurately record pressures.
- (10) In children old enough (and neurologically able) to respond: the sensation of filling should be ascertained according to the ICS standard sequence, as defined by: “first sensation of filling” and subsequently and respectively, “normal desire” and “strong desire to void.” These landmarks should be indicated on the urodynamic tracing.

#### **Filling cystometry**

- (11) Based on bladder diary notations or estimating capacity based on age ( $\text{age [yrs]} + 1 \times 30 = \text{capacity [mL]}$ ) bladder filling should occur at a rate approximating 5-10% of estimated capacity per minute, using saline, as recommended by the ICCS. Apart from the bladder diary, age related and expected capacities should be kept in mind.<sup>7,8</sup>
- (12) During filling, intravesical and abdominal pressures are recorded and subtracted simultaneously to obtain true detrusor pressure. During the recording, the flowmeter is kept in position so leakage or incontinence will be shown in the uroflow tracing curve.
- (13) When voiding or leakage occurs, or a strong desire to void is expressed (movement in newborns or infants or curling of toes in older children) these observations may be interpreted as a sign of a full bladder. The filling is stopped and this event marked as the end of filling. It also represents the end of the filling cystometry. Storage function is evaluated until this point.
- (14) Subsequently, as an older child is encouraged to urinate, voiding pressures, and uroflow measurements are recorded simultaneously, thus obtaining a pressure flow study. The pressure flow study will not be discussed further here.
- (15) Directly after voiding an evaluation of the technical quality as well as the clinical representativeness of the study should be undertaken to determine whether a second filling cystometry (and pressure flow study) is necessary. Depending on the specific question being asked or the local protocol, performing a second filling cystometry may be initiated. Often at this time the child

is relaxed enough so that a more accurate tracing of the filling phase is obtained.

#### **End of test**

- (16) When the filling cystometry (and pressure flow study) is conclusive, all catheters and the EMG electrodes are removed.
- (17) Children are instructed to carry out their normal activities but advised to drink an additional water after the test to “void away” any urethral irritation as well as to reduce chances of developing a urinary tract infection.
- (18) A clinical evaluation report is completed immediately after the test to be optimally able to integrate urodynamic observations and features with clinical observations during the measurement, while still fresh in the mind of the observer.

#### **Notes:**

1. For EMG kinesiological recording, surface electrodes are widely used in children to study pelvic floor activity. Electrophysiologic standards require that the skin should be degreased and desquamated tissue removed before applying a conductive gel and the electrodes. Hooked needle electrodes can be used for kinesiological EMG recording when it is important to determine denervation in neurologically compromised individuals; however, the invasiveness of obtaining this measurement should be weighed against the expected gain from the information. Concentric needle electrodes are useful for motor unit potential analysis during urodynamic testing when it is necessary to know if new onset or progressive sacral spinal cord denervation is present.
2. For retrograde filling, 0.9% saline is recommended. In young children, temperature of the filling solution as well as the medium itself may influence bladder capacity and detrusor activity. It has been established that filling rate and fluid medium have an impact on bladder function.<sup>9</sup> It is important to use an appropriate rate of filling (5-10% of estimated bladder capacity per minute) in infants.<sup>1,5</sup>
3. A double lumen catheter has the advantage that it can stay in place (especially during voiding if adequately secured) for a second filling cystometry, if deemed necessary.
4. It is unnecessary to routinely use a warmed infusion solution for urodynamic studies in children; however, for those younger than 2 years, a warmed solution (37°C) is recommended.<sup>10</sup>
5. The best position for the child during standard cystometry is in a sitting position, watching a video or DVD surrounded by one or both parents, so as to minimize anxiety. Young children (infants) may be held in their mother's (or caregiver's) arms to achieve a meaningful evaluation. It has not been proven in children that patient position during the procedure has a significant and

clinically relevant effect on cystometry. However, this has been proven in adults, patient position during the procedure plays a significant and clinically relevant role.<sup>11</sup>

6. The study should not be performed under general anesthesia; intranasal midazolam may be administered in certain situations, as it does not appear to have a significant effect on outcome.<sup>12</sup>

## 4 | INTERPRETATION

### *Parameters during the Filling Phase*

1. The filling detrusor pressure ( $P_{\text{det,fill}}$ ) means the detrusor pressure during filling. The maximum detrusor filling pressure ( $P_{\text{det,fill,max}}$ ) may be reported in the analysis. Detrusor compliance is calculated on the basis of the difference between the initial resting pressure and the detrusor pressure at cystometric capacity. Any phasic pressure increments, interpreted to be caused by detrusor overactivity, should be omitted in the evaluation of the detrusor compliance calculation. It may be advantageous to stop the infusion when reduced compliance is observed to allow the pressure to “equilibrate” for a minute or two in order to uncover artificially reduced compliance, which is sometimes observed as a consequence of too rapid filling rate.
2. Phasic detrusor pressure increments of any amplitude, during the filling cystometry (until end of filling and permission to void is given) are defined as detrusor overactivity. Detrusor overactivity may arise spontaneous or be provoked by a cough or Credé. When history and/or clinical examination have confirmed a relevant neurologic abnormality the term neurogenic detrusor overactivity is used.<sup>1-4,13</sup> Otherwise, idiopathic detrusor overactivity is the preferred term.
3. Detrusor compliance (compliance =  $\Delta V/\Delta P$ ) is an important parameter to note during cystometry. It represents detrusor elasticity or volume adaption. A value of  $<10 \text{ mL/cm H}_2\text{O}$  indicates low bladder compliance. Assessing the entire pressure curve during filling in this regard may determine when it is best to measure. The  $\Delta P$  represents the detrusor pressure difference until just before voiding (or pressure at the end of filling); consequently, compliance will represent the overall bladder compliance, from start to a completely full bladder. It has been suggested that quartiles of compliance measurements during filling be considered. The filled volume does not take into account the amount of actual diuresis occurring during the test. To integrate this volume the cystometric capacity and filling phase compliance should be calculated using voiding volume plus PVR measured immediately after voiding or emptying.

4. Incontinence is defined when any loss of fluid during the filling phase is detected. In children unable to void willingly, fluid loss occurring before the expected bladder capacity is also called incontinence (as opposed to physiologic—normal but uninhibited—voiding when it occurs at “normal for age” capacity).
5. Leak point pressure (LPP) indicates the pressure at which leakage occurs. Detrusor leak point pressure (DLPP) indicates the lowest value of detrusor pressure at which leakage is observed in the absence of increased abdominal pressure or a detrusor contraction. Abdominal leak point pressure (ALPP) refers to measures of the lowest value of intentionally increased intravesical pressure that provokes urinary leakage in the absence of a detrusor contraction. High DLPP (eg,  $>40 \text{ cm H}_2\text{O}$ ) is usually induced by a decrease in bladder compliance and/or detrusor underactivity, is associated with upper urinary tract deterioration.<sup>1,5</sup> Low DLPP indicated urethral incompetence.<sup>1,5</sup> Techniques and evaluation are not further standardized in this document describing filling cystometry.
6. Bladder filling sensation should be reported, on the basis of observations during the test or, when applicable, on the basis of the child's report. ICCS standard terms in this regard apply also for children.<sup>1,2,6</sup>

## 5 | RECOMMENDATIONS

Based on standards and clinical practice guidelines, the results of complete patient history, comprehensive clinical examination, bladder diary, uroflowmetry, and PVR should be available before considering a filling cystometry (and/or other invasive urodynamic tests).

Filling cystometry is preferably done with a 5-6Fr double lumen catheter and at a filling rate of  $\pm 10\%$  per minute of a diary determined maximum or age—expected bladder capacity.

Filling cystometry should be performed in the sitting position. When relevant medication or sedation is used it should be accounted for while evaluating the filling cystometry and be included in the report. In addition, it is important to note the time of last administration of medication in relation to the start of the cystometrogram, in order to determine the influence of any bladder modulating medication. Immediate evaluation of the test (before removing the catheters) should be done to determine technical quality and clinical relevance, as well as the ability to answer the clinical question that prompted the investigation, initially.

## 6 | CONCLUSION

To understand the characteristics as well as following good urodynamic practice (GUP), recommendations from the ICS

and ICCS are the basis of successful testing. This educational module provides recommendations for good clinical practice to completing filling cystometry in children using these standards. This narrative manuscript is based on expert consensus about the information contained in the existing literature. We hope that this teaching module will also serve as a challenge to improving (evidence-based) practice.

## Pressure flow study: outline

## Background

- Pressure flow study (PFS) is an important tool to evaluate the voiding function in children with lower urinary tract dysfunction (LUTD)/lower urinary tract symptoms (LUTS)
- PFS is defined as measuring the detrusor pressure & uroflow during the micturition or voiding phase. It begins when the child & the urodynamicist decide that 'permission to void' has been given or when uncontrollable voiding begins
- This section follows the guideline from ICS & ICCS on Good Urodynamic Practice

<http://www.ics.org/>

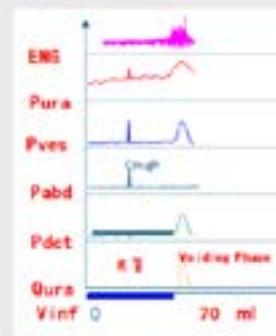

Oracle – “Pee”  
1000-2000 B. C.  
In China

ICS Education Module

## Pressure flow study (PFS)

- PFS has become the gold standard in assessing LUTD/LUTS
- During PFS  $Q_{max}$ , voided volume & detrusor pressure are recorded
- During voiding the either detrusor or urethral sphincter may be classified as normal, underactive, or overactive
- PFS can be obtained subsequent to filling cystometry with no specific additional equipment (apart from a flowmeter).

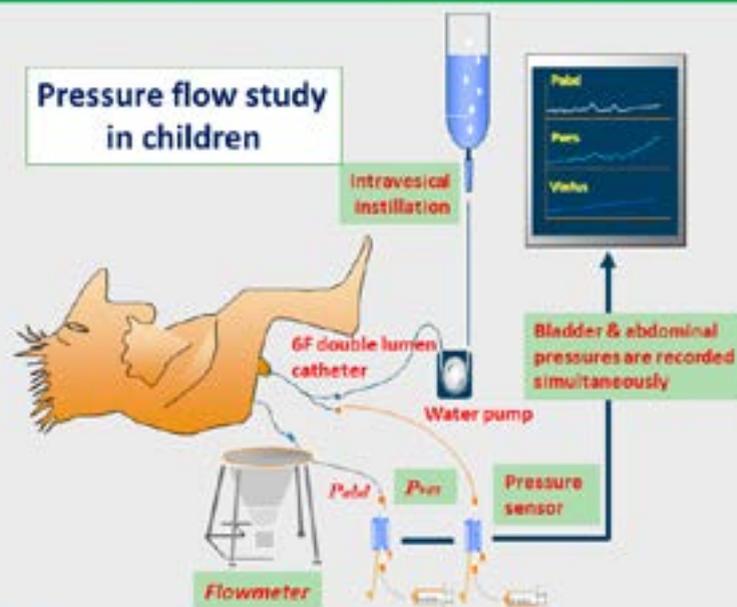

ICS Education Module

## Indications

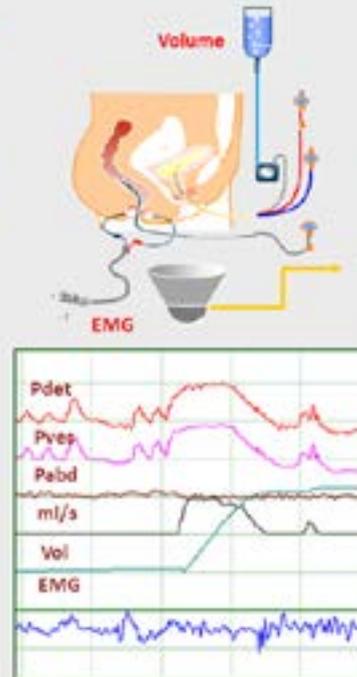

- Congenital malformations of the lower urinary tract (i.e., exstrophy, epispadias ureteroceles, multiple bladder diverticula)
- The procedure must have an impact on treatment strategies
- It is undertaken after history taking, physical examination, voiding diaries & uroflow/patch EMG recordings, if these measures do not answer the questions related to causes, nor provide effective management schemes for LUTD

## Technique: the setting is the same as in cystometry

## Technique: voiding phase

- The voiding is initiated when the urodynamicist allows, or when uncontrollable voiding begins
- During the recording a flowmeter connected to the urodynamic equipment allows flow rate parameters to be juxtaposed against pressure data & correlated with one another

ICS Education Module

## Technique: parameters recorded during voiding phase

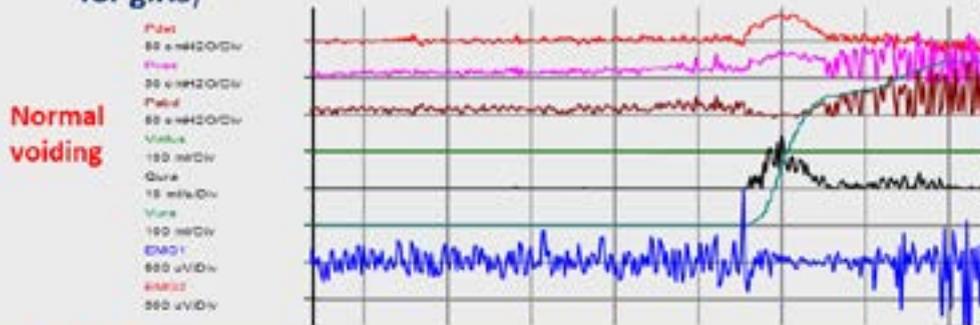

The terminology of voiding phase

ICS Education Module

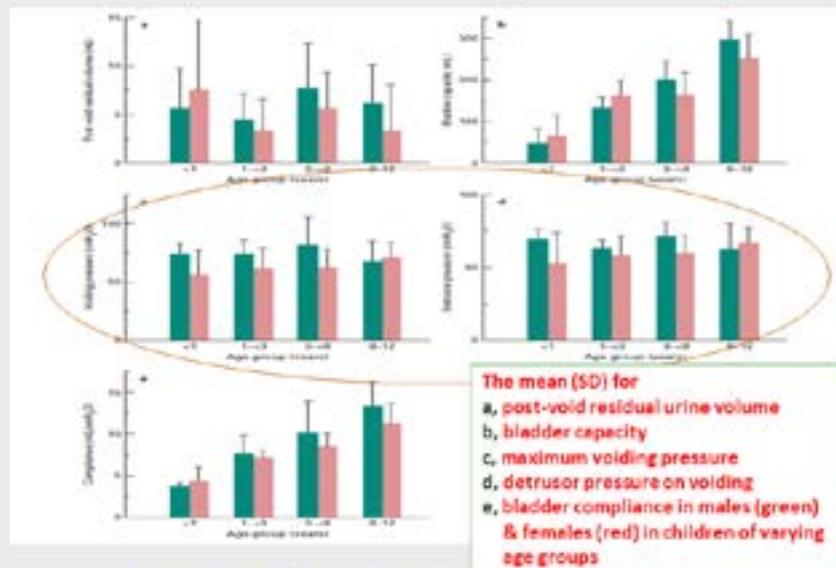

## Interpretation: normal voiding detrusor function

- Normal voiding is achieved by a voluntary, continuous detrusor contraction which leads to complete emptying of the bladder within an acceptable time span
- If the DSD occurred during the voiding, the  $P_{\text{detr,void,max}}$  is higher than that of adults (118 - 127 cm H<sub>2</sub>O for boys & 72 - 75 cm H<sub>2</sub>O for girls)

ICS Education Module

## Interpretation: voiding pressure

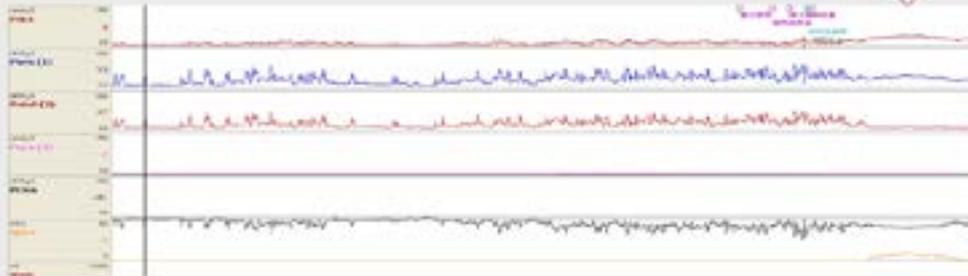

From Wen, et al. British Journal of Urology 1998 81, 468-73

ICS Education Module

## Interpretation: detrusor underactivity (DU)

DU is defined as a contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within the normal time span. This often results in an increase of PVR on the completion of voiding.

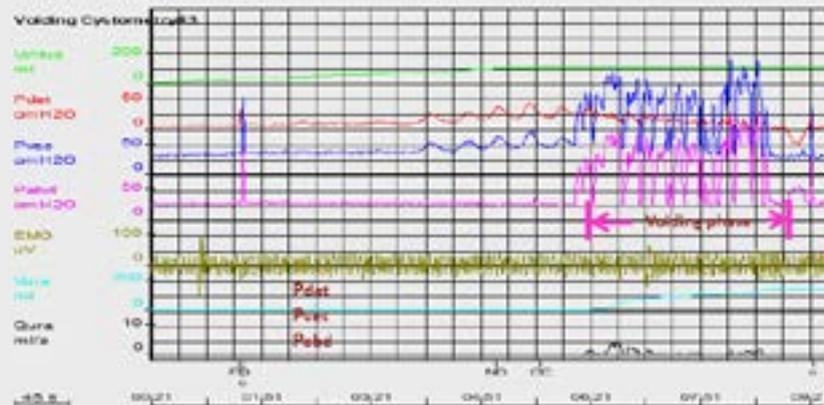

Detrusor underactivity (arrow)

ICS Education Module

## Interpretation: acontractile detrusor

An acontractile detrusor displays decreased contractile activity during urodynamic assessment

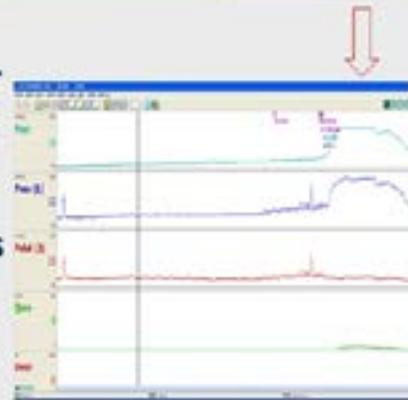

Acontractile detrusor in a child with neurogenic bladder; urination achieved by increasing abdominal pressure

ICS Education Module

## Interpretation: voiding phase

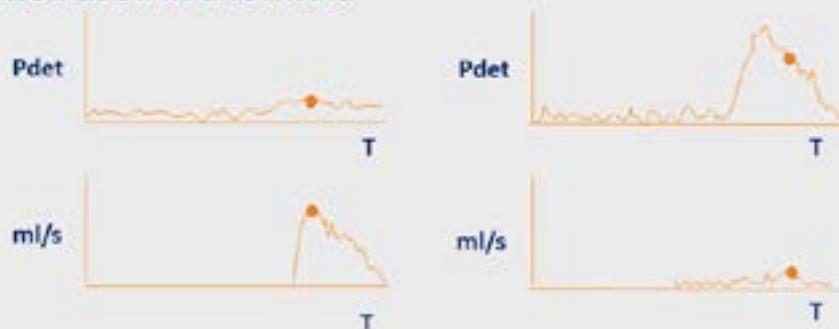

- The voiding efficiency is calculated by functional bladder capacity ( $V_{\text{fun.max.cap}}$ ) / maximum bladder capacity ( $V_{\text{max.cap}}$ )
- High voiding detrusor pressures which may be induced by significant resistance as is seen in BOO. Conversely, if urethral resistance is low this may be reflected by a low pressure contraction

High voiding detrusor pressure with low  $Q_{\text{max}}$  (arrow)

## Interpretation: voiding phase

Pressure at maximum flow, in combination with corresponding maximum uroflow, give a clinically relevant grading of bladder outlet with obstruction when used in a formula

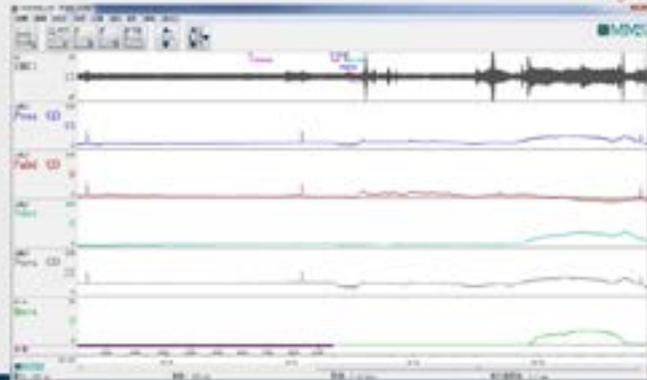

Without obstruction

Obstruction

## Interpretation: voiding phase

- DSD during voiding: a sustained or increased response or intermittent changes in urethral sphincter activity during the voiding phase
- DSD is common in infant boys. High  $P_{det,void,max}$  in infants or a staccato detrusor pressure curve during voiding indicates the existence of DSD

An increased response in urethral sphincter activity during the voiding phase (Arrow)

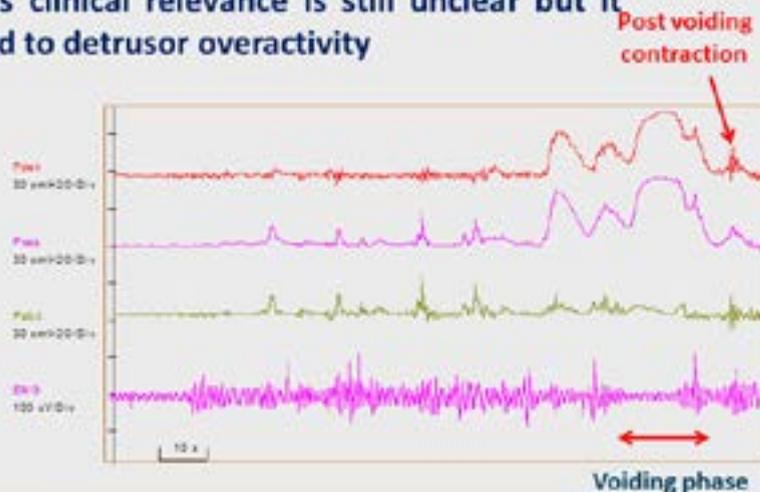

ICS Education Module

## Interpretation: voiding phase

A post voiding contraction indicates a detrusor contraction which occurs immediately after micturition has ended. Its clinical relevance is still unclear but it may be related to detrusor overactivity

A 2.5 months old baby with normal voiding

ICS Education Module

## Interpretation: how to exclude the artifact

- The parameters of free flow measurement such as the PVR & maximum flow rate are useful tools to be compared with the flow pattern during PFS. If the flow rate & PVR show big difference from that obtained from PFS, it indicates that artifacts may exist.
- For example, the flow rate was lower & the PVR substantially higher significantly compared to these parameters from the free flowmetry (before catheterization), the PFS results may be not representative of **“obstructed”, or “underactive” or “DSD” or “dysfunctional”**.

## Conclusions

- PFS is an useful tool to evaluate lower urinary tract function in children
- Investigators must keep in mind that normal bladder capacity increases with increasing age. DSD is common in infant boys so high  $P_{\text{detr.void.max}}$  is often seen
- To understand the characteristics in PFS, knowing normal voiding parameters as well as following ICS & ICCS recommendations are the basis of successful testing

**Aims:** To introduce the standard procedure and results interpretation of pressure/flow study (PFS) in children.

**Methods:** The literature on PFS in children in PubMed for the last 20 years was reviewed. The updated knowledge on PFS in children regarding indication, preparation, technique, and interpretation were summarized.

**Results:** This educational module explains when and how to do a PFS and how to analyze the results. All requirements and instructions for the PFS in children described in this document follow ICS reports on Good Urodynamic Practice and urodynamic equipment performance as well as guidelines from the ICCS. PFS can be obtained subsequent to filling cystometry with no specific additional equipment (apart from a flowmeter) or patient preparation needed. It requires both vesical and intra-abdominal pressures being recorded. Information from clinical history, physical examination, voiding diaries, and free uroflowmetry with or without perineal patch EMG and pertinent imaging results should be available before undertaking urodynamic testing.

**Conclusions:** Following ICS and ICCS guidelines, PFS is an easy procedure and a useful tool to provide information on voiding function in children.

## KEYWORDS

children, pressure/flow study, procedure, urodynamics

## 1 | INTRODUCTION

Pressure/flow study (PFS) provides information on voiding function (outflow obstruction, flow pattern, detrusor contractility, and its sustainability as well as intravesical pressure). Combined with filling cystometry, it is the gold standard for evaluating voiding function in children with lower urinary tract dysfunction (LUTD)/lower urinary tract symptoms (LUTS), especially when less invasive studies fail to provide an adequate explanation for the symptoms and/or the signs of dysfunction.<sup>1–7</sup>

The aim of pressure/flow studies is to reproduce symptoms, to identify the underlying causes for voiding symptoms, and to quantify related pathophysiological processes. It is used to establish as clearly as possible a

baseline, so that changes resulting from treatment and/or growth can be assessed, indicating that the investigation may need to be repeated, and to provide some guidelines for the choice of treatment (although results of urodynamic testing may not necessarily be the deciding factor).

The ICS Urodynamics Committee presents this educational module “Pressure/flow analysis in children” to serve as a standard education module of Good Urodynamic Practice for everyone concerned when prescribing, performing, and analyzing pressure/flow testing in general and especially in children with symptoms and signs of LUTD. The educational module consists of a presentation, in combination with this manuscript. This manuscript serves as a scientific background review; the evidence base, for the ICS PowerPoint presentation; available via <http://www.icsoffice.org/>. The presentation

explains when and how to do a PFS and how to analyze the results. The presentation and this manuscript use expert's opinion where evidence is, especially for the clinical practice aspects, unavailable and is marked with: "eo" (expert's opinion).

Voiding dysfunction is prevalent in pediatric urology practice. The subjective bias by both the child and the clinician and the considerable overlap between symptoms from varying disorders make it difficult to evaluate voiding function without employing some objective parameters. All requirements and instructions for the PFS in children described in this section follow ICS reports on Good Urodynamic Practice<sup>2,3</sup> and urodynamic equipment performance<sup>4</sup> as well as guidelines from the ICCS.<sup>5</sup> Pressure/flow measurements can be obtained subsequent to filling cystometry with no specific additional equipment (apart from a flowmeter) or patient preparation needed. It requires both vesical and intra-abdominal pressures being recorded. Information from clinical history, physical examination, voiding diaries, and free uroflowmetry with or without perineal patch EMG and pertinent imaging results should be available before undertaking urodynamic testing.

## 2 | INDICATIONS AND PREPARATION

The indications and preparation for PFS are similar to that for cystometry. Whether the child is able to void voluntarily or not, evaluation of the voiding, measured in a continuous fashion after the filling cystometry is complete, can be regarded as standard practice. The child and caregiver should be informed in advance along with an explanation as to why both phases, storage (filling), and voiding are going to be measured. The child's cooperation is explicitly sought whenever possible.

## 3 | TECHNIQUE

PFS is defined as measuring the detrusor pressure and uroflow during the micturition or voiding phase. The detrusor pressure is equal to the bladder pressure minus the abdominal pressure, thus representing the pressure produced by the detrusor. The voiding phase begins when the child and the urodynamicist decide that "permission to void" has been given, or when involuntary voiding begins.<sup>6</sup> This occurs when the maximum cystometric capacity (MCC) has been reached in children with no voiding dysfunction.<sup>7</sup> During this phase the detrusor contracts, producing voiding detrusor pressure as the bladder outlet relaxes. It is not always possible to have very young children follow instructions to void, but in older children it is.

At this phase, the detrusor pressure increases as the pelvic floor relaxes and the urethral pressure decreases resulting in

voiding. The pressures are recorded through the same catheter that is used for cystometry. During the recording, a flowmeter connected to the urodynamic equipment, allows flowrate parameters to be juxtaposed against pressure data and correlated with one another. At the completion of voiding the detrusor relaxes and the urethra/bladder outlet "closes."

During voiding the detrusor may be classified as normal, underactive, or acontractile. Normal voiding is achieved by a voluntarily initiated detrusor contraction; it is sustained and cannot be suppressed easily once it has begun. In the absence of bladder outlet obstruction, a normal contraction will lead to complete emptying.<sup>6</sup> When the child feels voiding is complete, this phase ends and storage phase begins again. During the voiding phase, a flowmeter connected to the urodynamic equipment, allows flowrate parameters to be juxtaposed against pressure data and correlated with one another.

During PFS  $Q_{max}$  and voided volume are recorded. Pressure parameters that can be obtained during the voiding phase are: pre-micturition pressure, opening pressure, opening time, maximum detrusor pressure, detrusor pressure at maximum flow, closing pressure, minimum voiding pressure. The maximum detrusor pressure ( $P_{det,max}$ ) is clinically relevant in determining the presence of bladder outlet obstruction (BOO) or contractile detrusor.

After the PFS, the PVR is measured again through the catheter and confirmed by ultrasound.

### 3.1 | Cooperation

Cooperation is important for successful cystometry and PFS. The following steps might be valuable for achieving this.

- Bowel or rectum preparation; defecation (at home) before the test whenever possible.
- Dedicated and knowledgeable staff able to provide an explanation about the procedure and the aim of urodynamic studies to the patient is paramount: if applicable, engage the child to increase cooperation.
- Administration of sedatives (not anesthetics), and documenting if the child was very fearful is mandatory.
- Prior application of 1% lidocaine jelly or a liquid solution instilled into the urethra as a topical anesthetic may aid in catheter insertion.
- The approach to urodynamic evaluation should be, start with as minimally invasive tests as possible and proceed with invasive investigations, as necessary, to answer the question.
- If the child is still agitated after inserting the catheter in the bladder, having parents present to help calm their child, is advisable.
- Toys, video games, or movies during the examination are very helpful to distract the child and minimize artifact.

- Two cycles of cystometry and PFS to determine the consistency or representativeness of findings is preferable.

#### 4 | INTERPRETATION

The aim is to analyze accurately, and to critically report results after carefully performing the PFS in children.

1. Normal voiding detrusor function- Normal detrusor function is characterized by an initial (voluntary) relaxation of the external urethral sphincter/pelvic floor followed immediately by a continuous detrusor contraction that leads to complete bladder emptying within a normal time span, in the absence of obstruction.
2. Maximum voiding detrusor pressure ( $P_{\text{detr-void,max}}$ ) should be reported and related to the flowrate to determine diagnosis. The flowrate should be compared to the free flowrate as one means of evaluating the representativeness of the (pressure/flow) voiding.
3. Detrusor-Sphincter Dyssynergia (DSD): describes a detrusor contraction concurrent with an involuntary contraction of the urethral and/or periurethral striated muscle. Occasionally the flow may be prevented altogether  
.. DSD is usually evaluated by a pressure/flow/EMG study or with simultaneous bladder/urethral pressure recordings. High  $P_{\text{detr.void,max}}$  in infants or a staccato detrusor pressure curve during voiding when flowrate reductions are synchronous with detrusor pressure increments indicate the existence of DSD.
4. PVR > 20 mL or > 15% of bladder capacity (BC) in children age 7-12 years and > 30 mL or > 21% BC for children 4-6 years on two consecutive uroflows indicates an abnormality.<sup>8</sup> The uroflow is considered normal if the bladder empties at least once during two uroflow measurements. If a low PVR is demonstrated during free flow uroflowmetry then any raised PVR during the urodynamic assessment can be considered as an artifact due to the artificial circumstances of the test and the presence of an in-situ urethral catheter.
5. Detrusor underactivity is defined as a voiding contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span.<sup>8</sup> Pressure flow nomograms or calculations are needed to quantify detrusor contractility. Detrusor underactivity may occur with or without an elevated PVR.
6. An acontractile detrusor does not demonstrate any contractile activity during urodynamic assessment. Some children, however, cannot or will not generate a detrusor contraction in a "laboratory" setting. This could be mistaken for a diagnosis. Spending extra time

encouraging the child to void, dripping water on the pubic area, or lower extremity and/or having the mother or caregiver encourage the child to void, helps in the process to induce the child to urinate.

7. A high voiding detrusor pressure (usually > 74 cmH<sub>2</sub>O in boys, 63 cmH<sub>2</sub>O in girls<sup>7</sup>) with a low urine flow indicates BOO; low pressure with a low flow indicates underactive detrusor. A pressure flow plot is useful to evaluate the pressure flow relationship in this regard, although clinical calibration is not yet available for children.
8. High voiding detrusor pressures may be induced by significant resistance as is seen in BOO where the detrusor compensates for BOO. Conversely if urethral resistance is low this may be reflected by a low pressure (high velocity) detrusor contraction.
9. A post voiding contraction indicates a detrusor contraction that occurs immediately after micturition is complete. Its clinical relevance is uncertain, but it may be related to detrusor overactivity and/or a sign of CNS dysfunction as well as collapsing mucosa on catheter pressure channel openings.
10. Bladder voiding efficiency (BVE) = (voided volume/total bladder capacity) × 100%.<sup>9</sup>
11. Cystometry volume parameters can be corrected for any diuresis during the test after pressure flow study by immediately recording the PVR and adding it to the voided volume.

The parameters of free flow measurement such as the PVR and maximum flowrate are useful for determining the accuracy of the flowrate and PVR obtained from PFS. If the flowrate and PVR show substantial differences from those obtained during PFS, it indicates an artifact may exist. For example, if the flowrate is lower and the PVR, significantly higher compared to that obtained from free flowmetry (before catheterization), the PFS results may be not representative.

#### 5 | CONCLUSION

PFS is a useful tool for evaluating lower urinary tract function in children. It should be considered as one procedure, along with a "free" voiding uroflowmetry and filling cystometry, but not the only one, to clarify the diagnosis and to make therapeutic decisions as well as to follow up treatment responses to the voiding dysfunction, when less invasive studies are inconclusive. To understand the characteristics in PFS, normal voiding parameters as well as following GUP recommendations from the ICS and ICCS are the basis of successful testing. We present the evidence background for the PowerPoint presentation, to be used for educational the practice of the test, as is available on the ICS website.

## 6. ICS GLOSSARY

Welcome to the ICS Glossary of Terminology. Find the latest terms standardised by ICS.

Please also visit [www.ics.org/glossary](http://www.ics.org/glossary) to browse by glossary section, by letter or search to find the terms and appropriate reference you need to cite in your work.

You may download from the online Glossary: (i) the full published document behind the most recent reference for each term; (ii) earlier references for each term.

**Bernard Haylen**  
ICS Glossary Editor

### A

#### **Abdominal leak point pressure (ALPP - cm H2O)**

##### *Investigation*

This is a dynamic test. It is the intentionally increased abdominal pressure that provokes urine leakage in the absence of a detrusor contraction.

#### **Abdominal Leak Point Pressure (female) - ALPP - cm H2O**

##### *Investigation*

Abdominal leak point pressure (abdominal LPP): This is a dynamic test. It is the lowest value of the intentionally increased intravesical pressure that provokes urinary leakage in the absence of a detrusor contraction.<sup>32</sup> The increase in pressure can be induced by a cough (cough LPP) or Valsalva (Valsalva LPP). Multiple estimates at a fixed bladder volume (200–300 ml) are desirable. Catheter size will influence LPP values and should be standardized. LPP values might also be affected by many other factors such as the technique to confirm urine loss, location of catheter, type of pressure sensor, bladder volume, rate of bladder filling, and patient position. A low abdominal LPP is suggestive of poor urethral function.

#### **Abdominal Massage**

##### *Conservative Management – Female*

Therapist or self-directed massage of the abdominal wall with the aim of stimulating peristalsis and relieving the symptoms of constipation. Generally the technique follows the ascending, transverse and descending colon to aid emptying. The effect may be mechanical or sensory.

#### **Abdominal Pressure Catheter for Urodynamics**

##### *Investigation*

'flaccid filled' punctured balloon in the rectal ampulla are used to measure abdominal ('perivesical') pressure. vaginal or stoma placement of the abdominal pressure catheter is used alternatively only if rectal catheter placement is impossible.

#### **Abdominal pressure (p abd - female)**

##### *Investigation*

The pressure surrounding the bladder. It is usually estimated from measuring the rectal pressure, though vaginal and infrequently the pressure through a bowel stoma can be measured as an alternative. The simultaneous measurement of abdominal pressure is essential for interpretation of the

intravesical pressure trace. Artefacts on the detrusor pressure trace may be produced by an intrinsic rectal contraction.

#### **Abdominal pressure (Pabd - cm H2O) - male**

##### *Investigation*

The pressure in the abdominal cavity surrounding the bladder. Usually estimated by measuring the rectal pressure, though pressure through a bowel stoma can be an alternative. The simultaneous measurement of abdominal pressure is essential for interpretation of the intravesical pressure trace. Artefacts on the detrusor pressure trace may be produced by a rectal contraction.

#### **Abdominal signs**

##### *Sign*

Amongst numerous possible abdominal signs are: (i) Bladder fullness / retention: The bladder may be felt by abdominal palpation or suprapubic percussion; (ii) Other abdominal masses: or distension (e.g. ascites); (iii) Scars: indicating previous relevant surgery or traumas or evidence of previous radiotherapy; (iv) Renal Area: Examination for tenderness, masses.

#### **Abnormal (bladder filling) sensations**

##### *Symptom*

Complaint of an awareness of sensation in the bladder, urethra or pelvis, described with words like "tingling", "burning" or "electric shock", in the setting of a clinically relevant neurologic disorder (e.g. incomplete spinal cord lesion).

#### **Abnormal sensations - Filling cystometry**

##### *Investigation*

Awareness of sensation in the bladder, urethra or pelvis described with the words like "tingling", "burning" or "electric shock" in the setting of a clinically relevant neurologic disorder (e.g. incomplete spinal cord lesion).

#### **Abnormal urethral function during voiding - pressure flow studies**

##### *Investigation*

The urethral sphincter(s) do not relax completely or they are (temporarily) contracted during voiding, resulting in increased detrusor pressure. Bladder emptying may be complete or incomplete (PVR present).

**Absence of Vas deferens***Diagnosis*

Congenital absence of vas deferens in the hemiscrotum. It may be either unilateral or bilateral.

**Absent bladder filling sensation***Symptom*

Complaint of both the absence of the sensation of bladder filling and a definite desire to void.

**Absent bladder sensation - filling cystometry***Investigation*

No bladder sensation during filling cystometry, at least to expected capacity of 500 mL.

**Absorbent incontinence product design: Absorbent core.***Conservative Management – Female*

The absorbent core of an absorbent incontinence product is where urine is captured and stored. It is made from (a) material(s) which absorb(s) urine readily and retains it under pressure, such as when the wearer changes posture or position.

**Absorbent incontinence product design: Acquisition and distribution layer (ADL).***Conservative Management – Female*

Absorbent incontinence products often have an ADL between the topsheet (above) and the absorbent core (below). The ADL is designed to allow urine to enter the product rapidly, and spread it over a large area of absorbent core. It is not intended to absorb urine itself.

**Absorbent incontinence product design: Backsheet***Conservative Management – Female*

The backsheet in an absorbent incontinence product is a layer of waterproof material which forms the outside surface of the product, away from the wearer's body. It may be breathable.

**Absorbent incontinence product design: Elastication***Conservative Management – Female*

Elastication is often used to give an incontinence product the desired shape and to achieve a close fit with the wearer. It is commonly used in the waist belts of all-in-ones (wrap-arounds, adult briefs), pull-on pads (protective underwear), and belted pads (belted products). In pull-on pads, it may be used across much of the area of the product. It is used along the edges of the crotch region in many different designs.

**Absorbent incontinence product design: Fasteners***Conservative Management – Female*

Fasteners (Tabs) enable the front and back regions of all-in-ones and belted pads to be secured to one another, helping to hold the product in the intended shape and enable a close fit to the wearer. Fasteners/tabs are most commonly faced with an adhesive (which usually allows them to be undone and refastened to achieve the desired fit) or a hook and loop fastening system.

**Absorbent incontinence product design: Leg cuffs.***Conservative Management – Female*

Leg cuffs (standing gathers) refer to a particular kind of elasticsation which may be used longitudinally on a product near the edges of the crotch region to promote close contact with the groin on either side of the body.

**Absorbent incontinence product design: Topsheet***Conservative Management – Female*

An absorbent incontinence product is the layer of fabric which lies against the wearer's skin. It is made from a water-permeable material that allows urine to pass readily through to the acquisition and distribution layer (ADL) and the absorbent core beneath.

**Absorbent Products***Conservative Management – Female*

Absorbent products are those that have been specifically developed to help manage leakage or soiling, such as absorbent pads and pants, absorbent bed sheets and chair covers.

**Abstinence (sexual) due to pelvic organ prolapse***Symptom*

Non-engagement in sexual activity due to prolapse or associated symptoms.

**Accuracy of Uroflowmeters***Investigation*

The desired clinical accuracy may differ from the technical accuracy of a flow meter. The ICS Technical report recommended the following standards: a range of 0-50 ml/s for Qmax and 0-1,000 ml for voided volume, maximum time constant of 0.75 s ; an accuracy of 5% relative to full scale, although a calibration curve representing the percentage error over the entire range of measurement should be made available.

However, technical specifications from the manufacturers are rare and often not in accordance with ICS recommendations: this situation should be rectified .

**Acontractile detrusor - pressure flow studies***Investigation*

The detrusor cannot be observed to contract (i.e. no increase in Pdet) during urodynamic studies resulting in failure to void (CHANGED). Limited voiding may occur by straining. The possibility of "inhibition" of a detrusor voiding contraction must be considered if the man subsequently voids normally post-cystometry. An acontractile detrusor can be of neurogenic or non-neurogenic origin.

**Acute on chronic retention***Diagnosis*

An individual with chronic retention goes into acute retention and is unable to void.

**Acute Pain***Symptom*

Pain related to acute trauma, infection or other well-defined disease process.

**Acute urinary retention***Symptom*

Complaint of a rapid onset, usually painful suprapubic sensation (from a full bladder) due to the inability to void (non-episodic), despite persistent intensive effort.

**Acute urinary retention***Diagnosis*

A patient is unable pass any urine despite having full bladder, which on examination is painfully distended and readily palpable or percussible.

**Acute urinary tract infection symptoms***Symptom*

Symptoms such as increased bladder sensation, urgency, frequency, dysuria/stranguria, pain in the lower urinary tract with or without urgency urinary incontinence might suggest lower urinary tract infection. Confirmation of a UTI requires evidence of significant microorganisms and pyuria.

**Adult***Sign*

Fully grown and physically mature.

**Adult neurogenic lower urinary tract dysfunction (ANLUTD)***Diagnosis*

Abnormal or difficult function of the bladder, urethra (and/or prostate in men) in mature individuals in the context of clinically confirmed relevant neurologic disorder.

**Adult neurogenic lower urinary tract dysfunction (ANLUTD) - symptoms***Symptom*

LUTS are classified neurogenic in the presence of a relevant neurological disease ONLY.

**Aims of Clinical Urodynamics***Investigation*

The aim of clinical urodynamics is to reproduce symptoms whilst making precise measurements in order to identify the underlying causes for the symptoms, and to quantify the related pathophysiological processes. By doing so, it should be possible to establish objectively the presence of a dysfunction and understand its clinical implications. Thus, we may either confirm a diagnosis or give a new, specifically urodynamic diagnosis. The quantitative measurement may be supplemented by imaging (video-urodynamics).

**Aims of filling cystometry***Investigation*

These are to assess bladder sensation, bladder capacity, detrusor activity and bladder compliance as well as to document (the situation of and detrusor pressures during) urine leakage.

**Algometry - Algometer/Algesiometer:***Investigation*

An instrument for measuring the pain response to a pressure stimulus. An algometry device measures pressure applied in Newtons or kg/cm<sup>2</sup> with an associated patient-reported pain response.

**Algometry - Algometry tests***Investigation*

(A) Pressure pain threshold (PPT): The minimum intensity of a pressure stimulus that is perceived as painful. (i.e. point at which a sensation changes from one of pressure to one of pain).

(2) Pressure pain tolerance (PPTol): The highest intensity of painful pressure stimulus that an individual is able to tolerate.

**Algometry - assessment of intravaginal pressure pain response***Investigation*

The assessor mounts a digital palpometer (sensor) to the palpating digit, covered by examination glove, and connected to an algometry device. The device applies a pre-set amount of pressure to the tissue. To assess pressure/pain in pelvic floor tissues, the assessor applies a pre-set amount of pressure (usually in the range of 0.5–2 N), starting at a low

pressure and assesses pain response to that pressure, or applying increasing amounts of pressure and instructing the patient to state when the pressure reaches the patient's threshold.

**Algometry - assessment of vulval or vestibular pain response***Investigation*

To assess vulval or vestibular pressure pain response, the assessor uses an algometer or a syringe with a pre-loaded or pre-set amount of pressure, called a vulvalgesiometer or a cotton swab against the vulval tissue and delivers the pressure. RESULTS: may be expressed as the pressure applied when the patient reports detection or tolerance of pain, or a specific pressure applied and the patient rating of pain at that pressure. A finding of pain with a low applied pressure may suggest allodynia, and a finding of pain with a moderate applied pressure may suggest hyperalgesia. VARIABILITY in readings can be caused by: (i) anatomical test site (muscle belly vs. tendon; mucosa vs. tendon); (ii) coexistence of other pain disorders; (iii) left vs. right; (iv) stage in menstrual cycle; (v) sex and gender; (vi) rate of pressure increase during test; (vii) dimensions of the pressure applicator.

**All-in-ones ([pads], wrap-around pads, adult briefs): Defining features***Conservative Management – Female*

One-piece products in which the absorbent core and the means to hold it in place are combined in a single design, secured using adjustable adhesive tabs or a hook and loop fastening system at the sides.

**All-in-ones ([pads], wrap-around pads, adult briefs): Main variant features***Conservative Management – Female*

Products may be used by either sex, but some are intended (by their color, style, or the placing of absorbent material, for example) just for men or just for women.

- Products come with different absorption capacities, and to fit different body sizes.
- Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit and comfort and prevent leakage.
- Products may have wetness indicators.
- Products may or may not be suitable for containing fi as well as UI.

**Altered libido***Symptom*

Complaint of change in interest in sexual activity

**Ambulatory ano-rectal manometry***Investigation*

Is a test performed using solid-state catheters in ambulant subjects over an extended period of time.

**Ambulatory urodynamics***Investigation*

A functional test of the lower urinary tract for which a transurethral catheter is placed in the bladder -performed outside the clinical setting, involving natural bladder filling by drinking and continuous recording of bladder pressure (Pves) for a longer period of time (e.g. 12 hours). It can reproduce bladder function and urine loss during an individual's everyday activities.

**Anal Canal - Endoanal ultrasonography (EAUS)***Imaging*

Anal Canal - The anal canal in adults is between 2.5 and 5cm in length and begins as the rectum narrows, passing posteriorly between the levator ani. Three levels of assessment in the axial plane.

(1) Upper level: the hyperechoic sling of the puborectalis muscle (PR) and the complete ring of the internal anal sphincter (IAS).

(2) Middle level: corresponds to the superficial part of the EAS (concentric band of mixed echogenicity), the conjoined longitudinal layer, the IAS (concentric hypoechoic ring), and the transverse superficial perineal muscles.

(3) Lower level: corresponds to the subcutaneous part of the EAS where the IAS is absent.

#### **Anal endosonography (AES) - ultrasound imaging (male)**

##### *Imaging*

Anal ultrasound imaging looking for sphincter defects.

#### **Anal fissures**

##### *Sign*

Longitudinal split in the skin of the anal canal, exposing the internal anal sphincter muscle. The majority of fissures are found in the mid-line posteriorly and there may be a skin tag associated with them.

#### **Anal gaping**

##### *Sign*

Noncoaptation of anal mucosa at rest: (i) present (note location of deformity with reference to a clock-face);

(ii) Absent.

#### **Anal incontinence**

##### *Symptom*

Complaint of involuntary loss of flatus or feces.

#### **Anal laxity**

##### *Symptom*

Complaint of the feeling of a reduction in anal tone.

#### **Anal Manometry**

##### *Investigation*

Anal manometry is a test to assess the mechanical strength of the anal sphincters. A range of methods is available, including water perfused, solid state, and micro-balloon systems. The length of the canal is measured either by station pull-through or continuous pull-through. Station pull-through involves inserting the catheter to 6cm from the anal verge, withdrawing the catheter at 5–10mm intervals and measuring for 1–5min at each “station”. Continuous pull-through involves withdrawing the catheter at a set speed by hand or by a mechanical puller. As normal values can differ substantially between laboratories according to the style of catheter used, each unit is encouraged to generate its own normal data. In patients with fecal incontinence the value of manometry is: (a) To define functional weakness of one or both sphincter muscles (as a complement to anal endosonography). (b) To support findings of other tests and to monitor outcome and predict response to biofeedback training. (c) In cases where anal endosonography is not available, vector manometry may help identify anatomic defects of the anal sphincter complex. In constipated patients the value of manometry is: (a) To exclude Hirschsprung’s disease. (b) To identify and predict responses to biofeedback training (pelvic floor dyssynergia = failure to expel a water-filled balloon).

#### **Anal Manometry - Balloon expulsion pressure**

##### *Investigation*

The balloon expulsion pressure is the anal canal pressure during straining with a filled balloon in the rectum. Balloon expulsion can be performed on patients with evacuatory difficulty. An inappropriate increase in sphincter pressure on attempted voiding evacuation is usually reported as a present or absent response, rather than numerically. Such increased pressure is referred to as “anismus” or “paradoxical sphincter contraction.”

#### **Anal Manometry - Endurance Squeeze Pressure**

##### *Investigation*

The endurance squeeze pressure is the length of time the individual is able to maintain the pressure during a voluntary contraction. To assess the endurance squeeze pressure, measurements are taken during a 5–10sec squeeze (normal 5sec). Incontinent patients typically have fatigue rate of greater than two-thirds of initial pressure at the end of the sustained squeeze. By calculating fatigability, the fatigue rate (using linear regression on the mean pressure over one second periods throughout the endurance squeeze) can be derived.

#### **Anal Manometry - Involuntary Maximum Squeeze Pressure**

##### *Investigation*

A common maneuver is a maximal cough to measure this involuntary increment, usually reported as a present or absent response, rather than numerically.

#### **Anal Manometry - Maximum resting pressure**

##### *Investigation*

The maximum resting pressure is the maximum resting pressure generated in the anal canal at rest. Strictly speaking, it is defined as the difference between the intrarectal pressure and the highest recorded rectal pressure at rest. However, rectal contents may affect the accuracy of rectal pressure measurements. The internal anal sphincter (IAS) exhibits continuous tonic activity and is responsible for 55–85% of the resting anal canal pressure. Its contribution to resting tone is variable along the length of the anal canal with the proximal two thirds being more reliant on IAS tone to maintain adequate resting pressures. The range of maximal resting pressure is typically between 60 and 120cm H<sub>2</sub>O. The EAS has constant tonic activity contributing to the resting anal canal pressure.

#### **Anal Manometry - Maximum Squeeze Pressure**

##### *Investigation*

The maximum squeeze pressure is the maximum pressure generated in the anal canal during a voluntary contraction. Although the EAS contributes to the resting pressure the specific function of the EAS can be assessed during the squeeze and cough maneuvers. The pressure increment above resting pressures during these maneuvers is a direct representation of EAS function. The normal range, as stated above, varies according to measurement modality in each laboratory, but is approximately above 60 cm H<sub>2</sub>O. Typically, higher values are obtained by automated pull-through rather than station withdrawal methodologies.

#### **Anal Manometry - Rectoanal Inhibitory Reflex (RAIR)**

##### *Investigation*

The recto-anal inhibitory reflex (RAIR) a relaxation response in the IAS following rectal distension. A drop of at least 25% of resting pressure has to occur with subsequent restoration to at least two thirds of resting pressure for it to be deemed present. It is elicited by rapid insufflation and disinflation of 50mls of air into a balloon positioned in the distal rectum during anal manometry at the level of the proximal high pressure zone. This reflex is absent in Hirschsprung’s disease: of greater physiological meaning, this reflex is thought to underlie the sampling response that allows rectal content to be sensed by the anal mucosa, thus ensuring continence of flatus and stool.

#### **Anal Manometry (Advanced) - High Resolution Manometry**

##### *Investigation*

In this technique, a catheter with a large number of pressure sensors spaced less than 0.5mm apart along the length of the catheter. This allows complete definition of the intra-anal pressure environment. The resulting data is displayed on a topographical three dimensional plot to allow easier pattern recognition. It is a measurement with the variables of pressure (displayed

as the color), distance into the anal canal (y-axis) and time (x-axis). Normal ranges are slightly higher than measured with standard manometry, but the readings agree well with each other.

### **Anal Manometry (Advanced) - Vector Manometry**

#### *Investigation*

Vector manometry is a quantitative measure of radial symmetry and volume of the anal sphincter. It involves withdrawing (commonly using a mechanical puller) a radially arranged multi-channel anorectal manometry catheter through the length of the anal canal. The following parameters are identified: Radial asymmetry index (RAI) is a quantitative measure of the radial symmetry and can be calculated at any level in the anal canal but most commonly refers to the level at which the highest resting pressure is generated. The principle is that an asymmetrical sphincter is more likely to have a sphincter defect. The vector volume is the volume of the 3D shape generated and provides a value which reflects the overall length and symmetry of the sphincter.

### **Anal Plugs**

#### *Conservative Management – Female*

Anal plugs are containment devices aimed at blocking the loss of stool to control fecal incontinence. Plugs come in different designs, sizes, and compositions, such as polyurethane and polyvinyl-alcohol.

### **Anal sexual practices with body parts**

#### *Symptom*

Stimulation of the anus and/or rectum with bodily parts other than the penis (e.g., finger, fist) for sexual purposes by the recipient and/or a partner.

### **Anal Sexual practices with non-living objects**

#### *Symptom*

Stimulation of the anus and/or rectum with non-living objects (e.g., dildo) for sexual purposes by the recipient and/or a partner.

### **Anal tone**

#### *Sign*

Increased or decreased anal sphincter tone might suggest similar changes in the urinary sphincter and may indicate neurologic disease.

### **Anal wind**

#### *Symptom*

Complaint of involuntary loss of flatus (gas)

### **Anejaculation**

#### *Symptom*

Complaint of the absence of seminal fluid emission. May be associated with the absence of the sensation of orgasm or anorgasmia.

### **Anodyspareunia**

#### *Symptom*

Complaint of pain or discomfort associated with attempted or complete anal penetration.

### **Anorectal examination - female position**

#### *Sign*

The patient lies in the left lateral position with hips flexed and ankles away from the examiner. Dorsal lithotomy position could also be used.

### **Anorectal examination (female) - perianal sensation/ reflex**

#### *Sign*

In patients with possible neurogenic pelvic floor dysfunction there should be particular note of those neurological signs related to S2-4 but these

should be complimented by a more general neurological examination as indicated. Specific to ano-rectal dysfunction, assessment of anal reflex, and perianal sensation should be performed.

### **Anorectal incontinence**

#### *Symptom*

Complaint of involuntary loss of flatus or feces.

### **Anorectal incontinence**

#### *Diagnosis*

(i) Definition: a diagnosis is by symptoms and clinical examination assisted by the results of investigations (anorectal manometry) and imaging (endo-anal ultrasonography). At times, endoscopic evaluation may be required.

(ii) Sphincteric anorectal incontinence: Anal sphincter defects or weakness are present.

(iii) Urge anorectal incontinence: Incontinence is due to involuntary anorectal spasms.

(iv) Artefactual anorectal incontinence: Infective, inflammatory or neoplastic etiology is identified.

### **Ano-rectal manometry**

#### *Investigation*

Is a pressure test to assess the structure and physiological function of the anorectal complex. Water perfused and solid-state pressure transducers are used in combination with a balloon positioned in the anal canal. The most commonly used PFM parameters and findings are listed separately.

### **Anorectal Manometry - Ambulatory**

#### *Investigation*

Using solid-state catheters, prolonged ano-rectal motor events have been recorded, including in ambulant subjects. The clinical applicability of these techniques has not been established.

### **Anorectal manometry parameters - Involuntary maximum squeeze pressure:**

#### *Investigation*

The pressure (in mmHg, hPa, or cmH<sub>2</sub>O) created involuntarily by the PFM during a maximal cough. RATING: (i) Present; numerical values of pressure change may be used to further quantify; (ii) Absent; associated with fecal incontinence.

### **Anorectal manometry parameters - Balloon expulsion pressure.**

#### *Investigation*

The anal canal pressure (in mmHg, hPa, or cmH<sub>2</sub>O) during straining with a filled balloon in the rectum. RATING: (i) Increase from resting pressure suggests paradoxical contraction and is associated with evacuation dysfunction; (ii) No change; (iii) Decrease from resting pressure (normal).

### **Anorectal manometry parameters - Duration of sustained contraction MVC/ endurance squeeze pressure.**

#### *Investigation*

This is the length of time (in seconds) the individual is able to maintain the pressure during the MVC. RATING: Shorter duration suggests a lower endurance. To assess the endurance squeeze pressure, measurements are taken during a 5–10 s squeeze. By calculating fatigability, the fatigue rate (using reduction of the mean pressure over 1-s periods throughout the endurance squeeze) can be derived.

**Anorectal manometry parameters - Functional anal length***Investigation*

The length (mm) of the anal canal over which resting pressure exceeds that of the rectum. The length of the canal is measured either by station pull-through or continuous pull-through. **RATING:** Functional anal canal length has been shown to be shorter in females with fecal incontinence and longer in females with chronic constipation.

**Anorectal manometry parameters - Maximum pressure during MVC/maximum squeeze pressure.***Investigation*

This is the anal canal pressure (in mmHg, hPa or cmH<sub>2</sub>O) measured during maximum voluntary contraction (MVC) in a specific location. **RATING:** The pressure increment above resting pressure during these maneuvers is primarily a representation of EAS function. Range of normative values varies according to the particular measurement device in a laboratory. Decreased voluntary anal sphincter contraction is associated with fecal incontinence especially fecal urgency.

**Anorectal manometry parameters - Maximum resting pressure***Investigation*

The highest pressure (in mmHg, hPa, or cmH<sub>2</sub>O) along the anal canal measured in the axial plane at a specific point. **RATING:** Internal anal sphincter (IAS) (smooth muscle) is responsible for 55%–85% of the anal pressure, and is variable along the length of the anal canal with the proximal two-thirds being more reliant on IAS tone to maintain adequate resting pressures. Low anal resting pressure is associated with passive fecal soiling. High anal resting pressure may be a feature of constipation.

**Ano-rectal manometry parameters - Recto-anal inhibitory reflex (RAIR).***Investigation*

The relaxation response in the IAS following rectal distension (in mmHg, hPa, or cmH<sub>2</sub>O). It is elicited by rapid inflation to first sensation of a balloon positioned in the distal rectum during anal manometry at the level of the proximal high-pressure zone. **RATING:** (i) Present: a drop of at least 25% of resting pressure has to occur with subsequent restoration to at least two-thirds of resting pressure for the RAIR to be deemed present. This reflex is thought to underlie the sampling response that allows rectal contents to be sensed by the anal mucosa, thus ensuring continence of flatus and stool. (ii) Absent: seen in Hirschsprung disease, fecal incontinence, constipation and after anorectal surgery.

**Anorectal Neurophysiology - Pudendal Nerve Terminal Motor Latencies (PNTML)***Investigation*

The PNTML is a measurement of the delay between the electrical stimulation of the pudendal nerve and the EMG activity of the EAS. The pudendal nerve is stimulated as it passes over the ischial spine using a specially designed electrode attached to the index finger of the assessor in the rectum. The surface EMG recording electrode which sits on the base of the assessor's index finger and measures external sphincter activity. The test does not reliably reflect the pudendal nerve damage. This may be because PNTMLs measure the speed of nerve conduction, which involves the fastest nerve fibers that are least susceptible to damage. The latencies are reported as normal if below 2.2msec, but are also very operator dependent, with poor reproducibility and hence not recommended for general clinical use.

**Anorectal neurophysiology - Surface EMG***Investigation*

Electrodes placed on the skin of the perineum or inside the vagina or rectum. Surface recordings from the sphincter show increased activity with body actions and decreased activity in sleep. Needle EMG however is regarded as superior. Some centers use surface EMG as an indicator of anal sphincter activity to provide feedback for patients undergoing behavioral biofeedback training for fecal incontinence or constipation.

**Anorectal Neurophysiology (female) - Concentric fibre EMG***Investigation*

Concentric needle EMG can be used to record activity in the external sphincter and puborectalis. The responses of these muscles to voluntary contraction, coughing and straining can be displayed. The data are qualitative and compared to appearances in these muscles at rest. The muscles can also be studied at several sites to define areas of functioning muscle and identify sites of muscle injury (sphincter mapping) although this has now been superseded by anal endosonography.

**Anorectal neurophysiology (female) - single fibre EMG***Investigation*

A single fiber needle EMG technique is used to measure the muscle fiber density in the external sphincter and puborectalis. A raised fiber density indicates re-innervation in the muscles, which may occur following partial denervation. Calculating EAS fiber density is another method of assessing denervation and re-innervation of the EAS. It is used almost exclusively as a research tool. Conventional EMG can be used to quantify the re-innervation of the EAS by detecting prolongation in the duration of the motor unit potential.

**Anorectal pain symptoms***Symptom*

Complaint of pain, pressure or discomfort particularly during defecation or straining to defecate, but can occur at any time.

Pain during defecation or straining to defecate.

Inflammatory: characterized by burning or stinging

Non-inflammatory: blunted anorectal or muscular-spasm type pain

**Anorectal Pain Syndromes (Female)***Diagnosis*

1: Levator ani syndrome: Episodic rectal pain caused by spasm of the levator ani muscle. Proctalgia fugax (fleeting pain in the rectum) and coccydynia (pain in the coccygeal region) are variants of levator ani syndrome. 2: Proctalgia fugax definition: Proctalgia fugax (or Levator syndrome) is a severe, episodic, rectal and sacrococcygeal pain. It can be caused by cramp of the pubococcygeus or levator ani muscles 3: Pudendal neuralgia Pudendal Neuralgia (PN) is a painful condition that is caused by inflammation of the pudendal nerve involving its dermatome. It can affect both men and women.

**Anorectal prolapse***Symptom*

Complaint of external protrusion (bulge) of the anus or rectum (differentiation on subsequent examination between rectal mucosal prolapse and full thickness rectal wall prolapse which includes muscle and serosal layers).

**Anorectal prolapse (female)***Symptom*

Complaint of a "bulge" or "something coming down" towards or through the anus/rectum. The woman may state she can either feel the bulge by direct palpation or see it aided with a mirror

**Anorectal prolapse (female)***Sign*

Full thickness eversion of the lower part of the rectum and anal canal. The exposed mucosa is red with circumferential folds around the central pit, which is the lumen of the rectum. Look for associated utero-vaginal prolapse, fistulas, sepsis, and ulcers.

**Anorectal sensory measurements (female) - Assessment of rectal sensation to distension***Investigation*

Rectal sensation to distension is most commonly assessed by manually inflating an intrarectal domestic balloon at a rate of approximately 5ml/second. The following are elicited: Volume which elicits the first sensation of balloon expansion (threshold) [typical normal range 12–25ml], Volume to get an urge to defecate (typical normal range 35–65ml), Maximal tolerated volume (typical normal range 120–300ml) - [normal ranges for the latter two sensations are highly variable due to lack of consensus on measurement technique especially of the nature and speed of inflation of the balloon]. The pressure required to elicit these sensations can also be measured using an electro-mechanical barostat and may be more reproducible. The barostat measures the volume and the pressure required to elicit these volumes sensations. Typically distension thresholds with a barostat are higher, with larger volumes being required to elicit the same sensation. However, again, the published ranges vary widely between units: typically distension volumes 1.5 to 3 times are published for thresholds with a barostat compared to manual balloon inflation. Distension sensitivity testing is of proven value in: (a) Patients with fecal incontinence to help with biofeedback training by normalization of the initial sensation sensory thresholds. (b) Identifying visceral hypersensitivity, poor rectal compliance, or rectal irritability if maximal tolerated volumes are low. There is no evidence to support use of the sensory thresholds for diagnosis and biofeedback training of patients with constipation. Compliance testing has also not proven valuable in identifying candidates for specific therapies.

**Anorectal sensory measurements (female) - Mucosal Electrosensitivity***Investigation*

This is test to measure anal and rectal sensory thresholds. Mucosal electrical stimulation is performed using a probe with two ring electrodes between which a small electrical potential is applied generating an alternating square wave with a variable frequency. Normal ranges have been established as anal electrosensation <10mA, and rectal as <30mA. In general, prolonged anal electrosensation is suggestive of damage to the sensory fibers of pudendal nerve, and prolonged rectal electrosensation is suggestive of autonomic neuropathy.

**Anorectal Sepsis***Diagnosis*

1: Abscess Infection in a (non Crohn's) anal gland, located at the base of the dentate line, that initially forms an abscess, which can be located in one of the potential spaces surrounding the anus and rectum. 2: Ano-rectal/vaginal/perineal fistula: Rectovaginal fistula is a communication from the rectum to the vagina and rarely the perineal area. An anovaginal/perineal fistula is an abnormal communication from the anal canal to the vagina or perineal area.

**Anorectal tract: PFF diagnoses - Definition***Diagnosis*

A diagnosis made by symptoms of an anorectal, signs of extra-anal leakage of feces or flatus, assisted by a probe or irrigant fluids (dye test), with imaging as required.

**Ano-rectal/vaginal/perineal fistula***Sign*

Is an abnormal communication from the anal canal to the vagina or perineal area.

**Anorectal-vaginal fistula***Sign*

- (i) Excoriation dermatitis: Inner thighs, external genitalia, generally
- (ii) Perineum or vagina with or without skin rashes, crusting or scabbing.
- (iii) Soiling: Perianal, vaginal, or perineal fecal soiling
- (iv) Discharge: Perianal or vaginal bloody or mucus discharge.
- (v) Scars, sinuses, deformities, hematoma

**Anorgasmia or difficulty in achieving orgasm (female)***Symptom*

Complaint of lack of orgasm; the persistent or recurrent difficulty, delay in or absence of attaining orgasm following sufficient sexual stimulation and arousal, which causes personal distress.

**Anorgasmic intercourse***Symptom*

Complaint of lack of orgasm; the persistent or recurrent difficulty, delay in or absence of attaining orgasm following sufficient sexual stimulation and arousal, which causes personal distress.

**Anoscopy of proctoscopy***Investigation*

This is the inspection of the anal canal to identify anal fissure, fistula, or hemorrhoids as a cause of anal symptoms.

**Anterior enterocele***Sign*

Hernia of peritoneum and possibly abdominal contents into the anterior vaginal vault, most commonly after prior reconstructive surgery.

**Anterior vaginal repair - colporrhaphy - native tissue***Surgery – Female*

Repair the vaginal by excision and suturing of the edges of any defect, most commonly by midline fascial plication.

**Anterior vaginal repair (colporrhaphy) - mesh or graft re-inforcement***Surgery – Female*

A structural addition or inclusion used to give additional strength in function. It should be noted whether the graft is biologic, absorbable synthetic or permanent synthetic.

**Anterior vaginal wall (compartment) prolapse***Sign*

Observation of descent of the anterior vaginal wall (compartment). Most commonly this might represent bladder prolapse (cystocele). Higher stage anterior vaginal wall prolapse will generally involve descent of uterus or vaginal vault (if uterus is absent). Occasionally there might be an anterior enterocele (hernia of peritoneum and possibly abdominal contents), most commonly after prior reconstructive surgery.

**Anterior vaginal wall (compartment) prolapse***Imaging*

Diagnosis by symptoms and clinical examination, assisted at times by any relevant imaging (i.e. clinically evident) descent of the anterior vaginal wall (compartment).

**Anterior vaginal wall (compartment) prolapse***Diagnosis*

Clinically evident (symptoms, signs or any relevant imaging) descent of the anterior vaginal wall (compartment).

**Anteverted uterus***Sign*

The axis of the uterus is directed forwards overlying the bladder. Cervix is noted in/ towards the posterior fornix with fundus perhaps palpable anteriorly on bimanual palpation.

**Anus - Keyhole deformity***Sign*

Characteristic posterior midline furrow deformity. This complication is seen when the anus is inspected by gently retracting the buttocks laterally. The anus is no longer slit-like, but appears in shape like a keyhole. RATING: (i) Present - note location of deformity with reference to a clock-face (where 12 o'clock is anterior/ventral); (ii) Absent.

**Artificial urinary sphincter***Surgery – Male*

Use of a prosthetic device, encircling the urethra which creates occlusion to restore continence. The cuff can be placed in the bulbar urethra or in the bladder neck to restore continence. There are a number of different devices available using two or three components with different techniques of implantation.

**Aseptic intermittent catheterization***Conservative Management – General*

This implies genital antiseptic preparation and the use of sterile (single-use) catheters and instruments/gloves in a designated clean area.

**B****Balanitis xerotica obliterans (BXO - syn lichen sclerosis et atrophicus)***Symptom*

Depigmentation of the penile skin, scrotum or glans.

**Balanoposthitis***Sign*

Inflammation of the foreskin and glans penis.

**Bearing down (as if defecating)***Sign*

A strain or push, which results in an increase in intraabdominal pressure, which exerts a downward pressure, usually accompanied by pelvic floor muscle relaxation.

**Behavioral and Cognitive Therapies***Conservative Management – Female*

The way someone behaves, especially toward other people, and behavioral science is the study of human behavior.

1. Behavior therapy: a type of psychotherapy that attempts to modify observable maladjusted patterns of behavior by substituting a new response or set of responses to a given stimulus. The treatment techniques involve the methods, concepts, and procedures derived from experimental psychology; they include assertiveness training, aversion therapy, contingency management, flooding, modeling, operant conditioning, and systematic

**Associated POP-related Radiology (female)***Imaging*

Defecography demonstrates normal anatomy of the anorectum as well as disorders of rectal evacuation. With barium paste inserted rectally prior to defecation, measurement of the anorectal angle is allowed with evidence of the presence, size or emptying of any rectocele. Enteroceles, rectal intussusception and mucosal prolapse might be diagnosed as well as a spastic pelvic floor (anismus).

**Atrophic***Sign*

Decrease from previous normal size of the body or a part, cell, organ, or tissue. An organ or body part's cells may be reduced in number, size or both. Atrophy of some cells and organs is normal at certain points in the life cycle. Other causes include malnutrition, disease, disuse, injury, and hormone over- or underproduction

**Autonomic dysreflexia***Diagnosis*

This is a syndrome resulting from upper thoracic or cervical spinal cord injury above T6, elicited by a stimulus in the field of distribution of the autonomic sympathetic nucleus, characterized by unregulated sympathetic function below the lesion and compensatory autonomic responses. Can be asymptomatic if there is an increase in blood pressure without any other symptoms.

**Average (urine) flow rate (AUFR - mL/s) - Qave***Investigation*

Voided volume divided by the flow time.

**Average voided volume***Sign*

Summation of volumes voided divided by the number of voided during an assessment period of frequency-volume chart (FVC).

desensitization. It is also called behavior modification. 2. Cognitive therapy: any of the various methods of treating mental and emotional disorders that help a person to change their attitudes, perceptions, and patterns of thinking, from rational to realistic thoughts about the self and situations. The technique is often used in association with behavior therapy principles. 3. Cognitive behavior therapy (CBT): Cognitive techniques are often used in association with behavior therapy principles; this is called cognitive behavior therapy (CBT).

**Belted pads (belted products): Defining features***Conservative Management – Female*

One-piece products in which the absorbent core, waterproof backing, and the means to hold it in place are combined in a single design, secured by means of an adjustable belt with adhesive tabs or a hook and loop fastening system.

**Belted pads (belted products): Main variant features***Conservative Management – Female*

Products may be used by either sex, but some are intended (by their color, style, or the placing of absorbent material, for example) just for men or just for women.

- Products come with different absorption capacities, and to fit different body sizes.

- Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit and comfort and prevent leakage.
- Products may have wetness indicators.
- Products may or may not be suitable for containing fi as well as UI.

### **Benign prostatic enlargement (BPE)**

#### *Diagnosis*

A term describing increased volume of the gland usually secondary to BPH. The precise volume that determines the lower limit of BPE remains to be defined; 20 ml has been suggested.

### **Benign prostatic hyperplasia (BPH)**

#### *Diagnosis*

A term that is used exclusively to describe the histologic changes related to benign prostatic growth.

### **Benign prostatic obstruction (BPO)**

#### *Diagnosis*

A term used to describe bladder outlet obstruction (BOO) secondary to BPE and, therefore, usually due to BPH. BOO is an urodynamic entity and can only be diagnosed via pressure-flow studies.

### **Bladder abnormalities - ultrasound imaging (male)**

#### *Imaging*

Tumor, foreign body, overdistension, stones, diverticulum.

### **Bladder compliance - factors affecting (female)**

#### *Investigation*

(i) Bladder filling: Faster filling is more provocative. An artifact may be produced which settles when filling is interrupted; (ii) Contractile / relaxant properties of the detrusor: e.g. post-radiation changes of the detrusor wall; (iii) Starting point for compliance calculations: Usually the detrusor pressure at the start of bladder filling and the corresponding bladder volume (usually zero); (iv) End point for compliance calculations: The detrusor pressure (and corresponding bladder volume) at cystometric capacity or immediately before the start of any detrusor contraction that causes significant leakage (and therefore causes the bladder volume to decrease, affecting compliance calculations). Both points are measured excluding any detrusor contraction.

### **Bladder (detrusor) compliance - filling cystometry (mL/cmH2O)**

#### *Investigation*

Relationship between the change in bladder volume and change in detrusor pressure as a measure for the distensibility of the bladder. Compliance = Change Vol/ change Pdet. Compliance reflects the amount of fluid in the bladder to increase the bladder pressure by 1 cm H2O (mL per cm H2O)

### **Bladder diary**

#### *Sign*

Adds to the Frequency Volume Chart (FVC), the fluid intake, pad usage, incontinence episodes, the degree of incontinence and the circumstances at the time of the leakage.

Episodes of urgency and sensation might also be recorded, as might be the activities performed during or immediately preceding the involuntary loss of urine. Additional information obtained from the bladder diary involves: severity of incontinence in terms of leakage episodes and pad usage.

### **Bladder distension**

#### *Surgery – Male*

Infusion of fluid usually saline, under anaesthesia with the intent to stretch or distend the bladder walls in excess of usual physiological capacity.

### **Bladder diverticulectomy**

#### *Surgery – Male*

Excision of a bladder pseudodiverticulum using a transvesical or extra vesical approach, by abdominal open, laparoscopic or robotic assisted techniques.

### **Bladder expression**

#### *Conservative Management – General*

This refers to various compression manoeuvres aimed at increasing intra-vesical pressure to facilitate bladder emptying with or without obvious sensation from the bladder.

### **Bladder filling (sensory) symptoms**

#### *Symptom*

Abnormal sensations experienced during bladder filling.

### **Bladder instillations**

#### *Surgery – Male*

This involves instillation of a chemical substance via a urethral catheter mostly under local anaesthesia. Usually there are multiple instillations spread over a period of time. EMDA treatment (electromotive drug administration) aims to increase drug concentration in the vesical wall by iontophoresis and electrophoresis to overcome the urothelial barrier.

### **Bladder neck**

#### *Surgery – Male*

The most proximal part of the urethra, creating its connection with the bladder.

### **Bladder neck incision with Y-V plasty - Open/ laparoscopic/ robot-assisted**

#### *Surgery – Male*

Complete incision through the anterior bladder neck tissue in Y-shape and resuturing the tissue in V-shape after open or laparoscopic approach of the retropubic space.

### **Bladder neck procedures: General**

#### *Surgery – Male*

Widening of the bladder neck with the intent of relieving bladder outlet obstruction, usually caused by primary bladder neck hypertrophy or secondary neck stenosis.

### **Bladder neck resection - Open/ laparoscopic/ robot-assisted**

#### *Surgery – Male*

Complete removal of the entire bladder neck via an open or laparoscopic approach and reconnection of the prostatic urethra to the bladder.

### **Bladder outlet obstruction (BOO - male)**

#### *Diagnosis*

A diagnosis based on urodynamic investigations (pressure-flow studies +/- imaging +/- EMG), generally (but not always) with relevant symptoms and signs, manifest by an abnormally slow urine flow rate, with evidence of abnormally high detrusor voiding pressures and abnormally slow urine flow during pressure-flow studies, with or without a high PVR.

BOO can be functional (bladder neck obstruction, detrusor sphincter dysfunctions or pelvic floor overactivity) or mechanical (prostatic enlargement, sphincter sclerosis, urethral stricture, meatal stenosis).

### **Bladder outlet obstruction (BOO) - pressure flow studies (male +/- VCU, EMG)**

#### *Investigation*

This is the generic term for obstruction during voiding. It is a reduced urine flow rate with a simultaneously increased detrusor pressure. PVR may be present.

**Bladder outlet obstruction (female)***Investigation*

This is the generic term for obstruction during voiding. It is a reduced urine flow rate and/or presence of a raised PVR and an increased detrusor pressure. It is usually diagnosed by studying the synchronous values of urine flow rate and detrusor pressure and any PVR measurements. A urethral stricture or obstruction due to higher degrees of uterovaginal prolapse or obstructed voiding after stress incontinence procedures are amongst possible causes.

**Bladder oversensitivity - filling cystometry***Investigation*

Increased sensation during bladder filling with: early first desire to void; early strong desire to void, which occurs at low bladder volume; lower cystometric bladder capacity; no abnormal increases in detrusor pressure.

**Bladder Oversensitivity (BO)***Diagnosis*

Increased perceived bladder sensation during bladder filling with specific cystometric findings of early first desire to void; early strong desire to void, which occurs at low bladder volume; low maximum cystometric bladder capacity; no abnormal increases in detrusor pressure.

**Bladder pain***Symptom*

Complaint of suprapubic or retropubic pain, pressure or discomfort related to the bladder, and usually associated with bladder filling. It may persist or be relieved after voiding.

**Bladder Pain Syndrome (BPS - Chronic)***Symptom*

Persistent or recurrent chronic pelvic pain, pressure or discomfort perceived to be related to the urinary bladder accompanied by at least one other urinary symptom such as an urgent need to void or urinary frequency.

**Bladder psoas-hitch***Surgery – Male*

fixation of bladder wall to the psoas muscle aponeurosis with the intent of reducing tension of a ureter to bladder anastomosis in case of shortened/strictured distal ureter.

**Bladder stone removal: Open, laparoscopic or robot-assisted***Surgery – Male*

Complete removal of a bladder stone (without fragmentation) by a suprapubic open or laparoscopic or robotic approach.

**Bladder wall injections***Surgery – Male*

Injection of a pharmaceutical agent into the bladder wall (to the suburothelial space or detrusor), using a needle inserted through the endoscope.

**Bladder wall thickness (BWT) - ultrasound imaging (male)***Investigation*

Distance from the outer border of the mucosa to the outer border of the adventitia on the anterior bladder wall with a linear 7,5MHz linear array in a bladder filled to over 250ml.

**Boari flap***Surgery – Male*

Use of a segment of bladder wall to create a tube, which is then anastomosed to the remaining ureter with the intent of substituting the terminal ureter in case of shortened/strictured distal ureter.

**Botulinum toxin to bladder neck***Surgery – Male*

This involves injection of botulinum toxin mixed with normal saline to the bladder neck for relief of functional obstruction.

**Botulinum toxin to external sphincter***Surgery – Male*

Endoscopic injection of toxin into the external sphincter complex.

**Bowel diary***Sign*

It is a recording of bowel actions. Bowel diaries have been widely used in diagnostic and intervention studies. Patient recall is less accurate than a diary. Patients tend to underestimate symptom frequency, in one study by over 50 %. However, there are few published examples and no consensus on what should be included. Elements that might be included: (i) urgency; (ii) fecal incontinence (amount, consistency); (iii) flatus incontinence; (iv) passive staining/soiling (tends not be discrete episodes); (v) pads (changes, degree of soiling); (vi) straining/difficulty/time in the toilet; (vii) unsuccessful attempts to defecate; (viii) assistive measures (e.g. digital stimulation, manual evacuation, irrigation); (ix) laxative or rectal evacuant use; (x) diet and fluids (type and/or timing). Patients often need careful and detailed instructions on how to complete a diary, and still many are poorly completed. An incomplete diary is difficult to interpret and is liable to misinterpretation as a low bowel/event frequency.

**Bulbar urethra***Surgery – Male*

The portion of the urethra between the distal membranous urethra until the conjunction of the left and right corpus cavernosum. The lumen is surrounded by and sits eccentrically toward the dorsal portion of the bulbospongiosus of the corpus spongiosum

**Bulbospongiosus reflex (BSR)***Sign*

A reflex contraction of the striated muscle of the pelvic floor (anal sphincter) and the bulbo-spongiosus muscle that occurs in response to various stimuli in the perineum or genitalia.

**Bulking agents***Surgery – Male*

Endoscopic injection of inert substance into proximal urethral wall to achieve continence by coaptation.

**Burch colposuspension - open, laparoscopic, robotic***Surgery – Female*

Elevation or attachment of the upper paraurethral tissue adjacent to the bladder neck region to the iliopectineal ligament bilaterally. Although a recognized treatment for stress incontinence, this procedure will often correct associated anterior wall prolapse.

**Buried Penis***Diagnosis*

A congenital or acquired condition in which penis is partially or totally embedded underneath the skin of the abdomen, thigh, or scrotum.

**Buttock and perineal skin rotation flaps***Surgery – Female*

The use of skin flaps from the buttock/perineal area to provide interposition fat and blood supply as well as increased vaginal skin surface area.

## C

### Catheterization

#### *Conservative Management – General*

This is a technique for bladder emptying employing a catheter to drain the bladder or a urinary reservoir.

### Catheterization - aseptic intermittent

#### *Conservative Management – General*

This implies genital antiseptic preparation and the use of sterile (single-use) catheters and instruments/gloves in a designated clean area.

### Catheterization - clean intermittent (CIC)

#### *Conservative Management – General*

This is the use of a clean technique. This implies ordinary hand and genitals washing techniques and use of disposable or cleansed reusable catheters.

### Catheterization - indwelling

#### *Conservative Management – General*

An indwelling catheter remains in the bladder, urinary reservoir or urinary conduit for a period longer than one emptying.

### Catheterization - intermittent (IC)

#### *Conservative Management – General*

Drainage of the bladder or a urinary reservoir with subsequent removal of the catheter mostly at regular intervals

### Catheterization - no-touch technique intermittent

#### *Conservative Management – General*

This was introduced as an easier way for the patient to perform self-intermittent catheterization with a ready-to-use catheter (pre-lubricated catheter, usually a hydrophilic catheter). A pull-in aid or special packages are used to handle the catheter without directly touching the sliding surface of the hydrophilic catheter.

### Catheterization - sterile intermittent

#### *Conservative Management – General*

Complete sterile setting, including genital skin antiseptics, sterile gloves, forceps, gown and mask.

### CatScan (CT) Imaging for fistula

#### *Imaging*

CT role is limited for imaging fistulas due to irradiation load on the patient combined with poor CT resolution of soft tissues. Radiopaque contrast improves soft tissue resolution. However multi-planar spiral CT provides accurate visualization of the pelvic floor soft and bony structures by reconstruction of axial images using 1 mm thick slices without gaps that provides high pelvic floor diagnostic accuracy (i.e., LAM trauma or fistula).

### Cavernous Nerves ("Nervi Erigentes")

#### *Surgery – Male*

These nerves are formed from the distal end of the pelvic plexus and supply sympathetic and parasympathetic innervation to the corpora cavernosa. The cavernous nerves are located at 3 and 9 O'clock positions at the level of the membranous urethra and at 2 and 10 O'clock positions at the level of the proximal bulbar urethra. These nerves are at risk during pelvic fracture urethral injury (and its repair) as well as bulbar urethroplasty.

### Central sensitization

#### *Symptom*

Nociceptor sensitization results in synaptic strengthening by incoming afferent volleys (sensitization) and is expressed as hyperalgesia (a form of

non-associative learning characterized by an increase in responsiveness upon repeated exposure to a stimulus)

### Centrally generated pain/ Deafferentiation pain

#### *Symptom*

Pain which may result from injury to either the peripheral or central nervous system, leading to burning pain below the level of the lesion. It can be sympathetic-nervous system maintained pain, which may result in chronic regional pain syndrome (CRPS). There is increased responsiveness of nociceptive neurons in the central nervous system to normal or sub-threshold afferent input.

### Chronic Bladder Pain Syndrome - Cystoscopic evaluation

#### *Investigation*

Cystoscopic findings by hydrodistension are important in subclassification of Bladder Pain Syndrome (BPS) / Interstitial Cystitis (IC).

i. Glomerulation during cystoscopy with hydrodistension, glomerulations, with or without waterfall lesions (blood trickling downwards), may often be observed ii. Hunner Lesion.

A Hunner lesion is not an ulcer, but an inflammatory infiltrate. Morphologic findings in Hunner Lesion

1. Inflammatory infiltrate on examination of biopsy taken with electro-resection or by cold cup biopsy. 2. Lymphocyte-like cells dominate in the infiltrate, but neutrophilic and eosinophilic granulocytes as well as plasma cells and mast cells are also found. 3. Perineural and perivascular arrangement of lymphocyte-like cell infiltrates. Granulation tissue.

### Chronic Intra-abdominal Female Genital Pain Syndrome - Evaluation

#### *Investigation*

1. Questionnaires

i. Visual Analog Scale for pain.

2. Laboratory Testing

i. Culture. ii. Complete blood count.

3. Laparoscopy (with or without biopsy) 4. Ultrasound (US) 5. MRI 6. Venography (to rule out Pelvic Congestive Syndrome)

### Chronic Musculoskeletal Pain Syndromes - Evaluation

#### *Investigation*

1. Questionnaires i. McGill Pain Questionnaire. ii. Pelvic floor Distress Inventory (PFDI). iii. Female Sexual Function Index (FSFI). iv. Female Sexual Distress Scale (FSDS). 2. Pain Location Drawing (Pain Mapping) i. Pain Chart body map. 3. Evaluation of Muscle Tension There is no single tool which is able to measure all components of muscle tone. Some tools may be able to measure aspects of tone such as contractility, stiffness or elasticity. Instrumented methods may have a role in the valid and reliable evaluation of muscle tone, for example, surface electromyography, dynamometry, real-time ultrasound, elastometry, myo-tonometry. i. Pressure manometry is the measurement of resting pressure or pressure rise generated during contraction of the pelvic floor muscles using a pressure device (a manometer) inserted into the urethra, vagina or anus. ii. Surface electromyography (sEMG) refers to the bioelectrical activity generated by muscle fibres. iii. Dynamometry is the measurement of pelvic floor muscle resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina. iv. Real-time ultrasound measures pelvic floor muscle morphology and function via a non-invasive (trans-abdominal or trans-perineal) probe. v. Elastometry measures the elasticity of a tissue. 4. Trigger point injection or needling has been used as a diagnostic test to identify pain generators. 5. *Imaging*

i. X-Ray. ii. Ultrasound. iii. MRI.

## Chronic Neuropathic Pain Syndromes - Evaluation

### Investigation

A. Neuropathic Pain Questionnaires 1. VAS Pain Score. 2. Pain DETECT (Validated for CPPS evaluation). 3. Leeds Assessment for neuropathic symptoms and signs (not validated for chronic pelvic pain). 4. Douleur Neuropathique 4 Questionnaire. B. Quantitative Sensory Testing

1. 1Q-tip touch sensitivity. 2. Sensory pain mapping. 3. Reflex evaluation. 4. Electromyography.

C. Nerve Blocks 1. May/may not be done under Computed Tomography, Ultrasound or EMG guidance.

### D. Imaging

1. Ultrasound 2. Magnetic resonance Imaging (MRI)

## Chronic Pain

### Symptom

Persistent or continuous/recurrent pain for at least 6 months. If non-acute and central sensitization pain mechanisms are well documented, then the pain may be regarded as chronic, irrespective of the time period.

## Chronic Pain and Fatigue Syndromes

### Diagnosis

Chronic pain and fatigue syndromes are characterized by pain, often widespread; fatigue; sleep disturbances; and disability. The symptoms are usually medically unexplained, have no known pathophysiology or organic basis and show no abnormal laboratory or imaging investigations. The literature suggests that many of these conditions share demographic characteristics, clinical course and psychosocial profiles. Examples are:

1. fibromyalgia: symptoms are widespread musculoskeletal pain, fatigue, non-restorative sleep, psychological distress, and regions of localized tenderness.
2. Temporomandibular Joint Disorders: symptoms consist of complaints of facial, jaw, neck, or shoulder pain. The pain is experienced in or around the ear with chewing, speaking, or opening the mouth, with or without migraine.
3. Chronic Fatigue Syndrome: is defined as clinically evaluated, unexplained, persistent or relapsing fatigue plus four or more specifically defined associated symptoms (self-reported impairment in short term memory or concentration; sore throat; tender cervical or axillary nodes; muscle pain; pain in multiple joints without redness or swelling; headaches of a new pattern or severity; unrefreshing sleep).

## Chronic Pelvic Floor Muscle Pain Syndrome

### Investigation

1. Questionnaires. i. Visual Analog Scale for pain. ii. Pelvic floor Distress Inventory (PFDI). iii. Prolapse and Incontinence Sexual Questionnaire (PISQ). 111

2. Laboratory Testing

i. Wet Mount, Culture. ii. Biopsy.

3. Imaging References

i. Ultrasound (4D if available for visualization of mesh, where applicable). ii. MRI (with or without defecography). iii. Defecography.

## Chronic Pelvic Joint, Ligament or Bone Pain Syndrome

### Diagnosis

1. Joint pain:

i. Sacroiliac or pubic symphysis joint.

2. Ligament pain:

i. Sacro-spinous or Sacro-tuberous ligament.

3. Bony pain:

i. Pain described in or along the margins of the pubic ramus, ilium, ischial spine or ischial tuberosity.

## Chronic Pelvic Pain

### Diagnosis

Chronic pelvic pain is characterized by persistent pain lasting longer than 6

months or recurrent episodes of abdominal/pelvic pain, hypersensitivity or discomfort often associated with elimination changes, and sexual dysfunction often in the absence of organic etiology.

## Chronic Pelvic Pain - Characteristics

### Symptom

a. Duration of pain: Six months or more of persistent pain. b. Location of pain: Pelvis, lower abdomen, low back, medial aspect of thigh, inguinal area, perineum. c. Perception of pain: Patients may describe the pain as sharp, burning, aching, shooting, stabbing, pressure or discomfort, sexual pain (dyspareunia). d. Modality of pain: Persistent and/or continuous, recurrent and/or episodic and/or cyclic (related to menstrual cycle).

## Chronic (persistent or recurrent) Anorectal Pain Syndrome

### Diagnosis

1. Chronic Proctalgia—rectal pain, more than 20min of duration per episode, for at least 3 months with symptom onset at least 6 months prior to diagnosis.

i. Persistent or recurrent rectal pain. ii. Rectal pressure or aching episodes. iii. In the absence of other causes of rectal pain.

2. Levator Ani Syndrome (the term may refer to the same syndrome as “pelvic floor muscle pain syndrome”/ “tension myalgia of the PFM”).

i. Pain with sitting. ii. Pain with defecation.

3. Proctalgia Fugax

i. Severe recurrent episodic pain localized in the anus or lower rectum. ii. Duration seconds to minutes. iii. No pain between episodes.

## Chronic (persistent or recurrent) Epididymal Pain Syndrome

### Diagnosis

Pain is specific/localized to the epididymis.

i. Persistent or recurrent episodic pain. ii. Spontaneous, or reproduced by digital pressure and physical activities. iii. Lower urinary tract symptoms or sexual dysfunction.

## Chronic (persistent or recurrent) Pelvic Muscle Pain Syndrome

### Diagnosis

1. Pelvic floor Muscle Pain (Pelvic floor Myalgia):

i. Pain in the muscles of the pelvic floor (perineal or levator ani).

2. Intra-pelvic Muscle Pain:

i. Pain in the pelvic side wall muscles (obturator internus, piriformis, coccygeus).

3. Anterior Pelvic/Lower Abdominal Muscle Pain:

i. Pain in the rectus abdominus, oblique or transverse abdominus muscles, described below the umbilicus.

4. Posterior Pelvic/Buttock Muscle Pain:

i. Pain in the gluteal muscles.

## Chronic (persistent or recurrent) penile pain syndrome

### Diagnosis

Pain within the penis that is not primarily in the urethra and may be: i. Persistent or recurrent. ii. Spontaneous, or reproduced by digital pressure and physical activities. iii. Lower urinary tract symptoms or sexual dysfunction.

## Chronic (persistent or recurrent) Prostate Pain Syndrome

### Diagnosis

Persistent or recurrent prostate pain, associated with symptoms suggestive of urinary tract and/or sexual dysfunction. No proven infection or other obvious pathology is present to account for the symptoms. Bladder, perineal, testicular, penile and/or groin pain.

i. Perception of pain: variable. ii. Persistent or recurrent. iii. Dyspareunia or erectile dysfunction. iv. Voiding and post micturition symptoms (for example: hesitancy, intermittency, feeling of incomplete emptying).

**Chronic (persistent or recurrent) Scrotal Pain Syndrome***Diagnosis*

Chronic scrotal pain (generic term used when site of pain is not clearly in the testis or epididymis).

i. Persistent or recurrent episodic pain, unilateral or bilateral. ii. Spontaneous, or reproduced by digital pressure and physical activities. iii. Pain is not in the skin of the scrotum but perceived within its contents. iv. Lower urinary tract symptoms or sexual dysfunction.

**Chronic (persistent or recurrent) testicular pain syndrome***Diagnosis*

i. Persistent or recurrent episodic pain. ii. Spontaneous, or reproduced by digital pressure and physical activities. iii. Lower urinary tract symptoms or sexual dysfunction.

**Chronic Prostatic Pain Syndrome - Evaluation***Investigation*

1. Quantitative assessments. i. Bladder diary. ii. CPSI (Chronic Prostatitis Symptom Index). iii. Visual Analog Scale for Pain (VAS).

## 2. Laboratory Testing

i. Urinalysis (including post prostate massage). ii. Urine Culture post prostate massage. iii. Semen Culture.

3. Uroflowmetry, Post voiding residual volume, pressure flow study 4. Cystoscopy 5. Ultrasonography, with or without biopsy

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP):***Diagnosis*

Persistent or recurrent prostate and/or pelvic pain, associated with symptoms suggestive of urinary tract and/or sexual dysfunction. No proven infection or other obvious pathology is present to account for the symptoms. Pain may be referred to the bladder, perineum, testicles, penis and/or groin.

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP): Acute bacterial prostatitis***Diagnosis*

Characterized by severe symptoms of prostatitis, systemic infection and acute bacterial urinary tract infection, requires hospitalization and parenteral fluid-antibiotic therapy.

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP): Asymptomatic inflammatory prostatitis***Diagnosis*

Characterized by histopathological evidence of prostatic inflammation in the absence of genitourinary symptoms. This is usually an incidental finding during evaluation for other conditions such as elevated PSA.

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP): Chronic bacterial prostatitis***Diagnosis*

Caused by chronic bacterial infection of the prostate with or without symptoms of prostatitis. It is usually associated with recurrent urinary tract infections caused by the same bacterial strain.

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP): Chronic bacterial prostatitis***Diagnosis*

Caused by chronic bacterial infection of the prostate with or without symptoms of prostatitis. It is usually associated with recurrent urinary tract infections caused by the same bacterial strain.

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP): CPSP***Diagnosis*

Characterized by chronic pelvic pain and LUT symptoms in the absence of urinary tract infection. It is subdivided into inflammatory (3A) and noninflammatory (3B) categories depending on the presence/absence of leukocytes in expressed prostatic secretion.

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP): NIH Prostatitis Classification***Diagnosis*

Prostatitis is classified as acute bacterial prostatitis (category I), chronic bacterial prostatitis (category II), CP/CPSP (category III) and asymptomatic inflammatory prostatitis.

**Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP): Symptoms***Symptom*

Intermittent pain.

Persistent or recurrent pain. Dyspareunia and/or Erectile dysfunction (ED). Voiding and post micturition symptoms (e.g., hesitancy, intermittency, feeling of incomplete emptying, dysuria).

**Chronic retention of urine (female)***Diagnosis*

This is defined as a nonpainful bladder, where there is a chronic high PVR.

**Chronic Scrotal, Epididymal, Testicular and Penile Pain Syndrome - Evaluation***Investigation*

1. Quantitative assessments i. VAS for Pain. 2. Ultrasonography

**Chronic Sexual Pain Disorder***Diagnosis*

Dyspareunia

i. Female sexual pain: Burning, ripping, tearing, or aching sensation associated with penetration. The pain can be at the vaginal opening, deep in the pelvis, or anywhere between. It may also be felt throughout the entire pelvic area and the sexual organs and may occur only with deep thrusting. ii. Male sexual pain: Sexual activity may induce a central sensitization process characterized by hypersensitivity or hyperalgesia. History should include duration of symptoms, identification of disorder, impact on quality of life, and partner relationship. Partner interviews may be very helpful as erectile dysfunction, delayed or premature ejaculation in males with hypoactive sexual desire disorder result in a 4–30 times increased risk of female partner desire, arousal or orgasmic disorder.

**Chronic sexual pain disorder (Male)***Diagnosis*

Sexual activity may induce a central sensitization process characterized by hypersensitivity or hyperalgesia before, during or after sexual activity.

**Chronic Sexual Pain Syndrome***Diagnosis*

i. Penile

1. Prior to penetration (example: pain with erection). 2. With penetration. 3. Post coital.

ii. Perineal

1. During intercourse. 2. After intercourse.

iii. Orgasmic Pain (during ejaculation)

1. Penile. 2. Anorectal. 3. Pelvic.

### Chronic Urethral Pain Syndrome - Evaluation

#### Investigation

1. Quantitative assessments
  - i. Bladder diary. ii. VAS for Pain.
2. Laboratory Testing
  - i. Urinalysis (including post prostate massage, Ureaplasma/Chlamydia as appropriate).
3. Urethroscopy/Urethrography 4. Ultrasonography

### Chronic urinary retention

#### Symptom

Complaint of chronic or repeated inability to empty the bladder, despite the ability to pass some urine. This may result in the frequent passage of small amounts of urine or urinary incontinence and a distended bladder.

### Chronic (urinary) retention

#### Diagnosis

This defined as a generally (but not always) painless and palpable or percussible bladder, where there is a chronic high PVR where the patient experiences slow flow and incomplete bladder emptying. Overflow incontinence can occur. Some individuals with retention present with impaired renal function and/or hydronephrosis.

### Chronic Vulvar, Vestibular and Clitoral Pain Syndromes - Evaluation

#### Investigation

1. Questionnaires i. Visual Analog Scale for pain. ii. Female Sexual Function Index (FSfi). iii. Female Sexual Distress Scale (FSDS).
2. Laboratory Testing
  - i. Culture. ii. Biopsy.
3. Diagnostic Testing
  - i. Vulvoscopy, with or without biopsy. ii. Quantitative Sensory Testing (Q-tip touch sensitivity test).

### Chyluria (albiduria)

#### Symptom

Complaint of the passage of chyle (pain or white, milky cloudy) urine.

### Classification

#### Surgery – Complication related

A systematic arrangement into classes or groups based on perceived common characteristics.

### Clean intermittent catheterization (CIC)

#### Conservative Management – General

This is the use of a clean technique. This implies ordinary hand and genitals washing techniques and use of disposable or cleansed reusable catheters.

### Climacturia

#### Symptom

Complaint of involuntary loss of urine at the time of orgasm.

### Closing pressure

#### Investigation

Pressure recorded at the end of measured flow.

### Closure of the Enterocele Sac - Open, Laparoscopic, Robotic

#### Surgery – Female

(a) Moschowitz procedure - Concentric purse-string suture(s) are placed around the cul-de-sac to include the posterior vaginal wall, pelvic side-walls and serosa of the sigmoid. (b) Halban procedure- Obliteration of the cul-de-sac by using successive sutures placed sagittally between the uterosacral ligaments. (c) Uterosacral ligament plication – transverse plication of the

uterosacral ligaments to obliterate the cul-de-sac. Successive sutures are placed into the medial portion of one ligament, into the back wall of the vagina and into the medial border of the opposing ligament. Variations in technique for all abdominal mesh/graft procedures

### Coccygeal pain (coccydynia)

#### Symptom

Complaint of pain, pressure or discomfort felt in the coccygeal region

### Coccyx Pain Syndrome

#### Diagnosis

Complaint of chronic or recurrent pain in the coccyx or sacro-coccygeal joint.

### Coital fecal (flatal) incontinence (female)

#### Symptom

Fecal (flatal) incontinence occurring with vaginal intercourse.

### Coital fecal incontinence

#### Symptom

Complaint of involuntary loss of stool occurring with intercourse.

### Coital fecal urgency (female)

#### Symptom

Feeling of impending bowel action during vaginal intercourse.

### Coital urinary incontinence

#### Symptom

Urinary incontinence occurring during or after vaginal intercourse.

### Coital urinary incontinence (female)

#### Symptom

Complaint of involuntary urine loss during or after coitus. This symptom might be further divided into that occurring with penetration and that occurring at orgasm.

### Coital urinary urgency (female)

#### Symptom

Feeling of urgency to void during vaginal intercourse.

### Colonic flaps

#### Surgery – Female

For vaginal reconstruction of a large PFF in the presence of complete vaginal loss.

### Colonoscopy

#### Investigation

The entire colon is examined following a full oral preparation to clear the bowel to allow this.

### Colo(rectal) vesical fistula (Co[R]VF)

#### Diagnosis

Abnormal connection between the bladder and either or both of the rectum and colon.

### Colo-uterine/cervical fistula (CoUtF/CoCxF)

#### Sign

Colo-uterine/cervical fistula (CoUtF/CoCxF): Abnormal connection between the colo/rectum and uterus (body and/or cervix).

With or without the observation of:

(i) R(C)UtF—Clinical exam only: Passing flatus/feces per cervix, menses per rectum, anorectal

tract fluid per vagina.

(ii) R(C)UF—Clinical exam plus irrigation or air injection: With bubbles passing through the abnormal connection through vaginal irrigant fluid after retrograde injection of air per rectum.

### Colo-vesical fistula (CoVF)

#### Sign

Colo-vesical) fistula (CoVF): Defect between the anorectum (or colon) and bladder.

with

or without observation of:

(i) CoVF—Clinical exam only: observation of flaturia, fecaluria.

(ii) CoVF—Clinical exam plus PR air injection: observation of flaturia, fecaluria bubbles passing through the urethra after retrograde injection of air per rectum.

(iii) CoVF—Clinical exam plus irrigation: observation of dyed irrigation fluid passing per anorectum after retrograde bladder fill per urethra.

### Colpocleisis

#### Surgery – Female

Operation for obliterating the lumen of the vagina.

### Colporecto-cystourethrography: (Colpo-cystodefecography)

#### Imaging

This involves the instillation of radio-opaque media into bladder, vagina and rectum simultaneously for pelvic floor evaluation with images obtained during rest and straining.

### Combination therapy (also known as polytherapy, multimodal therapy or combined modality therapy)

#### Conservative Management – Female

Combination therapy is the use of more than one intervention concurrently to treat a single condition with one or multiple symptoms, for example, a combination of medication with PFM training (PFMT).

1. Adjunctive therapies: any treatment or modality used to augment or assist the main treatment. In conservative treatments, adjunctive therapies often refer to equipment or a secondary therapy used to supplement the effect of the primary therapy, e.g., biofeedback-assisted PFMT or neuromuscular electrical stimulation to augment PFMT.

### Complaint

#### Symptom

The description of the symptom.

### Complex Regional Pain Syndrome (CRPS)

#### Diagnosis

Sympathetic, centrally generated pain. 1. CRPS 1- Triggered by tissue injury with no underlying nerve injury. 2. CRPS 2- Associated with nerve injury.

i. Burning pain. ii. Increased skin sensitivity. iii. Changes in skin temperature, color, and/or texture.

### Compliance - bladder (female)

#### Investigation

This describes the relationship between a change in bladder volume and change in detrusor pressure. Compliance is calculated by dividing the volume change (Change V) by the change in detrusor pressure (Change Pdet) during that change in bladder volume (Compliance = Change V/Change Pdet). Compliance is expressed as ml per cm H<sub>2</sub>O.

### Complication

#### Surgery – Complication related

A morbid process or event that occurs during the course of a surgery that is not an essential part of that surgery.

### Compressive sling

#### Surgery – Male

The sling compresses the urethra against the pubis.

(a) Adjustable slings: The pressure on the urethra can be readjusted over time.

(b) Non-adjustable slings: These cannot be adjusted once inserted in place.

### Compromise

#### Surgery – Complication related

Bring into danger.

### Computerized tomography (CT) - male

#### Imaging

(1) CT Urogram (CT-U): CT study of the urinary tract system using injected contrast, used to clarify diagnoses such as (i) tumors; (ii) renal disease; (iii) abnormal fluid collections/abscesses (iv) bladder pathology.

(2) CT Kidneys, ureter, bladder (CT- KUB): Non-contrast study aimed primarily at identifying stones but may identify other pathology. Aka “stone protocol”.

### Computerized tomography (CT) of the pelvic floor

#### Imaging

Computed tomography (CT) is not routinely recommended for imaging the pelvic floor mainly due to irradiation and poor soft tissue contrast. However multiplanar spiral CT may offer an accurate visualization of the pelvic floor soft and bony structures by reconstruction of axial images using 1 mm thick slices without gaps thus increasing the diagnostic accuracy of pelvic floor anatomical disorders (ie. LAM trauma).

### Conditions for cystometry - female

#### Investigation

(i) Pressures: All systems are zeroed at atmospheric pressure; (ii) External pressure transducers: Reference point is the superior edge of the pubic symphysis; (iii) Catheter mounted transducers: Reference point is the transducer itself; (iv) Initial bladder volume: Bladder should be empty; (v) fluid medium: Usually water or saline (or contrast if radiology involved); (vi) Temperature of fluid: Should ideally be warmed to body temperature; (vii) Position of patient: Sitting position is more provocative for abnormal detrusor activity than the supine position. At some point in the test, filling might desirably take place with the patient standing; (viii) filling rate: The filling rate, including any changes during testing, should be noted on the urodynamic report.

### Constipation (General)

#### Symptom

Complaint that bowels motions are infrequent and/or incomplete and/or there is a need for frequent straining or manual assistance to defecate (Rome IV criteria)

### Constipation (obstructed defecation)

#### Symptom

Complaint of difficulty in evacuation due to a mechanical obstruction.

### Constipation (slow transit)

#### Symptom

Infrequent bowel motions due to a delay in transit of bowel contents to reach rectum.

**Contained incontinence***Conservative Management – Female*

Successful management of incontinence with products. It can bring substantial benefits to "Quality of Life", even though a cure has not been achieved.

**Continent heterotopic urinary diversion: Ureterosigmoidostomy - Sigma rectum pouch (Mainz pouch II)***Surgery – Male*

Modification that involves detubularizing the rectosigmoid colon and reconfiguring the detubularized segment into a spherical shape, while maintaining bowel continuity.

**Continent stoma: Appendicovesicostomy (Mitrofanoff)***Surgery – Male*

Use of an isolated appendix on a vascularized pedicle as a catheterizable route of access to the bladder from the skin as an alternative to the urethra.

**Continent stoma: Stapled continent conduit (Bejany and Politano)***Surgery – Male*

A continent colonic urinary reservoir with a tapered distal ileal segment with a gastrointestinal anastomosis stapler with a catheterizable abdominal stoma.

**Continent stoma: The gastroileal reservoir (Lockhart)***Conservative Management – Male*

A continent urinary diversion where segment of stomach and proximal ileum is used to construct the reservoir.

**Continent stoma: Yang-Monti catheterizable channel***Surgery – Male*

A variant of the Mitrofanoff procedure in which a short segment of bowel is reconfigured into a long tube positioned between bladder and skin to permit intermittent catheterization

**Continent urinary diversion***Surgery – Male*

Re-routing of the urine from the urinary bladder. Reconstruction usually involves an isolated intestinal segment (stomach/small intestine/colon). Continence mechanisms may utilize existing sphincters (anal, urethral or ileocaecal valve) or be created by tunneling a bowel segment through the bladder/neobladder which requires catheterization. Egress of urine can therefore be via the anus (ureterosigmoidostomy) via the urethra (neobladder) or via a continent catheterisable channel (e.g. Mitrofanoff, Kock pouch, Mainz I).

**Continuous urinary incontinence***Symptom*

Complaint of continuous involuntary loss of urine

**Contraction***Surgery – Complication related*

Shrinkage or reduction in size.

**Contraction pressure at maximum flow***Investigation*

This is the difference between pressure at maximum flow and the premiturition pressure.

**Cotton swab test - vaginal vestibular tissue sensitivity***Sign*

A test for vestibular tissue sensitivity. The test is performed with a cotton swab moistened with water or lubricating gel. Gentle pressure is applied to the following areas of the vaginal vestibule in random order: 12:00, and quadrants 12–3:00, 3:00–6:00, 6:00–9:00, 9:00–12:00. RATING: (i) Positive if gentle pressure reproduces patient's pain. Report location of pain and severity on Numeric Rating Scale 0–10. (ii) Negative.

**Cough-Associated Detrusor Overactivity***Investigation*

Cough associated DO is reported when the onset of the DO (with or without leakage) occurs immediately following the cough pressure peak. No precise definition of cough associated detrusor activity is available. 'Cough induced DO' is sometimes reported, although the precise (patho-)physiology remains speculative and only the association in time can be observed. The ICS WG presents a descriptive definition and does not discuss the consequences for management.

**Counseling in Pelvic Floor Dysfunction***Conservative Management – Female*

Counseling is the provision of professional assistance and guidance in resolving personal or psychological problems and may be part of any clinician's management.

1. Patient education: providing patients with knowledge and understanding of their condition, thereby empowering them to play an active role in its management.
2. Motivational interviewing: a directive, client-centered counseling style for eliciting behavior change by helping clients to explore and resolve ambivalence. Compared with nondirective counseling, it is more focused and goal-directed. The examination and resolution of ambivalence is its central purpose, and the counselor/clinician is intentionally directive in pursuing this goal.
3. Coping strategies: intervention aimed at helping patients to live with the condition in the best way possible under the circumstances, to regain a feeling of being in control, to adjust their lifestyle where necessary, and to take a positive rather than a negative approach.
4. Self-care: the set of activities that comprise daily living, such as bed mobility, transfers, ambulation, dressing, grooming, bathing, eating, and toileting.
5. Self-help: various methods by which individuals attempt to remedy their difficulties without making use of formal care providers.
6. Self-efficacy: an individual's belief that he or she is capable of successfully performing a certain set of behaviors.

**Cremasteric reflex***Sign*

Contraction of the ipsilateral cremaster muscle, drawing the testis upwards, when the upper inner aspect of the thigh is stroked longitudinally.

**CTS Complication code***Surgery – Complication related*

The category (C), time (T) and site (S) classes and divisions have a sensitivity that should encompass all conceivable scenarios for describing insertion complications and healing abnormalities. The CTS code for each complication, involving three (or four) letters and three numerals is likely to be very suitable for any surgical audit or registry, particularly one that is procedure-specific.

**Cutaneous ureterostomy***Surgery – Male*

Direct anastomosis of the ureter to the skin. Can be loop or end cutaneous ureterostomy.

**Cyclical (menstrual) pelvic pain***Symptom*

Cyclical pelvic pain related to menses that raises the possibility of a gynecological cause.

**Cystectomy***Surgery – Male*

Removal of the urinary bladder using a transabdominal open/laparoscopic/robot-assisted approach. Cystectomies are most frequently done for the treatment of bladder cancer but can also be a valid option for treatment resistant bladder pain syndromes or small capacity bladder where minimally invasive treatments have failed.

**Cystic dilatations of epididymal tubules***Sign*

Cystic dilatations of epididymal tubules (epididymal cysts or spermatocele) and hydroceles (fluid collections between the visceral tunica albuginea and parietal layer of the testicular peritoneum)- usually benign. The examination of these structures would be generally non-tender and without pain.

**Cystic dilatations of the epididymis***Diagnosis*

Epididymal cysts (or spermatocele) and hydroceles (fluid collections between the visceral tunica albuginea and parietal layer of the testicular peritoneum) are usually benign. The examination of these structures would be generally non-tender and without pain.

**Cystodiathermy***Surgery – Male*

Selective cauterization of areas of the bladder using different energy sources through an endoscope with therapeutic intent.

**Cystolithotomy***Surgery – Male*

Surgical removal of a bladder stone through the abdomen and the bladder wall.

**Cystometric capacity - filling cystometry***Investigation*

Bladder volume at the end of filling cystometry, when a "permission to void" is usually given by the urodynamicist.

**Cystometric capacity - filling cystometry (mL)***Investigation*

Bladder volume at the end of filling cystometry, when a "permission to void" is usually given by the urodynamicist.

**Cystometrogram***Investigation*

Graphical recording of the bladder pressure(s) and volume(s) over time.

**Cystometry***Investigation*

Measurement of the pressure-volume relationship of the bladder during filling.

**Cystometry - Aftercontraction***Investigation*

An after-contraction, is a continued or new detrusor pressure rise immediately after flow ended. It is important to note if this occurs with the complete emptying of the bladder.

**Cystometry - Catheter flush***Investigation*

When one of the catheters is flushed during the test a steep pressure rise is observed in that pressure line for one or two seconds followed by an immediate fall to resting pressure.

**Cystometry - conditions (female)***Investigation*

(i) Pressures: All systems are zeroed at atmospheric pressure; (ii) External pressure transducers: Reference point is the superior edge of the pubic symphysis; (iii) Catheter mounted transducers: Reference point is the transducer itself; (iv) Initial bladder volume: Bladder should be empty; (v) fluid medium: Usually water or saline (or contrast if radiology involved); (vi) Temperature of fluid: Should ideally be warmed to body temperature; (vii) Position of patient: Sitting position is more provocative for abnormal detrusor activity than the supine position. At some point in the test, filling might desirably take place with the patient standing; (viii) filling rate: The filling rate, including any changes during testing, should be noted on the urodynamic report.

**Cystometry - Cough Pressure Peak***Investigation*

A cough pressure peak is recognizable during post-test evaluation as a phasic positive pressure change observed in pves and in pabd.

**Cystometry - Dead Signal***Investigation*

A signal that is not showing small pressure fluctuations and is not adequately responding on straining, patient movements or coughing is reported as a dead signal.

**Cystometry - Expelled Catheter***Investigation*

When a catheter is expelled, this is observed as a sudden drop in either pves or pabd, usually below zero.

**Cystometry - Poor Pressure Transmission***Investigation*

Poor pressure transmission has occurred when the cough/effort pressure peak signals on pves and pabd are not nearly equal.

**Cystometry - Position Change***Investigation*

A change in patient position, either active or passive (e.g. tilting), is visible on the cystometry trace by a lasting change of equal magnitude in both pves and pabd. Note: A position change should be (is readily) noted during the test and followed by readjustment of the external pressure sensors height to the standard so that the physiological pves and pabd are observed again. A position change should not affect pdet. The position change pattern should be recognized during post-test evaluation of the cystometry.

**Cystometry - Pressure Drift***Investigation*

Continuous slow fall or rise in (one of either) pressure, that is physiologically inexplicable.

**Cystometry - Pump Vibrations***Investigation*

Pump vibrations are visible as stable frequency oscillations of small but constant amplitude if the filling tube touches the pressure connecting tube (when a two catheter system is used) and the pump is switched on (switching of the pump can ascertain the situation).

Note: ICS standard is double lumen catheter, and despite the channels be-

ing side by side, with the usual filling rate and measuring scale, oscillations are not typically observable.

#### **Cystometry - Rectal Contractions**

##### *Investigation*

Rectal Contractions are temporary phasic increases in pabd without synchronous change in pves resulting in negative deflections of pdet.

#### **Cystometry - Straining**

##### *Investigation*

Straining is observable as a temporary increase in both pves and pabd pressure. Straining may be associated with (patient -active) position change (such as repositioning from leaning backwards to upright).

#### **Cystometry - Tube Knock**

##### *Investigation*

Tube Knock is observable as high frequency, short duration spikes visible in pves, pabd, or both, and with spikes also usually visible in pdet.

#### **Cystometry - Urodynamic Stress Test**

##### *Investigation*

The urodynamic stress test is used for any physical effort of the person tested, to elevate abdominal pressure, during cystometry with the aim of testing for (urodynamic) stress urinary incontinence.

ICS has defined urodynamic stress incontinence. Evidence is lacking (or conflicting) with regard to the preferred technique of stress testing. Note: The provocation method, the pressure measuring catheter(size) and method, the leak detection method as well as the absolute or relative (percentage of cystometric capacity) intravesical volume(s) while testing may be reported.

#### **Cystometry Position**

##### *Investigation*

ICS standard cystometry is done in the vertical position (standing or normally seated) whenever physically possible. A pressure-flow study is done comfortably seated (women, some men) or standing if that is preferred position (men).

#### **Cystoplasty**

##### *Surgery – Male*

A reconstructive procedure involving the addition of a detubularized bowel segment usually to the native bladder. The bladder is bivalved (as a clam) and the isolated piece of bowel is interposed between with the intention of increasing capacity, reducing bladder pressure or treating refractory detrusor overactivity. The outlet of this may be the native urethra (utilizing the in-

trinsic continence of the external urethral sphincter) or a created abdominal stoma (emptied via catheterization).

#### **Cystoplasty: Bladder auto-augmentation**

##### *Surgery – Male*

Removal or incision of a portion of the detrusor leaving behind the exposed mucosa which bulges out, with the aim of reducing bladder pressures.

#### **Cystoplasty: Colocystoplasty**

##### *Surgery – Male*

See also cystoplasty

Generally, sigmoid colon is used.

#### **Cystoplasty: Gastrocystoplasty**

##### *Surgery – Male*

See also cystoplasty.

An isolated piece of stomach is utilized to fashion an augmented bladder.

#### **Cystoplasty: ileocystoplasty**

##### *Surgery – Male*

See also cystoplasty

The piece of bowel used is terminal ileum at least 30 cm from ileo-caecal junction.

#### **Cystoplasty: Ureterocystoplasty**

##### *Surgery – Male*

The ureter is used to bridge the gap in a clammed bladder. This is only used if there is a mega ureter post severe long-standing dilatation of the upper tract with the ipsilateral non functioning kidney that will be removed at the same time or previously has been removed. This is mainly utilized in pediatric population.

#### **Cystorrhaphy**

##### *Surgery – Male*

Suture of a laceration, injury, or rupture in the urinary bladder.

#### **Cystoscopic cauterization of fistula**

##### *Surgery – Female*

Cauterization of the fistula under direct vision via cystoscopy. Used for tiny fistulas and may succeed. This is usually combined with prolonged catheter drainage. Theoretically, light (judicious) cautery of the fistula, allowing the bladder and vaginal tissues to heal.

## **D**

#### **Daytime**

##### *Sign*

The period between waking up with the intention of rising until going to bed with the intention of sleeping (awake hours - ideally recorded on chart or diary)

#### **Daytime (urinary) frequency**

##### *Sign*

Number of micturitions during daytime (awake hours, including first void after waking up from sleep and last void before sleep).

#### **De novo (postoperative) dyspareunia**

##### *Symptom*

Dyspareunia first reported after surgery or other interventions

#### **De novo postoperative) sexual dysfunction symptoms**

##### *Symptom*

New onset sexual dysfunction symptoms (not previously reported before surgery)

#### **Debridement of fistula**

##### *Surgery – Female*

Defined as removal of damaged tissue or foreign objects from a wound. May successfully be engaged as a primary therapy for small fresh RVaF and adjunctively for nonsurgical catheter treatment of VVaF.

#### **Decreased arousal (female)**

##### *Symptom*

Persistent or recurrent inability to achieve or maintain sexual excitement.

This may be expressed as lack of excitement, lack of lubrication, lack of vaginal and clitoral engorgement, or lack of expression of other somatic responses.

#### **Decreased libido (male)**

##### *Symptom*

Complaint of a decreased interest in sexual activity in comparison with previous experience

#### **Decreased libido or sexual desire (female)**

##### *Symptom*

Absent or diminished feelings of sexual interest or desire, absent sexual thoughts or fantasies, and a lack of responsive desire. Motivations (here defined as reasons/incentives) for attempting to become sexually aroused are scarce or absent. The lack of interest is considered to be beyond the normative lessening with lifecycle and relationship duration.

#### **Decreased (low) semen volume**

##### *Symptom*

Complaint of smaller amount of seminal fluid than normal or previously experienced.

#### **Deep dyspareunia**

##### *Symptom*

Complaint of pain or discomfort on deeper penetration (mid or upper vagina)

#### **Defecatory dysfunction (female)**

##### *Diagnosis*

A diagnosis by clinical history and examination, assisted, at times, by the results of diagnostic tests involving the confirmation of abnormal or difficult function in the initiation, passage or completion of defecation.

#### **Defecatory/Post-defecatory symptoms**

##### *Symptom*

Symptoms experienced during or following the act of defecation.

#### **Defecography (female)**

##### *Imaging*

This demonstrates normal anatomy of the anorectum as well as disorders of rectal evacuation. Barium paste is inserted rectally prior to defecation over a translucent commode. Measurement of the anorectal angle is allowed with evidence of the presence, size or emptying of any rectocele. Enteroceles, rectal intussusception and mucosal prolapse might be diagnosed as well as a spastic pelvic floor (anismus).

#### **Defecography (male)**

##### *Imaging*

This demonstrates the anatomy of the anorectum as well as disorders of rectal evacuation. Barium paste is inserted rectally prior to defecation over a translucent commode.

#### **Deficient perineum / cloacal-like defect**

##### *Sign*

A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina.

#### **Deficient perineum/total perineal defect**

##### *Sign*

A spectrum of tissue loss from the perineal body and rectovaginal septum

with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina.

#### **Deficient perineum/total perineal defect**

##### *Diagnosis*

A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina.

#### **Dehiscence**

##### *Surgery – Complication related*

A bursting open, splitting or gaping along natural or sutured lines.

#### **Delayed ejaculation**

##### *Symptom*

Complaint of an increase in the time taken for ejaculation to occur.

#### **Descended Perineum**

##### *Sign*

Perineal body rests below the plane of the ischial tuberosities.

#### **Detrusor acontractility (male)**

##### *Diagnosis*

A diagnosis by urodynamic investigation, generally (but not always) with relevant signs and symptoms, manifest by the absence of an observed detrusor contraction during pressure-flow studies resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span. Voiding is usually achieved by straining or manual pressure on the bladder resulting generally in an abnormally slow urine flow rate and/or an abnormally high postvoid residual.

##### Subtypes:

- (I) Neurogenic
- (II) Non-neurogenic

#### **Detrusor leak point pressure (DLPP - cm H2O)**

##### *Investigation*

This is a static test. The pressure is the lowest value of the detrusor pressure at which leakage is observed in the absence of either a detrusor contraction or increased abdominal pressure.

#### **Detrusor Leak Point Pressure (female) - DLPP - cm H2O**

##### *Investigation*

This a static test. The pressure is the lowest value of the detrusor pressure at which leakage is observed in the absence of increased abdominal pressure or a detrusor contraction. High detrusor LPP (e.g., over 40 cm H2O) may put patients at risk for upper urinary tract deterioration, or secondary damage to the bladder in the cases of known underlying neurological disorders such as paraplegia or MS. There are no data on any correlation between detrusor LPP and upper tract damage in nonneurogenic patients.

#### **Detrusor leak point volume (DLPV)**

##### *Investigation*

The bladder volume at which urine leakage first occurs, either with detrusor overactivity or low compliance.

#### **Detrusor opening pressure (cm H2O) - pressure flow studies**

##### *Investigation*

Detrusor pressure recorded immediately before the initial isovolumetric contraction.

**Detrusor overactivity - filling cystometry***Investigation*

The occurrence of detrusor contraction(s) during filling cystometry. These contractions, which may be spontaneous or provoked, produce a waveform on the cystogram, of variable duration and amplitude. Symptoms, e.g. urgency and/or urgency incontinence or perception of contraction may or may not occur.

**Detrusor overactivity - Subtypes***Diagnosis*

- (i) Idiopathic (primary) detrusor overactivity: No identifiable cause for the involuntary detrusor contraction(s).
- (ii) Neurogenic (secondary) detrusor overactivity: There is detrusor overactivity and evidence (history; visible or measurable deficit) of a relevant neurological disorder.
- (iii) Non-neurogenic (secondary) detrusor overactivity: An identifiable possible non-neurological cause exists for involuntary detrusor contraction(s) during bladder filling. e.g. functional (obstruction); stone, tumor (e.g. carcinoma in situ), UTI.

**Detrusor Overactivity (DO)***Diagnosis*

In men and women with LUT/PF symptoms when detrusor muscle contractions occur during filling cystometry.

**Detrusor overactivity (DO) - filling cystometry***Investigation*

The occurrence of detrusor contraction(s) during filling cystometry. These contractions, which may be spontaneous or provoked, produce a wave form on the cystometrogram, of variable duration and amplitude. The contractions may be phasic or terminal. They may be suppressed by the patient, or uncontrollable. Symptoms, e.g. urgency and/or urgency incontinence or perception of the contraction may (note if present) or may not occur.

**Detrusor Overactivity (female)***Diagnosis*

This diagnosis by symptoms and urodynamic investigations is made in women with lower urinary tract symptoms (more commonly OAB-type symptoms)—when involuntary detrusor muscle contractions occur during filling cystometry

**Detrusor overactivity leak point pressure (DOLPP)***Investigation*

Lowest detrusor pressure rise with detrusor overactivity at which urine leakage first occurs in the absence of a voluntary detrusor contraction or increased abdominal pressure.

**Detrusor pressure at end of flow (Pdet-ef – unit: cm H2O) - pressure flow studies***Investigation*

Detrusor pressure recorded at the end of urine flow.

**Detrusor pressure at maximum flow (Pdet-Qmax – unit: cm H2O)***Investigation*

Detrusor pressure recorded at maximum urinary flow rate.

**Detrusor pressure (Pdet - cm H2O)***Investigation*

The component of intravesical pressure that is created by forces in the bladder wall (passive and active). It is calculated by subtracting abdominal pressure from intravesical pressure (Pdet = Pves - Pabd).

**Detrusor sphincter dyssynergia (DSD) - female***Investigation*

This is incoordination between detrusor and sphincter during voiding due to a neurological abnormality (i.e. detrusor contraction synchronous with contraction of the urethral and/or periurethral striated muscle). This is a feature of neurological voiding disorders. Neurological features should be sought. Videocystourethrography (VCU) is generally valuable to conclude this diagnosis.

**Detrusor sphincter dyssynergia (DSD) - pressure flow studies (male +/- VCU, EMG)***Investigation*

Dyscoordination between detrusor and smooth or striated sphincter function during voiding due to a neurological abnormality (i.e. detrusor contraction synchronous with contraction of the urethral and/or periurethral striated muscle). This is a feature of neurological voiding disorders.

**Detrusor underactivity (DU)***Diagnosis*

A diagnosis based on urodynamic investigations, generally (but not always) with relevant symptoms and signs, manifest by low detrusor pressure or short detrusor contraction in combination with a low urine flow rate resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span (a high postvoid residual may be present).

**Detrusor underactivity (DU) - pressure flow studies.***Investigation*

Low detrusor pressure or short detrusor contraction time, usually in combination with a low urine flow rate resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span.

**Detrusor wall thickness (DWT) or Bladder wall thickness (BWT)***Imaging*

Transabdominal visualization of the anterior bladder wall with a (linear) high frequency ultrasound scanner for the detection of BOO if DWT is  $\geq 2$  mm in bladders filled with  $\geq 250$  ml (or BWT is  $\geq 5$  mm in bladders filled with 150 ml).

**Diagnosis***Diagnosis*

The determination of the nature of a disease; clinical: made from a study of the symptoms and signs of a disease; laboratory: investigative options/procedures to be mentioned.

**Digital assessment per vaginam - Levator injury/avulsion***Sign*

A discontinuity of the levator muscle at its attachment to the inferior pubic ramus. Discontinuity may represent a partial tear, full tear, or thinning. Test for levator injury/avulsion: palpation of levator tissue, by placing finger(s) between the side of the urethra and the edge of the muscle measured on each side. The test is performed at rest and confirmed by asking the patient to contract and feeling for the edge of the contractile tissue of the levator muscle. RATING: (i) Absent: Palpable PFM contraction next to the urethra on the inferior pubic ramus; (ii) Present: A distance of  $>3.5$  finger widths between the two sides of puborectalis muscle insertion on PFM contraction (rate number of finger widths palpable in the gap; several rating scales exist).

**Digital assessment per vaginam or per rectum - fasciculation***Sign*

Individual brief twitches in a muscle. They may occur at rest or after muscle contraction and may last several minutes. RATING: (i) Present; (ii) Absent.

**Digital assessment per vaginam or per rectum - presence of scarring***Sign*

Presence of scar tissue along vaginal walls or apex. Using a finger-tip, attempt to slide the scar in all directions. Assess for adhesion or lack of mucosal/vaginal wall mobility over underlying tissue.

(i) Present (location of adhesion, degree of healing, extent/magnitude; amount of scar, mobility)

(ii) Absent

**Digital assessment per vaginam or per rectum - Pudendal nerve provocation test***Sign*

Palpation of the pudendal nerve to reproduce patient's pain if entrapment is suspected. The nerve may be palpated at the ischial spine, sacrospinous and sacrotuberous ligaments, or pudendal canal. RATING: (i) Positive: pain response; (ii) Negative.

**Digital assessment per vaginam/ per rectum - tone in resting state***Sign*

The recommended position of the examining digit(s) is to place the palmar surface of the examining finger on the levator ani, PV, or PR. Pressure or stretch is applied

perpendicular to the muscle fibers to assess tone. RATING: (i) Normal; (ii) Decreased tone; (iii) Increased tone.

**Digital examination per vaginam / per rectum - sensation in resting state***Sign*

Test for presence, absence, or altered quality of light touch sensation. RATING: (i) Present; (ii) Absent; (iii) Altered - increased or decreased.

**Digital examination per vaginam or per rectum - palpable anal sphincter gap***Sign*

A clear "gap" in the anal sphincter on digital examination indicates an anal sphincter tear.

**Digital palpation of Pelvic floor muscle (PFM) contraction per vaginam or per rectum - Repeatability of contraction***Sign*

The ability to repeatedly develop near maximal or maximal force determined by assessing the maximum number of repetitions the patient can perform. RATING: Record number of contractions in a row.

**Digital palpation of Pelvic floor muscle (PFM) contraction per vaginal or per rectum - Co-contraction***Sign*

Contraction of two or more muscles at the same time. Co-contraction of muscles can be synergistic (e.g., resulting in an augmentation of motor activity) or it could be counterproductive to normal function (e.g., contraction of antagonistic muscles resulting in abnormal movement or training other muscles instead of the targeted ones, e.g., training of gluteal muscles instead of the PFM). Activation or inhibition of PFM contraction may be task-dependent. RATING: If present, identify which muscles are co-contracting, and whether the co-contraction is synergistic or counter-productive.

**Digital palpation of pelvic floor muscle (PFM) contraction per vaginam or per rectum - Co-ordination***Sign*

The ability to use different parts of the body together smoothly and efficiently. In the pelvic floor, co-ordination may be an action between PFMs and organ function (e.g., PFM relaxation during voiding), PFMs and an external environmental event (e.g., movement of a limb) and PFMs and a rise in IAP (e.g., PFM contraction before a cough). Co-ordination is an aspect of motor control. RATING: (i) Present; (ii) Absent. If absent, describe pattern of incoordination. e.g. paradoxical contraction: the inability to maintain PFM relaxation when it is expected; or lack of PFM contraction when it is expected.

**Digital palpation of pelvic floor muscle (PFM) contraction per vaginam or per rectum - Direction of pelvic floor movement***Sign*

Direction of pelvic floor movement during voluntary PFM contraction palpated PV (on the posterior vaginal wall) or PR. (i) Pelvic floor elevation: normal finding; (ii) Pelvic floor descent: palpation of downward movement of the PFM during attempted PFM contraction; (iii) No change.

**Digital palpation of pelvic floor muscle (PFM) contraction per vaginam or per rectum - Endurance***Sign*

Muscular endurance refers to the ability of a muscle or muscle group to perform repeated contractions or to maintain a contraction for a predetermined period of time.

**Digital palpation of Pelvic floor muscle (PFM) contraction per vaginam or per rectum - Fatigue***Sign*

A decreased capacity to perform a maximum voluntary muscle action or a series of repetitive contractions.

Fatigue may occur due to central or peripheral mechanisms. A fatigued muscle is unable to continue working even when the type of activity is changed. Record the time at which fatigue starts to occur, or the number of contractions in a row before onset of fatigue.

**Digital palpation of pelvic floor muscle (PFM) contraction per vaginam or per rectum - Number of rapid contractions performed***Sign*

Number of rapid contractions performed: The number of repeated, quick MVCs performed. This can be measured in two ways, according to the instruction:

Use the rating appropriate to the instruction: (1). Number of contractions repeated within a specific duration (i.e., a 10-s period); (2) The elapsed time to perform a pre-specified number of contractions (e.g., 10 s). A contraction should comprise an ascending and a descending phase with the PFM force returning to the resting state in between. If the maximal force declines, the assessment ceases.

RATING (appropriate to the instruction): (a) Record the number of contractions repeated and the duration allowed to perform them; (b) Specify the exact number of contractions to be repeated and record the number of seconds to completion; (c) Qualitative descriptions can include quality and extent of contraction and relaxation phases.

**Digital palpation of Pelvic floor muscle (PFM) contraction per vaginam or per rectum - PFM strength***Sign*

Digital muscle test (DMT): A test to evaluate PFM strength.

PFM Strength: Force-generating capacity of a muscle. Usually expressed as a

maximum voluntary contraction measurement (MVC). A manual muscle test (MMT) evaluates the strength of a muscle by moving the muscle through its full-range of motion against gravity and then against gravity with resistance. However, because joint range of motion is not being assessed in the pelvic floor and PFM examination is performed with a digit, not a hand, the term DMT is preferred. There are more than 25 published

DMT scales which provide grade of strength ranging from absence, to weakness to increasing strength. Commonly used scales include: (i) ICS scale: absent, weak, normal (we propose the word “moderate” instead of normal), or strong; (ii) modified Oxford grading scale 0–5; (iii) Brink scale: grades 3 components (pressure, displacement, and time) on a scale of 1–4; (iv) many others.

#### **Digital palpation of pelvic floor muscle (PFM) contraction per vaginam or per rectum - Relaxation postcontraction**

##### *Sign*

Return of the PFM to its original resting tone following the voluntary contraction. The patient is able to relax the PFMs on demand, after a contraction has been performed. Relaxation is felt as a termination of the contraction. RATING: (i) Yes: Relaxation felt directly after instruction: normal finding; (b) Partial or delayed relaxation; (c) No: Absent = non-relaxing PFM.

#### **Digital palpation of Pelvic floor muscle (PFM) contraction per vaginam or per rectum - Sustained contraction endurance test**

##### *Sign*

The number of seconds the patient can hold near maximal or maximal PFM contraction. Record number of seconds contraction is sustained at near maximal or maximal intensity.

#### **Digital palpation of Pelvic Floor Muscle (PFM) Contraction per vaginam/per rectum - Voluntary PFM contraction**

##### *Sign*

Self-initiated activation of the PFM. A contraction is felt as a tightening, lifting, and squeezing action under the examining finger. Technique: The recommended position of the examining digit(s) to assess levator ani contraction (PV) unilaterally is to place the palmar surface of the examining finger on the lateral levator ani muscle belly surface or “edge,” which may be identified by asking the patient to contract then relax. The recommended position of the examining digit to assess anal sphincter and puborectalis muscle function (PR) is to place the palmar surface of the well-lubricated examining finger at the anal verge initially, wait for relaxation of EAS, then insert gently along the posterior wall of the anal canal. Once anal sphincter function is assessed the examining digit remains pressed against the posterior wall and is inserted slowly into the rectum, passing over puborectalis at the anorectal junction.

Presence of a contraction may be rated as: (i) No contraction; (ii) correct contraction (cephalad and ventral movement); (iii) Contraction only with help from other muscles; (iv) Uncertain; (v) Straining; (vi) Absent: Non-contracting PFM: During palpation there is no palpable voluntary or involuntary contraction of the PFM.

#### **Digital palpation per vaginam - PFM in resting state - Flexibility of the vaginal opening.**

##### *Sign*

The capacity of the vaginal opening to expand in response to stretching. Assessed by separating index and middle finger in the medio-lateral direction. Digital assessment of the vaginal opening is likely to represent the width of the levator hiatus. RATING: (i) Estimate the number of finger widths between the muscle bellies; (ii) Can be converted to cm width for the recording from that assessor.

#### **Digital palpation per vaginam only - Levator closure**

##### *Sign*

Movement of right and left muscle bellies closer together during a PFM contraction (palpated on the lateral vaginal wall). May be tested unilaterally if bi-digital assessment is uncomfortable for the patient. RATING: (i) Yes: Levator closure movement palpable; (ii) Partial/uncertain: Some closure movement palpable, but could be uncertain, or asymmetrical; (c) No: No levator closure movement palpable.

#### **Digital palpation per vaginam only - Levator hiatus size**

##### *Sign*

The size of the levator hiatus measured during maximal contraction by a digital examination. RATING: With 2 fingers in the vagina, distance measured in centimeters (converted approximately from finger widths) during PFM contraction; (a) LH transverse: The distance between the left and right muscle bellies just inferior to the pubic bone; (b) LH sagittal: The distance between the back of the pubic symphysis and the midline raphe of the puborectalis.

#### **Digital palpation per vaginam only - Urethral lift**

##### *Sign*

Elevation of the urethra in a cephalad direction. Index finger is placed along the line of the urethra (on the anterior vaginal wall). RATING: (i) Yes: Urethral lift palpable; (ii) No: No urethral lift palpable.

#### **Digital palpation per vaginam or per rectum - Digital rectal examination (DRE)**

##### *Sign*

Palpatory examination of the anorectal tissues.

#### **Digital rectal examination (DRE - female)**

##### *Sign*

The gloved finger should be placed in the center of the anus with the finger parallel to the skin of the perineum in the midline. The finger should then be pressed gently into the anal canal but at the same time pressed backwards against the skin of the posterior wall of the anal canal and underlying sling of the puborectalis muscle. This overcomes most of the tone of anal sphincter and allows the finger to straighten and slip into the rectum. This will allow assessment of: (a) Resting anal tone, voluntary squeeze of the anal sphincter as well as the levator muscles, sustained squeeze over 5 sec and involuntary contraction elicited during a cough; (b) Obvious hemorrhoids can be palpated but grade II and grade III. Hemorrhoids are better assessed by proctoscopy. Painful examination may be associated with fistula in ano, fissure in ano, infection or pilonidal abscess; (c) Palpable anal sphincter gap. An assessment can be made of a palpable anal sphincter gap to assess if there has been previous obstetric or surgical damage. The perineal body can be assessed for deficiency; (d) Rectal contents. The contents of the rectum can be assessed. The feces may be hard or soft, the rectum may be empty or collapsed and sometimes ballooned out. This allows assessment of fecal impaction; (e) Confirmation of presence of rectocele, enterocele, or perineocele. Use of POP-Q for staging of prolapse; (f) Bidigital examination may be carried out with the patient supine in a gynecological examining position. By inserting the index finger in the vagina and the middle finger in the rectum, the rectovaginal septum and any intervening small bowel loops can be palpated to differentiate a rectocele from an enterocele, during a Valsalva maneuver; (g) Rectal lesions such as carcinoma, intussusception or recto-vaginal fistula. If a mass is felt on a fingertip, the patient should be asked to strain, and this will often move the mass down to bring it within reach; (h) An assessment can be made of the rectovesico/rectouterine pouch to look for extra rectal masses.

**Digital Recto-vaginal examination***Sign*

While the patient is straining and the prolapse is maximally developed. The aim is to try to differentiate between a high rectocele and an enterocele.

**Digitation (female)***Symptom*

Use of fingers in rectum or vagina to manually assist in evacuation of stool contents.

**Diminished rectal sensation (rectal hyposensitivity)***Symptom*

Complaint of diminished or absent sensation of filling in the rectum.

**Direct electrical neurostimulation***Conservative Management – General*

This is a direct stimulation of the nerves or neural tissue to effect function of the end organ. It is done through electrodes implanted directly or near the nerve or neural tissue.

**Directly***Surgery – Complication related*

Without an intermediary or intervening factor.

**Disability associated urinary incontinence***Symptom*

Complaint of urinary incontinence in the presence of a functional inability to reach a toilet/urinal in time because of a physical impairment, (e.g. orthopedic, neurological) and/or mental impairment.

**Discharge (female)***Sign*

Perianal or vaginal bloody or mucus discharge.

**Diurnal polyuria***Symptom*

Complaint that daytime urine excretion volume is noticeably larger than the previous experience.

**Division***Surgery – Complication related*

A separation into two or more parts.

**Dorsal nerves of the penis***Surgery – Male*

These nerves are the terminal branches of the pudendal nerves. They travel through the deep perineal pouch, exiting just inferior to the pubic symphysis and then run along the dorsal surface of the corpora to reach the glans. They supply sensory innervation to the penis and in particular the glans.

**Double dye test for urinary tract fistula***Investigation*

This includes oral intake of phenazopyridine (pyridium) 200 mg three times a day for one to two days until urine is bright orange, followed by retrograde bladder filling with blue irrigant through a bladder catheter. Diagnosis of a bladder or urethral fistula to the vagina (VVaF, UVaF) is supported if the vaginal swab turns blue. Diagnosis of a ureteric fistula to the vagina is supported if the swab turns orange, combination upper and lower urinary tract fistula to the vagina is supported if the swab turns both blue and

orange. Careful observation for backflow of blue irrigant per meatus must be ongoing to avoid false-positive test reporting.

**Double incontinence***Symptom*

Complaint of both anal incontinence and urinary incontinence.

**Dye and bubble tests for PFF***Investigation*

Dye tests may be used to detect small or unusual fistulas (less useful for large or multiple fistulas), such as utero-vaginal or cervico-vaginal fistulas and to differentiate ureteric fistula (clear or yellow urine in vault, “negative dye test with urine in vault”) from bladder fistula (“positive dye test”) or to detect small or distorted anorectal fistula (positive vaginal bubble or rectal dye test). Dye and bubble tests are typically done at time of clinical examination for PFF, thus their inclusion in the “Signs” section.

**Dynamic infusion cavernosometry and cavernosography (DICC)***Investigation*

A combined evaluation of intracavernosal pressures and radiographic assessment of penile blood flow. It is used to identify vasculogenic leak in patients being considered for penile vascular surgery.

**Dynamometry***Investigation*

An investigation that measures both muscle power and force. Both active (contractile) and passive (noncontractile) forces can be detected.

**Dynamometry - Intra-vaginal PFM dynamometry***Investigation*

Measurement of PFM resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina. Several PFM dynamometers have been developed to assess the PFM function in women. Different configurations have been proposed in terms of the number, shape and the sizes of the branches, the force vector recorded (i.e., antero-posterior, latero-lateral or multidirectional forces) and the device specifications (e.g., configuration of strain gauges to avoid a lever-arm effect—the influence of the force location in regard to the gauges). In some dynamometers, the branches can be separated at a constant speed either manually or with a motorized unit to assess the passive properties during dynamic stretches. Elastometry is a type of intra-vaginal PFM dynamometer used for this specific application of evaluating the passive properties during dynamic stretches. Table 8 (download document) describes the most frequent parameters measured with intra-vaginal dynamometers as well as their definitions, specifications and findings. Parameters can be assessed at different fixed vaginal apertures or during stretching (i.e., while imposing an elongation to the tissues by separating the speculum branches). The parameters measured with the dynamometer alone reflect the summative contribution of the active and passive components of tone. When combined with EMG, it enables the assessment of the differential contributions of tone components, that is, during passive stretch of the PFM, concurrent EMG activity detects any electrogenic contributions. The passive component can then be identified when the EMG remains negligible.

**Dysfunction***Diagnosis*

Difficult or abnormal function

**Dysfunctional voiding - pressure flow studies (male +/- VCU, EMG)***Investigation*

This is characterized by an intermittent and/or fluctuating flow due to inadequate or variable relaxation generally of the external sphincter during voiding in neurologically normal men (i.e. no historical, visible or measurable evidence of neurological disease).

**Dysfunctional voiding (female)***Investigation*

This is characterized by an intermittent and/or fluctuating flow rate due to involuntary intermittent contractions of the peri-urethral striated or levator muscles during voiding in neurologically normal women. This type of voiding may also be the result of an acontractile detrusor (abdominal voiding) with electromyography (EMG) or video-urodynamics required to distinguish between the two entities.

**Dyspareunia***Symptom*

Complaint of persistent or recurrent pain or discomfort associated with attempted or complete vaginal penetration.

**E****Ejaculatory dysfunction (EJD)***Symptom*

Complaint of alteration of the emission or expulsion of seminal fluids during ejaculation.

**Ejaculatory dysfunction (EJD) - Acquired delayed ejaculation***Diagnosis*

A distressing lengthening of ejaculatory latency that occurs in most (>50%) coital experiences after a period of normal ejaculatory function and/or a clinically meaningful change that results in distress.

**Ejaculatory dysfunction (EJD) - Anejaculation***Diagnosis*

Complaint of absence of seminal fluid emission or expulsion. May be associated with the absence of the sensation of orgasm or anorgasmia

**Ejaculatory dysfunction (EJD) - Anhedonic ejaculation***Diagnosis*

Ejaculation without the pleasurable sensation of orgasm

**Ejaculatory dysfunction (EJD) - Delayed ejaculation***Diagnosis*

Primary or acquired complaint of an increase in the time taken for ejaculation to occur.

**Ejaculatory dysfunction (EJD) - Primary delayed ejaculation***Diagnosis*

A lifelong experience of delayed ejaculation in all or almost all (75%–100%) occasions of coital activity, which causes distress.

**Ejaculatory function - Ejaculation***Symptom*

Process related to semen expulsion from the urethra,

**Ejaculatory function - Ejection***Symptom*

Synchronous contractions of the bulbospongiosus and ischiocavernosus muscles and external

**Dyspareunia - deep***Symptom*

Complaint of pain or discomfort on deeper penetration (mid or upper vagina).

**Dyspareunia - superficial (introital)***Symptom*

Complaint of pain or discomfort on vaginal entry or at the vaginal introitus.

**Dyspareunia with penile vaginal movement***Symptom*

Pain that is caused by and is dependent on penile movement.

**Dysuria***Symptom*

Complaint of pain, burning or other discomfort during voiding. Discomfort may be intrinsic to the lower urinary tract (e.g. bladder or urethra), external or referred from other adjacent similarly innervated structures e.g. lower ureter.

urethral sphincter that allows semen to be expelled antegrade through the urethra.

**Ejaculatory function - Emission***Symptom*

Process in which semen is deposited from the vas deferens into the urethra.

**Ejaculatory function - Orgasm***Symptom*

Sensation of pleasure that accompanies sexual climax.

**Ejaculatory function - Retrograde ejaculation***Diagnosis*

Expulsion of seminal fluid into the bladder because of bladder neck dysfunction and/or disturbances involving the peri-montanal area in the presence of otherwise normal emission and expulsion. There can be no or small amounts of antegrade ejaculation. Retrograde ejaculation is defined independently from the sensation of orgasm.

**Ejaculatory pain***Symptom*

Complaint of pain, pressure or discomfort felt in the perineum, suprapubic region and/or penis during ejaculation but may continue for a time afterwards.

**Electrical Currents Used in Pelvic Floor Therapies***Conservative Management – Female*

a) Faradic current: an alternating and interrupted low frequency current capable of stimulating (depolarizing) nerve fibers through the skin using surface-stimulating electrodes. It is used to stimulate innervated muscles, causing them to contract. b) TENS: an alternating and interrupted low-frequency current capable of stimulating (depolarizing) nerve fibers through the skin using surface-stimulating electrodes for pain modulation or pain relief. c) Interferential current: a medium frequency, amplitude modulated electrical current that results from the interference (hence the word interferential) caused by crossing two or more medium-frequency alternating sine wave currents with different carrier frequencies. The carrier frequency

of these medium, alternating sine wave currents ranges between 2,000 and 5,000 cycles per second.

### Electrical neuromodulation

#### *Conservative Management – General*

This is the stimulation of the nerves or neural tissue to modulate function and induce therapeutic response of the LUT.

### Electrical Therapies - Mode of Application

#### *Conservative Management – Female*

1. Surface electrodes: non-invasive placement of electrodes, including intra-vaginal and intra-anal electrodes, in contrast to electrodes that pierce the skin, i.e., needle stimulation. a) Non-invasive electrical nerve stimulation or transcutaneous electrical nerve stimulation (TENS): the application of electrical energy to stimulate cutaneous nerve and peripheral motor nerves, via suprapubic, perineal or sacral placement of electrodes, or other external sites, or intravaginal or intra-anal plug electrodes. Tibial nerve stimulation (TNS) is a form of peripheral neuromodulation targeting symptom relief of overactive bladder (OAB) and urinary urge incontinence. Indirect access to the sacral plexus is achieved by intermittent, electrical stimulation of the tibial nerve, which lies behind the medial malleolus, using skin surface electrodes applied to the medial malleolar area (transcutaneous TNS). There are two main types of electrical stimulation with surface electrodes: i) Long-term or chronic electrical stimulation: is delivered below the sensory threshold. It is aimed at inhibiting detrusor activity by afferent pudendal nerve stimulation. The device is used 6–12h per day for several months. ii) Maximal neuromuscular electrical stimulation: applies a high-intensity stimulus, set just below the pain threshold. It is aimed at improving urethral closure, via striated muscle recruitment. Detrusor inhibition by afferent pudendal nerve stimulation has also been suggested as a mechanism of effect. Maximal electrical stimulation (35–70Hz) is applied over short period (15 to 30min), is used several times per week (and up to 1–2 times daily), and may be provided via in-clinic application or via portable devices at home).

### Electrical Therapy

#### *Conservative Management – Female*

Electrical therapy is the use of electric potential or currents to elicit therapeutic responses. Current may be directed at motor or sensory functions. It is not within the scope of this document to define all electrical stimulation terms. Electrical muscle stimulation (also known as neuromuscular electrical stimulation or electromyostimulation). Electrical muscle stimulation (EMS) is the application of electric impulses directly to striated PFM (end-plate) to facilitate contraction. EMS is often referred to as “pelvic floor muscle electrical stimulation” (PFES) or “functional electrical stimulation.” PFES is the application of electrical current to the PFM. All of these stimulations may (indirectly) cause inhibition of the detrusor contraction.

### Electromyography

#### *Investigation*

Electromyography (EMG) is the recording of electrical potentials generated by the depolarization of muscle fibers. Electromyographic diagnosis is made by evaluating the state of the muscle (muscle pathology) by recording and analyzing the electrical activity generated by the muscle. 1. Intramuscular EMG: insertion of a wire or needle electrode into the muscle to record motor unit action potentials. 2. Surface electromyography: electrodes placed on the skin of the perineum or inside the urethra, vaginal or rectum.

### Electromyography (EMG - pelvic floor) - Artefact

#### *Investigation*

Extraneous information in the EMG signal from sources other than the target muscle, such as the environment (e.g., electromagnetic radiation) or other body functions.

Artifact examples include movement or contact quality artifact, heart rate, skin electrode shear, and electrode bridging.

### Electromyography - Surface (sEMG)

#### *Investigation*

Surface EMG is a recording of motor unit action potentials using surface electrodes placed on the skin or mucosa close to the muscle of interest. Recordings are also used in assessment of the activation pattern/“behavior” (sometimes referred to as kinesiological electromyography) of a particular muscle during a defined activity. sEMG requires electrodes placed on the skin of the perineum or inside the urethra, vagina or rectum. Parameters and findings evaluated with sEMG are described separately.

### Electromyography (EMG) - Intramuscular

#### *Investigation*

Intramuscular EMG is a recording of motor unit action potentials using needle (concentric or monopolar) or wire electrodes inserted into muscles. This is not typically used in clinical assessment. The electrodes can be inserted to assess the superficial (e.g., bulbocavernosus) and deep layers (e.g. levator ani) of the PFMs as well as the urethral and anal sphincters. This assessment as a rule focuses on the motor units to investigate motor unit physiology and pathophysiology. Parameters evaluated with concentric needle EMG can be used to differentiate between normal, denervated, reinnervated and myopathic muscle. Quantitative EMG includes analysis such as the multi-motor unit potential analysis and the interference pattern analysis (turns/zero crossing or amplitude).

### Electromyography (EMG - Pelvic floor)

#### *Investigation*

EMG is the recording of electrical potentials generated by the depolarization of muscle fiber membranes. Investigators reporting PFM EMG studies should state the position of the patient, the recording equipment and conditions used. Nerve conduction studies, for example, pudendal nerve testing, are beyond the scope of this document. Important considerations when interpreting EMG signals: Baseline and contractile sEMG amplitude is affected by (i) properties of the electrode, (ii) configuration of electrodes, (iii) recording system, and (iv) patient/individual characteristics. Raw amplitude cannot be compared between individuals because the signal's amplitude is affected by many factors (e.g., cutaneous/mucosal tissue thickness, vaginal lubrication, positioning/direction of electrodes with respect to the muscle and muscle fibers, and properties of the detection system). As a consequence, normalization of the sEMG amplitude is considered critical when comparing data across individuals.

### Electromyography (EMG - pelvic floor) - Amplifiers

#### *Investigation*

Amplifiers should be described by the following: (i) type (monopolar, differential, double differential, etc.); (ii) pre-amplification at the level of the electrode; (iii) input impedance; (iv) common Mode Rejection Ratio (CMRR); (v) actual gain range used.

### Electromyography (EMG - Pelvic floor) - Crosstalk

#### *Investigation*

Muscle activity from nearby muscles that can contribute to the recorded EMG amplitude and be misinterpreted as PFM activation.

### Electromyography (EMG - pelvic floor) - Filtering of raw EMG

#### *Investigation*

filtering of the raw EMG should be specified by: (i) low and/or high pass filter properties (e.g., cut-off

frequencies, order); (ii) filter types (e.g., Butterworth, Chebyshev, Notch, etc.); (iii) notch filter.

#### **Electromyography (EMG - pelvic floor) - Intramuscular wire electrode specifications**

##### *Investigation*

Reports on intramuscular wire electrodes should include: (i) wire material (e.g., stainless steel); (ii) if single- or multistrand; (iii) if single or bipolar wire; (iv) interelectrode distance; (v) insulation material; (vi) length of exposed tip; (vii) method of insertion (e.g., hypodermic needle); (viii) depth of insertion/method of insertion guidance; (ix) location of insertion in the muscle; (x) type of ground electrode used, location.

#### **Electromyography (EMG - pelvic floor) - Surface EMG specifications**

##### *Investigation*

Reports on surface EMG should include: (i) electrode material (e.g., Ag/AgCl); (ii) electrode geometry (discs, bars, rectangular); (iii) number and size (e.g., diameter, radius, width, length); (iv) interelectrode distance; (v) use of gel or paste; (vi) skin/mucosal preparation (e.g., alcohol applied to cleanse skin, skin abrasion, shaving of hair, etc.); (vii) electrode location, orientation over muscle with respect to tendons, motor point (if known) and muscle fiber direction; (viii) type of ground electrode used, location.

#### **Electrophysiological Parameters**

##### *Conservative Management – Female*

1. Electrical current: the flow (current) of electrons (electricity) from an electron source (stimulator) the wires and electrodes used to deliver such an electrical current to soft tissues. There are three types of current: direct, alternating, and pulsed. – a) Direct: the continuous, unidirectional flow of charged particles for 1s or longer, the direction of which is determined by the polarity selected. Polarity refers to two oppositely charged poles, one positive and one negative. Polarity determines the direction in which current flows. b) Alternating: the continuous, bidirectional flow of charged particles, for 1s or longer, relative to the isoelectric baseline. c) Pulsed: the noncontinuous, interrupted, and periodic flow of direct (DC) or alternating (AC) currents.

#### **Electrostimulation - direct electrical neurostimulation**

##### *Conservative Management – General*

This is a direct stimulation of the nerves or neural tissue to effect function of the end organ. It is done through electrodes implanted directly or near the nerve or neural tissue.

#### **Electrostimulation - electrical neuromodulation**

##### *Conservative Management – General*

This is the stimulation of the nerves or neural tissue to modulate function and induce therapeutic response of the LUT.

#### **Electrostimulation - pelvic electrical stimulation**

##### *Conservative Management – General*

This is the application of electrical current to stimulate the pelvic viscera or their nerve supply.

#### **Electrostimulation - transcutaneous electrical nerve stimulation (TENS)**

##### *Conservative Management – General*

This is electrical stimulation of the nerves through intact skin to modulate function and induce therapeutic response of the LUT.

#### **Endoanal Ultrasonography (EAUS) or Anal Endosonography (AES)**

##### *Imaging*

Ultrasound of the anal canal performed with a pole-like ultrasound probe placed in the anal canal giving a 360 degree image of the anal canal. It is

usually performed with the patient placed in the lithotomy, prone position or sometime left lateral. Two dimensional AES; three dimensional AES – three-dimensional reconstruction of the anal canal is performed using either axial or sagittal images.

#### **Endoanal ultrasound imaging: Parameters and findings**

##### *Imaging*

Anal sphincter defect (or pathology): Assessment of the internal and external anal sphincters to identify presence/absence of a defect; observed in cross-sectional images of the anal sphincter. This measure is obtained by a probe inserted into the anal canal to a depth of approximately 6 cm and gently withdrawn down the anal canal. The anal canal is divided into three levels of assessment in the axial plane referring to the following anatomical structures: (i) Proximal or lower level: corresponds to the subcutaneous part of the external anal sphincter where the internal anal sphincter is absent; (ii) Middle level: corresponds to the superficial part of the EAS (concentric band of mixed echogenicity), the conjoined longitudinal layer, the IAS (concentric hypoechoic ring) and the transverse superficial perineal muscles. (iii) Distal or upper level: the hyperechoic sling of the puborectal muscle and the complete ring of the internal anal sphincter are visualized. The probe should be rotated so that the anterior aspect of the anal canal is superior (12 o'clock) and left lateral is oriented right (3 o'clock) on the screen. The acquisition of a three-dimensional data volume (3D ultrasound) of the anal sphincter is also possible.

#### **Endoscopic bladder neck incision**

##### *Surgery – Male*

Transurethral incisions of bladder neck tissue at the 5 and/or 7 o'clock positions using a metal hook with electric current or a LASER beam. An additional incision can be made at the 12 o'clock position if the bladder neck is still incompletely opened. Some surgeons only incise unilaterally to reduce the risk of retrograde ejaculation.

#### **Endoscopic bladder neck resection**

##### *Surgery – Male*

Transurethral resection of bladder neck tissue using a metal loop with electric current.

#### **Endoscopy evaluations for Pelvic floor fistulas and PFRD**

##### *Investigation*

These are normally not included in investigations in ICS documents, nor in the ICS Glossary. However, they may have a role in assessing (i) a small PFF; (ii) different PFRD issues.

(i) Cystoscopy and urethroscopy: Cystoscopy and urethroscopy may be used to better understand the configuration of upper and lower urinary tract fistulas and the proximity of the lower urinary tract to the ureteric orifice. It will clearly identify other pathology, for example, stone, tumor. Cystoscopy may, however, only be possible in the smallest of fistulas where the bladder can still contain fluid.

(ii) Anoscopy and sigmoidoscopy: Lower gastrointestinal endoscopy may be used to better understand the configuration of upper and lower anorectal tract fistula. Anorectal endoscopy is also helpful when evaluating PFRD of the anorectal tract such as stricture, residual anorectal incontinence, rectal pain syndromes, and compromised rectovaginal fistula wound healing.

(iii) Genital tract examination: Vaginocopy may be undertaken with any endoscopic equipment or nasal speculum. It is particularly helpful in the evaluation of pediatric patients and women with severe vaginal stenosis. Hysteroscopy may be undertaken to evaluate cervical patency and endometrial integrity for women reporting PFRD amenorrhea and/or infertility.

**Endovaginal ultrasound imaging in the axial plane - Levator plate angle***Imaging*

The angle (in degrees) between the reference line and the plane of minimal levator hiatus dimensions/anorectal angle, identified via a multiplanar view. Rest: This angle quantifies the levator plate position in reference to the pubic bone and the perineal body.

**Endovaginal ultrasound imaging in the axial plane - Hiatal antero-posterior diameter:***Imaging*

The diameter (in mm or cm) from right to left is measured at the widest part, and perpendicular to antero-posterior diameter.

**Endovaginal ultrasound imaging in the axial plane - Hiatal area***Imaging*

Defined and measured as the area (in mm<sup>2</sup> or cm<sup>2</sup>) bordered by the pubo-visceral muscle, PS, and inferior pubic ramus in the plane of minimal hiatus dimensions.

**Endovaginal ultrasound imaging in the axial plane - Levator ani deficiency***Imaging*

Assessed from a 3D volume. Individual levator ani muscles are evaluated in their specific axial plane where the full length of muscle can be visualized. INTERPRETATION: Rest: The muscles on each side for each subgroup are scored based on thickness and detachment from the pubic bone: (i) 0 = no defect; (ii) 1 = minimal defect with <50% muscle loss; (iii) 2 = major defect with >50% muscle loss; (iv) 3 = total absence of the muscle. Significant levator ani deficiency is defined as a total score within the range of 12–18.

**Endovaginal ultrasound imaging in the axial plane - Levator ani thickness***Imaging*

Defined as the diameter of the levator ani muscle (in mm or cm) at the "9 o'clock" and "3 o'clock" positions. Rest: Provides morphologic measurements of the levator ani diameter.

**Endovaginal ultrasound imaging in the axial plane - Perineal body***Imaging*

This anatomical structure is visualized as an ovoid-shaped, mixed echogenicity structure. The width (latero-lateral diameter) (in mm or cm) of the perineal body can be measured in the axial plane.

**Endovaginal ultrasound imaging in the sagittal plane - Perineal body***Imaging*

The depth (antero-posterior diameter) and height (supero-inferior diameter) of the perineal body can be measured in mm or cm in this plane. INTERPRETATION: Rest: Visibility of the structure and biometric measurements are identified at rest; indicate if the perineal body is visible or not visible.

**Endovaginal ultrasound imaging in the sagittal plane - Levator plate position***Imaging*

The distance (in mm or cm) between the levator plate and endovaginal probe. INTERPRETATION: (A) Rest: Quantification of the distance between the levator plate and the probe with the PFM at rest. (B) PFM contraction: A reduction of the distance between the levator plate and the probe is expected during a maximal PFM contraction; may be called levator plate lift. A greater levator plate lift ratio (lift/rest × 100) detected by dynamic endo-

vaginal sonography has been associated with higher PFM strength as determined by the Modified Oxford Scale.

**Enterocoele***Sign*

Bulge of upper wall of the vagina associated with herniation of the peritoneal sac and loops of small bowel.

**Enterovesical fistula repair***Surgery - Male*

Excision of a fistula between the bladder and an intestinal segment, usually with reconstruction of the intestinal tube and bladder wall.

**Enuresis***Symptom*

Complaint of intermittent incontinence that occurs during periods of sleep. If it occurs during the main sleep period, then it could be qualified by the adjective "nocturnal". The patient has to be asleep when enuresis happens and is usually unaware of it.

**Enuresis***Sign*

"Wetting" while asleep

**Enuresis - acquired***Symptom*

Complaint of intermittent incontinence that occurs during periods of sleep that has developed in adulthood.

**Enuresis - primary***Symptom*

Complaint of intermittent incontinence that occurs during periods of sleep that has been present lifelong.

**Epididymitis/epididymo-orchitis***Diagnosis*

The inflammatory condition involving epididymis ± testis. Affected structures may be swollen and tender, and if severe, the inflammatory process may involve the whole scrotal content and the scrotal skin as well.

**Episodic inability to void***Symptom*

Complaint of inability to initiate voiding despite relaxation and/or intensive effort (by abdominal straining, Valsalva or suprapubic pressure).

**Epispadias***Sign*

Urethral meatus sited on dorsal surface of the penis, either congenital or acquired, proximal to its normal position on the tip of the glans.

**Erectile dysfunction (ED)***Symptom*

Consistent or recurrent inability to attain and/or maintain a penile erection sufficient for sexual satisfaction and/or sexual intercourse.

**Erectile dysfunction (ED)***Diagnosis*

Consistent or recurrent inability to attain and/or maintain a penile erection sufficient for sexual satisfaction and/or sexual intercourse.

**Erectile dysfunction (ED) - Endocrine***Diagnosis*

ED secondary to an endocrine pathology, most commonly hypogonadism, but may also be due to hyperprolactinemia, thyroid dysfunction and diabetes mellitus.

**Erectile dysfunction (ED) - End-organ***Diagnosis*

ED which is due to pathology within the penis itself (e.g., Peyronie's disease).

**Erectile dysfunction (ED) - Mixed***Diagnosis*

ED which has an organic cause as well psychogenic factors (e.g., anxiety or depression) playing a role.

**Erectile dysfunction (ED) - Neurogenic***Diagnosis*

ED which is secondary to pathology of the central (e.g., spinal cord injury) or peripheral (e.g., diabetic neuropathy) nervous system.

**Erectile dysfunction (ED) - Situational***Diagnosis*

ED which only occurs in certain circumstances (e.g., with a partner but not during masturbation). Generally understood to be due to psychological factors.

**Erectile dysfunction (ED) - Vasculogenic***Diagnosis*

ED which is secondary to a problem with arterial inflow (e.g., atherosclerosis) or venous outflow (e.g., venous leak).

**Erectile dysfunction (male)***Symptom*

Complaint of inability to achieve and sustain an erection firm enough for satisfactory sexual performance.

**Erectile function***Diagnosis*

Complex mechanism of involuntary, neuropsychological, hormone-mediated vascular event that occurs when blood rapidly flows into the penis and becomes trapped in its spongy chambers.

**Erectile function after treatment for prostate cancer***Symptom*

Ability to have successful intercourse by patient self-report after any treatment for prostate cancer.

**Erectile function recovery***Symptom*

Return to baseline erectile function after treatment.

**Excoriation***Sign*

Perianal excoriation, skin rashes.

**Exercise and Exercise Training***Conservative Management – Female*

Exercise is a form of leisure time activity that is usually performed on a repeated basis over an extended period of time (exercise training) with specific external objectives, such as improvement of fitness, physical performance, or health. Exercise training includes: endurance training, strength training, flexibility training, and motor control (including balance), all of which may apply to the PFM.

Therapeutic exercise/exercise therapy: consists of interventions directed toward maximizing functional capabilities. It includes a broad range of activities intended to improve strength, range of motion (including muscle length), cardiovascular fitness, flexibility, or to otherwise increase a person's functional capacity.

1. Rehabilitation/re-education: help individuals to regain skills and abilities that have been lost as a result of illness, injury or disease, or incarceration, restoring a disabled individual to maximum independence commensurate with his or her limitations. Mode of exercise training: is not only the type of activity to be performed (for instance, fast walking, jogging, or swimming, strength training), but also the temporal pattern of activity that is recommended (that is, continuous or intermittent activity), with a detailed specification of the duration of exercise and rest periods in the case of intermittent activity bouts. Authors are encouraged to specifically describe all components of the mode of exercise and the dose provided.

**Explant***Surgery – Female*

A surgically excised prosthesis or graft.

**Exposure***Surgery – Complication related*

A condition of displaying, revealing, exhibiting or making accessible e.g. vaginal mesh visualized through separated vaginal epithelium (NB: "erosion" is not an ICS definition).

**Extra-pelvic Muscle Activity***Conservative Management – General*

Is the contraction of muscles other than those that comprise the pelvic floor, for example the abdominal, gluteal and adductor muscles. Extra-pelvic muscle activity is needed for maximal pelvic floor muscle effort.

**Extra-urethral incontinence***Sign*

Observation of urine leakage through channels other than the urethral meatus, e.g. fistula.

**Extrusion***Surgery – Complication related*

Passage gradually out of a body structure or tissue, e.g. a loop of tape protruding into the vaginal cavity. (NB "Erosion" is not an ICS definition)

**F****Fecal (flatal) urgency incontinence.***Symptom*

Complaint of an involuntary loss of feces (flatus) associated with fecal urgency.

**Fecal incontinence***Symptom*

Complaint of involuntary loss of feces.

- when feces is solid and/or

- when feces is liquid

## Fecal Incontinence (Female)

### Diagnosis

Fecal incontinence: involuntary loss of solid or liquid stool and could be due to: 1: Anal sphincter disruption is due to discontinuity of the external anal sphincter, internal anal sphincter or both; 2: Hypocontractile/acontractile sphincter is due to neuropathy or atrophy; 3: Combined anal sphincter disruption and hypocontractile/acontractile sphincter. 4: Rectal overactivity due to exaggerated smooth muscle contraction of the rectum could also be associated with hypersensitivity; 5: Overflow incontinence seepage of stool due to fecal impaction.

## Fecal (rectal) urgency

### Symptom

Complaint of a sudden compelling desire to defecate that is difficult to defer.

## Fecal urgency warning time

### Symptom

Time from first sensation of urgency to voluntary defecation or fecal incontinence.

## Fecaluria

### Symptom

Complaint of passage of feces (per urethram) in the urine.

## Feeling of incomplete (bladder) emptying

### Symptom

Complaint that the bladder does not feel empty after voiding has ceased.

## Feeling of incomplete bowel evacuation

### Symptom

Complaint that the rectum does not feel empty after defecation. May be accompanied by the desire to defecate again.

## Female Anorectal Dysfunction - Assessment of Pelvic Floor Muscle Function Sign

Pelvic floor muscle function can be qualitatively defined by the tone at rest and the strength of a voluntary or reflex contraction as strong, normal, weak, or absent or by a validated grading symptom. Voluntary pelvic floor muscle contraction and relaxation may be assessed by visual inspection, by digital palpation (vaginal or anorectal) (circumferentially), electromyography, dynamometry, manometry, or ultrasound. Factors to be assessed include muscle strength (static and dynamic) (graded as strong, normal, weak or absent), voluntary muscle relaxation (graded as absent, partial, complete, delayed), muscular endurance (ability to sustain maximal or near maximal force), repeatability (the number of times a contraction to maximal or near maximal force can be performed), duration, co-ordination, and displacement. Assessment can be made of each side of the pelvic floor separately to allow for any unilateral defects and asymmetry. Assessment of displacement (perineal elevation or descent) of the pelvic floor can be made during cough or Valsalva. Normally, there is some downward movement of the pelvic floor muscles or there is a ventral movement (perineal elevation, inward (cephalad) and upward movement of vulva, perineum, and anus). Rectal examination observations can include: (a) Anal sphincter tone and strength: given the absence of a formal quantitative assessment via the rectal route, assessment of anal tone and strength on digital examination, can be graded using the same convention used when grading transvaginally—as strong, normal, weak, or absent or by a validated grading symptom. (b) Anal sphincter tear: may be recognized as a clear “gap” in the anal sphincter on digital examination.

## Female Anorectal Dysfunction - Clinical Applications of Defecating Proctography

### Imaging

Assuming that posterior wall prolapse and rectocele can be considered the same anatomic entity, clinical examination is not accurate in diagnosing anatomical defects of posterior vaginal wall and enteroceles compared to defecography as reference standard. Clinical examination overestimates the presence of the posterior wall defects (large false positive rates) but misses enterocele in patients with primary POP (large false negative rates). The major function of proctography is not merely to document evacuatory abnormalities, but also to classify those abnormalities into those potentially surgically relevant, those likely to benefit from behavioral biofeedback therapy alone, or indeed those which are incidental. 1: Pelvic floor descent: Pelvic floor descent, defined as the distance moved by the ARJ or ARA at rest to the point of anal canal opening, is considered abnormal if it exceeds 3cm. 2: Intussusception and prolapse Intussusception refers to infolding of the rectal wall into the rectal lumen. It may be described as intra-rectal, intra-anal or external to form a complete rectal prolapse. 3: Rectocele: Rectocele diagnosis on evacuation proctography is defined as any anterior rectal bulge. The depth of a rectocele is measured from the anterior border of the anal canal to the anterior border of the rectocele. A distance of <2cm is classified as small, 2–4cm as moderate and >4cm as large. Of more relevance however is barium trapping at the end of evacuation (defined as retention of >10% of the area, and this itself is related to the size of the rectocele. 4: Enterocele: An enterocele is diagnosed when small bowel loops enter the peritoneal space between the rectum and vagina. Diagnosis of an enterocele on proctography is only really possible if oral contrast has been administered before the examination. Herniation of the sigmoid into the rectogenital space (sigmoidocele) is significantly less common than an enterocele. 5: Dyssynergic defecation Various proctographic abnormalities have been described including prominent puborectal impression, a narrow anal canal and acute anorectal angulation. However these observations may be found in normal controls and are in themselves unreliable distinguishing features.

## Female Anorectal Dysfunction - Clinical Applications of MRI in the Posterior Compartment

### Imaging

1: Fecal incontinence Endoanal ultrasound and endoanal magnetic resonance imaging (MRI) have been demonstrated to be comparable in the detection of external sphincter defects. External phased array coil MRI can replace endoluminal MRI with comparable results. 2: Levator ani injuries Abnormalities of the LA are identified on MRI as present or absent. Defect severity is further scored in each muscle from 0 (no defect) to 3 (complete loss). A summed score for the two sides (0–6) is assigned and grouped as minor (0–3) or major (4–6). 3: Obstructed defecation During maximal Valsalva maneuver, dynamic MRI may be used to demonstrate: • Rectocele: measured as the depth of wall protrusion beyond the expected margin of the normal anorectal wall. Based on sagittal MR-sections through mid of pelvis, rectoceles are graded as small (<2cm), moderate (from 2 to 4cm), and large (>4cm), • Rectal intussusception: the infolding of the rectal mucosa occurring during defecation. Depending on the location, an intrarectal intussusception, limited to the rectum, is distinguished from an intra-anal intussusception extending into the anal canal. The location of the intussusception may be anteriorly, posteriorly, or circumferentially. The intussusception either involves only the mucosa or the full thickness of the rectal wall, • Enterocele: defined as a herniation of the peritoneal sac, which contains omental fat (peritoneocele), small bowel (enterocele) or sigmoid (sigmoidocele), into the rectovaginal or rectovesical space below the PCL. The largest distance between the PCL and the most inferior point of the enterocele is measured with a perpendicular line. Depending on this distance, small (<3cm), moderate (3–6cm), and large (>6cm) enteroceles are distinguished, • Dyssynergic defecation: different structural imaging findings can be seen on dynamic

pelvic MRI, including prominent impression of the puborectal sling, narrow anal canal, prolonged evacuation, a lack of descent of the pelvic floor and thus a failure to increase the ARA. In comparison with clinical examination (POP-Q), dynamic MRI has no additional value in the prediction of symptoms with increasing degree of POP. 4: Perianal abscesses and fistulas.

### **Female Anorectal Dysfunction - Defecating Proctography**

#### *Imaging*

Evaluates in real time the morphology of rectum and anal canal in correlation with pelvic bony components both statically and dynamically by injection of a thick barium paste into the rectum and its subsequent evacuation. Contrast administration into the bladder and vagina provides a more comprehensive assessment of the pelvic organs and has been labelled "dynamic cystoproctography." At rest, the anal canal is closed and rectum assumes its normal upright configuration. The position of the pelvic floor is inferred by reference to the PCL (inferior margin of pubic symphysis to the sacro-coccygeal junction). Perineal descent is measured from this line to the ARJ, and may be up to 1.8cm at rest. Some pelvic floor descent during evacuation is considered normal and a descent of up to 3cm from the rest position to anal canal opening is acceptable. The ARA is defined as the angle between the anal canal axis and the posterior rectal wall, and on average is around 90 degrees. The puborectalis length (PRL) can be estimated by measuring the distance between the ARA and symphysis pubis. A normal emptying phase at the proctogram is described by five elements: • Increase in the ARA by around 20–30 degrees; • Obliteration of the puborectalis impression and the PRL should increase by around 3–4cm; • Wide opening of the anal canal within a couple of seconds; • Evacuation of rectal contents proceeding promptly and to completion; • Lack of significant pelvic floor descent. After evacuation is complete, the anal canal should close, the ARA recover and the pelvic floor return to its normal baseline position. Post toilet imaging may be required, particularly in those suspected of retained barium within rectoceles.

### **Female Anorectal Dysfunction - Endoanal ultrasonography (EAUS)**

#### *Imaging*

The majority of current systems provide 2D & 3D Imaging which give a 360 degree axial view of the anal canal and of the rectal wall. Endoanal ultrasound can be performed with the patient placed in the dorsal lithotomy, left lateral or prone position. Irrespective of the position, the probe should be rotated so that the anterior aspect of the anal canal is superior (12 o'clock) and left lateral is right (3 o'clock) on the screen. The anal canal is divided into three levels of assessment in the axial plane referring to the following anatomical structures: • Upper level: the hyperechoic sling of the puborectalis muscle (PR) and the complete ring of the internal anal sphincter (IAS) are visualized • Middle level: corresponds to the superficial part of the EAS (concentric band of mixed echogenicity), the conjoined longitudinal layer, the IAS (concentric hypoechoic ring), and the transverse superficial perineal muscles; • Lower level: corresponds to the subcutaneous part of the EAS where the IAS is absent. The acquisition of a three-dimensional data volume (3D ultrasound) and the underlying techniques vary. Acquisition may be "free-hand" (low resolution 3D) or "automatic computer-controlled" (high resolution 3D).

### **Female Anorectal Dysfunction - Squeeze pressure**

#### *Sign*

Measurement of squeeze pressure involves the exertion of pressure, compressing the assessor's finger during digital palpation or using a mechanical device. The patient is asked to squeeze the PFM as hard as possible (maximum strength), to sustain the squeeze contraction (endurance), or to repeat squeeze contractions (repetitions). The measurement can be done in the anorectum using manual muscle testing with digital rectal palpation or pressure manometry in the vagina using manual muscle testing with digital

vaginal palpation or pressure manometry, or dynamometry. So far, not all quantitative assessments and scales of pelvic floor squeeze pressure have the same methodological qualities, like validity, reproducibility, and responsiveness. Pelvic floor muscle spasm was defined as persistent contraction of striated pelvic floor muscle that cannot be released voluntarily. If the contraction is painful, this is usually described as a cramp. Spasm over days or weeks may lead to a contracture. Pelvic floor muscle tenderness: sensation of discomfort with or without pain; discomfort of pelvic floor muscle elicited through palpation. Tenderness can be scored during a digital rectal (or vaginal) examination of levator ani, piriformis and internal obturator muscles bilaterally, according to each subject's reactions: 0, no pain; 1, painful discomfort; 2, intense pain; with a maximum total score of 12. Although not universally accepted, pelvic floor muscle traction is the use of a pulling force to examine or treat pelvic floor muscles, postulated to end pelvic muscle spasm or relieve pain.

### **Female Anorectal Dysfunction - Transperineal ultrasonography (TPUS)**

#### *Imaging*

Conventional convex transducers (frequencies between 3 and 6MHz and field of view at least 70 degrees) provide 2D imaging of the pelvic floor. Transperineal ultrasound is performed with the patient placed in the dorsal lithotomy position, with the hips flexed and abducted. If necessary, the patient can be examined standing, to maximise descent of pelvic organs, especially if the patient finds it difficult to produce an effective Valsalva maneuver. No rectal or vaginal contrast is used. Perineal ultrasound provides sagittal, coronal and oblique sectional imaging, with the mid-sagittal plane being the most commonly used as this gives an overall assessment of all anatomical structures (bladder, urethra, vaginal walls, anal canal, and rectum) between the posterior surface of the symphysis pubis (SP) and the posterior part of the levator ani (LA). The imaging is usually performed at rest, on maximal Valsalva maneuver and on pelvic floor muscle contraction (PFMC). The access to the mid-sagittal plane allows the following evaluations: • Integrity of the perineal body: appearing as a triangular shaped, slightly hyperechoic structure anterior to the anal sphincter, • Measurement of the anorectal angle (ARA): formed by the longitudinal axis of the anal canal and the posterior rectal wall, • Dynamic assessment of the posterior compartment. During Valsalva it is possible to visualize descent of an enterocele, to assess the movement of the anterior rectal wall to detect a rectocele, and to evaluate movement of the PR and ARA to diagnose pelvic floor dyssynergy. 3D TPUS may be performed with volumetric probes (electronic curved array of 4–8MHz). An advantage of this technique is the opportunity to obtain tomographic or multi-slice imaging, for example, in the axial plane, in order to assess the entire PR and its attachment to the pubic rami. It is also possible to measure the diameter and area of the levator hiatus (LH) and determine the degree of hiatal distension on Valsalva. Four dimensional (4D) imaging indicates real-time acquisition of volume ultrasound data.

### **Female Anorectal Dysfunction - Transvaginal Ultrasound (TVUS)**

#### *Imaging*

Transvaginal ultrasound is performed with the patient placed in the dorsal lithotomy position. Currently, the transducers used for pelvic floor 3D TVUS are high multi-frequency (9–16MHz), 360 degree rotational mechanical probe or radial electronic probe. The pelvic floor is divided into four levels of assessment in the axial plane referring to the following anatomical structures (not to be confused with Delancey's description of vaginal Levels of supports). • Level I: at the highest level the bladder base is visualized on the screen at 12 o'clock position and the inferior third of the rectum at 6 o'clock position. • Level II: corresponds to the bladder neck, the intramural region of the urethra and to the anorectal junction. At this level the subdivisions of the LA (pubovaginalis, puboperinealis, puboanalis, puborectalis, and iliococcygeus) may be identified. • Level III: corresponds to the midurethra and to the upper third of the anal canal. At this level, the LA is visualized as

a multilayer hyperechoic sling coursing lateral to the vagina and posteriorly to the anal canal and attaching to the inferior pubic ramus. In the axial plane of minimal hiatal dimensions, identified as the minimal distance between the inferior edge of the SP and the anterior border of the LA at the ARA, the biometric indices (anteroposterior and transverse diameters, area) of the LH can be determined. • Level IV: at the outer level, the perineal muscles (bulbospongiosus, ischiocavernosus, and superficial transverse perineii muscles), the perineal body, the distal urethra and the middle and inferior third of the anal canal are visualized. The anteroposterior diameter of the urogenital hiatus (UGH), corresponding to the SP-perineal body distance, can be determined. Transvaginal ultrasound may be also performed with electronic probes with linear array, which provide mid-sagittal image of the posterior compartment. The main advantage of this technique is the dynamic assessment of the anorectal region, during Valsalva and pelvic floor muscle contraction (PFMC).

### **Female Anorectal Dysfunction - Ultrasonography to Assess Fecal Incontinence**

#### *Imaging*

Anal inspection and digital rectal examination can give information about internal and external anal sphincter function but are inaccurate for determining external anal sphincter defects < 90 degrees and internal sphincter defects. Therefore, a sufficient diagnostic work-up should comprise at least rectal examination, anal inspection and endoanal ultrasonography. EAUS has become the gold standard for morphological assessment of the anal canal. The International Consultation on Incontinence (ICI) has recommended EAUS as the first line imaging investigation for fecal incontinence to differentiate between those with intact anal sphincters and those with sphincter lesions (defects, scarring, thinning, thickening, and atrophy). Routine use of transperineal, transvaginal and translabial ultrasonography to image the anal sphincter complex are not recommended, although research is ongoing. The operator should identify if there is a combined or isolated lesion of the IAS and EAS and report the number of defects, as well as the extent of the defect circumferentially (radial angle in degrees or in hours of the clock) and longitudinally (proximal, distal or full length). Using 3D EAUS, two scoring systems have been proposed to define the severity of anal sphincter damage. EAUS has an important role in detecting undiagnosed anal sphincter injuries following vaginal delivery and can be useful in the management of subsequent pregnancies following OASIS. It is also useful to evaluate the results of treatment (anterior sphincter repair, bulking agent injections).

### **Female Anorectal Dysfunction - Ultrasound Imaging (General)**

#### *Imaging*

Ultrasound is increasingly being incorporated as an investigation of posterior compartment disorders. An integrated multi-compartmental pelvic floor ultrasonography with a combination of different modalities has been described to assess pelvic floor dysfunction for a global and multi-compartmental perspective. Modalities in current routine clinical use: (a) Endoanal: intra-anal 360 degree sector scanning using rotational mechanical probe or radial electronic probe. (b) Transperineal: curved array probe applied in the perineum between the mons pubis and the anal margin. This term incorporates trans-labial ultrasound. Introital ultrasound is usually assumed to imply the placement of transducer with smaller footprints (such as end-firing endo-vaginal probe) within the introitus. (c) Transvaginal: intra-vaginal curvilinear, linear array, or 360 degree sector scanning.

### **Female Anorectal Dysfunction - Ultrasound in the Assessment of Levator Ani Injuries**

#### *Imaging*

Levator avulsion is the disconnection of the muscle from its insertion on the inferior pubic ramus and the pelvic sidewall, whereas tears may occur in any part of the muscle. Avulsion is a common consequence of overstretching of

the levator ani during the second stage of labor and it is detectable by 3D TVUS and 3D TPUS imaging as the lateral attachments of the pubic bone are clearly visualized. Defects are usually visualized most clearly on maximal PFMC. Tomographic ultrasound imaging is particularly useful. Levator ani injuries affect the size of the levator hiatus, with a hiatal enlargement to over 25sq cm on Valsalva maneuver defined as "ballooning," and are related to symptoms and signs of prolapse.

### **Female Anorectal Dysfunction - Ultrasound in the Assessment of Obstructed Defecation Syndrome (ODS)**

#### *Imaging*

The term obstructed defecation syndrome (synonym: "outlet obstruction") encompasses all pelvic floor dysfunctions, which are responsible for an incomplete evacuation of fecal contents from the rectum, straining at stool and vaginal digitations. During maximal Valsalva maneuver, dynamic TPUS and TVUS may be used to demonstrate. • Rectocele: herniation of a depth of over 10mm of the anterior rectal wall; • Rectal intussusception: invagination of the rectal wall into the rectal lumen, into the anal canal or exteriorized beyond the anal canal (rectal prolapse); • Enterocele: herniation of bowel loops into the vagina. It can be graded as small, when the most distal part descends into the upper third of the vagina, moderate, when it descends into the middle third of the vagina, or large, when it descends into the lower third of the vagina; • Dyssynergic defecation: the ARA becomes narrower, the LH is shortened in the anteroposterior dimension, and the PR muscle thickens as a result of contraction.

### **Female Anorectal Dysfunction - Use of a Contrast Enema**

#### *Imaging*

Contrast enema is used to identify colon pathology (benign and malignant lesions, diverticular disease, inflammatory conditions, congenital anomalies, intrinsic and extrinsic abnormalities). 1: Single-contrast barium enema: Using an appropriate catheter, a barium-water mixture or a water-soluble solution of diatrizoate sodium (Gastrografin) is inserted into the colon with the patient in the prone position until the column of barium reaches the splenic flexure. 2: Double-contrast or air-contrast barium enema: This procedure has become the routine study for evaluation of the bowel. With the double-contrast examination, the colon is coated with a thin layer of contrast material and the bowel is distended with air so that the entire mucosal circumference is visualized.

### **Female Anorectal Dysfunction - Use of Dynamic Magnetic Resonance Imaging (MRI)**

#### *Imaging*

With the development of fast multi-slice sequences MR imaging has gained increasing acceptance for dynamic imaging of the pelvic floor. Because the posterior compartment is traditionally in the focus of interest, dynamic MR imaging of the pelvic floor is often called "MR defecography." Dynamic pelvic imaging may be performed in an open-configuration MR system in the sitting position, or in a closed configuration MR-system in the supine position. Both techniques are equally effective in identifying most of the clinically relevant abnormalities of the pelvic floor. For evaluation of the posterior compartment of the pelvic floor, the rectum should be filled with a contrast agent (ultrasound gel or mashed potatoes, gadolinium-based MR contrast agent) to study the actual act of defecation. The use of reference lines for image evaluation is helpful. The most used reference line is the pubococcygeal line (PCL), which is defined on mid-sagittal images as the line joining the inferior border of the symphysis pubis to the last or second last coccygeal joint. The anorectal junction (ARJ) is defined as the cross point between a line along the posterior wall of the distal part of the rectum and a line along the central axis of the anal canal. To determine pathologic pelvic floor descent, the measurements are made on the images, which show maximal organ descent, usually during maximal straining or during evacuation. The

anorectal angle (ARA) is defined as the angle between the posterior wall of the distal part of the rectum and the central axis of the anal canal and can be measured at rest, squeezing and straining. The extent of rectoceles and enteroceles are measured. The degree of pelvic floor relaxation is measured with two reference lines: the H line which represents hiatal widening and extends from the inferior aspect of the symphysis pubis to the posterior wall of the rectum at the level of the ARJ and the M line which represents hiatal descent and extends perpendicularly from the PCL to the posterior end of the H line. Lesions of the pelvic musculofascial support result in widening of the hiatus and descent of the levator plate. Thus, the H and M lines tend to elongate with pelvic floor relaxation, widening the levator plate descent. Abnormal pelvic floor relaxation is present, when the H line exceeds 6cm, and when the M line exceeds 2cm in length.

#### **Female Anorectal Dysfunction - Use of Nuclear Colonic Transit Study**

##### *Imaging*

Colon scintigraphy is performed at 6, 24, and 48 hr in ventral and dorsal projection after oral administration of methacrylatecoated capsule of non-resorbable <sup>111</sup>In-DTPA micropellets. The geometric center, as the sum of products of colon segment activity and colon segment number (1 - ascending colon, 2 - transverse colon, 3 - descending colon, 4 - rectosigmoid, and 5 - evacuated feces) dividing by the total counts is used to determine the velocity of colonic transit. Meals normally reach the cecum at 6 hr and are evacuated in 30 to 58 hr. Retention of radioactivity in the proximal colon at 48hr, indicates slow colonic transit while retention in the rectum indicates anorectal dysfunction.

#### **Female Anorectal Dysfunction - Use of Radiological Colonic Transit Studies**

##### *Imaging*

Segmental and total colonic transit time is assessed with the use of radio-opaque markers and sequential abdominal X-rays. There are different protocols. Most frequently used, utilizes a capsule containing 24 markers of 1 x 4.5mm. Patient takes one capsule on day 0 by mouth and X-ray is performed on day 5. Patients who expel at least 80% markers on day5 have normal colonic transit. Patients who retain 6 or more markers may have follow-up abdominal X-rays within several days. If remaining markers are scattered about the colon, the condition is slow transit or colonic inertia. If the remaining markers are accumulated in the rectum or rectosigmoid, this suggests functional outlet obstruction.

#### **Female Anorectal Dysfunction - Use of Static Magnetic Resonance Imaging (MRI)**

##### *Imaging*

Static MRI provides detailed information of the pelvic floor anatomy. Current state-of-the art MR imaging of the pelvic floor includes imaging at a magnetic field strength of 1.5 Tesla (T), using pelvic or phased-array coils and T2-weighted fast-spin echo (FSE) sequences. The spatial resolution can be enhanced by using endoluminal (endorectal, endovaginal) coils. In combination with T2-weighted FSE sequences, endoluminal coils provide improved signal-to-noise ratio (SNR) and high resolution images. Based on T2-weighted turbo spin-echo sequences, muscles are relative hypointense, ligaments and fascia hypointense while fat and smooth muscle are hyperintense. The prominent pelvic floor structures of the posterior compartment visualized at MRI are: • Perineal body and superficial perineal muscles; • Anal sphincters: the IAS is easily recognized as a circular hyperintense structure. It is approximately 2.9mm thick on endoluminal MRI. The inter-sphincteric space is seen as a bright line on T2-weighted MRI. The EAS has a thickness of 4.1mm on endoluminal imaging; • Puborectalis muscle and levator ani; • Superficial perineal muscles; • Rectum and rectal support.

#### **Female Orgasmic Disorder**

##### *Diagnosis*

Presence of either of the following on all or almost all (75% - 100%) occasions of sexual activity: (i) Marked delay in, marked infrequency of, or absence of orgasm; (ii) Markedly reduced intensity of orgasmic sensations

#### **Female Sexual Dysfunction**

##### *Symptom*

Complaint of dyspareunia or impairment of sexual desire, arousal, or orgasm.

#### **Female Sexual Dysfunction - Conservative treatments - Lifestyle modification**

##### *Conservative Management – Female*

Alterations of certain behaviors may improve sexual function. These include weight loss, appropriate sleep, adequate physical fitness, and management of mood disorders. Vulvo-vaginal pain may be treated by dietary changes and perineal hygiene (avoiding irritant soaps, detergents, and douches), although data are conflicting. Dietary modifications may be disorder specific including low oxalate diet as reduction in dietary levels of oxalate may improve symptoms of vulvodinia, or a bladder friendly diet with reductions in acidic foods and bladder irritants may treat bladder pain and associated sexual pain.

#### **Female Sexual Dysfunction - Conservative Treatments - Topical Therapies**

##### *Conservative Management – Female*

Lubricants and moisturizers - Application of vaginal lubricant during sexual activity or vaginal moisturizers as maintenance may assist with atrophic symptoms and dyspareunia. Examples of some lubricants are described below, although no one lubricant or moisturizer has been adequately studied to recommend it over others. Additionally, not all products are available in all countries.

1: Essential arousal oil: Feminine massage oil applied to vulva prior to activity. Some evidence to support efficacy in treatment of sexual dysfunction, including arousal and orgasm, compared with placebo. 2: Vulvar soothing cream: Non-hormonal cream containing cutaneous lysate, to be applied twice daily. Study shows improvement in vulvar pain with use compared to placebo. 3: Prostaglandin E1 analogue, may help increase genital vasodilation. Ongoing trials to determine efficacy in arousal or orgasmic dysfunction.

#### **Female Sexual Dysfunction - Non-pharmacological treatments - Clitoral suction devices**

##### *Conservative Management – Female*

This is a battery-operated hand held device, designed to be placed over the clitoris. It provides a gentle adjustable vacuum suction with low-level vibratory sensation. Intended to be used three or more times a week for approximately 5min at a time. This therapy has been shown to increase blood flow to the clitoral area as well as to the vagina and pelvis. Small non-blinded studies have shown it may significantly improve arousal, orgasm, and overall satisfaction in patients with sexual arousal disorder.

#### **Female Sexual Dysfunction - Non-pharmacological treatments - Fractional CO2 Laser**

##### *Conservative Management – Female*

Use of thermoablative laser to vaginal mucosa may improve microscopic structure of epithelium. This results in increased thickness, vascularity, and connective tissue remodeling, which can improve climacteric symptoms. Although long term data are lacking, some studies have shown significant improvements in subject symptoms of vaginal dryness, burning, itching, and dyspareunia as well as quality of life.

### **Female Sexual Dysfunction - Non-pharmacological treatments - Vaginal dilators**

#### *Conservative Management – Female*

Vaginal forms or inserts, dilators are medical devices of progressively increasing lengths or girths designed to reduce vaginal adhesions after pelvic malignancy treatments or in treatment of vulvar/vaginal pain. Can be useful for perineal pain or introital narrowing following pelvic reconstructive repairs. However, routine use after surgery not supported. Dilators can also be used for pelvic floor muscle stretching (ie, Thiele massage) and was found helpful in women with interstitial cystitis and high-tone pelvic floor dysfunctions.

### **Female Sexual Dysfunction - Non-pharmacological treatments - Vaginal exercising devices**

#### *Conservative Management – Female*

Pelvic muscle strengthening tools in form of balls, inserts or biofeedback monitors. May improve pelvic floor muscle tone and coordination by improving ability to contract and relax. Studies are lacking assessing their use without concurrent physical therapy.

### **Female sexual dysfunction - Non-pharmacological treatments - Vaginal vibrators**

#### *Conservative Management – Female*

Vaginal vibrators, external and internal: May be associated with improved sexual function, data controversial. Possibility that use of vibrators for self-stimulation may negatively impact sexual function with partner related activity.

### **Female Sexual Dysfunction - Physical therapy**

#### *Conservative Management – Female*

Manual therapy: Techniques that include stretching, myofascial release, pressure, proprioceptive neuromuscular facilitation, and massage applied externally on the perineum and internally to increase flexibility, release muscle tensions and trigger points in the pelvic floor muscles. It was found to be effective to improve sexual function in women with pelvic floor disorders in recent meta-analysis and systematic review. These therapies have also been found helpful in women with genito-pelvic pain.

1: Pelvic muscle exercises with or without biofeedback: May improve sexual function in women with pelvic floor disorders or pain. 2: Dry needling: Placement of needles without injection in myofascial trigger points. 3: Trigger point injections i. Anesthetic: Injection of local anesthetics, often Lidocaine, directed by trigger point palpation, can be external or transvaginal. ii. Botox: Injection of Botulinum toxin type A, a potent muscle relaxant, into refractory myofascial trigger points to reduce pelvic pain.

### **Female sexual dysfunction - Prescription treatments - Hormonal**

#### *Conservative Management – Female*

1: Estrogen: Available via prescription for both systemic use (oral or transdermal preparations); or locally use (creams, rings, or tablets). May assist with overall well-being, sexual desire, arousal and dyspareunia. Role for topical use in treatment of post-surgical atrophy or mesh extrusion. 2: Ospemifene: Selective estrogen receptor modulator for treatment of moderate to severe dyspareunia related to vulvar and vaginal atrophy, in postmenopausal women. Acts as an estrogen agonist/antagonist with tissue selective effects in the endometrium. 3: Testosterone: Not approved for use in women in the USA or UK, may be available in other countries. Variety of preparations including transdermal, oral, or pellet administration. Long term safety unknown, studies suggest improvements in satisfying sexual events, sexual desire, pleasure, arousal, orgasm and decreased distress. 4: Tibolone: Synthetic steroid with estrogenic, progestogenic and androgenic properties. It is not currently available in the USA. Studies have suggested a positive effect on sexual function with use. 5: Prasterone: dehydroepiandrosterone

suppository available as a vaginal insert. It has been shown to be efficacious when compared to placebo in decreasing vulvovaginal atrophy.

### **Female Sexual Dysfunction - Prescription treatments - non-hormonal**

#### *Conservative Management – Female*

1: Bremelanotide; formerly PT-141- Melanocortin agonist, initially developed as a sunless tanning agent, utilizes a subcutaneous drug delivery system. Treatment significantly increased sexual arousal, sexual desire and the number of sexually satisfying events with associated decreased distress in premenopausal women with FSD. 2: Serotonin receptor agonist/antagonist; flibanserin-5-hydroxytryptamine (HT)1A receptor agonist and 5-HT2A receptor antagonist, initially developed as antidepressant. Challenges in FDA applications, due to possible long term risks. Studies show improved sexual desire, satisfying sexual events, and reduced distress. 3: Dual control model in differential drug treatments for hypoactive sexual desire disorder and female sexual arousal disorder: i. Testosterone in conjunction with phosphodiesterase type 5 inhibitor (PDE-5); ii. Testosterone in conjunction with a 5-HT1A agonist. May be able to target physiologic and subjective measures of sexual functioning in a more specific manner. Premise of two types of HASDD subjects: low sensitivity to sexual cues, or prone to sexual inhibition. Tailoring on demand therapeutics to different underlying etiologies may be useful to treat common symptoms in women with lack of sexual interest and provide the appropriate therapy. Testosterone is supplied as a short acting agent 4 h prior to sexual event to lessen the side effect/risk profile. 4: Apomorphine: Nonselective dopamine agonist that may enhance response to stimuli. 5: Antidepressants and Neuropathics: Include tricyclic antidepressant and anticonvulsants, may be useful in treating sexual pain, and vulvar pain. 6: Bupropion: Mild dopamine and norepinephrine reuptake inhibitor and acetylcholine receptor antagonist, it may improve desire and decrease distress or modulate Selective Serotonin Reuptake Inhibitor (SSRI) induced FSD.

### **Female Sexual Dysfunction - Psychological intervention**

#### *Conservative Management – Female*

Counseling and therapy are widely practiced treatments for female sexual dysfunction. Even when a sexual problem's etiology and treatment is primarily urogenital, once a problem has developed there are typically psychological, sexual, relationship, and body image consequences and it may be tremendously validating and helpful for these women to be referred to counselors or therapists with expertise in sexual problems. Psychological interventions include cognitive behavioral therapy (CBT), sex therapy, and mindfulness training. While there is insufficient evidence with regard to controlled trials studying the efficacy of psychological treatment in women with sexual dysfunction, the available evidence suggests significant improvements in sexual function after intervention with traditional sex therapy and/ or cognitive behavioral therapy. Specific techniques include: 1: Sex therapy: Traditional treatment approach with aim to improve individual or couple's sexual experiences and reduce anxiety related to sexual activity; 2: Cognitive-behavioral therapy: Incorporates sex therapy components but with larger emphasis on modification of thought patterns that may interfere with sexual pleasure; 3: Mindfulness: An ancient eastern practice with Buddhist roots. The practice of "relaxed wakefulness," and "being in the moment," has been found to be an effective component of psychological treatments for sexual dysfunction.

### **Female sexual dysfunction - the effect of pelvic reconstructive surgery for prolapse and incontinence on sexual health**

#### *Surgery – Female*

Women with pelvic floor dysfunction commonly report impaired sexual function, which may be associated with the underlying pelvic floor disorder. Treatment of the underlying disorders may or may not impact sexual function. While both urinary incontinence and pelvic organ prolapse affect

sexual function, prolapse is more likely than urinary incontinence to result in sexual inactivity. Prolapse is also more likely to be perceived by women as affecting sexual relations and overall sexual satisfaction. This perception is independent of diagnosis or therapy for urinary incontinence or prolapse. Very little is known about the impact of fecal incontinence on sexual function. The effect of pelvic reconstructive surgery on sexual function has increased but there is need for more focused research. Overall, randomized trials are lacking, varied outcome measures are used among studies. There is a lack of reporting per DSM-IV/DSM 5 categories and a lack of long-term follow-up. Level of Evidence (LOE) is poor in many studies and sexual dysfunction is usually reported as a secondary outcome measure. While any surgery can impact sexual function postoperatively, most commonly performed pelvic floor surgeries were not designed with the intent to improve sexual function. In general, successful surgical treatment of incontinence or prolapse may improve sexual symptoms associated with the underlying disorder. For example, coital incontinence improves after sling surgery, but whether it impacts other aspects of sexual function such as orgasm, desire, or arousal is unclear. Surgery for prolapse may improve underlying symptoms of laxity or embarrassment from bulge, which in turn may improve sexual function, but does not seem to have a direct impact on other aspects of sexual function. A small but significant number of patients will develop pain or other sexual disorders following surgery. These pain disorders spring from a variety of causes including those caused by the use of grafts. Prediction of who will develop these pain disorders is challenging. A recent paper which evaluated the effect of vaginal surgery on sexual function reported that women overall reported improved function, decrease in dyspareunia rates, and that de novo dyspareunia rates were low at 5% at 12 months and 10% at 24 months. Nonetheless, assessment of sexual activity and partner status and function prior to and following surgical treatment is essential in the evaluation of surgical outcomes. Because of the negative impact of pain on sexual function, assessment of sexual pain prior to and following procedures should also be undertaken.

#### **Female Sexual Dysfunction Diagnoses - Female Orgasmic Disorder (American Psychiatric Association)**

##### *Diagnosis*

Presence of either of the following on all or almost all (75-100%) occasions of sexual activity: 1: Marked delay in, marked infrequency of, or absence of orgasm; 2: Markedly reduced intensity of orgasmic sensations

#### **Female sexual dysfunction diagnoses - Female Sexual Interest/Arousal Disorder (American Psychiatric Association)**

##### *Diagnosis*

Lack of, or significantly reduced, sexual interest/arousal as manifested by 3 of the following: 1: Absent/reduced interest in sexual activity; 2: Absent/reduced sexual/erotic thoughts or fantasies; 3: No/reduced initiation of sexual activity and unresponsive to partner's attempts to initiate; 4: Absent/reduced sexual excitement/pleasure during sexual activity in almost all or all (75-100%) sexual encounters; 5: Absent/reduced sexual interest/arousal in response to any internal or external sexual/erotic cues (written, verbal, visual) 6: Absent/reduced genital or non-genital sensations during sexual activity in almost all or all (75-100%) sexual encounters.

#### **Female Sexual Dysfunction Diagnoses - General comments**

##### *Diagnosis*

The Diagnostic and Statistical Manual of Mental Disorders fifth edition (DSM-5), the International Classification of Diseases 10th edition (ICD-10), and the Joint Terminology from the fourth International Consultation of Sexual Medicine (ICSM) all have proposed diagnoses for sexual disorders in women. Many of the diagnoses from the various societies overlap; ICS have chosen the diagnoses from the DSM 5, as well as the diagnosis of genitourinary syndrome of menopause as these diagnoses seem most relevant

to the population of women with pelvic floor dysfunction. The DSM 5 has combined disorders that overlap in presentation and reduced the number of disorders from six to three. Hypoactive sexual desire disorder (HSDD) and female sexual arousal disorders (FSAD) have been combined into one disorder, now called Female Sexual Interest/Arousal Disorder (FSIAD), based on data suggesting that sexual response is not always a linear, uniform process, and that the distinction between certain phases, particularly desire and arousal, may be artificial. Although this revised classification has not been validated clinically and is controversial, it is the new adopted standardization. One reason offered for the new diagnostic name and criteria were clinical and experimental observations that sexual arousal and desire disorders typically co-occur in women and that women may therefore experience difficulties in both. The DSM-IV categories of vaginismus and dyspareunia have been combined to create "genito-pelvic pain/penetration disorder" (GPPPD). Female Orgasmic Disorder remains its own diagnosis. The DSM 5 has also changed the relevant specifiers of these disorders with the goal of increasing objectivity and precision and to avoid over-diagnosis of transient sexual difficulties. In particular, all diagnoses now require a minimum duration of approximately 6 months and are further specified by severity. Genitourinary syndrome of menopause (GSM) is a new term introduced by the International Society of Sexual Medicine to describe a variety of symptoms which may be associated with sexual health. Although not validated, this diagnosis was introduced in an effort to improve communication between providers and patients regarding symptoms which may be difficult to discuss. While not a sexual dysfunction diagnosis, given the age of women who typically develop pelvic floor dysfunction, symptoms associated with GSM may be relevant to the assessment of the sexual health of women with pelvic floor dysfunction. For each of the DSM-5 diagnoses, providers should indicate whether or not the condition is lifelong or acquired, generalized or situational, and rate the severity as mild, moderate or severe in terms of the distress it causes. All of the diagnoses, except for the pain diagnoses, need to meet the criterion that it has been present for 6 months, causes significant distress, and are not a consequence of non-sexual mental disorder, severe or primarily attributable to a medication or underlying illness. For genitourinary syndrome of menopause, not all signs and symptoms need be present, but the symptoms must be bothersome and not better accounted for by another diagnosis.

#### **Female Sexual Dysfunction Diagnoses - Genito-Pelvic Pain/Penetration Disorder (American Psychiatric Association)**

##### *Diagnosis*

Persistent or recurrent difficulties with 1 or more of the following: 1: Vaginal penetration during intercourse; 2: Marked vulvovaginal or pelvic pain during intercourse or penetration attempts; 3: Marked fear or anxiety about vulvovaginal or pelvic pain in anticipation of, during, or as a result of vaginal penetration; 4: Marked tensing or tightening of the pelvic floor muscles during attempted vaginal penetration.

#### **Female Sexual Dysfunction Diagnoses - Genitourinary syndrome of menopause**

##### *Diagnosis*

The genitourinary signs and symptoms of menopause that arise from decreasing level of estrogens and other steroids. This includes burning and irritation of reproductive organs and structures, dryness, pain with intercourse and urinary urgency, dysuria and recurrent infections.

#### **Female Sexual Interest/Arousal disorder**

##### *Diagnosis*

Lack of, or significantly reduced, sexual interest/arousal as manifested by 3 of the following: (i) Absent/reduced interest in sexual activity; (ii) Absent/reduced sexual/erotic thoughts or fantasies; (iii) No/reduced initiation of sexual activity and unresponsive to partner's attempts to initiate; (iv) Absent/

reduced sexual excitement/pleasure during sexual activity in almost all or all (75% - 100%) sexual encounters; (v) Absent/reduced sexual interest/arousal in response to any internal or external sexual/erotic cues (written, verbal, visual); (vi) Absent/reduced genital or non-genital sensations during sexual activity in almost all or all (75% -100%) sexual encounters.

### **Female Sexual Interest/Arousal Disorder (FSIAD)**

#### *Diagnosis*

Hypoactive sexual desire disorder (HSDD and female sexual arousal disorders (FSAD)) have been combined into one disorder, now called Female Sexual Interest/Arousal Disorder (FSIAD), based on data suggesting that sexual response is not always a linear, uniform process and that the distinction between certain phases, particularly desire and arousal, may be artificial.

### **Filling cystometry**

#### *Investigation*

Pressure-volume relationship of the bladder during bladder filling. It begins with the commencement of filling and ends when a "permission to void" is given by the urodynamicist or with incontinence (involuntary loss) of the bladder content.

### **Filling cystometry - intrinsic sphincter deficiency (ISD)**

#### *Investigation*

Very weakened urethral closure mechanism.

### **Filling cystometry - abnormal sensations**

#### *Investigation*

Awareness of sensation in the bladder, urethra or pelvis described with the words like "tingling", "burning" or "electric shock" in the setting of a clinically relevant neurologic disorder (e.g. incomplete spinal cord lesion).

### **Filling cystometry - absent bladder sensation.**

#### *Investigation*

No bladder sensation during bladder filling, at least to an expected capacity of 500mLs.

### **Filling cystometry - aims**

#### *Investigation*

These are to assess bladder sensation, bladder capacity, detrusor activity and bladder compliance as well as to document (the situation of and detrusor pressures during) urine leakage.

### **Filling cystometry - bladder (detrusor) compliance (mL/cm H<sub>2</sub>O)**

#### *Investigation*

Relationship between the change in bladder volume (Vol) and change in detrusor pressure (p<sub>det</sub>) as a measure of the distensibility of the bladder. Compliance = Change Vol / change P<sub>det</sub>. Compliance reflects the amount of fluid in the bladder to increase the bladder pressure by 1cm H<sub>2</sub>O (mL per cm H<sub>2</sub>O)

### **Filling cystometry - bladder oversensitivity**

#### *Investigation*

Increased sensation during bladder filling with: early first desire to void; early strong desire to void, which occurs at low bladder volume; lower cystometric bladder capacity; no abnormal increases in detrusor pressure.

### **Filling cystometry - bladder sensation**

#### *Investigation*

Usually assessed by questioning the individual in relation to the fullness of the bladder during cystometry.

### **Filling cystometry - cystometric capacity**

#### *Investigation*

Bladder volume at the end of filling cystometry, when "permission to void" is usually given by the urodynamicist. This endpoint and the level of the woman's bladder sensation at that time, for example, "normal desire to void", should be noted.

### **Filling cystometry - cystometric capacity (mL)**

#### *Investigation*

Bladder volume at the end of filling cystometry, when a "permission to void" is usually given by the urodynamicist.

### **Filling cystometry - detrusor overactivity**

#### *Investigation*

The occurrence of detrusor contraction(s) during filing cystometry. These contractions, which may be spontaneous or provoked, produce a waveform on the cystogram, of variable duration and amplitude. Symptoms, e.g. urgency and/or urgency incontinence or perception of contraction may or may not occur.

### **Filling cystometry - filling rate (male)**

#### *Investigation*

The filling rate, including any changes during testing, should be noted on the urodynamic report. A medium fill rate (25-50 mL/min) should be applicable in most routine studies. Much slower filling rates (under 25 mL/min) are appropriate in men where there are concerns for poor compliance or with a bladder diary showing low bladder capacity or those with neuropathic bladder. A higher filling rate is greater than 50mL/min.

### **Filling cystometry - first desire to void**

#### *Investigation*

The first feeling that the individual may wish to pass urine. The volume at which this occurs should be noted.

### **Filling cystometry - Idiopathic (primary) detrusor overactivity**

#### *Investigation*

No identifiable cause for the involuntary detrusor contraction(s)

### **Filling cystometry - incompetent urethral closure mechanism**

#### *Investigation*

Leakage occurs during activities which might raise intra-abdominal pressure in the absence of a detrusor contraction.

### **Filling cystometry - Initial bladder volume**

#### *Investigation*

Bladder should be empty.

### **Filling cystometry - maximum cystometric capacity (mL)**

#### *Investigation*

In an individual with normal sensation, this is the volume during filling cystometry when voiding can no longer be delayed.

### **Filling cystometry - Neurogenic (secondary) detrusor overactivity**

#### *Investigation*

Detrusor overactivity and evidence (history; visible or measurable deficit) of a relevant neurological disorder.

### **Filling cystometry - non-specific bladder awareness**

#### *Investigation*

Perception of bladder filling as abdominal fullness, vegetative symptoms (nausea, vomiting, faintness), spasticity or other "non-bladder"awareness,

in the setting of a clinically relevant neurologic disorder (e.g. incomplete spinal cord lesion).

**Filling cystometry - normal detrusor activity/function.**

*Investigation*

There is little or no change in detrusor pressure with filling or any provocative activities.

**Filling cystometry - normal urethral closure mechanism.**

*Investigation*

A positive urethral closure pressure is maintained during bladder filling, even in the presence of increased abdominal pressure, although it may be overcome by detrusor overactivity.

**Filling cystometry - pain**

*Investigation*

The complaint of pain during filling cystometry is abnormal. Its site, character and duration should be noted.

**Filling cystometry - Position of female patient**

*Investigation*

Sitting position is more provocative for abnormal detrusor activity than the supine position. At some point in the test, filling might desirably take place with the woman standing.

**Filling cystometry - position of male patient**

*Investigation*

Sitting (standing) position is more provocative for abnormal detrusor activity (i.e. overactivity) than the supine position. At some point in the test, filling might desirably take place with the patient standing (in those patients able to do so). Many men will void standing.

**Filling cystometry - reduced bladder sensation.**

*Investigation*

Bladder sensation perceived to be diminished during filling cystometry.

**Filling cystometry - temperature of fluid**

*Investigation*

fluid at room temperature is mostly used. It can be warmed to body temperature but without evidence that this influences results.

**Filling cystometry - urgency.**

*Investigation*

Sudden, compelling desire to void which is difficult to defer.

**Filling cystometry - urodynamic stress incontinence (USI)**

*Investigation*

Involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

**Filling cystometry: first sensation of bladder filling.**

*Investigation*

The feeling when the individual first becomes aware of bladder filling. filling volume when this occurs can be noted/recorded.

**Filling cystometry: normal desire to void.**

*Investigation*

The feeling that leads the individual to void at the next convenient moment, but voiding can be delayed if necessary

**Filling cystometry: strong desire to void.**

*Investigation*

The persistent desire to void without the fear of leakage.

**First desire to void - filling cystometry**

*Investigation*

The first feeling that an individual may wish to void. Volume when this occurs may be noted/recorded.

**First morning void**

*Sign*

The first void after waking with the intention of rising.

**First sensation of bladder filling - filling cystometry**

*Investigation*

The feeling when the individual first becomes aware of bladder filling.

**Fistula**

*Diagnosis*

fistula (Latin: fistula—"pipe, tube") refers to an abnormal or surgically made connection between a hollow or tubular organ and the body surface, or between two hollow or tubular organs. The plural noun may be either fistulas or fistulae - fistulas will be used.

**Fistula - Non-childbirth: Cancer-related fistula (CF)**

*Diagnosis*

Due to tissue compromise from malignancy or from treatment of malignancy such as radiation therapy or surgery.

**Fistula - Non-childbirth: Congenital fistula (ConF)**

*Diagnosis*

fistula present from birth

**Fistula - Non-childbirth: Congenital fistula: Ectopic ureter**

*Diagnosis*

Ureter terminating at a site other than the bladder.

**Fistula - Non-childbirth: Congenital fistula: Hypospadias**

*Diagnosis*

Opening of the urethra other than at the site of the external urinary meatus. For example, low- or mid- vaginal.

**Fistula - Non-childbirth: Congenital fistula: Imperforate anus with spontaneous rectovaginal rupture of anorectal tract.**

*Diagnosis*

Rectovaginal fistula caused by pressure in the rectum due to an imperforate anus.

**Fistula - Non-childbirth: Congenital fistula: Total perineal defect of the genital tract.**

*Diagnosis*

Absent perineal body.

**Fistula - Non-childbirth: Iatrogenic fistula (IF)**

*Diagnosis*

PFF occurring after non-obstetric pelvic procedures/surgery.

**Fistula - Non-childbirth: Inflammatory fistula (InF)**

*Diagnosis*

Due to inflammatory conditions such as inflammatory bowel disease (e.g., Crohns, ulcerative colitis).

**Fistula - Non-childbirth: Infection-related fistula (IxF)***Diagnosis*

Due to infections/abscess (e.g., tuberculosis, schistosomiasis, infectious breakdowns of obstetric perineal trauma, perianal abscess).

**Fistula - Non-childbirth: Traumatic fistula (TF)***Diagnosis*

Due to trauma to the genital tract such as pelvic crush/impalement injury, sexual violence, female genital tract cutting, insertion of vaginal foreign materials (packing with herbs/stones/salt/foreign bodies).

**Fistula closed and continent.***Diagnosis*

fistula closed after treatment (surgical or nonsurgical) without persistent or residual incontinence of the organ system (urinary tract or anorectal tract) that had the fistula.

**Fistula closed and incontinent.***Diagnosis*

fistula closed after treatment (surgical or nonsurgical) with persistent or residual incontinence of the organ system (urinary tract or anorectal tract) that had the fistula.

**Fistula in ano***Sign*

An anal fistula is an abnormal connection between the anal canal epithelium (or rarely rectal epithelium) and the skin epithelium. Patients may complain of pain, swelling, intermittent discharge of blood or pus from the fistula and recurrent abscesses formation.

**Fistula not closed.***Diagnosis*

fistula not closed during or after treatment (surgical or nonsurgical). Not-closed fistula have defined subcategories including (i) persistent; (ii) recurrent fistula diagnoses.

**Fistula repair***Surgery – Male*

Excision and closure of an abnormal passage between two epithelial surfaces

**Fistula: Childbirth related: Obstetric fistula (OF)***Diagnosis*

Due to prolonged obstructed labor with a fistula from the urinary tract and/or anorectal tract to the genital tract caused by ischemia and necrosis.

**Fistula: Iatrogenic Childbirth-related fistula (ICRF)***Diagnosis*

Directly due to injury to urinary tract/anorectal area during operative delivery (cesarean section/cesarean hysterectomy or instrumental delivery including episiotomy).

**Fistula: Mixed obstetric and iatrogenic fistula (MOIF)***Diagnosis*

Related to operative delivery for prolonged obstructed labor. Tissue integrity already compromised by obstructed labor before operative delivery.

**Fistula-in-ano (FIA) / Anocutaneous fistula (ACF)***Sign*

fIA/ACF: an abnormal connection between the anal canal epithelium and the skin epithelium.

(i) Patients may complain of pain, swelling, intermittent discharge of blood or pus from the fistula, and recurrent abscesses formation.

**Flatal incontinence.***Symptom*

Complaint of involuntary loss of flatus (gas).

**Flaturia***Symptom*

Complaint of passage of gas per urethra.

**Flexible sigmoidoscopy***Investigation*

This refers to the inspection of the distal colonic mucosa, typically up to the splenic flexure, with a 60 cm flexible endoscope following enema preparation.

**Flow delay (unit: s) - pressure flow studies***Investigation*

The time elapsed from initial rise in pressure to the onset of flow. This is the initial isovolumetric contraction period of micturition. It reflects the time necessary for the fluid to pass from the point of pressure measurement to the uroflow transducer.

**Flow time (FT - unit: s)***Investigation*

Time over which measurable flow actually occurs.

**Fossa Navicularis***Surgery – Male*

The distal portion of the penile urethra, located within the glans penis, just proximal to the urethral meatus.

**Fourth degree perineal tear***Sign*

Defined as an acquired childbirth injury and a subset of deficient perineum, involving both loss of the rectovaginal septum, full thickness anterior defect of the anal sphincter, and variable loss with lateral displacement of the fibromuscular architecture of the perineal body (total perineal defect).

**Fourth degree perineal tear***Diagnosis*

Defined as an acquired childbirth injury and a subset of deficient perineum, involving both loss of the rectovaginal septum, full thickness anterior defect of the anal sphincter, and variable loss with lateral displacement of the fibromuscular architecture of the perineal body (cloacal-like defect).

**Frequency-volume chart (FVC)***Sign*

Frequency-volume chart (FVC): The recording of the time of each micturition together with the volume voided for at least 24 hours. Ideally a minimum of three days of recording (not necessarily consecutive) will generally provide more useful clinical data. It is relevant to discriminate daytime and night-time micturition.

**Functional Anal Length - Anal Manometry***Investigation*

Functional anal canal length is defined as the length of the anal canal over which resting pressure exceeds that of the rectum by greater than 5mmHg

or, alternatively, as the length of the anal canal over which pressures are greater than half of the maximal pressure at rest.

#### **Functional profile length - Urethral pressure profile - female**

##### *Investigation*

The length of the urethra along which the urethral pressure exceeds intravesical pressure in women.

#### **Functional profile length (on stress) - urethral pressure profile (female)**

##### *Investigation*

The length over which the urethral pressure exceeds the intravesical pressure on stress.

## **G**

#### **Generalised Vulvar Pain Syndrome**

##### *Symptom*

i. Diffuse vulvar pain perceived to be in the vestibule or beyond. ii. Dyspareunia. iii. Provocation of pain with touch, pressure or friction.

#### **Genital hiatus**

##### *Sign*

This is measured from the middle of the external urethral meatus to the posterior margin of the hymen.

#### **Genital skin signs**

##### *Sign*

(i) Excoriation, redness, irritation secondary to urinary incontinence and the effect of pads or diapers. (ii) Mycotic infections (balanoposthitis, intertrigo, or scrotal): moist, red pruritic skin usually in men with urinary or fecal incontinence, immune suppression or poorly controlled diabetes mellitus; (iii) Skin pigmentation: balanitis xerotica obliterans (BXO – syn. lichen sclerosus) and vitiligo may cause depigmentation (penile skin, scrotum, glans); (iv) Cutaneous manifestations of sexually transmitted diseases: vesicles, ulcers.

#### **Genito-anorectal fistula**

##### *Diagnosis*

An abnormal connection between the genital tract (vagina/uterus/cervix) and the anorectum.

#### **Genito-Pelvic Pain/Penetration Disorder**

##### *Diagnosis*

Persistent or recurrent difficulties with 1 or more of the following: (i) vaginal penetration during intercourse; (ii) marked vulvovaginal or pelvic pain during intercourse or penetration attempts; (iii) marked fear or anxiety about vulvovaginal or pelvic pain in anticipation of, during, or as a result of vaginal penetration; (iv) marked tensing or tightening of the pelvic floor muscles during attempted vaginal penetration.

#### **Genito-pelvic pain/penetration disorder” (GPPPD)**

##### *Diagnosis*

The categories of vaginismus and dyspareunia have been combined to create “genito-pelvic pain/penetration disorder” (GPPPD)

#### **Genitourinary syndrome of menopause (urogenital aging)**

##### *Sign*

(i) Pallor/erythema: Pale genital mucosa; (ii) Loss of vaginal rugae: vaginal

rugae flush with the skin; (iii) Tissue fragility/fissures: genital mucosa that is easily broken or damaged; (iv) Vaginal petechiae: a petechia, plural petechiae, is a small (1–2 mm) red or purple spot on the skin, caused by a minor bleed (from broken capillary blood vessels); (v) Urethral eversion: urethral epithelium turned outside the lumen; (vi) Urethral prolapse: complaint of a lump at the external urethral meatus; (vii) Loss of hymenal remnants: absence of hymenal remnants; (viii) Prominence of urethral meatus vaginal canal shortening and narrowing: Introital retraction.

#### **Glans (penile) hypoesthesia**

##### *Sign*

Reduced sensitivity of the glans penis. This may be associated with hypospadias and its treatment, penile revascularization procedures, bulbar urethroplasty

#### **Good Urodynamic Practice - Key Elements**

##### *Investigation*

A Good Urodynamic Practice comprises three main elements: . A clear indication for and appropriate selection of relevant test measurements and procedures; Precise measurement with data quality control and complete documentation; Accurate analysis and critical reporting of results.

#### **Graft**

##### *Surgery – Female*

Any tissue or organ for transplantation. This term would be used to refer to biological materials inserted. (i) Autologous grafts: From patient's own tissues e.g. rectus sheath or fascia lata. (ii) Allografts: From post-mortem tissue banks. (iii) Xenografts: From other species e.g. modified porcine dermis, porcine small intestine and bovine pericardium. Terminology for grafts has not been separated into the different applications for POP and continence surgery.

#### **Granulation**

##### *Surgery – Complication related*

fleshy connective tissue projections on the surface of a wound, ulcer or inflamed tissue surface.

#### **Gynecomastia**

##### *Sign*

Excessive development of male breast tissue which may or may not be a sign of underlying endocrinological disorder.

## **H**

#### **Halban procedure**

##### *Surgery – Female*

Obliteration of the cul-de-sac by using successive sutures placed sagittally between the uterosacral ligaments.

#### **Hemospermia**

##### *Symptom*

Complaint of the appearance of visible blood in the seminal fluid. Colour of the seminal fluid may be red or brown.

**Hematuria***Symptom*

Complaint of passage of visible blood mixed with urine. This may be initial (at the beginning), terminal (at the end) or total (throughout bladder emptying).

**Hemorrhoids***Sign*

Abnormality of the normal cushion of specialized, highly vascular tissue in the anal canal in the submucosal space. Hemorrhoids can be divided into those originating above the dentate line which are termed internal and those originating below the dentate line which are termed external. Internal hemorrhoids are graded as follows: (I) Grade I bleeding without prolapse; (II) Grade II prolapse with spontaneous reduction; (III) Grade III prolapse with manual reduction; (IV) Grade IV incarcerated, irreducible prolapse. Grade II and Grade III hemorrhoids will become evident on asking the patient to bear down and grade IV hemorrhoids are obvious at the time of the examination. A proctoscopy is essential in examining for hemorrhoids unless they are completely prolapsed.

**Hesitancy***Symptom*

Complaint of a delay in initiating voiding (when the individual is ready to pass urine).

**Heterotopic - Neobladder: Charleston pouch***Surgery – Male*

Utilizes the same bowel segments of Indiana pouch with the addition of the appendix as the cutaneous catheterisable stoma.

**Heterotopic - Neobladder: General***Surgery – Male*

Reconstructed urine storage organ (neobladder), which is attached directly to the ureter(s). Created entirely from bowel (usually terminal ileum), this neobladder resides outside the pelvis, and requires a catheterisable continent channel to the skin.

**Heterotopic - Neobladder: Ileal reservoir***Surgery – Male*

This neo-bladder is made entirely of ileum. It is opened at the anti-mesenteric border and stitched back in a de-tubularised manner.

**Heterotopic - Neobladder: Indiana pouch***Surgery – Male*

Utilizes a segment of terminal ileum, caecum, and ascending colon. The ureteric implantation along the tinae coli and plication sutures of the ileal stoma conduit for improvement of continence.

**Heterotopic - Neobladder: Lundiana pouch***Surgery – Male*

Utilizes the ileocaecal segment with an instussuscepted ileal nipple, including the ileocaecal valve as efferent segment.

**Heterotopic - Neobladder: Mainz II pouch***Surgery – Male*

Also known as sigma-rectum pouch.

Hence the pouch is created from a segment of rectum and sigmoid colon. The Mainz-II can also be utilized to convert a uretero-sigmoidostomy or colonic conduit.

**Heterotopic - Neobladder: Mansoura (small bowel) pouch.***Surgery – Male*

Construction of a detubularized W-shaped ileal reservoir in which two serous lined troughs and two tapered ileal segments are used, one for reflux prevention and the other as a continent outlet.

**Heterotopic - Neobladder: Studer (small bowel) pouch***Surgery – Male*

Utilizes a segment of terminal ileum of approximately 54 cm length 25 cm proximal from the ileocaecal valve. The ureteric implantation site is located at the proximal end of a closed ileum segment (chimney usually at the right side with a length of 14 cm), whereas the rest of the ileum is opened at the anti-mesenteric border and stitched back to a plate which is then formed to a neobladder and anastomized to the urethra.

**High resolution (pelvic floor) manometry***Investigation*

Complete definition of the intra-anal pressure environment using a catheter with a large number of pressure sensors spaced less than 0.5 mm apart along the length of the catheter.

**Hispareunia***Symptom*

Male partner pain with intercourse after female reconstructive surgery.

**Hormonal assessment in female sexual dysfunction***Investigation*

Hormones such as estrogen, progesterin, and androgen influence sexual function and imbalance may lead to various symptoms including decreased libido, lack of arousal, vaginal dryness and dyspareunia. Depending on the underlying suspected conditions associated with sexual dysfunction, hormonal investigations such as estradiol (or FSH if symptoms of deficiency), serum testosterone, dehydroepiandrosterone acetate sulphate (DHEAS), free testosterone, dihydrotestosterone, prolactin, and thyroid function testing may be considered. Moreover, the evaluation of vaginal pH and vaginal maturation index (ie, percentage of parabasal cells, intermediate cells, and superficial cells) can be helpful in women with vulvovaginal atrophy as it has been shown to be correlated with patient's symptomatology.

**Hygiene***Conservative Management – Female*

Bladder hygiene: Bladder hygiene prevents UTI by using techniques such as wiping the urethral meatus with clean wipes in an anterior-to-posterior direction after voiding, wearing clean underwear, keeping the genital area clean, and emptying the bladder before and after sexual intercourse. Vulval hygiene: involves maintaining a clean perineum by means of washing the area on a regular basis, and wearing cotton underwear. To avoid vulval irritation, shampoo, perfumed creams or soap should be avoided. Anal hygiene: involves keeping the perianal region clean, which is especially important when fecal seepage is present. Advice includes using soft toilet paper or moist wipes (avoiding any with an alcohol base), always wiping from front to back, washing after a bowel movement, then gently patting dry. To avoid irritation from products, the vulval hygiene advice above should be followed.

**Hypersensitivity***Symptom*

Increased nerve activity from a standardized stimulus with an expected tissue/clinical response. The underlying mechanism remains to be defined.

**Hypogonadism (Male)***Diagnosis*

A term introduced to signify low testosterone levels associated with infertility. It has more recently been used interchangeably with the idea of low testosterone production alone.

**Hypogonadism (Male) - Low testosterone***Diagnosis*

Serum total testosterone level being less than 300 ng/dl. Threshold for low testosterone in the International System of Units: 11 nmol/l (USA), 12 nmol/l (Europe).

**Hypogonadism (Male) - testosterone deficiency (TD)***Diagnosis*

A state of low testosterone production combined with symptoms and/or signs that are associated with low serum total testosterone.

**Hypospadias***Sign*

Urethral meatus sited on ventral surface of the penis, either congenital or acquired, proximal to its normal position at the tip of the glans. Types: glans penis (glandular hypospadias); sulcus (coronal hypospadias); shaft (penile hypospadias); scrotum (scrotal hypospadias); perineum (perineal hypospadias).

**ICS STANDARD***Investigation*

Best practice, based on evidence, with the use of standard terms and standard techniques, evaluated and reported clinically or scientifically, in a complete and validated manner.

**ICS Standard Urodynamic Information Leaflet***Investigation*

Overview of the content of an ICS Standard Information Leaflet for Urodynamics.

- What is a urodynamic investigation?
- That the tests involves insertion of catheters into the bladder and rectum, and relevant technical issues.
- What is the usefulness of urodynamics? Why is the testing done?
- What are the different steps of urodynamic investigation and how they are performed (e.g. uroflowmetry, cystometry, urethral pressure measurement and pressure-flow)
- How dignity, communication and comfort during the investigation are maximized (What you do or offer in this regard).
- The symptoms that may occur following the investigation, what they indicate and how can they be handled or prevented, e.g. the fact that mild discomfort, frequency, dysuria and haematuria may be experienced, and a urinary tract infection may occasionally develop.
- Additional information including length of the investigation, sterility of relevant parts of equipment, lack of 'injections'.
- That the test is done interactively and that communication with the patient is a necessary part of the test.
- What the patient should do before the test (e.g. arrive if possible with a full bladder for uroflow, and also with an empty bowel if possible).
- Whether the patient should continue medication before the test, or whether there are specific medications that the patient should not take in (a defined period) before the test. Note: This should be individualized, e.g. with a tick box or a written instruction of the requester.
- What the patient should do after the test.
  - o e.g.: Immediately drink one portion of ½ - 1L extra fluid to ensure prompt voiding again, in order to relieve urethral irritation rapidly.
  - o All usual activities are permitted after the test.
  - o Symptoms and signs of urinary tract infection and what steps to take if these arise.

**ICS STANDARD URODYNAMIC PROTOCOL (ICS-SUP)***Investigation*

A patient undergoing collection of a clinical history (should include (a) valid symptom and bother score(s) and medication list), relevant clinical examination, (3 days-) bladder diary, representative uroflowmetry with post-void

residual (PVR) and a complete ICS standard urodynamic test, is referred to as having had the 'ICS standard urodynamics protocol (ICS-SUP).

**ICS Standard Urodynamic Test***Investigation*

Free uroflowmetry, postvoid residual, cystometry and pressure-flow study are termed ICS standard urodynamic test (ICS-SUT).

**ICS Standard Urodynamics Report***Investigation*

- Overall judgement of the technical quality and the clinical reliability of the test to represent the lower urinary tract function 'as usual', to be evaluated by the person who performed the tests.
- Uroflowmetry: Voiding position, urge (before the test) and representativeness, as reported by the patient.
- Introduction of catheters: sensation; (if occurring; pain), muscular (pelvic or adductor) defence and -perceptibly unusual- obstruction(s) during insertion.
- Position(s) during cystometry and pressure flow study.
- Patient's ability to report filling sensations and/ or urgency and/ or urine loss.
- Method of urodynamic stress test (if applicable).
- Pressure-flow: position and representativeness as reported by the patient.
- Accessory tests or measurements (if applicable -no further standard).
- Representativeness of the tests to reflect the 'usual LUT behaviour' as reported by the patient.
- filling sensation (with volumes) -diagnosis or urodynamic condition.
- Cystometry (detrusor) pressure pattern -diagnosis.
- Pressure-flow -diagnosis (compared with uroflowmetry) includes:
  - Bladder outflow function, or obstruction (and the method for assessment)
  - Detrusor contraction, (and the method for assessment)

**Idiopathic (primary) detrusor overactivity (DO) - filling cystometry***Investigation*

No identifiable cause for involuntary detrusor contraction(s).

**Ileal conduit***Surgery - Male*

A rerouting of the urine from the ureters through an isolated segment of terminal ileum to a premarked site on the skin. It is in most parts of the world the most common diversion performed after cystectomy.

**Ileocaecal reservoir***Surgery – Male*

This neo-bladder is constructed from terminal ileum and caecum incorporating the ileo-caecal valve. Again, this isolated piece is de-tubularized to be stitched back together to decrease the peristalsis and increase capacity of the reservoir.

**Ileocystoplasty***Surgery – Male*

See also cystoplasty.

The piece of bowel used is terminal ileum at least 30 cm from ileo-caecal junction.

**Ileovesicostomy***Surgery – Male*

A communication from the bladder through an isolated segment the ileum to the skin. This method is typically employed with high spinal lesion patients who cannot perform intermittent catheterization.

**Impaired cognition urinary incontinence***Symptom*

Complaint of periodic urinary incontinence that the individual with cognitive impairment reports to have occurred without being aware of it.

**Impaired mobility urinary incontinence***Symptom*

Complaint of inability to reach the toilet on time for voiding because of physical or medical disability (similar to "disability associated urinary incontinence").

**Implant***Surgery – Female*

A surgically inserted or embedded prosthesis or graft.

**Inability to void***Symptom*

Complaint of inability to initiate voiding despite an intensive effort (by abdominal straining, Valsalva or suprapubic pressure).

**Incompetent urethral closure mechanism - filling cystometry***Investigation*

Leakage occurs during activities which might raise intra-abdominal pressure in the absence of a detrusor contraction.

**Incompetent urethral closure mechanism (female)***Investigation*

Leakage of urine occurs during activities which might raise intra-abdominal pressure in the absence of a detrusor contraction.

**Incontinent diversion***Surgery – Male*

Rerouting of the urine from the urinary bladder, with or without removal of all or part of the urinary bladder. Reconstruction often involves addition of an isolated intestinal segment (stomach/small intestine/colon). Egress of urine is cutaneous and requires containment. Common incontinent diversions include ileal/colonic conduits, ileovesicostomy and ureterostomy.

**Increased bladder filling sensation***Symptom*

Complaint that the sensation of bladder filling occurs earlier or is more intense or persistent to that previously experienced. n.b. This differs from

urgency by the fact that micturition can be postponed despite the desire to void.

**Increased daytime defecation (female)***Symptom*

Complaint that defecation occurs more frequently during waking hours than previously deemed normal by the woman.

**Increased daytime urinary frequency***Symptom*

Complaint that voiding occurs more frequently during waking hours than previously deemed normal by the individual (or caregivers).

**Increased (high) semen volume***Symptom*

Complaint of higher amount of seminal fluid than normal or previously experienced.

**Increased libido (male)***Symptom*

Complaint of increased interest in sexual activity in comparison with previous experience.

**Increased rectal sensation (rectal hypersensitivity)***Symptom*

Complaint of a desire to defecate (during rectal filling) that occurs earlier or is more persistent to that previously experienced. Can be (i) first sensation; (ii) urge sensation; (iii) maximum tolerated volume.

**Increased urinary frequency***Symptom*

Complaint that voiding occurs more frequently than deemed normal by the individual (or caregivers). Time of day and number of voids are not specified.

**Indwelling catheterization***Conservative Management – General*

An indwelling catheter remains in the bladder, urinary reservoir or urinary conduit for a period longer than one emptying.

**Inflammatory Bowel Disease (IBD)***Diagnosis*

Inflammatory Bowel Disease (IBD)—Complaint of recurrent abdominal pain and discomfort of at least 3 days per month in the last 3 months. The majority of IBD patients experience periods of flares and remission.

i. Abdominal and anal pain, diarrhea which may be associated with blood, suggestive of ulcerative colitis. ii. Abdominal pain, fatigue, prolonged diarrhea with crampy abdominal pain, weight loss, and fever, with or without gross bleeding. Irregular bowel habits, with possible blood in the stool, are suggestive of Crohn's disease.

**Inflatable penile prosthesis (IPP)***Surgery – Male*

The penile prosthesis type which can be inflated by the patient to create an erection on demand and deflated at other times.

**Inflatable penile prosthesis (IPP) - 2-piece IPP***Surgery – Male*

The IPP type which works in a similar way as the 3-piece IPP, but the fluid reservoir is part of the pump implanted in the scrotum.

**Inflatable penile prosthesis (IPP) - 3-piece IPP***Surgery – Male*

3-piece IPP: This IPP type which consists of a fluid-filled reservoir implanted under the abdominal wall, a pump and a release valve placed in the scrotum, and two inflatable cylinders inside the penis.

**Infrasacral (cauda equina or peripheral nerves) lesion (CEPNL)***Diagnosis*

This is a neurological lesion affecting the cauda equina and/or peripheral nerves. Neurogenic lower urinary tract dysfunction in CEPNL: an acontractile detrusor and/or stress urinary incontinence may be present. In diabetic neuropathy, detrusor overactivity can be seen in combination with the above.

**Inguinal hernia: direct***Diagnosis*

Protrusion of abdominal content through a weakness of the posterior wall of the inguinal canal medial to the inferior epigastric vessels.

**Inguinal hernia: indirect***Diagnosis*

Protrusion of abdominal content through inguinal canal down to the scrotal sac, causing swelling, discomfort and jeopardizing the vascular supply of the herniated intestinal segment.

**Inguinal protrusion***Sign*

Examination and differentiation of hernia from hydrocele or cyst of spermatic cord or groin lymph nodes.

**Insensible urinary incontinence***Symptom*

Complaint of urinary incontinence where the individual is aware of urine leakage but unaware of how or when it occurred.

**Insertion***Surgery – Complication related*

Putting in.

**Intercurrent pathology - ultrasound imaging (male)***Investigation*

Prostate volume (transrectal), tumor, hydronephrosis, scrotal abnormalities.

**Intermittency (Intermittent stream)***Symptom*

Complaint of urine flow that stops and starts on one or more occasions during one voiding episode.

**Intermittent catheterization (IC)***Conservative Management – General*

Drainage of the bladder or a urinary reservoir with subsequent removal of the catheter mostly at regular intervals.

**Interpretation of Normality of Free Uroflowmetry (Female)***Investigation*

Because of the strong dependency of urine flow rates on voided volume, they are best referenced to nomograms where the cutoff for abnormally slow (MUFR, AUFR) has been determined and validated, as under the 10th centile of the respective Liverpool nomogram. References to a specific urineflow rate as the lower limit of normal provided a specific volume has been voided require further validation studies.

**Interpretation of normality of free uroflowmetry (men)***Investigation*

Because of the strong dependency of urine flow rates in men on voided volume and age, they are best referenced to nomograms where the cutoff for normality has been determined and validated. Ideally, abnormal uroflowmetry studies should be repeated.

**Interstitial Cystitis***Diagnosis*

As for Bladder Pain Syndrome (BPS), i.e. Persistent or recurrent chronic pelvic pain, pressure or discomfort perceived to be related to the urinary bladder accompanied by at least one other urinary symptom such as an urgent need to void or urinary frequency, though with a known Hunner's lesion present. Pain, pressure or discomfort often increases with bladder filling.

**Intimacy and sexual avoidance***Symptom*

Unwillingness or reluctance of engaging in sexual activity or intimacy with others.

**Intra-anal manometry***Investigation*

Manometry performed via the anal canal.

**Intra-urethral manometry***Investigation*

Manometry performed via the urethra. One example is the urethral pressure profile that is undertaken as part of a urodynamic investigation.

**Intravaginal Devices***Conservative Management – Female*

Intravaginal devices are intended to provide some support to the bladder neck and possibly some compression to the urethra, to correct urinary stress incontinence. These can be traditional tampons, pessaries, and contraceptive diaphragms and devices designed specifically to support the bladder neck (removable, reusable intravaginal ring or single-use disposable devices).

**Intra-vaginal manometry***Investigation*

Manometry performed via the vaginal canal.

**Intra-vaginal manometry - Compliance***Investigation*

The reciprocal of muscle stiffness (mm/N). RATING: The higher the mm/N, the more compliant the tissue.

**Intra-vaginal manometry - Hysteresis***Investigation*

The area between the lengthening and shortening curves (N × mm). It corresponds to the loss of energy associated with lengthening of visco-elastic tissues. RATING: Increased area indicates higher energy dissipated.

**Intra-vaginal manometry - Maximal aperture***Investigation*

The maximal vaginal opening in mm or cm of the dynamometer branches, without provoking a pain response. RATING: This aperture can be used to evaluate the flexibility of the PFMs.

**Intra-vaginal manometry - Maximal strength***Investigation*

Peak force in N generated during a MVC. The resting forces recorded before the effort are usually subtracted from the peak value. Specify: (i) The length of hold for the MVC, e.g., 10 s contraction duration; (ii) How the peak score was obtained, e.g., peak during a single MVC, best of or average of 3 contractions.

RATING: Higher peak value indicates higher muscle strength.

**Intra-vaginal manometry - Normalized area under the force curve***Sign*

The area under the force curve divided by maximal force and multiplied by 100 (in %  $\times$  prescribed s) during a sustained MVC. RATING: Higher normalized area is indicative of better muscle endurance.

**Intra-vaginal manometry - Number of rapid contractions***Investigation*

A contraction must comprise an ascending and a descending phase with the amplitude of the PFM forces returning to the resting state post contraction. RATING: Higher number of contractions are suggestive of higher speed of contraction but also better motor control, as the task requires alternation between MVC and complete rest.

**Intra-vaginal manometry - Passive forces at rest***Investigation*

Passive forces: The average forces in N recorded at rest. Specify: (i) Opening (distance between the two branches e.g., minimal opening, selected opening or maximal opening); (ii) While stretching (dynamic opening). RATING: The finding is the resting forces of the PFM's which are indicative of PFM tone, i.e., the summative contribution of the active and passive components of tone.

**Intra-vaginal manometry - Speed of contraction***Investigation*

Rate of force development measured as the mean slope of the ascending curve in N/s during a fast MVC. RATING: Higher rate of force (steeper slope) is indicative of a faster generation of force.

**Intra-vaginal manometry - Speed of relaxation***Investigation*

Rate of force reduction measured as the mean slope of the descending curve in N/s during PFM relaxation. RATING: Lower values are indicative of slower relaxation.

**Intra-vaginal manometry - Stiffness***Investigation*

The resistance to deformation. Passive elastic stiffness is defined as the ratio of the change in the passive resistance or passive force ( $\Delta F$ ) to the change in the length displacement ( $\Delta L$ ) or  $\Delta F/\Delta L$  (N/mm). Passive elastic stiffness should be computed for specific vaginal apertures. RATING: The higher the N/mm value, the stiffer the muscle. This is a physiological property of muscle which contributes to the overall measurement of tone.

**Intra-vaginal manometry - Visco-elastic stress relaxation during a static (sustained) stretch***Investigation*

The percentage loss in passive force during the application of a steady stretch over a prolonged period (e.g. 1 min). RATING: Higher percentage

of force decline is indicative of an enhanced visco-elastic stress relaxation response and muscle relaxation. This could be useful in quantifying tissue relaxation following stretching or lower force decline associated with strength training.

**Intravenous urography (IVU)***Imaging*

This provides an anatomical outline of the urinary tract including a nephrogram prior to passage of the contrast to the calyces, renal pelvis, ureter and bladder.

**Intravesical pressure (Pves - cm H2O)***Investigation*

The pressure within the bladder (as directly measured by the intravesical catheter)

**Intravesical prostatic protrusion (IPP) - ultrasound imaging (male)***Investigation*

The distance from the bladder base until the tip of the prostate in the bladder lumen. It is recommended to fill the bladder with 100-200mLs of fluid in order to receive representative measurements; bladder filling over 400 mL will lower IPP values. The IPP measurement can be divided into three grades: grade I = 0-4.9 mm; grade II = 5-10 mm; grade III = > 10 mm. IPP grade III is associated with prostate-related BOO.

**Intrinsic sphincter deficiency (ISD)***Diagnosis*

Very weakened urethral closure mechanism.

**Intrinsic sphincter deficiency (ISD) - Filling cystometry***Investigation*

Very weakened urethral closure mechanism.

**Intusseption***Diagnosis*

Full thickness invagination of the upper rectum without extrusion through the anus leading to interruption of flow of the fecal stream.

**Invagination***Surgery - Complication related*

Vaginal mucosa folded and entrapped on itself, characterized by a fixed and tight area on examination.

**Invasive Urodynamics***Investigation*

Any test that is invasive, as it involves insertion of one or more catheters or any other transducers into the bladder and/ or other body cavities, or insertion of probes or needles, for example for EMG measurement.

**Irritable Bowel Syndrome (IBS) - Functional (non-inflammatory)***Diagnosis*

i. Recurrent episodes of abdominal pain. ii. Changes in frequency, form or consistency of the stool. iii. Sensation of incomplete evacuation, straining, fecal urgency. iv. Sensation of nausea, fatigue, fullness, vomiting. v. Recurrent abdominal pain or discomfort at least 3 days/month in the last 3 months associated with two or more of the following: 1. Improvement of pain with defecation. 2. Onset associated with change in frequency of stool. 3. Onset associated with a change in the form (appearance) of stool

## J

### Joint therapies

#### *Conservative Management – Female*

1. Mobilization: skilled passive movement of a skeletal joint including graded passive oscillations at the joint to improve joint mobility, e.g., movement

## L

### Labia Majora fat-flap

#### *Surgery – Female*

The use of labial fibro-adipose tissue underneath the labia majora.

### Labia minora flap

#### *Surgery – Female*

The use of labia minora to provide a skin flap to help reconstruct the vagina.

### Labial thermistor

#### *Investigation*

Temperature measurement evaluated with a small metal clip attached to the labia minorum and equipped with a sensitive thermistor.

### Laparoscopic Assisted Vaginal Hysterectomy

#### *Surgery – Female*

A laparoscopic approach is used to divide the three uterine pedicles (broad ligament, uterine vessels and uterosacral/cardinal). The uterus is removed vaginal with the vaginal vault oversewn laparoscopically.

### Laparoscopic radical prostatectomy (LRP) or Robot-assisted radical prostatectomy (RARP)

#### *Surgery – Male*

Radical removal of the entire prostate and seminal vesicles via a minimally-invasive abdominal extraperitoneal or transperitoneal or even transperineal approach by using trocars and laparoscopic armamentarium for the treatment of prostate cancer.

### Laparoscopic/ robot-assisted adenomyectomy (enucleation of prostate)

#### *Surgery – Male*

Extraperitoneal or transperitoneal enucleation of prostate with laparoscopic or robotic armamentarium. The enucleation of the prostate adenoma is similar to open enucleation of the prostate and can be done by the transvesical (Freyer; Hryntschak) or transcapsular approach (Millin). These operations are usually done in large volume prostates (>80 cm<sup>3</sup>)

### Laser Doppler imaging of genital blood flow

#### *Investigation*

An imager positioned close to the vulva allows the assessment of skin/mucosae microcirculation at a depth of up to 2-3 mm. This method has been used to assess response to sexual stimulation and correlated with subjective arousal. It has also led to a better understanding of microvascular differences in women with provoked vestibulodynia compared to asymptomatic controls.

### Leak point pressure

#### *Investigation*

The leak point pressure is the pressure (spontaneous or provoked) that has caused fluid to be expelled from the bladder at the moment that it is visible outside the urethra (may also be used for extra-urethral urine loss or stoma). This may be Abdominal, Cough or Valsalva LPP or Detrusor LPP. Provocation and pressure recording site ('type of LPP') should be reported.

of the coccyx. 2. Manipulation: a passive (for the patient) therapeutic movement, usually of small amplitude and high velocity, at the end of the available joint range. Manipulation is a sudden small thrust that is controlled by the clinician.

### Levator defects/ trauma

#### *Sign*

Per-vaginal palpation for levator injury/defect/ "avulsion".

### Levator injury/avulsion

#### *Sign*

A discontinuity of the levator muscle at its attachment to the inferior pubic ramus. Discontinuity may represent a partial tear, full tear, or thinning. Test for levator injury/avulsion: palpation of levator tissue, by placing finger(s) between the side of the urethra and the edge of the muscle measured on each side. The test is performed at rest and confirmed by asking the patient to contract and feeling for the edge of the contractile tissue of the levator muscle. RATING: (i) Absent: Palpable pelvic floor muscle contraction next to the urethra on the inferior pubic ramus; (ii) Present: A distance of >3.5 finger widths between the two sides of puborectalis muscle insertion on pelvic floor muscle contraction. Rate number of finger widths palpable in the gap. Several rating scales exist. Under <3.5 cm may represent a partial avulsion, however, digital palpation cannot reliably determine this distance of discontinuity.

### Libido (Male)

#### *Symptom*

A person's overall sexual drive or desire for sexual activity.

### Lichen Sclerosis (LS)

#### *Diagnosis*

A chronic, inflammatory disease affecting genital skin that is characterized by hypomelanotic and sclerotic changes, often resulting in phimosis, meatal stenosis, and even panurethral strictures.

### Lifestyle Modification for Pelvic Floor Dysfunction

#### *Conservative Management – Female*

Lifestyle modification is the application of interventions in the management of lifestyle-related health problems, e.g., change to a healthy diet and regular participation in physical activity and smoking cessation. The following lifestyle modifications may be applied to treat pelvic floor dysfunctions, either in combination with other therapies or as "stand alone" treatments.

1. fluid consumption/restriction: fluid consumption is the intake of fluid over 24h. fluid restriction is the limitation of fluid to a prescribed amount over a period of 24h. These measures are often undertaken as part of a bladder training process.
2. Dietary modification: an alteration or adjustment of food to treat bowel disorders (e.g., constipation and fecal incontinence) or urinary disorders (e.g., incontinence or urgency), for example, increasing fiber to treat constipation. The specifics of the dietary changes should be described.
3. Elimination diet: a form of dietary modification. A diet designed to detect what ingredient in the food causes symptoms in the patient, food items to which the patient may be sensitive are withdrawn separately and successfully from the diet until the item that causes the symptoms is discovered. This is used frequently in patients with fecal incontinence, urinary urgency and urinary urgency incontinence (bladder diet). Physical activity: any body movement produced by the skeletal muscles that results in a substantial increase above resting energy expenditure. Physical activity can be

done at work, as transportation, as household and other chores, and as leisure time/sport and fitness activities.

### Localised Vulvar Pain Syndrome

#### *Symptom*

i. Vestibular pain syndrome—pain localized to one or more portions of the vulvar vestibule. ii. Clitoral pain syndrome—pain localized to or perceived in the clitoris.

## M

### Magnetic resonance imaging - male - general comments

#### *Imaging*

MRI provides the opportunity to examine the soft tissue structures of the pelvic support apparatus. It is non-invasive, has excellent soft tissue contrast resolution without exposure to ionizing radiation and allows the study of function of pelvic floor structures under different dynamic conditions. Several anatomical landmarks used for pelvic measurements are also easily identified in MRI and most measurements are thus highly reproducible. T-weighting assists enhancement of fluid-filled structures.

### Magnetic resonance imaging - uses in female

#### *Imaging*

MRI provides the opportunity to examine the soft tissue structures of the pelvic support apparatus in toto. It is non-invasive, has excellent soft tissue contrast resolution without exposure to ionizing radiation and allows the study of function of pelvic floor structures under different dynamic conditions such as increased abdominal pressure during Valsalva. Several anatomical landmarks used for pelvic measurements are also easily identified in MRI and most measurements are thus highly reproducible. Currently the clinical value of these examinations is still under investigation with its impact on therapeutic decisions not yet fully evaluated.

### Magnetic Resonance Imaging in Urogynecology - Current Possible Measurements

#### *Imaging*

Bladder neck and cervical descent/mobility: . Position of bladder neck and cervix at rest and on Valsalva. Pubo-coccygeal line: A line extending from the inferior border of the pubic symphysis to the last joint of the coccyx. Bladder neck or cervical descent >2 cm below this line with straining indicates weakness of the pelvic floor. If alternative landmarks are used in scientific papers they should be clearly described.

(b) Intercurrent pelvic pathology: For example, fibroids, ovarian pathology. (c) Uterine version :Anteverted or retroverted; flexion at the isthmus. (d) Bladder abnormalities: For example, tumor; foreign body. (e) Urethral abnormality: For example, diverticulum. (f) Postoperative findings: For example, bladder neck mobility. (g) Pelvic floor measurements/levator defects: Assessment of the configuration of pelvic floor muscles, in particular, the levator ani. (h) Descent of pelvic organs:

### Magnetic resonance imaging (MRI) - current female applications

#### *Imaging*

(i) Bladder neck and cervical descent / mobility: position of bladder neck and cervix at rest and on Valsalva; (ii) Intercurrent pelvic pathology: e.g. fibroids, ovarian pathology; (iii) Uterine version: anteverted or retroverted; flexion at the isthmus; (iv) Bladder abnormalities: e.g. tumor; foreign body; (v) Urethral abnormality: e.g. diverticulum; (vi) Postoperative findings: e.g. bladder neck mobility; (vii) Pelvic floor measurements / levator defects: assessment of the

### Low backache related to POP

#### *Symptom*

Complaint of low, sacral (or "period-like") backache associated temporally with pelvic organ prolapse (POP)

### Lower urinary tract symptom (LUTS)

#### *Symptom*

A symptom related to the lower urinary tract. It may originate from the bladder, urethra, prostate (men) and/or adjacent pelvic floor or pelvic organs, or at times be referred from similarly innervated anatomy e.g. lower ureter.

configuration of pelvic floor muscles, in particular, the levator ani; (ix) Descent of pelvic organs:

### Magnetic resonance imaging (MRI) - (male) - current possible measurements

#### *Imaging*

(1) Bladder abnormalities: e.g. tumor; foreign body, bladder wall abnormalities, intestine-vesical fistulae; (2) Urethral abnormality: e.g. diverticulum, recto-urethral fistulae. (3) Urethral sphincter length: prediction of post-prostatectomy incontinence; (4) Prostate abnormalities: e.g. benign enlargement, cancer, cysts, prostatorectal fistulae; (5) Intercurrent abnormalities: e.g. rectum - rectal dynamics are assessed during evacuation after adding ultrasound gel to the rectum. Anorectal and pelvic floor motion can be imaged providing pelvic images at rest and when the subject strains; (6) Congenital abnormalities: Detection of Mullerian duct remnants, aberrantly inserted ureters and duplicated pelvic structures; (7) Standardized MRI prostate imaging: PI-RADS – prostate imaging reporting and data system.

### Magnetic resonance Imaging (MRI) for fistula.

#### *Imaging*

In PFF, MRI maybe used to demonstrate concurrent conditions, such as urethral diverticulum and non-palpable abscesses. Though restricted in availability in low resource regions, where available, MRI imaging is helpful in cases of complex fistulas with adjacent organ system pathology.

### Magnetic Resonance Imaging (MRI) in Urogynecology

#### *Imaging*

MRI provides the opportunity to examine the soft tissue structures of the pelvic support apparatus in toto. It is noninvasive, has excellent soft tissue contrast resolution without exposure to ionizing radiation, and allows the study of function of pelvic floor structures under different dynamic conditions such as increased abdominal pressure during Valsalva. Several anatomical landmarks used for pelvic measurements are also easily identified in MRI and most measurements are thus highly reproducible. Currently, the clinical value of these examinations is still under investigation with its impact on therapeutic decisions not yet fully evaluated.

### Magnetic resonance Imaging (MRI -male) - Bladder abnormalities

#### *Imaging*

Excellent soft tissue contrast resolution looking at bladder tumor, foreign body, bladder wall abnormalities, intestinal-vesical fistulae.

### Magnetic resonance imaging (MRI -male) - Urethral abnormalities

#### *Imaging*

Excellent soft tissue contrast resolution looking for urethral diverticula, para-urethral cysts, recto-urethral fistulae.

## Magnetic Resonance Imaging (MRI) of the Pelvic Floor

### Imaging

Magnetic resonance imaging (MRI) of the pelvic floor: MRI allows the detection of ligamentous and muscular pelvic floor structures in fine detail. Although it does not use ionising radiation, it is a high cost technique. Static MRI relies on static sequences and high spatial resolution images, to delineate the passive and active elements of the pelvic organ support system. Most commonly, images are acquired in axial, sagittal and coronal planes. MRI has been proposed to be a useful method for diagnosing and staging POP. Several lines and levels of reference have been described in the literature. The most commonly used ones are either a line drawn from the inferior margin of the pubis symphysis to the last coccygeal joint (pubococcygeal line—PCL), in the sagittal plane, noted as midpubic line (MPL). Other applications of MRI are the assessment of the LAM morphology (size, thickness volume) and detection of LAM injuries/ defects/ (“avulsion”).

## Magnetic resonance imaging (MRI-male)

### Imaging

Excellent soft tissue contrast resolution looking for detection of mullerian remnants, aberrantly inserted ureters and duplicated pelvic structures.

## Magnetic resonance imaging of the vulvar area

### Imaging

Evaluation of the increase in clitoral structure volume related to tissue engorgement occurring during arousal.

## Magnetic stimulation

### Conservative Management – Female

Magnetic stimulation (or extracorporeal magnetic innervation): a pulsed magnetic technology developed for the transmission of nerve impulses that is aimed at causing PFM contraction. Patients receive therapy by sitting in a chair, which contains the device that produces the pulsing magnetic fields.

## Main (Chief) complaint

### Symptom

The primary symptom that an individual states in the main reason for seeking medical advice.

## Main sleep period

### Sign

The period from the time of falling asleep to the time of rising for the next day (as recorded on chart or diary).

## Male Chronic Genital Pain Syndromes

### Diagnosis

Male genital pain syndromes are often associated with symptoms suggestive of lower urinary tract and sexual dysfunction. Common complaints: genital pain, uncomfortable urination, dysuria, sensation of residual urine, increased daytime frequency, slow stream, urgency, dyspareunia. Absence of infection, previous operations, or other obvious pathology.

## Male examination - General principles.

### Sign

A comprehensive physical examination is done to seek potential influences on symptoms. It should include abdominal examination, focussing on the suprapubic area to detect an enlarged bladder, or other abdominal mass, and digital examination of the rectum (prostate) as well as examination of the external genitalia, the perineum and lower limbs. The hernia orifices should also be evaluated. Penile lesions including meatal stenosis, phimosis and penile cancer must be excluded. If a neurological diagnosis is suspected, then a focused neurological examination with evaluation of perianal

crude and pinprick sensations need to be tested. Also, the anal muscle tone can be assessed with finger in the rectum and asking the patient to squeeze.

## Male foreskin abnormalities

### Sign

. Tumor or infection (balanoposthitis i.e. inflammation of the glans penis and overlying foreskin).

. Phimosis: Partial or complete inability to retract the prepuce due to adhesion between the glans and the prepuce or a preputial ring.

Paraphimosis: Entrapment of the prepuce behind the glans.

## Male general (visual) observations

### Sign

(I) Mobility: generalized muscle strength and ability to ambulate independently or with assistance.

(ii) Skin: jaundice or pallor or skin irritation due to urinary loss.

(iii) Nutritional Status: cachexia (possible underlying malignancy); obesity (possible endocrine abnormality including metabolic syndrome).

(iv) Edema of genitalia and lower extremities: Possible cardiac decompensation, renal failure, nephrotic syndrome, or pelvic and/or retroperitoneal lymphatic obstruction.

## Male hypoactive sexual desire disorder

### Diagnosis

Persistent or recurrent deficiency or absence of sexual or erotic thoughts or fantasies and desire for sexual activity.

## Male pads: Defining features

### Conservative Management – Male

Waterproof-backed absorbent products for men that are designed to cover the penis and scrotum, and are held in place using separate, close-fitting (regular or specially designed) underwear.

## Male pads: Main variant features

### Conservative Management – Male

- Products come with different absorption capacities.
- Longitudinal elastic side barriers and leg cuffs at the sides may be included to improve fit and comfort and prevent leakage.
- Products may have an adhesive strip on the back to help secure them in underwear.

## Male pouches: Defining features

### Conservative Management – Male

Waterproof-backed absorbent products for men, fashioned into a pocket into which the penis—and sometimes the scrotum, too—is placed. They are held in place using separate, close-fitting (regular or specially designed) underwear.

## Male pouches: Main variant features

### Conservative Management – Male

- Products come with different absorption capacities.
- Products may have an adhesive strip on the back to help secure them in underwear.
- Products may have a hook and loop fastening system or adhesive tape to secure the product round the penis.

## Male sexual dysfunction related to LUTS/BPH - 5-Alpha reductase inhibitor (5-ARI)

### Conservative Management – Male

Medications that inhibit the enzyme responsible for the conversion of testosterone to dihydrotestosterone

(DHT), which is a more potent androgen and is responsible for prostate growth and development. There are two drugs in this category; finasteride inhibits only type 2 of 5-AR, and dutasteride inhibits both types 1 and 2.

#### **Male sexual dysfunction related to LUTS/BPH - 5-ARI and sexual dysfunction**

##### *Conservative Management – Male*

The effect of

5-ARI on sexual function in men with LUTS is modest with effects on penile erection, ejaculation, sexual desire, and includes a small risk of post-finasteride syndrome.

#### **Male sexual dysfunction related to LUTS/BPH - Alpha-blockers**

##### *Conservative Management – Male*

The first-line pharmacotherapeutic options for LUTS/BPH which are effective at relieving emptying phase symptoms via blockade of the alpha-adrenergic receptors in the prostate and the bladder neck.

#### **Male sexual dysfunction related to LUTS/BPH - Alpha-blockers and Ejaculatory Dysfunction (EjD)**

##### *Conservative Management – Male*

Alpha-adrenergic antagonists may cause anejaculation. The effect of alpha-blockers on EjD in men with LUTS is significantly affected by two agents (tamsulosin and silodosin). The other alpha-blockers have little or no impact on EjD.

#### **Male sexual dysfunction related to LUTS/BPH - Anticholinergics, Antimuscarinics**

##### *Conservative Management – Male*

Medications that exert their clinical effect via blocking muscarinic (predominantly M3 type) receptors in the bladder and can be used to address storage phase LUTS.

#### **Male sexual dysfunction related to LUTS/BPH - Beta-3 Agonists**

##### *Conservative Management – Male*

A medication class which can be used to improve storage phase LUTS. Mirabegron, a beta-3 agonist, exerts its clinical effect via relaxation of the bladder smooth muscle and increasing bladder storage capacity.

#### **Male sexual dysfunction related to LUTS/BPH - PDE5I**

##### *Conservative Management – Male*

PDE5i might be used to address LUTS/

BPH by inhibition of the PDE5 in the prostate, causing smooth muscle relaxation by a mechanism similar to the one postulated for alpha blockers.

#### **Male sexual dysfunction related to LUTS/BPH - Phytotherapy**

##### *Conservative Management – Male*

Utilization of herbal preparation (plant extracts) to address LUTS/BPH either alone or in combination with oral pharmacotherapy.

#### **Male sexual dysfunction related to LUTS/BPH - Watchful waiting**

##### *Conservative Management – Male*

Recommended treatment option for patients with an IPSS score of less than 7 who feel that their symptoms are manageable and do not have signs of postrenal compromise. This treatment consists of the patient decreasing their fluid intake, minimizing caffeinated and alcoholic beverages, and avoiding cholinergic medications.

#### **Male sexual dysfunction related to Overactive Bladder - Sacral neuromodulation (SNM)**

##### *Surgery – Male*

This neuromodulation technique consists in percutaneously implanting a set of electrodes in the S3 foramen connected to an external (temporary) or subcutaneous (permanent) stimulator to modulate the activity of bladder nerves.

#### **Male sexual dysfunction related to Overactive Bladder - Behavioural treatments for OAB**

##### *Conservative Management – Male*

Considered first-line treatment, these therapies aim at symptomatic improvement by changing behavioral and environmental issues.

#### **Male sexual dysfunction related to Overactive Bladder - Bladder training**

##### *Conservative Management – Male*

It consists of a program of patient education, along with a scheduled voiding regimen with gradually adjusted voiding intervals.

#### **Male sexual dysfunction related to Overactive Bladder - Dietary modification**

##### *Conservative Management – Male*

Consists of reducing or eliminating bladder irritants from the diet.

#### **Male sexual dysfunction related to Overactive Bladder - Double voiding**

##### *Conservative Management – Male*

The patient is taught to urinate, relax, and attempt to urinate again. It is especially useful for patients with incomplete voiding and high post-void residual.

#### **Male sexual dysfunction related to Overactive Bladder - Fourth-line treatments**

##### *Surgery – Male*

Considered as last resort for patients that have failed all previous treatments, these include augmentation cystoplasty and urinary diversion.

#### **Male sexual dysfunction related to Overactive Bladder - Frequency volume chart**

##### *Conservative Management – Male*

The recording of the time of each micturition together with the volume voided for at least 24 h. Ideally a minimum of 3 days of recording (not necessarily consecutive) will generally provide more useful clinical data. It is relevant to discriminate between daytime and night-time micturition.

#### **Male sexual dysfunction related to Overactive Bladder - Habit training**

##### *Conservative Management – Male*

Consists of a toileting schedule matched to the individual's voiding patterns based on their voiding diary. The toileting schedule is assigned to fit a time interval that is shorter than the person's normal voiding pattern and precedes the time period.

when incontinent episodes are expected

#### **Male sexual dysfunction related to Overactive Bladder - Intradermal botulinum toxin injection**

##### *Surgery – Male*

Injection of onabotulinum toxin A in the bladder wall to induce detrusor muscle relaxation.

**Male sexual dysfunction related to Overactive Bladder - Lifestyle modification***Conservative Management – Male*

Weight loss and smoking cessation have been shown to reduce LUTS, urgency and UI in patients with OAB.

**Male sexual dysfunction related to Overactive Bladder - Pelvic floor muscle training (PFMT)***Conservative Management – Male*

Exercise to improve PFM strength, endurance, power, relaxation, or a combination of these parameters.

**Male sexual dysfunction related to Overactive Bladder - Peripheral (or posterior tibial) nerve stimulation (PTNS)***Surgery – Male*

A neuromodulation technique that consists in stimulating the posterior tibial nerve with a transcutaneous or percutaneous electrode to modulate the neuronal activity of bladder nerves that share the same dorsal root as the posterior tibial nerve (S3)

**Male sexual dysfunction related to Overactive Bladder - Pharmacological treatments***Conservative Management – Male*

Considered second-line treatment, may be used in combination with first line treatments.

**Male sexual dysfunction related to Overactive Bladder - Prompted voiding***Conservative Management – Male*

It is used to teach people to initiate their own toileting through requests for help and positive reinforcement from caregivers, often done in combination with a scheduled voiding regimen, typically every 2 h.

**Male sexual dysfunction related to Overactive Bladder - Scheduled or timed voiding***Conservative Management – Male*

A passive toileting assistance program, initiated and maintained by caregivers for patients who cannot participate in independent toileting. It is a fixed voiding schedule.

**Male sexual dysfunction related to Overactive Bladder - Self-monitoring***Conservative Management – Male*

This strategy is part of bladder training and consists of registering voiding habits in a bladder diary.

**Male Sexual Health - Herbal therapy***Conservative Management – Male*

Plant-derived remedies that can provide alternatives for men to improve their sexual health.

**Male Sexual Health - Intracavernous injection (ICI)***Conservative Management – Male*

Injecting vasoactive agents into the corpus cavernosa of the penis to produce an erection. The four substances commonly used in clinical practice are alprostadil, papaverine, phentolamine, and atropine.

**Male Sexual Health - Intracavernous injection (ICI) - Bimix***Conservative Management – Male*

ICI of papaverine + phentolamine

**Male Sexual Health - Intracavernous injection (ICI) - In-office injection test***Conservative Management – Male*

An in-office consultation that has to be made with every patient being recommended ICI of vasoactive agents which aims to determine the appropriate dose and medication(s) to produce sufficient duration of response and to minimize adverse effects.

**Male Sexual Health - Intracavernous injection (ICI) - Quadmix***Conservative Management – Male*

ICI of alprostadil + papaverine + phentolamine + atropine.

**Male Sexual Health - Intracavernous injection (ICI) - Single agent***Conservative Management – Male*

ICI of alprostadil.

**Male Sexual Health - Intracavernous injection (ICI) - Trimix***Conservative Management – Male*

ICI of alprostadil + papaverine + phentolamine.

**Male Sexual Health - Intraurethral alprostadil***Conservative Management – Male*

Topical application of the vasoactive agent alprostadil, which is an analogue of prostaglandin E1. Herein, a specific formulation of alprostadil in a medicated pellet (MUSE™) that includes a permeation enhancer to facilitate absorption of alprostadil is administered via the urethral meatus.

**Male Sexual Health - Intraurethral alprostadil - in-office test***Conservative Management – Male*

An in-office consultation that has to be made with every patient being prescribed intraurethral alprostadil that includes instructions about the method, initial dose-titration, detailed counseling regarding possible adverse reactions and actions to take in response to potentially serious side effects

**Male Sexual Health - Lifestyle recommendations***Conservative Management – Male*

Lifestyle recommendations: Dietary changes, weight loss, physical activity increases, and smoking cessation that may improve overall health and ameliorate the comorbidities associated with ED.

**Male Sexual Health - Miscellaneous surgical treatments under investigation***Surgery – Male*

Low-intensity extracorporeal shock-wave therapy (LI-SWT), Platelet-rich plasma (PRP) therapy, Intracavernosal stem cell therapy, nerve graft.

**Male Sexual Health - Penile rehabilitation***Conservative Management – Male*

Program that aims to help men regain the ability to achieve erections sufficient for satisfactory sexual intercourse during rehabilitation from prostate cancer treatment, and ultimately return to pretreatment erectile function.

**Male Sexual Health - Phosphodiesterase type 5 inhibitors (PDE5i) - daily dosing***Conservative Management – Male*

PDE5i being taken on a daily basis, irrespective of sexual activity.

**Male Sexual Health - Phosphodiesterase type 5 inhibitors (PDE5i) - Instructions for appropriate use***Conservative Management – Male*

Instructions that include the fact that sexual stimulation is necessary and that more than one trial with the medication may be required to establish efficacy. It should include information regarding the medications' characteristics with regard to the onset of action, duration of action, and whether

food intake limits efficacy. Discussion on side effects should include common PDE5i side effects as well as drug-specific side effects.

**Male Sexual Health - Phosphodiesterase type 5 inhibitors (PDE5i) - on-demand dosing**

*Conservative Management – Male*

PDE5i being taken before anticipated sexual intercourse.

**Male Sexual Health - Phosphodiesterase type 5 inhibitors (PDE5i):**

*Conservative Management – Male*

Oral medication used to block the action of phosphodiesterase type 5 on cyclic guanosine monophosphate in the smooth muscle cells causing a vasodilation of the arteries in the corpora cavernosa of the penis facilitating an erection during sexual stimulation.

**Male Sexual Health - Psychotherapy**

*Conservative Management – Male*

Psychotherapy and psychosexual counseling focus on helping patients and their partners improve communication about sexual concerns, reduce anxiety related to entering a sexual situation and during a sexual situation, and discuss strategies for integrating ED treatments into their sexual relationship.

**Male sexual Health - Vacuum erection device (VED)**

*Conservative Management – Male*

Negative-pressure chambers that provide passive engorgement of the corpora cavernosa, together with a constrictor ring placed at the base of the penis to retain blood within the corpora.

**Manometry**

*Investigation*

An investigation that measures pressure.

**Manual defecatory assistance: External - perineal pressure or buttock separation.**

*Symptom*

Complaint of the need to press on the perineum or separate the buttocks to assist defecation.

**Manual defecatory assistance: Internal - anorectal digitation**

*Symptom*

Complaint of the need to use of fingers in the rectum to manually assist in evacuation of stool contents by scooping, stretching and/or stimulation.

**Manual Therapy (female)**

*Conservative Management – Female*

Manual therapy is a clinical approach utilizing skilled, specific hands-on techniques, including but not limited to, massage, manipulation or mobilization.

**Massage**

*Conservative Management – Female*

The manipulation of the soft tissues of the body for the purpose of affecting the nervous, muscular, respiratory and circulatory systems.

**Maximum cystometric capacity - filling cystometry (mL)**

*Investigation*

In individuals with normal sensation, this is the volume during filling cystometry when voiding can no longer be delayed.

**Maximum detrusor pressure (Pdet-max – unit: cm H2O) - pressure flow studies**

*Investigation*

Maximum registered detrusor pressure during voiding.

**Maximum urethral closure pressure (MUCP) - female**

*Investigation*

Maximum pressure in the UCPP, i.e. the maximum difference between the urethral pressure and the intravesical pressure.

**Maximum urethral pressure (MUP) - female**

*Investigation*

Maximum pressure in the UPP.

**Maximum urine flow rate (MUFR - mL/s) - Qmax**

*Investigation*

Maximum measured value of the urine flow rate (corrected for artefacts).

**Maximum voided volume**

*Sign*

Highest voided volume recorded during an assessment period of a frequency-volume chart (FVC).

**Mean maximum voided volume (functional capacity)**

*Sign*

Mean maximum voided volume in everyday activities (as recorded in chart or diary).

**Measurements of labial and vaginal oxygenation**

*Investigation*

A heated electrode and oxygen monitor are used to evaluate the arterial partial pressure of oxygen (PO<sub>2</sub>) transcutaneously. The temperature of the electrode is kept at a constant elevated temperature by an electric current. Increase in blood flow under the electrode results in more effective temperature dissipation (heat loss) with the result that more current is needed to maintain the electrode at its prefixed temperature. The changes in current provide an indirect measurement of blood flow during sexual stimuli. The electrode also monitors oxygen diffusion across the skin.

**Measuring Outcome in POP Surgery**

*Surgery – Female*

Measuring Outcome in POP surgeries: As per IUGA-ICS Report on outcome measures for POP surgery, every study evaluating POP surgery should report. (i) Perioperative data: i.e. blood loss, operating time, length of hospital stay, return to normal activities and complications. (ii) Subjective (patient-reported) outcomes: At its simplest level this can be reported as the presence or absence of vaginal bulge. Patient satisfaction and quality of life can be measured by validated instruments that cover prolapse, urinary, bowel and sexual function. (iii) Objective outcomes: POP-Q measurement generally and should be tabulated with absolute values and percentages to allow other studies to compare results. (iv) Secondary outcomes (e.g. lower urinary tract symptoms, stress urinary incontinence or bowel and sexual dysfunction) in their studies whenever possible.

**Meatal skin flap technique**

*Surgery – Male*

After meatotomy, a flap is mobilized from the prepuce or distal penile skin and sutured to the edge of the opened fossa navicularis.

Graft technique

After meatotomy, skin, buccal mucosa, or any other

suitable tissue is used as a free patch or a tube and sutured into the edge of the fossa navicularis or to substitute the urethra at this level.

### **Meatoplasty**

*Surgery – Male*

Reconstruction of the meatal segment of the urethra for cosmetic or functional purpose.

### **Meatotomy**

*Surgery – Male*

Incision of the meatus to enlarge the distal urethra to the caliber of the urethral lumen.

### **Median functional bladder capacity**

*Sign*

Median maximum voided volume in everyday activities (as per frequency-volume chart -FVC)

### **Membranous urethra**

*Surgery – Male*

The portion of the urethra which traverses the perineal membrane and is surrounded by the striated external urethral sphincter.

### **Mesh**

*Surgery – Female*

A (prosthetic) network fabric or structure; open spaces or interstices between the strands of the net. The use of this term would be for POP surgery with synthetic materials.

### **Mesh kit**

*Surgery – Female*

A set of articles or equipment utilised for POP surgery containing mesh with a system of trocars designed to achieve mesh fixation or allow mesh passage to or through specific areas within the pelvis.

### **Mesh, Tape & Graft Surgery Complication - CTS Classification - Category (C) 1A - 3A**

*Surgery – Complication related*

1A–3A: Asymptomatic—Abnormal mesh finding These are generally physician-diagnosed at any episode of clinical care. It can be argued that the “abnormal prosthesis or graft finding” aspects of category 1A, in particular, aren’t really complications as the patient isn’t bothered by the potential problem. It may be, however, that the woman may not have engaged in an activity that is likely to provoke symptoms for herself, e.g. pain or bleeding during sexual intercourse (or for her partner), which would convert these complications to category 1B. 1Aa–3Aa: Asymptomatic—Abnormal mesh finding —No pain. The addition of an “a” specifies that the patient experiences no pain in association with the abnormal finding.

### **Mesh, Tape & Graft Surgery Complication - CTS Classification - Category (C) 2**

*Surgery – Complication related*

Vaginal complication—(smaller) exposure: A smaller (1 cm or less) degree of vaginal epithelial separation is involved.

### **Mesh, Tape & Graft Surgery Complication - CTS Classification - Category (C) 3**

*Surgery – Complication related*

Vaginal complication—(larger) exposure or extrusion: A larger degree (more than 1 cm) of vaginal epithelial separation or prosthesis or graft extrusion is involved.

### **Mesh, Tape & Graft Surgery Complications - CTS Classification - Category (C) 1**

*Surgery – Complication related*

Vaginal complication—no epithelial separation: This incorporates the terms prominence (e.g. due to wrinkling or folding) or contraction (shrinkage). Also incorporated here is the palpation of mesh fibres.

### **Mesh, Tape and Graft Complication - CTS Classification - Category (C) 1B - 3B**

*Surgery – Complication related*

1B–3B: Symptomatic—Unusual discomfort or pain; dyspareunia (for either partner). Bleeding or discharge may be possible symptoms. 1Bb–3Bb: Symptomatic—Provoked pain only (during vaginal examination) The addition of a “b” to the category code specifies that pain, provoked only during vaginal examination, is associated with the abnormal finding. 1Bc–3Bc: Symptomatic—Pain during sexual intercourse The addition of a “c” to the category code specifies that pain, provoked during sexual intercourse (patient only), is associated with the abnormal finding. 1Bd–3Bd: Symptomatic—Pain during physical activities The addition of a “d” to the category code specifies that pain, provoked during physical activities, is associated with the abnormal finding. 1Be–3Be: Symptomatic—Spontaneous pain: The addition of an “e” to the category code specifies that pain, spontaneously present (i.e. without physical activity), is associated with the abnormal finding.

### **Mesh, Tape and Graft Surgery Complication - CTS Classification - Category 6**

*Surgery – Complication related*

Category 6: Skin and/or musculoskeletal complications: 6A: Asymptomatic: Physician-diagnosed complication at any episode of care. 6B: Symptomatic: For example, discharge, pain, lump. 6C: Infection from skin or musculoskeletal complication: Including sinus tract formation 6D: Abscess formation from skin or musculoskeletal complication.

### **Mesh, Tape and Graft Surgery Complication - CTS Classification - Category (C) 1C - 3C**

*Surgery – Complication related*

1C–3C: Clinical Infection: This is always a possibility with a synthetic prosthesis or graft. Signs of local tenderness are suggestive with the combination of redness and a purulent discharge being more conclusive. 1C–3C (b–e): Infection—Pain. The addition of the letters “b” through to “e” specifies that pain (as defined in Table 3) is part or all of the infected abnormal finding.

### **Mesh, Tape and Graft Surgery Complication - CTS Classification - Category (C) 4**

*Surgery – Complication related*

Category 4: Urinary tract compromise or perforation. This category class has been subdivided into:

4A: Small intraoperative defect: For example, bladder perforation. Such a complication does not generally create longer-term compromise for the bladder if recognized, prosthesis (graft) removed as indicated, defect oversewn (if necessary), and some minor precautions are taken, for example, short-term bladder drainage, with suitable antibiotics commenced. 4B: Other lower urinary tract (bladder or urethral) complication or compromise: This division would incorporate injuries causing longer-term bladder issues, for example, ongoing prosthesis or graft perforation, fistula, calculus around the prosthesis, or graft. This category also incorporates urinary retention directly related to the procedure requiring subsequent surgical intervention (apart from any form of bladder drainage). The time and site divisions relates to those for the surgical intervention. 4C: Ureteric or upper tract complication or compromise: This division is self-explanatory.

### Mesh, Tape and Graft Surgery Complication - CTS Classification - Category (C) 5

#### *Surgery – Complication related*

Category 5: Rectal or Bowel compromise or perforation. This category class has been subdivided into:

5A: Small intraoperative defect: Such a complication may not generally be expected to cause compromise if the defect is recognized, prosthesis (graft) removed as indicated, defect oversewn (as necessary) with appropriate precautions taken, for example, short-term bowel rest is instituted with suitable antibiotics commenced. 5B: Rectal injury or compromise: This division would incorporate injuries causing longer-term rectal issues, for example, ongoing prosthesis (graft) perforation, fistula. 5C: Small or large bowel injury or compromise: This division would incorporate injuries causing longer-term bowel issues, for example, ongoing prosthesis (graft) perforation, fistula, obstruction. 5D: Abscess formation from bowel injury/compromise.

### Mesh, Tape and Graft Surgery Complication - CTS Classification - Category (C) 7

#### *Surgery – Complication related*

Category 7: Patient compromise. This category recognizes that the patient might be brought into systemic danger with some of the complications in addition to any localized issue. 7A: Bleeding complication including hematoma: This division refers to any clinically diagnosed hematoma as well as those where blood transfusion or surgical intervention is a consideration. 7B: Major degree of resuscitation or intensive care: This division refers to significant hemodynamic or cardiopulmonary resuscitation directly related to the procedure, and/or patient transfer for management in intensive care facilities. 7C: Mortality: The insertion of the prosthesis, whilst not necessarily fatal at the time, has set in train further morbid events leading to mortality. N.B. Because of their systemic nature, 7B and 7C will not have a specific site division. They will be denoted S0.

### Mesh, Tape and Graft Surgery Complication - CTS Classification - Time Divisions

#### *Surgery – Complication related*

The time (T) for the complication is when it is clinically diagnosed. This section incorporates four time periods, all of the possible episodes where clinical care might be given by the physician or sought by the patient. It might not always be possible to predict with any prosthesis or graft when complications might be more frequently seen. This would depend on the results of a procedure-specific surgical audit using the classification. The earliest time division (T1) might involve more insertion issues, whilst later divisions (T2–T4) might be biased towards healing abnormality issues. T1: Intraoperative—48 hr: Insertion complications more likely. T2: 48 hr–2 months: Healing or infection complications more likely. T3: 2–12 months: Later healing abnormalities more likely. T4: Over 12 months: Late healing abnormalities and other mesh complications more likely.

### Mesh, Tape and Graft Surgery Complications - CTS Classification - Category (C) 1D - 3D

#### *Surgery – Complication related*

1D–3D: Abscess formation: This is a more serious possibility with a synthetic prosthesis or graft. 1D–3D (b–e): Infection—pain: The addition of the letters b through to e specifies that pain (as defined in Table 3) is part of the abnormal finding associated with abscess formation.

### Mesh, Tape and Graft Surgery Complications - CTS Classification - Site Divisions

#### *Surgery – Complication related*

The selection of these divisions incorporates the current sites where prosthesis or graft complications have been noted: S0: Systemic complications (no specific site): As mentioned earlier, category divisions 7B and 7C which

are systemic complications will be denoted S0. S1: Vaginal: area of suture line: Perhaps the commonest site for prosthesis and graft complications from vaginal surgery is close to the vaginal suture line. S2: Vaginal: away from the vaginal suture line: As most suture lines would be midline, this would generally be lateral in the vagina. S3: Trocar passage: The passage of any sharp surgical instrument can cause damage along the path of insertion. This division incorporates any extraperitoneal, bladder, or rectal complication, but not intra-abdominal complications which are S5. S4: Other skin or musculoskeletal site: This division is relevant to any skin or musculoskeletal complications away from the sites of trocar entry or exit. Included might be cutaneous sinus or fistula formation. S5: Intra-abdominal: Included in this section would be bowel perforation or obstruction.

### Micturating cystogram (MCU) - female

#### *Imaging*

The principal use is the detection of vesico-ureteric reflux, some fistulae and diverticula.

### Mid-perineal thickness (MPT)

#### *Surgery – Female*

Thickness (cm) of the mid-perineum in the midline.

### Mid-vaginal laxity (MVL - undisplaced - cm)

#### *Surgery – Female*

Laxity of the vaginal mucosa (anterior traction) midpoint in the vagina super-posteriorly and in the midline with the vaginal vault held in an undisplaced position (similar to that after vault fixation).

### Mid-vaginal laxity (MVL - undisplaced) - posterior colporrhaphy

#### *Surgery – Female*

Laxity (cm) of the vaginal mucosa (anterior traction) midpoint in the vagina super-posteriorly and in the midline with the vaginal vault held in an undisplaced position (similar to that after vault fixation).

### Miscellaneous Techniques for Bladder and Bowel Control

#### *Conservative Management – Female*

Other techniques consist of doing something that takes the patient's mind off the condition. Distraction techniques utilized in urgency may include (but are not limited to) counting backward from 100 in 7s, reciting a poem, doing breathing exercises, reading or working. Urgency suppression techniques: are methods/maneuvers that are used to decrease the feeling of urgency, which may include, but are not limited to: distraction, PFM contraction, perineal pressure such as sitting on a hard chair, relaxation and breathing, toe curling or plantar flexion of the ankle. Double voiding: the patient is taught to urinate, relax, and attempt to urinate again. Defecatory dynamics: is a postural and respiratory technique to aid defecation. The mechanics involves co-ordination of the diaphragm, abdominal and PFM, with the intent to maintain rectal support whilst releasing the anal outlet with sufficient expulsion to be effective. Bowel habit training: is aimed at establishing a regular, predictable pattern of bowel evacuation by patient teaching and adherence to a routine to achieve a controlled response to bowel urgency (modified from NICE guideline).

### Mixed bladder outlet obstruction and detrusor underactivity (male -BOO-DU)

#### *Diagnosis*

Urodynamically confirmed BOO occurring simultaneously with urodynamically confirmed DU in pressure-flow analyses.

**Mixed detrusor overactivity and bladder outlet obstruction (male - DO-BOO)***Diagnosis*

Detrusor overactivity (filling cystometry) in the presence of bladder outlet obstruction (pressure-flow studies). This is a relatively common diagnosis.

**Mixed detrusor overactivity with detrusor underactivity (male - DO-DU)***Diagnosis*

Urodynamically confirmed detrusor contractions during filling cystometry in combination with detrusor underactivity on pressure-flow.

**Mixed neuronal lesion***Diagnosis*

This results from lesions of the neural pathway at different levels of the central nervous system concurrently.

**Mixed storage and voiding dysfunction***Diagnosis*

(A) Bladder Outlet Obstruction and Detrusor Underactivity (BOO-DU): Urodynamic BOO occurring synchronous with urodynamic DU in pressure-flow analyses. (B) Detrusor Overactivity and Bladder Outlet Obstruction (DO-BOO): Urodynamic DO on filling cystometry in the presence of BOO on pressure-flow studies. (C) Detrusor Overactivity with Detrusor Underactivity (DO-DU)

Urodynamic DO on filling cystometry) in combination with urodynamic DU on pressure-flow studies. This diagnosis is intended to supersede the old expression “detrusor hyperactivity with impaired contractility” (DHIC) and detrusor overactivity with impaired contractility (DOIC). It is most common in the elderly group.

**Mixed urinary incontinence (MUI)***Symptom*

Complaints of both stress and urgency urinary incontinence, i.e. involuntary loss of urine associated with urgency and also with effort or physical exertion including sporting activities or on sneezing or coughing.

**Modified Manchester (Fothergill) Procedure***Surgery – Female*

This procedure combines anterior vaginal wall repair with amputation of the cervix and uterosacral ligament suspension with or without concurrent vaginal posterior wall repair.

**(Modified) Manchester repair (Fothergill operation)***Surgery – Female*

This procedure combines anterior vaginal wall repair (colporrhaphy) with amputation of the cervix and uterosacral ligament suspension with or without concurrent vaginal posterior wall repair (colporrhaphy).

**Moschovitz procedure***Surgery – Female*

Concentric purse string suture(s) are placed around the cul-de-sac to include the posterior vaginal wall, pelvic side-walls and serosa of the sigmoid.

**Muscle Action Characteristics***Investigation*

The decrease in size of muscle fibers as a result of inactivity, illness or aging.

**Muscle Action Characteristics - Anatomic Cross-sectional Area***Investigation*

For an individual muscle, the largest cross-sectional area along the length of that muscle and 90° on the muscle length.

**Muscle Action Characteristics - Antagonistic Contraction***Investigation*

Contraction of muscle/ muscle groups with the opposite action to the desired action (activity that hinders the targeted muscle/ muscle group from contracting).

**Muscle Action Characteristics - Bulk***Investigation*

The absolute volume of a muscle measured using imaging techniques such as anatomical magnetic resonance imaging and ultrasound.

**Muscle Action Characteristics - Co-Contraction***Investigation*

Contraction of two or more muscles at the same time. Co-contraction of muscles can be synergistic (e.g., resulting in an augmentation of motor activity) or it could be counterproductive to normal function (e.g., contraction of antagonistic muscles resulting in abnormal movement or training other muscles instead of the targeted ones, e.g., training of gluteal muscles instead of the PFM).

**Muscle Action Characteristics - Coordination***Investigation*

Property of movement characterized by the smooth and harmonious action of groups of muscles working together to produce a desired motion.

**Muscle Action Characteristics - Exteroception***Investigation*

Sensory information from receptors in the skin registering touch, vibration, heat, and cold.

**Muscle Action Characteristics - Flexibility***Investigation*

The ability of a muscle to lengthen and allow one joint (or more than one joint in a series) to move through a range of motion. Loss of flexibility is defined as a decrease in the ability of a muscle to deform.

**Muscle Action Characteristics - Hypertrophy***Sign*

The increase in size (volume) of the muscle fibers.

**Muscle Action Characteristics - Maximum Voluntary Contraction (MVC)***Investigation*

The attempt to recruit as many fibers in a muscle as possible for the purpose of developing force. MVC of the pelvic floor can be assessed by vaginal palpation, manometers, and dynamometers.

**Muscle Action Characteristics - Motor Control***Investigation*

The ability of the nervous system to control or direct the muscles in purposeful movements and postural adjustment by selective allocation of muscle tension across appropriate joint segments.

**Muscle Action Characteristics - Muscle Power***Investigation*

The explosive aspect of strength; the product of strength and speed of movement (force×distance/time).

**Muscle Action Characteristics - Muscle Strength***Investigation*

Force-generating capacity of a muscle. It is generally expressed as maximal voluntary contraction measurements and as the one repetition maximum (1RM) for dynamic measurements.

**Muscle Action Characteristics - Physiological Cross-sectional Area***Investigation*

The total area of cross-section perpendicular to the muscle fibers.

**Muscle Action Characteristics - Proprioception***Investigation*

Sensory information from receptors of muscles, joints, capsules, and ligaments that provides information related to posture and movement.

**Muscle Action Characteristics - Submaximal contraction***Investigation*

All contractions without maximal effort, expressed as a percentage of one repetition maximum (1RM).

**Muscle Action Characteristics - Synergistic Contraction***Investigation*

The combination of several muscle actions that serve to optimally achieve a motor task.

**Muscle Action Characteristics - Local Muscle Endurance***Investigation*

The ability to sustain near maximal or maximal force, assessed by the time a patient is able to maintain a maximal static or isometric contraction, or the ability to repeatedly develop near maximal or maximal force determined by assessing the maximum number of repetitions the patient can perform at a given percentage of 1RM.

**Muscle contracture***Sign*

An involuntary shortening of a muscle. Clinically, a muscle cramp and contracture may appear similar; however, contractures are electrically silent.

**Muscle Cramp***Sign*

A painful involuntary muscle contraction that occurs suddenly and can be temporarily debilitating. Pain is intense and localized. It tends to occur when the muscle is in the shortened position and contracting, is generated by motor units, and displays a high firing rate (20–150Hz).

**Muscle Fasciculation***Investigation*

A single, spontaneous, involuntary discharge of an individual motor unit. The source generator is the motor unit or its axon, before its terminal branches. Fasciculations display an irregular firing pattern of low frequency (0.1–10Hz). Clinically, fasciculations are recognized as individual brief twitches. They may occur at rest or after muscle contraction and may last several minutes.

**Muscle flap***Surgery – Female*

The use of muscle, for example, gracilis muscle or rectus abdominus muscle flap to provide tissue and blood supply.

**Muscle Hypertonicity***Sign*

An increase in muscle tone related to the contractile or viscoelastic components that can be associated with either elevated contractile activity and/or passive stiffness in the muscle. The terms neurogenic hypertonicity and non-neurogenic hypertonicity are recommended to describe the diagnosis and inform management.

**Muscle Hypotonicity (female)***Sign*

A decrease in muscle tone related to the contractile or viscoelastic components that can be associated with either reduced contractile activity and/or passive stiffness in the muscle. The terms neurogenic hypotonicity and non-neurogenic hypotonicity are recommended to describe the diagnosis and inform management.

**Muscle spasm***Sign*

Persistent contraction of striated muscle that cannot be released voluntarily. If the contraction is painful, this is usually described as a cramp. Spasms occur at irregular intervals with variable frequency and extent and over days or weeks may lead to a contracture.

**Muscle stiffness***Sign*

Resistance to deformation. Passive elastic stiffness is defined as the ratio of the change in the passive resistance or passive force ( $\Delta F$ ) to the change in the length displacement ( $\Delta L$ ) or  $\Delta F/\Delta L$ . The term should only be used if stiffness is measured quantitatively, such as with the use of instruments such as dynamometry or myotonometry.

**Muscle Tension***Sign*

May have a similar meaning to tone and stiffness. Muscle tension can be increased or decreased because of exogenous factors such as the amount of pressure applied and endogenous factors such as thickness/cross-sectional area of the muscle itself, fluid present within the muscle (swelling, inflammation), position (e.g., standing versus sitting) or increased neural activity.

**Muscle tone***Sign*

State of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement. Muscle tone has two components: the contractile component, created by the low frequency activation of a small number of motor units, and the viscoelastic component, which is independent of neural activity and reflects the passive physical properties of the elastic tension of the muscle fiber elements and the osmotic pressure of the cells.

**Muscle Tone - Assessment and Rating***Sign*

Tone can be assessed by application of digital site-specific compression and/or overall muscle stretch.

Digital palpation is inherently subjective and may be limited by pain provocation. Several scales to quantify resting PFM tone in the absence of a neurological disorder have been proposed using either a 3-point, 6-point or 7-point scale.

**Muscle tone - decreased pelvic floor muscle (PFM) tone***Sign*

A decrease in resting muscle tone in a patient without a neurological condition.

**Muscle Tone - Dystonia***Sign*

A disorder characterized by abnormalities of muscle tone and movements/postures in a patient with a neurological disorder. It is often due to damage to the basal ganglia or other brain regions that control movement.

**Muscle Tone - Hypertonicity***Sign*

An increase in muscle tone in a patient with a neurological disorder. It may be due to an upper motor neuron or extrapyramidal lesion, which in turn may lead to spasticity or rigidity.

**Muscle Tone - Hypotonicity***Sign*

A decrease in muscle tone in a patient with a neurological disorder. It may be due to a lower motor neuron or a muscle disorder. The term flaccidity is often used interchangeably.

**Muscle Tone - increased pelvic floor muscle (PFM) tone***Sign*

An increase in muscle resting tone in a patient without a neurological disorder. Increased tone may occur without patient report of pain.

**Muscle Tone - Measurement (female)***Investigation*

There is no single tool that is able to measure all components of muscle tone. Some tools may be able to measure aspects of tone such as contractility, stiffness or elasticity. Instrumented methods may play a role in the valid and reliable evaluation of muscle tone, e.g., surface electromyography (sEMG), wire and concentric electromyography, dynamometry, real-time ultrasound, elastometry, myotonometry.

**Muscle Tone - Muscle Spasm***Sign*

Persistent contraction of muscle that cannot be reduced voluntarily. Spasms may occur at irregular intervals with variable frequency and extent, and over time may lead to increased visco-elastic stiffness and shortening in the muscular and connective tissues.

**Muscle Tone - Physiologic Basis***Sign*

Muscle tone has two components: the physiological contractile component, created by the activation of motor units, and the noncontractile visco-elastic, or biomechanical component. The active component (EMG activity) of tone is the component that is related to the neural drive, therefore it is subject to variation and ongoing adjustment. The visco-elastic component is independent of neural activity and reflects the passive physical properties of the visco-elastic tension of the muscle tissues (e.g., the extensibility of actin-myosin cross-bridges); noncontractile cytoskeleton proteins and connective tissues surrounding the entire muscle (epimysium), muscle fascicle (perimysium), and muscle fiber (endomysium) as well as the osmotic pressure of the cells. Alterations in either the active or passive component can affect the resting tone; digital palpation cannot differentiate between these elements however investigations that combine

EMG with another measure that assesses passive properties can identify specific components. A localized area of increased tone within a muscle may be referred to as a taut band. A trigger point is considered to be a tender nodule within a taut band. The trigger point is considered by some authors to be part of the active component of tone given the local disturbance in electrical activity, and by others as a separate category distinct from the active or passive components of tone. Given the uncertainty about the characterization of a trigger point, we propose describing palpatory findings by use of the terms

“tender point” and “increased tone” if both observations coincide at the test-

ed site, or use only “tender point” or “increased tone” if only one of those signs is observed at the tested site.

**Muscle Tone - Transient increased muscle tone***Sign*

Increased muscle tone that decreases with verbal instruction, reassurance, or gentle pressure. Transient increase in tone may occur at any time during the examination.

**Myalgia***Symptom*

Muscle pain. Pelvic floor myalgia (a symptom) may be present with or without a change in PFM tone (a sign).

**Myofascial Pain***Symptom*

Pain caused by the presence of trigger points within muscles or their fascia.

**Myotonometry***Investigation*

An investigation that measures muscle tone characteristics by applying a mechanical impulse to the tissue. The device elicits oscillations of muscle after a probe applies a brief mechanical impulse with quick release under constant preload to the skin over the muscle belly. Myotonometry has been used externally on the perineum to measure superficial PFM stiffness. It cannot be used intra-vaginally to measure levator ani function as the probe must be perpendicular to the muscle and therefore cannot be used to interpret levator ani function. Separately listed are the most frequent parameters measured with myotonometry that can be computed from the oscillation curve as well as their definitions, specifications and findings.

It should be noted that the tissues that lie between the probe and the muscle (e.g., skin, adipose tissues, connective and fascial tissues) can also influence the measurements.

**Myotonometry parameters - Creep***Investigation*

The gradual elongation of a tissue over time when placed under a constant tensile stress: Measured by the ratio of relaxation time to deformation time (Deborah number). RATING: The higher the creep, the less elasticity the tissue has and the more likely is permanent stretch or deformation.

**Myotonometry parameters - Logarithmic decrement***Investigation*

Characterizes elasticity and dissipation of mechanical energy. Measured as  $1n(D = \ln[a1/a3])$ . It indicates the ability of the tissue (including muscle) to recover its shape after being deformed. RATING: Elasticity is inversely proportional to decrement, therefore, if the decrement of a muscle decreases, the muscle elasticity increases. The smaller the decrement value, the smaller will be the dissipation of mechanical energy and the higher the elasticity of a tissue.

**Myotonometry parameters - Mechanical stress relaxation time***Investigation*

The time for a muscle to recover its shape from deformation after a voluntary contraction or removal of an external force. Measured in milliseconds. RATING: The longer the time the more relaxation has occurred in the tissue.

**Myotonometry parameters - Oscillation frequency***Investigation*

Characterizes the intrinsic tension of the muscle in its passive or resting state in the absence of voluntary contraction. Measured in Hz. RATING: A higher oscillation frequency (Hz value) indicates higher muscle tone.

**N****Native***Surgery – Complication related*

Pertaining to birth; autologous.

**Native Surgery Complications (CTS Classification) - Category (C) 1***Surgery – Complication related*

Vaginal complication—no epithelial separation: This incorporates the terms prominence or excessive degrees of scarring or tethering.

**Native (tissue)***Surgery – Female*

Pertaining to birth - "in situ autologous"

**Native Tissue Surgery Complications - CTS Classification - Category 4***Surgery – Complication related*

Category 4: Urinary tract compromise or perforation: This category class has been subdivided into:

4A: Small intraoperative defect: e.g., bladder perforation. Such a complication does not generally create longer-term compromise for the bladder if the defect is recognized and oversewn (if necessary), and some minor precautions are taken, e.g., short-term bladder drainage, with suitable antibiotics commenced. 4B: Other lower urinary tract (bladder or urethral) complication or compromise: This division would incorporate injuries causing longer-term bladder issues, e.g., ongoing suture perforation, fistula, calculus around the suture. This category also incorporates urinary retention directly related to the procedure requiring subsequent surgical intervention (apart from any form of bladder drainage). The time and site divisions relates to those for the surgical intervention. 4C: Ureteric or upper tract complication or compromise: This division is self-explanatory.

**Native Tissue Surgery Complications - CTS Classification) - Category (C) 1D - 3D***Surgery – Complication related*

1D—3D: Abscess formation: This is a more serious possibility. 1D—3D (b–e): Infection—Pain The addition of the letters "b" through to "e" specifies that pain (as defined in Table 3) is part of the abnormal finding associated with abscess formation.

**Native Tissue Surgery Complications - CTS Classification - Category (C) 1B - 3B***Surgery – Complication related*

1B—3B: Symptomatic—Unusual discomfort or pain; dyspareunia (for either partner). Bleeding or discharge may be possible symptoms. 1Bb—3Bb: Symptomatic—Provoked pain only (during vaginal examination) The addition of a "b" to the category code specifies that pain, provoked only during vaginal examination, is associated with the abnormal finding. 1Bc—3Bc: Symptomatic—Pain during sexual intercourse The addition of a "c" to the category code specifies that pain, provoked during sexual intercourse (patient only), is associated with the abnormal finding. 1Bd—3Bd: Symptomatic—Pain during physical activities: The addition of a "d" to the category code specifies that pain, provoked during physical activities, is associated with

**Myotonometry parameters - Stiffness***Investigation*

As defined for dynamometry. However, the method of application of the force is different. With this device, an external sensor applies a deformation perpendicular to the tissue. RATING: A higher N/m value indicates higher muscle stiffness.

the abnormal finding. 1Be—3Be: Symptomatic—Spontaneous pain The addition of an "e" to the category code specifies that pain, spontaneously present (i.e., without physical activity), is associated with the abnormal finding.

**Native Tissue Surgery Complications - CTS Classification - Category (C) 1C - 3C***Surgery – Complication related*

1C—3C: Clinical Infection/Inflammation: Signs of local tenderness are suggestive with the combination of redness and a purulent discharge being more conclusive. The presence of granulation should be accepted as representing ongoing inflammation. 1C—3C (b–e): Infection Pain: The addition of the letters "b" through to "e" specifies that pain is part or all of the infected abnormal finding.

**Native Tissue Surgery Complications - CTS Classification - Category (C) 5***Surgery – Complication related*

Rectal or Bowel Perforation or Compromise: this is subdivided into: 5A: Small intraoperative defect: Such a complication may not generally be expected to cause compromise if the defect is recognized and oversewn (as necessary) with appropriate precautions taken, e.g., short term bowel rest is instituted with suitable antibiotics commenced. 5B: Rectal injury or compromise: This division would incorporate injuries causing longer-term rectal issues, e.g., ongoing suture perforation, fistula. 5C: Small or large bowel injury or compromise: This division would incorporate injuries causing longer-term bowel issues, e.g., ongoing suture perforation, fistula, obstruction. 5D: Abscess formation from bowel injury/compromise.

**Native Tissue Surgery Complications - CTS Classification - Category (C) 6***Surgery – Complication related*

Category 6: Skin and/or musculoskeletal complications: 6A: Asymptomatic: Physician-diagnosed complication at any episode of care. 6B: Symptomatic: e.g., discharge, pain, lump. 6C: Infection from skin or musculoskeletal complication: including sinus tract formation. 6D: Abscess formation from skin or musculoskeletal complication.

**Native Tissue Surgery Complications - CTS Classification - Category (C) 7***Surgery – Complication related*

Category 7: Patient compromise: This category recognizes that the patient might be brought into systemic danger with some of the complications in addition to any localized complication. 7A: Bleeding complication including hematoma: This division refers to any clinically diagnosed hematoma as well as those where blood transfusion or surgical intervention is a consideration. 7B: Major degree of resuscitation or intensive care: This division refers to significant hemodynamic or cardiopulmonary resuscitation directly related to the procedure, and/or patient transfer for management in intensive care facilities. Included in this division is hematoma associated with sepsis, thus increasing patient compromise. 7C: Mortality: The native tissue surgery, whilst not necessarily fatal at the time, has set in train further morbid events leading to mortality. N.B. Because of their systemic nature, 7B and 7C will generally not have a specific site division. They will then be denoted 50.

### **Native Tissue Surgery Complications - CTS Classification - Site Divisions S0 - S5**

#### *Surgery – Complication related*

SELECTION OF SITE (S) DIVISIONS: The selection of these divisions incorporates the current sites where complications have been noted: S0: Systemic complications (no specific site): As mentioned earlier, category divisions 7B (septic hematoma a possible exception) and 7C which are generally systemic complications will be denoted S0. S1: Vaginal: area of suture line: Perhaps the commonest site for complications from native tissue vaginal surgery is close to the vaginal suture line. S2: Vaginal: away from the vaginal suture line: As most suture lines would be midline, this would generally be lateral in the vagina. S3: Adjoining viscus: This division incorporates any extraperitoneal, bladder or rectal complication, but not intraabdominal complications which are S5. S4: Skin or musculoskeletal site: This division is relevant to any skin or musculoskeletal complications away from the sites of the primary wound. Included might be cutaneous sinus or fistula formation and deep muscle pain from suture fixation. S5: Intra-abdominal: Included in this section would be bowel perforation or obstruction.

### **Native Tissue Surgery Complications - CTS Classification - Time (T) - T1 - T4**

#### *Surgery – Complication related*

The time (T) for the complication is when it is clinically diagnosed. This section incorporates four time periods, all of the possible episodes where clinical care might be given by the physician or sought by the patient. It might not always be possible to predict with any particular surgery when particular complications might be more frequently diagnosed. This would depend on the results of a procedure-specific surgical audit using the classification. The earliest time division (T1) might involve more perioperative issues, whilst later divisions (T2–T4) might be biased towards healing abnormality issues.

T1: Intraoperative—48 hr: Perioperative complications clearly more likely. T2: 48 hr—2 months: Bleeding, infection or healing complications more likely. T3: 2 months—12 months: Later healing abnormalities more likely. T4: Over 12 months: Late healing abnormalities and other suture complications more likely.

### **Native Tissue Surgery Complications (CTS Classification) - Category (C) 1**

#### *Surgery – Complication related*

Vaginal complication—no epithelial separation: This incorporates the terms prominence or excessive degrees of scarring or tethering.

### **Native Tissue Surgery Complications (CTS Classification) - Category (C) 1A - 3A**

#### *Surgery – Complication related*

1A—3A: Asymptomatic - Abnormal finding. These are generally physician-diagnosed at any episode of clinical care. It can be argued that the “abnormal finding” aspects of category 1A, in particular, are not really complications, as the patient is not bothered by the potential problem. It may be, however, that the woman may not have engaged in an activity that is likely to provoke symptoms for herself, e.g. pain or bleeding during sexual intercourse (or for her partner), which would convert these complications to category 1B. 1Aa—3Aa: Asymptomatic—Abnormal finding The addition of an “a” specifies that the patient experiences no pain in association with the abnormal finding.

### **Native Tissue Surgery Complications (CTS Classification) - Category (C) 2**

#### *Surgery – Complication related*

Vaginal complication—smaller epithelial separation or ulcer: A smaller (1 cm or less) degree of vaginal epithelial separation or ulcer formation is involved.

### **Native Tissue Surgery Complications (CTS Classification) - Category (C) 3**

#### *Surgery – Complication related*

Vaginal complication—larger epithelial separation or ulcer or suture extrusion: A larger degree (more than 1 cm) of vaginal epithelial separation or ulcer formation or suture extrusion is involved.

### **Native Tissue Surgical Complications (CTS Classification) - Category (C) 1**

#### *Surgery – Complication related*

Vaginal complication—no epithelial separation: This incorporates the terms prominence or excessive degrees of scarring or tethering.

### **Native Tissue Surgical Complications (CTS Classification) - Category (C) 2**

#### *Surgery – Complication related*

Vaginal complication—smaller epithelial separation or ulcer: A smaller (1 cm or less) degree of vaginal epithelial separation or ulcer formation is involved.

### **Native Tissue Surgical Complications (CTS Classification) - Category (C) 3**

#### *Surgery – Complication related*

Vaginal complication—larger epithelial separation or ulcer or suture extrusion: A larger degree (more than 1 cm) of vaginal epithelial separation or ulcer formation or suture extrusion is involved.

### **Need to immediately re-void (“encore” or “double” voiding)**

#### *Symptom*

Complaint that further voiding is necessary soon after passing urine (cessation of flow).

### **Neural lesions**

#### *Diagnosis*

These are described according to the time of onset, risk of neurological progression, completeness and neurological level. The extent of loss of neurological function depends on which part(s) of the nervous system is affected. Relevant diagnoses (see separate descriptions) are (i) Spinal Shock Phase; (ii) Suprapontine Lesion (SPL); (iii) Suprasacral cord/pontine lesion (SSL); (iv) Sacral Spinal Cord Lesion (SSCL); (v) Infrasacral (cauda equine and peripheral nerves) lesion (CEPNL); (vi) Mixed Neuronal Lesion.

### **Neurogenic**

#### *Diagnosis*

Occurs in the presence of relevant neurological pathology ONLY.

### **Neurogenic acontractile detrusor - pressure flow studies**

#### *Investigation*

No visible detrusor contraction during voiding attempt in a man with evidence of a neurological disorder (either visible or measurable neurological deficit or history of neurological disease). This should replace the term “areflexia”.

### **Neurogenic detrusor overactivity - compound**

#### *Investigation*

A phasic detrusor contraction with a subsequent increase in detrusor and base pressure with each subsequent contraction occurs during filling cystometry in the setting of a clinically relevant neurologic disease.

### **Neurogenic detrusor overactivity - general**

#### *Investigation*

Involuntary detrusor muscle contractions occur during filling cystometry in the setting of a clinically relevant neurologic disease.

### **Neurogenic detrusor overactivity - high pressure**

#### *Investigation*

A phasic, terminal, sustained or compound high maximal detrusor overac-

tivity with high detrusor pressure occurs during filling cystometry in the setting of a clinically relevant neurologic disease. The investigator may consider whether such contractions might be potentially detrimental to the patient's renal function and/or health.

#### **Neurogenic detrusor overactivity - phasic**

##### *Investigation*

Phasic detrusor muscle contractions (characteristic waveform) occur during filling cystometry in the setting of a clinically relevant neurologic disease. These may or may not lead to urinary incontinence.

#### **Neurogenic detrusor overactivity - sustained**

##### *Investigation*

Continuous detrusor muscle contractions (without returning to the detrusor resting pressure) occur during filling cystometry in the setting of a clinically relevant neurologic disease.

#### **Neurogenic detrusor overactivity - terminal**

##### *Investigation*

Involuntary detrusor muscle contractions occur near or at the maximum cystometric capacity, in the setting of a clinically relevant neurologic disease. These contractions generally cannot be suppressed resulting in urinary incontinence or even reflex bladder emptying (reflex voiding).

#### **Neurogenic detrusor overactivity incontinence**

##### *Investigation*

Incontinence due to detrusor muscle contractions during filling cystometry in the setting of clinically relevant neurologic disease.

#### **Neurogenic detrusor overactivity (NDO)**

##### *Diagnosis*

In men and women with LUT/PF symptoms (more commonly storage symptoms) detrusor muscle contractions occur during filling cystometry in the setting of a clinically relevant neurologic disorder.

#### **Neurogenic (secondary) detrusor overactivity**

##### *Investigation*

Detrusor overactivity and evidence (history; visible or measurable deficit) of a relevant neurological disorder

#### **Neurological assessment of female sexual dysfunction**

##### *Investigation*

Related to intact sensation, neurological innervation is important for arousal and orgasm. Peripheral neuropathy or central nervous system disorders (eg, diabetic neuropathy, spinal cord injury) may lead to anorgasmia and decreased arousal. Different approaches can be used to evaluate motor and sensory neurological function.

1. Functional magnetic resonance imaging: Investigation of neural activation in anatomically localized cerebral regions evaluated through monitoring subtle changes in regional cerebral blood flow that occur with activation of the neurons. These patterns of activation and deactivation are used to examine the cerebral and cognitive response to sexual stimulation;
2. Quantitative sensory testing: Assessment of the sensitivity by applying different stimuli (light touch, pressure, temperature, or vibration) using an ascending or descending method in order to evaluate the detection threshold. These methods can be used to evaluate different vulvovaginal sites including the clitoris, labia minora, and majora as well as vaginal and anal margins;
3. Reflex examination: Evaluating sacral arc integrity, the bulbocavernosus reflex can be elicited by squeezing the clitoris and assessing the contraction of the anal sphincter. The external anal reflex is tested by repetitive pricking delivered to perianal skin and observing anal sphincter contraction. Latencies

can also be evaluated by stimulating the nerve and evaluating muscle response through a needle electrode.

#### **Neurological examination (female)**

##### *Sign*

For patients with possible neurogenic lower urinary tract or pelvic floor dysfunction, there should be particular note of those neurological signs related to S2-4, but these should be complemented by a more general neurological examination as indicated.

#### **Neurological examination (male)**

##### *Sign*

. Overall neurological status: abnormalities of speech, gait as well as upper and lower extremity dexterity should be noted as they may indicate a neurological cause for the urological symptoms. Neuropathy may impact also on management options.

. Level of neurologic abnormality: can occasionally be localized by the pattern of sensory or motor deficit noted during physical examination using a dermatome map.

. Penile, scrotal, or perianal sensory deficits: may indicate damage or injury to sacral roots or nerves. Reflex testing in the genital area may also be performed. The most important of these is the Bulbospongiosus reflex (BSR).

. Bulbospongiosus reflex (BSR) - a reflex contraction of the striated muscle of the pelvic floor (anal sphincter) and the bulbo-spongiosus muscle that occurs in response to various stimuli in the perineum or genitalia.

. Cremasteric reflex: contraction of the ipsilateral cremaster muscle, drawing the testis upwards, when the upper inner aspect of the thigh is stroked longitudinally.

#### **Neuromuscular Electrical Stimulation Parameters**

##### *Conservative Management – Female*

Neuromuscular electrical stimulation parameters: 1. Pulse frequency (or rate): the number of pulse cycles that are generated per unit of time (seconds). This is reported in hertz (Hz). 2. Pulse width: the determined period of time elapsing from the beginning to the end of one pulse cycle, usually expressed in microseconds or milliseconds. 3. Current amplitude: the magnitude of current relative to the isoelectric baseline, expressed in amperes (A). The current amplitude of therapeutic electrical stimulators ranges from micro- to milliamps. 4. Train: the continuous series of pulse cycles over time, usually lasting seconds. For example, a train of impulses may be the results of successive pulse cycles delivered at 50Hz for a duration of 5s. 5. Train ramp-up time and ramp-down time: ramp-up time is the time elapsed from the onset (or baseline) to the plateau current amplitude (or maximum) of the train, whereas ramp-down time is the time elapsed from the plateau current amplitude to zero baseline. 6. Duty cycle (D): the ratio of ON time to the summation of ON time + OFF time, expressed as a percentage ( $\text{duty cycle} = \frac{\text{ON}}{\text{ON} + \text{OFF time}} \times 100$ , e.g., a duty cycle of 20% is calculated when the ON and OFF times equal 10 and 40s respectively). 7. Impedance (electric resistance): the opposition of our biological tissues to the flow of an electrical current. Measured in ohms and designated as Z. 8. Evoked potentials: electrical potentials recorded from the nervous system following a delivered stimulus.

#### **Neurovascular Bundle (NVB)**

##### *Surgery – Male*

Concentration of nerves that are situated postero-laterally and symmetrically to the prostate that are important in preservation of erectile function. The nerves running through the NVB travel outside the capsule of the prostate and Denovilliers fascia until branches perforate the capsule where they enter the prostate.

**Night-time***Sign*

The individual's main daily period of sleep. It commences at the time of falling asleep and concludes when the individual decides to no longer attempt to sleep and rise for the next day (ideally recorded on chart or diary).

**Night-time (urinary) frequency***Sign*

Total number of night-time voids irrespective of sleep, i.e. the number of voids recorded from the time the individual goes to bed with the intention of sleeping till the time the individual wakes with the intention of rising.

**Nociceptive pain***Symptom*

Pain which arises from actual or threatened damage to non-neural tissue and is due to the activation of nociceptors.

**Nocturia***Symptom*

The number of times urine is passed during the main sleep period. Having woken to pass urine for the first time, each urination must be followed by sleep or the intention to sleep. This should be quantified using a bladder diary.

**Nocturia***Sign*

The number of times an individual passes urine during their main sleep period, from the time they have fallen asleep up to the intention to rise from that period. This is derived from the bladder diary.

**Nocturia - General Advice***Conservative Management – General*

General lifestyle advice, e.g. reducing caffeine and alcohol intake, and limiting excessive liquid/food volume intake before bedtime, can in some cases be sufficient to elicit a satisfactory response. However, care should be taken not to impose a general fluid restriction as this could have serious consequences in patients with undiagnosed diabetes insipidus. Patients should be encouraged to return to their doctor for further evaluation if they are not content with the results after their initial advice.

**Nocturia related to Bladder Storage***Investigation*

Reduced functional bladder capacity (e.g. significant post void residual); Reduced nocturnal bladder capacity Detrusor overactivity; Neurogenic (e.g. multiple sclerosis); Non-neurogenic Bladder hypersensitivity Bladder outlet obstruction with post void residual urine; Urogenital ageing.

**Nocturia related to Sleep Disorders***Investigation*

Insomnia Obstructive and central apnoea syndrome; Periodic legs syndrome; Restless legs syndrome Parasomnias; Sleep disorders related to medical diseases, e.g. chronic obstructive lung disease, cardiac diseases etc; Sleep disorders related to neurological diseases, e.g. Alzheimer's, Parkinson's and nocturnal epileptic seizures.

**Nocturnal***Sign*

Occurring or active at night.

**Nocturnal defecation***Symptom*

Complaint of interruption of sleep one or more times because of the need to defecate.

**Nocturnal enuresis***Symptom*

Complaint of involuntary voiding that occurs at night during the main sleep period (i.e. bedwetting)

**Nocturnal (night-time) polyuria***Sign*

Increased proportional production of urine during the night-time compared with the 24 hour urine volume. Nocturnal polyuria index (NPI) is most commonly used definition (night-time urine volume/24 hour urine volume) x 100%.

33% in elderly e.g. > 65 years.

>20% in younger individuals

20 - 33% in "middle age"

**Nocturnal penile tumescence (NPT) testing***Investigation*

A diagnostic test for evaluating the penile veno-occlusive mechanism. Penile rigidity is monitored using a specialized device (often the Rigiscan®) for at least two consecutive nights. Three periods of penile tip rigidity of greater than 70%, lasting for at least 10 min each, each night, defines normal nocturnal erectile function.

**Nocturnal polyuria***Symptom*

Complaint of passing large volumes of urine at night-time (during the main sleep period).

**Nocturnal polyuria***Sign*

Excessive production of urine during the individual's main sleep period. Should be quantified using a bladder diary.

**Nocturnal polyuria - Causes***Sign*

Water diuresis: Circadian defect in secretion or action of antidiuretic hormone Primary (Idiopathic). Secondary: (Excessive evening intake of fluid, caffeine, alcohol); Solute/water diuresis • Congestive heart failure • Autonomic dysfunction • Sleep apnoea syndrome • Renal insufficiency • Oestrogen deficiency.

**Nocturnal urine volume***Sign*

Total volume of urine produced during the individual's main sleep period. This includes the first void of the morning. Should be quantified using a bladder diary.

**Non-specific (atypical) bladder filling sensation (bladder dyesthesia)***Symptom*

The individual reports no specific bladder filling sensation, but may perceive, for example, abdominal fullness, vegetative symptoms (nausea, vomiting faintness), urethral sensations or spasticity as bladder filling awareness.

**Non-coital sexual pain***Symptom*

Pain induced by non-coital stimulation.

**Non-Functioning Pelvic Floor Muscles***Sign*

(Modified from Messelink et al, 2005): A situation in which there is no PFM action measurable either on instruction to contract (inability) or as the absence of an automatic response to an increase in intraabdominal pressure. This condition can be based on any pelvic floor symptom and on the sign of a non-contracting or non-relaxing pelvic floor.

**Non-functioning Pelvic Floor Muscles***Diagnosis*

A situation in which there is no pelvic floor muscle action palpable. This condition can be based on any pelvic floor symptom and on the sign of a non-contracting, non-relaxing pelvic floor.

**Non-functioning pelvic floor muscles (female)***Sign*

Pelvic floor muscles where there is no voluntary action palpable.

**Non-inflammatory anorectal pain***Symptom*

Complaint of blunted anorectal pain, as opposed to sharp stinging or burning type of pain (proctalgia fugax, Levator ani syndrome, pudendal neuralgia)

**Non-invasive Urodynamics***Investigation*

All urodynamics done without the insertion of catheters: e.g. uroflowmetry, PVR, penile compression-release test, penile cuff, condom catheter, or sonography.

**Non-neurogenic acontractile detrusor - pressure flow studies***Investigation*

No visible detrusor contraction during voiding attempt in a man without evidence of a neurological disorder.

**Non-neurogenic (secondary) detrusor overactivity (DO) - filling cystometry***Investigation*

An identifiable possible non-neurological cause exists for involuntary detrusor contraction(s) during bladder filling. e.g. functional (obstruction); pathology stone, tumor (e.g. carcinoma in situ), UTI.

**Non-specific (atypical) bladder filling sensation (bladder dysesthesia)***Symptom*

Complaint of abnormal bladder filling sensation such as the perception of vague abdominal bloating, vegetative symptoms (nausea, vomiting, faintness) or spasticity. It differs from normal bladder filling sensation or pain, pressure or discomfort of the bladder.

**Non-specific bladder awareness***Symptom*

The individual reports no specific bladder sensation, but may perceive, for example, abdominal fullness, vegetative symptoms, urethral sensations or spasticity as bladder filling awareness or a sign of bladder fullness.

**Non-specific bladder awareness - Filling cystometry***Investigation*

Perception of bladder filling as abdominal fullness, vegetative symptoms (nausea, vomiting, faintness), spasticity or other "non-bladder" awareness, in the setting of a clinically relevant neurologic disorder (e.g. incomplete spinal cord lesion).

**Non-Standard (Urodynamic) Tests***Investigation*

ICS Standard Urodynamic Testing (ICS-SUT) may be supplemented with EMG, with imaging, with continuous urethral pressure(s) and/ or with urethral pressure profile measurement. Cystometry may be done via a suprapubic catheter (specify supplements).

**Normal bladder filling sensation.***Symptom*

The individual is aware of bladder filling and increasing sensation up to a strong desire to void.

**Normal desire to void - filling cystometry***Investigation*

The feeling that leads the individual to void at the next convenient moment, but voiding can be delayed if necessary.

**Normal detrusor activity/function - filling cystometry***Investigation*

There is little or no change in detrusor pressure with filling or any provocative activities.

**Normal detrusor contractile function - pressure flow studies.***Investigation*

Normal voiding is achieved by an adequate continuous detrusor contraction that leads to complete bladder emptying within a normal time span.

**Normal detrusor function (female)***Investigation*

Normal voiding in women is achieved by an initial (voluntary) reduction in intraurethral pressure (urethral relaxation). This is generally followed by a continuous detrusor contraction that leads to complete bladder emptying within a normal time span. Many women will void successfully (normal flow rate and no PVR) by urethral relaxation alone, without much of a rise in detrusor pressure. The amplitude of the detrusor contraction will tend to increase to cope with any degree of bladder outflow obstruction.

**Normal Pelvic Floor Muscles***Diagnosis*

A situation in which the pelvic floor muscles can voluntarily and involuntarily contract and relax. Voluntary contraction will be normal or strong and voluntary relaxation complete. Involuntary contraction and relaxation are both present.

**Normal pelvic floor muscles (female)***Sign*

Pelvic floor muscles which can voluntarily and involuntarily contract and relax.

**Normal urethral closure mechanism (female)***Investigation*

A positive urethral closure pressure is maintained during bladder filling, even in the presence of increased abdominal pressure, although it may be overcome by detrusor overactivity.

**Normal urethral closure pressure - Filling cystometry***Investigation*

A positive urethral closure pressure is maintained during bladder filling, even in the presence of increased abdominal pressure, although it may be overcome by detrusor overactivity.

### Normal urethral function during voiding - pressure flow studies (male +/- VCU, EMG)

#### Investigation

The urethra opens and is continuously relaxed to allow micturition at a normal pressure and urine flow and results in complete emptying. The voiding is prompted by a detrusor contraction and simultaneous relaxation of the smooth and striated sphincters of the urethra and pelvic floor muscles.

### Normal urethral function during voiding (female)

#### Investigation

The urethra opens and is continuously relaxed to allow micturition at a normal pressure, urine flow and PVR.

## O

### Obstetric Anal Sphincter Injuries (OASIS)

#### Diagnosis

OASIS are reported to occur in 0.5–14% of vaginal deliveries (2.9–19% of primiparous vaginal deliveries). It has previously been shown in a prospective study that about one third of OASIS can be diagnosed 8 weeks after delivery by endoanal ultrasound alone. As these were not identified clinically, the injuries were believed to be “occult.” However, it has subsequently been proven that such injuries are not necessarily occult but in fact undiagnosed due to lack of expertise of midwives and doctors. Training in diagnosis and management of perineal trauma has been shown to be suboptimal and dedicated hands-on courses have shown significant improvements in diagnosis and classification of OASIS. Sultan therefore proposed a more descriptive classification of OASIS that has now been accepted internationally to support consistency in reporting. To avoid underestimation of the injury, if there is uncertainty regarding the full extent of the injury it should be classified as the greater degree, for example, if one is unsure as to whether an injury is a Grade 3a or 3b it should be classified as 3b. This classification also has clinical relevance as it ensures increased vigilance for internal sphincter injuries that are best repaired soon after delivery as persistent internal sphincter defects are associated with fecal incontinence. Examination techniques to improve detection of these injuries and avoiding pitfalls in diagnosis have been described in detail.

### Obstructed Defecation Syndrome

#### Diagnosis

Obstructed defecation: incomplete evacuation of fecal contents from rectum due to physical blockage of the fecal stream during defecation attempts. It includes symptoms such as straining to defecate, sensation of blockage, digitation, and splinting. Constipation due to slow transit, irritable bowel syndrome, Hirschsprung’s disease, megarectum, anismus are not within the remit of this standardization document. Associated features of obstructed defecation are: 1: Rectocele: Bulge in posterior vaginal wall associated with herniation of anterior wall of the rectum; 2: Enterocele/sigmoidocele: Bulge of upper wall of vagina associated with herniation of peritoneal sac and small bowel (enterocele) or sigmoid colon (sigmoidocele). 3: Intussusception: Full thickness invagination of the upper rectum without extrusion through the anus leading to interruption of flow of the fecal stream; 4: Internal mucosal prolapse: Mucosal prolapse of the anterior, posterior, or circumferential mucosal layer. 5: External rectal prolapse: Full thickness rectal prolapse outside the anal canal.

### Obstructed intercourse (female)

#### Symptom

Vaginal intercourse is difficult or not possible due to obstruction by genital prolapse or shortened vagina.

### No-touch technique intermittent catheterization

#### Conservative Management – General

This was introduced as an easier way for the patient to perform self-intermittent catheterization with a ready-to-use catheter (pre-lubricated catheter, usually a hydrophilic catheter). A pull-in aid or special packages are used to handle the catheter without directly touching the sliding surface of the hydrophilic catheter.

### Obstructed intercourse (male)

#### Symptom

Complaint that vaginal intercourse is not possible due to perceived obstruction. Whilst this may be a partner issue, it can occur in cases of penile curvature (Peyronie’s disease) or penile carcinoma.

### "Occult" urodynamic stress incontinence

#### Diagnosis

Where the diagnosis of urodynamic stress incontinence is only made when co-existent pelvic organ prolapse (POP) is reduced.

### Omental flap

#### Surgery – Female

The use of omentum to provide interposing fat and blood supply during abdominal surgery.

### Open perineal radical prostatectomy

#### Surgery – Male

Radical removal of the entire prostate and seminal vesicles via a perineal approach for the treatment of prostate cancer.

### Open suprapubic radical prostatectomy

#### Surgery – Male

Radical removal of the entire prostate and seminal vesicles via an open, extraperitoneal approach for the treatment of prostate cancer.

### Opening Time

#### Investigation

The time elapsed from initial rise in pressure to the onset of flow. This is the initial isovolumetric contraction period of micturition. It reflects the time taken for the fluid to pass from the point of pressure measurement to the uroflow transducer. flow measurement delay should be taken into account when measuring the opening time.

### Orgasmic disorder (Male)

#### Diagnosis

Presence of either of the following on all or almost all (75%–100%) occasions of sexual activity; marked delay in, marked infrequency of, or absence of orgasm; markedly reduced intensity of orgasmic sensations.

### Orgasmic disorder (Male) - Anorgasmia

#### Diagnosis

The inability to reach orgasm despite adequate and prolonged sexual stim-

ulation leading to adequate sexual arousal which might or might not lead to personal distress.

#### **Orgasmic disorder (Male) - Dysorgasmia**

##### *Diagnosis*

Painful orgasm

#### **Orgasmic disorder (Male) - Hypohedonic orgasm**

##### *Diagnosis*

Lifelong or acquired decreased or low level of sexual pleasure with orgasm.

#### **Orgasmic pain (during ejaculation)**

##### *Symptom*

Pain may be felt on the penis, ano-rectum, perineum or in the whole pelvis.

#### **Orgasmic urinary incontinence (female)**

##### *Symptom*

Urinary incontinence at orgasm.

#### **Orthoptic**

##### *Surgery – Male*

Reconstructed bladder reservoir (entirely or partially constructed from bowel; usually terminal ileum) anastomosed to the native urethra, usually utilizing the urethral sphincter as a continence mechanism. Diversion may be supratrigonal or total substitution.

#### **Outcome measurement in POP surgeries - objective outcomes**

##### *Surgery – Female*

POP-Q measurement generally and should be tabulated with absolute values and percentages to allow other studies to compare results.

#### **Outcome measurement in POP surgeries - perioperative data**

##### *Surgery – Female*

These data include blood loss, operating time, length of hospital stay, return to normal activities and complications.

#### **Outcome measurement in POP surgeries - subjective (patient reported outcomes)**

##### *Surgery – Female*

At its simplest level this can be reported as the presence or absence of vaginal bulge. Patient satisfaction and quality of life can be measured by validated instruments that cover prolapse, urinary, bowel and sexual function.

#### **Outcomes measurement in POP surgeries - secondary outcomes**

##### *Surgery – Female*

For example, lower urinary tract symptoms, stress urinary incontinence or bowel and sexual dysfunction in their studies whenever possible.

#### **Outcomes of Female Pelvic Floor Surgery - Economic Evaluation / Cost Analysis**

##### *Surgery – Female*

Despite considerable cost, sparse cost-effectiveness data exists related to POP surgery. Investigators are encouraged to include economic analyses in their studies whenever possible. Economic evaluation techniques provide systematic methods of comparing the costs and consequences of clinical and other health sector interventions. Cost-utility analysis (CUA), a form of cost-effectiveness analysis (CEA), is by far the most commonly used and requires quantifying the effects of interventions on both morbidity and mortality. In a CUA, benefits are measured in units of health gain (or loss), most commonly using quality-adjusted life-years (QALYs) and combined with estimates of cost to create a ratio of incremental costs to incremental con-

sequences (e.g., “incremental cost per QALY”). QALYs are usually calculated using a generic health status measure, such as Short Form (SF)36 or Euro-QOIEQ-5D, which can be used with a standard set of health state values or by other measures of utility, such as the standard gamble or time-trade off technique. These incremental cost effectiveness ratios (ICERs) enable comparison of competing interventions on the basis of the cost at which they create improvements in health-related quality-of-life. In economic evaluations, it is important to consider the perspective (e.g., patients, hospital, third-party payer, government and society) of the evaluation, as this will have significant influence on which costs should be included in the analysis. For example, the perspective of the analysis will influence whether it should include both direct and indirect costs. Direct medical costs typically relate to the intervention and the immediate impact of the intervention on the health system: e.g., personnel costs/time (physician, nurse, technician), diagnostic and laboratory tests, hospital costs, treatment costs (drugs, operating room time, etc.), treatment of side effects and outpatient visits. Indirect costs will be of more relevance to a patient and/or societal perspective (e.g., loss of productivity, time lost from work, loss of service to family and community and premature mortality) and are often more difficult to quantify and to put a monetary value on.

#### **Outcomes of Female Pelvic Floor Surgery - Patient Reported Outcomes**

##### *Surgery – Female*

The primary patient reported outcome should be subjective and would usually be the absence of a bulge. This can be regarded as a “subjective cure” and can be recorded as part of a symptom scale. Details of validated questionnaires for patient reported outcomes can be found on ICI’s website. To adhere with the SMART criteria, patient/subjective outcomes should be defined at a specific time interval and classified on a 7-point Likert scale (i.e. very much better, moderately better, a little better, no change, slightly worse, moderately worse, very much worse) such as the Patient Global Impression of Improvement (PGI-I) scale.

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Complications**

##### *Surgery – Female*

Complications specifically related to prostheses and grafts and native tissues should be reported as per the IUGA-ICS classifications of complications directly related to the insertion of prostheses and grafts or the use of native tissue in female pelvic floor surgery. These classifications both use the CTS Classification System: (C) Category of complication. (T) Time the complication was diagnosed in relation to primary surgery. (S) Site of the complication. There are seven Categories with subdivisions of (A–D). For the majority of complications, this would mean: (A) Asymptomatic, (B) Symptomatic, (C) Infection, (D) Abscess. For complications involving bowel or bladder injury or patient compromise, variations in the pattern of the increasing index of severity exist: e.g., Category 5: rectal or bowel injury (both classifications) (A) Small intraoperative defect; (B) rectal injury or compromise; (C) small or large bowel injury or compromise; (D) abscess. Studies, in particular of a specific surgical procedure, should have a procedure-specific list of complications using the CTS Classification Systems as part of the reporting. Only in this way can the nature and chronology of possible complications be determined (in relation to time of surgery) and at which sites they might most commonly occur. Note is also made of the generic Clavien-Dindo complication classification which consists of four severity grades of complications. This has been modified to include a fifth category. Grade IV IC/ICU organ or system dysfunction (a: single organ; b: multi-organ dysfunction) Grade V Death. Grade I requires no treatment; Grade II requires drug therapy; Grade III requires a procedure or intervention (a: in local; b: general anesthesia).

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Demographics**

##### *Surgery – Female*

The reporting of minimum demographics in POP surgery should include: A.

Age, B. Parity, C. Body mass index (BMI), D. Menopause status, E. Hormone replacement (HRT) usage, F. Prior hysterectomy, G. Prior POP surgery, H. Prior continence surgery, I. Chronic cough, J. Chronic constipation, K. Smoking

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Objective Outcomes Surgery – Female**

Objective outcomes (e.g., POPQ) should be tabulated with percentages achieving each level to allow studies to compare results, as definitions of success will vary among studies (see below). This report does not attempt to provide a definition for success and failure, as these are unknown. However, authors should report data on the leading edge of the prolapse for each site (e.g. patients who achieve points 1 and 0 postoperatively having had prolapse greater than 1 or 0 before surgery). These data, which may help identify the level of anatomical restoration that leads to improvement in symptoms, should be reported separately. When possible, raw data should be provided for POPQ, quality of life measures and all primary symptoms. These should be reported in separate tables, which can be published as supplementary material in the electronic (online) version rather than the printed version.

#### **Outcomes of Female Pelvic Floor Surgery - Reporting of Methodological Data**

##### *Surgery – Female*

General Criteria: The following should be defined: A. Inclusion criteria. B. Exclusion criteria. C. Recruitment time span. D. flow diagram including: (i) Number of patients evaluated. (ii) Number suitable for inclusion. (iii) Number agreed to participate. (iv) Clear documentation accounting for all patients' progress throughout the study period. Comparative Studies: A. Clear explanation of patient allocation to treatment groups. B. Allocation concealment from surgeon and/or patient. C. Randomized trials: explanation of randomization process. D. Stratification of associated issues utilized such as concomitant continence surgery or hysterectomy. Interventions: A. Clear documentation of interventions performed, experience level of surgeons and number of interventions performed prior to study commencement. B. Criteria for performing concomitant surgery. Evaluation Process: A. Who performed the evaluation and the training received. B. Were reviewers and/or participants blinded. C. Evaluation tools: were validated, patient-completed assessments standardized. D. Evaluation timeline: i. Very early (up to 3 months). ii. Early (up to 1 year). iii. Intermediate (12–36 months). iv. Late (3–5 years). v. Very late (>5 years). Power Analysis: Details of the assumptions made in the power calculation, estimate of the type 1 error and sample size should be reported.

#### **Outcomes of Female Pelvic Floor Surgery - Reporting of Patients' Preoperative Goals and Expectations**

##### *Surgery – Female*

To date, few studies have provided data on patients' preoperative goals and expectations. These might have advantages over objective measures of outcome. With this in mind, goals should be reported using SMART criteria. The aim of the SMART criteria is to help clinicians review and confirm the utility of the chosen endpoint and how it will relate to other studies and reports. Criteria comprise: Specific Defining goal (for POP: absence of bulge). Measurable validated symptom scale or objective measure such as the POPQ appropriate relevant to improving patient lifestyle realistic achievable by treatment Timely For example at 6 months/2 years. The following is an example of good and poor reporting of patient expectations and outcomes, using the SMART Schema: Good example: "The absence of bother from a vaginal bulge as measured using a defined tool at 2 years." This statement has Specific, Measurable, Appropriate, Realistic, and Timely attributes. Poor example: "Feeling perfect" when followed-up. "Perfect" is not specific (OB compared with absence of bulge), is less measurable (because it is difficult to define), has no defined timepoint and is not appropriate or relevant

to the surgery as many factors define "perfect." Definitions relating to the SMART criteria should be derived from the symptoms the researchers feel are important. When designing a study, the symptoms should be listed and then SMART should be applied. Authors should use this as a checklist to ensure that the methodology is sound and relevant.

#### **Outcomes of Female Pelvic Floor Surgery - Reporting of Randomized Controlled Trials**

##### *Surgery – Female*

There are already accepted standards for reporting RCTs such as the CONSORT (Consolidated Standards of Reporting Trials) which requires detailed information provided by authors to reviewers with a checklist added as an appendix. However, many studies fail to provide complete descriptions of critical information.

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Patient Satisfaction**

##### *Surgery – Female*

Patient satisfaction can be measured using qualitative measures, such as a patient-defined measure or a validated instrument (PGI-I scale). Qualitative assessment can include Expectations, Goal setting, Goal achievement and Satisfaction (EGGS). Again these should be in accordance with the SMART acronym. The number of pre-specified goals and the number achieved post-operatively should be recorded and reported for responsiveness and reliability of goal achievement.

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Perioperative Data**

##### *Surgery – Female*

Perioperative data includes blood loss (ml) and/or hemoglobin change, operating time, length of hospital stay, return to normal daily activities and complications.

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Postoperative Pain**

##### *Surgery – Female*

Pain associated with surgical complications is addressed separately in the IUGA-ICS classifications of complications of female pelvic floor surgery. The addition of a letter (a to e), as part of a subclassification to the CTS Classification System, specifies the presence of pain as part or all of the abnormal finding or complication and the grade in terms of the presence and severity of symptoms.

(a) Asymptomatic or no pain. (b) Provoked pain only (during vaginal examination). (c) Pain during sexual intercourse. (d) Pain during physical activities. (e) Spontaneous pain.

Additional information on pain may include "permanent or temporary" and "severity" as measured by impact on quality of life and treatment required (e.g., simple oral analgesia, compound analgesia, opiates, referral and management by pain team or further surgery).

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Quality of Life**

##### *Surgery – Female*

Appropriate and fully validated quality of life instruments should be used to cover prolapse, urinary, bowel and sexual function. New questionnaires can be included when they have demonstrated good psychometric properties (i.e., validity, reliability and responsiveness) in women with POP. It is important to verify that the questionnaire has been validated in the language of the trial investigator(s).

#### **Outcomes of Female Pelvic Floor Surgery - Reporting Secondary Outcomes**

##### *Surgery – Female*

Secondary outcomes to be reported include an assessment of other symptoms known to be associated with prolapse: Lower urinary tract symptoms (LUTS): Overactive bladder, stress urinary incontinence (either pre-existing or de-novo) and voiding dysfunction. Bowel dysfunction: Obstructed def-

ecation, feeling of incomplete emptying, constipation and digitation. Sexual dysfunction: Dyspareunia, loss of libido, abstinence due to prolapse symptoms and change in sexual satisfaction. Authors should report numbers of all patients who are sexually active with and without pain, pre and post-intervention. All participants in trials should be accounted for pre- and post-intervention. De novo/new onset symptoms (if not previously reported): LUTS, sexual dysfunction, pain and bowel dysfunction. Backache: Backache is a common presenting symptom, the resolution of this may be an important outcome.

### Outcomes of Female Pelvic Floor Surgery - Reporting Systematic Reviews and Meta-Analyses

#### *Surgery – Female*

Due to the lack of consistent descriptions of critical information reported from RCTs, a new instrument, Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), has been introduced to evaluate systematic reviews and meta-analyses. The aim of the PRISMA statement is to give authors an evidence-based minimum set of items to improve the reporting of systematic reviews and metaanalyses in POP issues. Other standards include the Standards for the Reporting of Diagnostic (STARD) accuracy studies, and STROBE (STrengthening the Reporting of OBservational studies in Epidemiology). Researchers should quote which standard they adopt and reference accordingly.

### Outcomes of Female Pelvic Floor Surgery - Timelines for Reporting

#### *Surgery – Female*

Timelines should be described chronologically, as outlined below, using the classification above. Of note, these timescales are different to those described in the classifications of complications reports related to female pelvic floor surgery using either prosthesis and meshes or native tissue. I.

Very early (up to 3 months). II. Early (up to 1 year). III. Intermediate (12–36 months). IV. Late (3–5 years). V. Very late (>5 years).

### Overactive bladder (OAB, Urgency) syndrome

#### *Symptom*

Urinary urgency, usually accompanied by increased daytime frequency and/or nocturia, with urinary incontinence (OAB-wet) or without (OAB-dry), in the absence of urinary tract infection or other detectable disease.

### Overactive Pelvic Floor Muscles

#### *Diagnosis*

A situation in which the pelvic floor muscles do not relax, or may even contract when relaxation is functionally needed for example during micturition or defecation. This condition is based on symptoms such as voiding problems, obstructed defecation, or dyspareunia and on signs like the absence of voluntary pelvic floor muscle relaxation.

### Overactive pelvic floor muscles (female)

#### *Sign*

Pelvic floor muscles which do not relax, or may even contract when relaxation is functionally needed, for example, during micturition or defecation.

### Overflow fecal incontinence

#### *Symptom*

Complaint of involuntary loss of stool due to an overfull rectum or fecal impaction.

### Overflow urinary incontinence.

#### *Symptom*

Complaint of urinary incontinence in the symptomatic presence of an excessively (over-) full bladder (no cause identified).

## P

### Pad testing

#### *Sign*

For individuals with urinary (fecal) incontinence symptoms, the quantification of the amount of urine (feces) lost over the duration of testing, by measuring the increase in the weight of the pads (weighed pre- and post-testing) used. This may give a guide to the severity of incontinence. Different durations from a short (1 hour) test to a 24 and 48-hour tests have been used with provocation varying from normal everyday activities to defined regimens.

### Pads: Defining features

#### *Conservative Management – Female*

Waterproof-backed absorbent products that are held in place using separate, close-fitting (regular or specially designed) underwear.

### Pads: Main variant features

#### *Conservative Management – Female*

Products may be used by either sex, but some are intended (by their color, style, shape, or the placing of absorbent material, for example) just for men or just for women.

- Products come with different absorption capacities.
- Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit, comfort, and prevent leakage.
- Products may have an adhesive strip on the back or adhesive wings to the sides to help secure them in

underwear.

- Products may have a wetness indicator.
- Products may or may not be suitable for containing fecal incontinence (fi) as well as urinary incontinence (UI).

### Pain

#### *Symptom*

A subjective phenomenon described as an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage. Pain should be characterized by site, type, frequency, duration, precipitating and relieving factors. NB: The word pain comes from the Latin "poena" meaning a fine or a penalty.

### Pain - filling cystometry

#### *Investigation*

The complaint of pain during filling cystometry is abnormal. Its site, character and duration should be noted.

### Pain - Neurobiology

#### *Symptom*

Alterations in gut and bladder motility, visceral perception and central processing of pain and motor function due to abnormalities in the visceral and central nervous systems may account for the symptoms.

**Pain - psychology***Symptom*

Pain is modulated by cognitive factors and emotional experience, memory, attention and context represented in descending modulation of pain, affecting pain experience from moment to moment and longer term. Pain has an impact on many aspects of daily life, affecting mood, sleep, relationships and activities. Therefore, attention to the psychological aspects of pain is an important part of effective assessment and treatment.

**Pain (during) - Filling cystometry***Investigation*

The complaint of pain during filling cystometry is abnormal. Its site, character and duration should be noted.

**Pain during straining/defecation (female)***Symptom*

Complaint of pain during defecation or straining to defecate.

**Pain Evaluation and Measurement***Investigation*

Pain rating(s) are essential in patient evaluation including: baseline and ongoing regular evaluation of severity, quality of life, questions about thoughts, emotions and behavior associated with the pain (questionnaires). Pain measurement: one of the most commonly used tools is the visual analogue scale (VAS), which is a 10cm line from "0" no pain to "10" extreme pain. Pain evaluation involves additional pain mapping by identifying pain generators through diagnostic procedures. These include EMG, Q-tip touch sensitivity testing, trigger point injections, nerve blocks and imaging.

**Pain experience***Symptom*

According to the most common views, pain constitutes the internal perception of bodily damage. It is unknown whether chronic pelvic pain syndromes (CPPS) are primarily an abnormal perception of a normal stimulus or a normal perception of an abnormal physiologic sensory stimulus.

**Painful bladder syndrome***Symptom*

Painful bladder syndrome is the complaint of suprapubic pain related to bladder filling, accompanied by other symptoms such as increased daytime and night-time frequency, in the absence of proven urinary infection or other obvious pathology.

**Palpation***Sign*

(latin origin: palpare): to touch gently or to use the fingers or hands to examine. Palpation allows the assessor to feel the texture, size, consistency, and location of certain body parts with the hands, or in the case of pelvic floor muscle assessment, with the fingers or finger tips.

**Paraphimosis***Sign*

Entrapment of the prepuce behind the glans usually due to a preputial ring.

**Paravaginal repair - open, laparoscopic, robotic***Surgery - Female*

Extraperitoneal bilateral reattachment of the lateral edge of the damaged fascia to the Arcus Tendineus Fasciae Pelvis (alt: white line).

**Partial cystectomy***Surgery - Male*

A segment of urinary bladder (e.g., bladder dome) is excised.

**Paruresis ('bashful' or 'shy' bladder)***Symptom*

Complaint of the inability to initiate voiding in public (i.e. voiding in the presence of other persons) despite there being no difficulty in private.

**Passive fecal incontinence (female)***Symptom*

Fecal soiling without sensation or warning or difficulty wiping clean.

**Passive fecal leakage (female)***Symptom*

Involuntary soiling of liquid or solid stool without sensation or warning or difficulty wiping clean.

**Passive (insensible) fecal incontinence.***Symptom*

Complaint of involuntary soiling of liquid or solid stool without sensation or warning.

**Patient Preparation and Information in advance of Invasive Urodynamics***Investigation*

Although evidence indicates that urodynamics is generally well tolerated, studies have examined pain and embarrassment, using a variety of questionnaire methods. Younger patients have been identified as a group that may experience more pain and apprehension associated with depression, anxiety and/or bladder pain syndrome. Effectiveness of patient information leaflets requires comprehensibility and communicative effectiveness. However, reports analysing existing information conclude that this is of poor quality. Studies to develop a detailed explanatory leaflet, which were used in a double-blind randomized controlled trial to conclude that 'leaflet' or 'no leaflet' intervention had a disappointing satisfaction outcome. Poor understanding of the test has been associated with lack of satisfaction with care and with, for example, the perception that the investigation in itself is therapeutic. Some evidence exists that information leaflets about urodynamic investigations are too difficult for patients to understand.

Young adults and patients with a bladder pain syndrome may have a relatively negative experience with urodynamic investigation. Conflicting evidence exists about which precise information is helpful to give to patients before urodynamic testing to reduce distress. Effective communication is an expectation in modern healthcare, so that patients become actively engaged in the test and their care delivery. A leaflet with a minimum set of items would facilitate informed decision making. Good information before and during the test increases a patient's acceptance and confidence, and will reduce confusion. Although in the absence of good evidence, that an explanatory leaflet about urodynamic investigation with sufficient information, which uses clear, unambiguous wording will be appreciated by the majority of patients.

**Pelvic Congestion Syndrome***Symptom*

i. Pressure, heaviness, dull aching pain in the pelvis and/or in the back. ii. Dysmenorrhoea.

**Pelvic electrical stimulation***Conservative Management - General*

This is the application of electrical current to stimulate the pelvic viscera or their nerve supply.

**Pelvic Floor***Conservative Management - General*

The term pelvic floor relates to the compound structure, which closes the bony pelvic outlet. The term pelvic floor muscles refers to the muscular layer

of the pelvic floor. The pelvic floor consists of different layers, the most cranial being the peritoneum of the pelvic viscera and the most caudal being the skin of vulva, scrotum and perineum. The middle layers of the pelvic floor are made up of predominantly muscular tissue. Apart from the pure pelvic floor muscles, fibro-muscular and fibrous elements, like the endo-pelvic fascia are found in this layer. Different well recognizable muscles together form the muscular layer of the pelvic floor: levator ani, striated urogenital sphincter, external anal sphincter, ischiocavernosus and bulbospongiosus. All these muscles are working together to seal the lower aspect of the pelvic cavity. Urethra, vagina, and rectum pass through the pelvic floor and are surrounded by the pelvic floor muscles. The pelvic bones are the structures to which the muscular layer is attached.

### **Pelvic Floor - Voluntary Contraction**

#### *Sign*

Voluntary contraction of the pelvic floor muscles means that the patient is able to contract the pelvic floor muscles on demand. A contraction is felt as a tightening, lifting and squeezing action under the examining finger. A voluntary contraction can be absent, weak, normal or strong.

### **Pelvic floor assessment in female sexual dysfunction - Pelvic floor manometry**

#### *Investigation*

Measurement of resting pressure or pressure rise generated during contraction of the PFMs using a manometer connected to a sensor which is inserted into the urethra, vagina, or rectum. Pelvic floor manometric tools measuring pressure in either mmHg, hPa, or cmH<sub>2</sub>O can be used to assess resting pressure, maximal squeeze pressure (strength), and endurance.

### **Pelvic Floor Dynamometry**

#### *Investigation*

A dynamometer is an instrument that measures power or force. Pelvic floor dynamometry: Measurement of PFM resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina. Dynamometry measures force in Newton units (N=1kg×m/s<sup>2</sup> (sq)).

### **Pelvic floor fistula (PFF)**

#### *Diagnosis*

Pelvic floor fistula (PFF) refers to a fistula affecting the upper or lower genital tract including the uterus, cervix, vagina, and/or the different vaginal compartments and the neighboring organs such as the upper and lower urinary tract (ureter, bladder, and urethra) and lower bowel (distal colon, rectum, and anus). A diagnosis of PFF fits the established model of symptoms corroborated by clear clinical signs and commensurate evaluation test results, starting with a woman having urinary or fecal incontinence symptoms, usually per vagina.

### **Pelvic floor fistula (PFF): Basic categories**

#### *Diagnosis*

Terms outlined will denote the proximal/distal locations along the urinary, colorectal, and genital tracts and site-specific categories (e.g., urethro-vaginal fistula [UVaF]). fistulas may, however, be large, straddle both proximal/distal locations and involve more than one anatomical site. More than one fistula may be present. The amount of scarring and residual tissue present (for surgical purposes) will be variable. The fistula may also be described by its anatomical location and antecedent event (e.g. obstetric, iatrogenic, combined).

These are localizing/descriptive terms and not a classification system as such.

The following acronyms will be used: F (fistula); V (bladder/vesico); U (ure-

thra); Va (vaginal); Vt (vaginal vault); Ut(uterine); Cx (cervical); Ur (ureteric); R (rectal); Co (colon); Pe (perineal); AC (ano-cutaneous).

### **Pelvic floor fistula (PFF): (Colo)-rectal to urinary tract - Recto (colo)-ureteric fistula (CoUrF/RUrF)**

#### *Diagnosis*

Abnormal connection between the rectum (colon) and the ureter.

### **Pelvic floor fistula (PFF): (Colo)-rectal to urinary tract fistula**

#### *Diagnosis*

Any abnormal connection between the rectum (colon) and any part of the urinary tract, without vaginal involvement.

### **Pelvic floor fistula (PFF): (Colo)-recto-vaginal fistula ([C]RVaF)**

#### *Diagnosis*

Abnormal connection between the rectum (colon) and the vagina.

### **Pelvic floor fistula (PFF): Uretero-uterine (cervical) fistula (UrUtF/ UrCxF)**

#### *Diagnosis*

Abnormal connection between the ureter and the uterus (cervix). Predominantly post-cesarean or post-supracervical hysterectomy.

### **Pelvic floor fistula (PFF): Uretero-vaginal fistula (UrVaF)**

#### *Diagnosis*

Abnormal connection between the ureter and the vagina.

### **Pelvic floor fistula (PFF): Uretero-vaginal fistula (UrVaF): Acquired**

#### *Diagnosis*

Following surgery or obstructed labor.

### **Pelvic floor fistula (PFF): Uretero-vaginal fistula (UrVaF): Congenital**

#### *Diagnosis*

e.g. Ectopic ureter

### **Pelvic floor fistula (PFF): Uretero-vesico-vaginal fistula (UrVVaF)**

#### *Diagnosis*

fistula involving the ureter(s), bladder, and vagina. This may be seen with a large obstetric fistula and the ureter is outside the VVaF

### **Pelvic floor fistula (PFF): Urethro-vaginal fistula (UVaF)**

#### *Diagnosis*

Abnormal connection between the urethra and the vagina.

### **Pelvic floor fistula (PFF): Urethro-vaginal fistula (UVaF) - Circumferential fistula (genito-urinary)**

#### *Diagnosis*

An entire segment (anterior, posterior, lateral urethra) from the anterior vaginal wall to the posterior aspect of the pubic symphysis is absent and destroyed. The circumferential fistula almost always involves the urethra and the fistula totally separates the proximal urethra/bladder from the distal portion. Bladder involvement with a circumferential fistula is common.

### **Pelvic floor fistula (PFF): Urethro-vaginal fistula (UVaF) - Partial UVaF**

#### *Diagnosis*

Urethral structure is evident with a demonstrable fistula defect

### **Pelvic floor fistula (PFF): Urethro-vaginal fistula (UVaF) - Total UVaF**

#### *Diagnosis*

Urethral structure is not evident.

**Pelvic floor fistula (PFF): Vesico-uterine fistula (VUtF)***Diagnosis*

Abnormal connection between the bladder and the uterus (body).

**Pelvic floor fistula (PFF): Vesico-vaginal fistula (VVaF)***Diagnosis*

Abnormal connection between the bladder and the vagina.

**Pelvic floor fistula (PFF): Vesico-vaginal fistula (VVaF): Vaginal walls***Diagnosis*

fistula affecting anterior vaginal wall and posterior bladder wall with or without involvement of the ureteric orifices.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Acute fourth degree tear.***Diagnosis*

Occurs at time of childbirth or other trauma.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Chronic fourth degree tear.***Diagnosis*

Unrepaired or dehiscence following repair at time of childbirth or other trauma, resulting in an absent perineal body with a total perineal defect.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Circumferential recto-vaginal fistula (RVaF)***Diagnosis*

Involves an entire segment of the rectum, involving the posterior vaginal wall, anterior and posterior rectum. The proximal rectal part of the fistula is completely separated from the distal portion.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Fistula-in-ano (FIA)/ ano-cutaneous fistula (ACF)***Diagnosis*

An abnormal connection between the anal canal epithelium and the skin epithelium.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Fourth-degree tears***Diagnosis*

Obstetric anal sphincter injury with disruption of the perineal body, connecting the vagina to the anorectum. The internal and external anal sphincters are disrupted.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Non-circumferential recto-vaginal fistula (RVaF)***Diagnosis*

Involves the posterior vaginal wall and anterior rectum.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Rectal/vaginal/perineal fistula (RVaPeF)***Diagnosis*

An abnormal communication from the anorectum to the vagina and perineal area.

**Pelvic floor fistula: Anorectal tract to vaginal (uterus): Recto-uterine-cervical fistula (RUtF/RCxF)***Diagnosis*

An abnormal connection from the rectum to the uterus or cervix.

**Pelvic floor fistula: Anorectal to vagina (uterus): Fistula-in-ano (FIA)/ Ano-cutaneous fistula (ACF)***Diagnosis*

An abnormal connection between the anal canal epithelium and the skin epithelium.

**Pelvic floor fistula: (colo) rectal to urinary tract - Colo-vesical fistula (CoVF)***Diagnosis*

Abnormal connection between the rectum (colon) and the bladder.

**Pelvic floor fistula: (colo) rectal to urinary tract: Colo-vesical fistula (CoVF)***Diagnosis*

Abnormal connection between the rectum (colon) and the bladder.

**Pelvic floor fistula: (colo) rectal to urinary tract: Recto (colo)-ureteric fistula (CoUrF/RUrF)***Diagnosis*

Abnormal connection between the rectum (colon) and the ureter.

**Pelvic floor fistula: Correlation of symptoms and signs***Sign*

Signs should correlate with symptoms e.g. patient report of urinary incontinence is corroborated by visualization of urine leakage into the genital tract through a fistula defect.

**Pelvic floor fistula: Fistula symptoms***Symptom*

A departure from normal sensation, structure, or function, reported by a woman as (i) leakage of urine and/or feces or flatus from the vagina or perineum or; (ii) less commonly as leakage of urine from the anus, or cyclic menouria or hematuria from the urinary tract; or (iii) menstrual flow or other cyclic blood per anum/rectum. Symptoms are often, but not always, continuous, severe and may vary with position including leakage when sleeping (supine). fistulas with a long tract or flap valve or small defect may make symptoms intermittent.

**Pelvic floor fistula: General examination***Sign*

Is fundamental to the surgical triage process to assure that patients undergoing fistula surgery are suitable for anesthetic and surgical intervention. Surgery scheduling should be delayed until underlying conditions are stabilized with treatment to the best possible state of health. General examination must also rigorously screen for any condition that will impair optimal wound healing, so that the condition may be treated, or cured, before elective reconstructive fistula surgery. Signs of conditions relevant for elective reconstructive surgical triage screening include amongst others: anemia, malnutrition, diabetes, malaria, and other parasites, hepatitis, hypertension, rehydration, renal dysfunction, STI, and HIV.

**Pelvic floor fistula: Overlap of PFF and non-PFF signs***Sign*

Because the signs of PFFs overlap with symptoms of urinary and fecal incontinence in patients who have never had a fistula, detailed pelvic exam is essential. fill tests, with or without dye, may also be used during physical examination to assess the defect(s). The aim is to first diagnose the fistula(s) and to identify the location of the fistula(s) and then to assess the injury by evaluating the amount of tissue defect and scarring/fibrosis.

**Pelvic Floor fistula: Published classification systems***Surgery – Female*

There are published classification systems used for female PFFs predicated on and devised from their ability to predict outcomes of surgery based on these classification systems. These classification systems are: (i) the Francophone System; (ii) the Waaldijk System; (iii) the Goh System; (iv) the Panzi Hospital System.

**Pelvic floor fistula: Vaginal bleeding, discharge***Sign*

Observed on vaginal examination of the fistula. This includes hematoma.

**Pelvic floor fistula: Vaginal scars, sinuses, deformities***Sign*

Vaginal scarring, vaginal sinus tracts, vaginal stenosis.

**Pelvic floor fistula: Vesico-cervical fistula (VCxF)***Diagnosis*

Abnormal connection between the bladder and the cervix. May occur after cesarean section, procedures to the cervix, supra-cervical hysterectomy

**Pelvic floor fistula: Vesico-vaginal vault fistula (VVtF)***Diagnosis*

Vesico-vaginal fistula located at vaginal vault (cuff) following hysterectomy.

**Pelvic Floor Function - General***Conservative Management – General*

The function of the pelvic floor is to support the pelvic organs. The function of the pelvic floor muscles is performed by contraction and relaxation. In its resting state, the pelvic floor gives support to the pelvic organs. Whether the support function is normal depends on the anatomical position of the muscles on the activity of the pelvic floor muscles at rest (active support) and on the integrity of the fascia (passive support). During intra-abdominal pressure rise, the pelvic floor muscles must contract to maintain the support function of the pelvic floor. A contraction of the pelvic floor muscles results in a ventral and cranial movement of the perineum, and an upward movement of the pelvic organs together with an anterior movement caused primarily by the vaginal and rectal parts of the levator ani. When the pelvic floor muscles contract the urethra closes, as do the anus and the vagina. This contraction is important in preventing involuntary loss of urine or rectal contents. For women it can also function as a defense mechanism against sexual intercourse. For maintaining continence, it is also important to realize that detrusor activity is inhibited by pelvic floor muscle contraction.

**Pelvic floor magnetic resonance imaging (MRI) - Levator ani defects***Imaging*

Is damage to muscle fibers ranging from disruption of a single fascicle, to complete disruption of the muscle origin. There is no universally accepted system for the diagnosis and evaluation of the extent of the injury. Essentially, abnormalities are judged to have occurred when the morphology of the pubococcygeal portion of the levator ani muscle deviates from what is seen in normal nulliparous women. INTERPRETATION: Levator ani damage on MRI can be diagnosed when one or more of the following is present: absence of pubococcygeal muscle fibers in at least one 4-mm section, or two or more adjacent 2-mm sections in both the axial and the coronal planes. Defect severity may be further scored in each muscle from 0 (no defect) to 3 (complete loss). A summed score for the two sides (0–6) is assigned and grouped as minor (0–3) or major (4–6).

**Pelvic floor magnetic resonance imaging (MRI) - Levator ani position in the pelvis:***Imaging*

Location of the levator ani in the sagittal plane in relation to defined landmarks and reference points/lines. INTERPRETATION: May be normal, elevated, or descended.

**Pelvic floor magnetic resonance imaging (MRI) - MRI defecography***Imaging*

Demonstrates the anatomy of the anorectum as well as disorders of rectal evaluation. Barium paste is inserted before defecation over a translucent commode. INTERPRETATION: This assessment focusses on anorectal function. When dyssynergia is diagnosed, this confirms PFM involvement.

**Pelvic floor manometry***Investigation*

Measurement of resting pressure or pressure rise generated during contraction of the PFM using a manometer connected to a sensor, which is inserted into the urethra, vagina or rectum.

**Pelvic Floor Manometry***Investigation*

A manometer is a device for measuring pressure. Pelvic floor manometry: measurement of resting pressure or pressure rise generated during contraction of the PFM using a manometer connected to a sensor, which is inserted into the urethra, vagina or rectum. Pelvic floor manometric tools measure pressure in mmHg, hPa or cmH<sub>2</sub>O. Conversion of data to the international standard unit of measurement (hPa) is recommended. Perineometer: the first PFM vaginal pressure device connected to a manometer developed by Kegel.

**Pelvic floor manometry parameters - Time to return to baseline pressure.***Investigation*

Time in seconds from maximal pressure to relaxation state. RATING: Longer duration suggests slower relaxation.

**Pelvic floor manometry parameters - Peak pressure during a maximum voluntary contraction***Investigation*

Highest pressure recorded during a PFM MVC in mmHg, hPa or cmH<sub>2</sub>O. As the pressure measured does not confirm its origin, it is important to ensure the validity of intra-vaginal measurement: (1) perform vaginal palpation before using the manometer to ensure the patient is able to correctly contract her PFMs; (2) observe the cranial movement of the vaginal probe during measurement of the muscle contraction, and (3) ignore contractions associated with elevated intra-abdominal pressure (e.g., Valsalva maneuver), hip muscle contraction or any movement of the pelvis. Specify: (a) The length of hold for the MVC, e.g., 3 s/5 s/10 s contraction duration; (b) How the peak score was obtained, e.g., peak s during a single MVC/best of or average of 3 contractions. RATING: Maximal pressure is often used as a surrogate of muscle strength, e.g., higher pressure being related to higher strength.

**Pelvic floor manometry parameters - resting pressure***Investigation*

The pressure recorded at rest in mmHg, hPa or cmH<sub>2</sub>O. For greater accuracy, a mean resting pressure may be calculated over a specified period to account for fluctuations. Resting pressure may be influenced by PFM tone (i.e., summative contribution of the active and passive components). RATING: Higher resting pressure may be a surrogate measure of increased PFM tone. However, the value should be

interpreted with caution as the measurement is not limited to pressure originating from the PFM (e.g., intra-abdominal pressure, vaginal tissue scaring, rectal contents may contribute to resting pressure).

#### **Pelvic floor manometry parameters - Speed of contraction**

##### *Investigation*

Rate of pressure rise measured as the mean slope of the ascending curve in hPa/s during a fast MVC. RATING: Higher rate of force (steeper slope) is indicative of a faster generation of pressure.

#### **Pelvic floor manometry parameters - Speed of relaxation**

##### *Investigation*

Rate of pressure reduction measured as the mean slope of the descending curve in hPa/s during PFM relaxation. RATING: Lower values are indicative of a slower relaxation.

#### **Pelvic floor manometry parameters - Time to peak pressure**

##### *Investigation*

Time in seconds from onset of muscle contraction to maximal pressure. RATING: Shorter time to peak is indicative of a faster generation of pressure.

#### **Pelvic Floor Muscle - Pain Assessment (female)**

##### *Investigation*

Pain evaluation consists of baseline and ongoing regular evaluation of severity, quality of life, thoughts, emotions, and behavior associated with the pain (via direct consultation or questionnaires) and investigations to identify well-defined/ confusable/non-pain syndromes. 1. Pain measurement: pain can only be measured subjectively. Patient-reported outcome measures include: a) Numerical rating scale (NRS), from 0 (no pain) to 10 (extreme pain), with half-points marked. b) Visual analogue scale (VAS), a 10-cm line with the same labels at the ends. c) A simple verbal rating scale can be used, e.g., "none," "mild," "moderate," "severe." 2. Pain mapping: identifying pain generators through diagnostic procedures such as questionnaires, digital palpation, EMG, quantitative sensory threshold measurement, trigger point injections, nerve blocks, and imaging. a) Questionnaires: several pain questionnaires can be used in the evaluation of musculoskeletal pain in the pelvis; the choice will be determined by which is most appropriate to the presenting pelvic floor dysfunction: McGill Pain Questionnaire, Pelvic floor Distress Inventory (PFDI), Female Sexual Function Index, Female Sexual Distress Scale, Pelvic Pain and Urgency/Frequency Questionnaire. b) Pain chart/body map: a simple line drawing of an outline of the front and back (or relevant body part) of the human body, onto which the patient sketches or ticks or marks areas of bodily pain to demonstrate the site and extent of perceived pain; c) Pain checklist: a list of anatomical locations from which the patient selects sites that are relevant to her complaint.

#### **Pelvic floor muscle assessment - Instruction to perform a maximum voluntary contraction (MVC)**

##### *Sign*

Provide details of the instruction (wording, number of repetitions, and rest between repetitions) to ensure the test can be reproduced as an MVC.

#### **Pelvic floor muscle assessment - Algometry**

##### *Investigation*

A test to assess the pain response to application of blunt pressure. It is used to evaluate the pain threshold and pain tolerance. Responses may reflect increased sensitivity (allodynia, hyperalgesia, hyperpathia) or loss of sensation. Algometry does not provide objective information regarding pathology or

neurophysiological function, as do other more sophisticated quantitative sensory testing methods.

#### **Pelvic floor muscle assessment - Contraction of muscles other than those of the pelvic floor.**

##### *Sign*

if this is perceived to influence the PFM assessment, an attempt to minimize this should be made unless the purpose is to assess function of the other muscle. List specific muscle, such as abdominal, hip adductor, etc.

#### **Pelvic floor muscle assessment - Digital palpation**

##### *Sign*

Number of digits (and which digit) used during digital palpation. For single digit examination (PV or PR), usually the index finger is used. For two-digit examination (PV), usually the index and middle digits are used.

#### **Pelvic floor muscle assessment - Orientation during internal digital palpation**

##### *Sign*

Orientation (e.g., lateral placement or posterior midline) and depth of examining finger(s) during internal digital palpation examination. The examining finger must be as close as possible to the PFM tissue to assess PFM response. When performing a PV examination, assessor decision as to which side or midline to examine will be determined by lumen capacity, presence of tenderness or defect and presence of firm stool within the rectum. When performing a PR examination, external anal sphincter and puborectalis strength should be assessed separately. Record depth of insertion of examining finger for differential assessment of perineal versus levator ani muscle layers. Further identification of individual muscles is not possible in all individuals.

#### **Pelvic floor muscle assessment - patient's body position**

##### *Sign*

Lying or upright: If lying, hip/knee flexion, supine, side-lying, or lithotomy; number of pillows, +/- support from assessor's body; bladder empty or not.

#### **Pelvic floor muscle assessment - Pressure application**

##### *Sign*

Amount of pressure (light/moderate/strong) applied during digital palpation tests. Particular care is required when undertaking a PFM assessment in the presence of pelvic floor pain, however, even in an asymptomatic individual the assessor may provoke pain or discomfort due to undue pressure applied during palpation or application of an instrument. If discomfort or pain is provoked, note pain location, intensity, duration (transient or persistent), if it reproduces the pain the patient complains of, and if referral of pain occurs to other locations.

#### **Pelvic floor muscle assessment - Symmetry - testing of right and left sides**

##### *Sign*

A measure of comparability of resting tone or shape between left and right sides of the muscle. If examining in side-lying, there will be a gravity effect and the dependent side may have a different feel to the upper side and appear as asymmetrical. This may affect assessor perception of PFM resting tone.

Record if symmetry/asymmetry is present at rest and on activity (contraction/relaxation). Rate as: (Symmetry between left and right (on a particular aspect/ parameter); (ii) Asymmetry present. Identify what aspect/parameter is asymmetrical, e.g., tone, L < R.

### **Pelvic floor muscle assessment in female sexual dysfunction - general comments**

#### *Investigation*

Assessment of pelvic floor muscle (PFM) function involves evaluating the tone, strength, endurance, coordination, reflex activation during rises in intra-abdominal pressure as well as the capacity to properly relax this musculature. These muscles are involved in sexual function as PFM contraction occurs during arousal and intensifies with orgasm and PFM tone is related to vaginal sensation. Superficial PFMs such as the bulbospongiosus and ischio-cavernosus are also involved in erection of the clitoris by blocking the venous escape of blood from the dorsal vein. Thus, reduction in PFM strength and endurance has been related to lower sexual function. Likewise, PFM hypotonicity may be related to vaginal hypoesthesia, anorgasmia and urinary incontinence during intercourse while hypertonicity may lead to dyspareunia.

### **Pelvic floor muscle assessment in female sexual dysfunction - Pelvic floor dynamometry**

#### *Investigation*

Measurement of PFM resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina. Dynamometry measures force in Newton (N). Several parameters such as tone, strength, endurance, speed of contraction and coordination can be evaluated.

### **Pelvic floor muscle assessment in female sexual dysfunction - Pelvic floor electromyography (EMG)**

#### *Investigation*

The recording of electrical potentials generated by the depolarization of PFM fibers. Intra-muscular EMG consists in the insertion of a wire or needle electrode into the muscle to record motor unit action potentials while surface EMG requires electrodes placed on the skin of the perineum or inside the urethra, vaginal or rectum. EMG amplitude at rest and contraction can be recorded.

### **Pelvic floor muscle assessment in female sexual dysfunction - Pelvic floor ultrasound imaging**

#### *Investigation*

Evaluation of PFM morphology at rest, during maximal contraction and Val-salva. Several parameters pertaining to assess the bladder neck and anorectal positioning and hiatus dimensions can be measured.

### **Pelvic floor muscle contraction - Digital muscle test (DMT)**

#### *Sign*

A test to evaluate pelvic floor muscle strength (NEW). Strength: Force-generating capacity of a muscle.

Usually expressed as a maximum voluntary contraction measurement (MVC). A manual muscle test (MMT)

evaluates the strength of a muscle by moving the muscle through its full-range of motion against gravity and then against gravity with resistance.<sup>14</sup> However, because joint range of motion is not being assessed in the pelvic floor and pelvic floor muscle examination is performed with a digit, not a hand, the

term DMT is preferred. There are more than 25 published DMT scales which provide grade of strength ranging from absence, to weakness to increasing strength. RATING: (i) Commonly used scales include: ICS scale: absent, weak, normal (we propose the word "moderate" instead of normal), or strong. (ii) modified Oxford grading scale 0–5; (iii) Brink scale: grades 3 components (pressure, displacement, and time) on a scale of 1–4; (iv) many others

### **Pelvic floor muscle contraction - Direction of pelvic floor movement**

#### *Sign*

Direction of pelvic floor movement during voluntary PFM contraction palpated PV (on the posterior vaginal wall) or PR. RATING: (i) Pelvic floor elevation: normal finding; (ii) Pelvic floor descent: palpation of downward movement of the PFM during attempted PFM contraction; (iii) No change.

### **Pelvic floor muscle contraction - Fatigue**

#### *Sign*

A decreased capacity to perform a maximum voluntary muscle action or a series of repetitive contractions. Fatigue may occur due to central or peripheral mechanisms. A fatigued muscle is unable to continue working even when the type of activity is changed. Record the time at which fatigue starts to occur, or the number of contractions in a row before onset of fatigue

### **Pelvic floor muscle contraction - Levator closure**

#### *Sign*

Movement of right and left muscle bellies closer together during a PFM contraction (palpated on the lateral vaginal wall). May be tested unilaterally if bi-digital assessment is uncomfortable for the patient. RATING: (i) Yes: Levator closure movement palpable; (ii) Partial/uncertain: Some closure movement palpable, but could be uncertain, or asymmetrical; (iii) No: No levator closure movement palpable.

### **Pelvic floor muscle contraction - Number of rapid contractions performed**

#### *Sign*

The number of seconds the patient can hold near maximal or maximal PFM contraction. Record number of seconds contraction is sustained at near maximal or maximal intensity.

### **Pelvic Floor Muscle Contraction - Repetition and Set**

#### *Conservative Management – Female*

Repetition: the completion of a whole cycle from the starting position, through the end of the movement, and back to the start e.g. one PFM contraction with relaxation. Set: the number of times the desired number of repetitions is performed e.g., three sets of 12 PFM contractions

### **Pelvic floor muscle contraction - Sustained contraction endurance test**

#### *Sign*

The number of seconds the patient can hold near maximal or maximal PFM contraction. Record number of seconds contraction is sustained at near maximal or maximal intensity.

### **Pelvic floor muscle contraction - Urethral lift**

#### *Sign*

Elevation of the urethra in a cephalad direction. Index finger is placed along the line of the urethra (on the anterior vaginal wall). RATING: (i) Yes: Urethral lift palpable; (ii) No: No urethral lift palpable.

### **Pelvic floor muscle diagnoses: General**

#### *Diagnosis*

Diagnosis: The act or process of identifying or determining the nature and cause of a disease or injury through evaluation of patient history, examination, review of investigations, and the opinion derived from such an evaluation.

The diagnostic process aims to identify the most specific disorder possible. Overarching diagnoses are used when there is less certainty about the presenting disorder. Diagnoses that are specific to the PFMs may coexist with and be used in addition to other pelvic floor diagnoses the patient presents with, for example, voiding dysfunction, pelvic organ prolapse. The diagnoses proposed below may change as evidence emerges to support or refute these terms as diagnostic terms. In some healthcare

settings, clinicians are required to assign a code for the presenting diseases, disorders, injuries, and other related health conditions using the International Classification of Diseases (ICD) coding system. Not all terms below have a corresponding ICD diagnostic code. As advised by ICD, “codes that describe symptoms and signs, as opposed to diagnoses, are acceptable for reporting purposes when a related definitive diagnosis has not been established (confirmed) by the provider.”

### **Pelvic floor muscle disorder/dysfunction**

#### *Diagnosis*

An alteration of normal PFM function. Any departure from normal function of the PFM that is of both to the patient and has an associated sign and/or a finding from an investigation that suggests a departure from normal structure or function. If a specific disorder can be diagnosed, more specific terms may be used relating to (i) Increased PFM tone; (ii) PFM pain; (iii) Decreased PFM tone; (iv) PFM Co-ordination; (v) Pudendal neuralgia.

### **Pelvic Floor Muscle Dyssynergia**

#### *Sign*

Incoordination of the PFM and another muscle group during a functional activity, for example, the pelvic floor muscles may not relax appropriately during micturition or defecation.

### **Pelvic floor muscle endurance (female)**

#### *Sign*

The ability to sustain near maximal or maximal force, assessed by the time one is able to maintain a maximal static or isometric contraction, or ability to repeatedly develop near maximal or maximal force determined by assessing the maximum number of repetitions one can perform at a given percentage of 1 RM (one-repetition maximum).

### **Pelvic Floor Muscle Exercises - Kegels**

#### *Conservative Management – Female*

A PFM contraction or PFM exercise. This term is named after Arnold Kegels, an American gynecologist who first described the clinical effect of PFMT in the late 1940s. ICS recommends the use of the term PFMT (not the word Kegels) to refer to exercises that specifically target the PFM.

### **Pelvic floor muscle hypertonicity (female)**

#### *Sign*

A general increase in muscle tone that can be associated with either elevated contractile activity and/or passive stiffness in the muscle. As the cause is often unknown the terms neurogenic hypertonicity and non-neurogenic hypertonicity are recommended.

### **Pelvic floor muscle hypotonicity (female)**

#### *Sign*

A general decrease in muscle tone that can be associated with either reduced contractile activity and/or passive stiffness in the muscle. As the cause is often unknown the terms neurogenic hypotonicity and nonneurogenic hypotonicity are recommended.

### **Pelvic floor muscle imaging - General**

#### *Imaging*

Refers to the process of creating images using high-energy modalities to allow visualization of body tissues. Imaging provides tissue-specific evaluation to identify if morphological properties (e.g., trauma or deficit) are present, which may relate to an individual's presenting symptoms. In this document, we focus on ultrasound and MRI assessment and the terms related to PFM morphology and function, as well as the influence of other structures on PFM support and contractility investigated using these tools. It

is not within the scope of this document to describe imaging of organ structures.

### **Pelvic floor muscle imaging - Magnetic resonance imaging (MRI)**

#### *Imaging*

MRI is a non-invasive diagnostic technique that produces computerized images of internal body tissues and is based on nuclear magnetic resonance of atoms within the body induced by the application of radio waves. This technique can be applied for many purposes in urology/gynecology/gastroenterology including the assessment of PFM injury, morphometry and positioning of the PFMs and related organs as well as anorectal functioning. Considering that MRI is rarely used in clinic to assess PFM morphometry and function, only a brief overview is provided and further details are available in other standardization documents.

### **Pelvic Floor Muscle Injury (PFMI)**

#### *Sign*

On clinical palpation, PFMI is diagnosed when one or more of the following is present: a) A discontinuity of the puborectalis muscle at its attachment to the inferior pubic ramus; b) A distance of >3.5 finger widths between the two sides of puborectalis muscle insertion; c) A gap in the continuity of the pubovisceral muscle between the pubic rami and the ano-rectum.

### **Pelvic Floor Muscle Injury (PFMI) - Detection by Magnetic Resonance Imaging (MRI)**

#### *Imaging*

PFM injury: can represent a full spectrum, from disruption of a single fascicle, to complete disruption of the muscle origin. At present, there is no universally accepted system for the diagnosis and evaluation of the extent of the injury. Essentially, abnormalities are judged to have occurred when the morphology of the pubococcygeal portion of the levator ani muscle deviates from what is seen in normal nulliparous women. Several groups have studied and defined levator damage on MRI when one or more of the following is present: absence of pubococcygeal muscle fibers in at least one 4-mm section, or two or more adjacent 2-mm sections in both the axial and the coronal planes. The degree of injury can be assessed based on the amount of muscle involved in the injury, with reasonable repeatability among different examiners in a single group. More than half the expected muscle bulk is associated with the presence of POP.

### **Pelvic Floor Muscle Injury (PFMI) - Ultrasound detection**

#### *Imaging*

PFMI is diagnosed on ultrasound when at least one of the following is present: a) Undetected puborectalis-to-ipsilateral sidewall attachment on any of the three central slices (full avulsion); b) Undetected puborectalis-to-ipsilateral sidewall attachment on at least one slice (partial avulsion); c) A levator-urethra gap (LUG) of greater than 2.5cm. PFM position in the pelvis: can be measured in the sagittal plane in relation to defined landmarks, and may be related to PFM dysfunction (elevated or descended pelvic floor). Hiatal dimension: is the cross-sectional area of the pelvic floor/levator hiatus, including anteroposterior and transverse distances.

### **Pelvic floor muscle manometry - Area under the pressure curve during a sustained contraction.**

#### *Investigation*

The area under the pressure curve in hPa multiplied by time in s during a sustained MVC or at a specific percentage of MVC. This represents the total work performed. Specify the duration of the contraction, e.g. 10 s, 30 s, etc.

### **Pelvic floor muscle manometry - Duration of a sustained contraction.**

#### *Investigation*

The length of time in seconds that a contraction can be sustained during

MVC or at a specific % of MVC. Specify if it is a maximal contraction or a % of MVC, e.g. 60% and the threshold used to indicate that the target is no longer maintained.

#### **Pelvic floor muscle (PFM) - relaxation**

##### *Sign*

Return of the perineum to its original resting position following the voluntary contraction. RATING: If present, rate as: (i) Yes: Full relaxation visible directly after instruction; normal finding; (ii) Partial or delayed relaxation; (iii) Non-relaxing PFM: No relaxation visualized of the PFM.

#### **Pelvic floor muscle (PFM) - voluntary contraction**

##### *Sign*

Self-initiated activation of the PFM. Contraction of the bulbospongiosus/bulbocavernosus, ischio-cavernosus, transverse perinei muscles may be observed. The assessor may need to gently move the external genitalia (parting of the labia, lifting of the scrotum to one side) to effectively visualize the perineal response. (i) Present; (ii) Uncertain; (iii) Absent. Response can be further described according to perineal movement observed:

(a) Perineal elevation: Inward (ventrocephalad) movement of the vulva (f), perineum, and anus = normal finding. (b) No change. (c) Sex-specific changes on perineal elevation - closure of the urethral meatus ("wink"); a clitoral "nod" (female); Closure of the anus, cephalad testicular lift and penile retraction (the shaft of the penis draws inc (male). (d) Perineal descent: Dorsocaudal movement of the perineum, or anus 1 cm or greater beyond resting level.

#### **Pelvic floor muscle (PFM) function (male) - contractile function**

##### *Sign*

- . Voluntary contractility: the individual is able to contract the PFM on demand. A contraction is felt as a tightening, lifting and squeezing action under/around the finger.
- . Strength: Force-generating capacity of a muscle. It is generally expressed as maximum voluntary contraction.
- . Endurance: the ability to sustain near maximal or maximal force, assessed by the time a patient is able to sustain a maximal static or isometric contraction.
- . Repeatability: the ability to repeatedly develop near maximal or maximal force, determined by assessing the maximum number of repetitions the patient can perform before detectable decline in force. Record number of contractions in a row.
- . Co-contraction: contraction or activation of two or more muscles at the same time. Identify which muscles are co-contracting and whether the co-contraction is synergistic.
- . Relaxation ability: return of the PFM to its original resting tone following the voluntary contraction. Also includes the ability to maintain PFM relaxation in anticipation of or during any type of touch.

#### **Pelvic floor muscle (PFM) function (male) - Diagnoses related to PFM examinations**

##### *Sign*

- . Overactive pelvic floor muscles: Pelvic floor muscles which do not relax, or may even contract when relaxation is functionally needed, for example, during voiding or defecation.
- . Underactive pelvic floor muscles: Pelvic floor muscles which cannot voluntarily contract when instructed to do so or when required.

#### **Pelvic floor muscle (PFM) function (male) - Examinations at rest**

##### *Sign*

- . Myalgia: provoked by palpation. Levator muscle pain/tenderness may be elicited by palpation of these muscles via rectal examination.
- Tender point: Tenderness to palpation at a specific soft tissue body site.
- . Tone: state of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement. Muscle tone has two components, the contractile component and the viscoelastic component. Muscle tone may be altered in the presence or absence of pain.
- . Increased PFM tone (non-neurogenic hypertonicity): increased tone in a patient without an intercurrent neurological diagnosis.
- . Decreased PFM tone (non-neurogenic hypotonicity): decreased tone in a patient without an intercurrent neurological diagnosis.
- . Symmetry: if examining in the left lateral, there will be a gravity effect and the dependent side will have a different feel to the upper side and appear as asymmetrical. This may affect PFM tone. Not so common in men.
- . PFM injury: e.g. palpable anal sphincter gap though overall not common unlike women.

#### **Pelvic floor muscle (PFM) function (male) - General**

##### *Sign*

The following signs of PFM function may be assessed via the perineum (visual or tactile examination) or per rectum (digital palpation) examination. Digital rectal examination (DRE) may be less useful in male urinary dysfunctions where the urethral sphincter, inaccessible to DRE, has a more important role.

#### **Pelvic floor muscle (PFM) function (male) - Perineal examination**

##### *Sign*

When the patient is asked to cough or bear down, the perineum should only show limited downward movement; ventral movement may occur because of the guarding actions of the pelvic floor muscles.

- Perineal elevation: This is the inward (ventro-cephalad) movement of the perineum and anus. Look for testicular lift and penile retraction. These need to be checked against movement of the scrotum and the whole penis. Correct movement occurs with the PFM only: the shaft of the penis draws in and the testes lift in a cephalad direction. These movements may be better visualized in standing than supine position.
- Perineal descent: This is the outward (dorso-caudal) movement of the perineum and anus.

#### **Pelvic Floor Muscle Relaxation**

##### *Conservative Management – General*

Pelvic floor muscle relaxation following contraction results in a reduction in the support given to the urethra, vagina and anus. The perineum and the pelvic organs return to their anatomical resting position. The pelvic floor muscles must relax in order to remove the passive continence mechanisms, thereby favoring normal micturition. The same is true for relaxation before and during defecation, allowing the anorectal angle to become obtuse, favoring rectal emptying

#### **Pelvic floor muscle strength (female)**

##### *Sign*

Force-generating capacity of a muscle. It is generally expressed as maximal voluntary contraction measurements and as the one-repetition maximum (1RM) for dynamic measurements.

#### **Pelvic floor muscle tenderness (female)**

##### *Sign*

Occurrence of the sensation of pain or painful discomfort of the pelvic floor muscles elicited through palpation.

**Pelvic floor muscle tone - Dystonia***Sign*

A disorder characterized by abnormalities of muscle tone and movements/postures in a patient with a neurological disorder. It is often due to damage to the basal ganglia or other brain regions that control movement.

**Pelvic floor muscle tone - Hypertonicity***Sign*

An increase in muscle tone in a patient with a neurological disorder. It may be due to an upper motor neuron or extrapyramidal lesion, which in turn may lead to spasticity or rigidity.

**Pelvic Floor Muscle Tone - Hypotonicity***Sign*

A decrease in muscle tone in a patient with a neurological disorder. It may be due to a lower motor neuron or a muscle disorder. The term flaccidity is often used interchangeably.

**Pelvic floor muscle tone - Transient increase in muscle tone***Sign*

Increased muscle tone that decreases with verbal instruction, re-assurance, or gentle pressure. Transient increase in tone may occur at any time during the examination.

**Pelvic floor muscle tone (female)***Sign*

In normally innervated skeletal muscle, tone is created by “active” (contractile) and “passive” (viscoelastic) components clinically determined by resistance of the tissue against stretching or passive movement.

**Pelvic Floor Muscle Training***Conservative Management – Female*

Exercise to improve PFM strength, endurance, power, relaxation or a combination of these parameters.

**Pelvic Floor Muscle Training - Biofeedback Training***Conservative Management – Female*

Feedback: is sensory information that is available as the result of an activity that a person has performed. It can be provided by an intrinsic source (from within the individual), or an extrinsic source (from the clinician), and can occur concurrently with the activity or post-activity, e.g., verbal information from the clinician to the patient during or following PFM assessment. Biofeedback: is the use of an external sensor to give an indication with regard to bodily processes, usually with the purpose of changing the measured quality. It is an adjunctive therapy.

**Pelvic Floor Muscle Training - Detraining***Conservative Management – Female*

Cessation of training, but also planned or unplanned reduced volume or intensity of training.

**Pelvic Floor Muscle Training - Dilator Therapy***Conservative Management – Female*

Dilator therapy: a conical or cylindrically shaped device (made of an inert material) inserted intravaginally or intra-anally, with the aim of increasing the flexibility or elasticity of the soft tissues via application of a prolonged elongation or stretch. Dilators may also be used as a desensitizer device, to reduce fear, anxiety or pain associated with vaginal touch and in conjunction with vaginismus or sexual pain. When combined with EMG, dilators can be used to train PFM relaxation during penetration. Dilators may also be used to increase the tolerance of skin to sliding when the dilator is moved in and out.

**Pelvic Floor Muscle Training - Dose-response issues related to exercise training***Conservative Management – Female*

1. Dose–response: amount/volume of training and its effect on the speed and degree of the effect of the training program. 2. Frequency of exercise: the number of activity sessions per day, week, or month. 3. Duration of exercise: the unit of time (number of seconds/ minutes)of activity in each repetition or session, e.g., a10-s PFM contraction. It also refers to the length of the whole training period (intervention), e.g., 3/6 months. 4. Intensity: the amount of resistance used or the effort associated with the physical activity. For strength training, it is often expressed as a percentage of one repetition maximum: 1RM (the maximum load a person can lift once), e.g., 70 % of maximum. 5. Session/bout: the block of time devoted to the training, e.g., a 1-h session.

**Pelvic Floor Muscle Training - EMG assessment of PFM***Conservative Management – Female*

Electromyography assessment of PFM consists of the use and interpretation of the surface EMG recording of a muscle for rehabilitation purposes should be done cautiously, recognizing that the main goal is the qualitative description of the muscle activation pattern, and not a qualitative diagnosis.

1. Baseline muscle activity: amount of microvolts generated by the target muscle during rest. 2. Peak microvolts: the highest EMG amplitude achieved. 3. Slow recruitment: slow initiation of muscle activation contraction. 4. Slow de-recruitment or slow latency to return to baseline: slow relaxation of the muscle contraction. 5. Inconsistent resting baseline: variation of baseline between contractions, between sets, or between days may be related to a change in patient symptoms, e.g., hypertonic PFM. 6. Excessive accessory muscle contraction: increased amplitude in accessory muscles often resulting in cross talk and is indicative of poor isolation of target muscle contraction.

**Pelvic Floor Muscle Training - EMG Biofeedback Unit Instrumentation***Conservative Management – Female*

1. EMG signal amplitude: number of microvolts ( $\mu\text{V}$ ) a muscle is generating. EMG biofeedback units can deliver either the actual amount of EMG activity in  $\mu\text{V}$  or an average  $\mu\text{V}$  value. 2. Artifact: extraneous information non-recognizable in the EMG signal from sources other than the target muscle such as the environment or other body functions. 3. Cross talk: muscle activity from nearby muscles that can artificially increase EMG amplitude; a type of artifact. 4. Dual-channel EMG: use of two channels to monitor two separate muscles or muscle groups at the same time, such as the PFM and abdominal muscles, with the goal of either promoting synergist activity or reducing EMG activity of one muscle while increasing the other. 5. Band pass: limits muscle fiber frequencies that are monitored and displayed in the EMG tracing.

**Pelvic Floor Muscle Training - EMG Training of PFM***Conservative Management – Female*

1. Up-training: EMG biofeedback training to increase the EMG activity of a hypotonic muscle with low EMG activity. 2. Down-training: EMG biofeedback training to decrease EMG activity and relax muscles.

**Pelvic Floor Muscle Training - Facilitation Technique***Conservative Management – Female*

Any method of increasing recruitment/response of a non-responding muscle. In the case of non-contractile or very weak PFMs, this may include a quick stretch of the PFM, with tapping or stretching the PFM digitally. An overflow effect from a strong contraction of a nearby synergistic muscle (e.g. external rotators) may also assist facilitation or recruitment of PFMs.

### **Pelvic Floor Muscle Training - Functional Training**

#### *Conservative Management – Female*

Functional training consists of training for tasks of daily living and self-care activities, e.g., squatting to train quadriceps and gluteal muscles. **EST** Functional PFM training: training and exercises that incorporate a correct PFM contraction into activities of daily living such as lifting, transferring out of bed, or sneezing. A PFM contraction before a rise in intraabdominal pressure, e.g., a cough (“the Knack”) is part of functional PFM training. 2. Coordination training: the ability to use different parts of the body together smoothly and efficiently. Related to PFM training, coordination training means PFM contraction with other muscles or other muscle groups, e.g. respiratory muscles. 3. Functional mobility training: an intervention directed at improving the physical ability to perform a daily task. For voiding/defecation, this may include: gait training, transfer training, stair training, and other mobility training to improve speed and safety in reaching the toilet.

### **Pelvic Floor Muscle Training - Individualized, Supervised, Group and Home**

#### *Conservative Management – Female*

1: Individualized PFMT: an individual PFM program aimed at improving the specific deficiencies in PFM structure or function based on assessment of the woman's ability to contract the PFM. 2: Supervised PFMT: a PFMT program taught and monitored by a health professional/clinician/instructor. 3: Group PFMT: PFMT conducted in an exercise class. Class participation may occur with or without previous individualized PFM instruction. Home training: home PFM exercise program: an unsupervised PFMT program, which the individual performs at home.

### **Pelvic Floor Muscle Training - Isometric/Static Contraction**

#### *Conservative Management – Female*

A muscular action during which no change in the length of the total muscle or joint angle takes place.

### **Pelvic Floor Muscle Training - Isotonic or eccentric contraction**

#### *Conservative Management – Female*

Isotonic contraction: A muscular action during which the tension developed by the muscle remains almost constant while the muscle shortens. Eccentric contraction: a muscular action in which the muscle lengthens in a controlled manner.

### **Pelvic Floor Muscle Training - Local Muscle Endurance Training**

#### *Conservative Management – Female*

Training with a low load and a high number of repetitions or holding the contraction over time.

### **Pelvic Floor Muscle Training - Maintenance Training**

#### *Conservative Management – Female*

A program designed to prevent loss of the previous level of functioning.

### **Pelvic Floor Muscle Training - Muscle Power Training**

#### *Conservative Management – Female*

All training with the aim of generating power; can be close to maximal contraction training and/or rapid contractions.

### **Pelvic Floor Muscle Training - Overload**

#### *Conservative Management – Female*

A situation in which the body is required to perform exercise beyond that to which the neuromuscular system is accustomed during routine activities. Training adaptation occurs in response to a progressive “overload”. Progressive overload: the gradual increase in stress placed upon the body during exercise training.

### **Pelvic Floor Muscle Training - Relaxation Training**

#### *Conservative Management – Female*

Relaxation: the ability to control muscle activity such that muscles not specifically required for a task are quiet and those that are required are fired at the minimal level needed to achieve the desired results. Relaxation can be considered a motor skill in itself because the ability to reduce muscle firing is as important to control as the generation of firing. a) General relaxation technique: a technique that involves the whole body, with the aim of effecting a global relaxation, including a decrease in the skeletal and smooth muscles, a decrease in the heart rate and respiration rate and an increase in parasympathetic activity. General relaxation techniques can also be used aimed at relaxing local muscles. b) Progressive muscular relaxation (also known as Jacobsen's technique): monitoring tension in each specific muscle group, by contracting, then relaxing the tension, with attention paid to the contrast between tension and relaxation. This type of relaxation is also termed “contract-relax.” c) Meditation: a practice of concentrated focus upon a sound, object, visualization, the breath, movement, or attention itself to increase awareness of the present moment, reduce stress, promote relaxation, and enhance personal and spiritual growth. d) Mindfulness: intentionally bringing one's attention to the internal and external experiences occurring in the present moment. Mindfulness is often taught through a variety of meditation exercises. e) EMG relaxation techniques: techniques to decrease EMG muscle activity or activation through a methods, including a conscious effort to relax.

### **Pelvic Floor Muscle Training - Resistance**

#### *Conservative Management – Female*

Resistance: the amount of force opposing a movement. Resistance devices: any object used to increase resistance to contraction, e.g., hand weights. Vaginal resistance device: objects inserted into the vagina or rectum that are inflated or spring-loaded devices to increase resistance to contraction.

### **Pelvic Floor Muscle Training - Strength Training**

#### *Conservative Management – Female*

Training with high resistance (close to maximal contractions) and few repetitions with the aim of increasing muscle volume and neural adaptations.

### **Pelvic Floor Muscle Training - Stretching**

#### *Conservative Management – Female*

Stretching (also referred to as flexibility training when the method is used on skeletal muscles where increased range of motion over the joints is the aim): the application of an external force to muscle and connective tissue to elongate it in the direction opposite to its shortened position. This can be done parallel or perpendicular to the muscle fiber direction. For the PFM this can be applied as a widening of the levator hiatus in the axial plane (latero-laterally) via a digit or use of a dilator, or a caudal movement (via a straining/bearing down maneuver) in the sagittal plane.

### **Pelvic Floor Muscle Training - Vaginal Cones**

#### *Conservative Management – Female*

Weighted vaginal cones: objects of different shapes, sizes, and weights, which are inserted into the vagina above the level of the PFM with the aim of providing sensory biofeedback and load on the PFM to increase muscle recruitment and strength.

### **Pelvic floor muscle ultrasound imaging - General**

#### *Imaging*

Pelvic floor ultrasound imaging measures PFM morphology and function via trans-abdominal, trans-perineal, trans-vaginal and trans-anal placement of the transducer). This investigation applies diagnostic techniques taken in B-mode that use high-frequency sound waves to image internal structures. The image is formed by the differing reflection signals

produced when a beam of sound waves is projected into the body and bounces back at interfaces between those structures. Ultrasound evaluation may be undertaken as: (a) Two-dimensional (2D) ultrasound: The transducer sends and receives ultrasound waves in one anatomical plane. The reflected waves are used to generate gray scale images of structures in the field of **banananana** view in this anatomical plane. (b) Three-dimensional (3D) ultrasound: Create volume data from multiple 2D images which are gathered by reflected waves at a variety of angles. Software integrates this information to create a single static 3D image. (c) Four-dimensional (4D) ultrasound: Is similar to 3D US, but the image is repeated at intervals over time. This technique requires the use of a 3D/4D transducer and enables real-time visualization of 3D images. (d) Tomographic ultrasound: Is viewing US imaging in sections. It allows the depiction of arbitrarily defined planes from volume data obtained in 3D or 4D US. Measurements are best understood by referring to anatomical planes of the body, that is, coronal (frontal), sagittal, and axial (horizontal or transverse) planes.

#### **Pelvic Floor Muscles - Involuntary Contraction**

##### *Sign*

Involuntary contraction of the pelvic floor muscles is the contraction that takes place preceding an abdominal pressure rise, such as due to a cough, to prevent incontinence. An involuntary contraction can be absent or present.

#### **Pelvic Floor Muscles - Involuntary Relaxation**

##### *Sign*

Involuntary relaxation of the pelvic floor muscles is the relaxation that takes place when the patient is asked to strain as if defecating. An involuntary relaxation can be absent or present.

#### **Pelvic Floor Muscles - Non-Contracting Pelvic Floor**

##### *Sign*

Involuntary relaxation of the pelvic floor muscles is the relaxation that takes place when the patient is asked to strain as if defecating. An involuntary relaxation can be absent or present.

#### **Pelvic Floor Muscles - Non-contracting, Non-relaxing pelvic floor**

##### *Sign*

Non-contracting, non-relaxing pelvic floor means that during palpation, there is neither a palpable contraction nor a palpable relaxation of the pelvic floor muscles.

#### **Pelvic Floor Muscles - Non-relaxing Pelvic Floor**

##### *Sign*

Non-relaxing pelvic floor means that during palpation, there is no palpable voluntary or involuntary relaxation of the pelvic floor muscles.

#### **Pelvic Floor Muscles - Voluntary Relaxation**

##### *Sign*

Voluntary relaxation of the pelvic floor muscles means that the patient is able to relax the pelvic floor muscles on demand, after a contraction has been performed. Relaxation is felt as a termination of the contraction. The pelvic floor muscles should return at least to their resting state. Voluntary relaxation can be absent, partial or complete

#### **Pelvic floor spasm (female)**

##### *Sign*

The presence of contracted, painful muscles on palpation and elevated resting pressures by vaginal manometry. This persistent contraction of striated muscle cannot be released voluntarily. If the contraction is painful, this is usually described as a cramp. Pelvic floor myalgia (a symptom) may be present with or without a change in PFM tone (a sign).

#### **Pelvic floor ultrasound - Endoanal ultrasound (EAUS)**

##### *Imaging*

An endocavity transducer is inserted into the anus (linear array 360 degree 3D transducer or radial array 360 degree 3D transducer). It can be used to assess the external anal sphincter (EAS) and internal anal sphincter (IAS). Parameters and findings evaluated with endoanal ultrasound imaging—during different activity states of the PFM (rest, contraction, and bearing down)—are described separately.

#### **Pelvic floor ultrasound - Endovaginal**

##### *Imaging*

An endocavity transducer is inserted into the vagina (rotational mechanical probe or radial electronic probe to assess pelvic floor morphology. It can be used to evaluate bladder neck/urethra, levator ani muscle, anal canal, and sphincters during different activity states of the PFM (rest, contraction and bearing down).

#### **Pelvic floor ultrasound - introital**

##### *Investigation*

2D/3D/4D imaging technique to scan pelvic floor structures using an endocavity transducer placed against the vaginal introitus/vulva or perineum. The transducer may be oriented ventrally/anteriorly to assess the pelvic floor structures (prolapse, levator ani muscle anatomy and function, and periurethral area), or oriented posteriorly to assess the anal sphincter structures.

#### **Pelvic floor ultrasound - perineal**

##### *Imaging*

2D/3D/4D imaging technique to scan pelvic floor structures using a convex transducer placed against the perineum/vulva. The transducer may be oriented longitudinally/sagittally (for bladder neck/urethra, prolapse, and levator ani muscle assessment), or oriented transversely (for assessment of anal canal, sphincters). The terms transperineal and translabial ultrasound are both used to refer to perineal ultrasound. Parameters and findings evaluated with perineal and introital pelvic floor ultrasound—during different activity states of the PFM or actions (rest, contraction, and bearing down).

#### **Pelvic floor ultrasound - transabdominal**

##### *Imaging*

A 2D imaging technique to scan pelvic floor structures, using a convex transducer is placed in the supra-pubic region. It can be oriented longitudinally to measure bladder base displacement base in the mid-sagittal or parasagittal plane or oriented transversely to measure bladder base symmetry and displacement in the transverse plane. Trans-abdominal pelvic floor ultrasound is primarily used in clinical settings rather than for research purposes due to limitations measuring the image (no bony landmarks in view and difficulties for operator to keep transducer in plane—operator error is high). Artifact in measurement may also occur with incorrect PFM contraction when abdominal muscle contraction occurs (which pushes the transducer ventrally) and varying levels of bladder fullness (adherence to a fluid intake protocol may mitigate this limitation). Poor agreement between transverse and sagittal findings suggests measurement in the two planes evaluate displacement at different locations during a PFM contraction. The parameters and anatomical landmarks evaluated in the mid-sagittal plane, during different activity states of the PFM: rest, contraction and bearing down. Parameters and findings evaluated with trans-abdominal imaging in the transverse plane—during different activity states of the PFM (rest, contraction, and bearing down).

#### **Pelvic floor ultrasound - Ultrasound elastography**

##### *Imaging*

A noninvasive imaging technique that allows quantification of mechanical

and elastic tissue properties following application of physical stress. Elastography imaging uses either compression/strain elastography or shear-wave elastography. The primary differences between elastography techniques relate to the type or source of applied stress, and the methods of detecting displacement of the examined structures. Parameters and findings evaluated with ultrasound-elastography imaging are described separately.

### **Pelvic organ**

#### *Surgery – Female*

This refers most commonly to the uterus and/or the different vaginal compartments and their neighboring organs such as bladder, rectum or bowel.

### **Pelvic organ prolapse - clinical diagnosis**

#### *Diagnosis*

Diagnosis by symptoms and clinical examination, assisted at times by any relevant imaging (i.e. clinically evident):

1. Uterine/ cervical prolapse: Clinically evident descent of the uterus or uterine cervix.
2. Anterior vaginal wall (compartment) prolapse: Clinically evident descent of the anterior vaginal wall (compartment).
3. Posterior vaginal wall (compartment) prolapse: Clinically evident descent of the posterior vaginal wall (compartment).
4. Vaginal vault (cuff scar) prolapse: Clinically evident descent of the vaginal vault (cuff scar after hysterectomy).

### **Pelvic organ prolapse - definition of sign**

#### *Sign*

The descent of one or more of the anterior vaginal wall, posterior vaginal wall, the uterus (cervix) or the apex of the vagina (vaginal vault or cuff scar after hysterectomy). The presence of any such sign should be correlated with relevant POP symptoms. Most commonly, this correlation would occur at the level of the hymen or beyond.

### **Pelvic organ prolapse - related radiology**

#### *Imaging*

Defecography demonstrates normal anatomy of the anorectum as well as disorders of rectal evacuation. With barium paste inserted rectally prior to defecation, measurement of the anorectal angle is allowed with evidence of the presence, size or emptying of any rectocele. Enteroceles, rectal intussusception and mucosal prolapse might be diagnosed as well as a spastic pelvic floor (anismus).

### **Pelvic Organ Prolapse - Signs**

#### *Sign*

All examinations for POP should be performed with the woman's bladder empty (and if possible an empty rectum). An increasing bladder volume has been shown to restrict the degree of descent of the prolapse. The choice of the woman's position during examination, e.g. left lateral (Sims), supine, standing or lithotomy is that which can best demonstrate POP in that patient and which the woman can confirm as the maximal extent she has perceived e.g. by use of a mirror or digital palpation. The degree of prolapse may be worse after a lengthy time in the upright position.

### **Pelvic organ prolapse (anatomical definition of sign of POP)**

#### *Sign*

The descent of one or more of the anterior vaginal wall, posterior vaginal wall, uterus (cervix) or vaginal vault (cuff scar after hysterectomy). The presence of any such sign should be correlated with relevant POP symptoms.

### **Pelvic organ prolapse (POP) - examination**

#### *Sign*

All examinations for POP should be performed with the woman's bladder

empty (and if possible an empty rectum). An increasing bladder volume has been shown to restrict the degree of descent of the prolapse. The choice of the woman's position during examination, e.g. left lateral (Sims), supine, standing or lithotomy is that which can best demonstrate POP in that patient and which the woman can confirm as the maximal extent she has perceived e.g. by use of a mirror or digital palpation. The degree of prolapse may be worse after a lengthy time in the upright position

### **Pelvic organ prolapse (POP) surgery - complications**

#### *Surgery – Female*

Complications related to POP native tissue repairs and surgeries using prostheses/grfts/mesh have been classified separately according to joint IUGA/ICS recommendations. The sorting system used in both documents utilizes specific category (C), time (T) and site (S) taxonomy together referred to as the CTS classification system. Classification is aided by on line calculators: <http://www.ics.org/complication> or <http://www.ics.org/ntcomplication>.

### **Pelvic organ prolapse (POP) surgery - further surgery**

#### *Surgery – Female*

Any subsequent procedure relating to the primary surgery: (i) primary surgery in a different (new) site/compartment; (ii) repeat surgery in the same site/compartment for POP symptom recurrence; (iii) surgery for complications e.g. mesh exposure, pain, infection, hemorrhage; (iv) surgery for non-POP-related issues usually urinary incontinence.

### **Pelvic organ prolapse (POP) surgery - objective outcomes.**

#### *Surgery – Female*

POP-Q measurement should be tabulated with absolute values and percentages to allow other studies to compare results.

### **Pelvic organ prolapse (POP) surgery - perioperative data**

#### *Surgery – Female*

Blood loss, operating time, length of hospital stay, return to normal activities and complications.

### **Pelvic organ prolapse (POP) surgery - primary surgery**

#### *Surgery – Female*

first procedure required for treating POP in any compartment.

### **Pelvic organ prolapse (POP) surgery - secondary outcomes**

#### *Surgery – Female*

Lower urinary tract symptoms, stress incontinence, or bowel and sexual dysfunction to be included in studies whenever possible.

### **Pelvic organ prolapse (POP) surgery - subjective (patient-reported) outcomes**

#### *Surgery – Female*

At its simplest level, this can be reported as the presence or absence of a vaginal bulge. Patient satisfaction and quality of life can be measured by validated instruments that cover prolapse, urinary, bowel and sexual function.

### **Pelvic organ prolapse (POP) symptoms**

#### *Symptom*

Complaints by a woman in reference to the position (descent) of her pelvic organs. Symptoms are generally worse at the times when gravity might make the prolapse worse (e.g. after long periods of standing or exercise) and better when gravity is not a factor, e.g. lying supine. Prolapse may be more prominent at times of abdominal straining, e.g. defecation.

### **Pelvic organ prolapse (POPQ) - stage 0**

#### *Sign*

No prolapse is demonstrated.

**Pelvic organ prolapse (POPQ - Stage I)***Sign*

Most distal portion of the prolapse is more than 1cm above the level of the hymen.

**Pelvic organ prolapse (POPQ - Stage II)***Sign*

The most distal portion of the prolapse is situated between 1cm above the hymen and 1cm below the hymen.

**Pelvic organ prolapse (POPQ - stage III)***Sign*

The most distal portion of the prolapse is more than 1cm beyond the plane of the hymen but everted at least 2cm less than the total vaginal length.

**Pelvic organ prolapse (POPQ - Stage IV)***Sign*

Complete eversion or eversion at least within 2cm of the total length of the lower genital tract is demonstrated.

**Pelvic organ prolapse (POPQ - Stage O)***Sign*

.No prolapse is demonstrated

**Pelvic pain - female***Symptom*

Complaint of pain perceived to arise in the pelvis, not associated with symptoms suggestive of lower urinary tract, sexual, bowel or gynaecological dysfunction.

**Pelvic pain (male)***Symptom*

Complaint of pain, pressure or discomfort related to the pelvis but not clearly related to the bladder, urethra, scrotum or perineum.

**Pelvic Pain Syndrome***Symptom*

Pelvic pain syndrome is the occurrence of persistent or recurrent episodic pelvic pain associated with symptoms suggestive of lower urinary tract, sexual, bowel or gynecological dysfunction. There is no proven infection or other obvious pathology.

**Pelvic pressure (female)***Symptom*

Complaint of increased heaviness or dragging in the suprapubic area and/or pelvis.

**Penetration urinary incontinence***Symptom*

Urinary incontinence at penetration (penile, manual or sexual device)

**Penetration urinary incontinence (female)***Symptom*

Urinary incontinence at penetration (penile or sexual device).

**Penile artery revascularization***Surgery – Male*

A variety of surgical techniques that may be used to reestablish arterial flow to the penis. This is generally reserved for patients with proven pudendal or penile arterial anomalies secondary to post-traumatic lesions or congenital disorders.

**Penile curvature***Sign*

Abnormal bend in the penis occurring during erection which might lead to sexual dysfunction by impairing the ability to penetrate and/or causing pain in the tumescent state.

**Penile duplex ultrasonography***Investigation*

Use of real-time ultrasound with and without vasoactive medications for pharmacologically induced erection to evaluate the flow velocities in the dorsal penile and cavernosal arteries.

**Penile glans and shaft examination***Sign*

. Penile plaque: palpation of node or plaque in the tunica usually on the dorsal aspect (perhaps related to Peyronie's disease).

. Lichen sclerosus: tight foreskin, cracking and bleeding.

**Penile pain with intercourse (male dyspareunia)***Symptom*

Complaint of any penile discomfort occurring during intercourse - may be caused by penile disease, vaginal anatomy (e.g. vaginal tightening, scarring or prosthesis exposure), and/or may relate to various positions with intercourse causing impingement on the uterine cervix.

**Penile Prosthesis Implantation***Surgery – Male*

The surgical implantation of a penile prosthesis for patients who do not respond to more conservative therapies or who prefer a permanent solution to their ED.

**Penile sexual pain***Symptom*

Penile pain that occurs before penetration (i.e. when an erection occurs), with penetration or postcoital.

**Penile shortening***Sign*

A subjective or objective decrease in penile length. Well known to be associated with plication procedures for Peyronie's disease. It is also associated with penile revascularization procedures, anastomotic and augmented urethroplasty, hypospadias repair and prostate cancer treatment such as radical prostatectomy (RP).

**Penile urethra***Surgery – Male*

The portion of the urethra extending from the urethral meatus to the distal part of the bulbocavernosus muscle. The lumen is centered in and completely invested by the corpus spongiosum.

**Penile, scrotal, or perianal sensory deficits.***Sign*

Neurological examination findings that may indicate damage or injury to sacral roots or nerves.

**Percutaneous cystolithotripsy / cystolitholapaxy***Surgery – Male*

Minimally invasive fragmentation of the bladder stone by ultrasonic or

pneumatic lithotripsy or LASER and removal of the stone fragments via a thin suprapubic channel and an abdominal access sheath.

### **Percutaneous Electrical Nerve Stimulation**

#### *Conservative Management – Female*

Percutaneous electrical nerve stimulation: a therapeutic modality that stimulates peripheral sensory nerves performed with a (few) needle electrode(s) that are placed in close proximity to the area to stimulate. Percutaneous neuromuscular electrical stimulation (e.g. posterior TNS) is a peripheral neuromodulation technique, in which the posterior tibial nerve is electrically stimulated three finger breadths above the medial malleolus, via insertion of a percutaneous needle electrode. This is coupled with an adhesive reference surface electrode placed near to the needle. This intervention is offered to patients with OAB.

### **Perforation**

#### *Surgery – Complication related*

Abnormal opening into a hollow organ or viscus.

### **Perianal examination (female)**

#### *Sign*

(i) Excoriation: perianal excoriation, skin rashes. (ii) Soiling: perianal fecal soiling or vaginal fecal soiling. (iii) Discharge: perianal or vaginal bloody or mucus discharge. (iv) Gaping anus: non-coaptation of anal mucosa at rest. (v) Scars, sinuses, deformities, condylomata, papillomata, hematoma. (vi) Deficient perineum/cloacal-like defect: A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina. (vii) Others described individually: anal fissure, hemorrhoids, anorectal prolapse, fistula-in-ano, recto-vaginal fistula, anorectal/ vaginal/perineal fistula.

### **Perianal itching/pruritus ani**

#### *Symptom*

Complaint of an itchy anus.

### **Perineal abnormalities (female)**

#### *Sign*

Scars, sinuses, deformities, condylomata, papillomata, hematoma.

### **Perineal and Introital ultrasound assessed in the in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally - Ano-rectal angle**

#### *Imaging*

The angle (in degrees), formed by the longitudinal axis of the anal canal and the posterior rectal wall.

INTERPRETATION: (A) Rest: Quantification of the anorectal angle at rest. Smaller anorectal angle could be suggestive of increased tone in the PFM. (B) PFM Contraction: A reduction in the anorectal angle during a PFM contraction. The excursion of the anorectal angle is calculated as the angle during contraction of the levator ani muscle minus the angle at rest. Larger excursion could be suggestive of stronger activation of the PFM. (C) Bearing down: Widening of the anorectal angle is expected. If absent, PFM dyssynergia may be present.

### **Perineal and Introital ultrasound assessed in the in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally - Bladder neck position**

#### *Imaging*

Refers to the bladder neck position relative to the pubic symphysis (PS). The position is analyzed in a horizontal (x-axis) and vertical position (y-axis) relative to a horizontal reference line (measured in mm or cm). Specify if using: the infero-posterior margin; the lowest margin; or the central axis (line drawn from the anterior to the posterior margin) of the PS; the middle of

the proximal urethra for the internal meatus; the anterior bladder neck or equidistant points along the urethra from bladder neck to external urethral meatus.

INTERPRETATION: (A) Rest: Quantification of bladder neck position at rest from the horizontal and vertical distances from the PS. Resting position of the bladder neck was found to be higher after PFM training.

(B) PFM contraction: Cranio-ventral displacement of the bladder neck measured as: a decrease in x-value and increase in y-value. The ventro-cranial displacement of the bladder neck is measured as displacement =  $\sqrt{(\Delta x)^2 + (\Delta y)^2}$ . The higher the value, the greater the ventro-cranial displacement of the bladder neck (bladder neck lift), which reflects the lifting action of the PFM. (C) Bearing down: On bearing down with the instruction to relax the PFM, the dorso-caudal displacement is measured at the point of maximal displacement during the manoeuvre. As the proximal urethra descends, the x-value increases and the y-value decreases. The higher the value, the greater the dorso-caudal displacement of the bladder neck (bladder neck descent or mobility). Higher mobility is observed in incontinent women.

### **Perineal and Introital ultrasound assessed in the in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally - Levator hiatus length**

#### *Imaging*

The distance (mm or cm) between the infero-posterior margin of the pubic symphysis to the anorectal angle, representing the levator hiatus antero-posterior diameter in the mid-sagittal view.

### **Perineal and Introital ultrasound assessed in the in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally - Levator plate angle**

#### *Imaging*

The angle (in degrees) between a horizontal reference line at the level of the infero-posterior margin of the PS intersecting a line from the infero-posterior margin of the PS to the anorectal angle. INTERPRETATION: (A) Rest: Quantification of the levator angle at rest. Elevated levator plate angle may be indicative of increased tone in the PFM. (B) PFM contraction: An increase of the levator plate angle in comparison to the angle at rest. Levator plate excursion is calculated by subtracting the angle at rest from the angle during contraction. (C) Bearing down: A decrease of the levator plate angle in comparison to the angle at rest. Levator plate excursion is measured as per contraction, smaller angle is expected.

### **Perineal and Introital ultrasound assessed in the in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally - Perineal body**

#### *Imaging*

Should appear as a triangular shaped, slightly hyperechoic (white) structure anterior to the anal sphincter.

INTERPRETATION: Indicates if the integrity of the perineal body is normal or compromised.

### **Perineal and Introital ultrasound assessed in the in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally- Angle $\gamma$ (Gamma)/Pubourethral angle:**

#### *Imaging*

Is the angle (in degrees) between the bladder neck and a line drawn from the anterior to the posterior margin of the pubic symphysis. INTERPRETATION: (A) Rest: Quantification of the angle at rest; (B)

PFM contraction: A change of the angle  $\gamma$  from rest to a maximal PFM contraction. A reduction of the angle is expected as the bladder neck; displaces ventrally and caudally. (C) Bearing down: Method to assess bladder neck descent/mobility. A larger angle indicates a greater descent of the bladder neck, which

has been related to incontinence.

**Perineal assessment - Anal reflex***Sign*

A reflex contraction of the anal sphincter in response to a painful pin prick delivered to the perianal skin. RATING: (i) Present; (ii) Absent.

**Perineal assessment - Bulbocavernosus reflex (female)***Sign*

A reflex contraction of the anal sphincter and bulbocavernosus in response to squeezing the clitoris. RATING: (i) Present; (ii) Absent.

**Perineal assessment - Bulbospongiosus reflex (male)***Sign*

A reflex contraction of the striated muscles of the pelvic floor (anal sphincter) including bulbospongiosus muscles that occurs in response to various stimuli in the perineum or genitalia. Most commonly tested by placing a finger in the rectum and then squeezing the glans penis. RATING: (i) Present; (ii) Absent.

**Perineal assessment - Sacral reflex testing***Sign*

A measure of the involuntary function of sacral nerves. RATING: (i) Present: Observation of anal sphincter contraction indicative of intact spinal reflex arcs (S2–S4 spinal segments) with afferent and efferent nerves through the pudendal nerve. (ii) Absent: No sphincter activity.

**Perineal assessment - Tenderness and tender point***Sign*

(A) Tenderness: Sensation of discomfort with or without pain; discomfort elicited through palpation of any tissue indicates unusual sensitivity to pressure or touch. May be generalized within a muscle.

(B) Tender point: Area of localized tenderness occurring in muscle, muscle-tendon junction, bursa, or fat pad.

RATING: Note location of pressure application; Note location of pain (where pressure applied, or if pain referral present, note location of pain referral). Rate severity of pain on a numeric rating scale (NRS) 0–10.

**Perineal assessment - tone***Sign*

State of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement. The recommended position of the examining digit(s) is to place the palmar surface of the examining finger on the ischiocavernosus, bulbospongiosus (female)/bulbocavernosus (male) or transverse perineal muscle belly at the thickest portion of the muscle belly, per perineum.

Pressure or stretch is applied perpendicular to the muscle fibers to assess tone. RATING: (i) normal; (ii) decreased tone; (iii) increased tone.

**Perineal body length***Sign*

Distance from posterior margin of vestibule to anterior anal verge. State if < or > 3cm.

**Perineal body (PB)***Sign*

This is measured from the posterior margin of the hymen to the mid-anal opening.

**Perineal body position at rest***Sign*

Relationship of the position of the perineal body to ischial tuberosities. TECHNIQUE: Palpate ischial tuberosity and visually estimate the relationship. RATING: (i) Descended perineum: Perineal body rests below the plane of the ischial tuberosities. (ii) Normal: At or slightly above the level of the ischial tuberosities. (iii) Elevated: Significantly in-drawn perineum at rest.

**Perineal descent (female)***Sign*

Excessive dorsocaudal movement of the vulva, perineum, and anus, for example, during coughing, Valsalva or straining.

**Perineal descent (male)***Sign*

This is the outward (dorso-caudal) movement of the perineum and anus (when the individual is asked to cough or bear down).

**Perineal elevation (female)***Sign*

Inward (ventrocephalad) movement of the vulva, perineum, and anus during, for example, PFM contraction.

**Perineal elevation (male)***Sign*

This is the inward (ventro-cephalad) movement of the perineum and anus. Look for testicular lift and penile retraction. These need to be checked against movement of the scrotum and the whole penis. Correct movement occurs with the PFM only: the shaft of the penis draws in and the testes lift in a cephalad direction. These movements may be better visualized in standing than supine position.

**Perineal examination (male)***Sign*

. This is generally performed with the patient in the lateral supine or in the lithotomy position.

. Perianal dermatitis: Skin infection at the perineum around the anus, usually associated with faecal incontinence or diarrhoea.

. fissures: A break or tear in the skin of the perineum, anal sphincter or distal rectum usually associated with anal pain.

**Perineal gap (PG)***Surgery – Female*

Thinned out medial area (cm) between Moynihan forceps placed bilaterally where the labia minora meet the perineum.

**Perineal length (PL)***Surgery – Female*

Distance from posterior margin of vestibule to anterior anal verge.

**Perineal Massage***Conservative Management – Female*

Intravaginal massage by the woman, her partner or the clinician. Technique includes alternating downward and sideward pressure, using thumb and forefinger and a natural oil, with the aim of stretching and elongating the tissue in preparation for vaginal childbirth, or for treatment of adherent scarring in the perineum.

**Perineal measurements - perineal length***Sign*

Distance from posterior margin of vestibule to anterior anal verge.

### **Perineal movement with a sustained increase in intraabdominal pressure (IAP)**

#### *Sign*

Direction of perineal movement during a sustained effort. As there may be a difference in PFM response to bearing down versus valsalva, it is important to state exact test instruction depending on the test, as the observed response may vary. RATING: (i) Perineal elevation; (ii) No change; (iii) Perineal descent; (iv) Excessive perineal descent with bearing down: Movement of the perineum 3 cm or more below resting position.

### **Perineal movement with rapid increase in intra-abdominal pressure**

#### *Sign*

Direction of perineal movement during a rapid increase in intra-abdominal pressure such as coughing, lifting, throwing. Clarify if the patient is instructed to contract PFM before cough to differentiate voluntary (learned) response from an involuntary response (un-learned). RATING: (i) Perineal elevation; May be due to: Voluntary contraction —precontraction may be a learned response; (ii) Involuntary contraction: A contraction which occurs reflexively or automatically, without volition or conscious control. Observe this response before instructing in a voluntary pre-contraction to differentiate from the voluntary pre-contraction response; (iii) No change; (iv) Perineal descent.

### **Perineal nerves**

#### *Surgery – Male*

Branches of the pudendal nerves, the perineal nerves supply motor innervation to the bulbocavernosus and ischiocavernosus muscles as well as sensory innervation via the posterior scrotal and bulbourethral nerves.

### **Perineal pain (female)**

#### *Symptom*

Complaint of pain felt between the posterior fourchette (posterior lip of the vaginal introitus) and the anus.

### **Perineal pain (male)**

#### *Symptom*

Complaint of pain, pressure or discomfort felt on the surface or in the depth of the tissue between the scrotum and the anus.

### **Perineal Pain Syndrome**

#### *Symptom*

Perineal pain syndrome is the occurrence of persistent or recurrent episodic perineal pain, which is either related to the micturition cycle or associated with symptoms suggestive of urinary tract or sexual dysfunction. There is no proven infection or other obvious pathology.

### **Perineal scarring**

#### *Sign*

Presence of scar tissue on perineum. TECHNIQUE: Using a finger-tip, attempt to slide the scar in all directions. Assess for adhesion or lack of skin mobility over underlying tissue. RATING: (i) Present; (ii) Degree of healing; (iii) Location of scar in relation to vulva/scrotum or anus; (iii) Location of adhesion; (iv) Extent/magnitude of scar mobility; (v) Absent.

### **Perineal sensation - external assessment by digital palpation.**

#### *Sign*

Test for presence, absence or altered quality of sensation in dermatomal dis-

tributions especially S2-4. May include light touch, blunt, sharp, pain, cold, vibration modalities. RATING: Allodynic, anesthetic, dysesthetic, hyperalgesic, hyperesthetic, hypoaesthetic, hypoesthetic, paresthetic, neuralgic.

### **Perineal sexual pain**

#### *Symptom*

May occur during intercourse or after intercourse.

### **Perineal skin assessment**

#### *Sign*

Assessment of the perineal skin to note presence of: scars, lesions (e.g., fissure), trophic changes/atrophy, color, erythema, swelling, and other conditions which could affect the function of the Pelvic floor Muscles.

RATING: (i) Normal skin; (ii) Altered (detail the observation including extent of alteration)

### **Perineal ultrasound (2D transducer) in the mid-sagittal plane (male) oriented longitudinally/sagittally - Ano-rectal junction**

#### *Imaging*

The ventral-most point of a line drawn along the ventral aspect of the rectum at the anorectal junction.

INTERPRETATION: For the displacement of the anatomical landmarks described below, the displacement during contraction and cough are measured in relation to the resting position values. Movement of these landmarks has been correlated with activation of levator ani (puborectalis)

For urethro-vesical and ano-rectal junctions: (A) Rest: The position of these landmarks in the caudo-cranial and antero-posterior planes can be quantified relative to the dorsal pole of the PS at rest. Lower resting position has been observed in incontinent men. (B) PFM contraction: Cranio-ventral displacement is expected. (C) Cough: Caudal-dorsal motion can be observed during the pressurization phase of cough due to levator ani muscle lengthening (probable eccentric contraction, but this cannot be confirmed from US

imaging) during the phase when intra-abdominal pressure increases. This is followed by cranial-ventral displacement that occurs due to PFM shortening (concentric contraction).

### **Perineal ultrasound (2D transducer) in the mid-sagittal plane (male) oriented longitudinally/sagittally - Bulb of the penis**

#### *Imaging*

The dorsal-most point on a line drawn around the bulb of the corpus cavernosum penis. INTERPRETATION: (A) Contraction: Cranio-ventral displacement is expected due to bulbocavernosus shortening. (B) Cough: Cranio-ventral displacement is expected due to bulbocavernosus shortening.

### **Perineal ultrasound (2D transducer) in the mid-sagittal plane (male) oriented longitudinally/sagittally - Mid-urethra**

#### *Imaging*

A point on the ventral border of the membranous urethra that undergoes the greatest dorsal movement during contraction. This point is located within 2.5 mm either side of a line drawn between the dorsal pole of the pubic symphysis and the most dorsal aspect of the bulb of the penis. INTERPRETATION: (A) PFM contraction: Dorsal displacement is expected due to striated urethral sphincter shortening; (B) Cough: Dorsal displacement of the mid-urethra due to striated urethral sphincter shortening.

### **Perineal ultrasound (2D transducer) in the mid-sagittal plane (male) oriented longitudinally/sagittally - Urethro-vesical junction**

#### *Imaging*

The point of maximal inflection of a line drawn along the dorsal border of the urethra and the bladder neck.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Integrity of the anterior/medial fibers of the levator ani:**

*Imaging*

To assess if a disruption or disconnection of the insertion is present, direct the patient to perform a PFM contraction, and identify the plane of minimal hiatal dimensions at maximal PFM contraction. Use this plane for tomographic ultrasound imaging of the puborectalis component of the levator ani, with an interslice interval of 2.5 mm. (A) Complete avulsion is diagnosed when the 3 central slices show a loss of integrity or defect in the anterior/medial fiber of the levator ani muscle on the inferior pubic ramus resulting in a levator-urethra gap. A gap of more than 2.5 cm has been suggested as an indicator of avulsion. (B) Partial avulsion: Is diagnosed when at one or two of the 3 central slices show a loss of integrity/defect of the medial fiber of the levator ani muscle.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Integrity of the anal sphincter complex:**

*Imaging*

Assessment of the internal and external anal sphincter to identify presence/absence of a defect (measured in degrees). Using tomographic ultrasound imaging, the anal canal is visualized in the mid-sagittal plane and a set of 8 transverse slices is placed to encompass the entire external anal sphincter by locating one slice cranial to the external anal sphincter (at level of puborectalis, Slice 1) and another caudal to the internal anal sphincter (at level of subcutaneous part of external anal sphincter, Slice 8), leaving six slices to delineate the entire muscle (Slices 2–7). Interslice interval is varied depending on external anal sphincter dimensions. INTERPRETATION: PFM contraction: A “significant” defect is diagnosed if four out of these six slices show a defect in >30% of the circumference of the external anal sphincter.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Levator ani muscle cross-sectional area:**

*Imaging*

Is the area (in mm<sup>2</sup> or cm<sup>2</sup>) delineated by tracing the outline of the levator ani muscle at the level of maximal muscle thickness.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Levator hiatus antero-posterior diameter:**

*Imaging*

The distance (in mm or cm) delineated from the PS (anteriorly) to the edge of the of the puborectalis muscle (posteriorly). INTERPRETATION: findings below apply to all measurements of hiatal dimensions. (A) Rest: Quantification of the levator hiatus diameters/area at rest. Smaller diameter/area has been observed in women with pelvic pain and is may suggest increased tone in the PFM. Conversely, a larger hiatus has been observed in women with pelvic organ prolapse. (B) PFM contraction: A reduction of the area/diameter is expected during a maximal PFM contraction. Hiatus reductions during contraction can be calculated as the percentage of change from baseline (i.e., levator hiatus narrowing = (levator hiatus at rest – levator hiatus at contraction)/levator hiatus at rest ×100). (C) Bearing down: An increase in the levator hiatus diameter/area is expected on bearing down with the instruction to relax the PFM. The difference (or percentage of change) between the diameter at rest and on bearing down determines the degree of hiatal distension. Higher distension has been observed in women with pelvic organ prolapse.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Levator hiatus area.**

*Imaging*

Defined and measured as the area (in mm<sup>2</sup> or cm<sup>2</sup>) bordered by the pubo-visceral muscle, PS and inferior pubic ramus in the plane of minimal hiatal dimensions. findings below apply to all measurements of hiatal dimensions. (a) Rest: Quantification of the levator hiatus diameters/area at rest. Smaller diameter/area has been observed in women with pelvic pain and may suggest increased tone in the PFM. Conversely, a larger hiatus has been observed in women with pelvic organ prolapse (b) PFM contraction: A reduction of the area/diameter is expected during a maximal PFM contraction. Hiatus reductions during contraction can be calculated as the percentage of change from baseline (i.e., levator hiatus narrowing = (levator hiatus at rest – levator hiatus at contraction)/levator hiatus at rest ×100). (c) Bearing down: An increase in the levator hiatus diameter/area is expected on bearing down with the instruction to relax the PFM. The difference (or percentage of change) between the diameter at rest and on bearing down determines the degree of hiatal distension. Higher distension has been observed in women with pelvic organ prolapse.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Levator hiatus left-right/latero-lateral/ transverse diameter**

*Imaging*

Latero-lateral diameter of the levator hiatus (in mm or cm) in the plane of minimal hiatal dimensions. The diameter from right to left is measured at the widest part, and perpendicular to the antero-posterior diameter. findings below apply to all measurements of hiatal dimensions: (A) Rest: Quantification of the levator hiatus diameters/area at rest. Smaller diameter/area has been observed in women with pelvic pain and may suggest increased tone in the PFM. Conversely, a larger hiatus has been observed in women with pelvic organ prolapse. (B) PFM contraction: A reduction of the area/diameter is expected during a maximal PFM contraction. Hiatus reductions during contraction can be calculated as the percentage of change from baseline (i.e., levator hiatus narrowing = (levator hiatus at rest – levator hiatus at contraction)/levator hiatus at rest ×100). (C) Bearing down: An increase in the levator hiatus diameter/area is expected on bearing down with the instruction to relax the PFM. The difference (or percentage of change) between the diameter at rest and on bearing down determines the degree of hiatal distension. Higher distension has been observed in women with pelvic organ prolapse.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Maximal levator ani muscle thickness**

*Imaging*

Is the maximum diameter of the levator ani muscle measured in two locations bilaterally (in mm or cm). This is usually located 1–1.5 cm above the minimal levator hiatus dimension. Measured perpendicular to the presumed levator ani fiber direction. INTERPRETATION: Rest: Increased thickness has been observed after PFM training. Increased thickness may be indirectly related to strength.

**Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Urethral sphincter volume**

*Imaging*

Ultrasound imaging of the urethral sphincter (morphometry of the rhabdosphincter). The internal sphincter volume (in mm<sup>3</sup> or cm<sup>3</sup>) including the longitudinal smooth muscle and the lumen is seen as a hypoechoic (black) core whereas the external sphincter volume or the circular striated muscle of the rhabdosphincter is seen as a hyperechoic (white) ellipsoid

structure. INTERPRETATION: Smaller sphincter volume is related to urinary incontinence severity and urethral pressure. PFM training results in increased sphincter volume.

#### **Perineal ultrasound (4D transducer) in the axial plane (female) oriented longitudinally - Hiatal dimensions**

##### *Imaging*

Cross-sectional area of the pelvic floor/levator hiatus, including antero-posterior and transverse distances.

Measured in the plane of minimal hiatal dimensions. A transverse view is obtained and the plane of minimal hiatal dimensions is identified by moving the field of view cranially and caudally until the distance between the hyperechogenic posterior aspect of the PS and the hyperechogenic anterior border of the pubovisceral muscle is at a minimum.

#### **Perineal urethrostomy**

##### *Surgery – Male*

Surgical creation of a neomeatus in the perineum.

#### **Perineocele**

##### *Sign*

Bulge in the perineum associated with herniation of the anterior wall of the rectum.

#### **Perineorrhaphy - commencement position (PCT)**

##### *Surgery – Female*

Where is Level III, the perineorrhaphy is commenced, e.g. hymen, mid-vestibule, posterior margin of vestibule.

#### **Perineorrhaphy - depth (PD)**

##### *Surgery – Female*

Depth of the excised perineum.

#### **Perineorrhaphy - mid-perineal thickness (MPT)**

##### *Surgery – Female*

Thickness (cm) of the mid-perineum in the midline.

#### **Perineorrhaphy - perineal gap (PG)**

##### *Surgery – Female*

Thinned out medial area (cm) between Moynihan forceps placed bilaterally where the labia minora meet the perineum.

#### **Perineorrhaphy - width (PW)**

##### *Surgery – Female*

Width of the excised perineum.

#### **Perineum - excessive descent with bearing down**

##### *Sign*

Movement of the perineum 3 cm or more below resting position.

#### **Peritoneal grafts and flaps**

##### *Surgery – Female*

The use of peritoneum flap/graft to provide interposing tissue and blood supply as well as increased vaginal non-dermal surface area. It may be used at vaginal or abdominal surgery.

#### **Persistent fistula**

##### *Symptom*

Continuation of urinary tract and/or anorectal tract incontinence symptoms immediately after fistula treatment caused by incomplete fistula wound healing. This includes inability to close the fistula during surgery.

#### **Persistent fistula**

##### *Sign*

Persistent fistula: The persistent fistula is not de novo to the patient.

- (i) Persistent urine or fecal (flatal) incontinence: Observation of involuntary, extra-urethral loss of urine and/or extra-anal loss of flatus/feces on examination.
- (ii) Incomplete fistula wound healing: after treatment which includes inability to close the fistula during surgery.

#### **Persistent fistula diagnosis**

##### *Diagnosis*

fistula that is not closed at conclusion of surgical or nonsurgical intervention or that re-opens in the immediate postintervention period. These treatment failures result from acute failure of wound healing or, in the specific case of failure to close the defect during surgical interventions, intra-operative failure of surgical technique.

#### **Persistent fistula-related disorder - PFRD Pain**

##### *Symptom*

Pain or discomfort in the vagina or vulva with sexual activity.

#### **Persistent fistula-related disorder (PFRD)**

##### *Symptom*

Symptoms from conditions concurrent with the fistula or occurring after successful closure of the fistula defect. PFRD may include a complex of disabling symptoms related to comorbidities of general health and well-being, mental, reproductive, and musculoskeletal organs, in addition to symptoms from disorders of the upper and lower urinary, genital and anorectal tracts

#### **Persistent fistula-related disorder: PFRD General health symptoms**

##### *Symptom*

- (i) Fatigue, malaise, and mental health symptoms which are often multifactorial in origin
- (ii) Emotional, musculoskeletal, gastrointestinal, or urinary tract symptoms related to types of abuse—physical, economic, and/or emotional.

#### **Persistent fistula-related disorder: PFRD mental health symptoms**

##### *Symptom*

- (i) Anxiety and/or depression, posttraumatic stress disorder
- (ii) Grieving/mourning, stigma, and social isolation, self-esteem, quality of life
- (iii) Suicidal ideation, loss of libido, body image disorders, dysphoria, insomnia

#### **Persistent fistula-related disorder: PFRD menstrual dysfunction symptoms**

##### *Symptom*

Amenorrhea, oligomenorrhea, dysmenorrhea, infertility.

#### **Persistent fistula-related disorder: PFRD mobility dysfunction symptoms**

##### *Symptom*

Difficulty walking or changing position or other range of motion symptoms.

#### **Persistent fistula-related disorder: PFRD Musculoskeletal symptoms**

##### *Symptom*

- (i) Difficulty with ambulation
- (ii) Complaint of other quality of life challenges related to activities of daily living caused by diastasis pubis, osteomyelitis, foot-drop, levator ani atrophy, exposed sacral nerve

roots, idiopathic chronic pelvic pain and other musculoskeletal diagnosis incident after index event causing the fistula.

**Persistent fistula-related disorder: PFRD psychological dysfunction symptoms**

*Symptom*

Anxiety, depression, adjustment disorder with depressed mood, mourning, or grieving may be due to the impact of body image. Effects of loss of income-generating potential or marital, family or social status.

**Persistent fistula-related disorder: PFRD urinary tract dysfunction symptoms**

*Symptom*

For example, flank pain, dysuria, hematuria, voiding dysfunction.

**Pessaries - General**

*Conservative Management – Female*

Pessaries are intravaginal devices used to try to restore the prolapsed organs to their normal position and hence to relieve symptoms. Vaginal pessaries can be broadly divided into two types: support pessaries (ring, ring with support, Gehrung, Hodge, shelf) and space-filling pessaries (donut, Gellhorn, cube, inflatable).

**Peyronie's Disease**

*Diagnosis*

A connective tissue disorder involving the growth of fibrous plaques in the soft tissue of the penis. Specifically, scar tissue forms in the tunica albuginea, causing pain, abnormal curvature, ED, indentation, loss of girth and shortening.

**PFF - Principles of fistula surgery**

*Surgery – Female*

- (i) Patient counseling: On the possibility of complications, including failure, and staged care.
- (ii) Optimizing patient health: Operating on patients who are in optimal health for wound healing.
- (iii) Tissue handling: Careful tissue handling during dissection and suturing.
- (iv) Wide dissection to well-mobilize the fistulized organs from each other.
- (v) No tension: Close the fistula defects under no tension.
- (vi) flaps and grafts: Judicious use of autologous interposition flaps and grafts to assure adequate blood supply for wound healing.
- (vii) Optimize functional result: Attention paid to both form (close the hole) and function (restore normal function to the urinary, genital and anorectal tracts).
- (viii) Intercurrent prolapse and incontinence surgery: Including but not limited to judicious use of prolapse reconstructive and incontinence procedures for concurrent pelvic floor disorders during the fistula repair.
- (ix) Bladder drainage: Catheterization

**PFF: Classification System A - the Francophone System**

*Surgery – Female*

The Francophone System, developed in 1959, has been for use in urinary tract PFF and is used in Francophone (French-influenced) Africa. It divides the fistula into “simple,” “complex,” or complicated with significance placed on destruction of bladder neck, urethra, and scarring. It is the original classification system that was translated into English to create the basis for the Waaldijk classification system.

**PFF: Classification System B - the Waaldijk System**

*Surgery – Female*

The Waaldijk System, published in 1995, is based on whether the continence mechanism is impaired and on the extent of circumferential damage. In the original paper, the classification of the fistula was performed under anesthesia. Type I fistulas do not involve ‘the closing mechanism’ whilst Type II involves “the closing mechanism.” The definition of the “closing mechanism” is unclear. Type III are ureteric and “other exceptional fistulas.” There is a sub-classification according to the size of the fistula. Studies have been conducted to assess this system. Comparative study with other systems demonstrates the Waaldijk system to be less predictive of closure.

**PFF: Classification System C - the Goh System**

*Surgery – Female*

The Goh System, published in 2004, is based on fixed reference points. The external urinary meatus (or its site if the urethra is absent) is the reference point for genito-urinary fistulas and the hymen is the reference point for anorectal-vaginal fistulas. This system is based on distance from these fixed reference points, size of the fistula, presence of scarring, and other “special” circumstances such as radiation

fistulas, circumferential fistulas, recurrent fistulas. Published studies using this system include intra- and interobserver concordances, correlations with urinary incontinence after surgical closure and grade of fistula and comparative studies with other systems.

**PFF: Classification System D - the Panzi Hospital System**

*Surgery – Female*

The Panzi Hospital System, published in 2018, is also known as the Panzi score. It is a descriptive and predictive scoring system based on retrospective review of surgical failure of fistula repair using characteristics from the Goh and Waaldijk systems. A scoring system was constructed by using the data obtained, correlating the score to likelihood of surgical outcomes. The score is based on whether the fistula is circumferential, the location and size of the fistula.

**PFM dysfunction - decreased PFM tone**

*Diagnosis*

A dysfunction which results from a reduction in PFM tone, due to either the contractile or the noncontractile components of tone:

CRITERIA:

SYMPTOMS: Loose, lax, gaping, sagging, open, weak, bulging, full, loss of control.

SIGNS: (i) Hypotonicity; (ii) decreased PFM tone; (iii) anal or introital gaping; (iv) excessive flexibility of the vaginal opening; (v) palpation of an anal sphincter gap or levator avulsion; (vi) Deficit in PFM contractile function: absence of voluntary PFM contraction, decreased strength (weakness), decreased

sustained and repeated endurance, lack of perineal or PFM elevation, no urethral lift, partial or uncertain levator closure, small to no change in levator hiatus on contraction.

INVESTIGATIONS: Any tool which measures tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound, or MRI). If EMG reveals a reduced signal amplitude or peak microvolts, or shorter duration of sustained contraction this suggests decreased myoelectrical activity, which may be termed “underactivity” in the PFM.

**PFM dysfunction - Disorder of PFM Co-ordination - Anismus**

*Diagnosis*

Spasm of the EAS with attempted defecation or anal penetration.

CRITERIA:

**SYMPTOMS:** Pain, tender, ache, discomfort during attempted defecation or anal penetration

**SIGNS:** (i) Perineal and/or PFM elevation with sustained increased IAP (bearing down) or attempted penetration; (ii) Increased PFM tone.

**INVESTIGATIONS:** (i) Balloon expulsion test; (ii) MR defecography; (iii) EMG: PFM activation during defecation suggesting poor motor control.

#### **PFM dysfunction - Disorder of PFM Co-ordination - PFM dyssynergia**

##### *Diagnosis*

Paradoxical PFM or sphincter contraction: a dysfunction of coordination between the PFM and a functional activity, such as a PFM contraction when relaxation is functionally required. These dyssynergias including vaginismus and anismus may share similar symptoms and signs.

#### **PFM dysfunction - Disorder of PFM Co-ordination - Vaginismus**

##### *Diagnosis*

Spasm of vaginal musculature that interferes with vaginal penetration. Vaginismus may also be termed genito-pelvic pain/ penetration disorder, which includes fear or anxiety as a component of the disorder.

##### **CRITERIA:**

**SYMPTOMS:** Pain, tight, tense, narrow, or constricted.

**SIGNS:** (i) Transient increased tone—inability to maintain relaxation with attempted vaginal penetration (f);

(ii) Increased PFM tone.

**INVESTIGATIONS:** (a) Assessment of resting tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound or MRI); (b) Increased activation of PFM shown by perineal or peri-anal EMG during attempted vaginal penetration.

#### **PFM dysfunction - increased tone - Pelvic floor myofascial pain syndrome**

##### *Diagnosis*

A pelvic floor pain syndrome of myofascial origin. This diagnosis has trigger points as a hallmark

feature. However, there is no consensus of the definition and diagnostic criteria associated with trigger

points. **CRITERIA FOR DIAGNOSIS:**

**SYMPTOMS:** Presence of pain.

**SIGNS:** (i) Tender point in a taut band (localized increased tone) of skeletal muscle, (ii) Patient pain recognition on tender point palpation; (iii) Referral pattern; (iv) Local twitch response; (v) The paired criteria of tender points in taut bands and predicted or recognized pain referral form the most frequently cited combination of diagnostic criteria.

**INVESTIGATIONS:** There is no consensus regarding objective laboratory tests for myofascial trigger point diagnosis. However, MR elastography and ultrasound elastography have been reported to investigate myofascial taut bands and trigger points in the trapezius muscle.

#### **PFM dysfunction - increased tone - Pelvic floor tension myalgia**

##### *Diagnosis*

A condition of pain and increased PFM tone. If the location can be confirmed as the levator ani, then the

term can be levator ani tension myalgia.

##### **CRITERIA FOR DIAGNOSIS:**

**SYMPTOMS:** May relate to sensation of pain: pain, tender, ache, discomfort. May relate to sensation of increased tone: tight, tense, narrow or constricted.

**SIGNS:** Tenderness or tender point on palpation of PFM's per perineum, per vaginam, or per rectum as well one or more of the

following signs: (i) Lack of perineal and/or PFM descent with sustained increased intra-abdominal pressure; (ii) Absent, partial or delayed relaxation of perineum and/or PFM after contraction; (iii) Nonrelaxing PFM; (iv) Hyper-tonicity, or increased PFM tone, on a continuum from transient increase in

tone to spasm (v) Fasciculation; (vi) Reduced flexibility of the vaginal opening.

**INVESTIGATIONS:** (i) Muscle tenderness as assessed by digital algometry (palpometry); (ii) finding of increased tone from any tool which measures tone (dynamometry, myotonometry, manometry, EMG, ultrasound or MRI); (iii) if EMG reveals an inconsistent or elevated resting baseline, or slow de-recruitment, this suggests increased myoelectrical activity, which may be termed overactivity in the PFM.

#### **PFM dysfunction - PFM pain - Pelvic floor myalgia**

##### *Diagnosis*

A disorder involving PFM pain.

##### **CRITERIA:**

**SYMPTOMS:** Pain, tender, ache, discomfort.

**SIGNS:** (i) Muscle tenderness or tender point on palpation of PFM's and normal tone in PFM per perineum, per vaginam, or per rectum.

**INVESTIGATIONS:** (i) Muscle tenderness as assessed by digital algometry (palpometry); (ii) finding of normal tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound, or MRI).

#### **PFM dysfunction - Pudendal neuralgia**

##### *Diagnosis*

Pudendal neuralgia is a chronic and severely disabling neuropathic pain syndrome caused by mechanical or nonmechanical injury of the pudendal nerve. The Nantes criteria list five essential diagnostic criterion including three symptoms, one sign and one investigation.

##### **CRITERIA:**

**SYMPTOMS:** (i) Pain in the distribution of the pudendal nerve and its referral areas, primarily the genitalia including the vulvovaginal, anorectal, and distal urethral areas; (ii) Worse in the sitting position; (iii) Pain does not wake the patient at night, (iv) no numbness of the perineum; (v) The patient may also have associated pelvic floor symptoms.

**SIGNS:** Nantes criteria sign: (i) No loss of sensation in the pudendal distribution on objective testing.

Other signs include: (ii) Tenderness to palpation anywhere along the length of the pudendal nerve; (iii) Increased tone and tenderness of the obturator internus or piriformis muscles (depending on the location of the nerve irritation); (iv) Positive pudendal nerve neurodynamic test; (v) Positive pudendal nerve provocation test.

**INVESTIGATIONS:** As per Nantes criteria: may be confirmed by relief of patient's pain after a pudendal nerve block with or without guided imaging

#### **Phimosis**

##### *Sign*

Partial or complete inability to retract the prepuce due to adhesion between the glans and the prepuce or a preputial ring.

#### **Physiotherapy for Female Pelvic Floor Dysfunction**

##### *Conservative Management – Female*

Physiotherapy involves “using knowledge and skills unique to physiotherapists” and “is the service only provided by, or under the direction and supervision of, a physiotherapist”. Adherence: is the extent to which a client/patient's behavior corresponds to the agreed treatment protocol and/or regime as recommended by their healthcare provider. It does not refer to the intervention itself; rather, the patient's commitment to undertaking the behavioral change to adhere to the intervention.

Compliance: is the extent to which a client/patient's behavior matches, or complies with their healthcare provider's recommended treatment protocol and/or regime.

**Pictorial stool chart***Sign*

It is a pictorial chart of stool consistencies. The "Bristol stool chart" seems to have widespread face validity and recognition and is useful in conversations with patients about their stool consistency, despite little validation work. It has not been validated as an outcome measure and a reported change in category may not represent sufficient degree of precision for use as a trial end point.

**Pneumaturia***Symptom*

Complaint of the passage of gas (or air) from the urethra during or after voiding.

**Polyuria***Sign*

Excessive production of urine. It has been defined as >40mls urine/kg body weight during 24 hours or 2.8 litres (70 kg individual).

**Polyuria - Causes***Sign*

Diabetes mellitus: Insulin dependent (Type I); Insulin independent (Type II).  
Diabetes insipidus: Pituitary, Renal, Gestational, Primary polydipsia (psychogenic, dipsogenic or iatrogenic).

**Polyuria (global symptom)***Symptom*

Complaint that the urine excretion volume over 24 hours is noticeably larger than the previous excretion.

**POP - anterior vaginal wall (compartment) prolapse***Diagnosis*

Clinically evident (symptoms, signs or any relevant imaging) descent of the anterior vaginal wall (compartment).

**POP - posterior vaginal wall (compartment) prolapse***Diagnosis*

Clinically evident (symptoms, signs or any relevant imaging) descent of the posterior vaginal wall (compartment).

**POP - uterine/ cervical prolapse***Diagnosis*

Clinically evident (symptoms, signs or any relevant imaging) descent of the uterus or uterine cervix.

**POP - vaginal vault (cuff scar) prolapse***Diagnosis*

Clinically evident (symptoms, signs or any relevant imaging) descent of the vaginal vault (cuff scar after hysterectomy).

**POPQ - anterior vaginal wall - Point Aa***Sign*

A point located in the middle of the anterior vaginal wall three (3) cm proximal to the external urethral meatus. By definition, the range of position of Point Aa relative to the hymen is -3 to +3cm.

**POPQ - anterior vaginal wall - Point Ba***Sign*

A point that represents the most distal (i.e., most dependent) position of any part of the upper anterior vaginal wall from the vaginal cuff or anterior vaginal fornix to Point Aa. By definition, Point Ba is at -3cm in the absence of prolapse and would have a positive value equal to the position of the

cuff (Point C) in women with total uterine prolapse or post-hysterectomy vaginal eversion.

**POPQ - defined points***Sign*

The anatomic position of the six defined points (two on the anterior vaginal wall, two in the superior vagina, and two on the posterior vaginal wall) for measurement should be centimeters (cm) above or proximal to the hymen (negative number) or cm below or distal to the hymen (positive number) with the plane of the hymen being defined as zero (0). For example, a cervix that protruded 3 cm distal to the hymen would be + 3 cm. All points are measured on maximal straining (except total vaginal length).

**POPQ - fixed point of reference***Sign*

The hymen is the fixed point of reference used throughout the POP-Q system of quantitative prolapse description.

**POPQ - Genital hiatus***Sign*

The genital hiatus (GH) is measured from the middle of the external urethral meatus to the posterior margin of the hymen.

**POPQ - Perineal body***Sign*

The perineal body (PB) is measured from the posterior margin of the hymen to the mid-anal opening.

**POPQ- Posterior vaginal wall - Point Bp***Sign*

A point that represents the most distal (i.e., most dependent) position of any part of the upper posterior vaginal wall from the vaginal cuff or posterior vaginal fornix to Point Ap. By definition, Point Bp is at -3 cm in the absence of prolapse and would have a positive value equal to the position of the cuff in a woman with total post-hysterectomy vaginal eversion.

**POPQ - recording measurements***Sign*

Intraoperative measurements with traction can be quite different than measurements made during Valsalva in clinic, both in regards to cervical location and the vaginal walls. Measurements directly after removing a vaginal pessary are unreliable and will tend to understage the degree of prolapse.

**POPQ - Superior vagina - Point D***Sign*

A point that represents the location of the posterior fornix in a woman who still has a cervix. It is included as a point of measurement to differentiate suspensory failure of the uterosacral-cardinal ligament "complex" from cervical elongation. When the location of Point C is significantly more positive than the location of Point D, this is indicative of cervical elongation which may be symmetrical or eccentric. Point D is omitted in the absence of the cervix.

**POPQ - Superior vaginal - Point C***Sign*

A point that represents either the most distal (i.e., most dependent) edge of the cervix or the leading edge of the vaginal cuff (hysterectomy scar) after total hysterectomy.

**POPQ - Total vaginal length***Sign*

The total vaginal length (TVL) is the length of the vagina (cm) from the

posterior fornix to hymen when Point C or D is reduced to its full normal position.

#### **POPQ- Posterior vaginal wall - Point Ap**

##### *Sign*

A point located in the midline of the posterior vaginal wall three (3) cm proximal to the hymen. By definition, the range of position of Point Ap relative to the hymen is -3 to +3 cm.

#### **POP-related vaginal bleeding, discharge, infection.**

##### *Symptom*

Complaint of vaginal bleeding, discharge or infection related to dependent ulceration of uterine and/or vaginal prolapse.

#### **Position-dependent voiding - female**

##### *Symptom*

Complaint of having to take specific positions to be able to void spontaneously or improve bladder emptying, (female) e.g. leaning forwards or backwards on the toilet seat or voiding in a semi-standing position.

#### **Position-dependent voiding - male**

##### *Symptom*

Complaint of having to adopt specific positions to be able to void spontaneously or to improve bladder emptying, e.g. needing (men) to void in a seated position.

#### **Possible Intercurrent Diagnoses of POP**

##### *Diagnosis*

(i) Urodynamic stress incontinence: Involuntary leakage of urine during filling cystometry, associated with increased intraabdominal pressure, in the absence of a detrusor contraction. In the circumstances where this diagnosis is only made when the POP is reduced, the additional term "occult" is appropriate. (ii) Detrusor overactivity: The occurrence of involuntary detrusor contractions during filling cystometry. (iii) Bladder oversensitivity: Increased perceived bladder sensation during bladder filling with: an early first desire to void; an early strong desire to void, which occurs at a low bladder volume; a low maximum cystometric bladder capacity. No abnormal increases in detrusor pressure are noted. (iv) Detrusor underactivity and Acontractile detrusor.

#### **Possible Prolapse-related Diagnoses**

##### *Diagnosis*

(i) Voiding dysfunction: A diagnosis by symptoms and urodynamic investigations is defined as abnormally slow and/or incomplete micturition, based on abnormal slow urine flow rates and/or abnormally high post void residuals, ideally on repeated measurement to confirm abnormality. Voiding cystometry can be required to determine the cause of the voiding dysfunction. (ii) Recurrent urinary tract infections(UTI): A diagnosis by clinical history assisted by the results of diagnostic tests involves the determination of the occurrence of at least three symptomatic and medically diagnosed urinary tract infections (UTI) over the previous 12 months. One possible POP-related cause is a chronically elevated postvoid residual. (iii) Defecatory dysfunction: A diagnosis by clinical history assisted, at times, by the results of diagnostic tests involving the confirmation of abnormal or difficult function in the initiation, passage or completion of defecation. (iv) Sexual dysfunction: A diagnosis by clinical history (including specific questionnaires) involving the confirmation of abnormal function and/or difficulty with sexual intercourse.

#### **Post coital pain (female)**

##### *Symptom*

Pain after intercourse such as vaginal burning sensation or pelvic pain.

#### **Post-5-alpha reductase inhibitor (5-ARI) syndrome**

##### *Diagnosis*

Persistent sexual, neurological, physical, and mental adverse reactions in patients who have taken 5-alpha reductase enzyme inhibitors (finasteride and dutasteride).

#### **Post-coital LUT symptoms (female)**

##### *Symptom*

Such as acute cystitis, worsened urinary frequency or urgency, dysuria, suprapubic tenderness.

#### **Post-defecatory soiling**

##### *Symptom*

Complaint of soiling occurring after defecation.

#### **Posterior colporrhaphy - mid-vaginal laxity (MVL - undisplaced)**

##### *Surgery – Female*

Laxity (cm) of the vaginal mucosa (anterior traction) midpoint in the vagina supero-posteriorly and in the midline with the vaginal vault held in an undisplaced position (similar to that after vault fixation).

#### **Posterior colporrhaphy - posterior vaginal vault descent (PVVD)**

##### *Surgery – Female*

Descent of the posterior vaginal vault (on traction) towards the anterior perineum (perineal gap). Subtract from the total posterior vaginal length (TPVL) the distance from the inferiorly displaced vaginal vault to the anterior perineum.

#### **Posterior colporrhaphy - recto-vaginal fascial laxity (RVFL - cm)**

##### *Surgery – Female*

Laxity in the recto-vaginal fascia (anterior traction) midpoint in the vagina supero-posteriorly (mucosa opened) and in the midline with the vaginal vault held in an undisplaced position.

#### **Posterior vaginal repair (colporrhaphy) - mesh or graft reinforcement**

##### *Surgery – Female*

A structural addition or inclusion used to give additional strength in function. It should be noted whether the graft is biologic, absorbable synthetic or permanent synthetic.

#### **Posterior vaginal repair (colporrhaphy) - native tissue**

##### *Surgery – Female*

Repair the vagina by excision and suturing the edges of any defect. Midline fascial plication represents the commonest procedure, involving dissection under the full thickness of the vaginal epithelium followed by central plication of the pre-rectal fascia over the rectum and excision of "excess" vaginal wall skin.

#### **Posterior vaginal vault descent (PVVD) - posterior colporrhaphy**

##### *Surgery – Female*

Descent of the posterior vaginal vault (on traction) towards the anterior perineum (perineal gap). Subtract from the total posterior vaginal length (TPVL) the distance from the inferiorly displaced vaginal vault to the anterior perineum.

#### **Posterior Vaginal Vestibule**

##### *Sign*

Posterior hymenal ring to anterior perineum (posterior margin of vestibule).

#### **Posterior vaginal wall (compartment) prolapse**

##### *Sign*

Observation of descent of the posterior vaginal wall. Commonly, this would

represent rectal protrusion into the vagina (rectocele). Higher stage posterior or vaginal wall prolapse after prior hysterectomy will generally involve some vaginal vault (cuff scar) descent and possible enterocele formation. Enterocele formation can also occur in the presence of an intact uterus.

#### **Posterior vaginal wall (compartment) prolapse**

##### *Diagnosis*

Diagnosis by symptoms and clinical examination, assisted at times by any relevant imaging (i.e. clinically evident) descent of the posterior vaginal wall (compartment).

#### **Posterior wall "bubble test" for anorectal tract fistula**

##### *Investigation*

With anterior vaginal wall retraction permitting visualization of the posterior vaginal wall, a Foley catheter

is inserted into the rectum, the balloon inflated, and held under gentle traction against the anus. Irrigant fluid is placed per vagina. A catheter-tipped, air-filled syringe is inserted into the catheter and slowly decompressed to insert air into the rectum. Vaginal inspection allows visualization of bubbles emanating per vagina through a fistula defect.

#### **Posterior wall irrigant/fluid per rectum for anorectal tract fistula**

##### *Investigation*

As with bladder dye testing, dye irrigation fluid may be instilled per rectal catheter. If colored irrigant passes per vagina, an anorectal fistula to the genital tract is confirmed.

#### **Post-micturition leakage**

##### *Symptom*

Complaint of a further involuntary passage of urine following the completion of micturition.

#### **Postoperative de novo dyspareunia**

##### *Symptom*

Dyspareunia first reported after surgery or other interventions.

#### **Postoperative de novo sexual dysfunction symptoms**

##### *Symptom*

New onset symptoms of sexual dysfunction (not previously reported before surgery).

#### **Postoperative findings - ultrasound imaging (male)**

##### *Imaging*

Post-prostatectomy (urethral shape), male sling position, artificial sphincter - placement of cuff and reservoir, bulking agents.

#### **Postorgasmic illness syndrome**

##### *Diagnosis*

Flu-like incapacitating physical and mental symptoms occurring within a few minutes to a few hours after an ejaculation, which usually lasts 3–7 days.

#### **Post-repaired fistula residual incontinence.**

##### *Symptom*

Urinary or anorectal tract incontinence symptoms after successful fistula closure.

#### **Postural urinary incontinence**

##### *Symptom*

Complaint of urinary incontinence during change of posture or position, e.g. from supine or seated to standing.

#### **Post-void residual (PVR)**

##### *Investigation*

Volume of urine left in the bladder at the completion of voiding.

#### **Post-void residual (PVR - abdominal) - ultrasound imaging**

##### *Imaging*

Volume = width (left to right) x depth (anterior to posterior) x length (cranial to caudal) x 0.52 (mL)

#### **Post-void residual (PVR - female) - assessment of normality**

##### *Investigation*

Quoted upper limits of normal reflect accuracy of measurement. Studies using "immediate" PVR measurement by ultrasound (within 60 seconds of voiding) suggest an upper limit of normal of 30ml. Studies using urethral catheterization (generally 5 - 10min delay) quote higher upper limits of 50ml or 100ml. An isolated finding of a raised PVR requires confirmation before being considered significant.

#### **Post-void residual (PVR - female - conditions for measurement)**

##### *Investigation*

PVR reading is erroneously elevated by delayed measurement due to additional urine production (1-14 mL/min). Ultrasonic techniques (transvaginal, translabial most accurately) allow immediate (within 60 s of voiding) measurement and possible repeat measurement. A short plastic female catheter provides the most effective drainage for PVR measurement by catheterization.

#### **Post-void residual (PVR - male) - assessment of normality**

##### *Investigation*

Upper limits in normal community dwelling men without LUTS are age dependent with studies reporting a cut-off value of 10-30 mL. There are no adequate currently available data from which to quote expected/typical ranges of PVR in men with symptoms of lower urinary tract dysfunction. Such studies would need to reflect the accuracy of measurement, including whether the PVR measurement is "immediate" (e.g. by ultrasound) or by urethral catheterization (unless also "immediate"). In the absence of such studies, our consensus view (D'Ancona, Haylen et al.) is that a PVR (ultrasound) over 50mL, following double voiding, might prompt the suspicion of voiding dysfunction.

#### **Post-void residual (PVR - male) - Conditions for measurement**

##### *Investigation*

PVR reading is erroneously elevated by delayed measurement due to additional renal input (1-14mL/min) into the bladder. Ultrasonic techniques allow immediate (within 60 seconds of micturition) measurement to minimize the error. Immediate insertion of a transurethral catheter for bladder drainage can still provide an effective and accurate PVR measurement. All urethral catheters, however, may not be of equal drainage efficacy. Ultrasound PVR measurement should ideally be repeated at least once if PVR is present. An overdistended rather than "comfortably full" bladder might lead to a falsely elevated initial PVR, assessed further by repeat voiding/ repeat PVR.

#### **Postvoiding detrusor contraction - pressure flow studies**

##### *Investigation*

An increase in detrusor pressure (Pdet) following the cessation of urinary flow.

#### **Post-voiding incontinence**

##### *Symptom*

Complaint of a further involuntary passage (incontinence) of urine or dribbling following the completion of voiding.

**Post-voiding symptom***Symptom*

Lower urinary tract symptom experienced after voiding.

**Post-voiding urgency***Symptom*

Complaint of persistent urgency post-voiding.

**Potential Sexual Side-Effects related to Treatments for Urethral Stricture:****Bulbar urethroplasty***Surgery – Male*

Erectile dysfunction, penile curvature, penile shortening, glans hypoesthesia, semen sequestration.

**Potential Sexual Side-Effects related to Treatments for Urethral Stricture: Direct visual internal urethrotomy (DVIU)***Surgery – Male*

Potential Side-Effect: Erectile dysfunction

**Potential Sexual Side-Effects related to Treatments for Urethral Stricture: Penile urethroplasty***Surgery – Male*

Potential side-effects: Poor penile cosmesis, erectile dysfunction (lower risk than bulbar urethroplasty).

**Potential Sexual Side-Effects related to Treatments for Urethral Stricture: Posterior urethral reconstruction***Surgery – Male*

Erectile dysfunction, penile curvature, penile shortening, glans hypoesthesia, semen sequestration, retrograde ejaculation.

**Premature ejaculation***Symptom*

Complaint of a persistent or recurrent pattern of too rapid achievement of ejaculation during partnered sexual activity, i.e. before the individual wishes it.

**Premature ejaculation - Acquired PE***Diagnosis*

A clinically significant and bothersome reduction in latency time, often to about 3 min or less.

**Premature ejaculation - Lifelong (Primary) PE***Diagnosis*

Ejaculation that always or nearly always occurs before or within about 1 min of vaginal penetration from the first sexual experience.

**Premature ejaculation (PE)***Diagnosis*

Complaint of a persistent or recurrent pattern of too rapid achievement of ejaculation during partnered sexual activity, that is, before the individual wishes it. It is accompanied by negative personal consequences, such as distress, bother, frustration, and/or the avoidance of sexual intimacy.

**Premicturition pressure***Investigation*

The pressure recorded immediately before the initial isovolumetric contraction.

**Pressure flow studies - detrusor opening pressure (cm H2O)***Investigation*

Detrusor pressure recorded immediately before the initial isovolumetric contraction.

**Pressure-flow studies***Investigation*

Pressure volume (urinary flow) relationship of the bladder during voiding. It begins when the "permission to void" is given and ends when the individual considers voiding has finished. Measurements to be recorded should be: detrusor pressure (Pdet); abdominal pressure (Pabd) with detrusor pressure (Pdet) calculated. Urine flow rate (mL/s) should also be recorded.

**Pressure-flow studies - acontractile detrusor***Investigation*

The detrusor cannot be observed to contract (i.e. no increase in Pdet) during pressure-flow studies resulting in failure to void. Limited voiding may occur by straining. May be neurogenic (evidence of a neurological disorder) or non-neurogenic (no evidence of a neurological disorder).

**Pressure-flow studies - delayed relaxation of the urethral sphincter (? neurogenic)***Investigation*

Impaired and hindered relaxation of the urethral sphincter during voiding attempt resulting in delay of urine flow.

**Pressure-flow studies - detrusor pressure at end flow (pdet-ef - cm H2O)***Investigation*

Detrusor pressure recorded at the end of urine flow.

**Pressure-flow studies - detrusor pressure at maximum flow (Pdet.qmax - cm H2O)***Investigation*

Detrusor pressure recorded at maximum urinary flow rate.

**Pressure-flow studies - detrusor underactivity (DU)***Investigation*

Low detrusor pressure or short detrusor contraction time, usually in combination with a low urine flow rate resulting in prolonged bladder emptying and/or failure to achieve complete bladder emptying within a normal time span.

**Pressure-flow studies - flow delay - unit: s)***Investigation*

The time elapsed from initial rise in pressure to onset of flow. It reflects the time necessary for the fluid to pass from the point of pressure measurement to the uroflow transducer.

**Pressure-flow studies - initiated reflex bladder emptying (?neurogenic)***Investigation*

An artificially elicited LUT reflex comprised of various manoeuvres (exogenous stimuli) performed by the patient or the therapist, resulting in complete or incomplete bladder emptying.

**Pressure-flow studies - maximum detrusor pressure (Pdet-max -cm H2O)***Investigation*

Maximum registered detrusor pressure during voiding.

**Pressure-flow studies - neurogenic detrusor underactivity***Investigation*

Low detrusor pressure or short detrusor contraction time, usually in combination with a low urine flow rate, resulting in prolonged bladder emptying

and/or failure to achieve complete bladder emptying within a normal time span in the setting of a clinically relevant neurologic disease.

#### **Pressure-flow studies - non-relaxing urethral sphincter (? neurogenic)**

##### *Investigation*

A non-relaxing, obstructing urethral sphincter resulting in reduced urine flow.

#### **Pressure-flow studies - normal detrusor contractile function.**

##### *Investigation*

Normal voiding in an individual is achieved by an adequate continuous detrusor contraction that leads to complete bladder emptying within a normal time span.

#### **Pressure-flow studies - postvoiding detrusor contraction (cm H2O)**

##### *Investigation*

An increase in detrusor pressure (Pdet) following the cessation of urinary flow.

#### **Pressure-flow studies - urethral opening pressure (Pdet-uo - cm H2O)**

##### *Investigation*

Detrusor pressure recorded at the onset of measured flow.

#### **Pressure-flow studies (male +/- VCU, EMG) - detrusor sphincter dyssynergia (DSD)**

##### *Investigation*

Dyscoordination between detrusor and smooth or striated sphincter function during voiding due to a neurological abnormality (i.e. detrusor contraction synchronous with contraction of the urethral and/or periurethral striated muscle).

#### **Pressure-flow studies (male +/- VCU, EMG) - dysfunctional voiding**

##### *Investigation*

This is characterized an intermittent and/or fluctuating urine flow due to inadequate or variable relaxation generally of the external sphincter during voiding in neurologically normal men.

#### **Pressure-flow studies (male +/- VCU,EMG) - abnormal urethral function during voiding.**

##### *Investigation*

The urethral sphincter(s) do not relax completely or they are (temporarily) contracted during voiding, resulting in increased detrusor pressure. Bladder emptying may be incomplete (PVR present).

#### **Pressure-flow studies (male +/- VCU,EMG) - bladder outlet obstruction (BOO)**

##### *Investigation*

The generic term for mechanical obstruction during voiding. It is a reduced urine flow rate with an increased detrusor pressure. PVR can be present.

#### **Pressure-flow studies (male +/- VCU,EMG) - normal urethral function during voiding.**

##### *Investigation*

The urethra opens and is continuously relaxed to allow micturition at a normal pressure and urine flow and results in complete bladder emptying. The voiding is prompted by a detrusor contraction and simultaneous relaxation of the smooth and striated sphincters of the urethra and pelvic floor muscles.

#### **Prevention of Pelvic Floor Dysfunction**

##### *Conservative Management – Female*

Prevention is the act of preventing or decreasing the risk of disease or disability. Activities that are directed toward slowing or stopping the occurrence

of both mental and physical illness and disease, minimizing the effects of a disease or impairment on disability, or reducing the severity or duration of an illness. 1. Primary prevention: prevention of the development of disease in a susceptible or potentially susceptible population through such specific measures as general health promotion efforts. 2. Secondary prevention: efforts to decrease the duration of illness, reduce the severity of diseases, and limit the sequelae through early diagnosis and prompt intervention. 3. Tertiary prevention: efforts to limit the degree of disability and promote rehabilitation and restoration of function in patients/clients with chronic and irreversible diseases.

#### **Primary and Further Surgery**

##### *Surgery – Female*

The following standardized terminology is proposed for surgical trials and clinical audit:

A. Primary Surgery: This indicates the first procedure required for the treatment of POP in any compartment. B. Further Surgery: Provides a global term for the number of subsequent procedures the patient undergoes, directly or indirectly, relating to the primary surgery. Further surgery per se should not be interpreted as a measure or failure as the definitions of success and failure will be defined within the context of the individual study. Further surgery is subdivided into: I. Primary prolapse surgery/different site: a prolapse procedure in a new site/compartment following previous surgery (e.g., anterior repair following previous posterior repair). II. Repeat surgery: a repeat operation for prolapse arising from the same site. Where combinations of procedures arise, such as new anterior repair plus further posterior repair, these should be reported separately as primary anterior repair and repeat posterior repair. III. Surgery for complications: mesh exposure or extrusion, pain, or patient compromise such as hemorrhage (see Complications section). IV. Surgery for non-POP related conditions: subsequent surgery for stress urinary incontinence or fecal incontinence.

#### **Primary enuresis**

##### *Symptom*

Complaint of intermittent incontinence that occurs during periods of sleep that has been present lifelong.

#### **Procidentia**

##### *Sign*

Complete eversion of the vagina and uterus (Stage IV utero-vaginal prolapse)

#### **Proctoscopy (anoscopy)**

##### *Investigation*

The inspection of the anal canal to identify anal fissure, fistula, or hemorrhoids as a cause of anal symptoms.

#### **Prolapse**

##### *Symptom*

A falling, slipping or downward displacement of a part or organ (Latin: Prolapsus - "a slipping forth")

#### **Prolapse (pelvic organ) symptoms**

##### *Symptom*

A departure from normal sensation, structure or function experienced by the woman in reference to the position of her pelvic organs. Symptoms are generally worse at the times when gravity might make the prolapse worse (e.g. after long periods of standing or exercise) and better when gravity is not a factor e.g. lying supine. Prolapse may be more prominent at times of abdominal straining e.g. defecation.

**Prominence***Surgery – Complication related*

Parts that protrude beyond the surface (e.g. due to wrinkling or folding with no epithelial separation).

**Prostate cancer (CaP)***Diagnosis*

Development of cancer from the prostate gland.

**Prostate cancer (CaP) - Localized***Diagnosis*

Cancer confined to the gland of the prostate.

**Prostate cancer (CaP) - Locally advanced***Diagnosis*

Spread of prostate cancer outside the prostate capsule, involvement of the seminal vesicles or involvement of adjacent organs without distant metastasis.

**Prostate cancer (CaP) - Metastatic***Diagnosis*

Distant spread of prostate cancer to other areas of the body beyond the pelvis, most notably bone and lymph nodes. Spread can also occur to the liver and lungs.

**Prostate procedures: General***Surgery – Male*

Partial removal of the prostate (transition zone) for the treatment of benign diseases (e.g., benign prostatic obstruction) or complete removal of the prostate and adjacent tissues for the treatment of malignant diseases (e.g. prostate cancer). The routes to the prostate may be through the urethra, abdomen (transperitoneal), retroperitoneal space (extraperitoneal), perineum or vessels (arteries).

**Prostate specific antigen (PSA)***Investigation*

Serum PSA level is measured for prostate cancer screening and to gather additional information about the size of the prostate and associated inflammatory changes.

**Prostate tenderness***Sign*

DRE of the prostate is usually painless. Pain with prostatic palpation may be indicative of CP/CPSP.

**Prostatic artery embolization (PAE)***Surgery – Male*

Destruction and secondary ablation of prostate tissue by uni- or bilateral embolization of prostatic arteries with microspheres. Tissue damage is done during the operation but desquamation (sloughing) of prostatic tissue occurs only during the next weeks or months, thereby reducing benign prostatic obstruction over time. PAE belongs to the secondary ablative procedures, is performed in local anesthesia and is a minimally-invasive procedure which aims to reduce morbidity compared to operations with immediate tissue removal.

**Prostatic urethra***Surgery – Male*

The portion of the urethra extending from the bladder neck to the proximal edge of the membranous urethra.

**Prostatitis***Diagnosis*

An inflammatory disease of the prostate generally affecting younger men and causing pain and discomfort mostly in the perineal and scrotal region which can be associated with lower urinary tract symptoms (LUTS) and/or sexual dysfunction. Prostatitis covers a wide range of clinical conditions including acute bacterial prostatitis, chronic bacterial prostatitis, CPPS (inflammatory and noninflammatory), and asymptomatic inflammatory prostatitis.

**Prosthesis***Surgery – Female*

A fabricated substitute to assist a damaged body part or to augment or stabilise a hypoplastic structure.

**Provocative Manoeuvres***Investigation*

Provocative manoeuvres are defined as techniques used during urodynamics in an effort to provoke detrusor overactivity, for example, rapid filling, use of cooled or acid medium, postural changes and hand washing.

**Pudendal Angiography***Investigation*

Imaging of the pudendal arteries for patency using injection of intravascular contrast and fluoroscopic imaging.

**Pudendal nerve neurodynamics - Digital assessment of the perineum***Sign*

Neurodynamic assessment evaluates the length and mobility of the nerve to assess neurogenic origin of pain. Tension is applied to the nerve or specific component of the nerve by lengthening the nerve or by distracting imposing tissues. RATING: (i) Positive: If pain, sensation of burning or stabbing are experienced in the distribution of the nerve. This assessment can be uncomfortable in asymptomatic individuals, however, reproduction of patient's pain is suggestive of a neurogenic origin of pain; (ii) Negative

**Pudendal nerve provocation test***Sign*

Palpation of the pudendal nerve to reproduce patient's pain if entrapment is suspected. The nerve may be palpated at the ischial spine, sacrospinous and sacrotuberous ligaments, or pudendal canal. RATING: (i) Positive (pain response); (ii) Negative.

**Pudendal nerves***Surgery – Male*

These nerves arise from the S2-S4 spinal nerves and provide somatic innervation to the pelvis and perineum. The pudendal nerve travels with the pudendal vessels in Alcock's canal, before giving off the inferior rectal nerve and perineal nerve, and then terminating as the dorsal nerve of the penis.

**Pudendal neuralgia***Sign*

Elicited or described by the patient as burning vaginal and vulva pain (anywhere between the anus and the clitoris) with tenderness over the course of the pudendal nerve.

**Pudendal pain (neuralgia)***Symptom*

Complaint of pain, pressure or discomfort in one or more areas innervated by the pudendal nerve (possible inflammation or entrapment of the pudendal nerve and involving its dermatome).

**Pudendal somatosensory evoked potentials (SEP)***Investigation*

A neurophysiologic test which can be used to support the diagnosis of a neurogenic cause of ED. The test should be performed as per the International Federation of Clinical Neurophysiology guidelines. A latency time >48 ms is considered abnormal (the mean normal latency is 37ms).

**Pull-on pads (protective underwear): Defining features***Conservative Management – Female*

Products in which the absorbent core, waterproof backing, and the means to hold it in place are combined in a

single design resembling regular underwear. Elastic linings around the waist and hips help give a close fit.

**Pull-on pads (protective underwear): Main variant features***Conservative Management – Female*

Products may be used by either sex, but some are intended (by their color, style, or the placing of absorbent material, for example) just for men or just for women.

- Products come with different absorption capacities, and fit different body sizes.
- Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit and comfort and prevent leakage.
- In some designs, side seams can be torn away for easy removal.
- Products may have wetness indicators.
- Products may or may not be suitable for containing fi as well as UI.

**Q****Q-Tip Testing***Sign*

Measurement of urethral axial mobility at rest and straining to assess degree of mobility.

**R****Radical cystectomy***Surgery – Male*

The entirety of the urinary bladder is removed along with adjacent organs or structures (prostate/seminal vesicles).

**Radiological imaging (male) - defecography (evacuation proctography)***Imaging*

This demonstrates the anatomy of the anorectum as well as disorders of rectal evaluation. Barium paste is inserted prior to defecation over a translucent commode.

**Radiological imaging (male) - intravenous urography (IVU)***Imaging*

Conventional X-ray or CT, this study provides an anatomical outline of the upper urinary tract, ureters and bladder as well as an evaluation of renal function by excretion of contrast media. Calcification may be shown in kidneys, ureter, bladder, seminal vesicles or vasa.

**Radiological imaging (male) - retrograde +/- antegrade urethrography***Imaging*

Unidirectional or combined contrast imaging is used to visualize the urethral lumen, to diagnose strictures and diverticula and to stage urethral trauma.

**Radiological imaging (male) - videocystourethrography (VCU)***Imaging*

Synchronous radiological screening of the bladder and urethra allowing direct observation of bladder events, the position and conformation of the bladder neck in relation to the pubic symphysis, diverticula of the bladder and urethra, recto-urethral fistulae and vesico-ureteric reflux.

**Radiological imaging (male) - Videourodynamics (pressure-flow studies)***Imaging*

A functional test of the lower urinary tract in which pressure, capacity and flow data are simultaneously combined with real-time imaging of the lower and upper urinary tract.

**Radiological imaging (male) - voiding (micturitional) cystourethrography***Investigation*

Imaging of the bladder neck, urethra and prostate during voiding looking for vesico-ureteric reflux, vesical or urethral fistulae, vesical or urethral diverticulae, strictures and the level of obstruction e.g. bladder neck or prostate.

**Rate of Nocturnal Urine Production***Sign*

Nocturnal urine volume / time asleep (i.e. night). Measured in mL/min.

**Receptive anal intercourse***Symptom*

Having a penis penetrating one's anus.

**Receptive urethral intercourse***Symptom*

Having a penis penetrating one's urethra (urethral coitus).

**Rectal advancement flap***Surgery – Female*

Mobilize/elevating a flap of the rectum above/below the fistula and using the flap to close over the fistula.

**Rectal (and prostate) examination (male)***Sign*

Digital rectal examination (DRE) is recommended as part of the physical

examination. Generally done with the patient standing and bent over the examining table, or with the patient in the left lateral knees bent position, or in the lithotomy position. DRE is usually pain-free.

. Anal examination: This can detect the following findings in the anal sphincter or distal rectum:

- Benign diseases: hemorrhoids, fissure, anal sphincter injury, levator discomfort or pain.

- Possible malignant diseases: anal, distal rectal and prostate carcinoma.

- Anal tone: increased or decreased anal sphincter tone might suggest similar changes in the urinary sphincter and may indicate neurologic disease.

- Anal stricture: a circumscribed narrowing or stenosis of the anal canal.

. Prostate gland characteristics: size, symmetry, firmness, nodules, and its relation to the pelvic sidewall and rectum can be assessed. The gland is about the size of a walnut and has a consistency similar to that of the contracted thenar eminence of the thumb.

. Prostate nodularity and/or firmness – May indicate possible abnormality requiring further investigation.

. Prostate tenderness: prostate palpation, as part of a DRE, is usually pain-free. Pain with prostatic palpation is variable though if present, it may be helpful in differentiating prostate/pelvic pain syndromes.

. Rectal examination (circumferential): this might lead to the detection of non-urological diseases such as rectal carcinoma, fistula and fecal impaction.

#### **Rectal bleeding/mucus**

##### *Symptom*

Complaint of the loss of blood or mucus per rectum.

#### **Rectal digitation**

##### *Symptom*

Use of fingers in the rectum to manually assist in the evacuation of stool contents.

#### **Rectal Dynamics - Attempted defecation and balloon expulsion**

##### *Investigation*

Patients with symptoms of prolapse and elderly patients with a history of constipation who present with passive incontinence should be thoroughly examined for the presence of a full thickness rectal prolapse. Patients are asked to strain as they would to pass stools whilst on a toilet or commode and given enough time to reproduce the prolapsing lump before examination. Expulsion of a water-filled balloon can be used in the assessment of constipated patients. The ability to expel the balloon within 1min may be a useful tool in demonstrating the absence of pelvic floor dyssynergia.

#### **Rectal Dynamics - Rectal Impedance Planimetry**

##### *Investigation*

These studies are the preserve of research institutions rather than clinical practice. The rationale is to calculate the diameter or cross sectional area of an intra rectal bag during a distension sequence. Impedance planimetry measures the cross sectional area which enables the circumferential wall tension to be calculated.

#### **Rectal dynamics (female) - Rectal Compliance**

##### *Investigation*

Rectal compliance is the term that describes the relationship between pressure and volume, reflecting the ability of the rectum to act as a reservoir and is assessed using a barostat, Inflating the bag within the rectum prior to the recording inflation protocol, known as conditioning, has been shown to improve the precision of compliance testing. Typically, compliance figures between 4 and 11 mmHg/ml are quoted as the normal range.

#### **Rectal examination (female)**

##### *Sign*

Observations can include: (i) Anal sphincter tone and strength: Assessment on digital examination, as good or poor in the absence of any quantitative assessment; (ii) Anal sphincter tear: May be recognized as a clear “gap” in the anal sphincter on digital examination; (iii) Confirm presence or absence of rectocele: and if possible, differentiate from enterocele. Diagnose perineal body deficiency; (iv) Confirm presence or absence of fecal impaction; (v) Other rectal lesions: Intussusception, rectovaginal fistula or tumor; (vi) Anal lesions; Hemorrhoids, fissure; (vii) Other perianal lesions: Anocutaneous fistula.

#### **Rectal Irrigation**

##### *Conservative Management – Female*

Rectal irrigation is the use of liquid solutions given by enema to remove material from the rectum.

#### **Rectal leakage of menses**

##### *Symptom*

Complaint of blood or bloody discharge passing per anus that the patient believes to be menstrual.

#### **Rectal leakage of urine**

##### *Symptom*

Complaint of urine passing per anus.

#### **Rectal musculature - Endoanal ultrasonography**

##### *Imaging*

(1) Internal anal sphincter - The caudal continuation of the circular smooth muscle of the rectum forms the internal anal sphincter, which terminates caudally in a clearly defined edge, at a variable distance from the anal verge.

(2) Longitudinal muscle - Comprises smooth muscle cells continuous with the outer layer of the rectal wall, and striated muscle from various pelvic floor muscles. The longitudinal muscle lies between the internal and external anal sphincters in the inter-sphincteric space.

(3) External anal Sphincter – It is made up of striated muscle and surrounds the longitudinal muscle forming the outer border of the inter-sphincteric space. The external sphincter is divided into deep, superficial and subcutaneous parts, with the deep and subcutaneous parts of the sphincter forming rings of muscle. Between them, elliptical fibres from the superficial part of the external anal sphincter run anteriorly from the perineal body to the coccyx posteriorly.

(4) Puborectalis - is formed from the most anterior fibres of the pubococcygeus muscle. This forms a sling pulling the rectum forward.

#### **Rectal prolapse**

##### *Symptom*

Complaint of external protrusion of the rectum (differentiation on subsequent examination between rectal mucosal prolapse and full thickness rectal wall prolapse which includes muscle and serosal layers).

#### **Recto/colo-uterine/cervical fistula (RCoUtF/RCoCxF)**

##### *Diagnosis*

An abnormal connection between the colo/rectum and uterus (body and/or cervix).

#### **Rectocele**

##### *Sign*

Bulge in posterior vaginal wall associated with herniation of anterior wall of the rectum. An aspect of posterior vaginal wall (compartment) prolapse.

**Recto-cervical fistula (RCxF)***Diagnosis*

Abnormal connection between the rectum and the uterine cervix

**Rectourethral fistula repair***Surgery – Male*

Excision of a fistula between the rectum and (prostatic) urethra, often associated with prostatectomy and temporary artificial anus.

**Recto-uterine fistula (RUF)***Diagnosis*

Abnormal connection between the rectum and the body of the uterus

**Recto-vaginal fascial laxity (RVFL - cm) - posterior colporrhaphy***Surgery – Female*

Laxity of the rectovaginal fascia (anterior traction) midpoint in the vagina super-posteriorly (mucosa opened) and in the midline with the vaginal vault held in an undisplaced position.

**Rectovaginal fistula***Sign*

Is a communication from the rectum to the vagina.

**Rectovaginal fistula (RVaF)***Sign*

Rectovaginal fistula (RVaF): Abnormal connection between the rectum to the vagina with or without observation of vaginal flatus/feces.

With or without the observation of:

- (i) RVaF—Clinical exam only: Anorectal fluid per vagina.
- (ii) RVaF = Clinical exam plus probe: Probe or examination finger passing per vagina through anus or per anus through vagina.
- (iii) RVaF—Clinical exam plus irrigation or air injection: Anorectal tract fluid per vagina, or with bubbles passing through the abnormal connection through vaginal irrigant fluid after retrograde injection of air per rectum.

**Rectovaginal fistula (RVaF)***Diagnosis*

Abnormal connection between the rectum and the vagina.

**Rectovaginal-perineal fistula (RVaPeF)***Sign*

RVaPeF: Is an abnormal communication from the anorectum to the vagina or perineal area.

- (i) RVaPeF—Clinical Exam only: Passing of flatus/feces per vagina or perineum through anus.
- (ii) RVaPeF—Clinical exam plus probe: Probe passing per vagina or perineum through anus.

**Rectovaginal-perineal fistula (RVaPeF)***Diagnosis*

An abnormal connection from the anal canal to the vagina and perineal areas.

**Recurrent fistula***Symptom*

Recurrence of fistula defect and incontinence after a period of transient complete fistula wound healing followed by delayed complications of wound healing causing fistula breakdown and fistula re-formation. It may also be caused by a new index event within the interval from successful

repair to recurrence of fistula after which another fistula forms. Examples of subsequent index events include subsequent pregnancy complications causing obstetric PFF, pelvic floor surgery complicated by iatrogenic PFF, malignancy, or pelvic trauma causing traumatic PFF.

**Recurrent fistula***Sign*

Recurrent fistula (signs): The recurrent fistula is de novo to the patient.

- (i) Recurrent urine or fecal (flatal) incontinence: Observation of recurrent involuntary, extra-urethral loss of urine and/or extra-anal loss of flatus/feces on examination.
- (ii) Recurrent fistula defect: Observation of within a clinical history context of previous fistula repair
  - (a) a period of transient complete fistula wound healing followed by delayed complications of wound healing causing fistula breakdown and fistula re-formation, or
  - (b) fistula recurring within the interval from successful treatment to recurrence of fistula after which another fistula forms.

**Recurrent fistula diagnosis***Diagnosis*

fistula that is closed post treatment, but recurs due to delayed failure of wound healing, or occurs subsequent to a follow-on index fistula-causing event. Subsequent index acquired fistula events are most commonly childbirth, surgery or pelvic trauma, but may also be inflammatory disease, infections, and pelvic malignancy.

**Recurrent urinary tract infection - diagnosis (female)***Diagnosis*

This diagnosis by clinical history assisted by the results of diagnostic tests involves the determination of the occurrence of at least three symptomatic and medically diagnosed urinary tract infection (UTI) over the previous 12 months.

**Recurrent Urinary Tract Infections (female)***Diagnosis*

This diagnosis by clinical history assisted by the results of diagnostic tests involves the determination of the occurrence of at least three symptomatic and medically diagnosed UTIs over the previous 12 months.

**Recurrent urinary tract infections (UTI - female)***Symptom*

A history of at least three symptomatic and medically diagnosed UTI in the previous 12 months. The previous UTI(s) should have resolved prior to a further UTI being diagnosed.

**Recurrent urinary tract infections (UTIs - male)***Symptom*

A history of at least two symptomatic and medically diagnosed UTIs in the previous 12 months. The previous UTI(s) should have resolved prior to a further UTI being diagnosed.

**Reduced bladder filling sensation***Symptom*

Complaint that the sensation of bladder filling is less intense or occurs later in filling than previously experienced.

**Reduced bladder sensation - filling cystometry***Investigation*

Bladder sensation perceived to be diminished during filling cystometry.

**Reduced compliance (storage dysfunction - RCSD) incontinence***Diagnosis*

Urinary incontinence directly related to the RCSD.

**Reduced compliance storage dysfunction (RCSD)***Diagnosis*

In individuals with lower urinary tract symptoms, more commonly storage symptoms, when there is a non-phasic (at times linear or exponential) rise in detrusor pressure during filling cystometry with generally reduced capacity indicating reduced compliance.

**Reflex bladder triggering***Conservative Management – General*

This comprises various manoeuvres performed by the patient or the therapist to elicit reflex bladder emptying by exteroceptive stimuli (relating to, being, or activated by stimuli received from outside the bladder).

**Related***Surgery – Complication related*

Connected

**Repeat Cystometry***Investigation*

There is no convincing evidence that the clinical diagnosis on the basis of the first cystometry is often changed on repetition of the test. There is no definite evidence that immediate repetition of an adequately performed urodynamic test 'for confirmation' is required. ICS does not recommend routine immediate repetition of invasive urodynamics 'for confirmation' if the test was technically adequate, has been considered representative, and has answered the clinical question. ICS recommends immediate repetition of the test when doubt exists as to whether the test has answered the clinical

question. ICS recommends repetition of a urodynamic test when technical errors and artefacts have been observed at immediate post test analysis.

**Reposition sling***Surgery – Male*

The sling pulls in and up the bulbous urethra.

**Retention with overflow***Diagnosis*

Involuntary loss of urine directly related to an excessively full bladder in retention.

**Retrograde urethrocytography and voiding cystourethrography***Imaging*

Unidirectional or combined contrast imaging of the urethra in a patient in the 30 degree oblique position to visualize the lumen, mainly to diagnose urethral strictures or diverticula. It is also of use to diagnose and stage urethral trauma.

**Retroverted uterus***Sign*

The axis of the uterus is directed backwards towards the hollow of the sacrum, away from its anteverted position overlying the bladder. Cervix is noted in/towards the anterior fornix with fundus perhaps palpable in the posterior fornix.

**Rigid sigmoidoscopy***Investigation*

This is a bedside test to inspect the rectal mucosa with no bowel preparation.

**S****Sacral spinal cord lesion (SSCL)***Diagnosis*

This is a neurological lesion in the sacral spinal cord. Neurogenic lower urinary tract dysfunction in SSCL: findings include acontractile detrusor with or without decreased bladder compliance and usually with impaired sphincter activity.

**Sacrocolpopexy - open, laparoscopic, robotic***Surgery – Female*

Suspension of the cervix (and usually vagina) utilizing mesh or graft to the anterior longitudinal ligament usually at the level of the sacral promontory. This procedure tends to be performed as an adjunct following subtotal hysterectomy for advanced utero-cervical prolapse.

**Sacrocolpopexy - open, laparoscopic, robotic***Surgery – Female*

Suspension of the vagina utilizing mesh or graft to the anterior longitudinal ligament usually at the level of the sacral promontory.

**Sacrohysteropexy - open, laparoscopic, robotic***Surgery – Female*

Suspension of the cervix (with or without additional vaginal attachment) utilizing mesh or graft to the anterior longitudinal ligament usually at the level of the sacral promontory. This tends to be performed for women who are keen to preserve their uterus.

**Sacrospinous Colpopexy (SSC)***Surgery – Female*

fixation of the vaginal vault to the sacrospinous ligament: (a) Unilateral or bilateral procedure. (b) Anterior or posterior approach. (c) Permanent or absorbable suture and number of 'bites' taken. (d) Type of suture placement device employed. (e) Direct vision or with the use of a specific instrument (tactile feedback).

**Sacrospinous hysteropexy***Surgery – Female*

fixation of the uterus to the sacrospinous ligament (SSL). Variations: (i) unilateral or bilateral; (ii) anterior or posterior approach; (iii) permanent or absorbable stitches; (iv) number of sutures; (v) direct vision or with use of a specific instrument (tactile feedback).

**Sarcopenia***Diagnosis*

A clinical condition characterized by loss of skeletal muscle and function. It might be a sign of hypogonadism.

**Scar massage***Conservative Management – Female*

A specific application of soft-tissue mobilization to an adherent scar.

**Scarred vagina - postoperative***Symptom*

Perception by the partner of a "stiff" vagina or a foreign body (stitches, mesh exposure, mesh shrinkage).

**Scheduled Voiding Regimes in Female Pelvic Floor Dysfunction***Conservative Management – Female*

Toileting on a fixed schedule around the patient's normal voiding pattern, which includes a progressive voiding schedule using relaxation and distraction techniques for urgency suppression. Scheduled voiding regimes have been categorized as: bladder training, timed voiding, habit training, and prompted voiding.

**Bladder training:** In the past, bladder training has also been referred to as bladder drill, bladder discipline, bladder re-education, and bladder retraining. It consists of a program of patient education, along with a scheduled voiding regimen with gradually adjusted voiding intervals. Specific goals are to correct faulty habit patterns of frequent urination, improve control over bladder urgency, prolong voiding intervals, increase bladder capacity, reduce incontinent episodes, and restore patient confidence in controlling bladder function. **Timed voiding:** is a passive toileting assistance program, initiated and maintained by caregivers for patients who cannot participate in independent toileting. It is a fixed voiding schedule.

**Habit training:** consists of a toileting schedule matched to the individual's voiding patterns based on their voiding diary. The toileting schedule is assigned to fit a time interval that is shorter than the person's normal voiding pattern and precedes the time period when incontinent episodes are expected.

**Prompted voiding:** is used to teach people to initiate their own toileting through requests for help and positive reinforcement from caregivers, often done in combination with a scheduled voiding regimen, typically every 2h.

**Scrotal examination***Sign*

**Normal:** The scrotum is a loose sac containing the testes and spermatic cord structures. The epididymis is palpable applied to the posterior surface of the testis as a ridge although occasionally it is sited on the anterior surface.

**Inflammation:** The epididymis may be swollen and tender, and if severe, the inflammatory process may involve the whole scrotal content (i.e. testis and epididymis [epididymo-orchitis]) and the scrotal skin as well.

**Cystic dilatations of the epididymis:** (epididymal cysts or spermatocele) and hydroceles (fluid collections between the visceral tunica albuginea and parietal layer of the testicular peritoneum) - usually benign. The examination of these structures would be generally non-tender and without pain.

**Inguinal bulge:** Examination and differentiation of hernia from hydrocele or cyst of spermatic cord or groin lymph nodes. (Use of transillumination may assist though ultrasound is generally diagnostic).

**Scrotal pain***Symptom*

Complaint of pain, pressure or discomfort felt in and around the scrotum. It may be localized to the testis, epididymis, cord structures or scrotal skin.

**Scrotal pain syndrome***Symptom*

Scrotal pain syndrome is the occurrence of persistent or recurrent episodic scrotal pain which is associated with symptoms suggestive of urinary tract or sexual dysfunction. There is no proven epididymo-orchitis or other obvious pathology.

**Semen sequestration***Sign*

Trapping of ejaculate in the bulbar urethra, resulting in a decreased force

and volume of emission; often secondary to damage to the perineal nerves and/or bulbospongiosus muscle. Manual pressure on the perineum at the level of the bulbar urethra may be required to expel sequestered semen.

**Semi-rigid (Malleable) penile prosthesis (MPP)***Surgery – Male*

The penile prosthesis type which consists of two flexible rods that are placed inside the penis. Once implanted with the malleable prosthesis, the penis can be bent away from the body for sexual intercourse and toward the body for concealment.

**Sensation of anorectal blockage - female***Symptom*

Complaint suggestive of anorectal obstruction.

**Sensory symptoms (female)***Symptom*

A departure from normal sensation or function, experienced by the woman during bladder filling. Normally, the individual is aware of increasing sensation with bladder filling up to a strong desire to void.

**Separation***Surgery – Complication related*

Physically disconnected (e.g. vaginal epithelium).

**Sex Hormone Binding Globulin (SHBG)***Investigation*

A plasma protein that is produced by the liver and transports sex hormones (estradiol, testosterone, dihydrotestosterone) in the blood as biologically inactive forms.

**Sexual activity urinary incontinence***Symptom*

Complaint of urinary incontinence associated with or during sexual activity (nb coital urinary incontinence [female] and sexual arousal incontinence [male]).

**Sexual arousal disorder (Male)***Diagnosis*

Lack of, or significantly reduced, sexual interest or arousal.

**Sexual arousal (female) - vascular assessment***Investigation*

Sexual arousal results in increased blood flow allowing genital engorgement, protrusion of the clitoris and augmented vaginal lubrication through secretion from the uterus and Bartholin's glands and transudation of plasma from engorged vessels in the vaginal walls. Several instruments are available to measure blood flow during sexual stimulation. Inadequate vasculogenic response may be related to psychological factors as well as vascular compromise due to atherosclerosis, hormonal influence, trauma or surgery.

**Sexual arousal incontinence***Symptom*

Complaint of involuntary loss of urine during sexual arousal, foreplay and/or masturbation.

**Sexual Arousal Incontinence or foreplay incontinence***Symptom*

Complaint of involuntary loss of urine during sexual arousal, foreplay and/or masturbation.

**Sexual aversion disorder (Male)***Diagnosis*

Persistent or recurrent extreme aversion to, and avoidance of, all or almost all, genital sexual contact with a sexual partner which causes distress or interpersonal difficulty.

**Sexual diaries (female)***Investigation*

A daily log of sexual thoughts, activities; supported by the US FDA as a primary outcome measure for the efficacy of interventions to improve sexual function.

**Sexual dysfunction***Diagnosis*

Difficulty experienced by an individual or a couple during any stage of normal sexual activity; including desire, arousal, and orgasm. Sexual dysfunction involves significant distress and interpersonal strain for at least 6 months.

**Sexual dysfunction (female)***Diagnosis*

A diagnosis by clinical history (including specific questionnaires) and examination, involving the confirmation of abnormal function and/or difficulty with sexual intercourse.

**Sexual dysfunction following treatment for LUTS/BPO - 5-Alpha reductase inhibitors***Conservative Management – Male*

Erectile dysfunction, loss of libido, reduction of ejaculate volume, post-finasteride syndrome.

**Sexual dysfunction following treatment for LUTS/BPO - Alpha blockers***Conservative Management – Male*

Potential side-effect: Retrograde ejaculation, reversible anejaculation.

**Sexual dysfunction following treatment for LUTS/BPO - Laser prostatectomy***Surgery – Male*

Potential side-effects: Retrograde ejaculation (lower risk than TURP)

**Sexual dysfunction following treatment for LUTS/BPO - Simple prostatectomy***Surgery – Male*

Potential side-effects: Retrograde ejaculation, anejaculation.

**Sexual dysfunction following treatment for LUTS/BPO - Trans-urethral incision of prostate (TUIP)***Surgery – Male*

Potential side-effects: Retrograde ejaculation (lower risk than TURP)

**Sexual dysfunction following treatment for LUTS/BPO - Transurethral resection of prostate (TURP)***Surgery – Male*

Potential side-effects: Retrograde ejaculation, anejaculation, erectile dysfunction.

**Sexual dysfunction related to Overactive Bladder - Bladder diary***Conservative Management – Male*

Adds to the FVC, the fluid intake, pad usage, incontinence episodes, the degree of incontinence and the circumstances at the time of the leakage. Episodes of urgency and sensation might also be recorded, as might be the activities performed during or immediately preceding the involuntary loss of urine.

Additional information obtained from the bladder diary involves: severity of incontinence in terms of leakage, episodes and pad usage.

**Sexual dysfunction related to Overactive Bladder - PDE5i***Conservative Management – Male*

This treatment reduces OAB symptoms through the phosphodiesterase–nitric oxide pathway.

**Sexual dysfunction related to Overactive Bladder - Third line (Surgical) treatments for OAB***Surgery – Male*

These therapies include intradetrusor botulinum toxin injection, peripheral tibial nerve stimulation (PTNS) and sacral neuromodulation (SNM).

**Sexual dysfunction symptoms - De-novo postoperative***Symptom*

Symptoms related to sexual dysfunction that were not reported before surgery.

**Sexual event logs***Investigation*

Record individual sexual events or activities. Each event is classified as a “sexually satisfying event (SSE)” or not. Event logs record individual events rather than activities on a daily basis.

**Sexual Function Questionnaires - (SFQ)***Investigation*

1. Pelvic floor condition specific sexual function measures: A validated sexual function measure which is developed to include concepts relevant to women with pelvic floor dysfunction. 2. Generic sexual function measures: A validated measure that was developed to evaluate sexual function but does not contain items relevant to pelvic floor dysfunction such as coital incontinence or vaginal looseness.

**EXAMPLES:**

- . ICIQ-flUTSsex (BflUTS) (International Consultation on Continence Questionnaire Female Lower Urinary Tract ICIQ-VS (International Consultation of Incontinence Questionnaire -Vaginal Symptoms).
- . GRISS (The Golombok-Rust Inventory of Sexual Satisfaction);
- . ICIQ-VS (International Consultation of Incontinence Questionnaire -Vaginal Symptoms);
- . PISQ (Pelvic Organ Prolapse Urinary Incontinence Sexual Questionnaire;
- . PISQ-12 (short form version of the PISQ-31);
- . PISQ IR (IUGA- revised version of the PISQ);
- . FSfi (Female Sexual Function Index);
- . SFQ (Sexual Function Questionnaire);
- . SQOL-F (Sexual Quality Of Life-Female).

**Sexual Health Questionnaires (Male): American Urological Association Symptom Index (AUA-SI) for BPH***Symptom*

A symptom index for BPH which was developed and validated by a multidisciplinary measurement committee of the AUA. It includes seven questions covering frequency, nocturia, weak urinary stream, hesitancy, intermittency, incomplete emptying, and urgency.

**Sexual Health Questionnaires (Male): Brief Male Sexual Function Inventory (BMSFI)***Symptom*

A validated, self-administered 11-item inventory evaluating male sexual function. There are five

domains: Sexual Drive, Erections, Ejaculation, Problem Assessment, and Overall Satisfaction.

**Sexual Health Questionnaires (Male): Index of premature ejaculation (IPE)**

*Symptom*

A 10-item validated tool which was developed to evaluate sexual satisfaction, control, and distress in men with PE.

**Sexual Health Questionnaires (Male): International Index of Erectile Function (IIEFF)**

*Symptom*

A multi-dimensional and validated self-report instrument for the evaluation of male sexual function.

**Sexual Health Questionnaires (Male): International Prostate Symptom Score (IPPS)**

*Symptom*

An 8-question written screening tool used to screen for, rapidly diagnose, track the symptoms of, and suggest management of the symptoms of BPH. It contains the seven questions of the AUA symptom index for BPH and one question related to the patient's perceived quality of life (bother score).

**Sexual Health Questionnaires (Male): Male sexual health questionnaire (MSHQ)**

*Symptom*

A tool for assessing key domains of sexual function and satisfaction in aging men with urogenital symptoms of LUTS and sexual dysfunction. It consists of 25 questions that constitute subscales for Erection, Ejaculation, and Satisfaction.

**Sexual Health Questionnaires (Male): Premature ejaculation profile (PEP)**

*Symptom*

A self-report questionnaire used to assess four components of PE: satisfaction with sexual intercourse, control over ejaculation, ejaculation-related distress, and interpersonal difficulty. Each of the four individual items is assessed on a 5-point scale, and the scores are averaged to provide an index PE score.

**Shortened vagina**

*Symptom*

Perception of a short vagina expressed by the woman or her partner.

**Shortened vagina (postoperative)**

*Symptom*

Perception of a short vagina expressed by the woman or her partner (following surgical intervention).

**Signoid or colon conduit**

*Surgery – Female*

A segment of sigmoid or colon is used for the urinary diversion where the ileum cannot be used or its appearance as a stoma onto healthy skin in the usual position is not possible. It is usually performed in cases of pelvic irradiation, regional enteritis, or short bowel syndrome.

**Simple dye test for urinary tract fistula**

*Investigation*

The bladder is filled retrograde through a urethral catheter using a dye to change the color of the irrigation fluid, for example, methylene blue or indigo carmine to turn the irrigation fluid blue. Observation

may begin with or without retractor(s) in the vagina, depending on digital and visual exam signs and patient symptoms, or following careful dissection. Blue fluid leakage per genital tract or per anus indicates a bladder or urethral fistula. Lack of blue fluid leakage combined with visualization of extra-meatal clear urine leakage increases suspicion of an upper urinary tract ureteric fistula.

**Simplified POPQ**

*Sign*

This is based on the POP-Q with similar ordinal staging but with only four points measured instead of nine. There is no Stage 0; it is combined with Stage 1. It is performed in the dorsal lithotomy position with patient forcefully bearing down, performing Valsalva or coughing: (i) Four points used: (i) Anterior vaginal segment: point Ba (estimated around 3cm proximal to hymenal remnants); (ii) Posterior vaginal segment: point Bp (estimated around 3cm proximal to hymenal remnants); (iii) Cervix point C; (iv) Apex/posterior fornix: point D (non-hysterectomized); point C (hysterectomized). Staging I, II, III, IV.

**Singapore flap (pudendal thigh/groin vasculocutaneous flap)**

*Surgery – Female*

For vaginal reconstruction (not dissimilar to buttock and perineal skin rotation flaps).

**Single channel urodynamics (UDS) - "Simple cystometrics"**

*Investigation*

Use of a catheter, catheter-tipped syringe, and sterile irrigant solution, may provide rudimentary yet valuable information to guide treatment algorithms. Any residual fistula needs to be excluded. Simple "cystometrics" requires the insertion of an indwelling catheter which is secured with inflation of the balloon. The bladder is filled with a catheter tipped syringe to approximately 300 ml of saline. The end of the catheter (after removing the syringe) is held vertically about 15 cm above the pubic symphysis and the level of the fluid in the catheter is noted. The volume for each filling sensation is noted. When there are no urge symptoms and no elevation of the meniscus, then the vesical pressure is considered "stable."

When the catheter is removed a cough test is performed to assess for stress urinary incontinence.

**Single-use body worn absorbent incontinence products**

*Conservative Management – Female*

Single-use (as opposed to reusable/washable) body worn (that is, worn on the body as opposed to bed and chairprotectors) absorbent incontinence products. The ICS defines absorbent products as "... those that have been specifically developed to help manage leakage or soiling, such as absorbent pads and pants, absorbent bed sheets and chair covers.

**Sinus tract formation**

*Surgery – Complication related*

(Localized) formation of a fistulous tract towards vagina or skin, where there is no visible implant material in the vaginal lumen or overlying skin.

**Situational types of urinary incontinence - neurogenic**

*Symptom*

Giggle incontinence or incontinence associated with epileptic seizures, sphincter denervation in cauda equina and in the Onuf's nuclei lesions in multiple system atrophy.

**Skin rolling**

*Conservative Management – Female*

A manual technique in which skin is pulled away from the underlying structures and elongated in various directions.

**Sling surgery***Surgery – Male*

A synthetic, biological, or composite sling placed ventrally of the urethra to treat stress urinary incontinence.

(sling already defined)

**Slow (urinary) stream***Symptom*

Complaint of a urinary stream perceived as overall slower than previous performance or in comparison with others.

**Soft-tissue Therapies***Conservative Management – Female*

1. Touch desensitisation: the manipulation of the soft tissues of the body for the purpose of affecting the nervous, muscular, respiratory, and circulatory systems. 2. Massage: the manipulation of the soft tissues of the body for the purpose of affecting the nervous, muscular, respiratory, and circulatory systems. 3. Abdominal massage: therapist or self-directed massage of the abdominal wall with the aim of stimulating peristalsis and relieving the symptoms of constipation. Generally, the technique follows the ascending, transverse, and descending colon to aid emptying. The effect may be mechanical or sensory. 4. Myofascial release techniques: the use of deep friction and stroking of the fascia of the body to improve the ability of the fascia to deform and move within the body. 5. Skin rolling: a manual technique in which skin is pulled away from the underlying structures and elongated in various directions. 6. Scar massage: a specific application of soft-tissue mobilization to an adherent scar. 7. Perineal massage: intravaginal massage by the woman, her partner or the clinician. Technique includes alternating downward and sideward pressure, using thumb and forefinger and a natural oil, with the aim of stretching and elongating the tissue in preparation for vaginal childbirth, or for treatment of adherent scarring in the perineum. 8. Transverse friction: the operator's fingertip is placed on the exact site of the lesion and rubbed firmly across the direction of the fibers of the affected tissue. 9. Thiele's massage: per-rectal digital massage of the levator ani, sweeping lengthwise along the muscle fibers. Massage is begun lightly, and pressure is increased as tenderness decreases. 10. TrP treatment: (sometimes called myofascial trigger point treatment): soft-tissue mobilization specifically targeting trigger points and may include ischemic pressure, massage, myofascial release, electrotherapy, ultrasound, laser, spray and-stretch, injection (a variety of chemicals including local anesthetic, botox or steroids), dry needling (insertion of a solid needle into the TrP), and stretching.

**Soiling (female)***Sign*

Perianal fecal soiling or vaginal fecal soiling.

**Somatic pain***Symptom*

Pain which arises from bone, joints, muscles, skin or connective tissue and is normally achy or throbbing and well localized.

**Sonourethrography***Investigation*

Ultrasound examination of the urethra, providing information on the location and length of stricture as well as the degree of spongiofibrosis.

**Sphincterotomy***Surgery – Male*

Transurethral incision of the external urethral sphincter with a mono- or bipolar electric hook or a LASER in patients with fibrotic sphincter stenosis or patients with detrusor-sphincter-dyssynergia.

**Spinal shock phase***Diagnosis*

This is usually temporary following acute neurologic insult or SCI that is characterized by loss of sensory, motor and reflex activity below the level of injury. Neurological lower urinary tract dysfunction in Spinal Shock is usually a temporary complete painless urinary retention.

**Splinting (female)***Symptom*

Support perineum or buttocks manually (usually with thumb or fingers) to assist in evacuation of stool content.

**Splinting/digitation due to POP***Symptom*

Complaint of the need to digitally replace the prolapse or to otherwise apply manual pressure e.g. to the vagina or perineum (splinting), or to the vagina or rectum (digitation) to assist voiding or defecation.

**Spraying (splitting) of urinary stream***Symptom*

Complaint that the urine passage is a spray or split rather than a single directional stream.

**Sterile intermittent catheterization***Conservative Management – General*

Complete sterile setting including genital skin antiseptics, sterile gloves, forceps, gown and mask.

**Storage dysfunction (SD)***Diagnosis*

Those diagnoses related to abnormal changes in bladder sensation, detrusor pressure or bladder capacity during filling cystometry.

**Storage symptom***Symptom*

A lower urinary tract symptom during the bladder storage phase.

**Storage symptoms***Symptom*

Lower urinary tract symptoms occurring during the bladder storage phase.

**Straining to defecate***Symptom*

Complaint of the need to make an intensive effort (by abdominal straining or Valsalva) or to use abdominal massage to either initiate, maintain or improve defecation.

**Straining to void***Symptom*

Complaint of the need to make an intensive effort to either initiate, maintain or improve voiding or the urinary stream.

**Stranguria***Symptom*

Complaint of voiding which is slow, difficult and spasmodic (at times "drop by drop"), usually associated with pain.

**Stress fecal incontinence (SFI)***Symptom*

Complaint of involuntary loss of feces on effort or physical exertion including sporting activities, or on sneezing or coughing.

**Stress incontinence on prolapse reduction (occult or latent stress incontinence)***Sign*

Stress incontinence only observed after reduction of co-existent pelvic organ prolapse (POP).

**Stress urinary incontinence***Symptom*

Complaint of involuntary loss of urine on effort or physical exertion including sporting activities, or on sneezing or coughing.

**Stress urinary incontinence (clinical stress leakage)***Sign*

Observation of involuntary leakage from the urethral orifice synchronous with effort or physical exertion, or on sneezing or coughing.

**Stretched penile length***Sign*

The penile length as measured by a rigid centimeter ruler, which is placed along the dorsal side of the penis (flaccid, and stretched as comfortably as possible), extending in a parallel fashion from the pubo-penile skin junction to the tip of the glans where the pre-pubic fat pad was pushed to the bone.

**Strong desire to void - Filling cystometry***Investigation*

The persistent desire to void without the fear of leakage.

**Superficial (introital) dyspareunia***Symptom*

Complaint of pain or discomfort on vaginal entry or at the vaginal introitus.

**Suprapontine lesion (SPL)***Diagnosis*

This is a neurological lesion above the pons (forebrain or midbrain). Neurogenic lower urinary tract dysfunction in SPL: there is a reflex contraction of the detrusor with impaired cerebral regulation and central inhibition and usually synergistic voiding/bladder emptying.

**Suprapubic catheter: Button cystostomy***Surgery – Male*

This procedure involves insertion of a gastrostomy button normally used for enteral nutrition into the bladder, using an endoscopic technique. Button cystostomy results in a continent device that permits urine drainage by suprapubic route, as well as suprapubic catheter, resulting in a more cosmetically acceptable, with less obstacles for sports activities, swimming, improving quality of life especially in children and young adults.

**Suprapubic catheter: General***Surgery – Male*

This involves insertion of a catheter via suprapubic route.

**Suprapubic catheter: Open/laparoscopic/robot-assisted technique***Surgery – Male*

This involves insertion of a catheter into bladder via the suprapubic route under direct visualization of the bladder puncture. This entails incising skin, subcutaneous tissues, and sheath of the anterior abdominal wall. It is ensured the bladder is as full as possible and under direct vision the catheter is inserted into the bladder.

**Suprapubic catheter: Seldinger technique***Surgery – Male*

The catheter is inserted into the bladder from the suprapubic route by

seldinger technique through a specially designed kit. After ensuring the bladder is full a needle is inserted from suprapubic skin directly into the bladder. Once aspiration of urine is confirmed the tract is dilated with a trocar and the catheter is inserted via a specially designed sheath. This process can be aided by direct endoscopic visualization or under ultrasound guidance

**Suprapubic open prostatectomy (prostate adenomyectomy, open enucleation of prostate)***Surgery – Male*

Removal of the prostatic adenoma (transitional zone) after lower abdominal wall incision, either through the bladder (Freyer; Hryntsckak) or anterior prostatic capsule (Millin). These operations are usually done in large volume prostates (>80 cm<sup>3</sup>).

**Suprasacral spinal cord/ pontine lesion (SSL)***Diagnosis*

This is a neurological lesion in the suprasacral spine and/or pons. Neurogenic lower urinary tract dysfunction in SSL: detrusor overactivity (DO) and DO incontinence are common, with or without detrusor-sphincter dyssynergia (DSD), often resulting in a significant post-void residual (PVR) and a "high pressure" bladder.

**Supratrigonal / substitutional reconstruction: General***Surgery – Male*

If an adequate reservoir capacity cannot be obtained using a bowel patch, then a substitution procedure is required. This reconstruction can include the trigone of the native urinary tract or consist of a reservoir created entirely from autologous tissue.

**Supratrigonal / substitutional reconstruction: Substitutional***Surgery – Male*

This reconstruction does not utilize any part of the native bladder. Following cystectomy, a reservoir is constructed from bowel (usually terminal ileum) and the ureters are anastomosed to this, that is, orthotopic neobladder. The reservoir is then, in turn, anastomosed to the native urethra.

**Supratrigonal / substitutional reconstruction: Supratrigonal***Surgery – Male*

The dome of the bladder is excised leaving the trigonal plate/bladder base, with attached ureters, to the native urethra. A reservoir (created from an isolated bowel segment) is then fashioned and anastomosed to the trigone. Although a number of bowel segments can be utilized, distal ileum is most commonly selected for reconstruction. A continent catheterisable stoma (usually catheterized via the anterior abdominal wall) can also be used in addition to this reconstructive technique. This technique usually spares the nerves maintaining sexual function.

**Supratrigonal cystectomy***Surgery – Male*

The entire bladder except the trigone and bladder neck is excised.

**Surface Electromyography (sEMG) - Parameters and findings - Baseline muscle activity:***Investigation*

The amount of microvolts generated by activation of motor units in the target muscle during rest. RATING: (1) Inconsistent resting baseline: the variation of baseline between contractions, between sets, or between days. (2) Elevated resting activity: An increase in the active component of muscle tone; (the passive/ viscoelastic component is not captured by sEMG).

**Surface Electromyography (sEMG) - Parameters and findings - Duration of sustained contraction***Investigation*

The duration in seconds that a contraction could be sustained at a specific % of MVC. RATING: A shorter duration suggests lower endurance.

**Surface Electromyography (sEMG) - Parameters and findings - Normalization of the amplitude***Investigation*

The value obtained during a specific task as a percent relative to the electrical activity detected during a MVC.

**Surface Electromyography (sEMG) - Parameters and findings - Peak amplitude***Investigation*

The highest sEMG amplitude achieved measured in microvolts. Specify the duration (s). Measured during an MVC or functional activities such as postural tasks or incontinence provocative activities.

**Surface Electromyography (sEMG) - Parameters and findings - Power spectrum***Investigation*

The distribution of frequency components of the sEMG signals, measured in Hz. RATING: The median frequency of the sEMG power spectrum shifts to lower frequencies as a muscle fatigues due to altered muscle fiber recruitment and other changes in the contractile properties.

**Surface Electromyography (sEMG) - Parameters and findings - Rate of change of amplitude during sustained contraction***Investigation*

The change in sEMG amplitude divided by the duration of the contraction:  $EMG_{final} - EMG_{initial} / \text{time}(s)$ . The contraction could be sustained or intermittent at different % of MVC. RATING: A higher rate of change will be indicative of lower endurance.

**Surface Electromyography (sEMG) - Parameters and findings - Reaction time***Investigation*

(i) Reaction time: The latency (time in ms) between a stimulus (or the command) and the onset of muscle activation. (ii) Time from command to peak: Time in ms from stimulus to peak activity. This term encompasses both the reaction time and the time to peak muscle activation. RATING: Slow reaction time: A longer time to initiate muscle activation.

**Surface Electromyography (sEMG) - Parameters and findings - Signal amplitude***Investigation*

Microvolts ( $\mu V$ ) a muscle generates. Specify: MVC contraction duration (s)—how the signal was processed. Signals are usually rectified and filtered to measure amplitude, i.e., average rectified value or root-mean-square. RATING: sEMG amplitude reflects muscle activation. Increase in sEMG amplitude is related to the recruitment of motor units and increased firing rate. The amplitude of the signal should not be interpreted as a direct force measurement because the relationship between force and EMG is generally not linear and is affected by type of contraction (concentric/isometric/eccentric), speed of contraction. During strength training, early gains in force output are mainly related to an increase in motor unit recruitment and discharge frequency which will result in a higher signal amplitude. Later gains explained by hypertrophy are not reflected in increased sEMG amplitude.

**Surface Electromyography (sEMG) - Parameters and findings - Time to peak muscle activation***Investigation*

Time in ms or s from onset of muscle activity to peak activity. Rate of change: The mean slope of the ascending curve in  $\mu V/s$  during a fast MVC. RATING: Slow recruitment: A longer time to peak muscle activation in s or a slower rate of change.

**Surface Electromyography (sEMG) - Parameters and findings - Time to return to baseline muscle activity***Investigation*

Time in s from peak activity to resting activity. Rate of change: The mean slope of the descending curve in  $\mu V/s$  during a fast MVC. RATING: Slow de-recruitment: Slow relaxation of the muscle contraction.

**Surface Electromyography (sEMG) - Parameters and findings - Timing of muscle activity:***Investigation*

Onset of the activation in milliseconds can be assessed in relation to onset of activation in other muscles, provocative activities or other aspects of a task. RATING: (i) Normal; (ii) Delayed: delayed activation of the PFM relative to the onset of a cough or a postural perturbation has been found in women with stress urinary incontinence.

**Surgery Type and Operated Compartment***Surgery – Female*

(a) Primary surgery: indicates the first procedure required for treating POP in any compartment. (b) Further surgery: provides a term for any subsequent procedure relating to primary surgery. Further surgery is subdivided into: Primary surgery in a different (new) site/compartment. Repeat surgery in the same site/compartment for POP symptom recurrence. Surgery for complications e.g. mesh exposure, pain, infection or hemorrhage. Surgery for non-POP-related conditions usually urinary or fecal incontinence.

**Suture hysteropexy - laparoscopic, robotic***Surgery – Female*

The plicated uterosacral ligaments are resutured to the cervix.

**Symptom***Symptom*

Any morbid phenomenon or departure from the normal in structure, function or sensation, possibly indicative of a disease or health problem. Symptoms are either volunteered by, or elicited from the individual, or may be described by the individual's partner or caregiver.

**Symptoms of sexual dysfunction***Symptom*

Complaint of abnormal sensation and/or function experienced by the individual during sexual activity.

**Symptoms of sexual dysfunction (female)***Symptom*

A departure from normal sensation and/or function experienced by a woman during sexual activity.

## T

### Tape (Sling)

#### *Surgery – Female*

A flat strip of synthetic material. The use of this term would be for incontinence surgery with synthetic materials.

### Tender Point

#### *Sign*

Tenderness to palpation at soft-tissue body sites.

### Tenderness

#### *Sign*

Sensation of discomfort with or without pain; discomfort elicited through palpation indicates unusual sensitivity to pressure or touch.

### Tenesmus

#### *Symptom*

Complaint of an urgent desire to evacuate the bowel accompanied by involuntary straining and the passage of little fecal matter.

### Tenesmus (female)

#### *Symptom*

A desire to evacuate the bowel, often accompanied by pain, cramping, and straining, in the absence of feces in the rectum.

### Terminal dribbling (dribble)

#### *Symptom*

Complaint that during the final part of voiding there is noticeable slowing of the flow to drops or a trickling stream.

### Testicular mass

#### *Sign*

Palpation of a mass originating from testis. This might be originating from the testicular parenchyma or its appendages and may be cystic or solid in nature and related to a benign or malignant (more commonly) neoplastic process.

### Testicular torsion

#### *Diagnosis*

Torsion of the spermatic cord structures that leads to vascular compromise involving the ipsilateral testicle. Physical examination might reveal a tender, swollen and erythematous hemiscrotum on the affected side.

### Testis - non-palpable

#### *Sign*

Absence of testis in the hemiscrotum or inguinal canal. This can be a finding related to cryptorchidism (undescended testicle), testicular atrophy or vanishing testis.

### Testis: atrophic

#### *Diagnosis*

Testicular dimensions being smaller than expected. Consistency of atrophic testes might be softer than usual. Diminished testis size may be accompanied by loss of function

### Testosterone - Bioavailable

#### *Investigation*

Bioavailable testosterone represents an assessment of the biologically active testosterone in serum. It includes the free plus weakly protein bound fractions of testosterone and is calculated by a formula integrating serum albumin, SHBG, and total testosterone.

### Testosterone - Free

#### *Investigation*

Fraction of total testosterone that is unbound plasma to proteins.

### Testosterone - Total

#### *Investigation*

Total testosterone can be measured in men with Erectile Dysfunction (ED) to determine if Testosterone deficiency (TD) is present.

### Thermal Modalities

#### *Conservative Management – Female*

**Cold treatment/cryotherapy:** Cold treatment is the application of ice for therapeutic purposes. It is used in the initial management of acute musculoskeletal injuries, to decrease edema through vasoconstriction and to reduce secondary hypoxic injury by lowering the metabolic demand of injured tissues. **Heat treatment (moist or dry):** Heat treatment consists of the application of heat to a body part, with the aim of relieving pain and/or stiffness. It is usually applied when an injury is older than 48h.

### Thermography or thermal imaging of the genital area

#### *Imaging*

Evaluation of genital temperature using a camera detecting infrared radiation from the skin during sexual stimulation. This method has been correlated with subjective arousal.

### Thiele's Massage

#### *Conservative Management – Female*

Per rectal digital massage of the levator ani, sweeping lengthwise along the muscle fibres. Massage is begun lightly and pressure is increased as tenderness decreases.

### Tight vagina

#### *Symptom*

Introital narrowing: vaginal entry is difficult or impossible (penis or sexual device). Vaginal narrowing: decreased vaginal calibre.

### Tight vagina (postoperative)

#### *Symptom*

(i) Introital narrowing: vagina entry is difficult or impossible (penis or sexual device).  
(ii) Vaginal narrowing: decreased vaginal calibre. These are de novo postoperative findings.

### Time to maximum urine flow rate (tQmax - unit: s)

#### *Investigation*

Elapsed time from the onset of urine flow to maximum urine flow.

### Tissue

#### *Surgery – Female*

A collection of similar cells and the intercellular substances surrounding them.

### Tissue

#### *Surgery – Complication related*

A collection of similar cells and the intercellular substances surrounding them.

### Total colpectomy

#### *Surgery – Female*

Total excision of the vagina in a woman with no uterus and vaginal eversion.

**Total Cystectomy***Surgery – Male*

The entirety of the organ (urinary bladder) is removed, usually for benign conditions

**Total vaginal length (TVL)***Sign*

This is the length of the vagina (cm) from posterior fornix to hymen with the posterior fornix reduced to its full normal position.

**Touch Desensitization***Conservative Management – Female*

Use of finger/hand, vibration or device to reduce hypersensitivity of soft tissues to touch/contact.

**Trans-abdominal ultrasound imaging in the mid-sagittal plane - Parameters and findings***Imaging*

Bladder base displacement; (a): A marker is placed at the point of greatest displacement (mm or cm) of the infero-posterior bladder wall at rest and at maximal contraction or bearing down. Direction and displacement of the bladder base movement from rest to final position. The bladder base is the most infero-posterior aspect of the bladder wall. INTERPRETATION: PFM contraction: Displacement from rest of the bladder base during (attempted) PFM contraction: (i) Elevation (normal response): Movement of the bladder base in a cephalad and ventral direction toward the pubic bone infers contraction of the levator ani/puborectalis; (ii) No change; (iii) Descent: Movement of the bladder base caudal and posterior away from the pubic bone infers elevated intra-abdominal pressure—PFMs may be active but this cannot be confirmed.

Bearing down: Displacement of the bladder base during sustained increased intra-abdominal pressure:

(i) Elevation; (ii) No change; (iii) Descent.

**Trans-abdominal ultrasound imaging in the transverse plane - Parameters and findings***Investigation*

(A) Symmetry of the bladder base: Equal curvature of bladder base with probe placed in the transverse plane; (B) Bladder base displacement: Movement of the bladder base (in mm or cm) is used as a surrogate measure for activity of the PFM.

INTERPRETATION: (A) Rest: Symmetrical or asymmetrical. Asymmetry can be related to

unilateral increased tone, unilateral decreased tone, operator error in probe position, or asymmetry of passive support (e.g., unilateral ligament damage/trauma). (B) Pelvic floor muscle contraction: Displacement of the bladder base during attempted PFM contraction: (i) Elevation (normal response): Movement of the bladder base in a cephalad/ventral direction; (ii) No change; (iii) Descent: Movement of the bladder base in a caudal/dorsal direction

(C) Bearing down: Displacement of the bladder base during sustained increased intra-abdominal pressure: (i) Elevation; (ii) No change; (iii) Descent (normal response).

**Transcutaneous electrical nerve stimulation (TENS)***Conservative Management – General*

This is electrical stimulation of the nerves through intact skin to modulate function and induce therapeutic response of the LUT.

**Transurethral vaporesection procedures of the prostate (ThuVAP): Thulium LASER***Surgery – Male*

Fragmented prostate tissue removal by resection and simultaneous vaporization using the continuous wave. Thulium LASER with a wavelength between 1940 and 2013 nm.

**Transurethral resection of the prostate (HoLRP): Holmium LASER***Surgery – Male*

Fragmented prostate tissue removal by using the pulsed 2140 nm wavelength holmium LASER.

**Transurethral resection of the prostate (ThuRP or TmLRP): Thulium LASER***Surgery – Male*

Fragmented prostate tissue removal by using the continuous wave thulium LASER with a wavelength between 1940 and 2013 nm.

**Transurethral resection of the prostate (TURP): Electrical***Surgery – Male*

Fragmented prostate tissue removal using a resection loop and monopolar (m-TURP) or bipolar electric current (b-TURP).

**Transurethral resection of the prostate (TURP): General***Surgery – Male*

Usually done in small to intermediate volume prostates but can be dependent on the experience and resection speed of the operating surgeon.

**Transurethral resection of the prostate: Aquablation***Surgery – Male*

Robot-assisted, fragmented prostate tissue removal by using a powerful waterjet stream (hydrodissection) under transrectal ultrasound control of the prostate.

**Transurethral bladder biopsy***Surgery – Male*

Removal of sample of bladder tissue or lesion by the endoscopic, transurethral route, by means of mechanical or diathermic instrument with diagnostic intent.

**Transurethral Catheter for Urodynamics***Investigation*

ICS standard invasive urodynamics is done with the thinnest possible (6-7F) transurethral double or triple lumen catheter or a suprapubic catheter.

**Transurethral cystolithotripsy / cystolitholapaxy***Surgery – Male*

Fragmentation of a bladder stone via the transurethral route with urethral removal of fragments. Different energy sources can be used, from direct mechanical to LASER impulses.

**Transurethral enucleation procedures of the prostate (DiLEP): Diode LASER***Surgery – Male*

En bloc removal of transition zone by using the diode LASER with a wavelength of 940, 980, 1318, or 1470 nm (depending of the used semiconductor) to approach the surgical capsule and blunt peeling of the prostatic adenoma with the shaft of the resectoscope.

**Transurethral enucleation procedures of the prostate (Green-LEP): "Green-light" LASER***Surgery – Male*

En bloc removal of the transition zone using the 532 nm wavelength KTP (kalium [potassium] titanyl phosphate) or LBO (lithium borat) LASER to approach the surgical capsule and blunt peeling of the prostatic adenoma with the shaft of the resectoscope

**Transurethral enucleation procedures of the prostate (HoLEP): Holmium LASER***Surgery – Male*

En bloc removal of the transition zone and separation of the tissue between the adenoma and surgical capsule by using the pulsed 2100 nm wavelength holmium LASER.

**Transurethral enucleation procedures of the prostate (ThuLEP): Thulium LASER***Surgery – Male*

En bloc removal of transition zone by using the thulium LASER with a wavelength between 1940 and 2013 nm to approach the surgical capsule and blunt peeling of the prostatic adenoma. The thulium LASER vapo-enucleation (ThuVEP) technique is identical.

**Transurethral enucleation procedures of the prostate (TUEP, TUBE or EEP): Electrical***Surgery – Male*

En bloc removal of the transition zone by using monopolar or bipolar electric current and specifically designed hooks or loops to approach the surgical capsule and blunt peeling of the prostatic adenoma with the shaft of the resectoscope afterwards.

**Transurethral enucleation procedures of the prostate (TUEP): General***Surgery – Male*

Usually done in large volume prostates (>80 cm<sup>3</sup>) but can also be done in small or intermediate volume prostates.

**Transurethral procedures of the prostate: General***Surgery – Male*

Various prostate operations through the urethra to widen the proximal prostatic urethra by removal or compression of the transition zone. Tissue removal may be immediate or delayed.

**Transurethral procedures of the prostate: with immediate tissue ablation***Surgery – Male*

Transurethral operations with removal of prostate tissue during the operation using different energy sources (electric current, LASERS, or highly focused waterjet) and tissue removal techniques (fragmented, en bloc, or by vaporization), with or without suprapubic trocar to aid bladder irrigation. The resection is limited to the proximal prostatic urethra (resection margin: verumontanum)

**Transurethral prostate procedures with delayed tissue removal: Botulinum toxin injections of the prostate.***Surgery – Male*

Destruction and secondary ablation of prostate tissue by transurethral (transrectal, transperineal) injection of 100–300 U onabotulinumtoxinA (Botox) or 300–600 U abobotulinumtoxinA (Dysport).

**Transurethral prostate procedures with delayed tissue removal: Convective water vapor energy (WAVE) ablation of the prostate.***Surgery – Male*

Destruction and secondary ablation of tissue by transurethral application of water vapor thermal energy injected into the prostate by needles.

**Transurethral prostate procedures with delayed tissue removal: Ethanol toxin injections of the prostate.***Surgery – Male*

Destruction and secondary ablation of prostate tissue by transurethral injection of dehydrated 95–98% ethanol.

**Transurethral prostate procedures with delayed tissue removal: NX-1207 injections of the prostate.***Surgery – Male*

Destruction and secondary ablation of prostate tissue by transurethral (or transrectal) injection of fexapotide trifluate (NX-1207).

**Transurethral prostate procedures with delayed tissue removal: PRX302 injections of the prostate.***Surgery – Male*

Destruction and secondary ablation of prostate tissue by transurethral (or transrectal) injection of topsalsysin (PRX302).

**Transurethral prostate procedures with delayed tissue removal: Transurethral microwave therapy (TUMT)***Surgery – Male*

Destruction and secondary ablation of prostate tissue by transurethral delivery of high-energy microwaves through an intraurethral antenna. Tissue is destroyed by being heated up to temperatures above cytotoxic thresholds (>45°) causing coagulation necrosis

**Transurethral prostate procedures with delayed tissue removal: Transurethral needle ablation of the prostate (TUNA).***Surgery – Male*

Destruction and secondary ablation of prostate tissue by insertion of needles into the prostate and application of radiofrequency thermal energy causing a coagulation necrosis.

**Transurethral prostate procedures without delayed tissue removal: General.***Surgery – Male*

Immediate relief of benign prostatic obstruction by incision or compression of prostatic tissue without tissue removal. Minimally-invasive procedures aim to reduce morbidity compared with operations with immediate tissue removal.

**Transurethral prostate procedures without delayed tissue removal: Prostatic stents.***Surgery – Male*

Transurethral implantation of metallic prostate stents of different shapes and materials. Prostate stents may be implanted temporarily (removable) or permanently (nonremovable). The latest development is the iTIND system made out of nitinol which is transurethral inserted into the prostatic urethra where it expands and incises the prostatic tissue at the 5 and 7 o'clock positions, similar to TUIP. The iTIND device is removed 5 days later.

**Transurethral prostate procedures without delayed tissue removal: Prostatic urethral lift (PUL).***Surgery – Male*

Transurethral implantation of small anchors (made of nitinol, stainless steel, and a polyester suture) through the entire anterior prostate which compress

prostatic tissue against the anatomic prostate capsule to widen the proximal anterior prostatic urethra. PUL works best in small to intermediate volume prostates ( $\leq 60$ – $80$  cm<sup>3</sup>).

**Transurethral prostate procedures without delayed tissue removal: Transurethral incision of the prostate (TUIP)..**

*Surgery – Male*

Diathermic incision of the transition zone at the 5 and 7 o'clock positions until the prostate capsule from the ureteral orifices until the verumontanum. TUIP works best in small volume prostates ( $\leq 30$  cm<sup>3</sup>). Some surgeons incise unilaterally to reduce the risk of retrograde ejaculation.

**Transurethral resection of the bladder**

*Surgery – Male*

Removal of bladder tissue or lesion by endoscopic transurethral route with both, diagnostic and therapeutic intent. Different energy sources can be used (electric energy, LASER)

**Transurethral resection of the urethra**

*Surgery – Male*

Mono- or bipolar electric ablation of intraluminal tissue of the penile or bulbar urethra using a resectoscope and a resection loop or LASER, mostly done for urethral tumors.

**Transurethral vaporessection of the prostate procedures (TUVRP, TUVVP): Electrical**

*Surgery – Male*

Fragmented prostate tissue removal by electric resection and simultaneous vaporization using a broad resection loop (combination of TURP and b-TUVP).

**Transurethral vaporessection of the prostate procedures: General**

*Surgery – Male*

Usually done in small to intermediate volume prostates ( $\leq 80$  cm<sup>3</sup>)

**Transurethral vaporization procedures of the prostate (B-TUVP): Bipolar**

*Surgery – Male*

Prostate tissue removal by vaporization using high-frequency bipolar electric current.

**Transurethral vaporization procedures of the prostate (D-VAP): Diode LASER**

*Surgery – Male*

Prostate tissue removal by vaporization using the diode LASER with a wavelength of 940, 980, 1318, or 1470 nm (depending of the used semiconductor)

**Transurethral vaporization procedures of the prostate (GreenLight-VAP): "Greenlight" LASER**

*Surgery – Male*

Prostate tissue removal by vaporization using the 532 nm wavelength KTP (kalium [potassium] titanyl phosphate) or LBO (lithium borat) LASER.

**Transurethral vaporization procedures of the prostate (HoLAP): Holmium LASER**

*Surgery – Male*

Prostate tissue removal by vaporization using the pulsed 2140 nm wavelength holmium LASER

**Transurethral vaporization procedures of the prostate (ThuVAP): Thulium LASER**

*Surgery – Male*

Prostate tissue removal by vaporization using the continuous wave thulium LASER with a wavelength between 1940 and 2013 nm.

**Transurethral vaporization procedures of the prostate: General**

*Surgery – Male*

Usually done in small to intermediate volume prostates ( $\leq 80$  cm<sup>3</sup>).

**Transverse friction**

*Conservative Management – Female*

The operator's fingertip is placed on the exact site of the lesion and rubbed firmly across the direction of the fibres of the affected tissue.

**Transurethral prostate procedures with delayed tissue removal: General**

*Surgery – Male*

Transurethral prostate operations using different energy sources or molecules which cause tissue damage during the operation and delayed desquamation (sloughing) of prostatic tissue during the next weeks or months, thereby reducing benign prostatic obstruction over time.

**Trattner double balloon catheter test for urethral fistula**

*Investigation*

The Trattner catheter has two balloons, one sits intravesically and the other inflates outside of the meatus to block efflux from the urethra. The irrigant flows out through a lumen that sits between the balloons, isolating fill to the urethra

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and Possible Sexual Dysfunction - Intravesical therapies (Pentosan polysulfate, DMSO, hyaluronic acid, chondroitin sulfate):**

*Surgery – Male*

Comment: No direct effect on sexual dysfunction.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Acupuncture**

*Conservative Management – Male*

Procedure that consists in inserting acupuncture needles in specific anatomic locations or "acupoints."

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Antibiotics**

*Conservative Management – Male*

This treatment is indicated for chronic bacterial prostatitis (category II of the NIH).

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Anticonvulsants**

*Conservative Management – Male*

Pregabalin may cause ED, anorgasmia and loss of libido.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Anti-inflammatory**

*Conservative Management – Male*

Nonsteroidal anti-inflammatory drugs (NSAIDs) treatment is based on decreasing the pain mediated by inflammatory pathways. Additional comment: no direct effect on sexual dysfunction.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Botulinum toxin injection.**

*Surgery – Male*

Comment: No direct effect on sexual dysfunction

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Cystoscopy and bladder hydrodistension**

*Surgery – Male*

Procedure that consists in distending the bladder during cystoscopy, at a pressure of 80–100 cm H<sub>2</sub>O, lasting 1–2 min and up to two times. Additional comment: No direct effect on sexual dysfunction.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Extracorporeal shockwave therapy**

*Conservative Management – Male*

Periodic stimulation of the perineum with extracorporeal low-energy shockwaves.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Lifestyle modification**

*Conservative Management – Male*

Treatment based on avoiding irritant food, having a balanced diet, adopting certain sexual habits, avoiding perineal trauma and having a healthy lifestyle. - Additional comment: usually beneficial

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Nerve blockade/epidural pain pump**

*Conservative Management – Male*

Treatment based on the administration of analgesics directly into the epidural space with a small catheter and a pump. Additional comment: usually beneficial though chronic use of opioids is associated with worsening of sexual dysfunction.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Neuromodulation**

*Surgery – Male*

Comment: Some studies have shown improvement in sexual function in a neurogenic patient.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Non-pharmacological therapies**

*Conservative Management – Male*

These therapies aim at symptomatic improvement by changing behavioral and environmental issues and also include minimally invasive therapies with a low risk for adverse events

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: PDE5I**

*Surgery – Male*

PDE5i may alleviate CP/CPPS symptoms by reducing oxidative stress and inflammation on the prostate and PF.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Physical Activity**

*Conservative Management – Male*

Treatment based on a regular exercise program. Additional comment: usually beneficial.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Transrectal thermotherapy**

*Conservative Management – Male*

Application of transrectal radiofrequency hyperthermia on the prostate.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Transurethral resection**

*Surgery – Male*

Comment: retrograde ejaculation may be a side-effect.

**Treatments for Chronic Prostatitis (CP)/ Chronic Pelvic Pain Syndrome (CPPS) and possible Sexual Dysfunction: Tricyclic antidepressants (TCA)**

*Conservative Management – Male*

Amitriptyline may have a negative impact on arousal and libido, especially on depressive patients.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Active surveillance (AS)**

*Conservative Management – Male*

A treatment plan that involves closely watching a patient's condition but not giving any treatment unless there are changes in test results that show the condition is getting worse. This is suitable for men with favorable-risk prostate cancer (very low to low-risk) who wish to avoid treatment associated

harm. Intervention for cure is pursued in those who experience disease progression while on AS. Additional comment: Erectile dysfunction, loss of sexual desire possible.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Androgen deprivation therapy (ADT)**

*Conservative Management – Male*

An

antihormone therapy used to control prostate cancer.

Prostate cancer cells require androgens to grow. ADT reduces the levels of androgens in the body thereby

slowing prostate cancer growth and progression. Additional comments on side-effects: Ejaculatory dysfunction, erectile dysfunction, hypogonadism, loss of sexual desire, orgasmic disorder, penile shortening.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Brachytherapy**

*Conservative Management – Male*

Delivery of radioactive material sealed in needles, seeds, wires or catheters directly into the prostate gland for curative management of prostate cancer.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Conformal Radiation Therapy**

*Conservative Management – Male*

A type of three-dimensional (3D) radiation therapy that uses computer-generated images to show the size and shape of the tumor. As a result, a higher and more effective dose of radiation can be delivered directly to cancerous cells.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Cryotherapy**

*Surgery – Male*

Focal delivery of the cryoprobe transrectally to the prostate to induce extremely low temperatures with subsequent thawing. This process results in direct cellular injury and a delayed inflammation-mediated mechanism of cellular destruction.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: External Beam Radiation Therapy**

*Conservative Management – Male*

A form of radiation therapy that uses multiple radiation beams and/or arcs to provide a highly conformal treatment of the prostate with normal tissue

sparing of adjacent organs, such as the rectum and bladder. Additional comment: Ejaculatory dysfunction, erectile dysfunction.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Focal therapy**

*Conservative Management – Male*

Tissue-preserving strategy aimed to target the cancer and not the whole organ when it is morphometrically possible to do so and thus reduce damage to collateral tissues. Additional comment: Erectile dysfunction still possible.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: High-dose rate (HDR) brachytherapy.**

*Conservative Management – Male*

Utilizes temporary catheters implanted in the prostate to allow for the delivery of a high-activity radiation source.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: High-intensity focused ultrasound (HIFU)**

*Conservative Management – Male*

Focal delivery of ultrasonic waves (frequencies 0.8 to 3.5 MHz) to selectively initiate cellular damage.

The energy of the ultrasonic waves is absorbed by the target tissue and converted to heat causing coagulative necrosis. Furthermore, inertial cavitation is caused by alternating cycles of compression and rarefaction.

13.5.3 Irreversi

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Intensity-Modulated Radiation Therapy**

*Surgery – Male*

A type of 3D radiation therapy that uses computer-generated images to show the size and shape of the tumor. Thin beams of radiation of different intensities are aimed at the tumor from many angles. This type of radiation therapy reduces the damage to healthy tissue near the tumor.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Irreversible electroporation**

*Surgery – Male*

Delivery using a Nanoknife system to deploy a low-energy direct current to a targeted region within the prostate.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Laser Ablation**

*Surgery – Male*

Utilization of a laser to focally ablate the tissue.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Low-dose rate (LDR) brachytherapy.**

*Conservative Management – Male*

Utilizes radioactive seeds that are implanted based on pretreatment and intraoperative image-guidance according to a computer plan.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Nerve-sparing Radical prostatectomy**

*Surgery – Male*

Avoidance of electrocautery and high anterior release with careful lateral dissection and gentle lateral traction preserves the NVBs as they course anterior to Denovilliers' fascia at the posterolateral edge of the prostate.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Photodynamic therapy**

*Surgery – Male*

Use of pharmacological agents that become active in the presence of light (photosensitizers) to kill malignant cells.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Proton Beam Radiation Therapy**

*Conservative Management – Male*

A type of radiation therapy that uses streams of protons (tiny particles with a positive charge) to kill tumor cells. This type of treatment can reduce the amount of radiation damage to healthy tissue near a tumor.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Radiation therapy.**

*Conservative Management – Male*

Delivery of ionizing radiation treatments to the prostate to control or kill malignant cells. Additional comment: Ejaculatory dysfunction, erectile dysfunction.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Radical Prostatectomy**

*Surgery – Male*

Climacturia, ejaculatory dysfunction, erectile dysfunction, orgasmic dysfunction, Peyronie's, penile shortening

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Radiofrequency ablation (RFA)**

*Imaging*

Use of a bipolar radiofrequency ablation probe transperineally to deliver radio waves that heat and destroy abnormal cells.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Salvage prostatectomy**

*Surgery – Male*

Operative removal of the prostate with the goal of successfully eradicating locally recurrent cancer after definitive radiation.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Stereotactic Body Radiation Therapy (SBRT)**

*Conservative Management – Male*

A form of radiation therapy that uses photon-based IMRT to deliver hypofractionated radiation usually in five or fewer fractions of treatment to kill malignant cells.

**Treatments for Prostate Cancer and possible Sexual Dysfunction: Watchful waiting (WW)**

*Conservative Management – Male*

Waiting until the disease progresses to intervene with a palliative approach. Historically, the aim of WW was to avoid treatment altogether among men with a limited life expectancy and advanced disease detected in an era when screening was not routine.

**Trigger Point (TrP)**

*Sign*

A tender, taut band of muscle that can be painful spontaneously or when stimulated. The taut band is electrically silent.

**Triple swab test for urinary tract fistula.***Investigation*

Three separate sponge swabs, one above the other, are placed in the upper, middle, and lower vagina.

The bladder is then filled with a colored irrigant such as diluted methylene blue, and the swabs are removed after 10 min (it can take up to 30 min for urine to come through a tiny tortuous fistula especially if it is in the cervix or uterus). Discoloration of only the lowest swab supports diagnosis of a low urethral fistula or urethral leakage. Diagnosis of a uretero-genital fistula is supported when the uppermost swab is wet but not discolored. A VVaF fistula diagnosis is supported when the upper swabs are wet with blue irrigant. Careful observation for backflow of blue irrigant per meatus must be ongoing to avoid false-positive test reporting.

**Trocar***Surgery – Female*

A surgical instrument with either a pyramidal, conical or needle-type cutting or dissecting point.

**Trophic***Sign*

Promoting cellular growth, differentiation, and survival. This is the normal status of an organ, tissue or cell with regard to nutrition, size, number, form, and function. Atrophic urogenital tract is usually well-estrogenized.

**U****Ulcer***Surgery – Complication related*

A lesion through the skin or a mucous membrane resulting from loss of tissue, usually with inflammation.

**Ultrasound applications in male LUT/PF dysfunction***Imaging*

(1) Post void residual (see separate heading); (2) Intercurrent abnormalities: prostate volume (transabdominal, intraabdominal, retroperitoneal or intrapelvic tumor, hydronephrosis); (3) Bladder abnormalities: tumor, foreign body, overdistension, stones; (4) Detrusor wall thickness (see separate heading); (5) Ultrasound estimated bladder weight (UEBW); (6) Intravesical prostatic protrusion (IPP): See separate heading; (7) Urethral abnormality: diverticulum, urethral stenosis, degree and depth of spongiofibrosis; (8) Postoperative findings: post-prostatectomy (urethral shape), male sling position, artificial urinary sphincter placement of cuff and reservoir, bulking agents; (9) Prostate ultrasound: determination of prostate and transition zone volume, prostate shape and visualization of the prostate parenchyma for calcifications, cysts, abscesses or enlargement.

**Ultrasound elastography imaging - Pelvic floor strain elastography***Imaging*

Strain elastography to assess deep PFM elasticity and periurethral elasticity as an estimate of urethral

mobility. (A) To assess deep PFM: A perineal transducer is placed perpendicular to the skin in the sagittal plane to identify levator ani muscle. The levator ani muscle is selected on screen and labeled as the target tissue (region of interest [ROI]A), and the adjacent anal canal is selected and labeled as reference tissue (ROI B).

(B) To assess urethral support tissues: an endovaginal transducer is placed parallel to the urethral meatus. The target tissue is the tissue between the urethra and the vagina (para-urethral tissue) (ROI A), and the reference tissue is set at the level of the posterior tissue of the bladder neck (ROI B).

INTERPRETATION: The higher the value of B/A, the stiffer the target tissue. A

**TrP Treatment (aka myofascial trigger point treatment)***Conservative Management – Female*

Soft-tissue mobilization specifically targeting trigger points and may include ischemic pressure, massage, myofascial release, electrotherapy, ultrasound, laser, spray-and-stretch, injection (a variety of chemicals including local anesthetic, botox or steroids), dry needling (insertion of a solid needle into the TrP), and stretching.

**Twenty-four (24) hour (urinary) frequency***Sign*

Total number of daytime and night-time micturitions during a specified 24-hour period.

**Twenty-four (24) hour urine volume***Sign*

Summation of all urine volumes during a specified 24-hour period. The first void after rising is discarded and the 24-hour period begins at the time of the next void and is completed by including the first void, after rising, the following day.

**Twenty-four (24) hour voided volume***Sign*

Total volume of urine voided in a 24 hour period. (1st void to be discarded; 24 hours begins at the time of the next void).

4-point elasticity score has been used to represent levator ani muscle elasticity.

**Ultrasound elastography imaging - Perineal shear wave elastography (SWE)***Imaging*

Shear wave elastography applied per perineum. Only 2D SWE has been applied to the PFM. A linear transducer is placed against the perineum/vulva. Orientation is longitudinal (for assessing urethral sphincter), or aligned with the muscle fibers for specific PFM (e.g., puborectalis) assessment. A linear or curved transducer can be used. Stiffness is evaluated using quantitative shear modulus maps represented in a color-coded elastogram displaying shear-wave velocities in meters per second or tissue elasticity (shear elastic modulus) in kilopascals. INTERPRETATION: Higher values indicate stiffer tissue. Measures may provide evidence of stiffer tissue at rest (e.g., high activation of PFM at rest) and should increase with contraction. Quality of measurement depends on orientation of the transducer (parallel with muscle fibers), accuracy of movement of the transducer to follow the movement of the muscle during contraction. Measures are compromised if there are areas in the image where the measure is saturated (stiffness greater than the measurable scale) or unable to be quantified by the system.

**Ultrasound elastography imaging - Shear wave elastography (SWE)***Imaging*

Ultrasound elastography using shear waves generated by the US beam. Different types are point SWE, 2D SWE, and transient elastography. 2D SWE uses an acoustic radiation force pulse sequence to generate shear waves, which propagate perpendicular to the ultrasound beam, causing transient displacements. The distribution of shear wave velocities at each pixel is directly related to the shear modulus in kilopascal (kPa), an absolute measure of the tissue's elastic properties. This technique is considered more objective than strain elastograph. INTERPRETATION: Higher values indicate stiffer tissue, as shear waves propagate faster in stiffer tissues. Stiffness measures include both active (muscle contraction) and passive (visco-elastic properties) components of the tissue.

### Ultrasound elastography imaging - Strain elastography

#### Imaging

Ultrasound elastography which measures strain in one tissue area proportional to another. Maps, or elastograms, are developed based on the relative differences in stiffness between the area of interest and the reference tissue. The assessor applies slight and constant vertical compression through the transducer along the major axis of the tissue. Elasticity is measured by means of the Young's modulus and is defined as the ratio between the pressure measured and the strain (deformation compared to the initial length) produced. Soft tissue is more compressible than harder tissue and therefore has a higher strain (displacement) for the same applied stress (force). The results of strain elastography can only be expressed qualitatively or semi-quantitatively. ANALYSIS: (i) Qualitative analysis: The different colors express different degrees of elasticity, usually varying from red (soft tissue) to blue (hard tissue) with intermediate colors representing intermediate degrees of stiffness. (2) Semi-quantitative analysis: the target tissue is selected and labeled as the region of interest (ROI) A, and the reference tissue is labeled as ROI B. Elasticity of tissue expressed as a strain ratio: B/A. The higher the value of B/A, the stiffer the target tissue.

### Ultrasound imaging - post-void residual (PVR - abdominal)

#### Imaging

Volume = width (left to right) x depth (anterior to posterior) x length (cranial to caudal) x 0.52 (mL)

### Ultrasound imaging - uses (female)

#### Imaging

(i) Bladder neck descent / mobility/ opening including position of bladder neck at rest and on Valsalva; (ii) Post void residuals; (iii) Intercurrent pelvic pathology: e.g. Uterine and adnexal pathology; (iv) Uterine version: Anteverted or retroverted; flexion at level of isthmus; (v) Bladder abnormalities: e.g. tumor; foreign body; (vi) Urethral abnormality: e.g. diverticulum; (vii) Postoperative findings: e.g. bladder neck position and mobility, position of meshes, tapes or implants; (viii) Pelvic floor / levator defects: Bladder neck elevation during pelvic floor contraction; (ix) Descent of pelvic organs: Visualization of descent of the bladder, uterine cervix and rectum during Valsalva and coughing.

### Ultrasound imaging (female) - 3D imaging of ballooning of the genital hiatus

#### Imaging

The presence of ballooning of the genital hiatus (= excessive distensibility of the levator hiatus) on Valsalva manoeuvre has also been associated to the severity of urogenital prolapse. An area of more than 25 cm<sup>2</sup>, 30 cm<sup>2</sup>, 35 cm<sup>2</sup> and 40 cm<sup>2</sup> has been defined as mild, moderate, marked and severe ballooning respectively.

### Ultrasound imaging (female) - 3D imaging of levator ani trauma

#### Imaging

The presence of levator ani trauma has been postulated to be associated to an increased risk of pelvic organ prolapse. This can be evaluated using a tomographic ultrasound imaging assessment of the levator ani muscles.

### Ultrasound imaging (female) - 3D of female urethra

#### Imaging

3D imaging of the rhabdosphincter overcomes the limits of MRI and two-dimensional (2D) ultrasound imaging that incorrectly measure the urethral sphincter volume using mathematical formulas based upon assumptions that the shape of the urethra is similar to that of an ellipse. Since the urethral shape is neither elliptical nor spherical, but rather an atypical geometric shape, equations should not be used.

### Ultrasound imaging (female) - combined with urodynamics

#### Imaging

Synchronous ultrasound screening of the bladder and/or urethra and measurement of the bladder and abdominal pressure during filling and voiding cystometry.

### Ultrasound imaging (female) - prolapse related - 3D (modalities)

#### Imaging

(i) Endovaginal ultrasound imaging may inadvertently compress tissues thus distorting the anatomy; (ii) Transanal ultrasound approach requires an expensive and dedicated transducer, and it is a more uncomfortable and embarrassing test for the woman. Its most common clinical indication is the assessment of sphincter integrity following obstetric trauma. (iii) Translabial/transperineal approach overcomes the limitations of endovaginal and transrectal techniques providing minimal pressure on local structures and it is least likely to alter surrounding anatomy.

### Ultrasound imaging (female) - prolapse related 3D evaluations

#### Imaging

The following pelvic floor abnormalities can be evaluated: (i) trauma (injury/damage) of the levator ani muscle (LAM); (ii) excessive distensibility of the puborectalis muscle and levator hiatus ("ballooning"); (iii) pathologies of the anterior vaginal compartment like urethral diverticula; (iv) bladder tumours or foreign bodies (sling, mesh, bulking agents); (v) Polypropylene meshes: highly echogenic and thus easily identified in the coronal and axial plane, unless they are obscured by vaginal prolapse; (vi) Periurethral bulking agents, used as a continence procedure, can also be depicted with 3D pelvic floor ultrasound.

### Ultrasound imaging (female) - prolapse related clinical applications

#### Imaging

(i) Bladder neck descent/mobility. The position of the bladder neck at rest and on Valsalva; (ii) Urethral funnelling: i.e., opening of the proximal third of the urethra during coughing or on Valsalva; (iii) Post void residual: Several formulas have been described in the literature to measure the bladder volume by ultrasound. An early formula [(h x d x w) x 0.7] has been demonstrated to give reproducible results with a percentage error of 21%; (iv) Bladder abnormalities: e.g. tumor, foreign body; (v) Urethral abnormality: e.g. diverticulum; (vi) Intercurrent uterine and/or pelvic abnormality: dependent on probe range; (vii) Postoperative findings: e.g., bladder neck position and mobility, position of meshes, tapes, or implants; (viii) Descent of pelvic organs: visualization of descent of the bladder, uterine cervix, and rectum during Valsalva and coughing; (ix) Assessment of voluntary pelvic floor muscle contractility; (x) Pelvic floor/ levator ani muscle defect and hiatal ballooning; (xi) Ultrasound measurements of bladder and detrusor wall thickness, and ultrasound estimated bladder weight (UEBW) are potential noninvasive clinical tools for assessing the lower urinary tract. UEBW is higher in women with overactive bladder and detrusor overactivity.

### Ultrasound imaging (male) - anal endosonography (AES)

#### Imaging

Looking for: Anal sphincter defects

### Ultrasound imaging (male) - bladder abnormalities

#### Imaging

Tumor, foreign, overdistension, stones, diverticulum.

### Ultrasound imaging (male) - bladder wall thickness (BWT)

#### Imaging

Distance from outer border of the mucosa to the outer border of the ad-

ventitia on the anterior bladder wall with a linear 7.5MHz linear array in a bladder filled over 250ml.

#### **Ultrasound imaging (male) - detrusor wall thickness (DWT)**

##### *Imaging*

Measured from the inner border of the mucosa to the inner border of the adventitia at the anterior bladder using linear 7.5MHz array in bladder filled over 250ml. Over 2mm points to BOO.

#### **Ultrasound imaging (male) - intercurrent pathology**

##### *Imaging*

Prostate volume (transrectal), tumor, hydronephrosis, scrotal abnormalities.

#### **Ultrasound imaging (male) - intravesical prostatic protrusion (IPP)**

##### *Investigation*

The distance from the bladder base until the tip of the prostate in the bladder lumen.

#### **Ultrasound imaging (male) - postoperative findings**

##### *Imaging*

Post-prostatectomy (urethral shape), male sling position, artificial sphincter - placement of cuff and reservoir, bulking agents.

#### **Ultrasound imaging (male) - prostatic volume (transrectal)**

##### *Imaging*

Prostatic volume = Anteroposterior (cm) x transverse (cm) x transrectal (cm)

#### **Ultrasound imaging (male) - urethral abnormality**

##### *Imaging*

Diverticulum, stenosis, degree and depth of spongiofibrosis.

#### **Ultrasound imaging modalities (female)**

##### *Imaging*

(i) Perineal: Curved array probe applied to the perineum. This term incorporates transperineal and translabial ultrasound; (ii) Introital: Sector probe applied to the vaginal introitus; (iii) Transvaginal (T-V): Intravaginal curvilinear, linear array or sector scanning; (iv) Transabdominal (T-A): Curvilinear scanning applied to the abdomen.

#### **Ultrasound imaging modalities (Male)**

##### *Imaging*

Transrectal (linear array or sector); transabdominal (curved or linear array); perineal (curved array); scrotal (curved array).

#### **Ultrasound imaging sites (male)**

##### *Imaging*

Renal, bladder, prostate, scrotum urethra, ano-rectum

#### **Ultrasound in Urogynecology**

##### *Imaging*

Ultrasound has become an increasingly frequent adjunct investigation in urogynecology and female urology both in the office and in the urodynamic laboratory.

#### **Ultrasound in Urogynecology - Current Routine Possible Uses**

##### *Imaging*

(a) Bladder neck descent/mobility/opening: Position of bladder neck at rest and on Valsalva.

N.B: Ideally the Valsalva should be standardized but it is appreciated that at present a reliable non-invasive method is lacking. Consensus has not been reached on criteria for excessive bladder neck mobility nor the relationship of this finding to a diagnosis of urodynamic stress incontinence. Position

of bladder neck during pelvic floor contraction. Retrovesical angle (RVA): that is, angle between proximal urethra and trigonal surface of the bladder. Urethral rotation: that is, rotation of the proximal urethra on Valsalva. Angle gamma: that is, angle defined by lines from the infero-posterior symphyseal margin to the bladder neck at rest and on Valsalva. Urethral funneling: that is, opening of the proximal third of the urethra during coughing or on Valsalva. Urine loss: full urethral opening during coughing, Valsalva, bladder contraction, or micturition.

(b) Postvoid residuals; (c) Intercurrent pelvic pathology: for example, uterine and adnexal pathology. (d) Uterine version: Anteverted or retroverted; flexion at level of isthmus; (e) Bladder abnormalities: for example, tumor, foreign body; (f) Urethral abnormality: for example, diverticulum; (g) Postoperative findings: For example, bladder neck position and mobility, position of meshes, tapes, or implants; (h) Pelvic floor/levator defects: Bladder neck elevation during pelvic floor contraction. (i) Descent of pelvic organs: Visualization of descent of the bladder, uterine cervix, and rectum during Valsalva and coughing.

#### **Ultrasound in Urogynecology - Modalities in Current Routine Clinical Use**

##### *Imaging*

(a) Perineal: Curved array probe applied to the perineum. This term incorporates transperineal and translabial ultrasound. (b) Introital: Sector probe applied to the vaginal introitus. (c) Transvaginal (T-V): Intravaginal curvilinear, linear array, or sector scanning. (d) Transabdominal (T-A): Curvilinear scanning applied to the abdomen.

#### **Ultrasound in Women - 3D and 4D**

##### *Imaging*

The potential of 3D ultrasound in urogynecology and female urology is currently being researched with validated applications likely to be included in future updates of this report and/or separate ultrasound reports. Applications with the most current research include: (i) major morphological abnormalities such as levator defects and (ii) excessive distensibility of the puborectalis muscle and levator hiatus ("ballooning"<sup>40</sup>). The additional diagnostic potential of 4D (i.e., the addition of movement) ultrasound awaits clarification by further research.

#### **Unbacked pads: Defining features**

##### *Conservative Management – Female*

Absorbent products without a waterproof backing used either (a) inside another product such as a category 6 product to supplement its absorption capacity or to reduce the frequency with which it needs to be changed (the unbacked pad may be changed with relative ease, without necessarily needing to also change the outer product), or (b) on its own, secured using separate, close-fitting, underwear which itself includes waterproofing in the pad area.

#### **Unbacked pads: Main variant features**

##### *Conservative Management – Female*

- Products may be used by either sex.
- Products may be rectangular or contoured to better fit the wearer.
- Products come with different absorption capacities.
- Products may or may not be suitable for containing fi as well as UI.

#### **Underactive Pelvic Floor Muscles**

##### *Diagnosis*

A situation in which the pelvic floor muscles cannot voluntarily contract when this is appropriate. This condition is based on symptoms such as urinary incontinence, anal incontinence or pelvic organ prolapse, and on signs like no voluntary or involuntary contraction of the pelvic floor muscles.

**Underactive pelvic floor muscles (female)***Sign*

Pelvic floor muscles which cannot voluntarily contract when this is appropriate.

**Ureter procedures: Anastomosis to a bowel segment - the Bricker technique***Surgery – Male*

Spatulating and anastomosing each ureter to the serosa of the bowel segment separately.

**Ureter procedures: Anastomosis to a bowel segment - Wallace I surgical technique***Surgery – Male*

Both ureters are spatulated to the same length. Their medial walls are anastomosed together, and the free edges of the newly conjoined ureters are then anastomosed to the proximal end of an open bowel segment.

**Ureter procedures: Anastomosis to a bowel segment - Wallace II surgical technique***Surgery – Male*

Head-to-tail anastomosis: Blood supply is protected by suturing the apex of one ureter to the end of the other. The posterior medial walls are sutured together and then the ends and lateral walls are sutured to the bowel segment.

**Ureter procedures: Endoluminal stents (ureteral stenting)***Surgery – Male*

Threading a thin tubular catheter into segments of the ureter, either down into the bladder internally, or to an external collection system, through the skin (percutaneously), or through the bladder via a cystoscope. Stents consist of an elongated body portion and a retention module.

**Ureter procedures: Endoureterotomy***Surgery – Male*

Endoscopic incision of a benign ureteral lesion or ureteroenteric strictures.

**Ureter procedures: Unilateral/bilateral retrograde pyelogram***Surgery – Male*

Evaluation of the ureter by injection contrast on either side and undertaking live fluoroscopy to delineate the anatomy of the ureter.

**Ureter procedures: Ureterolithotomy***Surgery – Male*

Open, laparoscopic or robot-assisted removal of a calculus lodged in the ureter through a direct incision of ureter over the calculus.

**Ureter procedures: Ureterolysis***Surgery – Male*

Mobilization and freeing of the ureter by surgical displacement of the ureters from the surrounding disease/adhesions, or from retroperitoneal fibrosis process with lateral/intraperitoneal transposition and/or omental wrapping of the involved ureter.

**Ureter procedures: Ureteroplasty: Flap ureteroplasty***Surgery – Male*

Use of bladder mucosa or bowel to substitute partially obliterated or strictured ureter.

**Ureter procedures: Ureteroplasty: General***Surgery – Male*

Any surgical reconstruction of the ureter.

**Ureter procedures: Ureteroplasty: Graft ureteroplasty***Surgery – Male*

Use of buccal mucosa, preputial skin, and bladder mucosa to graft partially obliterated or defective ureter.

**Ureter procedures: Ureteroplasty: Ileal ureteric replacement***Surgery – Male*

A segment of ileum is used to replace the damaged ureter.

**Ureter procedures: Ureteroscopy***Surgery – Male*

Upper urinary tract endoscopy performed with a semi rigid or flexible endoscope passed through the urethra, bladder and then directly into the upper urinary tract.

**Ureter procedures: Ureteroureterostomy***Surgery – Male*

An end-to-end anastomosis of the segments of the same ureter, with excision of the intervening injured, tumor, or scarred ureter. Transperitoneal ureteroureterostomy is a special urinary reconstruction with side-to-end anastomosis of the injured ureter from one side across the peritoneal cavity under the mesentery of the intestine to the healthy ureter on the opposite side.

**Uretero-cervical fistula (UrCxF)***Diagnosis*

Abnormal connection of the ureter into the uterine cervix.

**Uretero-uterine (cervical) fistula***Sign*

UrUtF/UrCxF: abnormal connection between the ureter(s) and the uterus/cervix.

With or without observation of:

- (i) UrUtF—Clinical exam only: Observation of urine passing through the cervix or pooling in the posterior vaginal fornix.
- (ii) UrUtF—Clinical exam plus irrigation: Observation of urine passing per cervical os; with or without pooling in the posterior vaginal fornix at the time of retrograde dyed irrigant fill test of the bladder through a bladder catheter (negative blue test, positive clear urine).
- (iii) UrUtF/UrCxF: Complex of multiple urinary tract fistulas concurrent between the ureter and uterus/cervix and between the bladder and uterus/cervix. Difficult to diagnose clinically. It is often diagnosed by hysterosalpingogram (HSG).

**Uretero-uterine fistula (UrUtF)***Diagnosis*

Abnormal connection of the ureter into the body of the uterus.

**Uretero-vaginal fistula (UrVaF)***Sign*

UrVaF: Abnormal connection between the ureter(s) and vagina.

With or without observation of:

- (i) UrVaF—Clinical exam only: Observation of urine pooling in the posterior vaginal fornix.

(ii) UrVaF—Clinical exam plus irrigation: Observation of urine pooling in the posterior vaginal fornix at the time of retrograde dyed irrigation fill test of the bladder through a bladder catheter (negative dye test, positive urine).

(iii) UrVaF—Occurrence in isolation: For example, at the vaginal vault following a hysterectomy including Cesarean hysterectomy.

(iv) UrVaF—Occurrence in combination: For example, in combination of a VVaF.

#### **Uretero-vaginal fistula (UrVaF)**

##### *Diagnosis*

Abnormal connection of ureter into the vagina.

#### **Urethra: End-to-end repair**

##### *Surgery – Male*

Open surgery for reconstruction of the urethra. After excision of the fibrotic urethral segment, the healthy proximal and distal urethra ends are reconnected by a primary tension-free anastomosis.

#### **Urethral calibration**

##### *Surgery – Male*

Measurement of the diameter of the (distal) urethral lumen with special urethral sounds.

#### **Urethral caruncle**

##### *Sign*

Small eversion of the urethral urothelium, generally involving the posterior lip.

#### **Urethral closure mechanism - incompetent (female)**

##### *Investigation*

Leakage of urine occurs during activities which might raise intra-abdominal pressure in the absence of a detrusor contraction.

#### **Urethral closure mechanism - normal (female)**

##### *Investigation*

A positive urethral closure pressure is maintained during bladder filling, even in the presence of increased abdominal pressure, although it may be overcome by detrusor overactivity.

#### **Urethral closure mechanism - urethral relaxation incompetence ("urethral instability") - female**

##### *Investigation*

Leakage due to urethral relaxation in the absence of raised abdominal pressure or a detrusor contraction.

#### **Urethral closure mechanism - urodynamic stress incontinence (female)**

##### *Investigation*

This is the involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

#### **Urethral closure pressure profile (UCPP) - female**

##### *Investigation*

The relevant pressure is the urethral closure pressure (urethral pressure minus the intravesical pressure).

#### **Urethral dilatation**

##### *Surgery – Male*

Distension of a stenotic segment with semi-rigid, rigid dilators or balloon distention.

#### **Urethral discharge**

##### *Symptom*

Seepage of mucus, pus or blood from the urethral meatus.

#### **Urethral diverticulectomy**

##### *Surgery – Male*

Excision of a pseudo diverticulum (out-pocketing) of the urethral mucosa.

#### **Urethral diverticulum**

##### *Sign*

The presence of a sac opening from the urethra. It might be suspected by a lump or tenderness along the line of the urethra or external urethral discharge on urethral massage.

#### **Urethral examination (male)**

##### *Sign*

Palpation: along the ventral aspect of the penis and inferiorly into the perineum to detect fibrosis, lumps or tenderness along the shaft. Tenderness: suggestive of urethral or periurethral inflammation, often secondary to a urethral stricture or sexually transmitted disease. Meatal stenosis: narrowing changes of the distal urethra; post-infection, post-surgery.

#### **Urethral fistulectomy**

##### *Surgery – Male*

Excision of a fistulous segment between the urethral lumen and the exit of the fistula (skin, bowel) and repair/reconstruction of the fistula openings.

#### **Urethral function during voiding - dysfunctional voiding**

##### *Investigation*

This is characterized by an intermittent and/or fluctuating flow rate due to involuntary intermittent contractions of the peri-urethral striated or levator muscles during voiding in neurologically normal women. This type of voiding may also be the result of an acontractile detrusor (abdominal voiding) with electromyography (EMG) or video-urodynamics required to distinguish between the two entities.

#### **Urethral function during voiding - normal (female)**

##### *Investigation*

The urethra opens and is continuously relaxed to allow micturition at a normal pressure, urine flow and PVR.

#### **Urethral function during voiding (female) - bladder outlet obstruction**

##### *Investigation*

This is the generic term for obstruction during voiding. It is a reduced urine flow rate and/or presence of a raised PVR and an increased detrusor pressure. It is usually diagnosed by studying the synchronous values of urine flow rate and detrusor pressure and any PVR measurements. A urethral stricture or obstruction due to higher degrees of uterovaginal prolapse or obstructed voiding after stress incontinence procedures are amongst possible causes.

#### **Urethral function during voiding (female) - detrusor sphincter dyssynergia**

##### *Investigation*

This is incoordination between detrusor and sphincter during voiding due to a neurological abnormality (i.e. detrusor contraction synchronous with contraction of the urethral and/or periurethral striated muscle). This is a feature of neurological voiding disorders. Neurological features should be

sought. Videocystourethrography is generally valuable to conclude this diagnosis.

### **Urethral function during voiding (voiding urethrocytometry) - female**

#### *Investigation*

This technique may assist in determining the nature of urethral obstruction to voiding. Pressure is recorded in the urethra during voiding. This may be at one specific point e.g. high pressure zone or it may be measured as a profile. A voiding urethral pressure profile (VUPP) uses a similar technique to that described above for the UPP measured during bladder filling. Simultaneous intravesical pressure measurement is required. Localization of the site of the intraurethral pressure measurement is desirable.

### **Urethral meatal abnormalities (male)**

#### *Sign*

- . Hypospadias: Refers to the urethral meatus sited on ventral surface of the penis, either congenital or acquired, proximal to its normal position on the tip of the glans. External urethral meatus may be on the glans penis (glandular hypospadias), sulcus (coronal hypospadias), shaft (penile hypospadias), scrotum (scrotal hypospadias) or perineum (perineal hypospadias).
- . Epispadias: Refers to the urethral meatus sited on dorsal surface of the penis, either congenital or acquired, proximal to its normal position on the tip of the glans.
- . Neoplastic or inflammatory lesions within the fossa navicularis.
- . Post-hypospadias/epispadias repair: including post-urethroplasty urethral fibrosis: palpated near the meatus or in the penile shaft.
- . Postoperative fistula: Urine is visible at or near the incision lines.

### **Urethral meatus**

#### *Surgery – Male*

The distal termination of the urethra. An orthotopic urethral meatus is a vertically oriented slit-like opening located on the glans penis.

### **Urethral mucosal prolapse**

#### *Sign*

Prolapse, generally circumferential and larger, of the distal urethral urothelium.

### **Urethral opening pressure (Pdet-uo – unit: cm H<sub>2</sub>O) - pressure flow studies**

#### *Investigation*

Detrusor pressure recorded at the onset of measured flow (consider time delay – usually under 1 s).

### **Urethral pain**

#### *Symptom*

Complaint of pain, pressure or discomfort felt in the urethra before, during and/or after voiding and the individual indicates the urethra as the site.

### **Urethral pain syndrome**

#### *Symptom*

Urethral pain syndrome is the occurrence of recurrent episodic urethral pain usually on voiding, with daytime frequency and nocturia, in the absence of proven infection or other obvious pathology.

### **Urethral Plugs**

#### *Conservative Management – Female*

Urethral plugs are containment products aimed at blocking urine leakage.

### **Urethral pressure - intraluminal (female)**

#### *Investigation*

This is the fluid pressure needed to just open a closed urethra.

### **Urethral pressure measurement (female)**

#### *Investigation*

Urethral pressure and urethral closure pressure are idealized concepts which represent the ability of the urethra to prevent leakage. Urethral pressure is currently measured by a number of different techniques which don't tend to have consistent results, either between methods or for a single method. For example the effect of catheter rotation will be relevant when urethral pressure is measured by a catheter mounted transducer. Urethral pressure might, nonetheless, be measured: (i) at rest, with the bladder at a given volume; (ii) During coughing or straining; (iii) During the process of voiding.

### **Urethral pressure profile - functional profile length (female)**

#### *Investigation*

The length of the urethra along which the urethral pressure exceeds intravesical pressure in women.

### **Urethral pressure profile - functional profile length (on stress) - female**

#### *Investigation*

The length over which the urethral pressure exceeds the intravesical pressure on stress.

### **Urethral pressure profile - pressure "transmission" ratio (female)**

#### *Investigation*

This is the increment in urethral pressure on stress as a percentage of the simultaneously recorded increment in intravesical pressure. For stress profiles obtained during coughing, pressure transmission ratios can be obtained at any point along the urethra. If single values are given, the position in the urethra should be stated. If several transmission ratios are defined at different points along the urethra, a pressure transmission "profile" is obtained. During "cough profiles", the amplitude of the cough should be stated if possible.

### **Urethral pressure profile (UPP) - female**

#### *Investigation*

This is a graph indicating the intraluminal pressure along the length of the urethra: (i) Resting UPP: The bladder and subject are at rest; (ii) Stress UPP: Defined applied stress (e.g. cough, strain, Valsalva).

### **Urethral pressure profile (UPP) - methodology (female)**

#### *Investigation*

All systems are zeroed at atmospheric pressure. For external transducers, the reference point is the superior edge of the symphysis pubis. For catheter mounted transducers, the reference point is the transducer itself. Intravesical pressure should be measured to exclude a simultaneous detrusor contraction. Methodology should be noted including: patient position; catheter type; transducer orientation; fluid and rate of infusion (if fluid-filling system); bladder volume; rate of catheter withdrawal.

### **Urethral prolapse**

#### *Symptom*

Complaint of a "lump" at the external urethral meatus.

### **Urethral prosthesis or stent**

#### *Surgery – Male*

Placement of a temporary or permanent synthetic tube splint device in a stenotic urethral segment to avoid restenosis of the urethra or to keep the external sphincter open in detrusor-external sphincter dyssynergia.

**Urethral relaxation incompetence ("urethral instability") - female***Investigation*

Leakage due to urethral relaxation in the absence of raised abdominal pressure or a detrusor contraction.

**Urethral stenosis - Posterior***Diagnosis*

Narrowing of the membranous urethra, prostatic urethra, or bladder neck, when the prostate is still in situ.

**Urethral stenosis: General***Diagnosis*

A narrowing of the anterior urethra, caused by spongiofibrosis of the corpus spongiosum.

**Urethral stricture - Post infection***Diagnosis*

Urethral stricture disease developing as a result of gonococcal and non-gonococcal (*Ureaplasma urealyticum*, *Mycoplasma genitalium*, schistosomiasis, and tuberculosis) urethritis.

**Urethral Trauma (Male) - Blunt***Diagnosis*

An injury to the urethra from a non-penetrating injury. May include straddle injuries, deceleration injuries, penile fracture, and pelvic fracture urethral injuries.

**Urethral trauma (Male) - Iatrogenic***Diagnosis*

Injury to the urethra resulting from instrumentation of the urethra, such as with cystoscopy or catheterization, or treatment of disease in the urethra or prostate, such as urethral dilation, transurethral resection of the prostate, prostate radiation, or RP.

**Urethral trauma (Male) - Pelvic fracture urethral injury (PFUI)***Diagnosis*

A urethral distraction injury, typically involving the bulbomembranous junction. Previously known as pelvic fracture urethral distraction defects, this term should be reserved for cases of PFUI with loss of urethral continuity.

**Urethral trauma (Male) - Penetrating***Diagnosis*

Injury to the urethra resulting from an object passing into or through the urethra from outside the body. Gunshot wounds, stab injuries, and penile amputation are examples of penetrating urethral trauma.

**Urethral trauma (Male) - Straddle injury***Diagnosis*

Injury to the bulbar urethra resulting from a blunt trauma which compresses the bulbar urethra against the inferior pubic rami. May be remote, or even not recalled by the patient.

**Urethrocystoscopy***Surgery – Male*

Direct visualization of the inner wall (mucosa) of urethra and bladder. It implies a form of endoscopic method.

**Urethrocystoscopy: Flexible***Surgery – Male*

Direct visualization of the bladder and urethra using a hand operated flexible scope, a thumb lever allows the scope to be deflected as required to

visualize the entire bladder. Can be performed under local or general anaesthesia predominantly for diagnostic purposes or can be combined with tissue ablation.

**Urethroplasty***Surgery – Male*

Open surgical reconstruction of the posterior (proximal to the external urethral sphincter) or anterior (distal to the external urethral sphincter) urethra. This involves incision/removal or substitution of the strictured part of the urethral segment followed by urethral reconstruction.

**Urethroplasty: Staged***Surgery – Male*

Usually two stage but occasionally additional stages are required in the treatment of urethral stricture.

**Urethroplasty: substitution***Surgery – Male*

Open surgery usually done for the reconstruction of bulbar urethral strictures with a stricture length  $\geq 1.5$  cm or penile urethral strictures. After incision of the fibrotic urethral segment, tissue from another part of the body, for example, buccal mucosa, lingual mucosa, or skin (graft/local flap/free flap—see below) are used to cover the incised area. The tissue may be placed dorsally/ventrally or combined (ventral and dorsal grafts). Substitution urethroplasty may be accomplished as a single-stage or as part of a multi (usually two-) stage procedure.

**Urethroplasty: with flap***Surgery – Male*

The use of flaps for urethral reconstruction of penile urethra stricture disease, local rotational flaps such as preputial skin or local genital skin (e.g., Orandi flap). flaps are often used in recurrent urethral stricture disease involving the penile urethra and navicular fossa.

**Urethroplasty: with graft***Surgery – Male*

The use of free graft for urethral reconstruction usually in urethral stricture disease, in any part of the urethra.

**Urethroscopy***Surgery – Male*

Endoscopic visualization of the inner wall of the urethra (mucosa), usually done with a flexible or rigid cystoscope.

**Urethroscopy: Rigid***Surgery – Male*

Direct visualization of the bladder and urethra using a rod-lens telescope optical system as well as a rigid sheath. Usually performed under local, regional, or general anaesthesia for diagnostic or therapeutic purposes.

**Urethrotomy - Blind***Surgery – Male*

Incision of an urethral stricture.

Blind urethrotomy (without visual guidance): Opening of the stricture with the use of a special instrument (Otis urethrotome) to perform the incision without direct visualization.

**Urethrotomy - Endoscopic***Surgery – Male*

(direct vision): Opening of the stricture with a cold incision (Sachse urethrotome using mechanical effect) or

energy (LASER) under urethroscopy.

### Urethrovaginal fistula

#### Diagnosis

Abnormal connection between the urethra and the vagina,

### Urethro-vaginal fistula (UVaF)

#### Sign

(i) UVaF—Clinical exam only: Observation of a defect between the urethra and vagina that may occur across a spectrum of tissue loss, from the urethral meatus to the level of the bladder neck, with variable appearance. With or without observation of:

(ii) UVaF—Clinical exam and probe: Probe passing through urethra into the vagina through a urethral defect or from the urethral defect back out through the urethral meatus.

(iii) UVaF—Clinical exam and fluid instillation: dyed irrigant fluid passing per defect at the time of retrograde fill test of the bladder through a bladder catheter (positive blue test).

(iv) UVaF—Clinical exam and Trattner catheter: Trattner catheter may be used to isolate retrograde blue test filling to the urethral lumen. without filling the bladder

### Urgency

#### Symptom

Complaint of sudden, compelling desire to pass urine which is difficult to defer.

### Urgency - filling cystometry

#### Investigation

Sudden, compelling desire to void which is difficult to defer.

### Urgency urinary incontinence

#### Sign

Observation of involuntary leakage from the urethral orifice associated with the individual reporting the sensation of a sudden, compelling desire to void.

### Urgency urinary incontinence (UUI)

#### Symptom

Complaint of involuntary loss of urine associated with urgency.

### Urinary Catheters

#### Conservative Management – Female

Urinary catheters are small tubes inserted via the urethra or into the bladder suprapubically, to allow the drainage of urine. Catheters are made of plastic, latex, teflon or silicone, and may be impregnated with antiseptic or antibiotic solution. 1. Self-catheterization: a procedure performed intermittently to empty the bladder by inserting a catheter into the urethra when normal voiding is not possible or if the bladder cannot be emptied completely. If a caregiver undertakes this procedure it is usually a sterile procedure; if a patient undertakes it, it is termed “self-catheterization” and is generally a clean rather than a sterile procedure.

### Urinary diversions and reconstructions: General

#### Surgery – Male

Urinary diversion is any surgical procedure that alters the usual passage of urine from the kidneys. It may or may not involve the addition of bowel into the urinary tract, either to reroute the urine or replace/augment the native urinary tract. All urinary diversions and reconstructions can be done as an open procedure, laparoscopically, or robot-assisted.

### Urinary incontinence

#### Symptom

Complaint of involuntary loss of urine.

### Urinary incontinence

#### Sign

Observation of involuntary loss of urine on examination.

### Urinary incontinence signs

#### Sign

All examinations for the evaluation of urinary incontinence are best performed with the individual's bladder comfortably full.

### Urinary incontinence symptoms

#### Symptom

Involuntary loss of urine experienced during the bladder storage phase.

### Urinary retention

#### Symptom

Complaint of the inability to empty the bladder completely.

### Urinary Tract Infection

#### Symptom

Scientific diagnosis of a UTI is the finding of microbiological evidence of significant bacteriuria and pyuria usually accompanied by symptoms such as increased bladder sensation, urgency, frequency, dysuria, urgency urinary incontinence, and/or pain in the lower urinary tract.

### Urine flow

#### Investigation

Urethral passage of urine. Pattern of urine flow may be: continuous - no interruption to urine flow; intermittent - urine flow is interrupted.

### Urine flow rate (UFR - mL/s)

#### Investigation

Volume of urine expelled via the urethra per unit time.

### Urodynamic clinical sequence of testing (female)

#### Investigation

This generally involves a woman attending with a comfortably full bladder for free (no catheter) uroflowmetry and post-void residual (PVR) measurement prior to filling cystometry and pressure-flow studies.

### Urodynamic clinical sequence of testing (male)

#### Investigation

This generally involves a man attending with a comfortably full bladder for free (no catheter) uroflowmetry and post-void residual urine volume (PVR) measurement prior to filling cystometry and pressure-flow study.

### Urodynamic stress incontinence - Filling cystometry

#### Investigation

Involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

### Urodynamic Stress Incontinence (female)

#### Diagnosis

The diagnosis by symptom, sign, and urodynamic investigations involves the finding of involuntary leakage during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

**Urodynamic stress incontinence (USI) - filling cystometry***Investigation*

Involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

**Urodynamic studies***Investigation*

These usually take place in a special clinical room (urodynamic laboratory) and involve (artificial) bladder filling with a specified liquid (ICS recommends physiological saline solution or X-ray contrast if video studies) at a specified rate.

**Urodynamics***Investigation*

Measurement of physiological parameters relevant to the function of the lower urinary tract.

**Uroflowmetry (female) - ideal conditions***Investigation*

For free (or spontaneous - no catheter) uroflowmetry, all studies should be performed in a completely private uroflowmetry room. Most modern uroflowmeters have a high degree of accuracy (+/- 5%) though regular calibration is important.

**Uroflowmetry (female) - interpretation of normality***Investigation*

Because of the strong dependency of urine flow rates in women on voided volume, they are best referenced to nomograms (e.g. Liverpool nomograms) where the cutoff for abnormally slow maximum (MUFR) and average (AUFR) urine flow rates has been determined and validated as under the 10th centile.

**Uroflowmetry (male) - ideal conditions***Investigation*

Ideally, all free uroflowmetry studies should be performed in a completely private uroflowmetry room. Most modern uroflowmeters have a high degree of accuracy (+/- 5%) though regular calibration is important.

**Uroflowmetry (male) - interpretation of normality***Investigation*

Because of the strong dependency of urine flow rates in men on voided volume and age, they are best referenced to nomograms where the cutoff for normality has been determined and validated.

**V****Vaginal agglutination***Sign*

Where the walls of the vagina are stuck together.

**Vaginal Anatomical Levels***Sign*

(i) Level I: Uterine cervix (if present) and/or upper 2.5cm of vagina. (ii) Level II: Mid-vagina from distal end of Level I to hymen. (iii) Level III (vaginal vestibule): Vaginal entrance (Latin: "vestibulum"- "a space at the entrance of a canal") from hymenal ring to just below the clitoris anteriorly (anterior vestibule), labia minora laterally and anterior perineum posteriorly (posterior margin of vestibule).

**Urogenital aging: genitourinary syndrome of menopause***Sign*

(i) Pallor/erythema: pale genital mucosa; (ii) Loss of vaginal rugae: vaginal rugae flush with the skin; (iii) Tissue fragility/fissures: genital mucosa that is easily broken or damaged; (iv) Vaginal petechiae: is a small (1–2 mm) red or purple spot on the skin, caused by a minor bleed (from broken capillary blood vessels); (v) Urethral eversion: urethral epithelium turned outside the lumen; (vi) Urethral prolapse: complaint of a lump at the external urethral meatus; (vii) Loss of hymenal remnants: absence of hymenal remnants; (viii) Prominence of urethral meatus vaginal canal shortening and narrowing: Intra-urethral retraction.

**Uterine / cervical prolapse***Diagnosis*

Clinically evident (symptoms, clinical examination, assisted at times by any relevant imaging) descent of the uterus or uterine cervix.

**Uterine retroversion***Sign*

The axis of the uterus is directed backwards towards the hollow of the sacrum, away from its anteverted position overlying the bladder. Cervix is noted in/towards the anterior fornix with the fundus perhaps palpable in the posterior fornix.

**Uterine/cervical prolapse***Sign*

Observation of descent of the uterus or uterine cervix.

**Uterosacral ligament plication - open, laparoscopic, robotic***Surgery – Female*

Transverse plication of the uterosacral ligaments to obliterate the cul-de-sac. Successive sutures are placed into the medial portion of one ligament, into the back wall of the vagina and into the medial border of the opposing ligament.

**Uterosacral (USL) Ligament vaginal vault fixation - intraperitoneal***Surgery – Female*

Intraperitoneal USL ligament plication to support the vaginal vault. This is usually associated with posterior wall fascial reconstruction and possible excision and closure of enterocele.

**Uterosacral (USL) vaginal vault fixation - extraperitoneal***Surgery – Female*

Extraperitoneal plication of the uterosacral ligaments to support the vaginal vault. This is usually combined with posterior vaginal wall fascial reconstruction with or without enterocele closure and/or excision.

**Vaginal and clitoral duplex doppler ultrasound.***Investigation*

The anatomical integrity of clitoral structures and the changes in clitoral and labial diameter associated with sexual stimulation can be evaluated in B mode. Movement of the blood relative to the transducer can be expressed as measurement of velocity, resistance, and pulsatility. Blood flow in arteries irrigating the clitoris and the vagina are more commonly assessed during sexual stimulation.

**Vaginal bulging***Symptom*

Complaint of a "bulge" or "something coming down" towards or through

the vaginal introitus. The woman may state she can either feel the bulge by direct palpation or see it with the aid of a mirror.

#### **Vaginal digitation**

##### *Symptom*

Use of thumb or fingers in the vaginal to assist in evacuation of stool.

#### **Vaginal dryness**

##### *Symptom*

Complaint of reduced vaginal lubrication or lack of adequate moisture in the vagina.

#### **Vaginal eversion**

##### *Sign*

Complete version of the vagina is Stage IV vaginal prolapse.

#### **Vaginal examination**

##### *Sign*

Examination for vaginal length and mobility, presence of scarring and/or pain, and estrogenization. The location of any vaginal pain should be noted.

#### **Vaginal feces**

##### *Symptom*

Complaint of passage of feces per vagina.

#### **Vaginal flatus**

##### *Symptom*

Complaint of passage of flatus per vaginam.

#### **Vaginal gaping**

##### *Symptom*

Complaint of a "wide open" vaginal introitus.

#### **Vaginal hysterectomy**

##### *Surgery – Female*

Removal of the uterus and cervix vaginally.

#### **Vaginal hysterectomy - with adjunctive McCall culdoplasty**

##### *Surgery – Female*

Culdoplasty sutures incorporate the uterosacral ligaments into the posterior vaginal vault to obliterate the cul-de-sac and support and suspend the vaginal vault after vaginal hysterectomy.

#### **Vaginal introital flexibility**

##### *Sign*

The capacity of the vaginal opening to expand in response to stretching. Assessed by separating index and middle finger in the medio-lateral direction. Digital assessment of the vaginal opening is likely to represent the width of the levator hiatus. RATING: Estimate the number of finger widths between the muscle bellies. Can be converted to cm width for the recording from that assessor.

#### **Vaginal introital gaping**

##### *Sign*

Opening, or non-coaptation of vagina at rest. If the introitus is not visible at rest the labia may need to be parted. RATING: (i) Present; (ii) Absent

#### **Vaginal laxity**

##### *Symptom*

Feeling of vaginal looseness.

#### **Vaginal leakage**

##### *Sign*

Urine, flatus, and/or stool observed leaking into the vagina or from the vagina.

#### **Vaginal length - anterior vaginal length**

##### *Sign*

Anterior hymenal ring to anterior vaginal vault (anterior cervicovaginal junction or anterior cuff post-hysterectomy).

#### **Vaginal length - total posterior vaginal length**

##### *Sign*

Posterior vaginal vault to posterior margin of vestibule (anterior perineum - cm), i.e., Levels I, II and III posteriorly.

#### **Vaginal length - total vaginal length**

##### *Sign*

Posterior vaginal vault to hymen (cm), i.e., Levels I and II posteriorly.

#### **Vaginal Levels - Level I**

##### *Sign*

Uterine cervix (if present) and/or upper 2.5 cm of vagina.

#### **Vaginal Levels - Level II**

##### *Sign*

Mid-vagina from distal end of Level I to hymen.

#### **Vaginal Levels - Level III (vaginal vestibule)**

##### *Sign*

Vaginal entrance (Latin: "vestibulum" = "space at the end of the canal"). From hymenal ring to just below the clitoris anteriorly (anterior vestibule), labia minora laterally and anterior perineum posteriorly (posterior margin of vestibule).

#### **Vaginal Lubricants**

##### *Conservative Management – Female*

Vaginal lubricants are pharmacological preparations aimed at reducing friction during coital or any other sexual activity and thereby alleviating dyspareunia, or at reducing discomfort associated with a clinical (per vaginum or per rectum) examination. Pharmacological preparations and natural plant-based oils may be used.

#### **Vaginal Pain Syndrome**

##### *Symptom*

Vaginal pain syndrome is the occurrence of persistent or recurrent episodic vaginal pain which is associated with symptoms suggestive of urinary tract or sexual dysfunction. There is no proven vaginal infection or other obvious pathology.

#### **Vaginal pessary - general**

##### *Conservative Management – Female*

A device that is inserted into the vagina to provide structural support to one or more of the descending vaginal compartments, i.e. the uterus, anterior vaginal wall (and bladder), posterior vaginal wall (and rectum) and/or vaginal vault (with or without small intestine) after a prior hysterectomy.

#### **Vaginal pessary - space filling pessaries**

##### *Conservative Management – Female*

Doughnut; cuboid; Gellhorn; inflatable; shelf (similar to a Gellhorn but asymmetric).

**Vaginal pessary - support pessaries***Conservative Management – Female*

Ring pessary with or without central support; Gehrung, Hodge pessaries.

**Vaginal photoplethysmography***Investigation*

A tampon shape intravaginal probe equipped with an incandescent light that projects toward the vaginal walls is inserted; the amount of light that reflects back to the photosensitive cell provides a measure of vaginal engorgement which can be expressed as vaginal blood volume or vaginal pulse amplitude depending on the mode of recording. Likewise, labial and clitoral photoplethysmography can also be evaluated.

**Vaginal scarring***Sign*

Presence of scar tissue along vaginal walls or vaginal vault.

**Vaginal tracelectomy for cervical stump prolapse (previous subtotal hysterectomy)***Surgery – Female*

The cervical stump is removed in an identical fashion to the initial steps of a vaginal hysterectomy.

**Vaginal Trachelectomy for Cervical Stump Prolapse***Surgery – Female*

(Previous subtotal hysterectomy) The cervical stump is removed in an identical fashion to the initial steps of a vaginal hysterectomy.

**Vaginal urine leakage***Symptom*

Complaint of urine leakage through the vagina. Symptoms are usually continuous but may be intermittent and may be associated with movement or specific changes of position.

**Vaginal vault (cuff scar) prolapse***Sign*

Observation of descent of the vaginal vault (cuff scar after hysterectomy).

**Vaginal vault (cuff scar) prolapse***Diagnosis*

Diagnosis by symptoms and clinical examination, assisted at times by any relevant imaging (i.e. clinically evident) descent of the vaginal vault (cuff scar after hysterectomy).

**Vaginal vestibule - Anterior***Sign*

Vaginal entrance from the hymenal ring to just below the clitoris anteriorly.

**Vaginal vestibule - posterior***Sign*

Posterior hymenal ring to anterior perineum (posterior margin of vestibule).

**Vaginal wind***Symptom*

Passage of air from vagina (usually accompanied by sound).

**Vaginal wind***Symptom*

An involuntary passage of odorless air through the vagina, which is often audible and/or sensible, and usually associated with a change in posture. This may occur when legs are abducted and a change of position occurs and during times of low estrogen (e.g., breast-feeding).

**Vaginismus***Symptom*

Recurrent or persistent spasm of vaginal musculature that interferes with vaginal penetration.

**Valsalva***Sign*

Forceful exhalation against a closed mouth, glottis, and nose. Valsalva has been shown to result in an increase in intra-abdominal pressure and usually an increase in pelvic floor muscle activation.

**Varicocele: General***Diagnosis*

Abnormal dilation of pampiniform venous plexus which drains blood from each testicle. Varicocele is graded based on the degree of dilation.

**Varicocele: Grade 1***Diagnosis*

Palpable with valsalva maneuver.

**Varicocele: Grade 2***Diagnosis*

Palpable when standing, without valsalva maneuver.

**Varicocele: Grade 3***Diagnosis*

Visible on inspection

**Varicocele: Subclinical***Diagnosis*

Seen on Doppler ultrasound imaging, no varicocele on exam.

**Vascular assessment of female sexual dysfunction - labial thermistor***Investigation*

Temperature measurement evaluated with a small metal clip attached to the labia minora and equipped with a sensitive thermistor.

**Vascular assessment of female sexual dysfunction - Laser Doppler imaging of genital blood flow***Investigation*

An imager positioned close to the vulva allows the assessment of skin/mucosae microcirculation at a depth of up to 2-3mm. This method has been used to assess response to sexual stimulation and correlated with subjective arousal. It has also led to a better understanding of microvascular differences in women with provoked vestibulodynia compared to asymptomatic controls.

**Vascular assessment of female sexual dysfunction - Magnetic resonance imaging of the genito-pelvic area***Investigation*

Evaluation of the increase in clitoral structure volume related to tissue engorgement occurring during arousal.

**Vascular assessment of female sexual dysfunction - Measurements of labial and vaginal oxygenation***Investigation*

A heated electrode and oxygen monitor are used to evaluate the arterial partial pressure of oxygen (PO<sub>2</sub>) transcutaneously. The temperature of the electrode is kept at a constant elevated temperature by an electric current. Increase in blood flow under the electrode results in more effective temperature dissipation (heat loss) with the result that more current is needed to maintain the electrode at its prefixed temperature. The changes in current

provide an indirect measurement of blood flow during sexual stimuli. The electrode also monitors oxygen diffusion across the skin.

#### **Vascular assessment of female sexual dysfunction - Thermography or thermal imaging of the genital area**

##### *Investigation*

Evaluation of genital temperature using a camera detecting infrared radiation from the skin during sexual stimulation. This method has been correlated with subjective arousal.

#### **Vascular assessment of female sexual dysfunction - vaginal and clitoral duplex Doppler ultrasound**

##### *Investigation*

The anatomical integrity of clitoral structures and the changes in clitoral and labial diameter associated with sexual stimulation can be evaluated in B mode. Movement of the blood relative to the transducer can be expressed as measurement of velocity, resistance, and pulsatility. Blood flow in arteries irrigating the clitoris and the vagina are more commonly assessed during sexual stimulation.

#### **Vascular assessment of female sexual dysfunction - vaginal photoplethysmography**

##### *Investigation*

A tampon shape intravaginal probe equipped with an incandescent light that projects toward the vaginal walls is inserted; the amount of light that reflects back to the photosensitive cell provides a measure of vaginal engorgement which can be expressed as vaginal blood volume or vaginal pulse amplitude depending on the mode of recording. Likewise, labial and clitoral photoplethysmography can also be evaluated.

#### **Vector manometry**

##### *Investigation*

A three-dimensional pressure profile of the anal canal. Measures of total anal canal pressure and symmetry are made. The vector volume is the volume of the 3D shape generated and provides a value which reflects the overall length and symmetry of the sphincter.

#### **Vesico-cervical fistula (VCxF)**

##### *Diagnosis*

Abnormal connection between the bladder and the cervix.

#### **Vesico-cutaneous fistula repair**

##### *Surgery – Male*

Excision of a fistula between bladder and skin.

#### **Vesico-rectal fistula (VRF)**

##### *Sign*

Vesico-rectal fistula (VRF): Abnormal connection between the bladder and rectum.

With or without observation of:

- (i) VRF—Clinical exam plus probe: probe passing per urethra through anus or per anus through urethra.
- (ii) VRF—Clinical exam plus irrigation: flaturia, fecaluria, bubbles passing through the urethra after retrograde injection of air per rectum, blue irrigant fluid passing per anorectum after retrograde bladder fill per urethra.

#### **Vesicostomy**

##### *Surgery – Male*

A method of creating a communication between the bladder and the skin. This procedure is indicated

in children with vesicourethral dysfunction (myelomeningocele, posterior urethral valve) who are unable to void or cannot catheterize through the urethra.

#### **Vesico-ureteric junction procedures: STING (subtrigonal injection of inert substance) procedure.**

##### *Surgery – Male*

This entails injection of an inert substance via endoscopic technique at the vesico-ureteric junction to treat reflux. Teflon was initially used but other inert substances can be used alternatively.

#### **Vesico-ureteric junction procedures: Ureteral re-implants: Cross-trigonal (Cohen) technique.**

##### *Surgery – Male*

#### **Vesico-ureteric junction procedures: Ureteral re-implants: Extravesical (Lich-Gregoir) techniques.**

##### *Surgery – Male*

An ureteroneocystostomy where the ureter is mobilized extravesically along the course of the ureter and the detrusor and then divided in the direction of the ureter. The ureter is then anastomosed to the bladder mucosa and the divided detrusor sutured to cover the ureter, creating a submucosal ureteral tunnel.

#### **Vesico-ureteric junction procedures: Ureteral re-implants: Intra-extra vesical technique (Paquin).**

##### *Surgery – Male*

A type of ureteroneocystostomy in which the ureter is excised from its attachment to the bladder and reattached in a more posteromedial position.

#### **Vesico-ureteric junction procedures: Ureteral re-implants: Intravesical (Politano-Leadbetter technique)**

##### *Surgery – Male*

A ureteroneocystostomy in which the ureter is excised from its attachment to the bladder and reattached intravesically in a more medial and superior position with a new sub-mucosal tunnel.

#### **Vesico-ureteric junction procedures: Ureteral re-implants: Ureteral advancement (Glenn-Andersen) reimplantation technique.**

##### *Surgery – Male*

The submucosal tunnel is made from the original ureteral meatus to the bladder neck—with or without incision of detrusor proximally from the original ureteral orifice—allowing the ureter to follow its natural course without the risk of folding or obstruction of the ureter.

#### **Vesico-ureteric junction procedures: Ureteral re-implants: Ureteroneocystostomy**

##### *Surgery – Male*

Direct reimplantation of the ureter into the bladder, primarily for disease involving the lower third portion of the ureter.

#### **Vesico-ureteric junction procedures: Ureterocele incision/resection.**

##### *Surgery – Male*

This involves endoscopic resection/incision of the ureterocele.

#### **Vesicourethral anastomotic stenosis (VAS)**

##### *Diagnosis*

Narrowing of the posterior urethra after RP.

**Vesico-uterine (cervical) fistula (VUtF/VCxF)***Sign*

Vesico-uterine(cervical) fistula (VUtF/VCxF): Defect between the uterus (and/or cervix) and

bladder, where the cervix may be intact or deficient.

with or without observation of:

(i) VUtF—Clinical Exam only: Menouria: (cyclical) hematuria coinciding with menstruation.

(ii) VUtF—Clinical exam plus probe: Probe passing though urethra into the cervical os or from the cervix through the urethral meatus.

(iii) VUtF—Clinical exam plus irrigation: Dyed irrigation fluid passing per cervical os at the time of retrograde dyed irrigant fill test of the bladder through a bladder catheter.

**Vesico-uterine fistula (VUtF)***Diagnosis*

Abnormal connection between the bladder and the body of the uterus.

**Vesico-vaginal fistula (VVaF)***Sign*

VVaF—(i) Clinical exam only: Observation of urine pooling in the vagina and observation of defect between the anterior vaginal wall (including vault) and the bladder.

With or without observation of:

(ii) VVaF—Clinical exam plus probe: Probe passing through urethra into the vagina or from the vagina through the urethral meatus.

(iii) VVaF—Clinical exam plus irrigation: Dyed irrigation fluid passing per defect at the time of retrograde fill test of the bladder through a bladder catheter (positive blue test).

(iv) VVaF—Clinical exam plus bladder mucosa seen: Bladder mucosa visible through the vagina on speculum examination.

**Vesico-vaginal fistula (VVaF)***Diagnosis*

Abnormal connection between the bladder and the vagina.

**Vesico-vaginal vault fistula (VVtF)***Diagnosis*

Abnormal connection between the bladder and vaginal vault (cuff after hysterectomy).

**Videocystourethrography (VCU - female)***Imaging*

Synchronous radiological screening of the bladder and measurement of the bladder and abdominal pressure during filling and voiding cystometry. When indicated for complex cases, VCU allows direct observation of the effects of bladder events, the position and conformation of the bladder neck in relation to the pubic symphysis, bladder neck closure during rest and stress, diverticula of the bladder and urethra, vesico-vaginal and urethro-vaginal fistulae, vesico-ureteric reflux and voiding events.

**Videourodynamics***Investigation*

Functional test of the lower urinary tract where filling cystometry and pressure studies are combined with real-time imaging of the lower urinary tract.

**Videourodynamics***Imaging*

A functional test of the lower urinary tract in which pressure, capacity and flow data are simultaneously combined with real-time imaging of the upper and lower urinary tract. It is a dynamic study with function, during bladder

filling and emptying. It is a kinetic technique that records morphological and functional changes of the lower urinary tract as a function of time. This feature distinguishes this technique from the static images obtained by cystography. It is a technique that is applied simultaneously with conventional urodynamic studies.

Image acquisition for the urinary tract can be performed with X-rays (fluoroscopy) or by ultrasound. Although in a strict sense, the "video" prefix refers to the recording of the images and not to their acquisition.

**Visceral pain***Symptom*

Pain which arises from visceral organs, with involvement of the organ capsule with aching, and is localized. There is obstruction of hollow viscus, causing intermittent cramping, which is poorly localized.

i. Nociceptive: direct injury or lesion of an internal organ such as: bladder stone, surgical injury.

ii. Inflammatory: acute/chronic inflammation of an internal organ such as urinary tract infection, pelvic inflammatory disease, colitis, endometriosis.

iii. Neuropathic: primary lesion of visceral nerves such as neuritis following mesh placement.

**Voided Percentage (Void%)***Investigation*

The numerical description of the voiding efficacy or efficiency which is the proportion of bladder content emptied. Calculation: [(volume voided/volume voided + PVR) \*100].

**Voided volume (VV - mL)***Investigation*

Total volume of urine expelled via the urethra during a single void.

**Voiding cystometry***Investigation*

This is the pressure volume relationship of the bladder during micturition. It begins when the "permission to void" is given by the urodynamicist and ends when the woman considers her voiding has finished. Measurements to be recorded should be the intravesical, intra-abdominal, and detrusor pressures and the urine flow rate.

**Voiding cystourethrography - male***Imaging*

Imaging of the bladder neck, urethra and prostate during voiding. The principal use is determining the site of any obstruction e.g. bladder neck or prostate. It can detect vesico-ureteric reflux, vesical or urethral fistulae, vesical or urethral diverticula and strictures.

**Voiding dysfunction - acute on chronic retention***Diagnosis*

An individual with chronic retention goes into acute retention and is unable to void.

**Voiding dysfunction - retention with overflow***Diagnosis*

Involuntary loss of urine directly related to an excessively full bladder in retention.

**Voiding dysfunction (female)***Diagnosis*

(A diagnosis by symptoms and urodynamic investigations is defined as) abnormally slow and/or incomplete micturition, based on abnormally slow urine flow rates and or abnormally high post-void residuals, ideally on re-

peated measurement to confirm abnormality. Pressure-flow studies can be required to determine the cause of the voiding dysfunction.

#### **Voiding dysfunction (male)**

##### *Diagnosis*

Abnormally slow and/or incomplete emptying, manifest as an abnormally slow urine flow rate and/or an abnormally high post-void residual, with confirmation by pressure-flow studies (including any related imaging).

#### **Voiding dysfunction (male) - acute urinary retention**

##### *Diagnosis*

No urine is able to be passed despite the man having a full bladder, which on examination is painfully distended, and readily palpable or percussible.

#### **Voiding dysfunction (male) - chronic retention of urine**

##### *Diagnosis*

Generally (but not always) painless and palpable or percussible bladder, where there is a chronic high postvoid residual and the man experiences slow urine flow and the sense of incomplete bladder emptying. Overflow incontinence and impaired renal function and/or hydronephrosis can occur in advanced cases.

#### **Voiding symptoms**

##### *Symptom*

Lower urinary tract symptoms experienced during the voiding phase (experienced during micturition).

#### **Voiding time (VT - unit: s)**

##### *Investigation*

Total duration of micturition, i.e. included interruptions. When voiding is completed without interruption, voiding time is equal to flow time.

#### **Voiding urethrocytometry - urethral function during voiding (female)**

##### *Investigation*

This technique may assist in determining the nature of urethral obstruction to voiding. Pressure is recorded in the urethra during voiding. This may be at one specific point e.g. high pressure zone or it may be measured as a profile. A voiding urethral pressure profile (VUPP) uses a similar technique to that described above for the UPP measured during bladder filling. Simultaneous intravesical pressure measurement is required. Localization of the site of the intraurethral pressure measurement is desirable.

#### **Vulval agglutination**

##### *Sign*

Labial lips fused.

#### **Vulval examination**

##### *Sign*

Possible abnormalities include cysts, other tumours, atrophic changes, or lichen sclerosis.

## **W**

#### **Women deemed incurable diagnosis (WDI)**

##### *Diagnosis*

Women with primary, persistent, and recurrent fistula for which anatomic repair is not possible. WDI require either supportive management and/or a diversion procedure, or they have a fistula complexity that exceeds the capacity(s) of the highest available surgical facility.

#### **Vulval gaping**

##### *Sign*

Non-coaptation of vulva at rest, commonly associated with increased size of genital hiatus.

#### **Vulval pain**

##### *Symptom*

Complaint of pain felt in and around the vulva.

#### **Vulval pain syndrome**

##### *Symptom*

Vulval pain syndrome is the occurrence of persistent or recurrent episodic vulval pain, which is either related to the micturition cycle or associated with symptoms suggestive of urinary tract or sexual dysfunction. There is no proven infection or other obvious pathology.

#### **Vulvar agglutination**

##### *Sign*

Labial lips stuck together.

#### **Vulvar gaping**

##### *Sign*

Non-coaptation of vulva at rest, commonly associated with increased size of genital hiatus.

#### **Vulvar pain**

##### *Symptom*

Complaint of pain felt in and around the vulva.

#### **Vulvodynia**

##### *Symptom*

Vulvar pain of at least 3 months' duration, without clear identifiable cause, which may have potential associated factors

#### **Vulvo-vaginal excoriation**

##### *Sign*

Skin excoriation and/or rash with or without crusting or scabbing on the tops (or soles as urine pools in plastic sandals) of feet, inner thighs, external genitalia, perineum or vagina

#### **Vulvo-vaginal hyperaesthesia**

##### *Sign*

Increased vulvo-vaginal sensitivity to touch, pressure, vibration or temperature.

#### **Vulvo-vaginal hypoesthesia**

##### *Sign*

Reduced vulvo-vaginal sensitivity to touch, pressure, vibration or temperature.

#### **Women deemed incurable (WDI)**

##### *Symptom*

Women with primary, persistent, and recurrent fistula for which anatomic repair is not possible. WDI require either supportive management and/or a diversion procedure, or they have a fistula complexity that exceeds the capacity(s) of the highest available surgical facility:

**Women deemed incurable (WDI)***Sign*

(i) Definition: The fistula, in this case, is “beyond repair” and may have never undergone treatment, but

usually the symptom history is consistent with Chronic fistula. Symptoms may be consistent with persistent fistula but there may also be symptoms consistent with recurrent fistula. There may be multiple attempts at repair and operations for persistent incontinence. WDI signs are often the most severe forms of fistula signs, be it treated or untreated.

(ii) Extra-urethral incontinence: Observation of urine leakage through channels other than the urethral

meatus, combined with (i) observation of severe or total loss of the bladder, and/or (ii) observation of a urinary tract fistula that exceeds local capacity for successful anatomic treatment.

(iii) Extra-anal incontinence: Observation of fecal or flatal leakage through channels other than the anal

verge, combined with (i) observation of severe or total loss of the anorectum, and/or (ii) observation of an anorectal fistula that exceeds local capacity for successful anatomic treatment.

## ACKNOWLEDGING EXCELLENCE IN SCIENCE

The ICS Scientific Committee honours the highest scoring abstracts every year. There are three overall highest scoring abstract prizes:

- Best Clinical Abstract
- Best Non-clinical Abstract
- Best Video

Scores are awarded by the ICS Scientific Committee Members, External Reviewers and Scientific Session Chairs. Abstracts are judged on the following criteria:

- Scientific Merit
- Originality / Topicality
- Clinical Relevance

View the award winning abstracts from recent years at:
