

# ICS STANDARDS 2023

 Vienna, Austria

The 2023 compilation of the International Continence Society Standardisations, Consensus statements, Educational modules, Terminology and Fundamentals documents, with the International Consultation on Incontinence algorithms

## ICS STANDARDS 2023

ICS Standards 2023 brings together many of the major initiatives of the International Continence Society in its role of supporting healthcare professionals to deliver care and develop knowledge.

Contained here are the current documents produced by the ICS community. As previously, we provide the ICS Consensus Statements, which reflect leading opinion in challenging areas of practice. The Fundamentals of Assessment section is a compilation of succinct reviews setting out the most important components for acquiring or consolidating clinical knowledge, with examples, in lower urinary tract symptoms, incontinence and prolapse. The Standardisations are the state-of-the-art reference sources for the specialist professional, developed by expert working groups overseen by the ICS Standardisation Steering Committee. The International Consultation on Incontinence algorithms are therapy pathways derived by expert committees responsible for detailed literature review and interpretation as part of the regular Consultations process - published most recently in 2017, and due for renewal and publication in late 2022. These documents are a powerful resource intended to help all healthcare professionals dealing with the broad scope of this clinical area.

I hope you will find this compilation very useful.

**David Castro-Diaz**  
ICS General Secretary

## 1. ICS STANDARDISATIONS

The ICS Standards book contains the Standardisation Reports as applicable in 2023. The ICS Standardisation Reports are flagship ICS documents and constitute the reference for all terminology used in the relevant clinical areas, but also in research. They are developed by the ICS Standardisation Committee, in cooperation with specific ICS Standardisation Subcommittees and the Board of Trustees, often in partnership with other professional bodies. These reports ensure that the term for a symptom, condition or disease and related topics, has the same meaning for all healthcare professionals, co-workers, and the patients. They are a series of evidence-based pragmatic documents, developed by experts following a defined process, and covering most relevant areas. The updated 2023 terminology underpins the advancement of research and clinical practice, and this Standards Book incorporates all the current ICS Standardisation Reports. For a quick search on individual terms, there is also a searchable glossary: [www.ics.org/glossary](http://www.ics.org/glossary)

The ICS also offers a historical compilation of older Standardisation Reports that have been superseded.

On behalf of the ICS Standardisation Committee

## Abstract

**Introduction:** The terminology for sexual health in men with lower urinary tract (LUT) and pelvic floor (PF) dysfunction has not been defined and organized into a clinically based consensus terminology report. The aim of this terminology report is to provide a definitional document within this context that will assist clinical practice and research.

**Methods:** This report combines the input of the members of sexual health in men with LUT and PF Dysfunction working group of the International Continence Society (ICS), assisted at intervals by external referees. Appropriate core clinical categories and a sub-classification were developed to give coding to definitions. An extensive process of 18 rounds of internal and external review was involved to exhaustively examine each definition, with decision-making by collective opinion (consensus). The Committee retained evidence-based definitions, identified gaps, and updated or discarded outdated definitions. Expert opinions were used when evidence was insufficient or absent.

**Results:** A terminology report for sexual health in men with LUT and PF dysfunction, encompassing 198 (178 *NEW*) separate definitions, has been

Bernard Haylen: Past Standardisation Steering Committee Chair, ICS (ICS Working Group on Sexual Health in men with LUT and PF dysfunction).

developed. It is clinically based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in all the different speciality groups involved. Conservative and surgical managements are major additions and appropriate figures have been included to supplement and clarify the text. Emerging concepts and measurements, in use in the literature and offering further research potential, but requiring further validation, have been included as an appendix. Interval (5–10 years) review is anticipated to keep the document updated.

**Conclusion:** A consensus-based terminology report for sexual health in men with LUT and PF dysfunction has been produced to aid clinical practice and research. The definitions that have been adopted are those that are most strongly supported by the literature at this time or are considered clinical principles or consensus of experts' opinions.

#### KEYWORDS

Dysfunction, Lower urinary tract, Male, Pelvic floor, Sexual health

## INTRODUCTION

Currently there is no comprehensive document addressing all elements required for diagnoses applicable to sexual health in men with lower urinary tract (LUT) and pelvic floor (PF) dysfunction. The term “diagnosis” is defined by “the determination of the nature of a disease” by clinical symptoms and signs and laboratory investigations.<sup>1</sup> Such a specific report requires a full outline of the terminology for all symptoms, signs, diagnostic tools, and therapeutic options for sexual health in males with LUT and PF dysfunction. Sexual dysfunctions are a large group of conditions that have been classified by the International Classification of Diseases, 10th Edition (ICD-10) by the World Health Organization as organic or as nonorganic even though a multifactorial etiology is often presumed.<sup>2</sup>

This terminology report is inherently and appropriately a definitional document, collating the definitions of terms, that is, words used to express a defined concept in a particular branch of study; sexual health in men with LUT and PF dysfunction. Emphasis has been on comprehensively including terms in current use in the relevant peer-reviewed literature. The aim is to assist clinical practice and research. Explanatory notes on definitions have been referred, where possible, to the “Endnotes section.” Table 1 lists the number of definitions: (i) new; (ii) changed; (iii) total by section, compared with the previous male-inclusive reports.<sup>3–6</sup>

As in earlier ICS Reports, qualities for a male-specific terminology report should be:

- (A) User-friendly: It should be able to be understood by all clinical and research users.
- (B) Clinically-based: Symptoms, signs, validated investigations and imaging should be presented for use in forming diagnoses.
- (C) Origin: Where a term's existing definition (from one of multiple sources used) is deemed appropriate, that definition will be included and duly referenced.
- (D) Able to provide explanations: Where a specific explanation is deemed appropriate to explain a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (Endnotes 1, 2, 3, etc.). Wherever possible, evidence-based medical principles will be followed.

A previous “backbone” terminology ICS paper on adult male LUT and PF symptoms and dysfunctions<sup>5</sup> has been previously published lacking the analysis of sexual male aspects. Disorders in functional urology often overlap with sexual dysfunctions, therefore we needed to promote this update to focus on male sexual health features. Dysfunctions in sexual health have been defined in Section 1 and their anatomical relation has been reported in Section 2. Clinical and diagnostic aspects of sexual dysfunctions have been discussed in Sections 3–6. According to diagnosis, 7 sections have been developed to define conservative and surgical treatments of male sexual dysfunctions as primary conditions or as secondarily related to benign prostatic obstruction (BPO), urethral stricture disease, overactive bladder (OAB), chronic

TABLE 1 Total, new, and changed definitions

Section	New definitions/ descriptions	Changed definitions/ descriptions	Total
Possible definitions and dysfunctions	38	8	46
Anatomical definitions	13	0	13
Symptoms and questionnaires	12	2	14
Signs, examination, and investigations	34	7	41
Conservative and pharmacological treatment	17	0	17
Surgical treatment	6	0	6
BPO treatment and sexual health	9	0	9
Urethral stricture disease and sexual health	3	0	3
Overactive bladder and sexual health	11	2	13
Chronic prostatitis/chronic pelvic pain syndrome and sexual health	10	1	11
Prostate cancer and sexual health	21	0	21
Treatments that warrant further investigation	4	0	4
Total	178	20	198

Abbreviation: BPO, benign prostatic obstruction.

prostatitis/chronic pelvic pain syndrome (CP/CPPS) and prostate cancer.

Commonly accepted terminology is needed given its influence on clinician approach to clinical diagnoses, their studies and investigations of analyses, and for a proper communication with the patients. Thus, this terminology report has a crucial role as it is able to provide definitions which are critical in facilitating research, enabling clinicians to communicate accurately to each other, to their patients, and health care systems. This study also enhances the training of future clinicians.

## SECTION 1: OUTLINE OF DEFINITIONS AND DYSFUNCTIONS IN SEXUAL HEALTH

**1.1 Erectile function:** Complex mechanism of involuntary, neuropsychological, hormone-mediated vascular event that occurs when blood rapidly flows into the penis and becomes trapped in its spongy chambers. (*NEW*)

**1.2 Sexual dysfunction:** Difficulty experienced by an individual or a couple during any stage of normal sexual activity; including desire, arousal, and orgasm. Sexual dysfunction involves significant distress and interpersonal strain for at least 6 months. (*NEW*)

**1.3 De-novo (postoperative) sexual dysfunction symptoms:** Symptoms related to sexual dysfunction that were not reported before surgery. (*NEW*)

**1.4 Erectile function recovery:** Return to baseline erectile function after treatment. (*NEW*)

**1.4.1 Erectile function after treatment for prostate cancer:** Ability to have successful intercourse by patient self-report after any treatment for prostate cancer. (*NEW*)

**1.5 Erectile dysfunction (ED):** Consistent or recurrent inability to attain and/or maintain a penile erection sufficient for sexual satisfaction and/or sexual intercourse. (*CHANGED*)

**1.5.1 Vasculogenic ED:** ED which is secondary to a problem with arterial inflow (e.g., atherosclerosis) or venous outflow (e.g., venous leak). (*NEW*)

**1.5.2 Neurogenic ED:** ED which is secondary to pathology of the central (e.g., spinal cord injury) or peripheral (e.g., diabetic neuropathy) nervous system. (*NEW*)

**1.5.3 End-organ ED:** ED which is due to pathology within the penis itself (e.g., Peyronie's disease). (*NEW*)

**1.5.4 Situational ED:** ED which only occurs in certain circumstances (e.g., with a partner but not during masturbation). Generally understood to be due to psychological factors. (*NEW*)

**1.5.5 Endocrine ED:** ED secondary to an endocrine pathology, most commonly hypogonadism, but may also

be due to hyperprolactinemia, thyroid dysfunction and diabetes mellitus. (*NEW*)

**1.5.6 Mixed ED:** ED which has an organic cause as well psychogenic factors (e.g., anxiety or depression) playing a role. (*NEW*)

**1.6 Male hypoactive sexual desire disorder:** Persistent or recurrent deficiency or absence of sexual or erotic thoughts or fantasies and desire for sexual activity.<sup>6</sup> (*NEW*)

**1.7 Sexual aversion disorder:** Persistent or recurrent extreme aversion to, and avoidance of, all or almost all, genital sexual contact with a sexual partner which causes distress or interpersonal difficulty.<sup>8</sup> (*NEW*)

**1.8 Hypogonadism:** A term introduced to signify low testosterone levels associated with infertility, sexual dysfunction, and systemic alterations (such as decreased muscle mass, depressed mood, sleep disturbances, loss of body hair, lethargy). It has more recently been used interchangeably with the idea of low testosterone production alone.<sup>9</sup> (*NEW*)

**1.8.1 Low testosterone:** Serum total testosterone level being less than 300 ng/dl.<sup>7,9</sup> Threshold for low testosterone in the International System of Units: 11 nmol/l (USA), 12 nmol/l (Europe). (*NEW*)

**1.8.2 Testosterone deficiency (TD):** A state of low testosterone production combined with symptoms and/or signs that are associated with low serum total testosterone.<sup>9,10</sup> (*NEW*)

**1.9 Libido:** A person's overall sexual drive or desire for sexual activity. (*NEW*)

**1.9.1 Altered libido:** Complaint of change in interest in sexual activity.<sup>5</sup>

**1.9.2 Decreased libido:** Complaint of decreased interest in sexual activity in comparison with previous experience.<sup>5</sup>

**1.9.3 Increased libido:** Complaint of increased interest in sexual activity in comparison with previous experience.<sup>5</sup>

### 1.10 Ejaculatory function

**1.10.1 Ejaculation:** Process related to semen expulsion from the urethra.<sup>11</sup> (*NEW*)

**1.10.2 Orgasm:** Sensation of pleasure that accompanies sexual climax.<sup>11</sup> (*NEW*)

**1.10.3 Emission:** Process in which semen is deposited from the vas deferens into the urethra.<sup>11</sup> (*NEW*)

**1.10.4 Ejection:** Synchronic contractions of the bulbospongiosus and ischiocavernosus muscles and external urethral sphincter that allows semen to be expelled antegrade through the urethra.<sup>11</sup> (*NEW*)

**1.11 Ejaculatory dysfunction (EJD):** Complaint of alteration of the emission or expulsion of seminal fluids during ejaculation.<sup>5</sup>

**1.11.1 Anejaculation:** Complaint of absence of seminal fluid emission or expulsion. May be associated with the absence of the sensation of orgasm or anorgasmia.<sup>5</sup>

**1.11.2 Delayed ejaculation:** Primary or acquired complaint of an increase in the time taken for ejaculation to occur.<sup>5</sup> (*CHANGED*)

**1.11.2.1 Primary delayed ejaculation:** A lifelong experience of delayed ejaculation in all or almost all (75%–100%) occasions of coital activity, which causes distress.<sup>6</sup> (*NEW*)

**1.11.2.2 Acquired delayed ejaculation:** A distressing lengthening of ejaculatory latency that occurs in most (>50%) coital experiences after a period of normal ejaculatory function and/or a clinically meaningful change that results in distress.<sup>6</sup> (*NEW*)

**1.11.3 Premature ejaculation (PE):** Complaint of a persistent or recurrent pattern of too rapid achievement of ejaculation during partnered sexual activity, that is, before the individual wishes it.<sup>5</sup> It is accompanied by negative personal consequences, such as distress, bother, frustration, and/or the avoidance of sexual intimacy.<sup>6</sup> (*CHANGED*)

**1.11.3.1 Lifelong (primary) PE:** Ejaculation that always or nearly always occurs before or within about 1 min of vaginal penetration from the first sexual experience.<sup>12</sup> (*NEW*)

**1.11.3.2 Acquired PE:** A clinically significant and bothersome reduction in latency time, often to about 3 min or less.<sup>12</sup> (*NEW*)

**1.11.4 Retrograde ejaculation:** Expulsion of seminal fluid into the bladder because of bladder neck dysfunction and/or disturbances involving the perimontanal area in the presence of otherwise normal emission and expulsion. There can be no or small amounts of antegrade ejaculation. Retrograde ejaculation is defined independently from the sensation of orgasm.<sup>6</sup> (*NEW*)

**1.11.5 Anhedonic ejaculation:** Ejaculation without the pleasurable sensation of orgasm.<sup>6</sup> (*NEW*)

**1.11.6 Hematospermia:** Complaint of the appearance of visible blood in the seminal fluid. Color of the seminal fluid may be red or brown.<sup>13</sup>

**1.12 Orgasmic disorder:** Presence of either of the following on all or almost all (75%–100%) occasions of sexual activity; marked delay in, marked infrequency of, or absence of orgasm; markedly reduced intensity of orgasmic sensations.<sup>7</sup>

**1.12.1 Anorgasmia (male):** The inability to reach orgasm despite adequate and prolonged sexual stimulation leading to adequate sexual arousal which might or might not lead to personal distress.<sup>6</sup> (*NEW*)

**1.12.2 Hypohedonic orgasm:** Lifelong or acquired decreased or low level of sexual pleasure with orgasm.<sup>6</sup> (*NEW*)

**1.13.3 Dysorgasmia:** Painful orgasm. (*NEW*)

**1.13 Postorgasmic illness syndrome:** Flu-like incapacitating physical and mental symptoms occurring within a few minutes to a few hours after an ejaculation, which usually lasts 3–7 days.<sup>6</sup> (*NEW*)

**1.14 Sexual arousal disorder:** Lack of, or significantly reduced, sexual interest or arousal.<sup>3,7</sup>

**1.15 Post-5-alpha reductase inhibitor (5-ARI) syndrome:** Persistent sexual, neurological, physical, and mental adverse reactions in patients who have taken 5-alpha reductase enzyme inhibitors (finasteride and dutasteride).<sup>14</sup> (*NEW*)

**1.16 Benign prostatic hyperplasia (BPH):** A term that is used exclusively to describe the histologic changes related to benign prostatic growth.<sup>8,\*\* 5,13</sup> (*NEW*)

**1.17 Benign prostatic enlargement (BPE):** A term describing increased volume of the gland usually secondary to BPH. The precise volume that determines the lower limit of BPE remains to be defined; 20 ml has been suggested.<sup>5,13</sup> (*NEW*)

**1.18 Benign prostatic obstruction (BPO):** A term used to describe bladder outlet obstruction (BOO) secondary to BPE and, therefore, usually due to BPH.<sup>5,13</sup> (*NEW*)

**1.19 Prostatitis:** An inflammatory disease of the prostate generally affecting younger men and causing pain and discomfort mostly in the perineal and scrotal region which can be associated with lower urinary tract symptoms (LUTS) and/or sexual dysfunction.<sup>17</sup> Prostatitis covers a wide range of clinical conditions including acute bacterial prostatitis, chronic bacterial prostatitis, CPPS (inflammatory and noninflammatory), and asymptomatic inflammatory prostatitis. (*NEW*)

**1.20 Overactive bladder (OAB) syndrome:** Urinary urgency, usually accompanied by increased daytime frequency and/or nocturia, with urinary incontinence (UI) (OAB-wet) or without (OAB-dry), in the absence of urinary tract infection or other detectable disease.<sup>††,5,22</sup>

**1.21 Sexual activity urinary incontinence or coital urinary incontinence:** Complaint of UI associated with or during sexual activity and sexual arousal.<sup>7,23</sup> (*CHANGED*)

**1.22 Climacturia:** Involuntary loss of urine at the time of orgasm. (*NEW*)

**1.23 Sexual arousal incontinence or foreplay incontinence:** Complaint of involuntary loss of urine during sexual arousal, foreplay and/or masturbation.<sup>24,25</sup> (*NEW*)

**1.24 Penile pain with intercourse (male dyspareunia):** Complaint of any penile discomfort occurring during intercourse. May be caused by penile disease, vaginal anatomy (e.g., vaginal tightening, scarring, or

exposed mesh) and/or may relate to various positions with intercourse.<sup>5</sup>

**1.24.1 Hispareunia:** Male partner pain with vaginal intercourse after female reconstructive surgery.<sup>7</sup> (*CHANGED*)

**1.25 Chronic sexual pain disorder:** Sexual activity may induce a central sensitization process characterized by hypersensitivity or hyperalgesia before, during or after sexual activity.<sup>26</sup> (*CHANGED*)

**1.26 Pain:** A subjective phenomenon described as an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage. Pain should be characterized by site, type, frequency, duration, precipitating and relieving factors. The word pain comes from the Latin "poena" meaning a fine or a penalty.<sup>26</sup>

**1.26.1 Acute pain:** Pain related to acute trauma, infection or other well-defined disease process.<sup>26</sup>

**1.26.2 Chronic pain:** Persistent or continuous/recurrent pain for at least 6 months. If non-acute and central sensitization pain mechanisms are well documented, then the pain may be regarded as chronic, irrespective of the time period.<sup>26</sup>

**1.26.3 Pelvic pain syndrome:** Occurrence of persistent or recurrent episodic pelvic pain associated with symptoms suggestive of LUT, sexual, bowel or gynecological dysfunction. There is no proven infection or other obvious disease.<sup>27</sup>

**1.26.4 Perineal pain syndrome:** Perineal pain syndrome is the occurrence of persistent or recurrent episodic perineal pain, which is either related to the micturition cycle or associated with symptoms suggestive of urinary tract or sexual dysfunction. There is no proven infection or other obvious disease.<sup>27</sup>

**1.26.5 Scrotal pain syndrome:** Scrotal pain syndrome is the occurrence of persistent or recurrent episodic scrotal pain which is associated with symptoms suggestive of urinary tract or sexual dysfunction. There is no proven epididymo-orchitis or other obvious disease.<sup>27</sup>

**1.26.6 Male chronic genital pain syndromes:** Male genital pain syndromes are often associated with symptoms suggestive of LUT and sexual dysfunction. Common complaints: genital pain, uncomfortable urination, dysuria, sensation of residual urine, increased daytime frequency, slow stream, urgency, dyspareunia. Absence of infection, previous operations, or other obvious disease.<sup>26</sup>

**1.26.6.1 Chronic (persistent or recurrent) epididymal pain syndrome:** Pain is specific/localized to the epididymis. (i) Persistent or recurrent episodic pain. (ii) Spontaneous, or reproduced by digital pressure and physical activities. (iii) LUT symptoms or sexual dysfunction.

**1.26.6.2 Chronic (persistent or recurrent) penile pain syndrome:** Pain within the penis that is not primarily in the urethra and may be: (i) Persistent or recurrent. (ii) Spontaneous, or reproduced by digital pressure and physical activities. (iii) LUT symptoms or sexual dysfunction.

**1.26.6.3 Chronic (persistent or recurrent) prostate pain syndrome:** See 1.30.

**1.26.6.4 Chronic (persistent or recurrent) scrotal pain syndrome:** Chronic scrotal pain (generic term used when the site of pain is not clearly in the testis or epididymis). (i) Persistent or recurrent episodic pain, unilateral or bilateral. (ii) Spontaneous, or reproduced by digital pressure and physical activities. (iii) Pain is not in the skin of the scrotum but perceived within its contents. (iv) LUT symptoms or sexual dysfunction.

**1.26.6.5 Chronic (persistent or recurrent) testicular pain syndrome:** (i) Persistent or recurrent episodic pain. (ii) Spontaneous, or reproduced by digital pressure and physical activities. (iii) LUT symptoms or sexual dysfunction.

**1.26.7 Chronic prostatitis/Chronic pelvic pain syndrome (CCP/CPSP):** Persistent or recurrent prostate and/or pelvic pain, associated with symptoms suggestive of urinary tract and/or sexual dysfunction. No proven infection or other obvious pathology is present to account for the symptoms. Pain may be referred to the bladder, perineum, testicles, penis and/or groin.<sup>26</sup> (**CHANGED**)

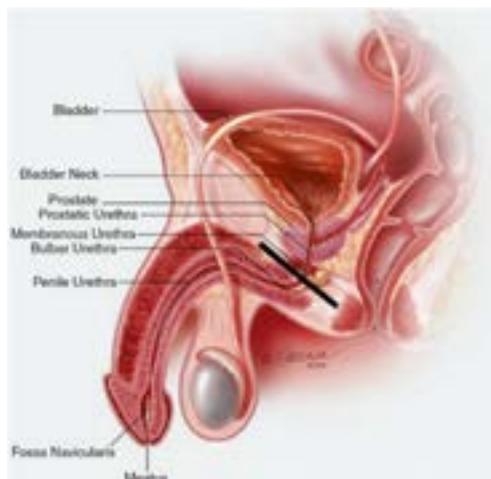

**1.26.7.1 Symptoms of CP/CPSP:** Intermittent pain. Persistent or recurrent pain. Dyspareunia and/or ED. Voiding and post micturition symptoms (e.g., hesitancy, intermittency, feeling of incomplete emptying, dysuria). (**CHANGED**)

**1.26.7.2 National Institutes of Health (NIH) prostatitis classification system.** Prostatitis is classified as acute bacterial prostatitis (category I), chronic bacterial prostatitis (category II), CP/CPSP (category III) and asymptomatic inflammatory prostatitis (category IV).<sup>34,35,36</sup>

**1.26.7.2.1 Acute bacterial prostatitis:** Characterized by severe symptoms of prostatitis, systemic infection and acute bacterial urinary tract infection, requires hospitalization and parenteral fluid-antibiotic therapy.<sup>17</sup>

**1.26.7.2.2 Chronic bacterial prostatitis:** Caused by chronic bacterial infection of the prostate with or without symptoms of prostatitis. It is usually associated with recurrent urinary tract infections caused by the same bacterial strain.<sup>17</sup>

**1.26.7.2.3 CPSP:** Characterized by chronic pelvic pain and LUT symptoms in the absence of urinary tract infection. It is subdivided into inflammatory (3A) and noninflammatory (3B) categories depending on the

**FIGURE 1** Sagittal view of the male urethra. The bold line delineates the anterior from posterior urethra<sup>111</sup>

presence/absence of leukocytes in expressed prostatic secretion.<sup>17</sup>

**1.26.7.2.4 Asymptomatic inflammatory prostatitis:** Characterized by histopathological evidence of prostatic inflammation in the absence of genitourinary symptoms. This is usually an incidental finding during evaluation for other conditions such as elevated PSA.<sup>9</sup>

## SECTION 2: ANATOMICAL DEFINITIONS RELATED TO SEXUAL DYSFUNCTION

**2.1 Urethral meatus:** The distal termination of the urethra. An orthotopic urethral meatus is a vertically-oriented slit-like opening located on the glans penis (Figure 1).<sup>37</sup> (**NEW**)

**2.2 Fossa navicularis:** The distal portion of the penile urethra, located within the glans penis, just proximal to the urethral meatus.<sup>33,37</sup> (**NEW**)

**2.3 Penile urethra:** The portion of the urethra extending from the urethral meatus to the distal part of the bulbocavernosus muscle. The lumen is centered in and completely invested by the corpus spongiosum.<sup>33,37</sup> (**NEW**)

**2.4 Bulbar urethra:** The portion of the urethra between the distal membranous urethra until the conjunction of the left and right corpus cavernosum. The lumen is surrounded by and sits eccentrically toward the dorsal portion of the bulbospongiosus of the corpus spongiosum.<sup>37</sup> (**NEW**)

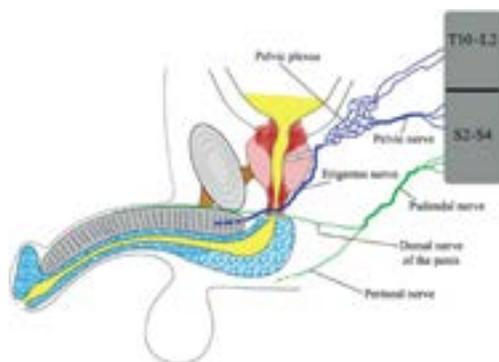

FIGURE 2 Relationship of the nerves to the urethra. From Palminteri et al.<sup>38</sup>

**2.5 Membranous urethra:** The portion of the urethra which traverses the perineal membrane and is surrounded by the striated external urethral sphincter.<sup>37</sup> (NEW)

**2.6 Prostatic urethra:** The portion of the urethra extending from the bladder neck to the proximal edge of the membranous urethra.<sup>37</sup> (NEW)

**2.7 Bladder neck:** The most proximal part of the urethra, creating its connection with the bladder. (NEW)

**2.8 Cavernous nerves (“Nervi Erigentes”):** These nerves are formed from the distal end of the pelvic plexus and supply sympathetic and parasympathetic innervation to the corpora cavernosa. The cavernous nerves are located at 3 and 9 O’clock positions at the level of the membranous urethra and at 2 and 10 O’clock positions at the level of the proximal bulbar urethra. These nerves are at risk during pelvic fracture urethral injury (and its repair) as well as bulbar urethroplasty (Figure 2).<sup>38</sup> (NEW)

**2.9 Pudendal nerves:** These nerves arise from the S2-S4 spinal nerves and provide somatic innervation to the pelvis and perineum. The pudendal nerve travels with the pudendal vessels in Alcock’s canal, before giving off the inferior rectal nerve and perineal nerve, and then terminating as the dorsal nerve of the penis.<sup>38,39</sup> (NEW)

**2.10 Perineal nerves:** Branches of the pudendal nerves (7.14), the perineal nerves supply motor innervation to the bulbocavernosus and ischiocavernosus muscles as well as sensory innervation via the posterior scrotal and bulbourethral nerves.<sup>38,40</sup> (NEW)

**2.11 Dorsal nerves of the penis:** These nerves are the terminal branches of the pudendal nerves. They travel through the deep perineal pouch, exiting just inferior to the pubic symphysis and then run along the dorsal surface of the corpora to reach the glans. The

supply sensory innervation to the penis and in particular the glans.<sup>38,40</sup> (NEW)

**2.12 Neurovascular bundle (NVB):** Concentration of nerves that are situated posterolaterally and symmetrically to the prostate that are important in preservation of erectile function. The nerves running through the NVB travel outside the capsule of the prostate and Denovilliers fascia until branches perforate the capsule where they enter the prostate (Figure 3).<sup>41</sup> (NEW)

## SECTION 3: SYMPTOMS AND QUESTIONNAIRES

### (A) Symptoms

**3.1 Symptom:** Any morbid phenomenon or departure from the normal in structure, function, or sensation, possibly indicative of a disease or health problem. Symptoms are either volunteered by, or elicited from the individual, or may be described by the individual’s partner or caregiver.<sup>3,4</sup>

**3.2 Complaint:** The description of the symptom.<sup>1</sup>

**3.3 Main (Chief) complaint:** The symptom that a patient states as the main reason for seeking medical advice.<sup>1</sup> The degree of “bother (worry, concern)” for other symptoms can be variable.<sup>42</sup>

**3.4 Lower urinary tract symptom (LUTS):** A symptom related to the LUT; it may originate from the bladder, prostate, urethra, and/or adjacent PF or pelvic organs, or at times be referred from similarly innervated anatomy, for example, lower ureter. §§§.5 (CHANGED)

**3.5 Urgency:** Complaint of sudden, compelling desire to pass urine which is difficult to defer.<sup>5,43,44</sup>

**3.6 Urinary incontinence (UI):** Complaint of involuntary loss of urine.<sup>5</sup>

**3.7 Urgency urinary incontinence (UUI):** Complaint of involuntary loss of urine associated with urgency.<sup>5</sup>

**3.8 Daytime (urinary) frequency:** Number of micturitions during daytime (awake hours).

**3.9 Nocturia:** The number of times urine is passed during the main sleep period. Having woken to pass urine for the first time, each urination must be followed by sleep or the intention to sleep. This should be quantified using a bladder diary.<sup>5</sup>

**3.10 Ejaculatory pain:** Complaint of pain, pressure, or discomfort felt in the perineum, suprapubic region and/or penis during ejaculation, but may continue for a time afterwards.<sup>5</sup>

**3.11 Decreased (low) semen volume:** Complaint of smaller amount of seminal fluid than normal or previously experienced.<sup>5</sup>

**3.12 Increased (high) semen volume:** Complaint of higher amount of seminal fluid than normal or previously experienced.<sup>5</sup>

**3.13 Semen sequestration:** Trapping of ejaculate in the bulbar urethra, resulting in a decreased force and volume of emission; often secondary to damage to the perineal nerves and/or bulbospongiosus muscle. Manual pressure on the perineum at the level of the bulbar urethra may be required to expel sequestered semen.<sup>38</sup> (NEW)

**3.14 Penile shortening:** A subjective or objective decrease in penile length. Well known to be associated with plication procedures for Peyronie's disease, it is also associated with penile revascularization procedures, anastomotic and augmented urethroplasty, hypospadias

repair, and prostate cancer treatment such as radical prostatectomy (RP).<sup>38,45</sup> (NEW)

**3.15 Intimacy and sexual avoidance:** Unwillingness or reluctance of engaging in sexual activity or intimacy with others.<sup>25,46</sup> (NEW)

**3.16 Pain:** A subjective phenomenon described as an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage.<sup>26</sup>

**3.17 Chronic pelvic pain:** Characterized by persistent pain lasting longer than 6 months or recurrent episodes of abdominal/pelvic pain, hypersensitivity or discomfort often associated with elimination changes, and sexual dysfunction often in the absence of organic etiology.<sup>26,47</sup>

TABLE 2 OAB questionnaires, and their correlation with sexual dysfunction

Questionnaire	Contents	Correlation with SD
OAB-SS (OAB symptom score)	Total score is a sum of four-item scores based on a self-administered questionnaire about four symptoms: daytime frequency (0–2), nighttime frequency (0–3), urgency (0–5), and urgency incontinence (0–5). <sup>60</sup>	In patients with diabetes, the component of urge incontinence has the strongest impact on ED (OR: 4.06, $p = 0.013$ ), followed by nocturia (OR: 2.71, $p < 0.01$ ) and urgency (OR: 1.87, $p = 0.046$ ). The OR of ED in patients with OAB or OAB wet compared with no OAB was 1.82 ( $p = 0.056$ ), and 3.6 ( $p = 0.026$ ), respectively. <sup>61,62</sup>
OAB-q (OAB Questionnaire) and HRQL (Health-Related Quality of Life)	33 items that assess impact of OAB bother score and its impact on QOL.	Low correlation with SD. <sup>63</sup>
OAB-q SF (OAB-q Short Form)	6 items that address urgency, urinary incontinence and nocturia and score them from 1 to 6 based on bother. <sup>64</sup>	No validation for sexual QOL
IPSS	See 3.22	There is a strong correlation between IPSS and erectile function, intercourse satisfaction, orgasmic and sexual desire. IPSS is also strongly correlated with IIEF. <sup>65</sup>
CLSS (Core Lower Urinary Tract Symptom Score)	10 symptoms: daytime frequency, nocturia, urgency, urgency incontinence, stress incontinence, slow stream, straining, incomplete voiding, bladder pain, and urethral pain.	Total score and all symptoms but daytime frequency and incomplete voiding have a significant relationship with total IIEF-5 score. <sup>66</sup>
BFLUTS (Bristol Female Lower Urinary Tract Symptoms Questionnaire)	Among other LUTS, this questionnaire assesses frequency, urgency, nocturia and urgency urinary incontinence.	OAB symptoms have a negative impact on sexual life, especially in patients with OABwet. <sup>66,67</sup>
ICIQ-OAB (International Consultation on Incontinence Questionnaire)	4 items: frequency, urgency, nocturia and UUI and bother scale from 0 to 10 of each item.	The ICIQ-mLUTSsex is and add-on of 4 items to assess impact of sex life: erection, ejaculation, pain during ejaculation and impact of urinary symptoms on sex life.

Abbreviations: ED, erectile dysfunction; IIEF, International Index of Erectile Function; LUTS, lower urinary tract symptoms; OAB, overactive bladder; OR, odds ratio; UUI, urgency urinary incontinence.

**3.18 Penile sexual pain:** Penile pain that occurs before penetration (ie when an erection occurs), with penetration or postcoital.<sup>26</sup>

**3.19 Perineal sexual pain:** may occur during intercourse or after intercourse.<sup>26</sup>

**3.20 Orgasmic pain (during ejaculation):** pain may be felt on the penis, ano-rectum, perineum or in the whole pelvis.<sup>26</sup> (**CHANGED**)

#### (B) Questionnaires

**3.21 American Urological Association (AUA) Symptom Index (AUA-SI) for BPH:** A symptom index for BPH which was developed and validated by a multi-disciplinary measurement committee of the AUA. It includes seven questions covering frequency, nocturia, weak urinary stream, hesitancy, intermittency, incomplete emptying, and urgency.<sup>\*\*\*\*,49</sup> (**NEW**)

**3.22 International Prostate Symptom Score (IPSS):** An 8-question written screening tool used to screen for, rapidly diagnose, track the symptoms of, and suggest management of the symptoms of BPH. It contains the seven questions of the AUA symptom index for BPH and one question related to the patient's perceived quality of life (bother score).<sup>††††,51</sup> (**NEW**)

**3.23 International Index of Erectile Function (IIEF):** A multi-dimensional and validated self-report instrument for the evaluation of male sexual function.<sup>††††,52</sup> (**NEW**)

**3.24 Sexual Health Inventory for Men (SHIM):** The SHIM questionnaire (also known as the IIEF-5) is an abridged and slightly modified 5-item version of the 15-item IIEF, to diagnose the presence and severity of ED in clinical settings.<sup>§§§§,53</sup> (**NEW**)

**3.25 Erection Hardness Score (EHS):** A single-item instrument that asks men to rate erection hardness on a scale that ranges from 0 (*penis does not enlarge*) to 4 (*penis is completely hard and fully rigid*).<sup>54</sup> (**NEW**)

**3.26 Male Sexual Health Questionnaire (MSHQ):** A tool for assessing key domains of sexual function and satisfaction in aging men with urogenital symptoms of LUTS and sexual dysfunction. It consists of 25 questions that constitute subscales for Erection, Ejaculation, and Satisfaction.<sup>\*\*\*\*\*,55</sup> (**NEW**)

**3.27 Premature Ejaculation Profile (PEP):** A self-report questionnaire used to assess four components of PE: satisfaction with sexual intercourse, control over ejaculation, ejaculation-related distress, and interpersonal difficulty. Each of the four individual items is assessed on a 5-point scale, and the scores are averaged to provide an index PE score.<sup>56</sup> (**NEW**)

**3.28 Index of Premature Ejaculation (IPE):** A 10-item validated tool which was developed to evaluate sexual satisfaction, control, and distress in men with PE.<sup>57</sup> (**NEW**)

**3.29 Brief male sexual function inventory (BMSFI):** A validated, self-administered 11-item inventory evaluating male sexual function. There are five domains: Sexual Drive, Erections, Ejaculation, Problem Assessment, and Overall Satisfaction.<sup>††††,59</sup> (**NEW**)

#### (C) Questionnaires for overactive bladder and correlation with sexual dysfunction

See Table 2.

## SECTION 4: SIGNS AND EXAMINATION

### (A) General signs and examination findings

**4.1 Cardiovascular examination:** Part of the physical examination that should include assessment of vital signs (especially blood pressure and pulse) and signs of hypertensive or ischemic heart disease as well as peripheral vascular disease.<sup>††††,§§§§</sup> (**NEW**)

**4.2 Gynecomastia:** Excessive development of male breast tissue which may or may not be a sign of underlying endocrinological disorder.<sup>\*\*\*\*\*</sup> (**NEW**)

**4.3 Sarcopenia:** A clinical condition characterized by loss of skeletal muscle and function. It might be a sign of hypogonadism. (**NEW**)

### (B) Penile examination

**4.4 Peyronie's disease:** A connective tissue disorder involving the growth of fibrous plaques in the soft tissue of the penis. Specifically, scar tissue forms in the tunica albuginea, causing pain, abnormal curvature, ED, indentation, loss of girth and shortening. (**NEW**)

**4.5 Stretched penile length:** The penile length as measured by a rigid centimeter ruler, which is placed along the dorsal side of the penis (flaccid, and stretched as comfortably as possible), extending in a parallel fashion from the pubopenile skin junction to the tip of the glans where the pre-pubic fat pad was pushed to the bone.<sup>68</sup> (**NEW**)

**4.6 Penile curvature:** Abnormal bend in the penis occurring during erection which might lead to sexual dysfunction by impairing the ability to penetrate and/or causing pain in the tumescent state. (**NEW**)

**4.7 Buried penis:** A congenital or acquired condition in which penis is partially or totally embedded underneath the skin of the abdomen, thigh, or scrotum. (**NEW**)

**4.8 Phimosis:** Partial or complete inability to retract the prepuce due to adhesion between the glans and the prepuce or a preputial ring.<sup>5</sup>

**4.9 Paraphimosis:** Entrapment of the prepuce behind the glans.<sup>5</sup>

**4.10 Hypospadias:** Refers to the urethral meatus sited on the ventral surface of the penis, either congenital

or acquired, proximal to its normal position on the tip of the glans.<sup>5</sup>

**4.11 Epispadias:** Refers to the urethral meatus sited on dorsal surface of the penis, either congenital or acquired, proximal to its normal position on the tip of the glans.<sup>5</sup>

**4.12 Urethral meatal stenosis:** Narrowing of the distal opening of the urethra which may be congenital or occur secondary to infection, inflammation, or as a result of surgical (open or endoscopic) intervention.<sup>5</sup> (CHANGED)

**4.13 Lichen sclerosus (LS):** A chronic, inflammatory disease affecting genital skin that is characterized by hypomelanotic and sclerotic changes, often resulting in phimosis, meatal stenosis, and even pan-urethral strictures.<sup>69</sup> (NEW)

#### (C) Scrotal examination findings

**4.14 Epididymitis/epididymo-orchitis:** The inflammatory condition involving epididymis ± testis. Affected structures may be swollen and tender, and if severe, the inflammatory process may involve the whole scrotal content and the scrotal skin as well.<sup>5</sup> (CHANGED)

**4.15 Cystic dilatations of the epididymis:** Epididymal cysts (or spermatocele) and hydroceles (fluid collections between the visceral tunica albuginea and parietal layer of the testicular peritoneum) are usually benign. The examination of these structures would be generally non-tender and without pain.<sup>5</sup> (CHANGED)

#### 4.16 Inguinal hernia:

**4.16.1 Indirect inguinal hernia:** Protrusion of abdominal content through inguinal canal down to the scrotal sac, causing swelling, discomfort and jeopardizing the vascular supply of the herniated intestinal segment. (NEW)

**4.16.2 Direct inguinal hernia:** Protrusion of abdominal content through a weakness of the posterior wall of the inguinal canal medial to the inferior epigastric vessels. (NEW)

**4.17 Varicocele:** Abnormal dilation of pampiniform venous plexus which drains blood from each testicle. Varicocele is graded based on the degree of dilation. (NEW)

**4.17.1 Subclinical varicocele:** Seen on Doppler ultrasound imaging, no varicocele on exam. (NEW)

**4.17.2 Grade 1 varicocele:** Palpable with valsalva maneuver. (NEW)

**4.17.3 Grade 2 varicocele:** Palpable when standing, without valsalva maneuver. (NEW)

**4.17.4 Grade 3 varicocele:** Visible on inspection. (NEW)

**4.18 Testicular mass:** Palpation of a mass originating from testis. This might be originating from the testicular parenchyma or its appendages and may be cystic

or solid in nature and related to a benign or malignant (more commonly) neoplastic process. (NEW)

**4.19 Nonpalpable testis:** Absence of testis in the hemiscrotum or inguinal canal. This can be a finding related to cryptorchidism (undescended testicle), testicular atrophy or vanishing testis. (NEW)

**4.20 Testicular torsion:** Torsion of the spermatic cord structures that leads to vascular compromise involving the ipsilateral testicle. Physical examination might reveal a tender, swollen and erythematous hemiscrotum on the affected side. (NEW)

**4.21 Absence of vas deferens:** Congenital absence of vas deferens in the hemiscrotum. It may be either unilateral or bilateral. ††††† (NEW)

**4.22 Atrophic testis:** Testicular dimensions being smaller than expected. Consistency of atrophic testes might be softer than usual. Diminished t'r size may be accompanied by loss of function. (NEW)

#### (D) Digital rectal examination (DRE) findings

**4.23 Rectal and prostate examination:** DRE that is generally done with the patient standing and bent over the examining table, or with the patient in the left lateral knees bent position, or in the lithotomy position.<sup>5</sup> It provides valuable information regarding prostate size, consistency, PF muscle tone, anal sphincter tone, constipation, and rectal/anal canal masses. It might also raise suspicion for prostate cancer (see Endnote †††††). (CHANGED)

**4.24 Anal tone:** increased or decreased anal sphincter tone might suggest similar changes in the urinary sphincter and may indicate neurologic disease. †††††.<sup>5</sup>

**4.25 Prostate tenderness:** DRE of the prostate is usually painless. Pain with prostatic palpation may be indicative of CP/CPPS. §§§§§.<sup>5</sup> (CHANGED)

#### (E) Neurological signs and examination findings

**4.26 Overall neurological status:** Assessment of the abnormalities of speech, gait, as well as upper and lower extremity dexterity which should be noted as they may indicate a neurological cause for the sexual dysfunction.<sup>5</sup> (CHANGED)

**4.27 Penile, scrotal, or perianal sensory deficits:** Neurological examination findings that may indicate damage or injury to sacral roots or nerves.<sup>5</sup> (CHANGED)

**4.28 Glans hypoesthesia:** Reduced sensitivity of the glans penis. This may be associated with hypospadias and its treatment, penile revascularization procedures, bulbar urethroplasty. †††††.<sup>38,45</sup> (NEW)

**4.29 Bulbospongiosus reflex (BSR):** A reflex contraction of the striated muscle of the PF (anal sphincter) and the bulbospongiosus muscle that occurs in response to various stimuli in the perineum or genitalia.<sup>5</sup>

**4.30 Cremasteric reflex:** Contraction of the ipsilateral cremaster muscle, drawing the testis upwards, when the upper inner aspect of the thigh is stroked longitudinally.<sup>5</sup>

## SECTION 5: INVESTIGATIONS

### (A) Laboratory tests

Blood tests are not normally included in ICS terminology reports. However, certain serum-based measurements hold critical importance in the diagnosis and treatment of ED.

**5.1 Testosterone:** Total testosterone can be measured in men with ED to determine if TD is present.<sup>††††††,48</sup> (NEW)

**5.1.1 Free testosterone:** Fraction of total testosterone that is unbound plasma to proteins. (NEW)

**5.1.2 Sex hormone binding globulin (SHBG):** A plasma protein that is produced by the liver and transports sex hormones (estradiol, testosterone, dihydrotestosterone) in the blood as biologically inactive forms. (NEW)

**5.1.3 Bioavailable testosterone:** Bioavailable testosterone represents an assessment of the biologically active testosterone in serum. It includes the free plus weakly protein bound fractions of testosterone and is calculated by a formula integrating serum albumin, SHBG, and total testosterone. (NEW)

**5.2 Prostate specific antigen (PSA):** Serum PSA level is measured for prostate cancer screening and to gather additional information about the size of the prostate and associated inflammatory changes.<sup>††††††</sup> (NEW)

### (B) Imaging studies

**5.3 Retrograde urethrography (RUG):** Imaging of the urethra with serial fluoroscopic images during retrograde injection of contrast material. The patient should be positioned obliquely to adequately visualize the urethra. Used mainly to diagnose urethral strictures or diverticula, it is also of use to diagnose and stage urethral trauma.<sup>5,70</sup> (NEW)

**5.4 Voiding cystourethrography (VCUG):** Imaging of the bladder, bladder neck, urethra, and prostate during voiding. The principal use is determining the site of any obstruction, for example, bladder neck or prostate. It can also detect vesicoureteric reflux, vesical or urethral fistulae, vesical or urethral diverticula and strictures.<sup>5,70</sup>

**5.5 Sonourethrography:** Ultrasound examination of the urethra, providing information on the location and length of stricture as well as the degree of spongiositis.<sup>71</sup> (NEW)

**5.6 Dynamic infusion cavernosometry and cavernosography (DICG):** A combined evaluation of

intracavernosal pressures and radiographic assessment of penile blood flow. It is used to identify vasculogenic leak in patients being considered for penile vascular surgery.<sup>§§§§§§,39</sup> (NEW)

**5.7 Penile duplex ultrasonography:** Use of real-time ultrasound with and without vasoactive medications for pharmacologically induced erection to evaluate the flow velocities in the dorsal penile and cavernosal arteries.<sup>39</sup> (NEW)

**5.8 Pudendal angiography:** Imaging of the pudendal arteries for patency using injection of intravascular contrast and fluoroscopic imaging.<sup>\*\*\*\*\*,39</sup> (NEW)

### (C) Other diagnostic tests/procedures

**5.9 Cystourethroscopy:** Direct visual inspection of the urethra and bladder with a rigid or flexible cystoscope. It is the gold-standard for diagnosing the presence or absence of urethral stricture disease, however it is not sufficient for complete staging.<sup>70</sup> (NEW)

**5.10 Urodynamic studies (UDS):** Measurement of all the physiological parameters relevant to the function and any dysfunction of the LUT. Urodynamic investigations generally involve an individual attending with a comfortably full bladder for free (no catheter) uroflowmetry and post-void residual (PVR) measurement before filling cystometry and pressure-flow study.<sup>††††††,5</sup>

**5.11 Nocturnal penile tumescence (NPT) testing:** A diagnostic test for evaluating the penile veno-occlusive mechanism. Penile rigidity is monitored using a specialized device (often the RigiScan®) for at least two consecutive nights. Three periods of penile tip rigidity of greater than 70%, lasting for at least 10 min each, each night, defines normal nocturnal erectile function.<sup>††††††,45,72</sup> (NEW)

**5.12 Pudendal somatosensory evoked potentials (SEP):** A neurophysiologic test which can be used to support the diagnosis of a neurogenic cause of ED. The test should be performed as per the International Federation of Clinical Neurophysiology guidelines. A latency time >48 ms is considered abnormal (the mean normal latency is 37ms).<sup>72,73</sup> (NEW)

## SECTION 6: DIAGNOSES

**6.1 ED:** Consistent or recurrent inability to attain and/or maintain a penile erection sufficient for sexual satisfaction and/or sexual intercourse.<sup>6</sup> (CHANGED)

**6.2 Hypogonadism:** A term introduced to signify low testosterone levels associated with infertility. It has more recently been used interchangeably with the idea of low testosterone production alone.<sup>9</sup> (NEW)

**6.3 PE:** Complaint of a persistent or recurrent pattern of too rapid achievement of ejaculation during partnered

sexual activity, that is, before the individual wishes it.<sup>5</sup> It is accompanied by negative personal consequences, such as distress, bother, frustration, and/or the avoidance of sexual intimacy.<sup>6</sup> (**CHANGED**)

**6.4 Retrograde ejaculation:** Expulsion of seminal fluid into the bladder because of bladder neck dysfunction in the presence of otherwise normal emission and expulsion. There can be no or small amounts of antegrade ejaculation. Retrograde ejaculation is defined independently from the sensation of orgasm.<sup>6</sup> (**NEW**)

**6.5 BPO:** A term used to describe BOO secondary to BPE and, therefore, usually due to BPH. BOO is an urodynamic entity and can only be diagnosed via pressure-flow studies.<sup>13</sup> (**NEW**)

**6.6 Prostatitis:** An inflammatory disease of the prostate generally affecting younger men and causing pain and discomfort mostly in the perineal and scrotal region which can be associated with LUTS and/or sexual dysfunction.<sup>17</sup> (**NEW**)

**6.7 OAB syndrome:** Urinary urgency, usually accompanied by increased daytime frequency and/or nocturia, with UI (OAB-wet) or without (OAB-dry), in the absence of urinary tract infection or other detectable disease.<sup>22</sup>

**6.8 Male chronic genital pain syndromes:** Male genital pain syndromes are often associated with symptoms suggestive of LUT and sexual dysfunction. Common complaints: genital pain, uncomfortable urination, dysuria, sensation of residual urine, increased daytime frequency, slow stream, urgency, dyspareunia. Absence of infection, previous operations, or other obvious pathology.<sup>26</sup>

**6.9 CP/CPPS:** Persistent or recurrent prostate and/or pelvic pain, associated with symptoms suggestive of urinary tract and/or sexual dysfunction. No proven infection or other obvious pathology is present to account for the symptoms. Pain may be referred to the bladder, perineum, testicles, penis and/or groin.<sup>26</sup> (**CHANGED**)

**6.10 Urethral stenosis:** A narrowing of the anterior urethra, caused by spongiofibrosis of the corpus spongiosum.<sup>37</sup> (**NEW**)

**6.11 Posterior urethral stenosis:** Narrowing of the membranous urethra, prostatic urethra, or bladder neck, when the prostate is still in situ.<sup>37,74</sup> (**NEW**)

**6.12 Vesicourethral anastomotic stenosis (VAS):** Narrowing of the posterior urethra after RP.<sup>74</sup> (**NEW**)

**6.13 Lichen sclerosus (LS):** A chronic, inflammatory disease affecting genital skin that is characterized by hypomelanotic and sclerotic changes, often resulting in phimosis, meatal stenosis, and even pan-urethral strictures.<sup>§§§§§§§§,69</sup> (**NEW**)

#### 6.14 Urethral trauma

**6.14.1 Blunt urethral trauma:** An injury to the urethra from a non-penetrating injury. May include straddle injuries, deceleration injuries, penile fracture, and pelvic fracture urethral injuries.<sup>37</sup> (**NEW**)

**6.14.2 Iatrogenic urethral trauma:** Injury to the urethra resulting from instrumentation of the urethra, such as with cystoscopy or catheterization, or treatment of disease in the urethra or prostate, such as urethral dilation, transurethral resection of the prostate, prostate radiation, or RP.<sup>37</sup> (**NEW**)

**6.14.3 Pelvic fracture urethral injury (PFUI):** A urethral distraction injury, typically involving the bulbomembranous junction. Previously known as *pelvic fracture urethral distraction defects*, this term should be reserved for cases of PFUI with loss of urethral continuity.<sup>37,75</sup> (**NEW**)

**6.14.4 Penetrating urethral trauma:** Injury to the urethra resulting from an object passing into or through the urethra from outside the body. Gunshot wounds, stab injuries, and penile amputation are examples of penetrating urethral trauma. (**NEW**)

**6.14.5 Straddle Injury:** Injury to the bulbar urethra resulting from a blunt trauma which compresses the bulbar urethra against the inferior pubic rami. May be remote, or even not recalled by the patient.<sup>76</sup> (**NEW**)

**6.15 Post-infectious stricture:** Urethral stricture disease developing as a result of gonococcal and nongonococcal (*Ureaplasma urealyticum*, *Mycoplasma genitalium*, schistosomiasis, and tuberculosis) urethritis.<sup>37,76</sup> (**NEW**)

**6.16 Prostate cancer (CaP):** Development of cancer from the prostate gland.<sup>\*\*\*\*\*,39</sup> (**NEW**)

**6.16.1 Localized:** Cancer confined to the gland of the prostate.<sup>††††††††,77</sup> (**NEW**)

**6.16.2 Locally advanced:** Spread of prostate cancer outside the prostate capsule, involvement of the seminal vesicles or involvement of adjacent organs without distant metastasis. (**NEW**)

**6.16.3 Metastatic:** Distant spread of prostate cancer to other areas of the body beyond the pelvis, most notably bone and lymph nodes. Spread can also occur to the liver and lungs.<sup>§§§§§§§§</sup> (**NEW**)

## SECTION 7: CONSERVATIVE AND PHARMACOLOGICAL TREATMENTS FOR SEXUAL DYSFUNCTION (GENERAL)

**7.1 Psychotherapy:** Psychotherapy and psychosexual counseling focus on helping patients and their partners improve communication about sexual concerns, reduce anxiety related to entering a sexual situation and during a

sexual situation, and discuss strategies for integrating ED treatments into their sexual relationship.<sup>48</sup> (NEW)

**7.2 Lifestyle recommendations:** Dietary changes, weight loss, physical activity increases, and smoking cessation that may improve overall health and ameliorate the comorbidities associated with ED.<sup>48</sup> (NEW)

**7.3 Herbal therapy:** Plant-derived remedies that can provide alternatives for men to improve their sexual health.<sup>§§§§§§§§,78</sup> (NEW)

**7.4 Phosphodiesterase type 5 inhibitors (PDE5i):** Oral medication used to block the action of phosphodiesterase type 5 on cyclic guanosine monophosphate in the smooth muscle cells causing a vasodilation of the arteries in the corpora cavernosa of the penis facilitating an erection during sexual stimulation.<sup>\*\*\*\*\*,†††††††††</sup> (NEW)

**7.4.1 On-demand dosing of PDE5i:** PDE5i being taken before anticipated sexual intercourse. (NEW)

**7.4.2 Daily dosing of PDE5i:** PDE5i being taken on a daily basis, irrespective of sexual activity.<sup>\*\*\*\*\*</sup> (NEW)

**7.4.3 Instructions in the appropriate use of PDE5i:** Instructions that include the fact that sexual stimulation is necessary and that more than one trial with the medication may be required to establish efficacy. It should include information regarding the medications' characteristics with regard to the onset of action, duration of action, and whether food intake limits efficacy. Discussion on side effects should include common PDE5i side effects as well as drug-specific side effects. (NEW)

**7.5 Vacuum erection device (VED):** Negative-pressure chambers that provide passive engorgement of the corpora cavernosa, together with a constrictor ring placed at the base of the penis to retain blood within the corpora.<sup>15</sup> (NEW)

**7.6 Intraurethral alprostadil:** Topical application of the vasoactive agent alprostadil, which is an analogue of prostaglandin E1. Herein, a specific formulation of alprostadil in a medicated pellet (MUSE™) that includes a permeation enhancer to facilitate absorption of alprostadil is administered via the urethral meatus.<sup>15</sup> (NEW)

**7.6.1 In-office test of intraurethral alprostadil:** An in-office consultation that has to be made with every patient being prescribed intraurethral alprostadil that includes instructions about the method, initial dose-titration, detailed counseling regarding possible adverse reactions and actions to take in response to potentially serious side effects.<sup>48</sup> (NEW)

**7.7 Intracavernous injection (ICI):** Injecting vasoactive agents into the corpus cavernosa of the penis to produce an erection. The four substances commonly used in clinical practice are alprostadil, papaverine, phentolamine, and atropine.<sup>§§§§§§§§,48</sup> (NEW)

**7.7.1 Single agent:** ICI of alprostadil. (NEW)

**7.7.2 Bimix:** ICI of papaverine + phentolamine. (NEW)

**7.7.3 Trimix:** ICI of alprostadil + papaverine + phentolamine. (NEW)

**7.7.4 Quadmix:** ICI of alprostadil + papaverine + phentolamine + atropine. (NEW)

**7.8 In-office injection test:** An in-office consultation that has to be made with every patient being recommended ICI of vasoactive agents which aims to determine the appropriate dose and medication(s) to produce sufficient duration of response and to minimize AEs.<sup>\*\*\*\*\*,48</sup> (NEW)

**7.9 Penile rehabilitation:** Program that aims to help men regain the ability to achieve erections sufficient for satisfactory sexual intercourse during rehabilitation from prostate cancer treatment, and ultimately return to pre-treatment erectile function.<sup>†††††††††,79</sup> (NEW)

## SECTION 8: SURGICAL TREATMENTS FOR SEXUAL DYSFUNCTION (GENERAL)

**8.1 Implantation of penile prosthesis:** The surgical implantation of a penile prosthesis for patients who do not respond to more conservative therapies or who prefer a permanent solution to their ED.<sup>15</sup> (NEW)

**8.1.1 Inflatable penile prosthesis (IPP):** The penile prosthesis type which can be inflated by the patient to create an erection on demand and deflated at other times.<sup>10</sup> (NEW)

**8.1.1.1 3-piece IPP:** The IPP type which consists of a fluid-filled reservoir implanted under the abdominal wall, a pump and a release valve placed in the scrotum, and two inflatable cylinders inside the penis.<sup>10</sup> (NEW)

**8.1.1.2 2-piece IPP:** The IPP type which works in a similar way as the 3-piece IPP, but the fluid reservoir is part of the pump implanted in the scrotum.<sup>10</sup> (NEW)

**8.1.2 Semirigid (malleable) penile prosthesis (MPP):** The penile prosthesis type which consists of two flexible rods that are placed inside the penis. Once implanted with the malleable prosthesis, the penis can be bent away from the body for sexual intercourse and toward the body for concealment.<sup>15</sup> (NEW)

**8.2 Penile artery revascularization:** A variety of surgical techniques that may be used to reestablish arterial flow to the penis. This is generally reserved for patients with proven pudendal or penile arterial anomalies secondary to posttraumatic lesions or congenital disorders.<sup>45</sup> (NEW)

**8.3 Treatments that warrant further investigation (see Appendix A):** Low-intensity extracorporeal shock-wave therapy (LI-SWT), Platelet-rich plasma (PRP) therapy, Intracavernosal stem cell therapy, nerve graft.

**TABLE 3** Potential sexual side effects related to LUTS/BPH treatment

Treatment	Potential sexual side effect
Alpha-blockers	Retrograde ejaculation, reversible anejaculation
5-Alpha reductase inhibitors	Erectile dysfunction, loss of libido, reduction of ejaculate volume, post-finasteride syndrome
Transurethral resection of prostate (TURP)	Retrograde ejaculation, anejaculation, erectile dysfunction
Transurethral incision of prostate (TUIP)	Retrograde ejaculation (lower risk than TURP)
Simple prostatectomy	Retrograde ejaculation, anejaculation
Laser prostatectomy	Retrograde ejaculation (lower risk than TURP)

*Note:* Interventions for LUTS/BPH have numerous sexual side effects, including retrograde ejaculation, orgasmic dysfunction, and erectile dysfunction. Sexual side effects from surgical treatments are more likely to be permanent than those from medical treatments, which can often be reversed by stopping medical treatment or switching to an alternative treatment. Surgical interventions which involve resection and/or incision at the level of bladder neck (TURP, TUIP, open prostatectomy) increase the risk of retrograde ejaculation.

Abbreviations: BPH, benign prostatic hyperplasia; LUTS, lower urinary tract symptoms.

## SECTION 9: TREATMENTS FOR LUTS/BPH AND RELATED SEXUAL DYSFUNCTIONS

### (A) Conservative and pharmacological treatment options for LUTS/BPH

**9.1 Watchful waiting:** Recommended treatment option for patients with an IPSS score of less than 7 who feel that their symptoms are manageable and do not have signs of postrenal compromise. This treatment consists of the patient decreasing their fluid intake, minimizing caffeinated and alcoholic beverages, and avoiding cholinergic medications.<sup>15,48</sup> (NEW)

**9.2 Phytotherapy:** Utilization of herbal preparation (plant extracts) to address LUTS/BPH either alone or in combination with oral pharmacotherapy.<sup>\*\*\*\*\*6</sup> (NEW)

**9.3 Alpha-blockers:** The first-line pharmacotherapeutic options for LUTS/BPH which are effective at relieving emptying phase symptoms via blockade of the alpha-adrenergic receptors in the prostate and the bladder neck.<sup>80</sup> (NEW)

**9.3.1 Alpha-blocker and EjD:** Alpha-adrenergic antagonists may cause anejaculation. The effect of alpha-blockers on EjD in men with LUTS is significantly affected by two agents (tamsulosin and silodosin). The other alpha-blockers have little or no impact on EjD.<sup>6</sup> (NEW)

**9.4 5-Alpha reductase inhibitors (5-ARI):** Medications that inhibit the enzyme responsible for the conversion of testosterone to dihydrotestosterone (DHT), which is a more potent androgen and is responsible for prostate growth and development. There are two drugs in this category; finasteride inhibits only

type 2 of 5-AR, and dutasteride inhibits both types 1 and 2.<sup>80</sup> (NEW)

**9.4.1 5-ARI and sexual dysfunction:** The effect of 5ARI on sexual function in men with LUTS is modest with effects on penile erection, ejaculation, sexual desire, and includes a small risk of post-finasteride syndrome.<sup>§§§§§§§§§§6</sup> (NEW)

**9.5 Beta-3 agonists:** A medication class which can be used to improve storage phase LUTS. Mirabegron, a beta-3 agonist, exerts its clinical effect via relaxation of the bladder smooth muscle and increasing bladder storage capacity. (NEW)

**9.6 Anticholinergics (Antimuscarinics):** Medications that exert their clinical effect via blocking muscarinic (predominantly M3 type) receptors in the bladder and can be used to address storage phase LUTS.<sup>81</sup> (NEW)

**9.7 PDE5i:** PDE5i might be used to address LUTS/BPH by inhibition of the PDE5 in the prostate, causing smooth muscle relaxation by a mechanism similar to the one postulated for alpha blockers. (NEW)

### (B) Surgical treatment options for LUTS/BPH<sup>82</sup>

See Table 3.

## SECTION 10: TREATMENTS FOR URETHRAL STRICTURE DISEASE AND RELATED SEXUAL DYSFUNCTIONS

### (A) Nomenclature of urethral stricture disease

**10.1 Urethral stenosis:** A narrowing of the anterior urethra, caused by spongiofibrosis of the corpus spongiosum.<sup>37</sup> (NEW)

TABLE 4 Treatment modalities addressing urethral stricture disease, and their sexual health-related side effects

Treatment	Potential sexual side effects
Direct visual internal urethrotomy (DVIU)	Erectile dysfunction
Penile urethroplasty	Poor penile cosmesis, erectile dysfunction (lower risk than bulbar urethroplasty)
Bulbar urethroplasty	Erectile dysfunction, penile curvature, penile shortening, glans hypoesthesia, semen sequestration
Posterior urethral reconstruction	Erectile dysfunction, penile curvature, penile shortening, glans hypoesthesia, semen sequestration, retrograde ejaculation

Note: Other terms such as visual internal urethrotomy (VIU) and optical internal urethrotomy (OIU) are sometimes used, but DVIU is the preferred term. Erectile dysfunction after DVIU occurs at a rate between around 2%–10% of cases; mechanisms include damage to the cavernous nerves, fistula creation between corpus cavernosum and spongiosum, and fibrosis from extravasation of irrigant and infectious complications.<sup>83</sup>

**10.2 Posterior urethral stenosis:** Narrowing of the membranous urethra, prostatic urethra, or bladder neck, when the prostate is still in situ.<sup>\*\*\*\*\*, ††††††††††††, 37, 74 (NEW)</sup>

**10.3 Vesicourethral anastomotic stenosis (VAS):** Narrowing of the posterior urethra after RP (see Endnote \*\*\*\*\*).<sup>74 (NEW)</sup>

**(B) Surgical treatment options for urethral stricture disease**<sup>82</sup>

See Table 4.

## SECTION 11: TREATMENTS FOR OAB AND RELATED SEXUAL DYSFUNCTION

**(A) Conservative and pharmacological treatment options for OAB**

**11.1 Behavioral treatments for OAB:** considered first-line treatment, these therapies aim at symptomatic improvement by changing behavioral and environmental issues. (NEW)

**11.1.1 Bladder training:** It consists of a program of patient education, along with a scheduled voiding regimen with gradually adjusted voiding intervals.<sup>††††††††††, 84</sup>

**11.1.2 Prompted voiding:** is used to teach people to initiate their own toileting through requests for help and positive reinforcement from caregivers, often done in combination with a scheduled voiding regimen, typically every 2 h.<sup>84</sup>

**11.1.3 Double voiding:** The patient is taught to urinate, relax, and attempt to urinate again. It is especially useful for patients with incomplete voiding and high post-void residue.<sup>84 (CHANGED)</sup>

**11.1.4 Scheduled or timed voiding:** A passive toileting assistance program, initiated and maintained by caregivers for patients who cannot participate in independent toileting. It is a fixed voiding schedule.<sup>84</sup>

**11.1.5 Self-monitoring:** This strategy is part of bladder training and consists of registering voiding habits in a bladder diary. (NEW)

**11.1.6 Habit training:** Consists of a toileting schedule matched to the individual's voiding patterns based on their voiding diary. The toileting schedule is assigned to fit a time interval that is shorter than the person's normal voiding pattern and precedes the time period when incontinent episodes are expected.<sup>84</sup>

**11.1.7 Lifestyle modifications:** Weight loss and smoking cessation have been shown to reduce LUTS, urgency and UI in patients with OAB.<sup>85 (NEW)</sup>

**11.1.8 Dietary modifications:** Consists of reducing or eliminating bladder irritants from the diet.<sup>§§§§§§§§§§, 84 (CHANGED)</sup>

**11.2 Pelvic floor muscle training (PFMT):** Exercise to improve PFM strength, endurance, power, relaxation, or a combination of these parameters.<sup>84</sup>

**11.3 Frequency volume chart (FVC):** The recording of the time of each micturition together with the volume voided for at least 24 h. Ideally a minimum of 3 days of recording (not necessarily consecutive) will generally provide more useful clinical data. It is relevant to discriminate between daytime and night-time micturition.<sup>5</sup>

**11.3.1 Bladder diary:** Adds to the FVC, the fluid intake, pad usage, incontinence episodes, the degree of incontinence and the circumstances at the time of the leakage. Episodes of urgency and sensation might also be recorded, as might be the activities performed during or immediately preceding the involuntary loss of urine. Additional information obtained from the bladder diary involves: severity of incontinence in terms of leakage episodes and pad usage.<sup>5</sup>

**11.4 Pharmacologic treatment for OAB:** Considered second-line treatment, may be used in combination with first-line treatments. (NEW)

**11.4.1 Antimuscarinics:** See 9.6.

TABLE 5 Effect of OAB treatments on sexual dysfunction

Treatment	Effect on SD
Lifestyle modifications	A healthy lifestyle has been shown to reduce OAB, SD, and their risk factors. <sup>89,90</sup>
Antimuscarinics	Transdermal oxybutinin for OAB showed an improvement in patient's sex life, a positive effect on relationships and an increase in sexual interest. <sup>91</sup>
PDE5i	A well-known treatment for SD, daily tadalafil has been shown to also improve OAB symptoms. <sup>88</sup>
Sacral neuromodulation	Some studies have shown improvement in sexual function in neurogenic patients. <sup>92,93</sup>

Abbreviations: OAB, overactive bladder; PDE5i, phosphodiesterase type 5 inhibitors; SD, sexual dysfunction.

**11.4.2 Beta-3 agonists:** See 9.5

**11.4.3 Combination therapy:** This treatment consists of administering an antimuscarinic together with a beta-3 agonist.<sup>87</sup> (NEW)

**11.4.4 PDE5i:** This treatment reduces OAB symptoms through the phosphodiesterase–nitric oxide pathway.<sup>88</sup> (NEW)

**(B) Surgical (invasive) treatment options for OAB**

**11.5 Third-line treatment for OAB:** These therapies include intradetrusor botulinum toxin injection, peripheral tibial nerve stimulation (PTNS) and sacral neuromodulation (SNM). (NEW)

**11.5.1 Intradetrusor botulinum toxin injection:** Injection of onabotulinumtoxinA in the bladder wall to induce detrusor muscle relaxation. (NEW)

**11.5.2 Peripheral (or posterior tibial) nerve stimulation (PTNS):** A neuromodulation technique that consists in stimulating the posterior tibial nerve with a transcutaneous or percutaneous electrode to modulate the neuronal activity of bladder nerves that share the same dorsal root as the posterior tibial nerve (S3). (NEW)

**11.5.3 Sacral neuromodulation (SNM):** This neuromodulation technique consists in percutaneously implanting a set of electrodes in the S3 foramen connected to an external (temporary) or subcutaneous (permanent) stimulator to modulate the activity of bladder nerves. (NEW)

**11.6 Fourth-line treatment for OAB:** Considered as last resort for patients that have failed all previous treatments, these include augmentation cystoplasty and urinary diversion. (NEW)

See Table 5.

## SECTION 12: TREATMENTS FOR CP/CPPS AND RELATED SEXUAL DYSFUNCTION<sup>94–96</sup>

**(A) Conservative and pharmacological treatment options for CP/CPPS**

**12.1 Nonpharmacological therapies for CP/CPPS:** These therapies aim at symptomatic improvement by changing behavioral and environmental issues and also

include minimally invasive therapies with a low risk for adverse events.<sup>97</sup> (NEW)

**12.1.1 Acupuncture:** Procedure that consists in inserting acupuncture needles in specific anatomic locations or “acupoints.”<sup>98</sup> (NEW)

**12.1.2 Lifestyle modifications:** Treatment based on avoiding irritant food, having a balanced diet, adopting certain sexual habits, avoiding perineal trauma and having a healthy lifestyle.<sup>99</sup> (NEW)

**12.1.3 Physical activity:** Treatment based on a regular exercise program.<sup>100</sup> (NEW)

**12.1.4 Extracorporeal shockwave therapy:** Periodic stimulation of the perineum with extracorporeal low-energy shockwaves.<sup>101</sup> (NEW)

**12.1.5 Transrectal thermotherapy:** Application of transrectal radiofrequency hyperthermia on the prostate.<sup>102</sup> (NEW)

**12.1.6 Cystoscopy and bladder hydrodistention:** Procedure that consists in distending the bladder during cystoscopy, at a pressure of 80–100 cm H<sub>2</sub>O, lasting 1–2 min and up to two times.<sup>26,103</sup> (CHANGED)

**12.1.7 Neuromodulation:** See 11.5.3.

**12.1.8 Transurethral resection:** See 9.10.

**12.1.9 PFMT:** See 11.2.

**12.2 Pharmacological therapies for CP/CPPS:** Different treatments that aim at alleviating and controlling CP and CPPS via pharmacological pathways.<sup>104</sup> (NEW)

**12.2.1 Alpha blockers:** See 9.3.

**12.2.2 5-ARI:** See 9.4.

**12.2.3 Antibiotics:** This treatment is indicated for chronic bacterial prostatitis (category II of the NIH, see 1.30.2).<sup>104</sup> (NEW)

**12.2.4 Anti-inflammatories:** Nonsteroidal anti-inflammatory drugs (NSAIDs) treatment is based on decreasing the pain mediated by inflammatory pathways.<sup>104</sup> (NEW)

**12.2.5 Phytotherapy:** See 9.2.

**12.2.6 Nerve blockade/Epidural pain pump:** Treatment based on the administration of analgesics directly into the epidural space with a small catheter and a pump. (NEW)

TABLE 6 Treatment modalities addressing CP/CPPS, and their sexual health-related side effects

Treatment	Direct effect on SD
Tension reduction, relaxation, physical therapy, lifestyle modifications	Usually beneficial <sup>94-96</sup>
Psychotherapy and multidisciplinary pain management	Usually beneficial <sup>94-96</sup>
Nonsteroidal anti-inflammatory drugs (NSAID)	No direct effect on SD
Opioids	Chronic use is associated with worsening of SD <sup>106</sup>
Tricyclic antidepressants (TCA)	Amitriptyline may have a negative impact on arousal and libido, especially on depressive patients <sup>107</sup>
Anticonvulsants	Pregabalin may cause ED, anorgasmia and loss of libido <sup>108</sup>
PDE5i	May improve CPPS symptoms as well as SD <sup>109</sup>
Pentosan polysulfate (PPS)	No direct effect on SD
Intravesical therapy (Pentosan polysulfate, DMSO, hyaluronic acid, chondroitin sulfate)	No direct effect on SD
Bladder hydrodistention	No direct effect on SD
Nerve blockade/Epidural pain pump	No direct effect on SD
Botulinum toxin injection	No direct effect on SD
Neuromodulation	Some studies have shown improvement in sexual function in neurogenic patients <sup>92,93</sup>
Transurethral resection	Retrograde ejaculation

Abbreviations: CP/CPPS, chronic prostatitis/chronic pelvic pain syndrome; ED, erectile dysfunction; PDE5i, phosphodiesterase type 5 inhibitors; SD, sexual dysfunction.

### 12.1.7 Botulinum toxin injections of the prostate<sup>82</sup> and/or bladder: See 11.5.1.

**12.1.8 PDE5i:** See 7.4. PDE5i may alleviate Cp/CPPS symptoms by reducing oxidative stress and inflammation on the prostate and PF.<sup>105</sup> (NEW)

See Table 6.

## SECTION 13: TREATMENTS FOR PROSTATE CANCER AND RELATED SEXUAL DYSFUNCTIONS

### (A) Conservative, pharmacological, and nonsurgical treatment options for prostate cancer

**13.1 Active surveillance (AS):** A treatment plan that involves closely watching a patient's condition but not giving any treatment unless there are changes in test results that show the condition is getting worse. This is suitable for men with favorable-risk prostate cancer (very low to low-risk) who wish to avoid treatment associated harm. Intervention for cure is pursued in those who experience disease progression while on AS.<sup>110</sup> (NEW).

**13.2 Watchful waiting (WW):** Waiting until the disease progresses to intervene with a palliative approach. Historically the aim of WW was to avoid

treatment altogether among men with a limited life expectancy and advanced disease detected in an era when screening was not routine.<sup>39</sup> (NEW)

**13.3 Androgen deprivation therapy (ADT):** An antihormone therapy used to control prostate cancer. Prostate cancer cells require androgens to grow. ADT reduces the levels of androgens in the body thereby slowing prostate cancer growth and progression. \*\*\*\*\*,122 (NEW)

**13.4 Radiation therapy:** Delivery of ionizing radiation treatments to the prostate to control or kill malignant cells. \*\*\*\*\*,123 (NEW)

**13.4.1 Brachytherapy:** Delivery of radioactive material sealed in needles, seeds, wires or catheters directly into the prostate gland for curative management of prostate cancer.<sup>110,123</sup> (NEW)

**13.4.1.1 Low-dose rate (LDR) brachytherapy:** Utilizes radioactive seeds that are implanted based on pretreatment and intraoperative image-guidance according to a computer plan. \*\*\*\*\*,123 (NEW)

**13.4.1.2 High-dose rate (HDR) brachytherapy:** Utilizes temporary catheters implanted in the prostate to allow for the delivery of a high-activity radiation source. \*\*\*\*\*,123 (NEW)

**13.4.2 External beam radiation therapy (EBRT):** A form of radiation therapy that uses

multiple radiation beams and/or arcs to provide a highly conformal treatment of the prostate with normal tissue sparing of adjacent organs, such as the rectum and bladder.<sup>123</sup> (NEW)

**13.4.3 Conformal radiation therapy:** A type of three-dimensional (3D) radiation therapy that uses computer-generated images to show the size and shape of the tumor. As a result, a higher and more effective dose of radiation can be delivered directly to cancerous cells.<sup>125</sup> (NEW)

**13.4.4 Intensity-modulated radiation therapy (IMRT):** A type of 3D radiation therapy that uses computer-generated images to show the size and shape of the tumor. Thin beams of radiation of different intensities are aimed at the tumor from many angles. This type of radiation therapy reduces the damage to healthy tissue near the tumor.<sup>110</sup> (NEW)

**13.4.5 Stereotactic body radiation therapy (SBRT):** A form of radiation therapy that uses photon-based IMRT to deliver hypofractionated radiation usually in five or fewer fractions of treatment to kill malignant cells.<sup>123</sup> (NEW)

**13.4.6 Proton beam radiation therapy:** A type of radiation therapy that uses streams of protons (tiny particles with a positive charge) to kill tumor cells. This type of treatment can reduce the amount of radiation damage to healthy tissue near a tumor.<sup>110</sup> (NEW)

**13.5 Focal therapy:** Tissue-preserving strategy aimed to target the cancer and not the whole organ when it is morphometrically possible to do so and thus reduce damage to collateral tissues.<sup>116</sup> (NEW)

**13.5.1 Cryotherapy:** Focal delivery of the cryoprobe transrectally to the prostate to induce extremely low temperatures with subsequent thawing. This process results in direct cellular injury and a delayed inflammation-mediated mechanism of cellular destruction.<sup>116</sup> (NEW)

**13.5.2 High-intensity focused ultrasound (HIFU):** Focal delivery of ultrasonic waves (frequencies 0.8 to 3.5 MHz) to selectively initiate cellular damage. The energy of the ultrasonic waves is absorbed by the target tissue and converted to heat causing coagulative necrosis. Furthermore, inertial cavitation is caused by alternating cycles of compression and rarefaction.<sup>116</sup> (NEW)

**13.5.3 Irreversible electroporation:** Delivery using a Nanoknife system to deploy a low-energy direct current to a targeted region within the prostate.<sup>126</sup> (NEW)

**13.5.4 Laser ablation:** Utilization of a laser to focally ablate the tissue.<sup>126</sup> (NEW)

**13.5.5 Photodynamic therapy:** Use of pharmacological agents that become active in the presence of light (photosensitizers) to kill malignant cells.<sup>126</sup> (NEW)

**13.5.6 Radiofrequency ablation (RFA):** Use of a bipolar radiofrequency ablation probe transperineally to

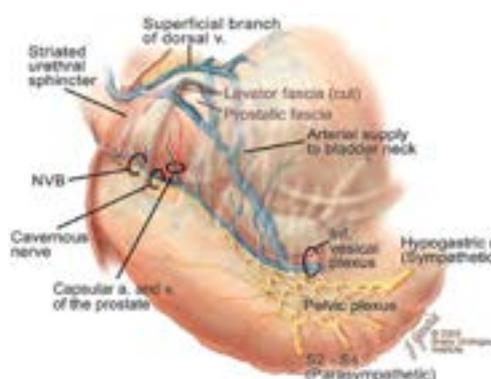

FIGURE 3 Anatomical landmarks related to prostatic neurovascular bundle (NVB)<sup>39</sup>

TABLE 7 Potential sexual side effects of each prostate cancer treatment

Treatment	Potential sexual side effect
Active surveillance (AS)	Erectile dysfunction, loss of sexual desire <sup>112,113</sup>
Androgen deprivation therapy (ADT)	Ejaculatory dysfunction, erectile dysfunction, hypogonadism, loss of sexual desire, orgasmic disorder, penile shortening <sup>114,115</sup>
Focal therapy	Erectile dysfunction <sup>116,117</sup>
Radiation therapy	Ejaculatory dysfunction, erectile dysfunction <sup>118</sup>
Radical prostatectomy (RP)	Climacturia, ejaculatory dysfunction, erectile dysfunction, orgasmic dysfunction, peyronie's, penile shortening <sup>119-121</sup>
Watchful waiting (WW)	-

deliver radio waves that heat and destroy abnormal cells.<sup>110,126</sup> (NEW)

### (B) Surgical treatment options for prostate cancer 13.6 RP<sup>82</sup>

**13.6.1 Nerve spare:** Avoidance of electrocautery and high anterior release with careful lateral dissection and gentle lateral traction preserves the NVBs (Figure 3) as they course anterior to Denovilliers' fascia at the posterolateral edge of the prostate. (NEW)

**13.6.2 Salvage prostatectomy:** Operative removal of the prostate with the goal of successfully eradicating locally recurrent cancer after definitive radiation therapy. (NEW)

See Table 7.

## AREAS FOR FURTHER RESEARCH

This consultation was performed by several experts in the field of male sexual dysfunction and functional urology. The definitions have different levels of empirical support, and some are based on expert clinical opinion, rather than a strong evidence base. Further research should be conducted to determine the support for these definitions and that, where necessary, appropriate modifications will be made to reflect these research findings.

## ACKNOWLEDGMENTS

No discussion on terminology should fail to acknowledge the fine leadership shown by the ICS over many years. The legacy of that work by many dedicated clinicians and scientists is present in all the Reports by the different Standardisation Committees and Working Groups. It is pleasing that the ICS leadership has accepted this vital initiative as a means of progress in this important and most basic area of Terminology and its Standardisation.

This document has involved 18 rounds of full review, by coauthors, of an initial draft (O. A., E. K.) with the collation of comments and figures. Included in the review process were as follows: (i) six external expert reviewers; (ii) an open ICS website review; (iii) ICS Standardisation Steering Committee review and (iv) ICS Board of Trustees review. The process was subject to live meetings in Florence (September 2017, planning), and in-person Working Group Meetings in Philadelphia (August 2018), and Gothenburg (September 2019). There were also two teleconferences (March and May 2019). Thereafter, we held monthly online Working Group Meetings, between February and November 2020. Versions 8

to 13 underwent comprehensive reformatting based on the comments of BH (Ex chair, ICS SSC), which included structural changes, redactions, and revisions with regard to scientific content. We are extremely grateful for the valuable inputs and extensive comments provided by the six expert external reviewers (Kari Tikkinen, Tufan Tarcan, Sherif Mourad, Carlos D'Ancona, Roger Dmochowski, Mehri Mehrad). Version 14 was reviewed by Dr. Matthias Oelke (Chair, ICS SSC) and further revisions were applied based on his recommendations. Version 15 was subject to ICS website publication and an open public forum discussion again through the ICS website and ICS social media accounts. We would like to express our sincere gratitude to everyone who provided formal and/or informal feedback throughout this process. Version 16 was sent for SSC review. Version 17 was subject to ICS Board review. Version 18 was submitted to Neurourology and Urodynamics. This document and all the NEW or CHANGED definitions will be uploaded to the ICS GLOSSARY ([www.ics.org/glossary](http://www.ics.org/glossary)) where immediate electronic access to definitions and document download is available.

## CONFLICT OF INTERESTS

Ervin Kocjancic: Neomedic (Speaker honorarium), Nex-Hand (Patent owner), Allergan (Consultant), Pfizer (Speaker honorarium), Astellas (Consultant), Boston Scientific (Consultant). Mauricio Plata: Astellas (Speaker), Neomedic (Speaker), Pfizer (Speaker). The remaining authors declare that there are no conflict of interests.

## AUTHOR CONTRIBUTIONS

*Conceived and designed the analysis, collected the data; contributed data or analysis tools, and critical revision of the manuscript:* Ervin Kocjancic. *Collected the data and contributed data or analysis tools:* Eric Chung. *Collected the data:* Joaquin Alvarez Garzon. *Conceived and designed the analysis, collected the data, contributed data or analysis tools, wrote the paper, and critical revision of the manuscript:* Bernard Haylen. *Collected the data, contributed data or analysis tools, and wrote the paper:* Valerio Iacovelli, Jorge Jaunarena, Jennifer Locke, and Alexandra Millman. *Collected the data and contributed data or analysis tools:* Irmina Nahon, Samuel Ohlander, and Ran Pang. *Collected the data, contributed data or analysis tools, and critical revision of the manuscript:* Mauricio Plata. *Conceived and designed the analysis, collected the data, contributed data or analysis tools, performed the analysis, and wrote the paper:* Omer Acar.

## DATA AVAILABILITY STATEMENT

Data are available within the article and its supplementary tables and figures.

## ENDNOTES

\*History should include duration of symptoms, identification of disorder, impact on quality of life, and partner relationship. Partner interviews may be very helpful as erectile dysfunction, delayed or premature ejaculation in males with hypoactive sexual desire disorder result in a 4–30 times increased risk of female partner desire, arousal or orgasmic disorder.

†The diagnosis of low testosterone should be made only after two total testosterone measurements taken on separate occasions with both conducted in the morning (until 10 a.m.).<sup>9</sup>

‡This disorder should include three of the following: (i) Absent/reduced interest in sexual activity; (ii) Absent/reduced sexual/erotic thoughts or fantasies; (iii) No/reduced initiation of sexual activity and unresponsive to partner's attempts to initiate; (iv) Absent/reduced sexual excitement/pleasure during sexual activity in almost all or all (75%–100%) sexual encounters; (v) Absent/reduced sexual interest/arousal in response to any internal or external sexual/erotic cues (written, verbal, visual); (vi) Absent/reduced genital or nongenital sensations during sexual activity in almost all or all (75%–100%) sexual encounters.

§Epidemiological studies have demonstrated consistent evidence for an association between lower urinary tract symptoms (LUTS)/benign prostatic hyperplasia (BPH) and sexual dysfunction, regardless of age, other comorbidities and various lifestyle factors.<sup>15</sup>

\*\*Several possible pathophysiological mechanisms exist, including NOS/NO (the nitric oxide synthase) and the Rho-kinase activation pathways, autonomic hyperactivity, pelvic ischemia and microvascular dysfunction, inflammatory pathways, sex hormones, iatrogenic and psychological factors.<sup>16</sup>

††According to the EpiLUTS study, patients with ED had 3 times more storage LUTS, 2.6 times more voiding LUTS and 4 times more voiding and storage LUTS.<sup>18,19</sup> In this study, both OAB wet and OAB dry were associated with worse sexual health, reduced sexual activity, and diminished enjoyment of sex ( $p < 0.0001$ ) when compared with patients without OAB.<sup>18,19</sup> Coyne et al. conclude that the impact of OAB in sexual health is evident in both men and women, and sexual health should be assessed in patients presenting with OAB.<sup>20</sup> This was also shown by a nested case-control study, where not only was ED more frequent in OAB patients, but this group had significantly reduced sexual activity and sexual enjoyment because of urinary symptoms<sup>21</sup> (including first void after waking up from sleep and last void before sleep).<sup>5</sup>

‡‡Several factors have been proposed to establish a connection between chronic pelvic pain and sexual dysfunction, including

vasculogenic, endocrine, neurogenic and psychological determinants. Shoskes et al. established that patients with chronic pelvic pain are more likely to have nitric oxide-mediated vascular endothelial dysfunction compared to asymptomatic controls, which could contribute to sexual dysfunction.<sup>28</sup> Psychological factors including anxiety have been described by Mo et al. and Cortes et al.,<sup>29,30</sup> and depression is more frequent in men with chronic pelvic pain and SD.<sup>29,31</sup>

§§CP/CPSP patients are more likely to present with sexual dysfunction or depression.<sup>32</sup> Lee et al. found that SD was present in 72% of patients with CP/CPSP and most of them (42%) had both ED and ejaculatory dysfunction.<sup>33</sup> Also, patients with SD and CP/CPSP had significantly worse symptoms and quality of life. Another study designed to estimate the prevalence of CP/CPSP in Austria found that IIEF-5 was significantly worse in patients with moderate or severe symptoms, thus showing a negative impact of CP/CPSP on sexual function.<sup>34</sup> These patients are also more likely to present with erectile dysfunction and premature ejaculation.<sup>35</sup>

\*\*\*An older term “glanular urethra” should not be used.<sup>37</sup>

†††The term pendulous urethra is no longer used.

‡‡‡As per the 2002 Stockholm WHO conference and according to the 2010 International Consultation on Urethral Strictures, the terms “anterior” and “posterior” urethra should not be used.<sup>37</sup>

§§§LUTS are often associated with male sexual dysfunctions.

\*\*\*\*History taking in a man presenting with ED should include questions about; age, comorbid medical (endocrinopathies, cardiovascular diseases, neurological disorders) and psychological conditions, prior surgeries, medications, family history of vascular disease, substance use, tobacco use.<sup>48</sup>

††††The specific LUTS can be divided into storage symptoms (urgency, frequency, nocturia, and urge incontinence) and voiding symptoms (poor stream, hesitancy, feeling of incomplete emptying). Patients are classified into having none or mild, moderate, or severe LUTS based on the IPSS (0–7, 8–21, and 21–35 points, respectively).<sup>50</sup>

‡‡‡‡The IIEF consists of 15 questions that quantify 5 domains (sexual desire, erectile function, intercourse satisfaction, ejaculatory/orgasmic function, overall sexual satisfaction). The erectile function domain quantifies ED severity on a scale of 5–30, with scores of: 26–30: normal erectile function; 18–25: mild ED; 11–17: moderate ED; ≤10: severe ED.

§§§§The SHIM score characterizes the severity of the patient's ED in the following manner: 22–25: no ED; 17–21: mild ED; 12–16: mild-to-moderate ED; 8–11: moderate ED; 5–7: severe ED.

\*\*\*\*\*A 4-question version of the ejaculation subscale of MSHQ is also available to measure ejaculatory dysfunction.

†††††The BMFSI originally developed by O'Leary has been adapted for use in patient with urethral stricture disease by Erickson et al.<sup>58</sup>

§§§§§As obesity is one of the most important risk factors for ED, it should be assessed and documented during ED work-up.

§§§§§§Abdominal or femoral artery bruits and asymmetric or absent lower extremity pulses may be indicative of underlying

vasculogenic etiology. Skin and hair pattern evidence of vascular insufficiency should be noted.

- \*\*\*\*\* General physical examination of patients with ED should include assessment for signs of testosterone deficiency (e.g., gynecomastia, underdeveloped facial/pubic/axillary hair), penile skin lesions and placement/configuration of the urethral meatus, documentation of flaccid stretched penile length (especially if the man is considering penile prosthesis implantation or surgical intervention), the presence/absence of a palpable plaque, general assessment of the scrotal skin and palpation of the testicles to assess for size, consistency, and location.
- +++++ Congenital absence of vas deferens is commonly associated with cystic fibrosis that occurs as a result of a mutation in the CFTR gene. A smaller percentage of patients might have unilateral renal agenesis.
- +++++ Digital rectal examination (DRE) is not required for evaluation of ED; however, BPH is a common comorbid condition in men with ED and may merit evaluation and treatment. During DRE, prostate size and consistency can be estimated, although DRE tends to underestimate true prostate size. DRE may also allow assessment of the bulbocavernosus reflex, which provides information on neural integrity of the pelvis. Anal tone can help in the assessment of pelvic floor muscle tone and may be used to teach and tailor pelvic floor muscle exercises.<sup>48</sup>
- §§§§§ Non-urological conditions such as anal fissure, abscess or hemorrhoids or other painful situations of the anal canal can elicit pain upon DRE.
- \*\*\*\*\* Although less recognized, penile hypoesthesia may not be limited to the glans. Procedures requiring penile disassembly may also result in penile shaft hypoesthesia.
- +++++ Routine blood work-up of ED that includes the measurements of serum testosterone, glucose/hemoglobin A1c, and in some cases serum lipids.<sup>48</sup>
- +++++ Studies that might be appropriate in some men if recent laboratory results are not available. These include; serum BUN/Cr, fasting lipids, fasting glucose or hemoglobin A1c, and morning testosterone, thyroid function studies (i.e., thyroid-stimulating hormone, free T4) and PSA.<sup>48</sup>
- §§§§§ DICC useful in patients with a history of pelvic trauma or those with primary (lifelong) erectile dysfunction. Nevertheless, it is not commonly used within the context of ED diagnostic work-up.
- \*\*\*\*\* After PFUI, if neither pudendal artery is intact, the patient may benefit from penile artery revascularization before PFUI repair to improve erectile potency.
- +++++ Urodynamic studies might need to be conducted if sexual dysfunction is thought to be originating from lower urinary tract dysfunction. Better assessment and treatment of the underlying urinary condition with the help of urodynamic studies might serve to improve the management of sexual health-related problems.
- +++++ A normal NPT rules out a veno-occlusive cause of erectile dysfunction, but other etiologies are still possible.
- §§§§§ Lichen sclerosus was previously known as *Balanitis Xerotica Obliterans (BXO)*, but this term is no longer in wide-spread use.
- \*\*\*\*\* The most common pathologic subtype of prostate cancer is adenocarcinoma. Other types include small cell carcinoma, neuroendocrine tumor, urothelial carcinoma and sarcoma.<sup>39</sup>
- +++++ Localized prostate cancer can be categorized based on PSA, PSA density, clinical stage digital rectal exam, grade group, amount of cancer on biopsy and imaging results. This risk stratification allows for better prediction of survival and appropriate counseling regarding treatment options.<sup>77</sup>
- +++++ This section is composed of a selection of relevant diagnoses which have been included in other sections of this terminology report. Therefore, the number of “NEW” and “CHANGED” definitions of Section 6 is not included in Table 1.
- §§§§§ Panax ginseng, Butea superba, Epimedium herbs (icariin), Tribulus terrestris, Securidaca longipedunculata, Piper guineense, and yohimbine have been investigated for ED.<sup>78</sup>
- \*\*\*\*\* The FDA-approved oral PDE5i available for management of ED in the United States include sildenafil, tadalafil, vardenafil, and avanafil. Several other PDE5i have been approved for use in other countries.<sup>48</sup>
- +++++ For men with LUTS/BPH and ED, sildenafil and tadalafil appear to have similar efficacy to treat ED. There are no studies of vardenafil or avanafil that focused on men with LUTS/BPH and ED. All studies of men with LUTS/BPH and ED used daily dosing because of the beneficial urinary tract effects of PDE5i.<sup>48</sup>
- +++++ This approach is particularly suitable for tadalafil 5 mg.
- §§§§§ Only alprostadil is FDA-approved in the United States for ICI.<sup>48</sup>
- \*\*\*\*\* This in-office test also helps the man achieve confidence with the technique and to facilitate adherence.<sup>48</sup>
- +++++ The use of any intervention or interventions whose goal is broadly thought of as being aimed at restoring satisfactory erectile functioning.<sup>79</sup>
- +++++ They are derived from the roots, seeds, bark, or fruits of the various plants used. Saw palmetto (*serenoa repens*), pygeum africanum, cucurbita pepo, secale cereale, urtica dioica and quercetin have all been reported as possible treatments for LUTS/BPH.<sup>6</sup>
- §§§§§ The impact on ejaculation is likely more significant than that on erection and libido. There seems to be no significant difference between the two agents that are currently available.<sup>5</sup>
- \*\*\*\*\* Commonly secondary to treatment for prostate cancer such as brachytherapy or external beam radiation. May also be secondary to treatments for BPH such as TURP.
- +++++ Posterior urethral stenosis and vesicourethral anastomotic stricture are preferred over other terms such as

bladder neck stenosis or contracture, prostatic urethral stenosis, and bulbomembranous stricture.

\*\*\*\*\* In the past, bladder training has also been referred to as bladder drill, bladder discipline, bladder re-education, and bladder retraining. Specific goals are to correct faulty habit patterns of frequent urination, improve control over bladder urgency, prolong voiding intervals, increase bladder capacity, reduce incontinent episodes, and restore patient confidence in controlling bladder function.

\*\*\*\*\* Bladder irritants include oxalate-rich food (ie spinach, orange, berries, chocolate, coffee, black tea, tofu, soya, sodas), alcoholic drinks and spicy food.

\*\*\*\*\* PDE5i have also been combined with  $\beta$ 3-adrenoceptor agonists with good results.<sup>86</sup>

\*\*\*\*\* Despite it has not been officially recommended in international guidelines, the effects of PDE5i have been well established in randomized clinical trials and have a positive effect in patients with SD.<sup>88</sup>

\*\*\*\*\* ADT is used as a radiosensitizer with radiation therapy to cure localized prostate cancer or alone to control locally-advanced or metastatic prostate cancer.

\*\*\*\*\* Radiation therapy is used in combination with androgen deprivation therapy to treat localized prostate cancer with curative intent.<sup>123</sup>

\*\*\*\*\* Standard LDR brachytherapy is 120 Gy.<sup>124</sup>

\*\*\*\*\* Standard HDR brachytherapy is 38 Gy delivered in four fractions, two times daily for 2 days.<sup>124</sup>

\*\*\*\*\* The sparing of nerves during radical prostatectomy is the only method to date that can preserve erectile function.<sup>127,128</sup>

\*\*\*\*\* A meta-analysis of studies with >12 months follow-up post RP reported that use of bilateral nerve spare with associated with a 60% erectile function recovery rate (95% confidence interval [CI]: 58.0–62.0; 21 studies) compared to a rate of 47% (95% CI: 42.0–53.0; 12 studies for use of a unilateral nerve-sparing technique).<sup>129</sup>

\*\*\*\*\* To be a candidate the patient must have excellent health with a life expectancy of more than 15 years, no evidence of metastatic disease with prostate biopsy, histologic grade, clinical examination findings and serum PSA levels suggesting localized disease.<sup>39</sup>

## APPENDIX A

### Low-intensity extracorporeal shock-wave therapy (LI-SWT)

Extracorporeal application of low-intensity shockwave which is a kind of acoustic wave that carries energy and that, when propagating through a medium, can be targeted and focused noninvasively to affect a distant selected anatomic region. When LI-ESWT is applied to penis, the shockwaves interact with the targeted tissues and induce a cascade of biological reactions which in turn triggers neovascularization with subsequent improvement of the blood supply.<sup>130</sup> **(NEW)**

### Platelet-rich plasma (PRP) therapy

PRP is an autologous product obtained from whole blood that contains high concentrations of platelet-derived growth factors and provides a fibrin framework over platelets that has the potential to support the regenerative matrix and promote recovery in damaged tissues. PRP therapy denotes intracavernosal injection of autologous platelet-rich plasma concentrates to address ED.<sup>131</sup> **(NEW)**

### Intracavernosal stem cell therapy

Intracavernosal injection of stem cells, which are derived from multiple tissue sources (such as bone marrow, adipose tissue) and have the potential for self-replication, proliferation and differentiation, to restore erectile function.<sup>132</sup> **(NEW)**

### Nerve graft

Interposition of sural nerve graft at the time of RP is proposed to help recovery of erectile function in men who had both cavernous nerves resected.<sup>133</sup> **(NEW)**

## Abstract

**Introduction:** The terminology for female and male pelvic floor muscle (PFM) assessment has expanded considerably since the first PFM function and dysfunction standardization of terminology document in 2005. New terms have entered assessment reports, and new investigations to measure PFM function and dysfunction have been developed. An update of this terminology was required to comprehensively document the terms and their definitions,

Beth Shelly and Giuseppe Alessandro Digesu: Standardization Steering Committees ICS.

1217

and to describe the assessment method and interpretation of the finding, to standardize assessment procedures and aid diagnostic decision making.

**Methods:** This report combines the input of members of the Standardisation Committee of the International Continence Society (ICS) Working Group 16, with contributions from recognized experts in the field and external referees. A logical, sequential, clinically directed assessment framework was created against which the assessment process was mapped. Within categories and subclassifications, each term was assigned a numeric coding. A transparent process of 12 rounds of full working group and external review was undertaken to exhaustively examine each definition, plus additional extensive internal development, with decision making by collective opinion (consensus).

**Results:** A Terminology Report for the symptoms, signs, investigations, and diagnoses associated with PFM function and dysfunction, encompassing 185 separate definitions/descriptors, has been developed. It is clinically based with the most common assessment processes defined. Clarity and user-friendliness have been key aims to make it interpretable by clinicians and researchers of different disciplines.

**Conclusion:** A consensus-based Terminology Report for assessment of PFM function and dysfunction has been produced to aid clinical practice and be a stimulus for research.

#### KEYWORDS

clinical assessment, diagnosis, muscle dysfunction, pelvic floor

## 1 | INTRODUCTION

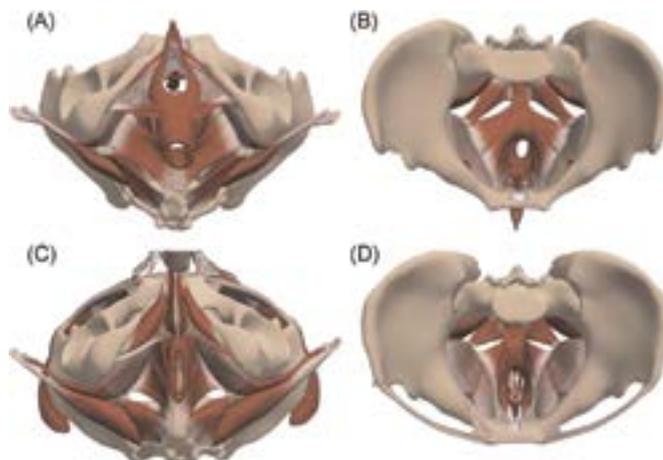

The current terminology used in the assessment and diagnosis of pelvic floor muscle (PFM) function and dysfunction is both diverse and variably defined, with no current consensus which captures, defines, and describes all terms. This document lists and describes terms which are used in the neuro-myo-fascial assessment and diagnosis of the PFM to aid teaching and standardization of terminology in this field. The terminology covers the assessment of both structure and function of the PFM. The pelvic floor structures defined in this document include muscular tissues in the pelvic floor and their neural connections, and the fascial (connective tissue) layers surrounding the PFM fibers/fascicles. In this document, assessment of the PFM is presented according to the perineal and pelvic regions of PFM. While PFM anatomy nomenclature varies according to texts, the following structures are considered to be the muscles that make up the perineum and the pelvic floor/levator ani.<sup>1</sup> The perineal region is divided into the anterior and posterior triangles. The anterior urogenital triangle comprises the superficial urogenital muscles (bulbospongiosus/

bulbocavernosus, ischiocavernosus, and the superficial transverse perinei), and the deep urogenital muscles (external urethral sphincter and deep transverse perinei). The posterior (anal) triangle comprises the external anal sphincter. The levator ani is comprised of pubococcygeus (which includes puborectalis, pubovisceralis, pubovaginalis, etc.), iliococcygeus, and ischiococcygeus/coccygeus (considered vestigial). The female and male perineal and PFM, inferior and superior views, are illustrated in Figure 1 (see page 3).

When referencing this document, the reader is asked to keep the term in context with PFM assessment. The PFM terms included apply to adult females and males presenting with different types of pelvic floor disorders. Assessment techniques are undertaken externally (*per perineum* [PP], and internally (*per vaginam* [PV] or *per rectum* [PR]). Where the definition or description of the term requires modification to differentiate between female (*f*) and male (*m*) assessment, this is indicated.

The search strategy used for this document was performed according to International Continence Society (ICS) Standardisation Steering Committee guidelines. The working group of multinational and

**FIGURE 1** (A) Muscles of the female perineum and pelvic floor inferior view (reprinted with permission from Primal pictures<sup>2</sup>). (B) Muscles of the female perineum and pelvic floor superior view (reprinted with permission from Primal pictures<sup>2</sup>). (C) Muscles of the male perineum and pelvic floor inferior superior view (reprinted with permission from Primal pictures<sup>2</sup>). (D) Muscles of the male perineum and pelvic floor superior view (reprinted with permission from Primal pictures<sup>2</sup>)

multidisciplinary committee members applied expert opinion to identify existing terms that refer to PFM assessment. Existing published ICS Standardization of Terminology documents were searched and terms added to cover all published terms or in common clinical use that refer to the assessment of PFM function and dysfunction. Inclusion of the final list of terms was achieved via a consensus process, which took place between 2017 and 2019. The final list of terms serves as a reference for future refinement and testing for clinical utility. This document is not a clinical protocol or guideline for how to perform a PFM assessment, it defines and describes terms which may be used in a clinical assessment of PFM function. As such, this document does not include within its scope other important considerations when undertaking a PFM assessment. These include but are not limited to competency of the assessor, clinical reasoning required for diagnostic decision making, protocol when conducting a sensitive examination of an intimate body part, appropriate informed consent, and ethical and legal considerations.<sup>3</sup> Further, only a brief, introductory-level description of how to undertake the test is provided, not

a detailed description of the exercise protocol using that tool, with the reader directed to other texts for more detailed description.

The number of total, new, and changed ICS definition terms relevant to PFM assessment are shown in Table 1 (see below). If a term does not currently exist in an ICS Standardisation of Terminology document, it is indicated here as a “**NEW**” term. When a term appears in an existing ICS Standardisation of Terminology document, the term definition and description is reproduced here with reference to the original terminology document, to present a complete framework of PFM assessment. When a modification to the existing term occurs, the word “**CHANGED**” is used. If the change is a significant alteration from the existing term, a footnote is used to explain the reason for modification, and a reference to the original term cited. Several of the terms related to ultrasound imaging have been drawn from the AIUM/IUGA practice parameter for the performance of Urogynecological ultrasound examinations document.<sup>4</sup> Similarly, terms in the algometry section already exist in the field of pain science, and terms related to muscle

**TABLE 1** Total, new, and changed ICS definition terms

Section	New definitions/descriptors	Changed definitions/descriptors	Unchanged definitions/descriptors	Total
Introduction and symptoms	1	1	0	2
Signs	31	15	12	58
Investigations	80	18	17	115
Diagnoses	7	3	0	10
Total	119 (64%)	37 (20%)	29 (16%)	185

Abbreviation: ICS, International Continence Society.

function exist in the field of exercise physiology, and so forth. These terms are labeled **NEW** for the purposes of this document however we acknowledge that these terms are already published and may be in widespread use.

There is a plethora of existing terms and conceptual and operational definitions related to PFM function and dysfunction.<sup>5</sup> Saltiel et al.<sup>5</sup> observed inconsistency and redundancy in PFM function terminology and suggested that a further consideration of PFM function terms relevant to research and to clinical practice is required.<sup>5</sup> A mapping of PFM function terms to the WHO International Classification of Functioning, Disability and Health (ICF) framework has been recently proposed,<sup>6</sup> leading to a list of the most frequently used terms.<sup>7</sup> In this paper, we define the assessment term, describe the application of the test and interpretation of its finding within a framework of diagnostic decision making and clinical reasoning. This follows the usual order of assessment undertaken by a clinician or researcher (referred to in this paper as an “assessor”), leading to a presumed diagnosis and formulation of a treatment plan, to help guide clinical practice. This process includes the use of a patient’s history, patient-reported symptoms/outcomes, and information gained from clinical signs and the results of investigations. It is important to recognize that neuro-musculo-skeletal structures beyond the PFM muscles (e.g., intra- and extra-pelvic muscles, the bony pelvis and pelvic girdle joints, and central nervous system factors) may impact on PFM function, however, terminology relating to the assessment of these structures and systems is beyond the scope of this paper.

We hope the terminology sited within this framework provides greater clarity and aids standardization of the usage of these terms. Where possible, the sequence of the terminology follows this order: the region of assessment, the type of evaluation being undertaken, the name (“term”) of the test/assessment being undertaken, the definition of that term, the description of how that assessment method is undertaken, how the assessment is rated and the terminology used to describe the finding.

#### **Limitations**

Normative data of PFM structure and function are lacking for the majority of PFM terms, which hinders the ability to rate or interpret the finding as “normal” or “abnormal.” In addition, due to the lack of known validity, reliability, and responsiveness to change and diagnostic test accuracy (sensitivity, specificity) of many of the commonly used PFM clinical assessment methods, investigations, and diagnoses, the clinical utility of these terms remains unknown. Therefore, this document is not intended to be an evidence-based recommendation of which tests should be included in a PFM assessment; rather our aim is to define and describe currently used terms, which subsequent

research may recommend for or against using in PFM assessment. Evidence to support or abandon the use of any of these terms and assessment methods is eagerly awaited. In the meantime, we advise assessors to exercise great caution in their interpretation of clinical findings, especially those measured with visual observation, digital palpation, and outputs of some of the available assessment tools, as despite their widespread clinical usage, these tests can yield subjective and highly variable findings. Due to the abundance and variety of terms used in the literature related to methods and techniques of measurements, word count has necessitated that this document describes only the most frequently published, or methods and techniques using that particular tool in common clinical usage.

With these limitations in mind, we recommend rating of PFM symptoms as present or absent; if present, a severity and/or bother scale can be added to aid reassessment in response to an intervention. Some of the signs and investigations terms have rating scales associated with their method and these should be used; if not, we recommend that assessors employ linear measurements (mm/cm) or specify ISI international units of measurement (e.g., s = seconds) where applicable to aid objectivity of the assessment method. If “normal” observations or values are not known, we recommend avoidance of the term “abnormal” or suggestion of pathology or disorder, as this cannot be confirmed with current knowledge. When using assessment methods which measure on a continuous scale but lack reference data of a “normal” value, the terms “increased”/“elevated”/“higher”/“faster,” or “decreased”/“reduced”/“lower”/“slower” may be used as this is the limit of our certainty at this point in time. Nevertheless, we acknowledge the subjectivity of these relative rating terms.

## **2 | SECTION 1: SYMPTOMS**

This section lists symptoms a patient may use to describe a sensation which could be related to a disorder of PFM structure or function. We recommend the assessor accurately documents the term the patient uses to describe the symptom, rather than an assessor-interpreted term, as symptoms may be used as a patient-reported outcome. A patient-reported outcome is any report of the status of a patient’s health condition that comes directly from the patient, without interpretation of the patient’s response by an assessor.<sup>8,9</sup>

PFM-related symptoms are divided into sensory and motor categories. PFM-related symptoms may coexist with symptoms of pelvic floor disorders such as urinary incontinence, voiding dysfunction, fecal incontinence, defecatory dysfunction, sexual dysfunction, or pelvic

organ prolapse, as well as coexist with other disorders of neuro-musculo-skeletal structures in the pelvis or spine<sup>i</sup>; the assessor should document the patient's symptoms and identify which of these s/he considers to be related to the PFM. Examples are provided of words a patient may use to describe their symptoms to the assessor. These words are not specific to neural or myofascial structures in the PFM—they are generic and may be used by a patient to describe altered sensation in any body part—and are therefore not different to standard definitions of these terms in English dictionaries. For this reason, definitions are not provided for these terms in this document, as they are not PFM-specific. The likely exception is the term “wind,” which is defined below. In addition to documenting the patient's symptom (term) and any other descriptors the patient uses to describe the symptom, the assessor documents the perceived location, frequency of occurrence, severity, distress, bother or impact of these symptoms to the patient.

**1.1 PFM sensory symptoms:** Patient terms may include numbness, reduced feeling, decreased sensation, tingling, pins and needles, sensitivity/hypersensitivity, or increased or unusual sensation in the region the patient perceives to be related to the PFM. Terms used to describe painful symptoms may include pain, tender, ache, burning, or discomfort in the region the patient perceives to be related to the PFM; use of existing descriptors in published scales<sup>10</sup> is recommended.

**1.2 PFM motor symptoms:** Patient terms may include loose, lax, gaping, sagging, open, weak, bulging, heaviness, full, loss of control, or difficulty to relax, tight, tense, narrow, or constricted. A patient may describe “wind” as a noise or passage of gas.

**1.2.1 Vaginal wind:** An involuntary passage of odorless air through the vagina, which is often audible and/or sensible, and usually associated with a change in posture (**CHANGED**).<sup>11,12,ii</sup> This may occur when legs are abducted and a change of position occurs and during times of low estrogen (e.g., breast-feeding).

**1.2.2 Anal wind<sup>iii</sup>:** Complaint of involuntary loss of flatus (gas). (**NEW**)

Following the assessment of a patient's symptom(s), the assessor will formulate provisional differential diagnoses which will be refined following the clinical examination.

### 3 | SECTION 2: SIGNS

Signs are elicited from the clinical examination, which includes visual observation, physical inspection, and simple tests.<sup>iv</sup> The majority of PFM clinical signs are

tested using digital palpation. The term “palpation” (latin origin: *palpare*) means to touch gently or to use the fingers or hands to examine.<sup>14</sup> Palpation allows the assessor to feel the texture, size, consistency, and location of certain body parts with the hands, or in the case of PFM assessment, with the fingers or finger-tips.<sup>v</sup> Due to the inherent subjective nature of visual and digital assessment, many of these characteristics and properties of the PFM are more accurately assessed using investigations. While some terms will be defined in signs, the measurement of that term may be better done in investigations. If an assessor does not have access to investigations, findings from signs may be used to guide practice, however, subsequent research may cast doubt on the certainty of findings from signs.

There are several aspects for the assessor to be aware of during the clinical assessment which apply to all measured aspects of PFM function, as variations in the examination conditions or maneuvers may alter the results of the test and reduce the certainty of the finding. These are listed in Box 1 (see page 6). We recommend all of these aspects should be reported by assessors to enable reproducibility of assessment. Akin to published checklists for exercise prescription,<sup>17</sup> checklists of clinical assessment may improve completeness and quality of research reports.

This section divides the clinical examination into an external PP assessment and an internal PV or PR assessment. The order of examination for PP assessment is visual observation before digital palpation. The full description of each term appears in the subsequent tables and text. Not all tests may be applicable for each patient; the decision to perform a test should be based upon clinical judgment.

#### 2.1 External assessment per perineum

**Visual observation:** All terms related to the visual observation per perineum under different PFM states (at rest, on contraction, and with raised intra-abdominal pressure [IAP]) are listed and defined in Table 2 (see page 7).

**Digital palpation:** All terms related to digital palpation *per perineum* under different PFM states (at rest, on contraction, and with raised IAP) are listed and defined in Table 3 (see page 8).

#### 2.2 Internal assessment per vaginam (PV) or per rectum (PR) by digital palpation

**Resting state:** The following terms (in Tables 4 (see page 9) and 5 (see page 10)) are used to define, describe and rate PFM assessment in the resting state *per vaginam* (PV) or *per rectum* (PR) by digital palpation. Terms related to muscle tone are expanded upon in subsequent text to provide greater explanation of the term definitions and descriptions.

**Box 1 Checklist of PFM clinical assessment, applicable to signs and investigations**

Aspect to standardize	Details to record
1. Patient's body position for the PFM assessment	<ul style="list-style-type: none"> <li>• Lying or upright</li> <li>• If lying, hip/knee flexion, supine, side-lying, or lithotomy</li> <li>• Number of pillows, +/- support from assessor's body</li> <li>• Bladder empty or not</li> </ul>
2. Testing of left and right sides of PFM. Symmetry: A measure of comparability of resting tone or shape between left and right sides of the muscle. If examining in side-lying, there will be a gravity effect and the dependent side may have a different feel to the upper side and appear as asymmetrical. This may affect assessor perception of PFM resting tone	<p>Record if symmetry/asymmetry is present at rest and on activity (contraction/relaxation). Rate as:</p> <ul style="list-style-type: none"> <li>• Symmetry between left and right (on a particular aspect/parameter)</li> <li>• Asymmetry present. Identify what aspect/parameter is asymmetrical, e.g., tone, L&lt;R<sup>15</sup></li> </ul>
3. Amount of pressure (light/moderate/strong) applied during digital palpation tests. Particular care is required when undertaking a PFM assessment in the presence of pelvic floor pain, however, even in an asymptomatic individual, the assessor may provoke pain or discomfort due to undue pressure applied during palpation or application of an instrument	<ul style="list-style-type: none"> <li>• If discomfort or pain is provoked, note pain location, intensity, duration (transient or persistent), if it reproduces the pain the patient complains of, and if referral of pain occurs to other locations</li> </ul>
4. Number of digits (and which digit) used during digital palpation	<ul style="list-style-type: none"> <li>• For single digit examination (<i>PV</i> or <i>PR</i>), usually the index finger is used</li> <li>• For two-digit examination (<i>PV</i>), usually the index and middle digits are used</li> </ul>
5. Orientation (e.g., lateral placement or posterior midline) and depth of examining finger(s) during internal digital palpation examination <sup>vi</sup>	<ul style="list-style-type: none"> <li>• The examining finger must be as close as possible to the PFM tissue to assess PFM response</li> <li>• When performing a <i>PV</i> examination, assessor decision as to which side or midline to examine will be determined by lumen capacity, presence of tenderness or defect and presence of firm stool within the rectum</li> <li>• When performing a <i>PR</i> examination, external anal sphincter and puborectalis strength should be assessed separately</li> <li>• Record depth of insertion of examining finger for differential assessment of perineal versus levator ani muscle layers. Further identification of individual muscles is not possible in all individuals</li> </ul>
6. Instruction to perform a maximum voluntary contraction (MVC)	<ul style="list-style-type: none"> <li>• Provide details of the instruction (wording, number of repetitions, and rest between repetitions) to ensure the test can be reproduced as an MVC</li> </ul>
7. Contraction of muscles other than those of the pelvic floor	<ul style="list-style-type: none"> <li>• if this is perceived to influence the PFM assessment, an attempt to minimize this should be made unless the purpose is to assess function of the other muscle.</li> <li>• List specific muscle, such as abdominal, hip adductor, etc.</li> </ul>

Abbreviations: L, left; MVC, maximum voluntary contraction; PFM, pelvic floor muscle(s); *PR*, *per rectum*; *PV*, *per vaginam*; R, right.

TABLE 2 External assessment *per perineum*: Visual observation

Test	Rating
<i>Tests of visual observation per perineum at rest</i>	
<b>2.1.1 Perineal skin assessment:</b> Assessment of the perineal skin to note presence of: scars, lesions (e.g., fissure), trophic changes/atrophy, color, erythema, swelling, and other conditions which could affect the function of the PFM (NEW)	<ul style="list-style-type: none"> <li>• Normal skin</li> <li>• Altered (detail the observation including extent of alteration)</li> </ul>
<b>2.1.2 Perineal body length (f):</b> Distance from posterior margin of vestibule to anterior anal verge <sup>18</sup>	<ul style="list-style-type: none"> <li>• State if &lt; or &gt;3 cm<sup>19,20</sup></li> </ul>
<b>2.1.3 Perineal body position at rest:</b> Relationship of the position of the perineal body to ischial tuberosities <sup>3</sup> (NEW). Palpate ischial tuberosity and visually estimate the relationship	<ul style="list-style-type: none"> <li>• <b>2.1.3.1 Descended perineum:</b> Perineal body rests below the plane of the ischial tuberosities<sup>21</sup> (NEW)</li> <li>• Normal: At or slightly above the level of the ischial tuberosities</li> <li>• Elevated: Significantly indrawn perineum at rest</li> </ul>
<b>2.1.4 Introital gaping:</b> Opening, or noncoaptation of vagina at rest. (NEW) If the introitus is not visible at rest the labia may need to be parted	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<b>2.1.5 Keyhole deformity at anus:</b> Characteristic posterior midline furrow deformity. This complication is seen when the anus is inspected by gently retracting the buttocks laterally. The anus is no longer slit-like, but appears in shape like a keyhole <sup>22</sup> (NEW)	<ul style="list-style-type: none"> <li>• Present</li> <li>• Note location of deformity with reference to a clock-face (where 12 o'clock is anterior/ventral)</li> <li>• Absent</li> </ul>
<b>2.1.6 Anal gaping:</b> Noncoaptation of anal mucosa at rest <sup>11</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Note location of deformity with reference to a clock-face</li> <li>• Absent</li> </ul>
<i>Tests of visual observation per perineum with a PFM contraction</i>	
<b>2.1.7 Voluntary contraction of the PFM:</b> Self-initiated activation of the PFM. (CHANGED) <sup>23</sup> Contraction of the bulbospongiosus/bulbocavernosus, ischiocavernosus, transverse perineal muscles may be observed <sup>9</sup> . The assessor may need to gently move the external genitalia (parting of the labia, lifting of the scrotum to one side) to effectively visualize the perineal response	<ul style="list-style-type: none"> <li>• Present</li> <li>• Uncertain</li> <li>• Absent</li> <li>• Response can be further described according to perineal movement observed: <ul style="list-style-type: none"> <li>• <b>2.1.7.1 Perineal elevation:</b> Inward (ventrocephalad) movement of the vulva (f), perineum, and anus<sup>11,24</sup> = normal finding</li> <li>• No change</li> <li>• Sex-specific changes on perineal elevation: <ul style="list-style-type: none"> <li>• f: closure of the urethral meatus (“wink”); a clitoral “nod”</li> <li>• m: Closure of the anus, cephalad testicular lift and penile retraction (the shaft of the penis draws in)<sup>25–27</sup></li> </ul> </li> <li>• <b>2.1.7.2 Perineal descent:</b> Dorsocaudal movement of the perineum, or anus 1 cm or greater beyond resting level (CHANGED)<sup>24</sup></li> </ul> </li> </ul>
<b>2.1.8 Relaxation of the PFM:</b> Return of the perineum to its original resting position following the voluntary contraction (NEW)	<p>If present, rate as:</p> <ul style="list-style-type: none"> <li>• Yes: Full relaxation visible directly after instruction; normal finding<sup>15</sup></li> <li>• Partial or delayed relaxation<sup>15</sup></li> <li>• <b>2.1.8.1 Nonrelaxing PFM:</b> No relaxation visualized of the PFM (CHANGED)<sup>23d</sup>.</li> </ul>
<i>Tests of visual observation per perineum with an increase in intra-abdominal pressure (IAP)</i>	
<b>2.1.9 Perineal movement with a sustained increase in IAP:</b> Direction of perineal movement during a sustained effort <sup>e</sup> . (NEW). As there may be a difference in PFM response to	<ul style="list-style-type: none"> <li>• Perineal elevation (see 2.1.7.1)<sup>f</sup></li> <li>• No change</li> <li>• Perineal descent (see 2.1.7.2)<sup>f</sup></li> </ul>

(Continues)

TABLE 2 (Continued)

Test	Rating
<p>bearing down versus valsalva,<sup>28</sup> it is important to state exact test instruction depending on the test, as the observed response may vary</p> <ul style="list-style-type: none"> <li>• <b>2.1.9.1 Valsalva:</b> Forceful exhalation against a closed mouth, glottis, and nose.<sup>28</sup> (NEW) Valsalva has been shown to result in an increase in IAP and usually an increase in PFM activation<sup>28</sup></li> <li>• <b>2.1.9.2 Bearing down (as if defecating):</b> A strain or push, which results in an increase in IAP which exerts a downward pressure, usually accompanied by PFM relaxation (NEW)</li> </ul>	<ul style="list-style-type: none"> <li>• <b>2.1.9.3 Excessive perineal descent with bearing down:</b> Movement of the perineum 3 cm or more below resting position<sup>29b</sup> (NEW)</li> </ul>
<p><b>2.1.10 Perineal movement with rapid increase in IAP:</b> direction of perineal movement during a rapid increase in IAP such as coughing, lifting, throwing. (NEW) Clarify if the patient is instructed to contract PFM before cough to differentiate voluntary (learned) response from an involuntary response (un-learned)</p>	<ul style="list-style-type: none"> <li>• Perineal elevation (see 2.1.7.1)<sup>23i,j</sup></li> <li>• May be due to:</li> <li>• Voluntary contraction (see 2.1.19)—precontraction may be a learned response<sup>k</sup></li> <li>• <b>2.1.10.1 Involuntary contraction:</b> A contraction which occurs reflexively or automatically, without volition or conscious control. Observe this response before instructing in a voluntary pre-contraction to differentiate from the voluntary pre-contraction response. (CHANGED)<sup>23</sup></li> <li>• No change</li> <li>• Perineal descent<sup>l</sup></li> </ul>

Abbreviations: *f*, female; IAP, intra-abdominal pressure; *m*, male; PFM, pelvic floor muscles.

<sup>a</sup>Visual observation of the exact position may be influenced by variations in adipose tissue over the ischial tuberosities.<sup>21,29–31</sup>

<sup>b</sup>As the levator ani are likely to be co-contracting with the superficial PFM, the observed response is unlikely to be due to the superficial PFM layer alone, as the levator ani contraction is likely to be contributing to the observed response.

<sup>c</sup>These movements may be observed alongside perineal elevation and may be better visualized in standing than supine. These observations to be checked against movement of the scrotum and the whole penis.

<sup>d</sup>The term “nonrelaxing PFM”<sup>23</sup> was previously used as a diagnosis, however, this term describes a sign, and is not recommended to be used as a diagnosis. This sign may be combined with symptoms to inform a clinical diagnosis.

<sup>e</sup>The term “involuntary relaxation” is not recommended to define perineal movement as it not possible to determine if the downward PFM movement is related to voluntary muscle relaxation or passive elongation of noncontractile tissue.

<sup>f</sup>Some patients will not allow full relaxation during assessment for fear of releasing gas or urine, therefore may voluntarily contract during this test.

<sup>g</sup>Modification: The word “excessive” has been removed from the previous definition<sup>24</sup> as some downward movement of the perineum is normal with coughing or bearing down such as in defecation.

<sup>h</sup>Adipose tissue at the ischial tuberosities will affect the measurement.<sup>29</sup>

<sup>i</sup>Perineal elevation with cough is expected but not always present.

<sup>j</sup>Messelink et al.<sup>23</sup> described the response of perineal elevation to a rapid increase in IAP as the test for an involuntary contraction. However, it is not possible to say if this is an involuntary or reflex activation of muscle spindles resulting in a contraction, or a voluntary pre-contraction of the PFM before increased IAP. Strategies may differ or be combined.<sup>28</sup>

<sup>k</sup>This manoeuvre is also called “the knock.”<sup>32</sup>

<sup>l</sup>A small degree of descent may be normal.<sup>33</sup>

TABLE 3 External assessment *per perineum*: Digital palpation

Test	Rating
<i>Tests of digital palpation per perineum at rest</i>	
<p><b>2.1.11 Sensation:</b> Test for presence, absence or altered quality of sensation in dermatomal distributions especially S2-4. May include light touch, blunt, sharp, pain, cold, vibration modalities (NEW)</p>	<ul style="list-style-type: none"> <li>• Allodynic, anesthetic, dysesthetic, hyperalgesic, hyperesthetic, hypoalgesic, hypoesthetic, paresthetic, neuralgic<sup>34</sup></li> </ul>
<p><b>2.1.12 Perineal scarring:</b> Presence of scar tissue on perineum (NEW). Using a finger-tip, attempt to slide the scar in all directions. Assess for adhesion or lack of skin mobility over underlying tissue<sup>a</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Degree of healing</li> <li>• Location of scar in relation to vulva/scrotum or anus</li> <li>• Location of adhesion</li> <li>• Extent/magnitude of scar mobility<sup>35</sup></li> <li>• Absent</li> </ul>

TABLE 3 (Continued)

Test	Rating
<p><b>2.1.13 Tone:</b> state of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement.<sup>24</sup> The recommended position of the examining digit(s) is to place the palmar surface of the examining finger on the ischiocavernosus, bulbospongiosus (<i>f</i>)/bulbocavernosus (<i>m</i>) or transverse perineal muscle belly at the thickest portion of the muscle belly, <i>per perineum</i>. Pressure or stretch is applied perpendicular to the muscle fibers to assess tone. Tone is described in more detail in 2.2.3</p>	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Decreased tone (see 2.2.3.4)</li> <li>• Increased tone (see 2.2.3.5)</li> </ul>
<p><b>2.1.14 Tenderness:</b> Sensation of discomfort with or without pain; discomfort elicited through palpation of any tissue indicates unusual sensitivity to pressure or touch.<sup>24</sup> May be generalized within a muscle</p> <p><b>2.1.14.1 Tender point:</b> Area of localized tenderness occurring in muscle, muscle-tendon junction, bursa, or fat pad (CHANGED)<sup>24b</sup></p>	<ul style="list-style-type: none"> <li>• Note location of pressure application</li> <li>• Note location of pain (where pressure applied, or if pain referral present, note location of pain referral)</li> <li>• Rate severity of pain on a numeric rating scale (NRS) 0–10<sup>36</sup></li> </ul>
<p><b>2.1.15 Pudendal nerve neurodynamics:</b> Neurodynamic assessment evaluates the length and mobility of the nerve to assess neurogenic origin of pain<sup>37</sup> (NEW). Tension is applied to the nerve or specific component of the nerve by lengthening the nerve or by distracting imposing tissues.<sup>37</sup></p>	<ul style="list-style-type: none"> <li>• Positive: If pain, sensation of burning or stabbing are experienced in the distribution of the nerve. This assessment can be uncomfortable in asymptomatic individuals, however, reproduction of patient's pain is suggestive of a neurogenic origin of pain</li> <li>• Negative</li> </ul>
<p><b>2.1.16 Cotton swab test (<i>f</i>):</b> A test for vestibular tissue sensitivity. (NEW) The test is performed with a cotton swab moistened with water or lubricating gel. Gentle pressure is applied to the following areas of the vaginal vestibule<sup>d</sup> in random order: 12:00, and quadrants 12–3:00, 3:00–6:00, 6:00–9:00, 9:00–12:00<sup>e</sup></p>	<ul style="list-style-type: none"> <li>• Positive if gentle pressure reproduces patient's pain</li> <li>• Report location of pain and severity on NRS 0–10<sup>36</sup></li> <li>• Negative</li> </ul>
<i>Tests of digital palpation per perineum for sacral reflex function</i>	
<p><b>2.1.17 Sacral reflex testing:</b> a measure of the involuntary function of sacral nerves. (CHANGED)<sup>12f</sup> Tests are described below.</p>	<ul style="list-style-type: none"> <li>• Present: Observation of anal sphincter contraction. Indicative of intact spinal reflex arcs (S2–S4 spinal segments) with afferent and efferent nerves through the pudendal nerve<sup>38</sup></li> <li>• Absent: No sphincter activity</li> </ul>
<p><b>2.1.17.1 Bulbocavernosus reflex (<i>f</i>):</b> A reflex contraction of the anal sphincter and bulbocavernosus in response to squeezing the clitoris (CHANGED)<sup>12</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<p><b>2.1.17.2 Bulbospongiosus reflex (<i>m</i>):</b> A reflex contraction of the striated muscles of the pelvic floor (anal sphincter) including bulbospongiosus muscles that occurs in response to various stimuli in the perineum or genitalia. Most commonly tested by placing a finger in the rectum and then squeezing the glans penis<sup>39</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<p><b>2.1.17.3 Anal reflex:</b> A reflex contraction of the anal sphincter in response to a painful pin prick delivered to the perianal skin<sup>12</sup> (CHANGED)<sup>g</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<i>Tests of digital palpation per perineum with PFM contraction<sup>h</sup></i>	
<p><b>2.1.18 Voluntary contraction of the PFM:</b> Self-initiated activation of the PFM (same term as 2.1.7). Each of the bulbospongiosus/bulbocavernosus, ischiocavernosus, and transverse perinei muscles may be palpated separately. The assessor may need to gently move the</p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> <li>• Uncertain</li> </ul>

TABLE 3 (Continued)

Test	Rating
external genitalia (parting of the labia, lifting of the scrotum to one side) to effectively palpate the perineal response	

Abbreviations: *f*, female; *m*, male; NRS, numeric rating scale; PFM, pelvic floor muscles.

<sup>a</sup>Adherent skin could impact function of PFM beneath the scar.

<sup>b</sup>Tender points (2.1.15.1) differ from trigger points (see 2.2.3) therefore the terms should not be used interchangeably.<sup>40</sup>

<sup>c</sup>This test is also referred to as the "Q Tip test." "Cotton swab" is preferred to avoid proprietary names.

<sup>d</sup>Excessive pressure could provoke underlying structures (such as the PFM) misleading the report of pain to vestibular tissues.

<sup>e</sup>Examination tip: In patients with high irritability, it is recommended to test the most severe pain area last to avoid an amplified response due to carry-over irritation as the test progresses.<sup>41,42</sup> In addition if an area provokes increased pain, it is important to wait for the pain to subside before testing other locations.

<sup>f</sup>This term is listed as a modification of the term in Rogers et al.<sup>12</sup>

<sup>g</sup>In contrast to the bulbocavernosus reflex the anal reflex is a nociceptive reflex and the correct stimulus is painful. If a single stimulus does not activate the reflex, several pricks in a fast sequence should be delivered. It is often difficult to elicit in the elderly, and it should not be declared absent if only a single stimulus is used. A "voluntary" movement away from the (painful) stimulus (pin prick) can usually be interpreted correctly. The patient should be told that painful stimuli are going to be delivered, and usually they can "keep still" and only the reflex contraction of the anal sphincter is observed. It is often absent even in patients without a neural lesion.

<sup>h</sup>Some of the tests performed in the external examination section may be repeated during the internal examination.

TABLE 4 Tests of digital palpation *per vaginam/per rectum*, resting state

Test	Rating
<b>2.2.1 Sensation:</b> test for presence, absence, or altered quality of light touch sensation as for 2.1.12	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> <li>• Altered: increased or decreased</li> </ul>
<b>2.2.2 Presence of scarring:</b> Presence of scar tissue along vaginal walls or apex. (NEW). Using a finger-tip, attempt to slide the scar in all directions. Assess for adhesion or lack of mucosal/vaginal wall mobility over underlying tissue <sup>a</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Location of adhesion</li> <li>• Degree of healing</li> <li>• Extent/magnitude amount of scar mobility</li> <li>• Absent</li> </ul>
<b>2.2.3 Tone:</b> see 2.1.13. The recommended position of the examining digit(s) is to place the palmar surface of the examining finger on the levator ani, <i>PV</i> , or <i>PR</i> . Pressure or stretch is applied perpendicular to the muscle fibers to assess tone Further details regarding terminology and assessment of muscle tone are provided in text section 2.2.3	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Decreased tone (see 2.2.3.4)</li> <li>• <b>Increased tone (see 2.2.3.5)</b></li> </ul>
<b>2.2.4 Fasciculation:</b> individual brief twitches in a muscle. They may occur at rest or after muscle contraction and may last several minutes <sup>24,43</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<b>2.2.5 Tenderness:</b> See 2.1.15 and 2.1.15.1	See 2.1.15 and 2.1.15.1
<b>2.2.6 Pudendal nerve provocation test:</b> Palpation of the pudendal nerve to reproduce patient's pain if entrapment is suspected. The nerve may be palpated at the ischial spine, sacrospinous and sacrotuberous ligaments, or pudendal canal <sup>44,45</sup> (NEW)	<ul style="list-style-type: none"> <li>• Positive (pain response)</li> <li>• Negative</li> </ul>
<i>Per rectum only</i>	
<b>2.2.7 Digital rectal examination (DRE)<sup>b</sup>:</b> Palpatory examination of the anorectal tissues <sup>c</sup> (CHANGED) <sup>39</sup>	

TABLE 4 (Continued)

Test	Rating
<b>2.2.8 Palpable anal sphincter gap (PR):</b> a clear “gap” in the anal sphincter on digital examination indicates an anal sphincter tear ( <b>CHANGED</b> ) <sup>11d</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> <li>• Note location</li> </ul>

Abbreviations: NRS, numeric rating scale; PR, *per rectum*.

<sup>a</sup>Adherent skin could impact function of PFM beneath the scar.

<sup>b</sup>Despite the name (DRE), the purpose of the examination is usually to assess anal canal tissue, not rectal tissue.

<sup>c</sup>DRE may be less useful in male urinary dysfunctions where the urethral sphincter, inaccessible to DRE, has a more important role.<sup>46</sup>

<sup>d</sup>An assessment can be made of a palpable anal sphincter gap to assess if there has been previous obstetric or surgical damage.<sup>11</sup>

TABLE 5 Tests of digital palpation *per vaginam* only with the PFM in a resting state

Test	Rating
<b>2.2.9 Flexibility of the vaginal opening:</b> The capacity of the vaginal opening to expand in response to stretching. ( <b>NEW</b> ) Assessed by separating index and middle finger in the medio-lateral direction. <sup>47</sup> Digital assessment of the vaginal opening is likely to represent the width of the levator hiatus <sup>3</sup>	<ul style="list-style-type: none"> <li>• Estimate the number of finger widths between the muscle bellies</li> <li>• Can be converted to cm width for the recording from that assessor</li> </ul>
<b>2.2.10 Levator injury/avulsion:</b> A discontinuity of the levator muscle at its attachment to the inferior pubic ramus. ( <b>NEW</b> ) Discontinuity may represent a partial tear, full tear, or thinning. Test for levator injury/avulsion: palpation of levator tissue, by placing finger(s) between the side of the urethra and the edge of the muscle measured on each side. The test is performed at rest and confirmed by asking the patient to contract and feeling for the edge of the contractile tissue of the levator muscle	<ul style="list-style-type: none"> <li>• Absent: Palpable PFM contraction next to the urethra on the inferior pubic ramus</li> <li>• Present: A distance of &gt;3.5 finger widths between the two sides of puborectalis muscle insertion on PFM contraction<sup>24b</sup></li> <li>• Rate number of finger widths palpable in the gap.</li> <li>• Several rating scales exist<sup>48,49</sup></li> </ul>

Abbreviation: PFM, pelvic floor muscles.

<sup>a</sup>Levator hiatus may be better measured with instruments (see Section 3).

<sup>b</sup><3.5 cm may represent a partial avulsion, however, digital palpation cannot reliably determine this distance of discontinuity

### 2.2.3 Muscle tone

Tone exists on a continuum, from hypotonicity (low tone) to hypertonicity (high tone). Normal tone may overlap with abnormally decreased muscle tone or abnormally increased muscle tone at either end of the tone spectrum, as illustrated in Figure 2. Tone is a dynamic physiological state modulated by many inputs: spinal cord, cortex, brainstem relays, stretch reflexes and cutaneous receptors, visceromotor reflex pathways, emotions, and pain (anticipation or experience of pain).

We recommend terms to indicate alterations to normal tone are differentiated according to the presence or absence of a neurological disorder, as illustrated in Figure 3 (see page 12). Abnormal tone related to a neurological disorder (hypotonicity, hypertonicity, dystonia) should not be used when describing PFM tone in a patient who does not have a diagnosed neurological disorder.

#### Physiological basis of muscle tone

Muscle tone has two components: the physiological contractile component, created by the activation of

motor units, and the noncontractile viscoelastic, or biomechanical component. The active component (EMG activity) of tone is the component that is related to the neural drive, therefore it is subject to variation and ongoing adjustment. The viscoelastic component is independent of neural activity and reflects the

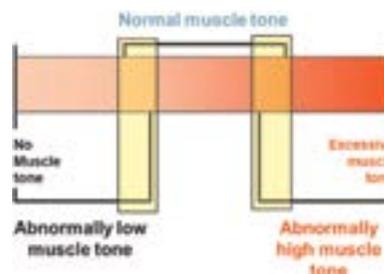

FIGURE 2 Spectrum of muscle tone (adapted from Allen and Widener 2009, with permission<sup>50</sup>)

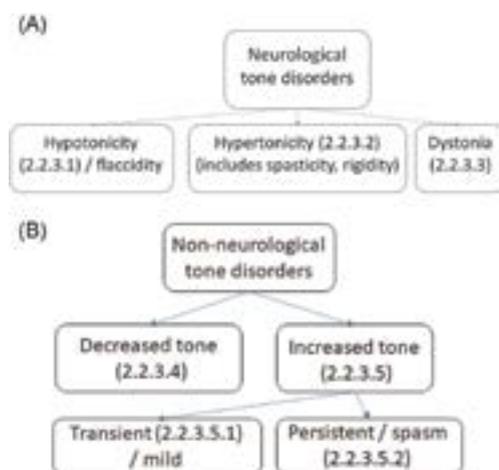

FIGURE 3 Terms for disorders of tone due to a neurological disorder (A) and a nonneurological disorder (B)

passive physical properties of the viscoelastic tension of the muscle tissues (e.g., the extensibility of actin-myosin cross-bridges); noncontractile cytoskeleton proteins and connective tissues surrounding the entire muscle (epimysium), muscle fascicle (perimysium), and muscle fiber (endomysium) as well as the osmotic pressure of the cells. Alterations in either the active or passive component can affect the resting tone; digital palpation cannot differentiate between these elements however investigations that combine EMG with another measure that assesses passive properties can identify specific components.

A localized area of increased tone within a muscle may be referred to as a taut band.<sup>51</sup> A trigger point is considered to be a tender nodule within a taut band.<sup>51</sup> The trigger point is considered by some authors to be part of the active component of tone<sup>51</sup> given the local disturbance in electrical activity, and by others as a separate category distinct from the active or passive components of tone.<sup>52</sup> Given the uncertainty about the characterization of a trigger point,<sup>53,54</sup> we propose describing palpatory findings by use of the terms “tender point” (2.1.15.1) and “increased tone” (2.2.3.4) if both observations coincide at the tested site, or use only “tender point” (2.1.15.1) or “increased tone” (2.2.3.4) if only one of those signs is observed at the tested site.

#### Assessment and rating

Tone can be assessed by application of digital site-specific compression and/or overall muscle stretch.

Digital palpation is inherently subjective and may be limited by pain provocation.

Several scales to quantify resting PFM tone in the absence of a neurological disorder have been proposed using either a 3-point,<sup>55,56</sup> 6-point,<sup>48</sup> or 7-point<sup>57</sup> scale.

#### Definitions and descriptions

**2.2.3.1 Hypotonicity:** A decrease in muscle tone in a patient **with** a neurological disorder. It may be due to a lower motor neuron or a muscle disorder. The term flaccidity<sup>58</sup> is often used interchangeably. (NEW)

**2.2.3.2 Hypertonicity:** An increase in muscle tone in a patient **with** a neurological disorder. It may be due to an upper motor neuron or extrapyramidal lesion, which in turn may lead to spasticity<sup>58</sup> or rigidity.<sup>58</sup> (NEW)

**2.2.3.3 Dystonia:** A disorder characterized by abnormalities of muscle tone and movements/postures in a patient **with** a neurological disorder.<sup>59</sup> It is often due to damage to the basal ganglia or other brain regions that control movement. (NEW)

**2.2.3.4 Decreased PFM tone:** A decrease in resting muscle tone in a patient **without** a neurological condition (CHANGED)<sup>43</sup>

**2.2.3.5 Increased PFM tone:** An increase in muscle resting tone in a patient **without** a neurological disorder. (CHANGED).<sup>43</sup> Increased tone may occur without patient report of pain.

**2.2.3.5.1 Transient increased muscle tone:** Increased muscle tone that decreases with verbal instruction, reassurance, or gentle pressure (NEW). Transient increase in tone may occur at any time during the examination.

**2.2.3.5.2 Muscle spasm:** Persistent contraction of muscle that cannot be reduced voluntarily.<sup>11,24,43</sup> Spasms may occur at irregular intervals with variable frequency and extent, and over time may lead to increased viscoelastic stiffness and shortening in the muscular and connective tissues.<sup>vii,viii</sup>

**Resting state per vaginam (PV) only (f):** Terms related to digital palpation of the vaginal tissues with the PFMs in a resting state are listed in Table 5.

**PFM contraction:** The following terms in Table 6 (see page 13) are used in the definition and the ratings of digital assessment *per vaginam/per rectum* of the PFMs during contraction.

**PFM contraction per vaginam (PV) only (f):** Terms related to digital palpation *per vaginam* only (f), on PFM contraction are listed in Table 7 (see page 14).

**PFM response to intra-abdominal pressure per vagina morper rectum**

**2.2.22 Direction of PFM movement during sustained increase in IAP:** As per 2.1.9. Specify task instruction, as response may differ depending on wording. Rate as elevation, no change, descent (normal finding), excessive descent.

TABLE 6 Tests of digital palpation *per vaginam/per rectum* on PFM contraction

Test	Rating
<p><b>2.2.11 Voluntary contraction of the PFM:</b> Self-initiated activation of the PFM (same term as 2.1.7). A contraction is felt as a tightening, lifting, and squeezing action under the examining finger. Technique:</p> <ul style="list-style-type: none"> <li>• The recommended position of the examining digit(s) to assess levator ani contraction (<i>PV</i>) unilaterally is to place the palmar surface of the examining finger on the lateral levator ani muscle belly surface or “edge,” which may be identified by asking the patient to contract then relax</li> <li>• The recommended position of the examining digit to assess anal sphincter and puborectalis muscle function (<i>PR</i>) is to place the palmar surface of the well-lubricated examining finger at the anal verge initially, wait for relaxation of EAS, then insert gently along the posterior wall of the anal canal.<sup>60</sup> Once anal sphincter function is assessed the examining digit remains pressed against the posterior wall and is inserted slowly into the rectum, passing over puborectalis at the anorectal junction</li> </ul>	<p>Presence of contraction may be rated as:</p> <ul style="list-style-type: none"> <li>• No contraction</li> <li>• correct contraction (cephalad and ventral movement)</li> <li>• Contraction only with help from other muscles</li> <li>• Uncertain</li> <li>• Straining<sup>51</sup></li> </ul> <p>Absent: <b>2.2.11.1 Noncontracting PFM:</b> During palpation there is no palpable voluntary or involuntary contraction of the PFM<sup>23a</sup></p>
<p><b>2.2.12 Digital muscle test (DMT):</b> A test to evaluate PFM strength (<b>NEW</b>).</p> <p><b>2.2.12.1 Strength:</b> Force-generating capacity of a muscle. Usually expressed as a maximum voluntary contraction measurement (MVC).<sup>24</sup> A manual muscle test (MMT) evaluates the strength of a muscle by moving the muscle through its full-range of motion against gravity and then against gravity with resistance.<sup>14</sup> However, because joint range of motion is not being assessed in the pelvic floor and PFM examination is performed with a digit, not a hand, the term DMT is preferred. There are more than 25 published DMT scales<sup>62,63</sup> which provide grade of strength ranging from absence, to weakness to increasing strength</p>	<ul style="list-style-type: none"> <li>• Commonly used scales include: ICS scale: absent, weak, normal (we propose the word “moderate” instead of normal), or strong<sup>23</sup></li> <li>• modified Oxford grading scale 0–5<sup>64</sup></li> <li>• Brink scale<sup>65</sup> grades 3 components (pressure, displacement, and time) on a scale of 1–4</li> <li>• many others<sup>62,63</sup></li> </ul>
<p><b>2.2.13 Direction of pelvic floor movement:</b> Direction of pelvic floor movement during voluntary PFM contraction palpated <i>PV</i> (on the posterior vaginal wall) or <i>PR</i> (<b>NEW</b>)</p>	<ul style="list-style-type: none"> <li>• Pelvic floor elevation: normal finding</li> <li>• Pelvic floor descent: palpation of downward movement of the PFM during attempted PFM contraction</li> <li>• No change</li> </ul>
<p><b>2.2.14 Endurance:</b> Muscular endurance refers to the ability of a muscle or muscle group to perform repeated contractions or to maintain a contraction for a predetermined period of time<sup>66,67</sup> (<b>CHANGED</b>)<sup>24</sup></p>	<p><b>2.2.14.1 Fatigue:</b> A decreased capacity to perform a maximum voluntary muscle action or a series of repetitive contractions. (<b>NEW</b>) Fatigue may occur due to central or peripheral mechanisms.<sup>68</sup> A fatigued muscle is unable to continue working even when the type of activity is changed<sup>b</sup></p> <p>Record the time at which fatigue starts to occur, or the number of contractions in a row before onset of fatigue</p>
<p><b>2.2.14.2 Sustained contraction endurance test:</b> the number of seconds the patient can hold near maximal or maximal PFM contraction (<b>NEW</b>)</p>	<ul style="list-style-type: none"> <li>• Record number of seconds contraction is sustained at near maximal or maximal intensity</li> </ul>
<p><b>2.2.14.3 Repeatability of contraction:</b> The ability to repeatedly develop near maximal or maximal force determined by assessing the maximum number of repetitions the patient can perform (<b>CHANGED</b>)<sup>24c</sup></p>	<ul style="list-style-type: none"> <li>• Record number of contractions in a row</li> </ul>
<p><b>2.2.15 Number of rapid contractions performed:</b> The number of repeated, quick MVCs performed (<b>NEW</b>). This can be measured in two ways, according to the instruction:</p>	<p>Use the rating appropriate to the instruction:</p>

(Continues)

TABLE 6 (Continued)

Test	Rating
<p>1. Number of contractions repeated within a specific duration (i.e., a 10-s period<sup>b</sup>)</p> <p>2. The elapsed time to perform a pre-specified number of contractions (e.g., 10 s<sup>69</sup>) A contraction should comprise an ascending and a descending phase with the PFM force returning to the resting state in between. If the maximal force declines, the assessment ceases</p>	<ul style="list-style-type: none"> <li>Record the number of contractions repeated and the duration allowed to perform them</li> <li>Specify the exact number of contractions to be repeated and record the number of seconds to completion.</li> <li>Qualitative descriptions can include quality and extent of contraction and relaxation phases</li> </ul>
<p><b>2.2.16 Relaxation postcontraction:</b> Return of the PFM to its original resting tone following the voluntary contraction (<b>CHANGED</b>)<sup>23d</sup>. The patient is able to relax the PFMs on demand, after a contraction has been performed. Relaxation is felt as a termination of the contraction</p>	<ul style="list-style-type: none"> <li>Yes: Relaxation felt directly after instruction: normal finding</li> <li>Partial or delayed relaxation</li> <li>No: Absent = nonrelaxing PFM (see 2.1.8.1)</li> </ul>
<p><b>2.2.17 Co-ordination:</b> The ability to use different parts of the body together smoothly and efficiently.<sup>24</sup> In the pelvic floor, co-ordination may be an action between PFMs and organ function (e.g., PFM relaxation during voiding), PFMs and an external environmental event (e.g., movement of a limb) and PFMs and a rise in IAP (e.g., PFM contraction before a cough). Co-ordination is an aspect of motor control.</p>	<ul style="list-style-type: none"> <li>Present</li> <li>Absent. If absent, describe pattern of incoordination. e.g., paradoxical contraction: the inability to maintain PFM relaxation when it is expected; or lack of PFM contraction when it is expected</li> </ul>
<p><b>2.2.17.1 Co-contraction:</b> Contraction of two or more muscles at the same time.<sup>24</sup> Co-contraction of muscles can be synergistic (e.g., resulting in an augmentation of motor activity) or it could be counterproductive to normal function (e.g., contraction of antagonistic muscles resulting in abnormal movement or training other muscles instead of the targeted ones, e.g., training of gluteal muscles instead of the PFM).<sup>24</sup> Activation or inhibition of PFM contraction may be task-dependent</p>	<ul style="list-style-type: none"> <li>If present, identify which muscles are co-contracting, and whether the co-contraction is synergistic or counter-productive<sup>e</sup></li> </ul>

Abbreviations: DMT, digital muscle test; EAS, external anal sphincter; *f*, female; IAP, intra-abdominal pressure; *m*, male; MVC, maximum voluntary contraction; PFM, pelvic floor muscles; *PR*, *per rectum*; *PV*, *per vaginam*.

<sup>a</sup>This term is referring to a sign and not recommended to be used as a diagnosis. This sign may be combined with symptoms to inform a clinical diagnosis.

<sup>b</sup>Endurance training can delay the onset of fatigue.<sup>70</sup>

<sup>c</sup>Modification from Bo et al.<sup>24</sup>: removal of “at a given percentage of 1 RM” as definition already states “near maximal or maximal force.”

<sup>d</sup>This can only be graded if the patient is able to generate a PFM contraction.

<sup>e</sup>Antagonistic contraction has not been included in this document as there is not a muscle whose action counteracts the action of the PFM.

TABLE 7 Tests of digital palpation *per vaginam* only (*f*), on PFM contraction<sup>a</sup>

Test	Rating
<p><b>2.2.19 Urethral lift:</b> Elevation of the urethra in a cephalad direction.<sup>15</sup> (<b>NEW</b>) Index finger is placed along the line of the urethra (on the anterior vaginal wall)</p>	<ul style="list-style-type: none"> <li>Yes: Urethral lift palpable</li> <li>No: No urethral lift palpable</li> </ul>
<p><b>2.2.20 Levator closure:</b> Movement of right and left muscle bellies closer together during a PFM contraction (palpated on the lateral vaginal wall).<sup>15</sup> (<b>NEW</b>) May be tested unilaterally if bi-digital assessment is uncomfortable for the patient</p>	<ul style="list-style-type: none"> <li>Yes: Levator closure movement palpable</li> <li>Partial/uncertain: Some closure movement palpable, but could be un-certain, or asymmetrical</li> <li>No: No levator closure movement palpable</li> </ul>
<p><b>2.2.21 Levator hiatus size:</b> The size of the levator hiatus measured during maximal contraction by a digital examination<sup>71b</sup> (<b>NEW</b>)</p>	<ul style="list-style-type: none"> <li>With 2 fingers in the vagina, distance measured in centimeters (converted approximately from finger widths) during PFM contraction</li> <li>LH transverse: The distance between the left and right muscle bellies just inferior to the pubic bone</li> <li>LH sagittal: The distance between the back of the pubic symphysis and the midline raphe of the puborectalis<sup>71</sup></li> </ul>

Abbreviations: LH, levator hiatus; *PV*, *per vaginam*.

<sup>a</sup>These tests are likely to produce more accurate results if measured using ultrasound imaging.

<sup>b</sup>This test was performed in patients with POP; the same technique may be uncomfortable in women with pelvic floor pain or increased tone.

Following the assessment of a patient's clinical signs, the assessor will formulate a provisional differential diagnosis which will be refined following the results of the investigations.

#### 4 | SECTION 3: INVESTIGATIONS

An investigation is part of the differential diagnostic decision-making process. A PFM investigation is the measurement of the morphometry or function of the PFMs using mechanical or technological methods. The findings may be considered more accurate than findings from a clinical evaluation which relies on digital palpation. Some points to note regarding PFM investigations that should be considered in clinical and research application and interpretation of the finding: all devices are different and may not give the same information of a specific PFM physiological parameter or function. In addition, device specifications and analysis software options influence both the availability and measurement of PFM parameters,<sup>72,73</sup> the size and shape of a probe/sensor/electrode/transducer also influence the interpretation of findings<sup>72–74</sup> and raw values may need to be normalized. New devices to measure PFM properties may become available in the near future which do not fit the existing categories entirely, and new categories may need to be added to this living document.

**3.1 Dynamometry:** An investigation that measures both muscle power and force (**CHANGED**). Both active (contractile) and passive (noncontractile) forces can be detected.

**3.1.a Intra-vaginal PFM dynamometry:** Measurement of PFM resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina<sup>75</sup> (**CHANGED**).

Several PFM dynamometers have been developed to assess the PFM function in women.<sup>76–84</sup> Different configurations have been proposed in terms of the number, shape and the sizes of the branches, the force vector recorded (i.e., antero-posterior, latero-lateral or multi-directional forces) and the device specifications (e.g., configuration of strain gauges to avoid a lever-arm effect—the influence of the force location in regard to the gauges). In some dynamometers, the branches can be separated at a constant speed either manually or with a motorized unit to assess the passive properties during dynamic stretches.<sup>81,85</sup> Elastometry is a type of

intra-vaginal PFM dynamometer used for this specific application of evaluating the passive properties during dynamic stretches.<sup>81</sup>

Table 8 (see page 16) describes the most frequent parameters measured with intra-vaginal dynamometers as well as their definitions, specifications and findings. Parameters can be assessed at different fixed vaginal apertures or during stretching (i.e., while imposing an elongation to the tissues by separating the speculum branches).<sup>81,84</sup> The parameters measured with the dynamometer alone reflect the summative contribution of the active and passive components of tone. When combined with EMG, it enables the assessment of the differential contributions of tone components,<sup>86</sup> that is, during passive stretch of the PFM, concurrent EMG activity detects any electrogenic contributions. The passive component can then be identified when the EMG remains negligible.<sup>86,87</sup>

**3.2 Myotonometry:** An investigation that measures muscle tone characteristics by applying a mechanical impulse to the tissue.<sup>89–91</sup> (**NEW**) The device elicits oscillations of muscle after a probe applies a brief mechanical impulse with quick release under constant preload to the skin over the muscle belly. Myotonometry has been used externally on the perineum to measure superficial PFM stiffness. It cannot be used intra-vaginally to measure levator ani function as the probe must be perpendicular to the muscle and therefore cannot be used to interpret levator ani function. Table 9 (see page 17) describes the most frequent parameters measured with myotonometry that can be computed from the oscillation curve as well as their definitions, specifications and findings.<sup>92</sup> It should be noted that the tissues that lie between the probe and the muscle (e.g., skin, adipose tissues, connective and fascial tissues) can also influence the measurements.

**3.3 Manometry: An investigation that measures pressure**<sup>24,75</sup>

**3.3.1 Pelvic floor manometry:** Measurement of resting pressure or pressure rise generated during contraction of the PFM using a manometer connected to a sensor, which is inserted into the urethra, vagina or rectum.<sup>24</sup>

**3.3.1.a Intra-urethral manometry:** Manometry performed via the urethra. One example is the urethral pressure profile that is undertaken as part of a urodynamic investigation.<sup>94</sup> (**NEW**)

**3.3.1.b Intra-vaginal manometry:** Manometry performed via the vaginal canal. (**NEW**)

TABLE 8 Parameters and findings evaluated with intravaginal dynamometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<p><b>3.1.1 Passive forces:</b> The average forces in N recorded at rest<sup>84</sup> (NEW)</p> <p>Specify:</p> <ul style="list-style-type: none"> <li>– Opening (distance between the two branches e.g., minimal opening, selected opening or maximal opening)</li> <li>– While stretching (dynamic opening)</li> </ul>	The finding is the resting forces of the PFMs which are indicative of PFM tone, i.e., the summative contribution of the active and passive components of tone
<p><b>3.1.2 Maximal aperture:</b> The maximal vaginal opening in mm or cm of the dynamometer branches, without provoking a pain response<sup>86</sup> (NEW)</p>	This aperture can be used to evaluate the flexibility <sup>1</sup> of the PFMs
<p><b>3.1.3 Viscoelastic stress relaxation during a static (sustained) stretch:</b> The percentage loss in passive force during the application of a steady stretch over a prolonged period (e.g., 1 min)<sup>85,88</sup> (NEW)</p>	Higher percentage of force decline is indicative of an enhanced viscoelastic stress relaxation response and muscle relaxation. This could be useful in quantifying tissue relaxation following stretching or lower force decline associated with strength training <sup>88</sup>
<i>(b) Parameters assessed at rest during dynamic stretching</i>	
Dynamic stretches are applied by repeatedly separating the speculum branches at a constant speed until maximal vaginal aperture (lengthening phase) and then, closing back to the minimal aperture (shortening phase)	
<p><b>3.1.4 Stiffness:</b> The resistance to deformation. Passive elastic stiffness is defined as the ratio of the change in the passive resistance or passive force (<math>\Delta F</math>) to the change in the length displacement (<math>\Delta L</math>) or <math>\Delta F/\Delta L</math> (N/mm)<sup>24,43,75b</sup>. Passive elastic stiffness should be computed for specific vaginal apertures<sup>81,84</sup></p>	The higher the N/mm value, the stiffer the muscle. This is a physiological property of muscle which contributes to the overall measurement of tone
<p><b>3.1.5 Compliance:</b> the reciprocal of muscle stiffness (mm/N)<sup>43</sup> (NEW)</p>	The higher the mm/N, the more compliant the tissue
<p><b>3.1.6 Hysteresis:</b> The area between the lengthening and shortening curves (N × mm). It corresponds to the loss of energy associated with lengthening of viscoelastic tissues<sup>85</sup> (NEW)</p>	Increased area indicates higher energy dissipated
<i>(c) Parameters evaluating contractile properties</i>	
<p><b>3.1.7 Maximal strength:</b> Peak force in N generated during a MVC. (NEW). The resting forces recorded before the effort are usually subtracted from the peak value<sup>78</sup></p> <p>Specify:</p> <ul style="list-style-type: none"> <li>– The length of hold for the MVC, e.g., 10 s contraction duration</li> <li>– How the peak score was obtained, e.g., peak during a single MVC, best of or average of 3 contractions</li> </ul>	Higher peak value indicates higher muscle strength
<p><b>3.1.8 Speed of contraction:</b> Rate of force development measured as the mean slope of the ascending curve in N/s during a fast MVC<sup>79</sup> (NEW)</p>	Higher rate of force (steeper slope) is indicative of a faster generation of force
<p><b>3.1.9 Speed of relaxation:</b> Rate of force reduction measured as the mean slope of the descending curve in N/s during PFM relaxation<sup>86</sup> (NEW)</p>	Lower values are indicative of slower relaxation
<p><b>3.1.10 Number of rapid contractions:</b> See section 2.2.16 for definition and rating. A contraction must comprise an ascending and a descending phase with the amplitude of the PFM forces returning to the resting state post contraction<sup>79</sup></p>	Higher number of contractions are suggestive of higher speed of contraction but also better motor control, as the task requires alternation between MVC and complete rest

TABLE 8 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.1.11 Normalized area under the force curve:</b> The area under the force curve divided by maximal force and multiplied by 100 (in % × prescribed s) during a sustained MVC <sup>79</sup> (NEW)	Higher normalized area is indicative of better muscle endurance

Abbreviations: MVC, maximum voluntary contraction; N, Newtons; PFM, pelvic floor muscles.

<sup>a</sup>See section 2.2.9 for definition.

<sup>b</sup>Using the dynamometer alone, the stiffness value will reflect the summative contribution of the active and passive components of tone. If dynamometry is combined with EMG, the passive contribution can be identified.<sup>86</sup>

**3.3.1.c) Intra-anal manometry<sup>ix</sup>:** Manometry performed via the anal canal. (NEW)

Pelvic floor manometric tools traditionally have measured pressure in mmHg, hPa, or cmH<sub>2</sub>O, however, new and future devices may provide output using different units. It should be specified whether the device is calibrated to zero/atmospheric pressure before insertion.<sup>24</sup> The most common parameters assessed with pelvic floor manometry (intra-vaginal and intra-anal) and their findings are described in Table 10 (see page 18).

Several common parameters are illustrated in Figure 4 (see page 19).

**3.3.2 Anorectal manometry<sup>x</sup>:** Is a pressure test to assess the structure and physiological function of the anorectal complex (CHANGED).<sup>11</sup> Water perfused and solid-state pressure transducers are used in combination with a balloon positioned in the anal canal.<sup>23</sup> The most commonly used PFM parameters and findings are described in Table 11 (see page 20).<sup>xi</sup>

TABLE 9 Parameters and findings evaluated with myotonometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.2.1 Oscillation frequency:</b> Characterizes the intrinsic tension of the muscle in its passive or resting state in the absence of voluntary contraction. <sup>93</sup> (NEW) Measured in Hz	A higher oscillation frequency (Hz value) indicates higher muscle tone <sup>92,93</sup>
<i>(a) Biomechanical properties</i>	
<b>3.2.2 Stiffness:</b> As defined in 3.1.4 for dynamometry. However, the method of application of the force is different to that described in 3.2.2; with this device, an external sensor applies a deformation perpendicular to the tissue	A higher N/m value indicates higher muscle stiffness.
<b>3.2.3 Logarithmic decrement:</b> Characterizes elasticity and dissipation of mechanical energy. Measured as $1n(D = \ln[a1/a3])$ . <sup>93</sup> It indicates the ability of the tissue (including muscle) to recover its shape after being deformed (NEW)	Elasticity is inversely proportional to decrement, therefore, if the decrement of a muscle decreases, the muscle elasticity increases. The smaller the decrement value, the smaller will be the dissipation of mechanical energy and the higher the elasticity of a tissue
<i>(b) Viscoelastic properties</i>	
<b>3.2.4 Mechanical stress relaxation time:</b> The time for a muscle to recover its shape from deformation after a voluntary contraction or removal of an external force (NEW). Measured in milliseconds <sup>92</sup>	The longer the time the more relaxation has occurred in the tissue
<b>3.2.5 Creep:</b> The gradual elongation of a tissue over time when placed under a constant tensile stress. (NEW): Measured by the ratio of relaxation time to deformation time (Deborah number)	The higher the creep, the less elasticity the tissue has and the more likely is permanent stretch or deformation

Abbreviations: Hz, hertz; N/m, newtons/meter.

TABLE 10 Parameters and findings evaluated with pelvic floor manometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<p><b>3.3.1.1 Resting pressure:</b> The pressure recorded at rest in mmHg, hPa or cmH<sub>2</sub>O. For greater accuracy, a mean resting pressure may be calculated over a specified period to account for fluctuations<sup>95,96</sup> (NEW)</p> <p>Resting pressure may be influenced by PFM tone (i.e., summative contribution of the active and passive components)</p>	Higher resting pressure may be a surrogate measure of increased PFM tone. However, the value should be interpreted with caution as the measurement is not limited to pressure originating from the PFMs (e.g., intra-abdominal pressure, vaginal tissue scarring, rectal contents may contribute to resting pressure)
<i>(b) Parameters evaluating contractile properties</i>	
<p><b>3.3.1.2 Peak pressure during a maximum voluntary contraction:</b> highest pressure recorded during a PFM MVC in mmHg, hPa or cmH<sub>2</sub>O (NEW)</p> <p>As the pressure measured does not confirm its origin, it is important to ensure the validity of intra-vaginal measurement: (1) perform vaginal palpation before using the manometer to ensure the patient is able to correctly contract her PFMs; (2) observe the cranial movement of the vaginal probe during measurement of the muscle contraction, and (3) ignore contractions associated with elevated intra-abdominal pressure (e.g., Valsalva maneuver), hip muscle contraction or any movement of the pelvis<sup>97,98a</sup></p> <p>Specify:</p> <ul style="list-style-type: none"> <li>- The length of hold for the MVC, e.g., 3 s/5 s/10 s contraction duration</li> <li>- How the peak score was obtained, e.g., peak during a single MVC/best of or average of 3 contractions<sup>99-106</sup></li> </ul>	Maximal pressure is often used as a surrogate of muscle strength, e.g., higher pressure being related to higher strength
<p><b>3.3.1.3 Time to peak pressure:</b> Time in seconds from onset of muscle contraction to maximal pressure (NEW)</p>	Shorter time to peak is indicative of a faster generation of pressure
<p><b>3.3.1.4 Speed of contraction:</b> Rate of pressure rise measured as the mean slope of the ascending curve in hPa/s during a fast MVC (NEW)</p>	Higher rate of force (steeper slope) is indicative of a faster generation of pressure
<p><b>3.3.1.5 Speed of relaxation:</b> Rate of pressure reduction measured as the mean slope of the descending curve in hPa/s during PFM relaxation (NEW)</p>	Lower values are indicative of a slower relaxation
<p><b>3.3.1.6 Number of rapid contractions:</b> See 2.2.16 and 3.1.10 for definitions and ratings</p>	See 3.1.10 for interpretation
<p><b>3.3.1.7 Time to return to baseline pressure:</b> Time in seconds from maximal pressure to relaxation state (NEW)</p>	Longer duration suggests slower relaxation
<p><b>3.3.1.8 Duration of a sustained contraction:</b> The length of time in seconds that a contraction can be sustained during MVC or at a specific % of MVC. (NEW). Specify if it is a maximal contraction or a % of MVC, e.g., 60%<sup>96,99,101,102,105</sup> and the threshold used to indicate that the target is no longer maintained</p>	A shorter duration suggests a lower endurance. Duration of contraction could be used as an indication of endurance, e.g., longer contraction being related to better endurance
<p><b>3.3.1.9 Area under the pressure curve during a sustained contraction:</b> The area under the pressure curve in hPa multiplied by time in s during a sustained MVC or at a specific percentage of MVC. This represents the total work performed. (NEW). Specify the duration of the contraction, e.g., 10 s, 30 s, etc.<sup>95,100</sup></p>	Higher area under the pressure curve above resting pressure reflects better muscle endurance

Abbreviations: MVC, maximum voluntary contraction; PFM, pelvic floor muscles.

<sup>a</sup>It is not recommended to use intravaginal pressure manometry to assess the reflex contraction of the PFM during coughing.<sup>107</sup> Bo and Constantinou<sup>107</sup> explained that pressure measurement is a summation of signals including PFM and intra-abdominal pressure caused by the cough itself and therefore, it is unlikely that the PFM reflex can be assessed in isolation using pressure manometry. In contrast, ano-rectal manometry can be used to assess a reflex during an involuntary PFM contraction<sup>108</sup> if the transducer is located in the anus, caudal to the puborectalis/ano-rectal junction; therefore it is not impacted directly by intra-abdominal pressure.

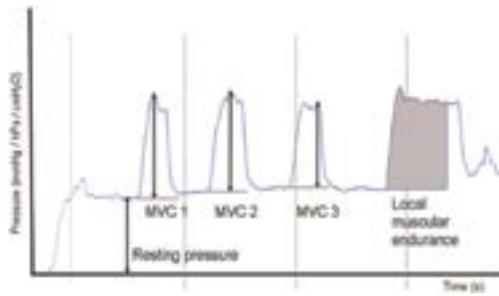

FIGURE 4 Graphical illustration of pelvic floor muscle manometry readings (modified from Ingeborg H Braekken, with permission)

**3.3.2.9 Vector manometry:** A three-dimensional pressure profile of the anal canal. (CHANGED).<sup>11</sup> Measures of total anal canal pressure and symmetry are made. The vector volume is the volume of the 3D shape generated and provides a value which reflects the overall length and symmetry of the sphincter.

**3.3.2.10 High resolution manometry:** Complete definition of the intra-anal pressure environment using a catheter with a large number of pressure sensors spaced less than 0.5 mm apart along the length of the catheter.<sup>11</sup>

**3.3.2.11 Ambulatory anorectal manometry:** Is a test performed using solid-state catheters in ambulant subjects an over an extended period of time (CHANGED).<sup>11</sup>

**3.4 Electromyography (EMG):** Is the recording of electrical potentials generated by the depolarization of muscle fiber membranes.<sup>24</sup> Investigators reporting PFM EMG studies should state the position of the patient, the recording equipment<sup>23</sup> and conditions used as summarized in Box 2 (see page 21). Nerve conduction studies, for example, pudendal nerve testing, are beyond the scope of this document.

Important considerations when interpreting EMG signals: Baseline and contractile sEMG amplitude is affected by properties of the electrode, configuration of electrodes, recording system, and patient/individual characteristics. Raw amplitude cannot be compared between individuals because the signal's amplitude is affected by many factors (e.g., cutaneous/mucosal tissue thickness, vaginal lubrication, positioning/direction of electrodes with respect to the muscle and muscle fibers, and properties of the detection system<sup>114–116</sup>). As a consequence, normalization of the sEMG amplitude is considered critical when comparing data across individuals.<sup>117</sup>

**3.4.a Artifact:** Extraneous information in the EMG signal from sources other than the target muscle, such as the environment (e.g., electromagnetic radiation) or

other body functions. Artifact examples include movement or contact quality artifact, heart rate, skin electrode shear, and electrode bridging (CHANGED).<sup>24</sup>

**3.4.b Crosstalk:** Muscle activity from nearby muscles that can contribute to the recorded EMG amplitude and be misinterpreted as PFM activation.<sup>24,xiii</sup>

**3.4.1 Intramuscular EMG:** Is a recording of motor unit action potentials using needle (concentric or monopolar) or wire electrodes inserted into muscles<sup>75,119</sup> (CHANGED).<sup>24</sup> This is not typically used in clinical assessment. The electrodes can be inserted to assess the superficial (e.g., bulbocavernosus) and deep layers (e.g., levator ani) of the PFMs as well as the urethral and anal sphincters.<sup>120</sup> This assessment as a rule focuses on the motor units to investigate motor unit physiology and pathophysiology. Parameters evaluated with concentric needle EMG can be used to differentiate between normal, denervated, reinnervated and myopathic muscle<sup>121,122</sup> Quantitative EMG includes analysis such as the multi-motor unit potential analysis<sup>122</sup> and the interference pattern analysis (turns/zero crossing or amplitude).<sup>122</sup>

**3.4.2 Surface electromyography (sEMG):** Is a recording of motor unit action potentials using surface electrodes placed on the skin or mucosa close to the muscle of interest. Recordings are also used in assessment of the activation pattern/“behavior” (sometimes referred to as kinesiological electromyography) of a particular muscle during a defined activity.<sup>121</sup> sEMG requires electrodes placed on the skin of the perineum or inside the urethra, vagina or rectum (CHANGED).<sup>12,24</sup> Parameters and findings evaluated with sEMG are described in Table 12 (see page 22). Several common parameters are illustrated in Figure 5 (see page 23).

**3.5 Imaging:** Refers to the process of creating images using high-energy modalities to allow visualization of body tissues. Imaging provides tissue-specific evaluation to identify if morphological properties (e.g., trauma or deficit) are present, which may relate to an individual's presenting symptoms.<sup>24,75</sup> In this document, we focus on ultrasound and MRI assessment and the terms related to PFM morphology and function, as well as the influence of other structures on PFM support and contractility investigated using these tools. It is not within the scope of this document to describe imaging of organ structures.

**Ultrasound imaging:** Pelvic floor ultrasound imaging measures PFM morphology and function via trans-abdominal, trans-perineal, trans-vaginal and trans-anal placement of the transducer (CHANGED).<sup>12,43</sup> This investigation applies diagnostic techniques taken in B-mode that use high-frequency sound waves to image internal structures. The image is formed by the differing reflection signals produced when a beam of

TABLE 11 Parameters and findings evaluated with anorectal manometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<b>3.3.2.1 Functional anal length:</b> The length (mm) of the anal canal over which resting pressure exceeds that of the rectum. <b>(CHANGED)</b> <sup>11</sup> The length of the canal is measured either by station pull-through or continuous pull-through <sup>11</sup>	Functional anal canal length has been shown to be shorter in females with fecal incontinence and longer in females with chronic constipation <sup>109</sup>
<b>3.3.2.2 Maximum resting pressure:</b> The highest pressure (in mmHg, hPa, or cmH <sub>2</sub> O) along the anal canal measured in the axial plane at a specific point <b>(CHANGED)</b> <sup>11</sup>	Internal anal sphincter (IAS) (smooth muscle) is responsible for 55%–85% of the anal pressure, and is variable along the length of the anal canal with the proximal two-thirds being more reliant on IAS tone to maintain adequate resting pressures. Low anal resting pressure is associated with passive fecal soiling. High anal resting pressure may be a feature of constipation <sup>110</sup>
<i>(b) Parameters evaluating contractile properties</i>	
<b>3.3.2.3 Maximum pressure during MVC/maximum squeeze pressure:</b> Is the anal canal pressure (in mmHg, hPa or cmH <sub>2</sub> O) measured during maximum voluntary contraction (MVC) in a specific location <b>(CHANGED)</b> <sup>11</sup>	The pressure increment above resting pressure during these maneuvers is primarily a representation of EAS function. Range of normative values varies according to the particular measurement device in a laboratory. <sup>11</sup> Decreased voluntary anal sphincter contraction is associated with fecal incontinence especially fecal urgency <sup>110</sup>
<b>3.3.2.4 Duration of sustained contraction MVC/endurance squeeze pressure:</b> Is the length of time (in seconds) the individual is able to maintain the pressure during the MVC <b>(CHANGED)</b> <sup>11</sup>	Shorter duration suggests a lower endurance. To assess the endurance squeeze pressure, measurements are taken during a 5–10 s squeeze. By calculating fatigability, the fatigue rate (using reduction of the mean pressure over 1-s periods throughout the endurance squeeze) can be derived <sup>11</sup>
<b>3.3.2.5 Number of rapid contractions:</b> See 2.2.16 and 3.1.10 for definitions and ratings	See 3.1.10 for interpretation.
<b>3.3.2.6 Involuntary maximum squeeze pressure:</b> The pressure (in mmHg, hPa, or cmH <sub>2</sub> O) created involuntarily by the PFM during a maximal cough <sup>108</sup> <b>(CHANGED)</b> <sup>11a</sup>	<ul style="list-style-type: none"> <li>• Present; numerical values of pressure change may be used to further quantify</li> <li>• Absent; associated with fecal incontinence<sup>111</sup></li> </ul>
<b>3.3.2.7 Balloon expulsion pressure:</b> The anal canal pressure (in mmHg, hPa, or cmH <sub>2</sub> O) during straining with a filled balloon in the rectum <sup>11</sup>	<ul style="list-style-type: none"> <li>• Increase from resting pressure suggests paradoxical contraction (see 4.3.1) and is associated with evacuation dysfunctions</li> <li>• No change</li> <li>• Decrease from resting pressure (normal)</li> </ul>
<b>3.3.2.8 Rectoanal inhibitory reflex (RAIR):</b> The relaxation response in the IAS following rectal distension (in mmHg, hPa, or cmH <sub>2</sub> O). <sup>11</sup> It is elicited by rapid inflation to first sensation of a balloon positioned in the distal rectum during anal manometry at the level of the proximal high-pressure zone	<ul style="list-style-type: none"> <li>• Present: a drop of at least 25% of resting pressure has to occur with subsequent restoration to at least two-thirds of resting pressure for the RAIR to be deemed present. This reflex is thought to underlie the sampling response that allows rectal contents to be sensed by the anal mucosa, thus ensuring continence of flatus and stool<sup>11,112</sup></li> <li>• Absent: seen in Hirschsprung disease, fecal incontinence, constipation, and after anorectal surgery<sup>110</sup></li> </ul>

Abbreviations: IAS internal anal sphincter; MVC, maximum voluntary contraction; PFM, pelvic floor muscles.

<sup>a</sup>This contrast with vaginal manometry where the source of pressure during an involuntary contraction cannot be assumed to be the levator ani contraction.

## Box 2 EMG system specifications

### Recommendations for reporting EMG studies (based on the recommendations of the International Society of Electrophysiology and Kinesiology<sup>113</sup>).

Reports on surface EMG should include:

- electrode material (e.g., Ag/AgCl)
- electrode geometry (discs, bars, rectangular)
- number and size (e.g., diameter, radius, width, length)
- interelectrode distance
- use of gel or paste
- skin/mucosal preparation (e.g., alcohol applied to cleanse skin, skin abrasion, shaving of hair, etc.)
- electrode location, orientation over muscle with respect to tendons, motor point (if known) and muscle fiber direction.
- type of ground electrode used, location

Reports on intramuscular wire electrodes should include:

- wire material (e.g., stainless steel)
- if single- or multistrand
- if single or bipolar wire
- interelectrode distance
- insulation material
- length of exposed tip
- method of insertion (e.g., hypodermic needle)
- depth of insertion/method of insertion guidance
- location of insertion in the muscle
- type of ground electrode used, location

Amplifiers should be described by the following:

- type (monopolar, differential, double differential, etc.)
- pre-amplification at the level of the electrode
- input impedance
- Common Mode Rejection Ratio (CMRR)
- actual gain range used

Filtering of the raw EMG should be specified by<sup>xii</sup>:

- low and/or high pass filter properties (e.g., cut-off frequencies, order)
- filter types (e.g., Butterworth, Chebyshev, Notch, etc.)
- notch filter

sound waves is projected into the body and bounces back at interfaces between those structures. Ultrasound evaluation may be undertaken as:

**3.5.1.a** Two-dimensional (2D) ultrasound: The transducer sends and receives ultrasound waves in one

anatomical plane. The reflected waves are used to generate gray scale images of structures in the field of view in this anatomical plane.

**3.5.1.b** Three-dimensional (3D) ultrasound: Creates volume data from multiple 2D images which are gathered by reflected waves at a variety of angles. Software integrates this information to create a single static 3D image.

**3.5.1.c** Four-dimensional (4D) ultrasound: Is similar to 3D US, but the image is repeated at intervals over time. This technique requires the use of a 3D/4D transducer and enables real-time visualization of 3D images.

**3.5.1.d** Tomographic ultrasound: Is viewing US imaging in sections. It allows the depiction of arbitrarily defined planes from volume data obtained in 3D or 4D US.<sup>134,135</sup>

Measurements are best understood by referring to anatomical planes of the body, that is, coronal (frontal), sagittal, and axial (horizontal or transverse) planes.

**3.5.1.1 Trans-abdominal pelvic floor ultrasound:** A 2D imaging technique to scan pelvic floor structures, using a convex transducer is placed in the supra-pubic region. (**NEW**) It can be oriented longitudinally to measure bladder base displacement in the mid-sagittal or parasagittal plane or oriented transversely to measure bladder base symmetry and displacement in the transverse plane. Trans-abdominal pelvic floor ultrasound is primarily used in clinical settings rather than for research purposes due to limitations measuring the image (no bony landmarks in view and difficulties for operator to keep transducer in plane—operator error is high). Artifact in measurement may also occur with incorrect PFM contraction when abdominal muscle contraction occurs (which pushes the transducer ventrally) and varying levels of bladder fullness (adherence to a fluid intake protocol may mitigate this limitation). Poor agreement between transverse and sagittal findings suggests measurement in the two planes evaluate displacement at different locations during a PFM contraction.<sup>136</sup> Table 13 (see page 25), describes the parameters and anatomical landmarks evaluated in the mid-sagittal plane, during different activity states of the PFM: rest, contraction and bearing down.

Parameters and findings evaluated with trans-abdominal imaging in the transverse plane—during different activity states of the PFM (rest, contraction, and bearing down)—are described in Table 14 (see page 26).

**3.5.1.2 Introital pelvic floor ultrasound:** 2D/3D/4D imaging technique to scan pelvic floor structures using an endocavity<sup>xvi</sup> transducer placed against the vaginal introitus/vulva or perineum.<sup>4</sup> (**NEW**) The transducer may be oriented ventrally/anteriorly to assess the pelvic floor structures (prolapse, levator ani muscle anatomy and function, and periurethral area), or oriented posteriorly to assess the anal sphincter structures.

TABLE 12 Parameters and findings evaluated with sEMG

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<b>3.4.2.1 Baseline muscle activity:</b> The amount of microvolts generated by activation of motor units in the target muscle during rest <sup>24,75a,b</sup>	<b>3.4.2.1.1 Inconsistent resting baseline:</b> The variation of baseline between contractions, between sets, or between days <sup>24,75</sup> <b>3.4.2.1.2 Elevated resting activity:</b> An increase in the active component of muscle tone; (the passive/viscoelastic component is not captured by sEMG) (NEW)
<i>(b) Parameters evaluating contractile properties</i>	
<b>3.4.2.2 Signal amplitude:</b> Microvolts ( $\mu\text{V}$ ) a muscle generates <sup>24</sup>  Specify: MVC contraction duration (s)—how the signal was processed. Signals are usually rectified and filtered to measure amplitude, <sup>114</sup> i.e., average rectified value or root-mean-square <sup>114</sup>	sEMG amplitude reflects muscle activation. <sup>117</sup> Increase in sEMG amplitude is related to the recruitment of motor units and increased firing rate. <sup>118</sup> The amplitude of the signal should not be interpreted as a direct force measurement because the relationship between force and EMG is generally not linear and is affected by type of contraction (concentric/isometric/eccentric), speed of contraction. During strength training, early gains in force output are mainly related to an increase in motor unit recruitment and discharge frequency which will result in a higher signal amplitude. Later gains explained by hypertrophy <sup>24</sup> are not reflected in increased sEMG amplitude
<b>3.4.2.3 Peak amplitude:</b> The highest sEMG amplitude achieved measured in microvolts. <sup>24,75</sup> Specify the duration (s). Measured during an MVC or functional activities such as postural tasks or incontinence provocative activities <sup>123,124c</sup>	
<b>3.4.2.4 Normalization of the amplitude:</b> The value obtained during a specific task as a percent relative to the electrical activity detected during a MVC <sup>113,117</sup> (NEW)	
<b>3.4.2.5 Time to peak muscle activation:</b> Time in ms or s from onset of muscle activity to peak activity (NEW) <b>Rate of change:</b> The mean slope of the ascending curve in $\mu\text{Vs}$ during a fast MVC. (NEW)	<b>3.4.2.5.1 Slow recruitment:</b> A longer time to peak muscle activation in s or a slower rate of change <sup>125</sup> (CHANGED) <sup>24d,e</sup>
<b>3.4.2.6 Reaction time:</b> The latency (time in ms) between a stimulus (or the command) and the onset of muscle activation <sup>126</sup> (NEW) <sup>f</sup>	<b>3.4.2.6.1 Slow reaction time:</b> A longer time to initiate muscle activation (NEW)
<b>3.4.2.7 Time from command to peak:</b> Time in ms from stimulus to peak activity (NEW) This term encompasses both the reaction time and the time to peak muscle activation	
<b>3.4.2.8 Time to return to baseline muscle activity:</b> Time in s from peak activity to resting activity (NEW) <b>Rate of change:</b> The mean slope of the descending curve in $\mu\text{Vs}$ during a fast MVC	<b>3.4.2.8.1 Slow de-recruitment:</b> Slow relaxation of the muscle contraction <sup>24</sup>
<b>3.4.2.9 Rate of change of amplitude during sustained contraction:</b> The change in sEMG amplitude divided by the duration of the contraction: $\text{EMG}_{\text{final}} - \text{EMG}_{\text{initial}}/\text{time(s)}$ . <sup>127</sup> (NEW). The contraction could be sustained or intermittent at different % of MVC <sup>127</sup>	A higher rate of change will be indicative of lower endurance
<b>3.4.2.10 Timing of muscle activity:</b> Onset of the activation in milliseconds can be assessed in relation to onset of activation in other muscles, provocative activities or other aspects of a task (NEW)	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Delayed: delayed activation of the PFM relative to the onset of a cough or a postural perturbation has been found in women with stress urinary incontinence<sup>124</sup></li> </ul>

TABLE 12 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.4.2.11 Duration of a sustained contraction:</b> The duration in seconds that a contraction could be sustained at a specific % of MVC <sup>127</sup> (NEW)	A shorter duration suggests lower endurance
<b>3.4.2.12 Power spectrum:</b> The distribution of frequency components of the sEMG signals, measured in Hz <sup>114</sup> (NEW)	The median frequency of the sEMG power spectrum shifts to lower frequencies as a muscle fatigues due to altered muscle fiber recruitment and other changes in the contractile properties <sup>128,129</sup>

Abbreviations: MVC, maximum voluntary contraction; PFM, pelvic floor muscles; sEMG, surface electromyography;  $\mu$ V microvolts.

<sup>a</sup>The recording of resting activity is highly susceptible to contamination by ambient noise. A low proportion of noise in the signal (or higher signal-to-noise ratio) is necessary for accurate assessment.

<sup>b</sup>Unlike many other skeletal muscles,<sup>130,131</sup> the PFMs are thought to have a level of constant EMG activity to maintain continence and support of pelvic/abdominal contents.

<sup>c</sup>Advanced EMG techniques are needed to prevent inaccurate interpretation from artifacts and muscle crosstalk.

<sup>d</sup>Slow recruitment could be a sign of PFM dysfunction if it leads to leakage during coughing and sneezing when a quick muscle contraction is needed to counteract increased intra-abdominal pressure.<sup>24,75</sup>

<sup>e</sup>The definition for this term used in Bo et al.<sup>24</sup> is the definition this document calls “slow reaction time.”

<sup>f</sup>This may also be considered in the motor control domain.

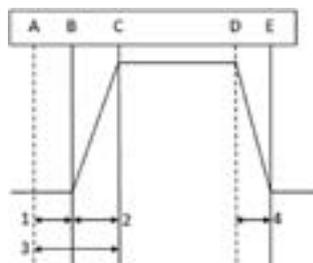

FIGURE 5 Parameters measured using electromyography. Parts of the EMG tracing: A = signal to contract, B = onset of muscle activity, C = peak muscle recruitment, D = signal to relax, E = return to baseline; 1 = Reaction time, 2 = Time to peak activation, 3 = Time from command to peak, 4 = Time to return to baseline muscle activity

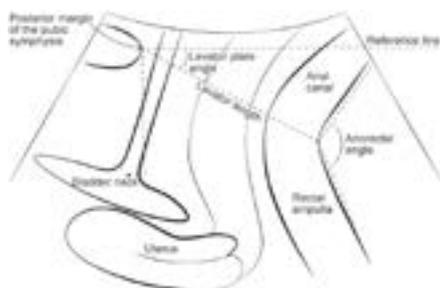

FIGURE 6 Perineal ultrasound parameters and anatomical landmarks assessed in the mid-sagittal plane using a horizontal reference line drawn from infero-posterior margin of the pubic symphysis

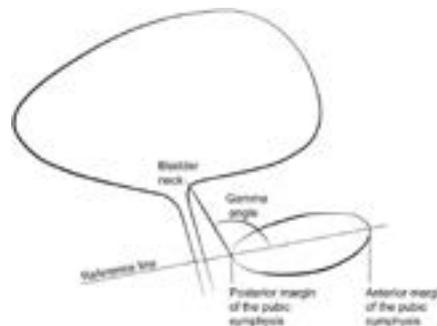

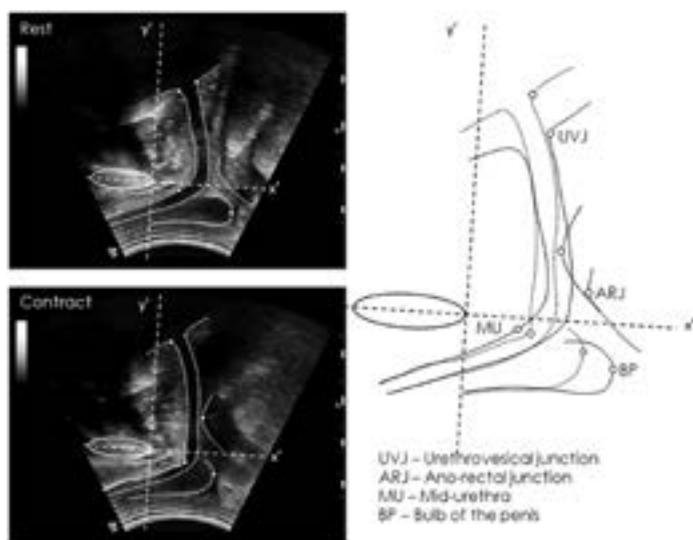

FIGURE 7 Perineal ultrasound parameter (gamma angle) assessed in the mid-sagittal plane using a reference line drawn from the anterior to the posterior margin of the pubic symphysis

**3.5.1.3 Perineal pelvic floor ultrasound:** 2D/3D/4D imaging technique to scan pelvic floor structures using a convex transducer placed against the perineum/vulva.<sup>4</sup> (NEW) The transducer may be oriented longitudinally/sagittally (for bladder neck/urethra, prolapse, and levator ani muscle assessment), or oriented transversely (for assessment of anal canal, sphincters). The terms transperineal and translabial ultrasound are both used to refer to perineal ultrasound. Parameters and findings evaluated with perineal and introital pelvic floor ultrasound—during different activity states of the PFM or actions (rest, contraction, and bearing down)—are presented in Table 15 (see page 26).

**3.5.1.4 Endovaginal pelvic floor ultrasound:** an endocavity transducer is inserted into the vagina (rotational mechanical probe or radial electronic probe)<sup>4</sup> to

**FIGURE 8** Parameters and anatomical landmarks assessed in the mid-sagittal plane using a two-dimensional transducer oriented longitudinally/sagittally in men (reproduced with permission from Stafford et al.<sup>132</sup>). The sketch overlays two images illustrating the anatomy at rest (continuous lines) and during maximal pelvic floor contraction (dotted-lines)

assess pelvic floor morphology. **(NEW)** It can be used to evaluate bladder neck/urethra, levator ani muscle, anal canal, and sphincters during different activity states of the PFM (rest, contraction and bearing down), as described in Table 16 (see page 29).

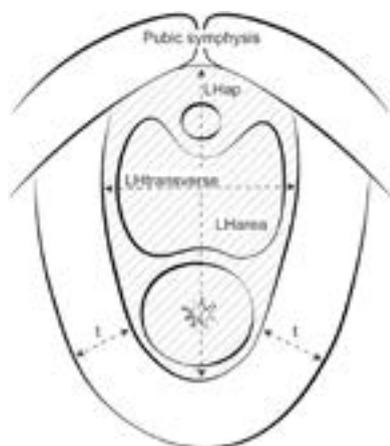

**3.5.1.5 Endoanal ultrasound (EAUS):** An endocavity transducer is inserted into the anus (linear array 3600 3D transducer or radial array 3600 3D transducer).<sup>4</sup> **(NEW)** It can be used to assess the external anal

sphincter (EAS) and internal anal sphincter (IAS). Parameters and findings evaluated with endoanal ultrasound imaging—during different activity states of the PFM (rest, contraction, and bearing down)—are described in Table 17 (see page 30).

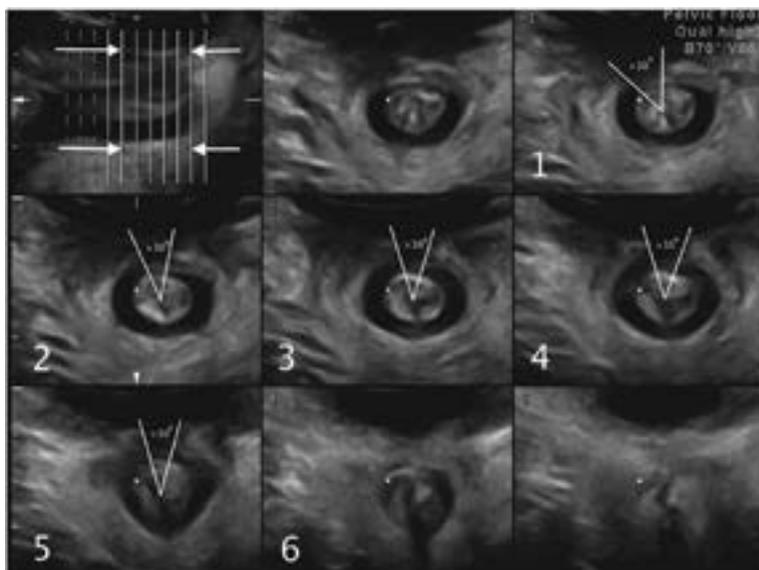

**3.5.1.6 Ultrasound elastography:** A noninvasive imaging technique that allows quantification of mechanical and elastic tissue properties following application of physical stress.<sup>174</sup> **(NEW)** Elastography imaging uses either compression/strain elastography or shear-wave elastography.<sup>156,175–179</sup> The primary differences between elastography techniques relate to the type or source of applied stress, and the methods of detecting displacement of the examined structures. Comparison between the elastography types and B-mode ultrasound is shown in Figure 11 (see page 31).

Parameters and findings evaluated with ultrasound elastography imaging are described in Table 18 (see page 31).

**3.5.2 Magnetic resonance imaging (MRI):** Is a noninvasive diagnostic technique that produces computerized images of internal body tissues and is based on nuclear magnetic resonance of atoms within the body induced by the application of radio waves.<sup>184</sup> **(NEW)** This technique can be applied for many purposes in urology/gynecology/gastroenterology including the assessment of PFM injury, morphometry and positioning of the PFMs and related organs as well as anorectal functioning. Considering that MRI is rarely used in clinic to assess PFM morphometry and function, only a brief overview is provided in Table 19 (see page 32) and further details are available in other standardization documents.<sup>11,150</sup>

**FIGURE 9** Levator hiatal dimensions measured using perineal ultrasound. LHap, levator hiatus antero-posterior diameter; LHarea, levator hiatus area; LHtransverse, levator hiatus transverse diameter; t, pubovisceral thickness

**FIGURE 10** Assessment of the integrity of the anal sphincter complex assessed with tomographic ultrasound imaging plane (reproduced with permission from Guzman Rojas et al.<sup>135</sup>)

**3.6 Algometry:** A test to assess the pain response to application of blunt pressure. It is used to evaluate the pain threshold and pain tolerance. **(NEW)** Responses may reflect increased sensitivity (allodynia, hyperalgesia, hyperpathia) or loss of sensation. Algometry does not

provide objective information regarding pathology or neurophysiological function, as do other more sophisticated quantitative sensory testing methods.

Parameters and findings evaluated with algometry are described in Table 20 (see page 33).

**TABLE 13** Parameters and findings evaluated with trans-abdominal ultrasound imaging in the mid-sagittal plane

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.5.1.1.1 Bladder base displacement<sup>a</sup>:</b> A marker is placed at the point of greatest displacement (mm or cm) of the infero-posterior bladder wall at rest and at maximal contraction or bearing down.<sup>137</sup> Direction and displacement of the bladder base movement from rest to final position. <b>(NEW)</b>. The bladder base is the most infero-posterior aspect of the bladder wall</p>	<p><i>PFM contraction:</i> Displacement from rest of the bladder base during (attempted) PFM contraction<sup>138</sup>:</p> <ul style="list-style-type: none"> <li>Elevation (normal response): Movement of the bladder base in a cephalad and ventral direction toward the pubic bone infers contraction of the levator ani/puborectalis</li> <li>No change</li> <li>Descent: Movement of the bladder base caudal and posterior away from the pubic bone infers elevated intra-abdominal pressure—PFMs may be active but this cannot be confirmed</li> </ul> <p><i>Bearing down:</i> Displacement of the bladder base during sustained increased intra-abdominal pressure:</p> <ul style="list-style-type: none"> <li>Elevation</li> <li>No change</li> <li>Descent</li> </ul>

Abbreviation: PFM, pelvic floor muscles.

<sup>a</sup>Factors that may compromise the measurement of bladder base displacement include: the lack of bony landmark as a fixed starting point and the fact that movement of the bladder base does not always reflect movement of the bladder neck.<sup>137</sup>

TABLE 14 Parameters and findings evaluated with trans-abdominal ultrasound imaging in the transverse plane

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.1.2 Symmetry of the bladder base:</b> Equal curvature of bladder base with probe placed in the transverse plane ( <b>NEW</b> )	<i>Rest:</i> Symmetrical or asymmetrical. Asymmetry can be related to unilateral increased tone, unilateral decreased tone, operator error in probe position, or asymmetry of passive support (e.g., unilateral ligament damage/trauma) <sup>1</sup>
<b>3.5.1.1.3 Bladder base displacement<sup>b</sup>:</b> See 3.5.1.1.1. Movement of the bladder base (in mm or cm) is used as a surrogate measure for activity of the PFM	<p><i>PFM contraction:</i> Displacement of the bladder base during attempted PFM contraction:</p> <ul style="list-style-type: none"> <li>Elevation (normal response): Movement of the bladder base in a cephalad/ventral direction. No change</li> <li>Descent: Movement of the bladder base in a caudal/dorsal direction</li> </ul> <p><i>Bearing down:</i> Displacement of the bladder base during sustained increased intra-abdominal pressure:</p> <ul style="list-style-type: none"> <li>Elevation</li> <li>No change</li> <li>Descent (normal response)</li> </ul>

Abbreviation: PFM, pelvic floor muscles.

<sup>a</sup>This finding must be correlated with findings of other tests and signs (especially digital vaginal/rectal palpation) to determine reason for asymmetry.

<sup>b</sup>Factors that may affect the measurement of bladder base displacement include: the lack of boney landmark as a fixed starting point and the fact that movement of the bladder base does not always reflect movement of the bladder neck.<sup>137</sup>

TABLE 15 Parameters and findings evaluated with perineal and introital ultrasound imaging assessed in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally/sagittally

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters and anatomical landmarks assessed in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally (f)</i>	
<b>Bladder neck parameters:</b> Measurement of bladder neck position	<i>Rest:</i> Quantification of bladder neck position at rest from the horizontal and vertical distances from the PS <sup>140,146</sup> . Resting position of the bladder neck was found to be higher after PFM training <sup>145</sup>
<b>3.5.1.3.1 Bladder neck position:</b> Refers to the bladder neck position relative to the pubic symphysis (PS). <sup>139</sup> The position is analyzed in a horizontal (x-axis) and vertical position (y-axis) relative to a horizontal reference line (measured in mm or cm) ( <b>NEW</b> ) Specify if using: the infero-posterior margin (Figure 6 on page 23), <sup>140a</sup> the lowest margin, <sup>141</sup> or the central axis (line drawn from the anterior to the posterior margin) of the PS (Figure 7 on page 23) <sup>142</sup> ; the middle of the proximal urethra for the internal meatus, <sup>143</sup> the anterior bladder neck <sup>144</sup> or equidistant points along the urethra from bladder neck to external urethral meatus <sup>145</sup>	<p><i>PFM contraction:</i> Cranio-ventral displacement of the bladder neck<sup>18</sup> measured as: a decrease in x-value and increase in y-value. The ventro-cranial displacement of the bladder neck is measured as displacement = <math>\sqrt{(\Delta x^2 + \Delta y^2)}</math>.<sup>143,146</sup> The higher the value, the greater the ventro-cranial displacement of the bladder neck (bladder neck lift), which reflects the lifting action of the PFM<sup>143,147-149</sup></p> <p><i>Bearing down:</i> On bearing down with the instruction to relax the PFM, the dorso-caudal displacement is measured at the point of maximal displacement during the manoeuvre.<sup>146</sup> As the proximal urethra descends, the x-value increases and the y-value decreases. The higher the value, the greater the dorso-caudal displacement of the bladder neck (bladder neck descent or mobility).<sup>18,143,149</sup> Higher mobility is observed in incontinent women</p>
<b>3.5.1.3.2 Angle <math>\gamma</math> (Gamma)/Pubo-urethral angle:</b> Is the angle (in degrees) between the bladder neck and a line drawn from the anterior to the posterior margin of the pubic symphysis <sup>150</sup> ( <b>NEW</b> ) (see Figure 7)	<p><i>Rest:</i> Quantification of the angle at rest<sup>151</sup></p> <p><i>PFM contraction:</i> A change of the angle <math>\gamma</math> from rest to a maximal PFM contraction. A reduction of the angle is expected as the bladder neck displaces ventrally and caudally.</p> <p><i>Bearing down:</i> Method to assess bladder neck descent/mobility.<sup>150</sup> A larger angle indicates a greater descent of the bladder neck,<sup>140</sup> which has been related to incontinence</p>

TABLE 15 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.3.3 Perineal body:</b> Should appear as a triangular shaped, slightly hyperechoic (white) structure anterior to the anal sphincter <sup>11</sup>	Indicates if the integrity of the perineal body is normal or compromised.
<b>3.5.1.3.4 Levator plate angle:</b> The angle (in degrees) between a horizontal reference line at the level of the infero-posterior margin of the PS intersecting a line from the infero-posterior margin of the PS to the anorectal angle <sup>146,152</sup> <b>(NEW)</b> (see Figure 6)	<i>Rest:</i> Quantification of the levator angle at rest. Elevated levator plate angle may be indicative of increased tone in the PFM <sup>148</sup> <i>PFM contraction:</i> An increase of the levator plate angle in comparison to the angle at rest. Levator plate excursion is calculated by subtracting the angle at rest from the angle during contraction <sup>148</sup> <i>Bearing down:</i> A decrease of the levator plate angle in comparison to the angle at rest. Levator plate excursion is measured as per contraction, smaller angle is expected <sup>146</sup>
<b>3.5.1.3.5 Levator hiatus length:</b> The distance (mm or cm) between the infero-posterior margin of the pubic symphysis to the anorectal angle, representing the levator hiatus antero-posterior diameter in the mid-sagittal view <sup>147,152</sup> <b>(NEW)</b> (see Figure 6)	<i>Rest:</i> Quantification of the levator hiatus? at rest. Smaller levator plate length could be suggestive of high tone in PFM <sup>148</sup> <i>PFM contraction:</i> A reduction of the levator hiatus It has been demonstrated to reflect a PFM contraction <sup>139,151</sup> <i>Bearing down:</i> An increase of the levator plate length is expected
<b>3.5.1.3.6 Anorectal angle:</b> The angle (in degrees), formed by the longitudinal axis of the anal canal and the posterior rectal wall <sup>11</sup>	<i>Rest:</i> Quantification of the anorectal angle at rest. Smaller anorectal angle could be suggestive of increased tone in the PFM <sup>148</sup> <i>PFM Contraction:</i> A reduction in the anorectal angle during a PFM contraction. The excursion of the anorectal angle is calculated as the angle during contraction of the levator ani muscle minus the angle at rest. Larger excursion could be suggestive of stronger activation of the PFM <sup>148,153,154</sup> <i>Bearing down:</i> Widening of the anorectal angle is expected. <sup>154</sup> If absent, PFM dysynergia may be present
<i>(b) Parameters and anatomical landmarks assessed in the mid-sagittal plane using a 2D transducer oriented longitudinally/sagittally (m)</i>	
Displacement or position (in mm or cm) of anatomical landmarks are assessed to interpret activation of individual PFM <sup>25,27</sup>	For the displacement of the anatomical landmarks described below, the displacement during contraction and cough are measured in relation to the resting position values. <sup>25,155</sup> Movement of these landmarks has been correlated with activation of levator ani (puborectalis) <sup>25</sup>
<b>3.5.1.3.7 Urethro-vesical junction:</b> The point of maximal inflection of a line drawn along the dorsal border of the urethra and the bladder neck <sup>25,27</sup> <b>(NEW)</b>	<b>For 3.5.1.3.7 and 3.5.1.3.8:</b> <i>Rest:</i> The position of these landmarks in the caudo-cranial and antero-posterior planes can be quantified relative to the dorsal pole of the PS at rest (see Figure 8 on page 24). Lower resting position has been observed in incontinent men <sup>155</sup>
<b>3.5.1.3.8 Anorectal junction:</b> The ventral-most point of a line drawn along the ventral aspect of the rectum at the anorectal junction <b>(NEW)</b>	<i>PFM contraction:</i> Cranio-ventral displacement is expected <sup>25,156</sup> <i>Cough:</i> Caudal-dorsal motion can be observed during the pressurization phase of cough due to levator ani muscle lengthening (probable eccentric contraction, but this cannot be confirmed from US imaging) during the phase when intra-abdominal pressure increases. This is followed by cranial-ventral displacement that occurs due to PFM shortening (concentric contraction)
<b>3.5.1.3.9 Bulb of the penis:</b> the dorsal-most point on a line drawn around the bulb of the corpus cavernosum penis <b>(NEW)</b>	<i>Contraction:</i> Cranio-ventral displacement is expected due to bulbocavernosus shortening <sup>25,27,155</sup> <i>Cough:</i> Cranio-ventral displacement is expected due to bulbocavernosus shortening <sup>27</sup>
<b>3.5.1.3.10 Mid-urethra:</b> A point on the ventral border of the membranous urethra that undergoes the greatest dorsal movement during contraction. This point is located within 2.5 mm either side of a line drawn between the	<i>PFM contraction:</i> Dorsal displacement is expected due to striated urethral sphincter shortening <sup>25,27</sup> <i>Cough:</i> Dorsal displacement of the mid-urethra due to striated urethral sphincter shortening <sup>25,27</sup>

(Continues)

TABLE 15 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
dorsal pole of the pubic symphysis and the most dorsal aspect of the bulb of the penis (NEW) (see Figure 8)	
<i>(c) Parameters and anatomical landmarks assessed in the axial plane using the 4D transducer oriented longitudinally (f)</i>	
<b>3.5.1.3.11 Hiatal dimensions:</b> Cross-sectional area of the pelvic floor/levator hiatus, including antero-posterior and transverse distances <sup>24</sup> Measured in the plane of minimal hiatal dimensions. <sup>18</sup> A transverse view is obtained and the plane of minimal hiatal dimensions is identified by moving the field of view cranially and caudally until the distance between the hyperechogenic posterior aspect of the PS and the hyperechogenic anterior border of the pubovisceral muscle is at a minimum <sup>157</sup>	
<b>3.5.1.3.11.1 Levator hiatus antero-posterior diameter:</b> The distance (in mm or cm) delineated from the PS (anteriorly) to the edge of the puborectalis muscle (posteriorly) (NEW)	Findings below apply to all measurements of hiatal dimensions. <i>Rest:</i> Quantification of the levator hiatus diameters/area at rest. Smaller diameter/area has been observed in women with pelvic pain and is may suggest increased tone in the PFM. <sup>148</sup> Conversely, a larger hiatus has been observed in women with pelvic organ prolapse
<b>3.5.1.3.11.2 Levator hiatus left-right/latero-lateral/transverse diameter:</b> Latero-lateral diameter of the levator hiatus (in mm or cm) in the plane of minimal hiatal dimensions. (NEW) The diameter from right to left is measured at the widest part, and perpendicular to the antero-posterior diameter. <sup>11,149</sup>	<i>PFM contraction:</i> A reduction of the area/diameter is expected during a maximal PFM contraction. Hiatus reductions during contraction can be calculated as the percentage of change from baseline (i.e., levator hiatus narrowing = (levator hiatus at rest – levator hiatus at contraction)/levator hiatus at rest × 100) <sup>148</sup>
<b>3.5.1.3.11.3 Levator hiatus area:</b> Defined and measured as the area (in mm <sup>2</sup> or cm <sup>2</sup> ) bordered by the pubovisceral muscle, PS and inferior pubic ramus in the plane of minimal hiatal dimensions <sup>149</sup> (NEW)	<i>Bearing down:</i> An increase in the levator hiatus diameter/area is expected on bearing down with the instruction to relax the PFM. <sup>157</sup> The difference (or percentage of change) between the diameter at rest and on bearing down determines the degree of hiatal distension. <sup>11</sup> Higher distension has been observed in women with pelvic organ prolapse <sup>158</sup>
<b>3.5.1.3.12 Maximal levator ani muscle thickness:</b> Is the maximum diameter of the levator ani muscle measured in two locations bilaterally (in mm or cm). (NEW) (see Figure 9 (see page 24)). This is usually located 1–1.5 cm above the minimal levator hiatus dimension. Measured perpendicular to the presumed levator ani fiber direction <sup>149,157</sup>	Provides morphologic measurements of the muscle diameter and area at rest. <sup>157</sup> <i>Rest:</i> Increased thickness has been observed after PFM training. <sup>159</sup> Increased thickness may be indirectly related to strength <sup>159</sup>
<b>3.5.1.3.13 Levator ani muscle cross-sectional area:</b> Is the area (in mm <sup>2</sup> or cm <sup>2</sup> ) delineated by tracing the outline of the levator ani muscle at the level of maximal muscle thickness (NEW)	
<b>3.5.1.3.14 Integrity of the anterior/medial fibers of the levator ani:</b> To assess if a disruption or disconnection of the insertion is present, direct the patient to perform a PFM contraction, and identify the plane of minimal hiatal dimensions at maximal PFM contraction. Use this plane for tomographic ultrasound imaging of the puborectalis component of the levator ani, with an interslice interval of 2.5 mm <sup>4</sup> (NEW)	<b>3.5.1.3.14.1 Complete avulsion<sup>b</sup></b> is diagnosed when the 3 central slices show a loss of integrity or defect in the anterior/medial fiber of the levator ani muscle on the inferior pubic ramus resulting in a levator-urethra gap <sup>7</sup> (NEW). A gap of more than 2.5 cm has been suggested as an indicator of avulsion <sup>160</sup> <b>3.5.1.3.14.2 Partial avulsion:</b> Is diagnosed when at one or two of the 3 central slices show a loss of integrity/defect of the medial fiber of the levator ani muscle (CHANGED) <sup>24</sup>
<b>3.5.1.3.15 Urethral sphincter volume:</b> Ultrasound imaging of the urethral sphincter (morphometry of the rhabdosphincter). <sup>18</sup> (NEW) The internal sphincter volume (in mm <sup>3</sup> or cm <sup>3</sup> ) including the longitudinal smooth muscle and the lumen is seen as a hypoechoic (black) core whereas the external sphincter volume or the circular striated muscle of the rhabdosphincter is seen as a hyperechoic (white) ellipsoid structure <sup>161–163</sup>	Smaller sphincter volume is related to urinary incontinence severity <sup>164</sup> and urethral pressure. <sup>163</sup> PFM training results in increased sphincter volume <sup>165</sup>

TABLE 15 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(d) Parameters and anatomical landmarks assessed with tomographic ultrasound imaging plane using the 4D transducer oriented transversely</i>	
<b>3.5.1.3.16 Integrity of the anal sphincter complex:</b> assessment of the internal and external anal sphincter to identify presence/absence of a defect (measured in degrees). <b>(NEW)</b> Using tomographic ultrasound imaging, the anal canal is visualized in the mid-sagittal plane and a set of 8 transverse slices is placed to encompass the entire external anal sphincter by locating one slice cranial to the external anal sphincter (at level of puborectalis, Slice 1) and another caudal to the internal anal sphincter (at level of subcutaneous part of external anal sphincter, Slice 8), leaving six slices to delineate the entire muscle (Slices 2–7) (see Figure 10 on page 25). Interslice interval is varied depending on external anal sphincter dimensions <sup>133,166</sup>	<i>PFM contraction:</i> A “significant” defect is diagnosed if four out of these six slices show a defect in >30° of the circumference of the external anal sphincter. <sup>4,166</sup>

Abbreviations: *f*, females; *m*, males; MVC, maximum voluntary contraction; PFM, pelvic floor muscles; PS, pubic symphysis.

<sup>a</sup>The horizontal reference line drawn from antero-posterior margin or the lowest margin of the PS may be influenced by the angle of the transducer.

<sup>b</sup>Synonyms are puborectalis/pubovisceralis defects or injury.

TABLE 16 Parameters and findings evaluated with endovaginal ultrasound imaging

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters and anatomical landmarks assessed in the sagittal plane (2D)</i>	
<b>3.5.1.4.1 Levator plate position:</b> the distance (in mm or cm) between the levator plate and endovaginal probe <sup>167</sup> <b>(NEW)</b>	<i>Rest:</i> Quantification of the distance between the levator plate and the probe with the PFM at rest. <i>PFM contraction:</i> A reduction of the distance between the levator plate and the probe is expected during a maximal PFM contraction; may be called levator plate lift. A greater levator plate lift ratio (lift/rest × 100) detected by dynamic endovaginal sonography has been associated with higher PFM strength as determined by the Modified Oxford Scale <sup>167</sup>
<b>3.5.1.4.2 Perineal body:</b> See 3.5.1.3.3. The depth (antero-posterior diameter) and height (supero-inferior diameter) of the perineal body can be measured in mm or cm in this plane <sup>11,168</sup>	<i>Rest:</i> Visibility of the structure and biometric measurements are identified at rest; indicate if the perineal body is visible or not visible <sup>168</sup>
<b>3.5.1.4.3 Anorectal angle:</b> See 3.5.1.3.6.	<i>Rest:</i> Quantification of the anorectal angle at rest <sup>169</sup>
<i>(b) Parameters and anatomical landmarks assessed in the axial plane (3D)</i>	
<b>3.5.1.4.4 Hiatal dimensions:</b> measurements of the following parameters are taken in the place of minimal hiatal dimension, <sup>49</sup> as described in Table 17	<i>Rest:</i> Quantification of the levator hiatus diameters/area at rest <sup>49</sup>
<b>3.5.1.4.4.1: Hiatal antero-posterior diameter:</b> Antero-posterior diameter (in mm or cm) of the levator hiatus measured at the level of minimum dimension <b>(NEW)</b>	
<b>3.5.1.4.4.2 Hiatal transverse diameter:</b> The diameter (in mm or cm) from right to left is measured at the widest part, and perpendicular to antero-posterior diameter <b>(NEW)</b>	

(Continues)

TABLE 16 (Continued)

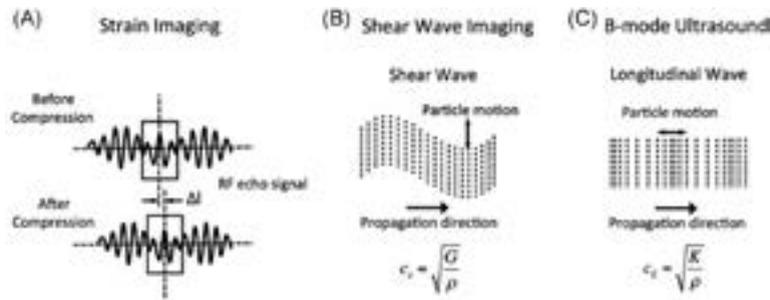

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.4.4.3 Hiatal area:</b> Defined and measured as the area (in mm <sup>2</sup> or cm <sup>2</sup> ) bordered by the pubovisceral muscle, PS, and inferior pubic ramus in the plane of minimal hiatal dimensions (NEW)	
<b>3.5.1.4.4.5 Levator ani thickness:</b> Defined as the diameter of the levator ani muscle (in mm or cm) at the “9 o'clock” and “3 o'clock” positions <sup>49</sup> as described in Table 15 (NEW)	<i>Rest:</i> Provides morphologic measurements of the levator ani diameter.
<b>3.5.1.4.4.6 Levator plate angle:</b> The angle (in degrees) between the reference line and the plane of minimal levator hiatal dimensions/anorectal angle, identified via a multiplanar view <sup>169</sup> (NEW)	<i>Rest:</i> This angle quantifies the levator plate position in reference to the pubic bone and the perineal body <sup>169</sup>
<b>3.5.1.4.4.7 Levator ani deficiency:</b> Assessed from a 3D volume. Individual levator ani muscles are evaluated in their specific axial plane where the full length of muscle can be visualized <sup>170,171</sup> (NEW)	<i>Rest:</i> The muscles on each side for each subgroup are scored based on thickness and detachment from the pubic bone: <ul style="list-style-type: none"> <li>• 0 = no defect</li> <li>• 1 = minimal defect with &lt;50% muscle loss</li> <li>• 2 = major defect with &gt;50% muscle loss</li> <li>• 3 = total absence of the muscle</li> </ul> Significant levator ani deficiency is defined as a total score within the range of 12–18 <sup>170,171</sup>
<b>3.5.1.4.4.8 Perineal body:</b> This anatomical structure is visualized as an ovoid-shaped, mixed echogenicity structure. The width (latero-lateral diameter) (in mm or cm) of the perineal body can be measured in the axial plane <sup>168</sup>	as per 3.5.1.3.3

Abbreviations: PFM, pelvic floor muscles; PS, pubic symphysis

TABLE 17 Parameters and findings evaluated with endoanal ultrasound imaging

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.5.1 Anal sphincter defect (or pathology):</b> Assessment of the internal and external anal sphincters to identify presence/absence of a defect; observed in cross-sectional images of the anal sphincter. (NEW) This measure is obtained by a probe inserted into the anal canal to a depth of approximately 6 cm and gently withdrawn down the anal canal. The anal canal is divided into three levels of assessment in the axial plane referring to the following anatomical structures <sup>11,172,173</sup> : <ol style="list-style-type: none"> <li>i. Proximal or lower level: corresponds to the subcutaneous part of the external anal sphincter where the internal anal sphincter is absent</li> <li>ii. Middle level: corresponds to the superficial part of the EAS (concentric band of mixed echogenicity), the conjoined longitudinal layer, the IAS (concentric hypoechoic ring), and the transverse superficial perineal muscles</li> <li>iii. Distal or upper level: the hyperechoic sling of the puborectal muscle and the complete ring of the internal anal sphincter are visualized<sup>11</sup></li> </ol> The probe should be rotated so that the anterior aspect of the anal canal is superior (12 o'clock) and left lateral is oriented right (3 o'clock) on the screen. The acquisition of a three-dimensional data volume (3D ultrasound) of the anal sphincter is also possible	Indicate if defect is present or absent

Abbreviations: EAS, external anal sphincter; IAS, internal anal sphincter.

**FIGURE 11** Ultrasound elastography physics, measurement methods (reproduced with permission from Sigrist et al.<sup>174</sup>). In strain imaging (A), tissue displacement is measured by correlation of radiofrequency echo signals between search windows (boxes) in the states before and after compression. In shear wave imaging (B), particle motion is perpendicular to the direction of wave propagation, with shear wave speed  $c_s$  related to shear modulus  $G$ . In B-mode ultrasound (C), particle motion is parallel to the direction of wave propagation, with longitudinal wave speed  $c_L$  related to bulk modulus  $K$

**TABLE 18** Parameters and findings evaluated with ultrasound elastography imaging

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.5.1.6.1 Shear wave elastography (SWE):</b> Ultrasound elastography using shear waves generated by the US beam. (NEW). Different types are point SWE, 2D SWE, and transient elastography. 2D SWE uses an acoustic radiation force pulse sequence to generate shear waves, which propagate perpendicular to the ultrasound beam, causing transient displacements. The distribution of shear wave velocities at each pixel is directly related to the shear modulus in kilopascal (kPa), an absolute measure of the tissue's elastic properties. This technique is considered more objective than strain elastography<sup>180</sup></p>	<p>Higher values indicate stiffer tissue, as shear waves propagate faster in stiffer tissues. Stiffness measures include both active (muscle contraction) and passive (viscoelastic properties) components of the tissue</p>
<p><b>3.5.1.6.1.1 Perineal shear wave elastography:</b> Shear wave elastography applied per perineum. (NEW). Only 2D SWE has been applied to the PFM.<sup>156,175,179</sup> A linear transducer is placed against the perineum/vulva. Orientation is longitudinal (for assessing urethral sphincter), or aligned with the muscle fibers for specific PFM (e.g., puborectalis) assessment. A linear or curved transducer can be used. Stiffness is evaluated using quantitative shear modulus maps represented in a color-coded elastogram displaying shear-wave velocities in meters per second or tissue elasticity (shear elastic modulus) in kilopascals<sup>181</sup></p>	<p>Higher values indicate stiffer tissue. Measures may provide evidence of stiffer tissue at rest (e.g., high activation of PFM at rest) and should increase with contraction.<sup>156,175,179</sup> Quality of measurement depends on orientation of the transducer (parallel with muscle fibers), accuracy of movement of the transducer to follow the movement of the muscle during contraction. Measures are compromised if there are areas in the image where the measure is saturated (stiffness greater than the measurable scale) or unable to be quantified by the system</p>
<p><b>3.5.1.6.2 Strain elastography:</b> Ultrasound elastography which measures strain in one tissue area proportional to another. (NEW). Maps, or elastograms, are developed based on the relative differences in stiffness between the area of interest and the reference tissue. The assessor applies slight and constant vertical compression through the transducer along the major axis of the tissue. Elasticity is measured by means of the Young's modulus and is defined as the ratio between the pressure measured and the strain (deformation compared to the initial length) produced.<sup>182</sup> Soft tissue is more compressible than harder tissue and therefore has a higher</p>	<ul style="list-style-type: none"> <li>• <b>Qualitative analysis:</b> The different colors express different degrees of elasticity, usually varying from red (soft tissue) to blue (hard tissue) with intermediate colors representing intermediate degrees of stiffness<sup>182</sup></li> <li>• <b>Semi-quantitative analysis:</b> the target tissue is selected and labeled as the region of interest (ROI) A, and the reference tissue is labeled as ROI B. Elasticity of tissue expressed as a strain ratio: B/A. The higher the value of B/A, the stiffer the target tissue</li> </ul>

(Continues)

TABLE 18 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p>strain (displacement) for the same applied stress (force). The results of strain elastography can only be expressed qualitatively or semi-quantitatively<sup>180,182</sup></p>	
<p><b>3.5.1.6.2.1 Pelvic floor strain elastography:</b> strain elastography to assess deep PFM elasticity<sup>176,177</sup> and periurethral elasticity as an estimate of urethral mobility<sup>183</sup> (NEW)</p> <ul style="list-style-type: none"> <li>To assess deep PFM: A perineal transducer is placed perpendicular to the skin in the sagittal plane to identify levator ani muscle. The levator ani muscle is selected on screen and labeled as the target tissue (region of interest [ROI] A), and the adjacent anal canal is selected and labeled as reference tissue (ROI B)<sup>176</sup></li> <li>To assess urethral support tissues: an endovaginal transducer is placed parallel to the urethral meatus. The target tissue is the tissue between the urethra and the vagina (para-urethral tissue) (ROI A), and the reference tissue is set at the level of the posterior tissue of the bladder neck (ROI B)</li> </ul>	<p>The higher the value of B/A, the stiffer the target tissue. A 4-point elasticity score has been used to represent levator ani muscle elasticity<sup>176,177</sup></p>

Abbreviations: PFM, pelvic floor muscles; ROI, region of interest; SWE, shear wave elastography.

TABLE 19 Parameters and findings evaluated with pelvic floor MRI

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.5.2.1 Levator ani defects:</b> Is damage to muscle fibers ranging from disruption of a single fascicle, to complete disruption of the muscle origin (CHANGED)<sup>24a</sup></p> <p>There is no universally accepted system for the diagnosis and evaluation of the extent of the injury. Essentially, abnormalities are judged to have occurred when the morphology of the pubococcygeal portion of the levator ani muscle deviates from what is seen in normal nulliparous women<sup>24</sup></p>	<p>Levator ani damage on MRI can be diagnosed when one or more of the following is present: absence of pubococcygeal muscle fibers in at least one 4-mm section, or two or more adjacent 2-mm sections in both the axial and the coronal planes<sup>24</sup></p> <p>Defect severity may be further scored in each muscle from 0 (no defect) to 3 (complete loss). A summed score for the two sides (0–6) is assigned and grouped as minor (0–3) or major (4–6)<sup>11</sup></p>
<p><b>3.5.2.2 Levator ani position in the pelvis:</b> Location of the levator ani in the sagittal plane in relation to defined landmarks and reference points/lines<sup>126</sup> (NEW)</p>	<p>May be normal, elevated, or descended<sup>24</sup></p>
<p><b>3.5.2.3 Hiatal dimension:</b> See 3.5.1.3.11</p>	<p>See 3.5.1.3.11</p>
<p><b>3.5.2.4 MR defecography:</b> Demonstrates the anatomy of the anorectum as well as disorders of rectal evaluation. Barium paste is inserted before defecation over a translucent commode (CHANGED)<sup>29</sup></p>	<p>This assessment focusses on anorectal function. When dyssynergia is diagnosed (see definition 4.3.1) this confirms PFM involvement<sup>11</sup></p>

Abbreviations: MRI, magnetic resonance imaging; PFM, pelvic floor muscles.

<sup>a</sup>The term levator injury is also used synonymously.<sup>11,185</sup>

TABLE 20 Parameters and findings evaluated with algometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.6.1 Algometer/Algesiometer:</b> An instrument for measuring the pain response to a pressure stimulus. <b>(NEW)</b> An algometry device measures pressure applied in Newtons or kg/cm<sup>2</sup>, with an associated patient-reported pain response</p> <ul style="list-style-type: none"> <li>To assess vulval or vestibular pressure pain response, the assessor uses an algometer<sup>186</sup> or a syringe with a pre-loaded or pre-set amount of pressure, called a vulvalgesiometer<sup>187</sup> or a cotton swab<sup>188</sup> against the vulval tissue and delivers the pressure</li> <li>To assess intra-vaginal pressure pain response, the assessor mounts a digital palpometer (sensor) to the palpating digit, covered by examination glove, and connected to an algometry device. The device applies a pre-set amount of pressure to the tissue.<sup>188–190</sup> To assess pressure/pain in pelvic floor tissues, the assessor applies a pre-set amount of pressure (usually in the range of 0.5–2 N<sup>188,191,192</sup>), starting at a low pressure and assesses pain response to that pressure, or applying increasing amounts of pressure and instructing the patient to state when the pressure reaches the patient's threshold</li> </ul> <p>Algometry tests:</p> <ul style="list-style-type: none"> <li><b>3.6.1.1 Pressure pain threshold (PPT):</b> The minimum intensity of a pressure stimulus that is perceived as painful.<sup>193</sup> (i.e., point at which a sensation changes from one of pressure to one of pain) <b>(NEW)</b></li> <li><b>3.6.1.2 Pressure pain tolerance (PPTol):</b> The highest intensity of painful pressure stimulus that an individual is able to tolerate<sup>193</sup> <b>(NEW)</b></li> </ul>	<p>Results may be expressed as the pressure applied when the patient reports detection or tolerance of pain, or a specific pressure applied and the patient rating of pain at that pressure. A finding of pain with a low applied pressure may suggest allodynia, and a finding of pain with a moderate applied pressure may suggest hyperalgesia</p> <p>Variability in readings can be caused by: anatomical test site (muscle belly vs. tendon<sup>194</sup>; mucosa vs. tendon,<sup>191</sup> coexistence of other pain disorders<sup>195</sup>; left vs. right,<sup>196</sup> stage in menstrual cycle,<sup>197</sup> sex and gender,<sup>198</sup> rate of pressure increase during test, dimensions of the pressure applicator</p>

## 5 | SECTION 4: DIAGNOSES

**Diagnosis:** The act or process of identifying or determining the nature and cause of a disease or injury through evaluation of patient history, examination, review of investigations, and the opinion derived from such an evaluation.<sup>199</sup>

**(CHANGED)** The diagnostic process aims to identify the most specific disorder possible. Overarching diagnoses are used when there is less certainty about the presenting disorder. Diagnoses that are specific to the PFM may coexist with and be used in addition to other pelvic floor diagnoses the patient presents with, for example, voiding dysfunction, pelvic organ prolapse. The diagnoses proposed below may change as evidence emerges to support or refute these terms as diagnostic terms. In some healthcare settings, clinicians are required to assign a code for the presenting diseases, disorders, injuries, and other related health conditions, using the International Classification of Diseases (ICD) coding system.<sup>200</sup> Not all terms below have a

corresponding ICD diagnostic code. As advised by ICD, “codes that describe symptoms and signs, as opposed to diagnoses, are acceptable for reporting purposes when a related definitive diagnosis has not been established (confirmed) by the provider.”

**4.0. PFM disorder/dysfunction:** An alteration of normal PFM function. **(NEW)** Any departure from normal function of the PFM that is of bother to the patient and has an associated sign and/or a finding from an investigation that suggests a departure from normal structure or function. If a specific disorder can be diagnosed, the following terms may be used.

### 4.1 Disorder of increased PFM tone

**4.1.1 Pelvic floor tension myalgia:** A condition of pain and increased PFM tone **(NEW)**.<sup>xv</sup> If the location can be confirmed as the levator ani, then the term can be levator ani tension myalgia. Criteria for diagnosis of pelvic floor tension myalgia are described in Table 21 (see page 34).

**4.1.2 Pelvic floor myofascial pain syndrome:** A pelvic floor pain syndrome of myofascial origin.

TABLE 21 Criteria for diagnosis of pelvic floor tension myalgia

Assessment	Findings
Symptoms	<ul style="list-style-type: none"> <li>• May relate to sensation of pain: pain, tender, ache, discomfort</li> <li>• May relate to sensation of increased tone: tight, tense, narrow or constricted</li> </ul>
Signs	<p>Tenderness or tender point on palpation of PFM<sup>s</sup> per perineum, per vaginam, or per rectum as well one or more of the following signs:</p> <ul style="list-style-type: none"> <li>• Lack of perineal and/or PFM descent with sustained increased intra-abdominal pressure</li> <li>• Absent, partial or delayed relaxation of perineum and/or PFM after contraction</li> <li>• Nonrelaxing PFM</li> <li>• Hypertonicity, or increased PFM tone, on a continuum from transient increase in tone to spasm</li> <li>• Fasciculation</li> <li>• Reduced flexibility of the vaginal opening</li> </ul>
Investigations	<p>Muscle tenderness as assessed by digital algometry (palpometry)</p> <p>Finding of increased tone from any tool which measures tone (dynamometry, myotonometry, manometry, EMG, ultrasound or MRI)</p> <ul style="list-style-type: none"> <li>• if EMG reveals an inconsistent or elevated resting baseline, or slow de-recruitment, this suggests increased myoelectrical activity, which may be termed overactivity in the PFM<sup>b</sup></li> </ul>

Abbreviations: EMG, electromyography; MRI, magnetic resonance; PFM, pelvic floor muscles.

<sup>a</sup>When assessing sensory changes *PV* or *PR*, the clinician needs to determine whether s/he is detecting sensory change in the mucosa (mucosal sensitivity), or the underlying muscle (muscle tenderness) by differentiating the depth and firmness of palpation.

<sup>b</sup>The previously proposed term "overactive PFM"<sup>23</sup> has been used to refer to increased tone in a muscle, however if the source of the increased tone (contractile or noncontractile component of tone) cannot be determined, this term is not recommended.

TABLE 22 Criteria for diagnosis of pelvic floor myofascial pain syndrome

Assessment	Findings
Symptoms	Presence of pain
Signs	<p>Tender point in a taut band (localized increased tone) of skeletal muscle<sup>53,54</sup></p> <p>Patient pain recognition on tender point palpation</p> <p>Referral pattern</p> <p>Local twitch response</p> <p>The paired criteria of tender points in taut bands and predicted or recognized pain referral form the most frequently cited combination of diagnostic criteria</p>
Investigations	<p>There is no consensus regarding objective laboratory tests for myofascial trigger point diagnosis however MR elastography and ultrasound elastography have been reported to investigate myofascial taut bands<sup>202</sup> and trigger points<sup>203</sup> in the trapezius muscle</p>

Abbreviation: MR, magnetic resonance

Assessment	Findings
Symptoms	Pain, tender, ache, discomfort
Signs	Muscle tenderness or tender point on palpation of PFM <sup>s</sup> <sup>a</sup> and normal tone in PFM <i>per perineum, per vaginam, or per rectum</i>
Investigations	<p>Muscle tenderness as assessed by digital algometry (palpometry)</p> <p>Finding of normal tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound, or MRI)</p>

Abbreviations: EMG, electromyography; MRI, magnetic resonance imaging; PFM, pelvic floor muscles; *PR*, per rectum; *PV*, per vaginam.

<sup>a</sup>When assessing sensory changes *PV* or *PR*, the clinician needs to determine whether s/he is detecting sensory change in the mucosa (mucosal sensitivity), or the underlying muscle (muscle tenderness) by differentiating the depth and firmness of palpation.

TABLE 23 Criteria for diagnosis of pelvic floor myalgia

Assessment	Findings
Symptoms	Pain, tender, ache, discomfort
Signs	Muscle tenderness or tender point on palpation of PFM <sup>s</sup> <sup>a</sup> and normal tone in PFM <i>per perineum, per vaginam, or per rectum</i>
Investigations	<p>Muscle tenderness as assessed by digital algometry (palpometry)</p> <p>Finding of normal tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound, or MRI)</p>

Abbreviations: EMG, electromyography; MRI, magnetic resonance imaging; PFM, pelvic floor muscles; *PR*, per rectum; *PV*, per vaginam.

<sup>a</sup>When assessing sensory changes *PV* or *PR*, the clinician needs to determine whether s/he is detecting sensory change in the mucosa (mucosal sensitivity), or the underlying muscle (muscle tenderness) by differentiating the depth and firmness of palpation.

TABLE 24 Criteria for diagnosis of decreased PFM tone

Assessment	Findings
Symptoms	Loose, lax, gaping, sagging, open, weak, bulging, full, loss of control
Signs	Hypotonicity, decreased PFM tone, anal or introital gaping, excessive flexibility of the vaginal opening, palpation of an anal sphincter gap or levator avulsion.  Deficit in PFM contractile function: absence of voluntary PFM contraction, decreased strength (weakness), decreased sustained and repeated endurance, lack of perineal or PFM elevation, no urethral lift, partial or uncertain levator closure, small to no change in levator hiatus on contraction
Investigations	Any tool which measures tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound, or MRI) – If EMG reveals a reduced signal amplitude or peak microvolts, or shorter duration of sustained contraction this suggests decreased myoelectrical activity, which may be termed “underactivity” in the PFM <sup>a</sup>

Abbreviations: EMG, electromyography; MRI, magnetic resonance imaging; PFM, pelvic floor muscles.

<sup>a</sup>The previously proposed term “underactive PFM”<sup>2,3</sup> has been used to refer to decreased tone in a muscle, however, if the source of the decreased tone (contractile or noncontractile component of tone) cannot be determined, this term is not recommended.

TABLE 25 Criteria for diagnosis of vaginismus

Assessment	Findings
Symptoms	Pain, tight, tense, narrow, or constricted
Signs	Transient increased tone—inability to maintain relaxation with attempted vaginal penetration ( <i>f</i> )  Increased PFM tone
Investigations <sup>a</sup>	Assessment of resting tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound or MRI)  Increased activation of PFM shown by perineal or peri-anal EMG during attempted vaginal penetration

Abbreviations: *f*, female; EMG, electromyography; MRI, magnetic resonance imaging; PFM, pelvic floor muscles.

<sup>a</sup>Investigations may be in-conclusive, as PFM tone values may overlap in conditions such as dyspareunia and vaginismus, therefore the PFM resting tone and response to attempted penetration may not exclusively diagnose vaginismus.

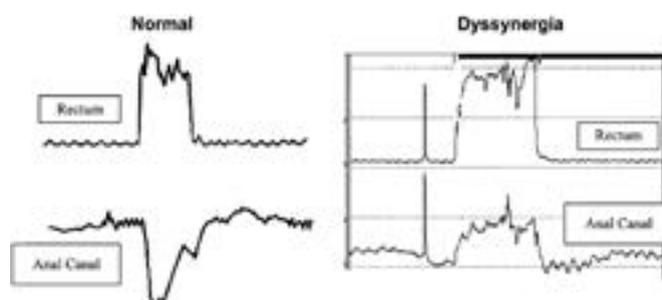

FIGURE 12 A normal and abnormal (dyssynergic) pattern of defecation (reproduced with permission from Rao<sup>206</sup>). A normal pattern consists of a rise in the intrarectal pressure coordinated with relaxation of anal sphincter pressure. In contrast, a dyssynergic pattern is associated with a paradoxical increase in anal sphincter pressure. Typical patterns for a normal and dyssynergic pattern of defecation as measured during anorectal manometry with a pressure sensor in the rectum and a pressure sensor in the anal canal

(NEW) this diagnosis has trigger points as a hallmark feature.<sup>53</sup> However there is no consensus of the definition and diagnostic criteria associated with trigger

points.<sup>53,54</sup> The criteria most consistently used for diagnosis amongst researchers and expert clinicians are shown in Table 22 (see page 34).

TABLE 26 Criteria for diagnosis of anismus

Assessment	Findings
Symptoms	Pain, tender, ache, discomfort during attempted defecation or anal penetration
Signs	Perineal and/or PFM elevation with sustained increased IAP (bearing down) or attempted penetration Increased PFM tone
Investigations	Balloon expulsion test MR defecography EMG: PFM activation during defecation suggesting poor motor control <sup>207</sup>

Abbreviations: EMG, electromyography; IAP, intra-abdominal pressure; MR, magnetic resonance; PFM, pelvic floor muscles.

## 4.2 Disorder of PFM pain

**4.2.1 Pelvic floor myalgia:** A condition of PFM pain. (NEW). Criteria for diagnosis of pelvic floor myalgia are described in Table 23 (see page 34).

**4.3 Disorder of decreased PFM tone:** A condition which results from a reduction in PFM tone, due to either the contractile or the noncontractile components of tone.<sup>xvi</sup> (NEW) Criteria for diagnosis of decreased PFM tone are described in Table 24 (see page 35).

## 4.4 Disorder of PFM coordination

**4.4.1 PFM dyssynergia:**<sup>xvii</sup> Paradoxical PFM or sphincter contraction: a dysfunction of coordination between the PFM and a functional activity, such as a PFM contraction when relaxation is functionally required. (NEW) These dyssynergias may share similar symptoms and signs.<sup>xviii,xix</sup>

**4.4.1.1 Vaginismus:** Spasm of vaginal musculature that interferes with vaginal penetration (CHANGED).<sup>12,xx</sup> Criteria for diagnosis of vaginismus are described in Table 25 (see page 35).

Vaginismus may also be termed genito-pelvic pain/penetration disorder, which includes fear or anxiety as a component of the disorder.<sup>204,205</sup>

**4.4.1.2 Anismus:** Spasm of the EAS with attempted defecation or anal penetration (CHANGED).<sup>11,xxi</sup> This dyssynergia is shown in Figure 12 (see page 35).

Criteria for diagnosis of anismus are described in Table 26.

**4.5 Pudendal neuralgia:** Pudendal neuralgia is a chronic and severely disabling neuropathic pain syndrome caused by mechanical or nonmechanical injury of the pudendal nerve.<sup>208</sup> (NEW) The Nantes criteria list five essential diagnostic criterion including three symptoms, one sign and one investigation.<sup>209</sup> These criteria are described in Table 27 (see below).

Assessment	Findings
Symptoms	Pain in the distribution of the pudendal nerve and its referral areas, primarily the genitalia including the vulvovaginal, anorectal, and distal urethral areas Worse in the sitting position Pain does not wake the patient at night, no numbness of the perineum The patient may also have associated pelvic floor symptoms <sup>208</sup>
Signs	Nantes criteria <sup>209</sup> sign: No loss of sensation in the pudendal distribution on objective testing Other signs include: <ul style="list-style-type: none"> <li>• Tenderness to palpation anywhere along the length of the pudendal nerve</li> <li>• Increased tone and tenderness of the obturator internus or piriformis muscles (depending on the location of the nerve irritation)</li> <li>• Positive pudendal nerve neurodynamic test</li> <li>• Positive pudendal nerve provocation test</li> </ul>
Investigations	As per Nantes criteria <sup>209</sup> : may be confirmed by relief of patient's pain after a pudendal nerve block with or without guided imaging <sup>g</sup>

<sup>g</sup>Pudendal nerve blocks are technically difficult to perform accurately and lack of pain relief after the procedure does not rule out the condition.<sup>208</sup>

TABLE 27 Criteria for diagnosis of pudendal neuralgia

## 6 | CONCLUSION

This report has drawn together the most frequently published methods of PFM assessment that appear in the published literature. This process has highlighted the plethora of terms in current use. We have attempted to provide the most precise yet clinically meaningful definitions and descriptions of these terms, and where available, provided an explanation of the finding from the assessment method. We hope this will provide clinicians and researchers with clarity and standardization in the recording of PFM function and dysfunction. It is anticipated that some of these terms will be discarded over time and new terms will emerge, and a revision of this document will be required in the future. It is important to remember that visual observation and digital palpation are subjective forms of assessment, and the assessor must be aware that conclusions of PFM function or dysfunction based on these clinical observations may be uncertain. At present, PFM tone and involuntary action remain less well understood than properties such as strength. Where available, the use of quantitative assessment tools (investigations), may strengthen the certainty of the finding. In some instances, it may not be possible to identify a specific classification of PFM disorder, beyond the first level of diagnosis of “PFM disorder.”

## 7 | AREAS FOR FURTHER RESEARCH

A core outcome set for PFM assessment would be valuable, however, this requires knowledge of the clinimetric properties of the many assessment methods currently used in clinical practice and research, and a comparison of these properties amongst the assessment methods; such knowledge is lacking. There is an urgent need for a report to compile the validity, reliability, and responsiveness of PFM assessment methods, especially for the more subjective methods of visual observation and digital palpation. The clinimetric properties of some aspects of the more objective methods of PFM assessment (simple and sophisticated tools) has been undertaken, however many gaps in testing remain. Whether any of these assessment methods provide diagnostic test accuracy of PFM function and dysfunction is unknown. Future research in this area is required.

### ACKNOWLEDGMENTS

We thank the following individuals for their contributions to this document: Paul McCrory, Neurologist, Ph.D., Melbourne, Australia; Paul Hodges, Physiotherapist, Ph.D., Brisbane, Australia; Ryan Stafford, Ph.D., Brisbane, Australia; Dawson Kidgell, Neuromuscular Physiologist, Ph.D., Melbourne, Australia; Ashlyn Frazer, Human

Physiologist, Ph.D., Melbourne, Australia; Hans Peter Dietz, Urogynaecologist, Ph.D., Sydney, Australia; Irmina Nahon, Physiotherapist, Ph.D., Canberra, Australia; Patricia Neumann, Physiotherapist, Ph.D., Adelaide, Australia; Shaza Kadah, Physiotherapist, Ph.D. student, Melbourne, Australia. This document has involved 20 rounds of reviews of individual sections and 12 rounds of full manuscript review by working group members, with cochair checking, collation, and feedback of all comments. Additional multiple rounds of development and refinement were undertaken by the cochairs in-between section and full working group reviews. The process was subject to live Meetings in Florence (September 2017), Philadelphia (2018), and Gothenburg (2019). Comprehensive and constructive review was undertaken by expert external reviewers, and we thank them for their considered input: Bert Messelink, David Vodusek, Chantale Dumoulin, Margaret Sherburn, Paul Hodges, and MJ Strauhal. A further round of revisions was undertaken in response to the external review. Following ICS website publication, there was a further round of review to address membership comments. Version 12 will be submitted for website and NAU journal publication.

### CONFLICT OF INTERESTS

Mohammad S. Rahnama'i: Consultant for Bioness, Dr. Pflieger, Astellas and Janssen. Marijke Slieker-ten Hove: KOL Indiba. The remaining authors declare that there are no conflict of interests.

### ENDNOTES

<sup>i</sup>For complete assessment, include as indicated: posture, abdominal, spinal, functional.

<sup>ii</sup>“Vaginal flatus” is the term used by Sultan<sup>11</sup>, however, Neels<sup>13</sup> distinguishes vaginal “wind” from vaginal “flatus”; assigning the term flatus to wind that is passed through the vagina due to an enterovaginal fistula. This type of “vaginal wind” will not be odorless. The term ‘vaginal flatus’ is more likely to be used by the clinician, not the patient.

<sup>iii</sup>This symptom is called “flatus incontinence” by Sultan et al.<sup>11</sup>

<sup>iv</sup>Included in the physical examination may be the use of simple tools, such as a pin, cotton wool, reflex hammer, and so forth.

<sup>v</sup>When assessing sensory changes *PV* or *PR*, the clinician needs to determine whether s/he is detecting sensory change in the mucosa (mucosal sensitivity), or the underlying muscle (muscle tenderness) by attempting to differentiate the depth and firmness of palpation.

<sup>vi</sup>Depth of insertion of examining finger has been described for *per vaginam* assessment.<sup>16</sup>

<sup>vii</sup>Terms such as short or elevated PFM may not be discernible via digital palpation and are therefore not recommended as sign terms.

<sup>viii</sup>If the spasm is painful, this is usually described as a muscle cramp.

<sup>ix</sup>This term refers to simple manometry that measures pressure in the anal sphincter. This is differentiated from sophisticated anorectal manometry—see Section 3.3.2.

<sup>x</sup>This investigation is termed “anal manometry” in Sultan et al.<sup>11</sup>

<sup>xi</sup>This is not an exhaustive list of anorectal manometry parameters.

<sup>xii</sup>Clinical EMG devices mainly offer preset filter settings.

<sup>xiii</sup>Reducing the size of electrode and the inter-electrode distance may increase the system selectivity and reduce crosstalk.<sup>118</sup>

<sup>xv</sup>An endocavity probe consists of an elongated probe used to perform endovaginal or endorectal examination.

<sup>xv</sup>This term was first used by Sinaki et al.,<sup>201</sup> however, in their case series, they did not assess PFM tone or tension. Nevertheless, they proposed the cause of the pain was “habit contraction or chronic spasm of the PFM.” We propose that this term should be used only when both pain and increased tone are present.

<sup>xvi</sup>It may be impossible to distinguish between the two subsets of this condition without access to an investigation which is able to separate the measurement of the contractile from the non-contractile components of tone. Even so, the certainty of the contribution from the contractile component of tone recorded by sEMG needs to consider the limitations of sEMG findings (noise, cross-talk, etc.).

<sup>xvii</sup>Dyssynergia may be similar to the condition termed “overactive pelvic floor muscles” as described by Messelink et al.<sup>23</sup>: “A situation in which the pelvic floor muscles do not relax, or may even contract when relaxation is functionally needed for example during micturition or defecation. This condition is based on symptoms such as voiding problems, obstructed defecation, or dyspareunia and on signs like the absence of voluntary pelvic floor muscle relaxation.”

<sup>xviii</sup>PFM-related symptoms reported by patients may be secondary to more bothersome functional symptoms such as inability to void, defaecate or allow vaginal entry.

<sup>xix</sup>Difficulty voiding may be due to paradoxical contraction of the urethral sphincter, as occurs in conditions such as detrusor sphincter dyssynergia or voiding dysfunction, however, there is no hallmark PFM-related symptom that the patient reports.

<sup>xx</sup>As stated in Rogers et al.,<sup>12</sup> there is often (phobic) avoidance and anticipation/fear/experience of pain, along with variable involuntary PFM contraction. Patients with vaginismus could present with severe fear avoidance without vulvar pain or fear avoidance with vulvar pain. Structural or other physical abnormalities must be ruled out/addressed. There is controversy of whether or not this term should be retained, with the Diagnostic and Statistical Manual of Mental Disorders 2013 proposal to replace dyspareunia and vaginismus with the term “Genito-Pelvic Pain/Penetration Disorder (GPP/PD),”<sup>204</sup> and the lack of consensus on this term.<sup>205</sup>

<sup>xxi</sup>Anismus is the PFM component of dyssynergic defecation. Diagnosis of dyssynergic defecation includes functional constipation criteria, prolonged transit, and ineffective motility to expel feces.<sup>206</sup>

## Abstract

**Introduction:** The terminology for female pelvic floor fistulas (PFF) needs to be defined and organized in a clinically based consensus Report.

**Methods:** This Report combines the input of members of the International Continence Society (ICS) assisted at intervals by external referees. Appropriate core clinical categories and a sub-classification were developed to give a coding to definitions. An extensive process of 19 rounds of internal and external review was

Judith Goh, Lauri Romanzi, Sohier Elneil (Production and Content) and Bernard Haylen (Production, Content and Mentor) are equal first authors.

Bernard Haylen: Standardization Steering Committees ICS (ICS Working Group on the Terminology for Pelvic Floor Fistulas).

[Correction added on 29 October 2021, after first online publication: The authorship list, correspondence, footnotes, and disclosures have been updated in this version.]

involved to examine each definition, with decision-making by collective opinion (consensus).

**Results:** A terminology report for female PFF, encompassing 416 (188 *NEW*) separate definitions, has been developed. It is clinically based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in different specialty groups involved in female pelvic floor dysfunction and PFF. Female-specific imaging (ultrasound, radiology, and magnetic resonance imaging) and conservative and surgical PFF managements as well as appropriate figures have been included to supplement and clarify the text. Interval (5–10 years) review is anticipated to keep the document updated and as widely acceptable as possible.

**Conclusion:** A consensus-based terminology report for female PFF has been produced to aid clinical practice and research.

#### KEYWORDS

Female urinary incontinence, Pelvic Floor Fistula, Pelvic reconstructive surgery

## 1 | INTRODUCTION

Fistula (Latin: fistula—“*pipe, tube*”) refers to an abnormal or surgically made connection between a hollow or tubular organ and the body surface, or between two hollow or tubular organs. The plural noun may be either fistulas or fistulae - fistulas will be used.

Pelvic floor fistula (PFF) refers to a fistula affecting the upper or lower genital tract including the uterus, cervix, vagina, and/or the different vaginal compartments and the neighboring organs such as the upper and lower urinary tract (ureter, bladder, and urethra) and lower bowel (distal colon, rectum, and anus). The term genital tract fistula (GTF) should not be used. A diagnosis of PFF fits the established model of symptoms corroborated by clear clinical signs and commensurate evaluation test results, starting with a woman having urinary or fecal incontinence symptoms, usually per vagina.

There is currently no single document encompassing all elements required for diagnoses in female PFF that includes a full outline of the terminology for symptoms, clinical examination signs, and diagnostic investigations. It would also encompass etiology, classification, and terminology for the different nonsurgical and surgical treatment modalities.

Core terminology documents that will be referenced are (i) 2010 IUGA-ICS Joint Terminology Report on Female Pelvic Floor Dysfunction<sup>1</sup> and (ii) the equivalent 2019 Male Terminology for Lower Urinary Tract and Pelvic Floor Dysfunction (with its greatly expanded range of definitions).<sup>2</sup> Also referenced will be the 2016 IUGA-ICS Joint Terminology Report on Pelvic Organ Prolapse<sup>3</sup> and the World Health Organization's fistula publication.<sup>4,5</sup> An

original aim of the IUGA-ICS Joint Terminology reports<sup>1,2</sup> has been to provide a general terminology, forming the “core” terminology to which more specific terminologies can be attached. Reference will also be made to three other published Standardization Reports<sup>6–8</sup> and six joint IUGA-ICS Female Terminology Reports.<sup>9–14</sup>

No standardization document exists on female PFF, though work by groups in the field including the International Society of Obstetric Fistula Surgeons, the World Health Organization International Classification of Disease System, and the International Obstetric Fistula Working Group at the United Nations Population Fund (UNFPA) have defined segments of PFF terminology that were reviewed pursuant to the creation of this document.<sup>15</sup> To devise this first PFF standardization document, the PFF Working Group reviewed all available published documents that used a clinical framework to develop terminology incorporating fistula aetiologies, symptoms, signs, staging and classifications, investigations, diagnoses, and treatments. By including concurrent and subsequent pelvic floor disorders, this document functions as a patient-centered terminology resource that reflects frameworks for cost-effective service integration.<sup>16,17</sup>

Female-specific imaging advances in urodynamics (UDS), video-endoscopic images, ultrasound, radiology, and magnetic resonance imaging (MRI) have been commonly used by surgeons in well-resourced settings and are increasingly available to surgeons in resource-constrained settings across sub-Saharan Africa and South and South-east Asia. The indications for imaging in PFF and the utility of multi-channel urodynamics (MUDS) in the evaluation and management of women with lower urinary tract

symptoms (LUTS) after successful urinary tract fistula closure or LUTS concurrent with rectovaginal fistula will be illustrated in this terminology document.

The terminology document defines methods for non-surgical treatment of fistula with catheter, debridement, and fulguration. This report acknowledges that PFF may not occur in isolation but may be associated with pelvic organ prolapse (POP)<sup>18–21</sup> and voiding, defecatory and/or sexual dysfunctions and/or other pelvic floor dysfunction, and/or other diagnoses of musculoskeletal, renal, reproductive, and mental health aetiologies.

As with all ICS Terminology documents, this terminology report collates the definitions of PFF terms, that is, “the technical or special terms or expressions used in a business, art science or special subject” or “nomenclature in a field of study.”<sup>22</sup> Emphasis will continue the ICS tradition of terms in current use in the relevant peer-reviewed literature. The aim is to assist clinical practice and research. Some new and revised terms have been included. Explanatory notes on definitions have been referred, where possible, to the “Endnotes” section.

This document aims to comprehensively cover all terminology for PFF management (i) for any etiology (including congenital, obstetric, and iatrogenic); (ii) for management anywhere in the world (though we realize there will be vast differences in access to investigations and other resources); (iii) inclusive of intercurrent pathology (e.g., POP); (iv) inclusive of the latest update of ICS terminology on lower urinary tract dysfunctions,<sup>2</sup> (so there is no need for the reader to seek additional documents). It is all included in the current document.

Like all the other joint ICS female-specific terminology reports, every effort has been made to ensure this report is:

(1) *User-friendly*: It should be able to be understood by all clinical and research users.

(2) *Clinically based*: Symptoms, signs, and validated assessments/investigations should be presented for use in forming workable diagnoses for PFF and associated dysfunctions. Sections 1–6 will address etiology, classification, symptoms, signs, and investigations and imaging for PFF and associated diagnoses. Radiologic investigations including MRI and computerized tomography (CT) have also been incorporated. Section 7 will address fistula diagnoses, possible fistula-related diagnoses and common comorbidity diagnoses. Sections 8 and 9 will list the terminology for conservative and surgical treatments of PFF.

(3) *Origin*: Where a term’s existing definition (from one of the multiple sources used) is deemed appropriate, that definition will be included and duly referenced. Many terms in female pelvic floor prolapse and dysfunction, because of their long-term use, have now become generic, as apparent by their listing in medical dictionaries. The terms used in PFF will be defined for the first time in this document.

(4) *Able to provide explanations*: Where a specific explanation is deemed appropriate to describe a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (Endnotes 1, 2, 3, etc.). Wherever possible, evidence-based medical principles will be followed (Table 1).

It is suggested that acknowledgment of these standards in written publications related to female PFF, be indicated by a footnote to the section “Methods and Materials” or its equivalent, to read as follows: “Methods, definitions and units conform to the standards recommended by the International Continence Society, except where specifically noted.”

## 2 | SECTION 1: ETIOLOGY

The etiology of a PFF can be many and varied, including both congenital and acquired causes. To further clarify etiology as currently used within the academic fistula surgeon community of practice, aetiologies are further stratified into two groups based on whether the fistula is related to childbirth, or not related to childbirth. Congenital causes define etiology across the urinary, genital, and anorectal tracts. Acquired causes include obstetric, iatrogenic, mixed obstetric-iatrogenic, traumatic, inflammatory, infection-based, and fistulas caused by cancer.

### 1.1 Childbirth related

**1.1.1 Obstetric fistula (OF)**: Due to prolonged obstructed labor with a fistula from the urinary tract and/or anorectal tract to the genital tract caused by ischemia and necrosis. *NEW*

**1.1.2 Iatrogenic childbirth-related fistula (ICRF)**: Directly due to injury to urinary tract/anorectal area during operative delivery (cesarean section/cesarean hysterectomy or instrumental delivery including episiotomy). *NEW*

**1.1.3 Mixed obstetric and iatrogenic fistula (MOIF)**: Related to operative delivery for prolonged obstructed labor. *NEW*

**1.1.3.1 Tissue integrity already compromised by obstructed labor before operative delivery.** *NEW*

### 1.2 Non-childbirth related

**1.2.1 Congenital fistula (ConF)**: Fistula present from birth. *NEW*

**1.2.1.1 Hypospadias**: Opening of the urethra other than at the site of the external urinary meatus. For example, low- or mid- vaginal. *NEW*

**1.2.1.2 Ectopic ureter**: Ureter terminating at a site other than the bladder. *NEW*

**1.2.1.3 Total perineal defect of genital tract**:\* Absent perineal body. *NEW*

**1.2.1.4 Imperforate anus with spontaneous rectovaginal rupture of anorectal tract**: Rectovaginal

fistula caused by pressure in the rectum due to an imperforate anus. **NEW**

**1.2.2 Iatrogenic fistula (IF):** PFF occurring after non-obstetric pelvic procedures/surgery. **NEW**

**1.2.3 Traumatic fistula (TF):** Due to trauma to the genital tract such as pelvic crush/impalement injury, sexual violence, female genital tract cutting, insertion of vaginal foreign materials (packing with herbs/stones/salt/foreign bodies). **NEW**

**1.2.4 Inflammatory fistula (InF):** Due to inflammatory conditions such as inflammatory bowel disease (e.g., Crohns, ulcerative colitis). **NEW**

**1.2.5 Infection-related fistula (IxF):** Due to infections/abscess (e.g., tuberculosis, schistosomiasis, infectious breakdowns of obstetric perineal trauma, perianal abscess). **NEW**

**1.2.6 Cancer-related fistula (CF):** Due to tissue compromise from malignancy or from treatment of malignancy such as radiation therapy or surgery. **NEW**

### 3 | SECTION 2: CLASSIFICATION

No consensus on a classification system for female PFF exists<sup>23</sup> (current proposed classification systems are outlined in the endnotes of this section). Terms outlined below will denote the proximal/distal locations along the urinary, colorectal, and genital tracts and site-specific categories (e.g., urethro-vaginal fistula [UVaF]). Fistulas may, however, be large, straddle both proximal/distal locations and involve more than one anatomical site. More than one fistula may be present. The amount of scarring and residual tissue present (for surgical purposes) will be variable. The fistula may also be described by its anatomical location and antecedent event (e.g. obstetric, iatrogenic, combined).

#### 2.1 Basic categories of PFF

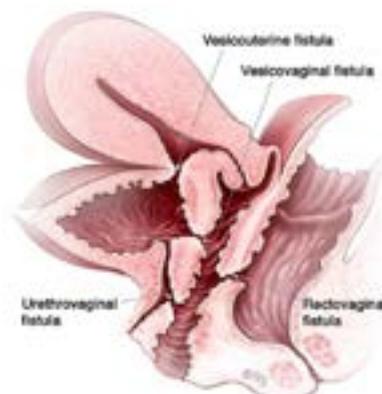

The following terms are defined, each in relation to the hollow organ system component involved in the fistula defect (Figure 1). These are localizing/descriptive terms and not a classification system as such. The following acronyms will be used: F (fistula); V (bladder/vesico); U (urethra); Va (vaginal); Vt (vaginal vault); Ut (uterine); Cx (cervical); Ur (ureteric); R (rectal); Co (colon); Pe (perineal); AC (ano-cutaneous).

**2.1.1 UVaF:** Abnormal connection between the urethra and the vagina. **NEW**

**2.1.2 Vesico-vaginal fistula (VVaF):** Abnormal connection between the bladder and the vagina. **NEW**

**2.1.3 Vesico-uterine fistula (VUtF):** Abnormal connection between the bladder and the uterus. **NEW**

**2.1.4 Uretero-vaginal fistula (UrVaF):** Abnormal connection between the ureter and the vagina. **NEW**

1. Pelvic floor fistula anatomy

FIGURE 1 Basic pelvic floor fistula anatomy. © Levent Efe

**2.1.5 (Colo)-recto-vaginal fistula (RVaF):** Abnormal connection between the rectum (colon) and the vagina. **NEW**

**2.1.6 (Colo)-rectal to urinary tract:** Any abnormal connection between the rectum (colon) and any part of the urinary tract, without vaginal involvement. **NEW**

#### 2.2 UVaF

**2.2.1 Partial UVaF:** Urethral structure is evident, with a demonstrable fistula defect (Figure 2). **NEW**

**2.2.2 Total UVaF:** Urethral structure is not evident (Figure 3). **NEW**

**2.2.3 Circumferential fistula (genito-urinary):** An entire segment (anterior, posterior, lateral urethra) from the anterior vaginal wall to the posterior aspect of the pubic symphysis is absent and destroyed.<sup>23,24</sup> The circumferential fistula almost always involves the urethra and the fistula totally separates the proximal urethra/bladder from the distal portion (Figure 4). Bladder involvement with a circumferential fistula is common. **NEW**

#### 2.3 VVaF

**2.3.1 VVaF:** Fistula affecting anterior vaginal wall and posterior bladder wall with or without involvement of the ureteric orifices (Figure 5A,B). **NEW**

**2.3.2 Circumferential fistula (genito-urinary):** See 2.2.3. It almost always involves the urethra. **NEW**

**2.3.3 Vesico-vaginal vault fistula (VVtF):** VVaF located at vaginal vault (cuff) following hysterectomy (Figure 6A,B). **NEW**

#### 2.4 VUtF

**2.4.1 Vesico-cervical fistula (VCx):** Abnormal connection between the bladder and the cervix. May occur after cesarean section, procedures to the cervix, supra-cervical hysterectomy. **NEW**

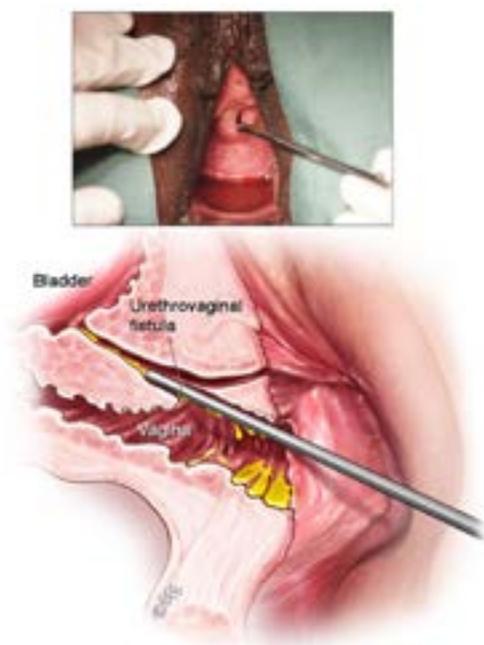

FIGURE 2 Urethro-vaginal fistula (UVaF) demonstrated by metal catheter—1 cm above the external urethral meatus. © J Goh (above) © Levent Efe (below)

**2.4.2 VUtF:** Abnormal connection between the bladder and the body of the uterus. **NEW**

#### 2.5 UrVaF

**2.5.1 UrVaF:** Abnormal connection between the ureter and the vagina. **NEW**

**2.5.1.1 UrVaF** may be congenital (ectopic ureter) **NEW** or

**2.5.1.2 Acquired** (e.g., following surgery or obstructed labor) **NEW**

**2.5.2 Uretero-vesical-vaginal fistula (UrVVaF):** Fistula involving the ureter(s), bladder, and vagina. This may be seen with a large obstetric fistula and the ureter is outside the VVaF. **NEW**

**2.5.3 Uretero-uterine (cervical) fistula (UrUtF/UrCxF):** Abnormal connection between the ureter and the uterus (cervix). Predominantly post-cesarean or post-supracervical hysterectomy. **NEW**

#### 2.6 PFF—Anorectal tract to vagina (uterus)

**2.6.1 Fourth-degree tears:** Obstetric anal sphincter injury with disruption of the perineal body, connecting the vagina to the anorectum. The internal and external anal sphincters are disrupted. **NEW**

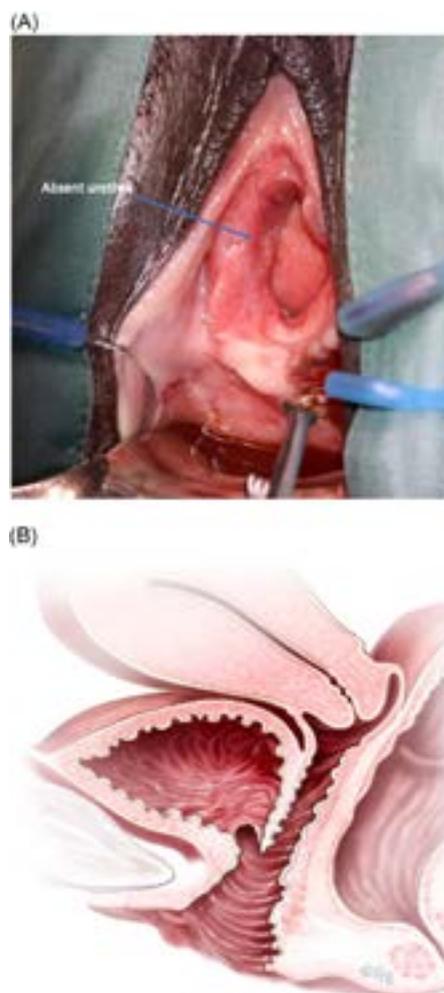

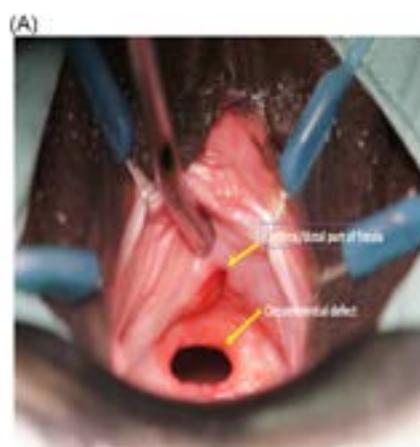

FIGURE 3 (A, left) Total urethro-vaginal fistula (UVaF)—Total absence of anterior vaginal wall and posterior urethra from external urinary meatus to bladder neck. © J Goh. (B, right) © Levent Efe

**2.6.1.1 Acute fourth degree tear**—Occurs at time of childbirth or other trauma. **NEW**

**2.6.1.2 Chronic fourth degree tear**—Unrepaired or dehiscence following repair at time of childbirth or other trauma, resulting in an absent perineal body with a total perineal defect<sup>2</sup> (Figure 7A,B). **NEW**

**2.6.2 RVaF:** Abnormal connection between the rectum and the vagina. **NEW**

**2.6.2.1 Non-circumferential RVaF:** Involves the posterior vaginal wall and anterior rectum. **NEW**

(B)

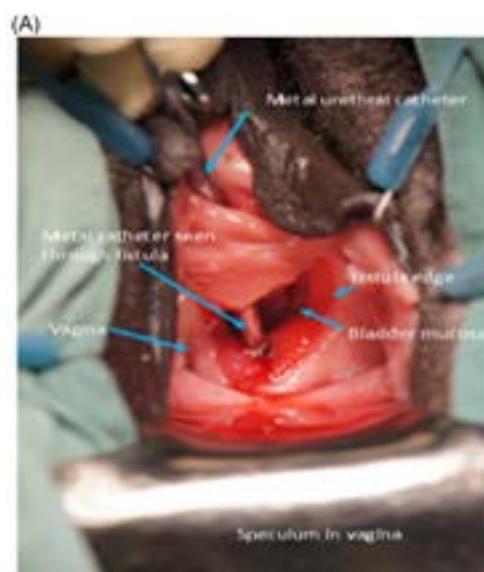

**FIGURE 4** (A, left) Circumferential fistula—An entire segment of the urethra (anterior, lateral, posterior) and anterior vaginal wall is absent. Proximal (bladder) part of the fistula is completely disconnected from the distal (urethra) portion. © J Goh. (B, right) © Levent Efe

**2.6.2.2 Circumferential RVaF:** Involves an entire segment of the rectum, involving the posterior vaginal wall, anterior and posterior rectum. The proximal rectal part of the fistula is completely separated from the distal portion. **NEW**

**2.6.2.3 Rectal/vaginal/perineal fistula (RVaPeF):** An abnormal communication from the anorectum to the vagina or perineal area. **NEW**

**2.6.3 Recto-uterine-cervical fistula (RUtF/RCxF):** An abnormal connection from the rectum to the uterus or cervix. **NEW**

(B)

**FIGURE 5** (A, left) Vesico-vaginal fistula (VvAF): Metal catheter inserted in urethra visible through VvAF. © J Goh. (B, right) © Levent Efe

**2.6.4 Fistula in ano (FIA)/ano-cutaneous fistula (ACF):** An abnormal connection between the anal canal epithelium and the skin epithelium.

**2.7 PFF—(colo) rectal to urinary tract**

**2.7.1 Colo-vesical fistula (CoVF):** Abnormal connection between the rectum (colon) and the bladder. **NEW**

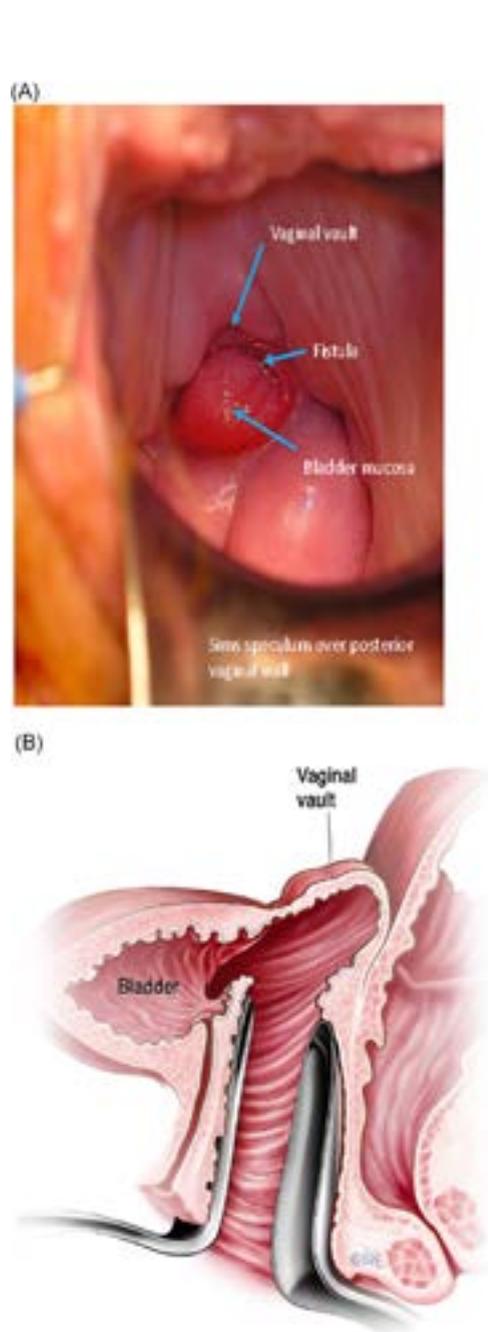

FIGURE 6 (A, left) Vesicovaginal vault fistula (VVtF) after hysterectomy © J Goh. (B, right) © Levent Efe

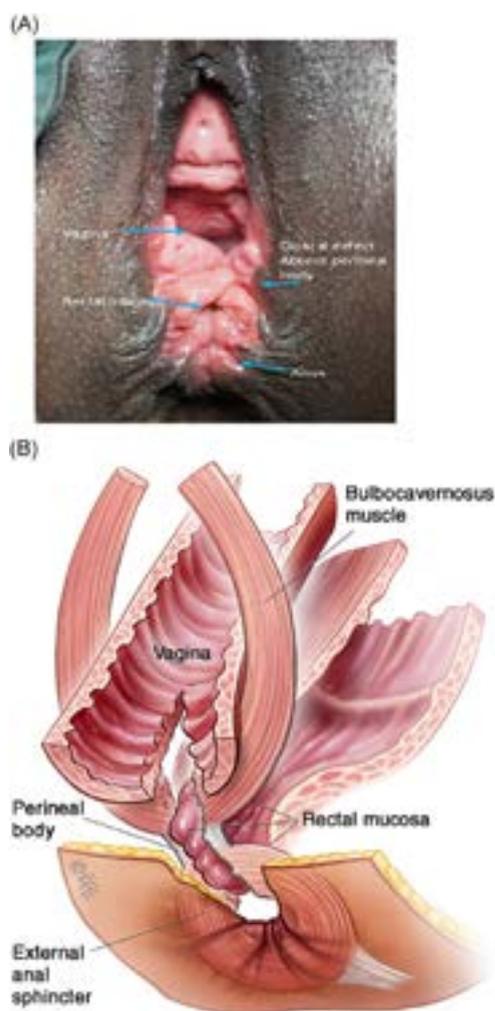

FIGURE 7 (A) Fourth degree rectovaginal tear with perineal body disruption. Congenital defects of a similar configuration may also occur. © J Goh. (B) © Levent Efe

**2.7.2 Recto (colo)-ureteric fistula (CoUrF/RUrF):** Abnormal connection between the rectum (colon) and the ureter.<sup>‡</sup> **NEW**

### 2.8 Published classification systems of PFF

There are published classification systems used for female PFFs predicated on and devised from their ability to predict outcomes of surgery based on these classification systems.<sup>§,\*\*,††,‡‡,§§</sup> These classification systems are: (i) the Francophone System; (ii) the Waaldijk System; (iii) the Goh System; (iv) the Panzi Hospital System.

## 4 | SECTION 3: SYMPTOMS

*Symptom:* Any morbid phenomenon or departure from the normal in structure, function, or sensation, experienced by the woman and indicative of disease or a health problem.<sup>1,2</sup> Symptoms are either volunteered by or elicited from the woman or may be described by the woman's caregiver.

*Fistula symptoms:* A departure from normal sensation, structure, or function, reported by a woman as (i) leakage of urine and/or feces or flatus from the vagina or perineum or; (ii) less commonly as leakage of urine from the anus, or cyclic menouria or hematuria from the urinary tract; or (iii) menstrual flow or other cyclic blood per anum/rectum. Symptoms are often, but not always, continuous, severe and may vary with position including leakage when sleeping (supine). Fistulas with a long tract or flap valve or small defect may make symptoms intermittent **NEW**.

### 3.1 PFF symptoms

**3.1.1 Discomfort or pain:** Complaint of discomfort/pain on the vulva, buttocks, thigh, or legs due to urine or fecal irritation, with or without ulceration or bleeding. **NEW**

**3.1.2 Vaginal urine leakage:** Complaint of urine leakage through the vagina. Symptoms are usually continuous but may be intermittent and may be associated with movement or specific changes of position. **NEW**

**3.1.3 Vaginal flatus/feces:** Complaint of passage of flatus or feces per vaginam.<sup>1,2</sup> Symptoms are usually continuous but may be intermittent and may be associated with movement or specific changes of position. **NEW**

**3.1.4 Hematuria:** Complaint of the passage of visible blood mixed with urine.<sup>2</sup>

### 3.2 Urinary tract fistula symptoms<sup>\*\*\*</sup>

**3.2.1 Urinary incontinence:** Complaint of involuntary loss of urine.<sup>1-3,6,7</sup>

**3.2.2 Continuous (urinary) incontinence:** Complaint of continuous involuntary loss of urine.<sup>1-3,6,7</sup>

**3.2.3 Postural (urinary) incontinence:** Complaint of involuntary loss of urine associated with change of body position, for example, rising from a seated or lying position.<sup>1,3</sup>

**3.2.4 Nocturnal enuresis:** Complaint of involuntary loss of urine which occurs during the main sleep period.<sup>32</sup>

**3.2.5 Insensible (urinary) incontinence:** Complaint of urinary incontinence where the woman is aware of urine leakage but unaware of how or when it occurred.<sup>33</sup>

**3.2.6 Coital incontinence:** Complaint of involuntary loss of urine during or after vaginal intercourse.<sup>14</sup> This symptom might be further divided into that occurring

with penetration or intromission and that occurring at orgasm.

**3.2.7 Menouria:** Complaint of cyclic hematuria that the patient believes to be menstrual. It may represent a VUtF. **NEW**

### 3.3 Anorectal tract fistula symptoms

**3.3.1 Anal incontinence (symptom):** Complaint of involuntary loss of flatus or feces.<sup>1,12</sup>

**3.3.2 Fecal incontinence:** Complaint of involuntary loss of feces.

#### 3.3.2.1 Solid<sup>1,12</sup>

#### 3.3.2.2 Liquid<sup>1,12</sup>

**3.3.3 Flatal incontinence:** Complaint of involuntary loss of flatus (gas).<sup>12</sup>

**3.3.4 Double incontinence:** Complaint of both anal incontinence and urinary incontinence.<sup>12</sup>

**3.3.5 Coital fecal (flatal) incontinence:** Fecal (flatal) incontinence occurring with vaginal intercourse.<sup>12</sup>

**3.3.6 Passive fecal leakage:** Involuntary soiling of liquid or solid stool without sensation or warning or difficulty wiping clean.<sup>12</sup>

**3.3.7 Overflow fecal incontinence:** Seepage of stool due to an overfull rectum or fecal impaction.<sup>12</sup>

**3.3.8 Nocturnal defecation:** Complaint of interruption of sleep one or more times because of the need to defecate.<sup>12</sup>

**3.3.9 Flaturia:** Complaint of passage of gas per urethra.<sup>12</sup>

**3.3.10 Fecaluria:** Complaint of passage of fecal material (per urethra) in the urine.<sup>2</sup>

**3.3.11 Rectal leakage of menses:** Complaint of blood or bloody discharge passing per anus that the patient believes to be menstrual. **NEW**

**3.3.12 Rectal leakage of urine:** Complaint of urine passing per anus. **NEW**

### 3.4 Chronic fistula symptoms

**3.4.1 Persistent fistula (symptom):** Continuation of urinary tract and/or anorectal tract incontinence symptoms immediately after fistula treatment caused by incomplete fistula wound healing. This includes inability to close the fistula during surgery. **NEW**

**3.4.2 Recurrent fistula (symptom):** Recurrence of fistula defect and incontinence after a period of transient complete fistula wound healing followed by delayed complications of wound healing causing fistula breakdown and fistula re-formation. **NEW**. It may also be caused by a new index event within the interval from successful repair to recurrence of fistula after which another fistula forms. Examples of subsequent index events include subsequent pregnancy complications causing obstetric PFF, pelvic floor surgery complicated by iatrogenic PFF, malignancy, or pelvic trauma causing traumatic PFF.

### 3.4.3 Post-repaired fistula residual incontinence

**symptoms:** Urinary or anorectal tract incontinence symptoms after successful fistula closure. **NEW\*\***

### 3.5 Persistent fistula-related disorder (PFRD) symptoms

Symptoms from conditions concurrent with the fistula or occurring after *successful* closure of the fistula defect. PFRD may include a complex of disabling symptoms related to comorbidities of general health and well-being, mental, reproductive, and musculoskeletal organs, in addition to symptoms from disorders of the upper and lower urinary, genital and anorectal tracts. **NEW**

Co-morbidities include but not limited to:

**3.5.1 PFRD pain:** For example, pain or discomfort in the vagina or vulva with sexual activity. **NEW**

**3.5.2 PFRD mobility dysfunction symptoms:** Difficulty walking or changing position or other range of motion symptoms. **NEW**

**3.5.3 PFRD menstrual dysfunction symptoms:** Amenorrhea, oligomenorrhea, dysmenorrhea, infertility. **NEW**

**3.5.4 PFRD urinary tract dysfunction symptoms:** For example, flank pain, dysuria, hematuria, voiding dysfunction. **NEW**

**3.5.5 PFRD psychological dysfunction symptoms:** Anxiety, depression, adjustment disorder with depressed mood, mourning, or grieving may be due to the impact of body image. Effects of loss of income-generating potential or marital, family or social status. **NEW**

**N.B.** This terminology document will restrict detailed PFRD terminology definitions to urinary, genital, and anorectal tract for the remainder of the document.

### 3.5.6 Other common PFRD symptoms

#### 3.5.6.1 General health symptoms<sup>35</sup>: **NEW**

**3.5.6.1.1** Fatigue, malaise, and mental health symptoms which are often multi-factorial in origin

**3.5.6.1.2** Emotional, musculoskeletal, gastrointestinal, or urinary tract symptoms related to types of abuse—physical, economic, and/or emotional

#### 3.5.6.2 Mental health symptoms<sup>36–38</sup>: **NEW**

**3.5.6.2.1** Anxiety and/or depression, posttraumatic stress disorder

**3.5.6.2.2** Grieving/mourning, stigma, and social isolation, self-esteem, quality of life

**3.5.6.2.3** Suicidal ideation, loss of libido, body image disorders, dysphoria, insomnia

#### 3.5.6.3 Musculoskeletal symptoms<sup>35,36,39</sup>: **NEW**

**3.5.6.3.1** Difficulty with ambulation

**3.5.6.3.2** Complaint of other quality of life challenges related to activities of daily living caused by diastasis pubis, osteomyelitis, foot-drop, levator ani atrophy,

exposed sacral nerve roots, idiopathic chronic pelvic pain, or other musculoskeletal condition incident after index event causing the fistula.

#### 3.5.6.4 Reproductive health symptoms<sup>36</sup>: **NEW**

**3.5.6.4.1** Amenorrhea, oligomenorrhea, dysmenorrhea

#### 3.5.6.4.2 Infertility

**3.5.7 Women deemed incurable (WDI):** Women with primary, persistent, and recurrent fistula for which anatomic repair is not possible. WDI require either supportive management and/or a diversion procedure, or they have a fistula complexity that exceeds the capacity (s) of the highest available surgical facility:<sup>†††</sup> **NEW**

**3.6 PFRD symptoms of the urinary tract may include:**

**3.6.1 PFRD sensory urinary tract symptoms:** A departure from normal sensation or function, experienced by the woman during bladder filling. Normally, the individual is aware of increasing sensation with bladder filling up to a strong desire to void.<sup>1</sup>

**3.6.1.1 Increased urinary frequency:** Complaint that voiding occurs more frequently than deemed normal by the individual (or caregivers). Time of day (daytime or nocturnal) or number of voids are not specified.<sup>2</sup>

**3.6.1.2 Increased bladder sensation:** Complaint that the desire to void during bladder filling occurs earlier or is more persistent to that previously experienced. This differs from urgency by the fact that micturition can be postponed despite the desire to void.<sup>1</sup>

**3.6.1.3 Reduced bladder sensation:** Complaint that the definite desire to void occurs later to that previously experienced despite an awareness that the bladder is filling.<sup>1</sup>

**3.6.1.4 Absent bladder sensation:** Complaint of both the absence of the sensation of bladder filling and of a definite desire to void.<sup>1</sup>

**3.6.2 PFRD voiding and postmicturition symptoms:** A departure from normal sensation or function, experienced by the woman during or following the act of voiding.<sup>2</sup>

**3.6.2.1 Hesitancy:** Complaint of a delay in initiating voiding (when the individual is ready to pass urine).<sup>2</sup>

**3.6.2.2 Slow stream:** Complaint of a urinary stream perceived as slower compared to previous performance or in comparison with others.<sup>1</sup>

**3.6.2.3 Intermittency:** Complaint of urine flow that stops and starts on one or more occasions during voiding.<sup>1</sup>

**3.6.2.4 Straining to void:** Complaint of the need to make an intensive effort (by abdominal straining, Valsalva or suprapubic pressure) to either initiate, maintain, or improve the urinary stream.<sup>1</sup>

**3.6.2.5 Spraying (splitting) of urinary stream:** Complaint that the urine passage is a spray or a split stream rather than a single discrete stream.<sup>1</sup> **CHANGED**

**3.6.2.6 Feeling of incomplete (bladder) emptying:** Complaint that the bladder does not feel empty after voiding has ceased.<sup>2</sup>

**3.6.2.7 Need to immediately re-void:** Complaint that further voiding is necessary soon after passing urine (cessation of urine flow).<sup>2</sup>

**3.6.2.8 Postmicturition leakage:** Complaint of a further involuntary passage or loss of urine following the completion of micturition.<sup>1</sup> **CHANGED**

**3.6.2.9 Position-dependent micturition:** Complaint of having to take specific positions to be able to micturate spontaneously or to improve bladder emptying, for example, leaning forwards or backwards on the toilet seat or voiding in the semi-standing position.<sup>1,3</sup>

**3.6.2.10 Dysuria:** Complaint of burning or other discomfort during voiding. Discomfort may be intrinsic to the lower urinary tract or external (vulvar dysuria).<sup>2</sup>

**3.6.2.11 Urinary retention:** Complaint of the inability to pass urine despite persistent effort.<sup>1</sup>

**3.6.3 PFRD lower urinary tract infection (UTI) symptoms:**

**3.6.3.1 UTI:** Defined as microbiological evidence of significant bacteriuria and pyuria usually accompanied by symptoms such as increased bladder sensation, urgency, frequency, dysuria, urgency urinary incontinence, and/or pain in the lower urinary tract.

**3.6.3.2 Recurrent UTIs:** At least three symptomatic and medically diagnosed UTI in the previous 12 months. The previous UTI(s) should have resolved before a further UTI being diagnosed.

**3.6.3.2.1** Other related history: hematuria, catheterization.

**3.6.4 PFRD lower urinary tract pain symptoms:**

**3.6.4.1 Bladder pain:** Complaint of suprapubic or retropubic pain, pressure, or discomfort, related to the bladder, and usually increasing with bladder filling. It may persist or be relieved after voiding.<sup>1,3</sup>

**3.6.4.2 Urethral pain:** Complaint of pain felt in the urethra and the woman indicates the urethra as the site.<sup>1,3</sup>

**3.7 PFRD POP symptoms<sup>3</sup>:** A departure from normal sensation, structure, or function, experienced by the woman in reference to the position of her pelvic organs. Symptoms are generally worse at the times when gravity might make the prolapse worse (e.g., after long periods of standing or exercise) and better when gravity is not a factor (e.g. lying supine). Prolapse may be more prominent at times of abdominal straining, for example, defecation. Other associated terms include:

**3.7.1 Vaginal bulging:** Complaint of a “bulge” or “something coming down” towards or through the vaginal introitus.<sup>3</sup>

**3.7.2 Vaginal gaping:** Complaint of a “wide open” vaginal introitus. **NEW**

**3.7.3 Pelvic pressure:** Complaint of increased heaviness or dragging in the suprapubic area and/or pelvis.<sup>1,3</sup>

**3.7.4 Bleeding, discharge, infection:** Complaint of vaginal bleeding, discharge, or infection related to prolapse.<sup>3</sup>

**3.7.5 Splinting/digitation:** Complaint of the need to digitally replace the prolapse<sup>3</sup> or to avoid prolapse descent during periods of increased abdominal pressure. **CHANGED**

**3.7.6 Low backache:** Complaint of low, sacral (or “period-like”) backache associated with POP.<sup>3</sup>

**3.8 PFRD Sexual dysfunction symptoms<sup>1,14</sup>:** A departure from normal sensation and/or function experienced by a woman during sexual activity.

**3.8.1 Dyspareunia:** Complaint of persistent or recurrent pain or discomfort associated with attempted or complete vaginal penetration.<sup>1,14</sup>

**3.8.2 Superficial (introital) dyspareunia:** Complaint of pain or discomfort on vaginal entry or at the vaginal introitus.<sup>1,14</sup>

**3.8.3 Deep dyspareunia:** Complaint of pain or discomfort on deeper penetration (mid or upper vagina).<sup>1</sup>

**3.8.4 Obstructed intercourse:** Complaint that vaginal penetration is not possible due to obstruction.<sup>14</sup>

**3.8.5 Vaginal laxity:** Complaint of excessive vaginal laxity.<sup>14</sup>

**3.9 PFRD genital pain symptoms<sup>1,14</sup>:**

**3.9.1 Vulval pain:** Complaint of pain felt in and around the vulva.<sup>14</sup>

**3.9.2 Vaginal pain:** Complaint of pain felt internally within the vagina, above the Introitus.<sup>1,14</sup>

**3.9.3 Perineal pain:** Complaint of pain felt between the posterior fourchette (posterior lip of the introitus) and the anus.<sup>14</sup>

**3.9.4 Pelvic pain:** The complaint of pain perceived to arise in the pelvis.<sup>14</sup>

**3.9.5 Cyclical (menstrual) pelvic pain:** Cyclical pelvic pain related to menses that raises the possibility of a gynecological cause.<sup>14</sup>

**3.9.6 Pudendal neuralgia:** Burning vaginal or vulval (anywhere between anus and clitoris) pain associated with tenderness over the course of the pudendal nerves.<sup>14</sup>

**3.9.7 Chronic lower urinary tract and/or other pelvic pain syndromes<sup>1</sup>:**

**3.10 PFRD anorectal tract symptoms<sup>1,12</sup>:**

**3.10.1 Straining to defecate:** Complaint of the need to make an intensive effort (by abdominal straining or Valsalva) to either initiate, maintain, or improve defecation.<sup>1,12</sup>

**3.10.2 Feeling of incomplete (bowel) evacuation:** Complaint that the rectum does not feel empty after defecation.<sup>12</sup>

**3.10.3 Diminished rectal sensation:** Complaint of diminished or absent sensation in the rectum.<sup>1,2</sup>

**3.10.4 Constipation:** Complaint that bowel movements are infrequent and/or incomplete and/or there is a need for frequent straining or manual assistance to defecate.<sup>1,2</sup>

**3.10.5 Rectal prolapse:** Complaint of external protrusion of the rectum.<sup>1,2</sup>

**3.10.6 Rectal bleeding/mucus:** Complaint of the loss of blood or mucus per rectum.<sup>1,2</sup>

**3.10.7 Pain during straining/defecation:** Complaint of pain during defecation or straining to defecate.<sup>1,2</sup>

**3.10.8. Levator ani syndrome:** Episodic rectal pain caused by spasm of the levator ani muscle. Proctalgia fugax (fleeting pain in the rectum) and coccydynia (pain in the coccygeal region) are variants of levator ani syndrome.<sup>1,2</sup>

**3.10.9 Proctalgia fugax** is a severe, episodic, generally sacrococcygeal pain.<sup>1,2</sup>

**3.10.10 Fecal incontinence:** Involuntary loss of feces or flatus.<sup>1,2</sup>

## 5 | SECTION 4: PFF SIGNS

### 4.1 General principles of PFF signs

**4.1.1 Sign:** Any abnormality indicative of disease or a health problem, discoverable on examination of the patient; an objective indication of disease or a health problem.<sup>1</sup>

**4.1.2 Correlation of signs and symptoms:** Signs should correlate with symptoms e.g. patient report of urinary incontinence is corroborated by visualization of urine leakage into the genital tract through a fistula defect.

**4.1.3 Overlap of PFF and non-PFF signs:** Because the signs of PFFs overlap with symptoms of urinary and fecal incontinence in patients who have never had a fistula, detailed pelvic exam is essential. Fill tests, with or without dye, may also be used during physical examination to assess the defect(s). The aim is to first diagnose the fistula(s) and to identify the location of the fistula(s) and then to assess the injury by evaluating the amount of tissue defect and scarring/fibrosis.<sup>\*\*\*</sup>

**4.1.4 General examination:** Is fundamental to the surgical triage process to assure that patients undergoing fistula surgery are suitable for anesthetic and surgical intervention. Surgery scheduling should be delayed until underlying conditions are stabilized with treatment to the best possible state of health. General examination must also rigorously screen for any condition that will impair optimal wound healing, so that the condition may be treated, or cured, before elective reconstructive fistula

FIGURE 8 Vulvar dermatitis from exposure to urine © J Goh

surgery. Signs of conditions relevant for elective reconstructive surgical triage screening include amongst others: anemia, malnutrition, diabetes, malaria, and other parasites, hepatitis, hypertension, rehydration, renal dysfunction, STI, and HIV.

### 4.2 Vaginal fistula signs

**4.2.1 Vaginal leakage:** Urine, flatus, and/or stool observed leaking into the vagina or from the vagina. *NEW*

**4.2.2 Excoriation:** Skin excoriation and/or rash with or without crusting or scabbing on the tops (or soles as urine pools in plastic sandals) of feet, inner thighs, external genitalia (Figure 8), perineum or vagina.<sup>1,2</sup> *CHANGED*

**4.2.3 Bleeding, discharge:** Observed on vaginal examination of the fistula. This includes hematoma. *NEW*

**4.2.4 Scars, sinuses, deformities:** Vaginal scarring, vaginal sinus tracts, vaginal stenosis. *NEW*

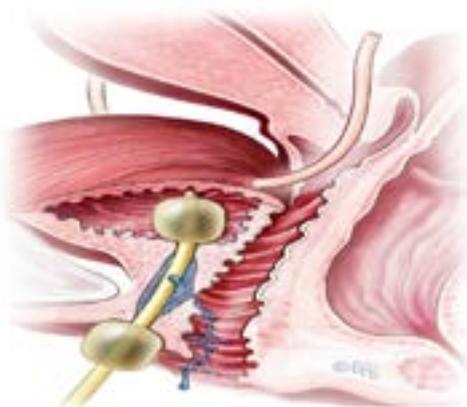

### 4.3 Urinary tract PFF signs

**4.3.1 Extra urethral incontinence:** Observation of urine leakage through channels other than the urethral meatus, for example, fistula.<sup>1,2</sup> The fistula may be described anatomically from one structure to another. Below are anatomical descriptions of PFF. The PFF defects may occur between 2 or more structures.

#### 4.3.2 Lower urinary tract PFF<sup>§§§</sup>

**4.3.2.1 UVaF—Clinical exam only:** Observation of a defect between the urethra and vagina that may occur across a spectrum of tissue loss, from the urethral meatus to the level of the bladder neck, with variable appearance (Figures 2 and 3)<sup>\*\*\*\*</sup> *NEW* With or without observation of:

**4.3.2.1.1 UVaF—Clinical exam and probe:** Probe passing through urethra into the vagina through a urethral defect or from the urethral defect back out through the urethral meatus. *NEW*

**FIGURE 9** Trattner double balloon urethral catheter demonstrating retrograde blue dye for detection of small urethral fistula

**4.3.2.1.2 UVaF—Clinical exam and fluid instillation:** dyed irrigant fluid passing per defect at the time of retrograde fill test of the bladder through a bladder catheter (positive blue test) (Figure 9). *NEW*

**4.3.2.1.3 UVaF—Clinical exam and Trattner catheter:** Trattner catheter (Figure 9) may be used to isolate retrograde blue test filling to the urethral lumen without filling the bladder. *NEW*

**4.3.2.2 VVaF—Clinical exam only:** Observation of urine pooling in the vagina and observation of defect between the anterior vaginal wall (including vault) and the bladder (Figure 5). *NEW* With or without observation of (Figure 10):

**4.3.2.2.1 VVaF—Clinical exam plus probe:** Probe passing through urethra into the vagina or from the vagina through the urethral meatus. *NEW*

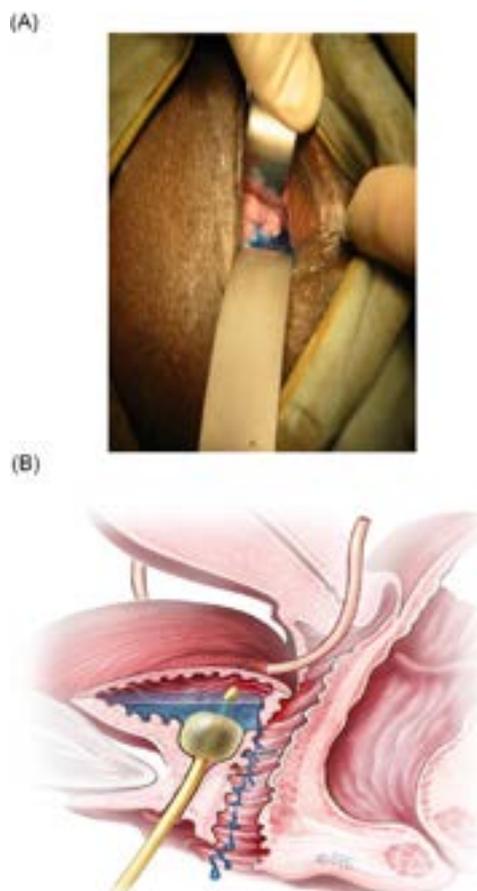

**4.3.2.2.2 VVaF—Clinical exam plus irrigation:** Dyed irrigation fluid passing per defect at the time of retrograde fill test of the bladder through a bladder catheter (positive blue test). *NEW*

**4.3.2.2.3 VVaF—Clinical exam plus bladder mucosa seen:** Bladder mucosa visible through the vagina on speculum examination (Figure 6). *NEW*

**4.3.2.3 Vesico-uterine(cervical) fistula (VUtF/VCxF):** Defect between the uterus (and/or cervix) and bladder, where the cervix may be intact or deficient. *NEW* with or without observation of:

**4.3.2.3.1 VUtF—Clinical Exam only:** Menouria: (cyclical) hematuria coinciding with menstruation. *NEW*

**4.3.2.3.2 VUtF—Clinical exam plus probe:** Probe passing through urethra into the cervical os or from the cervix through the urethral meatus (Figure 11). *NEW*

**FIGURE 10** (A) Retrograde blue test positive for vesico-vaginal fistula (VVaF) © L J Romanzi. (B) © Levent Efe

**4.3.2.3.3 VUtF—Clinical exam plus irrigation:** Dyed irrigation fluid passing per cervical os at the time of retrograde dyed irrigant fill test of the bladder through a bladder catheter. *NEW*

**4.3.2.4 Colo-vesical) fistula (CoVF):** Defect between the anorectum (or colon) and bladder. *NEW* with or without observation of:

**4.3.2.4.1 CoVF—Clinical exam only:** observation of flaturia, fecaluria. *NEW*

**4.3.2.4.2 CoVF—Clinical exam plus PR air injection:** observation of flaturia, fecaluria bubbles passing through the urethra after retrograde injection of air per rectum. *NEW*

**4.3.2.4.3 CoVF—Clinical exam plus irrigation:** observation of dyed irrigation fluid passing per anorectum after retrograde bladder fill per urethra. *NEW*

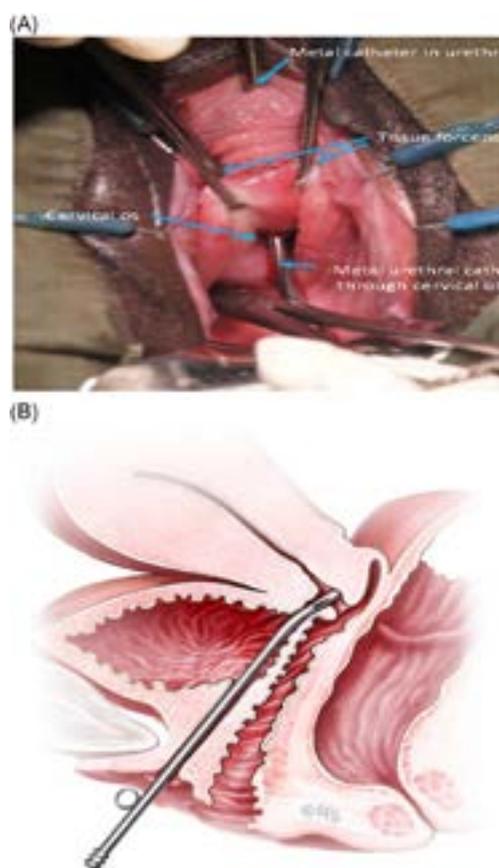

FIGURE 11 (A, above) Vesico-cervical fistula (: Metal catheter inserted per urethra is visible within the cervical os. © J Goh; (B, below) © Levent Efe

### 4.3.3 Upper urinary tract PFF

**4.3.3.1 UrVaF:** Abnormal connection between the ureter(s) and vagina.

**NEW** With or without observation of:

**4.3.3.1.1 UrVaF—Clinical exam only:** Observation of urine pooling in the posterior vaginal fornix. **NEW**

**4.3.3.1.2 UrVaF—Clinical exam plus irrigation:** Observation of urine pooling in the posterior vaginal fornix at the time of retrograde dyed irrigation fill test of the bladder through a bladder catheter (negative dye test, positive urine). **NEW**

**4.3.3.1.3 UrVaF—Occurrence in isolation:** For example, at the vaginal vault following a hysterectomy including Cesarean hysterectomy. **NEW**

**4.3.3.1.4 UrVaF—Occurrence in combination:** For example, in combination of a VVaF. **NEW**

**4.3.3.2 UrUtF/UrCxF:** abnormal connection between the ureter(s) and the uterus/cervix. **NEW** With or without observation of:

**4.3.3.2.1 UrUtF—Clinical exam only:** Observation of urine passing through the cervix or pooling in the posterior vaginal fornix. **NEW**

**4.3.3.2.2 UrUtF—Clinical exam plus irrigation:** Observation of urine passing per cervical os; with or without pooling in the posterior vaginal fornix at the time of retrograde dyed irrigant fill test of the bladder through a bladder catheter (negative blue test, positive clear urine). **NEW**

**4.3.3.3 UrUtF/UrCxF:** Complex of multiple urinary tract fistulas concurrent between the ureter and uterus/cervix and between the bladder and uterus/cervix. **NEW** Difficult to diagnose clinically. It is often diagnosed by hysterosalpingogram (HSG).<sup>††††.††††.§§§§</sup>

## 4.4 Anorecto-vaginal fistula signs<sup>12</sup>

### 4.4.1 General signs

**4.4.1.1 Excoriation dermatitis:** Inner thighs, external genitalia, generally

**4.4.1.1.1 Perineum or vagina with or without skin rashes, crusting or scabbing.** **CHANGED**

**4.4.1.2 Soiling:** Perianal, vaginal, or perineal fecal soiling.<sup>1,12</sup>

**4.4.1.3 Discharge:** Perianal or vaginal bloody or mucus discharge.<sup>1,12</sup>

**4.4.1.4 Scars, sinuses, deformities, hematoma**<sup>1,12</sup>

**4.4.2 Deficient perineum/total perineal defect:** A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina.<sup>12</sup>

**4.4.3 Fourth degree perineal tear (4<sup>o</sup>PT):** Defined as an acquired childbirth injury and a subset of deficient perineum, involving both loss of the rectovaginal septum, full thickness anterior defect of the anal sphincter, and variable loss with lateral displacement of the fibromuscular architecture of the perineal body (total perineal defect) (Figure 7).

**4.4.4 Rectovaginal fistula (RVaF):** Abnormal connection between the rectum to the vagina with or without observation of vaginal flatus/feces.<sup>12</sup> With or without the observation of:

**4.4.4.1 RVaF—Clinical exam only:** Anorectal fluid per vagina. **NEW**

**4.4.4.2 RVaF = Clinical exam plus probe:** Probe or examination finger passing per vagina through anus or per anus through vagina (Figure 12). **NEW**

**4.4.4.3 RVF—Clinical exam plus irrigation or air injection:** Anorectal tract fluid per vagina, or with bubbles passing through the abnormal connection

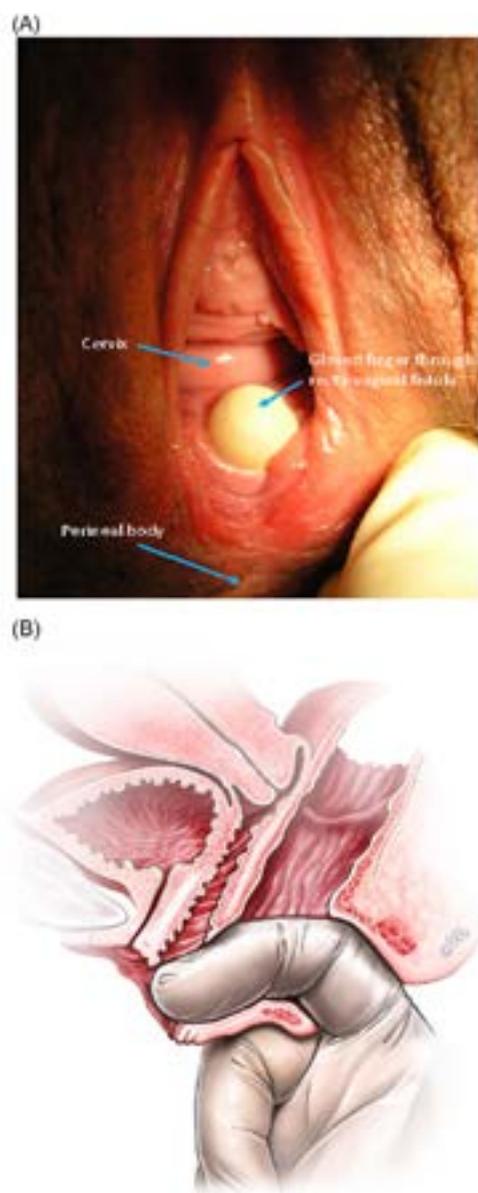

FIGURE 12 (A) Recto-vaginal fistula (RVaF), low in the vagina, just proximal to the anus ©J Goh. (B) © Levent Efe

through vaginal irrigant fluid after retrograde injection of air per rectum. **NEW**

**4.4.5 Colo-uterine/cervical fistula (CoUtF/CoCxF):** Abnormal connection between the colo/rectum and uterus (body and/or cervix). **NEW** With or without the observation of:

**4.4.5.1 R(C)UtF—Clinical exam only:** Passing flatus/feces per cervix, menses per rectum, anorectal tract fluid per vagina. **NEW**

**4.4.5.2 R(C)UF—Clinical exam plus irrigation or air injection:** With bubbles passing through the abnormal connection through vaginal irrigant fluid after retrograde injection of air per rectum. **NEW**

**4.4.6 RVaPeF:** Is an abnormal communication from the anorectum to the vagina or perineal area. **NEW**

**4.4.6.1 RVaPeF—Clinical Exam only:** Passing of flatus/feces per vagina or perineum through anus.

**4.4.6.2 RVaPeF—Clinical exam plus probe:** Probe passing per vagina or perineum through anus.

**4.4.7. Vesico-rectal fistula (VRF):** Abnormal connection between the bladder and rectum. **NEW** With or without observation of:

**4.4.7.1 VRF—Clinical exam plus probe:** probe passing per urethra through anus or per anus through urethra. **NEW**

**4.4.7.2 VRF—Clinical exam plus irrigation:** Flat-uria, fecaluria, bubbles passing through the urethra after retrograde injection of air per rectum, blue irrigant fluid passing per anorectum after retrograde bladder fill per urethra. **NEW**

**4.4.8 FIA/ACF:** an abnormal connection between the anal canal epithelium and the skin epithelium.

**4.4.8.1** Patients may complain of pain, swelling, intermittent discharge of blood or pus from the fistula, and recurrent abscesses formation.<sup>12</sup>

#### 4.5 Chronic fistula signs

**4.5.1 Persistent fistula:** The persistent fistula is not de novo to the patient.

**4.5.1.1: Persistent urine or fecal (flatal) incontinence:** Observation of involuntary, extra-urethral loss of urine and/or extra-anal loss of flatus/feces on examination. **NEW**

**4.5.1.2 Incomplete fistula wound healing:** after treatment which includes inability to close the fistula during surgery. **NEW**

**4.5.2 Recurrent fistula (signs):** The recurrent fistula is de novo to the patient.

**4.5.2.1 Recurrent urine or fecal (flatal) incontinence:** Observation of recurrent involuntary, extra-urethral loss of urine and/or extra-anal loss of flatus/feces on examination. **NEW**

**4.5.2.2 Recurrent fistula defect:** Observation of, within a clinical history context of previous fistula repair (i) a period of transient complete fistula wound healing followed by delayed complications of wound healing causing fistula breakdown and fistula re-formation, or (ii) fistula recurring within the interval from successful treatment to recurrence of fistula after which another fistula forms. **NEW**

#### 4.6 WDI signs

**4.6.1. Definition:** The fistula, in this case, is “beyond repair” and may have never undergone treatment, but usually the symptom history is consistent with Chronic Fistula. Symptoms may be consistent with *persistent fistula* but there may also be symptoms consistent with *recurrent fistula*. There may be multiple attempts at repair and operations for persistent incontinence. WDI signs are often the most severe forms of fistula signs, be it treated or untreated. **NEW**

**4.6.2 Extra-urethral incontinence:** Observation of urine leakage through channels other than the urethral meatus, combined with (i) observation of severe or total loss of the bladder, and/or (ii) observation of a urinary tract fistula that exceeds local capacity for successful anatomic treatment. **CHANGED**

**4.6.3 Extra-anal incontinence:** Observation of fecal or flatal leakage through channels other than the anal verge, combined with (i) observation of severe or total loss of the anorectum, and/or (ii) observation of an anorectal fistula that exceeds local capacity for successful anatomic treatment. **NEW**

## 6 | SECTION 5: INVESTIGATIONS

### 5.1 Dye and bubble tests for PFF

Dye tests may be used to detect small or unusual fistulas (less useful for large or multiple fistulas), such as utero-vaginal or cervico-vaginal fistulas and to differentiate ureteric fistula (clear or yellow urine in vault, “negative dye test with urine in vault”) from bladder fistula (“positive dye test”) or to detect small or distorted anorectal fistula (positive vaginal bubble or rectal dye test). Dye and bubble tests are typically done at time of clinical examination for PFF, thus their inclusion in the “Signs” section. **NEW**

#### 5.1.1 Simple dye test for urinary tract fistulas

The bladder is filled retrograde through a urethral catheter using a dye to change the color of the irrigation fluid, for example, methylene blue or indigo carmine to turn the irrigation fluid blue (Figure 10). Observation may begin with or without retractor(s) in the vagina, depending on digital and visual exam signs and patient symptoms, or following careful dissection. Blue fluid leakage per genital tract or per anus indicates a bladder or urethral fistula. Lack of blue fluid leakage combined with visualization of extra-meatal clear urine leakage increases suspicion of an upper urinary tract ureteric fistula. **NEW**

#### 5.1.2 Triple swab test for urinary tract fistula

Three separate sponge swabs, one above the other, are placed in the upper, middle, and lower vagina. The bladder is then filled with a colored irrigant such as diluted methylene blue, and the swabs are removed after

10 min (it can take up to 30 min for urine to come through a tiny tortuous fistula especially if it is in the cervix or uterus). Discoloration of only the lowest swab supports diagnosis of a low urethral fistula or urethral leakage. Diagnosis of a uretero-genital fistula is supported when the uppermost swab is wet but not discolored. A VVaF fistula diagnosis is supported when the upper swabs are wet with blue irrigant. Careful observation for backflow of blue irrigant per meatus must be ongoing to avoid false-positive test reporting. **NEW**

#### 5.1.3 Double dye test for urinary tract fistula:

This includes oral intake of phenazopyridine (pyridium) 200 mg three times a day for one to two days until urine is bright orange, followed by retrograde bladder filling with blue irrigant through a bladder catheter. Diagnosis of a bladder or urethral fistula to the vagina (VVaF, UVaF) is supported if the vaginal swab turns blue. Diagnosis of a ureteric fistula to the vagina is supported if the swab turns orange, combination upper and lower urinary tract fistula to the vagina is supported if the swab turns both blue and orange. Careful observation for backflow of blue irrigant per meatus must be ongoing to avoid false-positive test reporting. **NEW**

#### 5.1.4 Trattner double balloon catheter test for urethral fistula:

The Trattner catheter has two balloons, one sits intravesically and the other inflates outside of the meatus to block efflux from the urethra. The irrigant flows out through a lumen that sits between the balloons, isolating fill to the urethra (Figure 9). **NEW**

#### 5.1.5 Posterior wall irrigant/fluid per rectum for anorectal tract fistula:

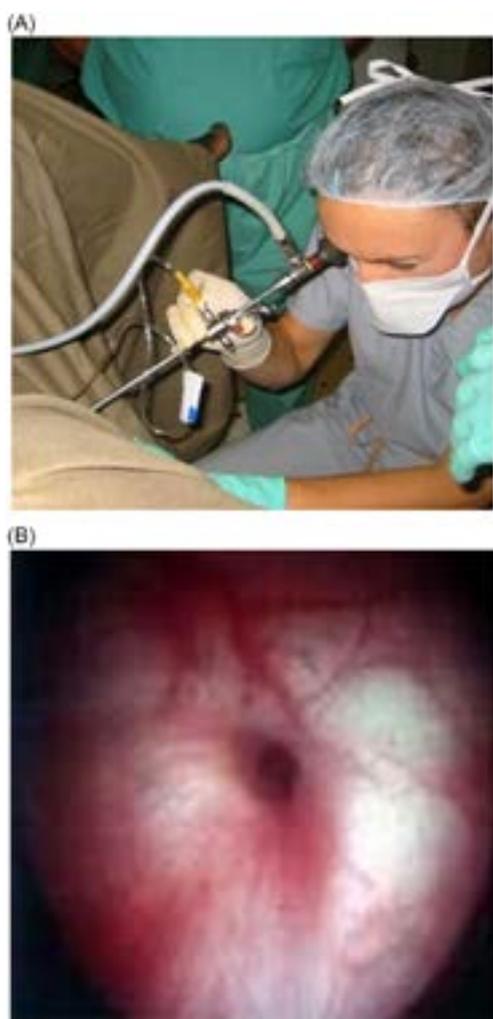

As with bladder dye testing, dye irrigation fluid may be instilled per rectal catheter. If colored irrigant passes per vagina, an anorectal fistula to the genital tract is confirmed. **NEW**

#### 5.1.6 Posterior wall “bubble test” for anorectal tract fistula:

With anterior vaginal wall retraction permitting visualization of the posterior vaginal wall, a Foley catheter is inserted into the rectum, the balloon inflated, and held under gentle traction against the anus. Irrigant fluid is placed per vagina. A catheter-tipped, air-filled syringe is inserted into the catheter and slowly decompressed to insert air into the rectum. Vaginal inspection allows visualization of bubbles emanating per vagina through a fistula defect. **NEW**

### 5.2. Endoscopy evaluations for PFF and PFRD:

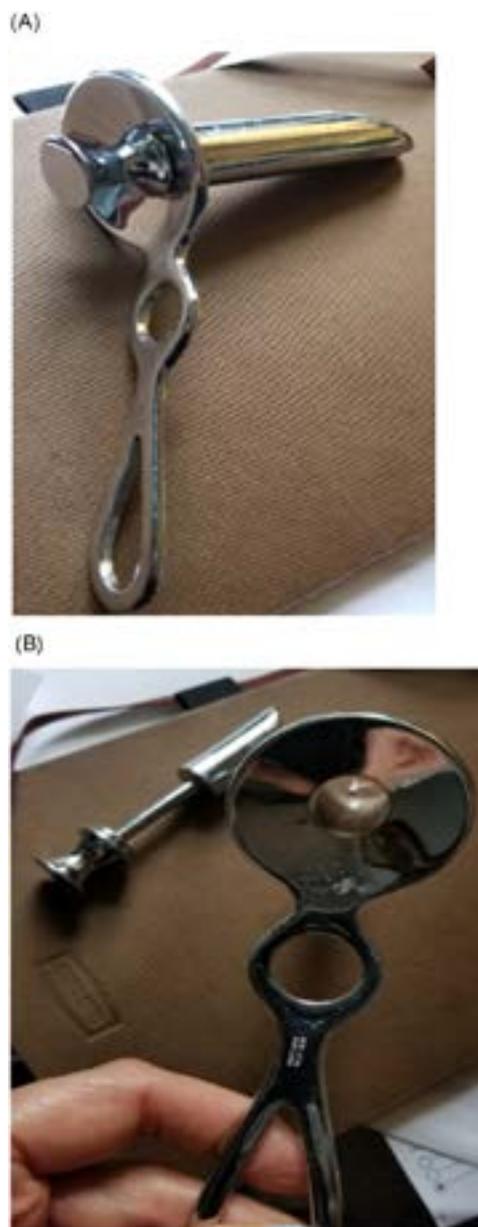

These are normally not included in investigations in ICS documents, nor in the ICS Glossary. However, they may have a role in assessing (i) a small PFF; (ii) different PFRD issues.

**FIGURE 13** (A) Cystoscopy in a fistula patient in Niamey, Niger. (B) Cystoscopic image of fistula defect. ©L J Romanzi and Badlani

### 5.2.1 Cystoscopy and urethroscopy

Cystoscopy and urethroscopy may be used to better understand the configuration of upper and lower urinary tract fistulas (Figure 13A,B) and the proximity of the lower urinary tract to the ureteric orifice. <sup>\*\*\*\*\*</sup> **NEW** It will clearly identify other pathology, for example, stone, tumor. Cystoscopy may, however, only be possible in the smallest of fistulas where the bladder can still contain fluid (see Figure 13A,B). <sup>\*\*\*\*\*</sup>

**FIGURE 14** (A) Anoscope and (B) anoscope demonstration. ©L J Romanzi

### 5.2.2 Anoscopy and sigmoidoscopy

Lower gastrointestinal endoscopy may be used to better understand the configuration of upper and lower anorectal tract fistula. Anorectal endoscopy is also helpful when evaluating PFRD of the anorectal tract

(Figure 14A,B), such as stricture, residual anorectal incontinence, rectal pain syndromes, and compromised rectovaginal fistula wound healing. **NEW**

### 5.2.3 Genital tract examination

Vaginoscopy may be undertaken with any endoscopic equipment or nasal speculum. It is particularly helpful in the evaluation of pediatric patients and women with severe vaginal stenosis. Hysteroscopy may be undertaken to evaluate cervical patency and endometrial integrity for women reporting PFRD amenorrhea and/or infertility. **NEW**

### 5.3 Bladder function studies for PFRD

There is no defined role for urodynamic investigations before the closure of urethral or bladder fistulas—for example, pressure readings would be unreliable if an organ is leaking.

#### 5.3.1 Functional evaluation (UDS) for lower urinary tract PFRD<sup>1</sup>

**5.3.1.1 UDS:** Measurement of all the physiological parameters relevant to the function and any dysfunction of the lower urinary tract<sup>40,41</sup>

**5.3.1.2 Urodynamic usage in low resource regions:** MUDS is becoming increasingly available in low resource regions. A brief overview of UDS evaluation for common bladder pathologies occurring after fistula repair surgery will be reviewed in this document. Simple, single-channel urodynamics (“Simple Cystometrics”), a technique more commonly available in resource-constrained facilities, is also reviewed in this section.<sup>†††††</sup>

**5.3.2 Single channel UDS (“Simple Cystometrics”)<sup>42</sup>:** Use of a catheter, catheter-tipped syringe, and

sterile irrigant solution, may provide rudimentary yet valuable information to guide treatment algorithms. Any residual fistula needs to be excluded. Simple “cystometrics” requires the insertion of an indwelling catheter which is secured with inflation of the balloon (not present in Figure 15). The bladder is filled with a catheter tipped syringe to approximately 300 ml of saline. The end of the catheter (after removing the syringe) is held vertically about 15 cm above the pubic symphysis and the level of the fluid in the catheter is noted. The volume for each filling sensation is noted. When there are no urge symptoms and no elevation of the meniscus, then the vesical pressure is considered “stable.” When the catheter is removed a cough test is performed to assess for stress urinary incontinence. **NEW**

**5.3.3 MUDS<sup>40,41</sup>** Combines measurement of bladder and rectal pressures, filling volume and voided volume (VV), and urine flow rate (UFR) (with or without video cystography). In centers where MUDS capacity exists, it is the preferred method for evaluating the complex aetiologies that often contribute to residual lower urinary tract dysfunction after fistula repair.

**5.3.3.1 Clinical sequence of UDS testing<sup>1,2</sup>** Urodynamic investigations generally involve an individual attending with a comfortably full bladder for free (no catheter) uroflowmetry and post-void residual (PVR) measurement before filling cystometry and pressure-flow study.

#### 5.3.4 Uroflowmetry:

**5.3.4.1 Ideal conditions for free (no catheter) uroflowmetry:** Ideally, all free uroflowmetry studies

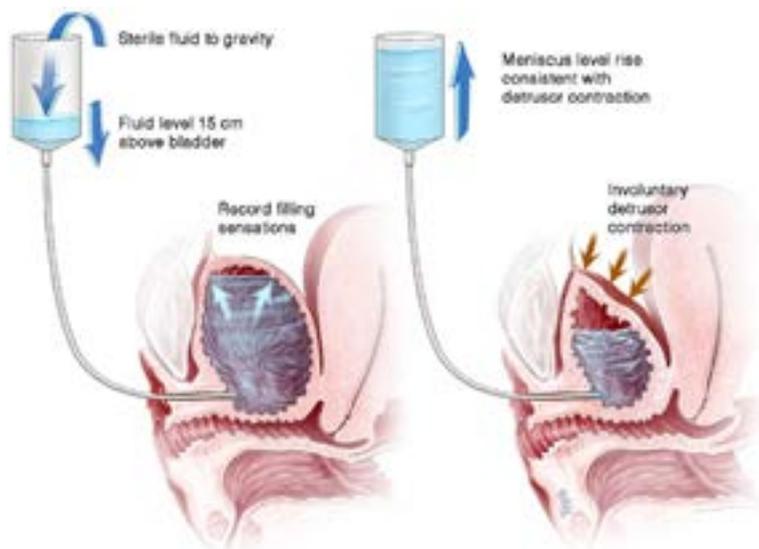

FIGURE 15 Simple urodynamics catheter placement and process overview

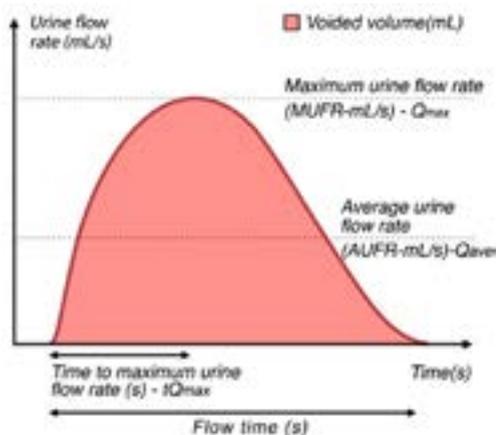

FIGURE 16 A schematic representation of urine flow over time and parameters of uroflowmetry

should be performed in a completely private uroflowmetry room.

Most modern uroflowmeters have a high degree of accuracy ( $\pm 5\%$ ) though regular calibration is important.

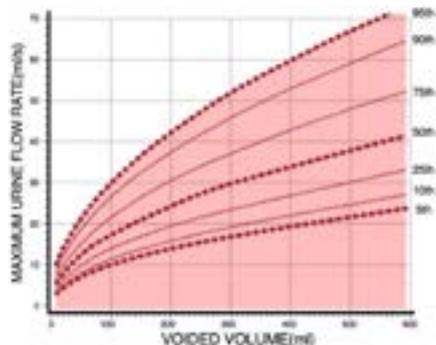

**5.3.4.2 Urine flow:** Urethral passage of urine where the pattern of urine flow may be.<sup>1,2,43,44</sup>

**5.3.4.2.1 Continuous urine flow:** No interruption to urine flow.

**5.3.4.2.2 Intermittent urine flow:** Urine flow is interrupted.

**5.3.4.3 UFR (ml/s):** Volume of urine expelled via the urethra per unit time.<sup>1,2,43,44</sup>

**5.3.4.4 VV (ml):** Total volume of urine expelled via the urethra during a single void.<sup>1,2,43,44</sup>

17. Liverpool nomogram.

FIGURE 17 Liverpool Nomogram for maximum urine flow rate in women.<sup>43</sup>  $\text{Ln}(\text{Maximum urine flow rate}) = 0.511 + 0.505 \times \text{Ln}(\text{voided volume})$ . Root mean square error = 0.340. Reference: <sup>43</sup> (Reproduced with permission)

**5.3.4.5 Maximum (urine) flow rate (MUFR, ml/s)— $Q_{\max}$ :** Maximum measured value of the UFR corrected for artefacts.<sup>1,2,43,44</sup>

**5.3.4.6 Flow time (FT, s):** Time over which measurable flow actually occurs.<sup>1,2,43,44</sup>

**5.3.4.7 Average (urine) flow rate (AUFR, ml/s)— $Q_{\text{ave}}$ :** VV divided by the FT (Figure 16).<sup>1,2,43,44</sup>

**5.3.4.8 Voiding time (VT, s):** Total duration of micturition, that is, includes interruptions.

When voiding is completed without interruption, VT is equal to FT.<sup>1,2,43,44</sup>

**5.3.4.9 Time to maximum UFR ( $t_{Q_{\max}}$ , s):** Elapsed time from the onset of urine flow to maximum urine flow.<sup>1,2,6,7</sup>

**5.3.4.10 Interpretation of the normality of free uroflowmetry:** Because of the strong dependency of UFRs in women on VV,<sup>43</sup> they are best referenced to nomograms<sup>43</sup> where the cutoff for normality has been determined and validated and where the cut-off for abnormally slow (MUFR, AUFR) urine flow has been determined and validated as under the 10th centile of the respective Liverpool nomogram (Figure 17).<sup>44</sup>

**5.3.5 Postvoid residual (PVR):** Volume of urine left in the bladder at the completion of micturition.<sup>1,2</sup>

**5.3.5.1 Conditions for PVR measurement<sup>1,2</sup>:** PVR reading is erroneously elevated by delayed measurement due to additional renal input (1–14mls/min) into bladder volume. Ultrasonic techniques allow immediate (within 60 seconds of micturition) measurement.<sup>45,46</sup> A short plastic female catheter provides the most effective bladder drainage for PVR measurement.<sup>45</sup>

**5.3.5.2 Assessment of normality of PVR:** Quoted upper limits of normal may reflect the accuracy of measurement. Studies using “immediate” PVR measurement (e.g. ultrasound) suggest an upper limit of normal of 30mls. Studies using urethral catheterization (up to 10-min delay) quote higher upper limits of normal of 50 ml or more.<sup>45</sup> An isolated finding of a raised PVR requires confirmation before being considered significant.

**5.3.6 Filling cystometry:** is the pressure/volume relationship of the bladder during bladder filling.<sup>1,2,6,7,40,41</sup> It begins with the commencement of filling and ends when a “permission to void” is given. When multi-channel cystometry is done with fluoroscopy it is known as video cystometrogram (CMG) or VCMG.

**5.3.6.1: CMG:** Graphical recording of the bladder pressure(s) and volume(s) over time.<sup>1,2,6,7,40,41</sup>

**5.3.6.2 Conditions for cystometry including:**

**5.3.6.2.1: Fluid:** Water or saline unless radiological imaging.<sup>1,2</sup>

**5.3.6.2.2 Temperature of fluid:** Fluid at room temperature is mostly used.<sup>1,2</sup>

**5.3.6.2.3 Position of patient:** Sitting position is more provocative for abnormal detrusor activity (i.e., overactivity) than the supine position.<sup>1,2</sup>

**5.3.6.2.4 Filling rate:** A medium fill rate (50 ml/min) should be applicable in most routine studies. Much slower filling rates (under 25 ml/min) are appropriate in women in whom there are concerns about poor compliance (or with a bladder diary showing low bladder capacity or those with neuropathic bladder).<sup>1,2</sup>

**5.3.6.3 Intravesical pressure ( $P_{ves}$ , cm H<sub>2</sub>O):** The pressure within the bladder (as directly measured by the intravesical catheter).<sup>1,2,40,41</sup>

**5.3.6.4 Abdominal pressure ( $P_{abd}$ , cm H<sub>2</sub>O):** The pressure in the abdominal cavity surrounding the bladder. It is usually estimated by measuring the rectal pressure or vaginal pressure, though the pressure through a bowel stoma can be measured as an alternative. The simultaneous measurement of abdominal pressure is essential for interpretation of the intravesical pressure trace.<sup>1,40,41</sup> Artifacts on the detrusor pressure trace may be produced by a rectal contraction.<sup>1,40,41</sup>

**5.3.6.5 Detrusor pressure ( $P_{det}$ , cm H<sub>2</sub>O):** The component of intravesical pressure that is created by forces in the bladder wall (passive and active). It is calculated by subtracting abdominal pressure from intravesical pressure ( $P_{det} = P_{ves} - P_{abd}$ ).<sup>1,40,41</sup>

**5.3.6.6 Aims of filling cystometry:** To assess bladder sensation, bladder capacity, detrusor activity, and compliance as well as to document (the situation of and detrusor pressures during) urine leakage.<sup>1</sup>

**5.3.6.7 Bladder sensation during filling cystometry:** Usually assessed by questioning the individual in relation to the fullness of the bladder during cystometry.

**5.3.6.7.1 First sensation of bladder filling:** The feeling when the woman first becomes aware of bladder filling.<sup>1</sup>

**5.3.6.7.2 First desire to void:** The first feeling that the woman may wish to pass urine.<sup>1</sup>

**5.3.6.7.3 Normal desire to void:** The feeling that leads the woman to want to pass urine at the next convenient moment, but voiding can be delayed if necessary.<sup>1</sup>

**5.3.6.7.4 Strong desire to void:** The persistent desire to pass urine without the fear of leakage.<sup>1</sup>

**5.3.6.7.5 Urgency:** Sudden, compelling desire to void which is difficult to defer.<sup>1</sup>

**5.3.6.7.6 Cystometric capacity:** Bladder volume at the end of filling cystometry (Figure 18).<sup>1</sup>

**5.3.6.8 Abnormal bladder sensation during filling cystometry**

**5.3.6.8.1 Bladder oversensitivity**<sup>1</sup>—Increased bladder sensation during bladder filling with (i) earlier first desire to void; (ii) earlier strong desire to void, which occurs at low bladder volume; (iii) lower maximum cystometric bladder capacity; (iv) no abnormal increases in detrusor pressure.

**5.3.6.8.2 Reduced bladder sensation:** Bladder sensation perceived to be diminished during filling cystometry.

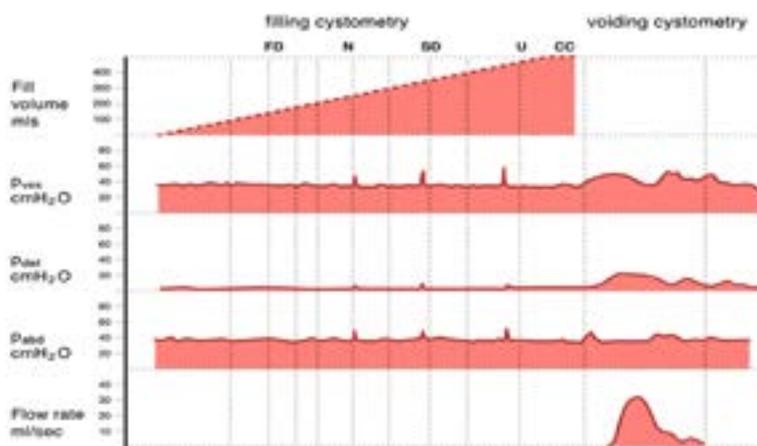

FIGURE 18 48-year-old female with urinary frequency. No phasic activity during filling. Voided with normal urine flow rate at normal detrusor voiding pressure. Normal study. CC, cystometric capacity (permission to void given); FD, first desire to void; ND, normal desire to void; SD, strong desire to void; U, urgency

**5.3.6.8.3 Absent bladder sensation:** No bladder sensation during filling cystometry, at least to expected capacity of 500 ml.

### 5.3.6.9 Detrusor function during filling cystometry

#### 5.3.6.9.1 Normal detrusor activity/function<sup>2</sup>:

There is little or no change in detrusor pressure with filling. There are no detrusor contractions, spontaneous or provoked with activities such as postural changes, coughing or hearing the sound of running water (Figure 19).

**5.3.6.9.2 Detrusor overactivity (DO)<sup>2</sup>:** The occurrence of detrusor contraction(s) during filling cystometry. These contractions, which may be spontaneous or provoked, produce a wave form on the CMG, of variable duration and amplitude. The contractions may be phasic or terminal. They may be suppressed by the patient, or uncontrollable. Symptoms, for example, urgency and/or urgency incontinence or perception of the contraction may (note if present) or may not occur.

**5.3.6.9.2.1 Idiopathic (primary) DO<sup>2</sup>:** No identifiable cause for involuntary detrusor contraction(s).

**5.3.6.9.2.2 Neurogenic (secondary) DO<sup>2</sup>:** DO and evidence (history; visible or measurable deficit) of a relevant neurological disorder.

**5.3.6.9.2.3 Non-neurogenic (secondary) DO<sup>2</sup>:** An identifiable possible non-neurological cause exists for involuntary detrusor contraction(s) during bladder filling. e.g. functional (obstruction); stone, tumor, UTI

#### 5.3.6.9.3 Bladder (detrusor) compliance (ml/cm H<sub>2</sub>O)<sup>2</sup>

**5.3.6.9.3.1 Description:** Relationship between the change in bladder volume and change in detrusor pressure as a measure for the distensibility of the bladder.<sup>2</sup>

**5.3.6.9.3.2 Calculation<sup>2</sup>:** Divide the change of volume ( $\Delta V$ ) by the simultaneous change in detrusor pressure ( $\Delta P_{det}$ ) during filling cystometry—( $C = \Delta V / \Delta P_{det}$ ). The compliance reflects the amount of fluid in the bladder to increase bladder pressure by 1 cm H<sub>2</sub>O and is expressed as ml/cm H<sub>2</sub>O.

**5.3.6.9.3.3 Normal values<sup>2</sup>:** Low compliance has been defined (in women) as bladder compliance < 10 ml/cm H<sub>2</sub>O (neurogenic) or < 30 ml/cm H<sub>2</sub>O (non-neurogenic). Normal compliance is > 30 ml/cm H<sub>2</sub>O (neurogenic) and 40 ml/cm H<sub>2</sub>O (non-neurogenic).

**5.3.6.10 Urethral function during filling cystometry (filling urethro-cystometry):** Urethral closure mechanism.

**5.3.6.10.1 Normal urethral closure mechanism<sup>2</sup>:** A positive urethral closure pressure is maintained during bladder filling, even in the presence of increased abdominal pressure, although it may be overcome by DO.

**5.3.6.10.2 Incompetent urethral closure mechanism<sup>2</sup>:** Leakage of urine occurs during activities which might raise intra-abdominal pressure in the absence of a detrusor contraction.

**5.3.6.10.3 Urodynamic stress incontinence (USI)<sup>2</sup>:** Involuntary leakage of urine during filling

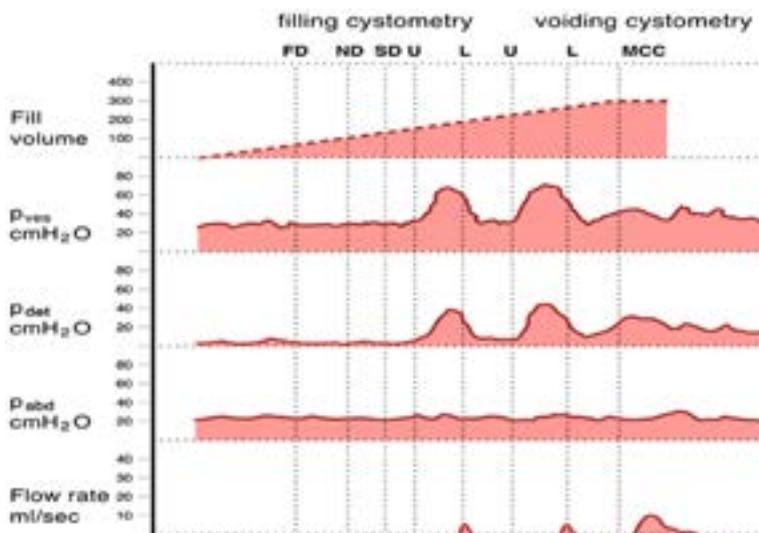

FIGURE 19 52-year-old female with urgency and frequency. Phasic detrusor activity during filling. Leakage is associated with urgency and detrusor contractions. FD, first desire to void; L, leakage; MCC, maximum cystometric capacity; ND, normal desire to void; SD, strong desire to void; U, urgency

cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

**5.3.6.10.4 Subtype: Intrinsic sphincter deficiency (ISD)<sup>2</sup>:** Very weakened urethral closure mechanism.

**5.3.7 Voiding cystometry<sup>1,2</sup> (pressure-flow studies):** This is the pressure–volume relationship of the bladder during micturition. It begins when the “permission to void” is given by the urodynamicist and ends when the woman considers her voiding has finished. Measurements to be recorded should be the intravesical, intra-abdominal, and detrusor pressures during the voiding urinary flow, including the UFR. A partial synopsis of some voiding cystometry measures is included here.

**5.3.7.1 Pressure and other measurements during voiding cystometry:**

**5.3.7.1.1 Detrusor opening pressure (cm H<sub>2</sub>O)<sup>1,2</sup>:** Detrusor pressure recorded immediately before the commencement of urine flow.

**5.3.7.1.2 Flow delay (s)<sup>2</sup>:** The time elapsed from initial rise in pressure to the onset of flow. This is the initial isovolumetric contraction period of micturition. It reflects the time necessary for the fluid to pass from the point of pressure measurement to the uroflow transducer.

**5.3.7.1.3 Urethral opening pressure (P<sub>det-uo</sub>, cm H<sub>2</sub>O)<sup>2</sup>:** Detrusor pressure recorded at the onset of measured flow (consider time delay—usually under 1 s).

**5.3.7.1.4 Maximum detrusor pressure (P<sub>det-max</sub>, cm H<sub>2</sub>O)<sup>2</sup>:** Maximum registered detrusor pressure during voiding.

**5.3.7.1.5 Detrusor pressure at maximum flow (P<sub>det-Qmax</sub>, cm H<sub>2</sub>O)<sup>2</sup>:** Detrusor pressure recorded at maximum urinary flow rate.

**5.3.7.1.6 Detrusor pressure at end of flow (P<sub>det-ef</sub>, cm H<sub>2</sub>O)<sup>2</sup>:** Detrusor pressure recorded at the end of urine flow.

**5.3.7.1.7 Postvoiding detrusor contraction<sup>2</sup>:** An increase in detrusor pressure (P<sub>det</sub>) following the cessation of urinary flow (**NEW**)

**5.3.7.2 Detrusor function during voiding cystometry**

**5.3.7.2.1 Normal detrusor function:** Normal voiding in women is achieved by an initial (voluntary) reduction in intra-urethral pressure (urethral relaxation). This is generally followed by a continuous detrusor contraction that leads to complete bladder emptying within a normal time span. Many women will void successfully (normal flow rate and no PVR) by urethral relaxation alone, without much of a rise in detrusor pressure. The amplitude of the detrusor contraction will tend to increase to cope with any degree of bladder outflow obstruction.

**5.3.7.2.2 Detrusor underactivity:** Detrusor contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span (Figure 20).

**5.3.7.2.3. Acontractile detrusor:** The detrusor cannot be observed to contract during urodynamic studies resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span. The term “areflexia” has been used where there is a neurological cause but should be replaced by *neurogenic acontractile detrusor*.

**5.3.7.2.4 BOO:** This is the generic term for obstruction during voiding. It is a reduced UFR and/or presence of a raised PVR and an increased detrusor pressure. It is usually diagnosed by studying the synchronous values of UFR and detrusor pressure and any PVR measurements. A urethral stricture or obstruction due to higher degrees of uterovaginal prolapse or obstructed voiding after stress incontinence procedures are among possible causes.

## 7 | SECTION 6: IMAGING FOR PFF AND PFRD

This section profiles the imaging methods used worldwide in the evaluation of PFF and PFRD and defines the utility of each. Within the range of modalities, access and utilization will vary depending on global location, level of health system capacity in each country, and level of local facilities within countries. Imaging methods and PFF/PFRD applications defined here are radiologic, ultrasound, magnetic resonance and CT methods.

### 6.1 Ultrasound imaging

#### 6.1.1 Ultrasound 2-D methods

**6.1.1.1. Transabdominal (T-A)<sup>1</sup>:** Curvilinear scanning applied to the abdomen.

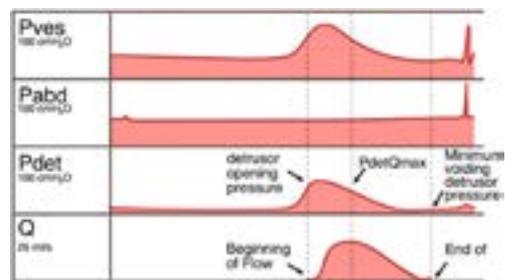

FIGURE 20 A schematic diagram of a pressure-flow study and pressure-flow parameters

**6.1.1.2 Perineal<sup>1</sup>:** Curved array probe applied to the perineum. Includes trans-perineal and trans-labial ultrasound.

**6.1.1.3 Introital<sup>1</sup>:** Sector probe applied to the vaginal introitus.

**6.1.1.4 Transvaginal (T-V)<sup>1</sup>:** Intravaginal curvilinear, linear array, or sector scanning.

**6.1.2 Ultrasound imaging 2-D PFF and PFRD applications**

**6.1.2.1 Bladder neck descent/mobility**

**6.1.2.1.1 Urethral funneling:** That is, opening of the proximal third of the urethra during coughing or on Valsalva. *NEW*.

**6.1.2.1.2 Urine loss:** Full urethral opening during coughing, Valsalva, bladder contraction or micturition. *NEW*

**6.1.2.2 Post void residual (PVR)<sup>1,2,45–47</sup>:** See Section 5.3.5 in investigations.

**6.1.2.3 Bladder and urethral masses/foreign bodies<sup>1</sup>:** Stone, tumor, foreign body or diverticula.

**6.1.2.4 Uterine, adnexal (upper genital tract) pathology<sup>1</sup>—Masses**

**6.1.2.5 POP<sup>1,3</sup>:** Visualization of descent of the bladder, cervix/uterus and rectum during Valsalva and coughing

**6.1.2.7 Uterine version<sup>1,3</sup>:** Anteverted, retroverted, flexion at isthmus (retroflexion)

**6.1.2.7 Postoperative findings<sup>1,3,9</sup>:** For example, bladder neck position and mobility, position of meshes, tapes, or implants.

**6.1.2.8 Pelvic floor/levator ani muscle:** Voluntary control, defect (“avulsion”) and ballooning.<sup>48,49</sup>

**6.1.2.9 Bladder wall thickness, and ultrasound estimated bladder weight (UEBW).** UEBW is higher in women with DO.<sup>50</sup>

**6.1.3 Ultrasound imaging—3-D methods:**

**6.1.3.1 Endo-vaginal ultrasound** imaging may compress tissues, distorting the anatomy.

**6.1.3.2 Trans-anal ultrasound** requires an expensive and dedicated transducer, is more uncomfortable and embarrassing.

**6.1.3.3 Trans-labial/trans-perineal** minimizes tissue distortion and patient discomfort.

**6.1.4 Ultrasound imaging 3-D PFRD applications**

**6.1.4.1 Levator ani muscle (LAM):** Trauma, atrophy, ballooning.<sup>48,49</sup>

**6.1.4.2 Anal ultrasound (Endosonography):** This is the gold standard investigation in the assessment of anal sphincter integrity. There is a high incidence of defecatory symptoms in women with anal sphincter defects.<sup>1,12</sup>

**6.1.4.3 Urinary tract pathology:** Stones, scarring, diverticula, tumors or foreign bodies.<sup>1,2</sup>

**6.1.4.4 Other assessments:** Synchronous ultrasound screening of the bladder and/or urethra and

measurement of the bladder and abdominal pressure during filling and voiding cystometry.

**6.2 Radiologic imaging**

**6.2.1 Pyelography of the urinary tract:** A technique to generate an image of the upper and lower urinary tract by the introduction of radiopaque fluid (intravenous or retrograde via the ureter).<sup>\*\*\*\*</sup>

**6.2.1.1 Intravenous urography (IVU)<sup>1,2</sup>:** Provides an anatomical outline of the upper urinary tract, ureters, and bladder as well as the evaluation of the kidney function and excretion of contrast media (Figure 21).

**6.2.1.2 Retrograde urethrocytography and voiding cystourethrography<sup>1,2</sup>:** Unidirectional or combined contrast imaging of the urethra in a patient in the 30-degree oblique position to visualize the lumen mainly to diagnose urethral strictures or diverticulum. It is also of use to diagnose and stage urethral trauma.

**6.2.1.3 Retrograde pyelograms:** May be performed when an IVU does not clearly define the anatomy of a suspected ureteral fistula.

**6.2.2 Video UDS<sup>1,2</sup>:** A functional test of the lower urinary tract in which filling cystometry and pressure-flow studies are combined with real-time imaging of the lower urinary tract<sup>2</sup> (Figure 22).

**6.2.3 HSG:** Is an imaging test to assess the endometrial cavity and fallopian tubes by introducing radiopaque fluid into the uterus. It may be used as an investigation for urinary and colorectal fistula tract into the uterus/cervix. *NEW*

**6.2.4 Contrast enema:** Is used to identify colonic pathology.<sup>12</sup> It is a retrograde radio-opaque imaging technique that may assist in the diagnosis of an anorectal tract fistula. Due to the open anorectal tract preventing

**FIGURE 21** (Right) Ureterovaginal fistula in a woman with a watery vaginal discharge. Video urodynamics was normal, but IVU shows obstruction of the left ureter (probably due to adjacent surgical clip (arrow), as well as a fistula, which is faintly outlined by contrast material and resultant opacification of the vagina. © L J Romanzi

**FIGURE 22** (Left) Video urodynamics showing vesico-vaginal Fistula. © L J Romanzi and Badlani (L'Hopital Nacional de Reference, Niamey, Niger 2003)

full luminal distension with radio-opaque contrast, a barium enema is prone to false-negative images following subsequent evacuation.<sup>12</sup>

### 6.3 CT

**6.3.1 CT urogram (CT-U)<sup>2</sup>:** CT study of the urinary tract system using injected intravenous contrast, used to clarify diagnoses such as (i) tumors; (ii) renal disease; (iii) abnormal fluid collections/abscesses (iv) bladder pathology.

**6.3.2 CT Kidneys, ureter, bladder (CT-KUB)<sup>2</sup>:** Non-contrast study aimed primarily at identifying stones but may identify other pathology. Also known as “stone protocol.”

**6.3.3 CT Imaging for fistula:** CT role is limited for imaging fistulas due to irradiation load on the patient combined with poor CT resolution of soft tissues. Radiopaque contrast improves soft tissue resolution. However multi-planar spiral CT provides accurate visualization of the pelvic floor soft and bony structures by reconstruction of axial images using 1 mm thick slices without gaps that provides high pelvic floor diagnostic accuracy (i.e., LAM trauma or fistula) (Figure 23). **NEW**

**6.4 MRI:** In PFF, MRI maybe used to demonstrate concurrent conditions, such as urethral diverticulum and non-palpable abscesses. Though restricted in availability in low resource regions, where available, MRI imaging is helpful in cases of complex fistulas with adjacent organ system pathology.

## 8 | SECTION 7: DIAGNOSIS

### 7.1 Urinary tract PFF diagnoses:

**7.1.1 Definition:** A diagnosis made by symptoms of a urinary tract fistula, signs of extraurethral leakage

**FIGURE 23** Computed tomography urogram showing fistula between the bladder and the vaginal vault. © S Elneil

assisted by a probe or irrigant fluids (dye test), with imaging as required. **NEW**

**7.1.2 Genito-urinary tract fistula:** An abnormal connection between the genital tract and urinary tract. **§§§§NEW**

**7.1.2.1 Specific diagnoses for lower urinary tract** may include:

**7.1.2.1.1 Deficiency of the urethra or urethro-vaginal fistula (UVaF—see 2.1.1 and 4.3.2.1):** Abnormal connection between the urethra and the vagina. **NEW**

**7.1.2.1.2 Vesicovaginal fistula (VVaF—see 2.1.2 and 4.3.2.2):** Abnormal connection between the bladder and the vagina. **NEW**

**7.1.2.1.3 Vesico-vaginal-vault fistula (VVtF—see 2.3.3):** Abnormal connection between the bladder and vaginal vault (cuff after hysterectomy).

**7.1.2.1.4 VCxF (see 2.4.1 and 4.3.2.3):** Abnormal connection between the bladder and the cervix. **NEW**

**7.1.2.1.5 VUtF (see 2.4.2 and 4.3.2.3):** Abnormal connection between the bladder and the body of the uterus. **NEW**

**7.1.2.2 Specific diagnoses for upper urinary tract** may include:

**7.1.2.2.1 UrVaF (see 2.1.4):** Abnormal connection of ureter into the vagina. **NEW**

**7.1.2.2.2 Uretero-cervical fistula (UrCxF—see 2.5.3):** Abnormal connection of the ureter into the uterine cervix. **NEW**

**7.1.2.2.3 UrUtF (see 2.5.3):** Abnormal connection of the ureter into the body of the uterus. **NEW**

**7.1.3 CoVF (see 2.7.1 and 4.3.2.4):** Abnormal connection between the bladder and either or both of the rectum and colon. **NEW**

**7.1.4 Single or multiple fistula sites:** The fistula may occur at a single or multiple sites with or without an ano/rectal/colo – fistula. **NEW**

#### 7.2 Anorectal tract PFF diagnoses

**7.2.1. Definition:** A diagnosis made by symptoms of an anorectal, signs of extra-anal leakage of feces or flatus, assisted by a probe or irrigant fluids (dye test), with imaging as required. **NEW**

**7.2.2 Genito-anorectal fistula:** An abnormal connection between the genital tract (vagina/uterus/cervix) and the anorectum. **NEW**

**7.2.3 Specific diagnoses:** may include:

**7.2.3.1. Deficient perineum/total perineal defect:** A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina. **NEW**

**7.2.3.2 Fourth degree perineal tear (4<sup>o</sup>PT—see 2.6.1.2):** Defined as an acquired childbirth injury and a subset of deficient perineum, involving both loss of the rectovaginal septum, full thickness anterior defect of the anal sphincter, and variable loss with lateral displacement of the fibromuscular architecture of the perineal body (cloacal-like defect). **NEW**

**7.2.3.3 Rectovaginal fistula (RVaF—see 2.6.2 and 4.4.4):** Abnormal connection between the rectum and the vagina.

**7.2.3.4 Recto-cervical fistula (RCxF—see 2.6.3):** Abnormal connection between the rectum and the uterine cervix. **NEW**

**7.2.3.5 Recto-uterine fistula (RUtF—see 2.6.3):** Abnormal connection between the rectum and the body of the uterus. **NEW**

#### 7.2.4 Complex recto-utero-cervical fistula

**7.2.4.1 RVaPeF (see 2.6.2.3):** An abnormal connection from the anal canal to the vagina or perineal area. **NEW**

**7.2.4.2 Recto-vesical fistula (RVF same as VRF—see 4.4.7):** Abnormal connection between the bladder and the rectum. **NEW**

**7.2.4.3 Recto/colo-uterine/cervical fistula (RCoUtF/RCoCxF—see 4.4.5):** An abnormal connection between the colo/rectum and uterus (body and/or cervix). **NEW**

**7.2.5 FIA (see 2.6.4 and 4.4.8):** An abnormal connection between the anal canal epithelium (or rarely rectal epithelium) and the skin epithelium. **CHANGED**

**7.2.6 Single or multiple fistula sites:** The fistula may occur at a single or multiple sites with or without a urinary tract fistula. **NEW**

#### 7.3 Incontinence diagnostic categories

Fistula patients are typically pooled into three broad global health treatment outcome categories.<sup>48</sup> These are:

**7.3.1 Fistula closed and continent:** Fistula closed after treatment (surgical or nonsurgical) without persistent or residual incontinence of the organ system (urinary tract or anorectal tract) that had the fistula. **NEW**

**7.3.2 Fistula closed and incontinent:** Fistula closed after treatment (surgical or nonsurgical) with persistent or residual incontinence of the organ system (urinary tract or anorectal tract) that had the fistula. **NEW**

**7.3.3 Fistula not closed:** Fistula not closed during or after treatment (surgical or nonsurgical). Not-closed fistula have defined subcategories including: **NEW**

**7.3.3.1 Persistent fistula diagnosis (see 3.4.1):** Fistula that is not closed at conclusion of surgical or nonsurgical intervention or that re-opens in the immediate postintervention period. These treatment failures result from acute failure of wound healing or, in the specific case of failure to close the defect during surgical interventions, intra-operative failure of surgical technique. **NEW**

**7.3.3.2 Recurrent fistula diagnosis (see 3.4.2):** Fistula that is closed post treatment, but recurs due to delayed failure of wound healing, or occurs subsequent to a follow-on index fistula-causing event. Subsequent index acquired fistula events are most commonly childbirth, surgery or pelvic trauma, but may also be inflammatory disease, infections, and pelvic malignancy. **NEW**

#### 7.4 Woman deemed incurable (WDI)

**7.4.1 WDI diagnosis (see 3.5.7):** Women with primary, persistent, and recurrent fistula for which anatomic repair is not possible. WDI require either supportive management and/or a diversion procedure, or they have a fistula complexity that exceeds the capacity(s) of the highest available surgical facility. **NEW**

#### 7.5 PFRD functional urinary diagnoses

**Storage dysfunction (SD)<sup>2</sup>** Those diagnoses related to abnormal changes in bladder sensation, detrusor pressure, or bladder capacity during filling cystometry.

##### Bladder Factor

**7.5.1 Bladder oversensitivity (BO—see 5.3.6.8.1)<sup>1,2</sup>**

**7.5.1.1 Definition<sup>1,2</sup>:** Bladder oversensitivity, a clinical diagnosis made by *symptoms and urodynamic investigations* is defined as increased perceived bladder sensation during bladder filling with specific cystometric findings of (i) early first desire to void; (ii) early strong desire to void, which occurs at low bladder volume; (iii) low maximum cystometric bladder capacity; and (iv) no abnormal increases in detrusor pressure. Specific bladder volumes at which these findings occur vary in different populations.

**7.5.2 DO (see 5.3.6.9.2)<sup>2</sup>**

**7.5.2.1 Definition<sup>1,2</sup>:** This diagnosis by *symptoms and urodynamic investigations* is made in individuals with LUTSs, more commonly overactive bladder symptoms when detrusor muscle contractions occur during filling cystometry.

#### 7.5.2.2 Subtypes

**(i) Idiopathic (primary) DO<sup>2</sup> (see 5.3.6.9.2.1):** No identifiable cause for the involuntary detrusor contraction(s).

**(ii) Neurogenic (secondary) DO<sup>2</sup> (see 5.3.6.9.2.2):** There is DO and evidence (history; visible or measurable deficit) of a relevant neurological cause.

**(iii) Non-neurogenic (secondary) DO<sup>2</sup> (see 5.3.6.9.2.3):** An identifiable possible non-neurological cause exists for involuntary detrusor contraction(s) during bladder filling, e.g. functional (obstruction); stone, tumor, UTI.

**7.5.3 Reduced compliance storage dysfunction (RCSD—see 5.3.6.9.3)<sup>2</sup>:** A diagnosis by *symptoms and urodynamic investigations* is made in individuals with LUTSs, more commonly storage symptoms, when there is a non-phasic (at times linear or exponential) rise in detrusor pressure during filling cystometry with generally reduced capacity indicating reduced compliance.

**7.5.3.1 Reduced compliance (RCSD) incontinence<sup>2</sup>:** Urinary incontinence directly related to the RCSD.

**7.5.4 Outlet Factor (Urethra/Sphincter dysfunction—decreased urethral resistance—incompetence/insufficiency)**

#### 7.5.4.1 USI (see 5.3.6.10.3)<sup>1,2</sup>

**7.5.4.1.1 Definition<sup>1,2</sup>:** A diagnosis by *symptom, sign and urodynamic investigations* involves the finding of involuntary leakage during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor muscle contraction.

**7.5.4.1.2 Subtype: ISD (see 5.3.6.10.4)<sup>2</sup>:** Very weakened urethral closure mechanism.

**Voiding dysfunction (VD)<sup>2</sup>:** Those diagnoses related to abnormally slow and/or incomplete bladder emptying manifest as an abnormally slow UFR and/or an abnormally high PVR with confirmation by pressure-flow studies (including any related imaging).

**7.5.5 Bladder factor—(Poor or absent detrusor activity)**

**7.5.5.1 Detrusor underactivity (DUA—see 5.3.7.2.2)<sup>2</sup>**

**7.5.5.1 Definition of DUA<sup>2</sup>** A diagnosis based on *urodynamic investigations* generally (but not always) with relevant *symptoms* and *signs* manifest by low detrusor pressure or short detrusor contraction in combination with a low UFR resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying

within a normal time span, with or without a high PVR (c.f. “hypocontractile detrusor”—detrusor contraction of reduced strength)

**7.5.5.2 Detrusor acontractility (DAC—see 5.3.7.2.3)<sup>2</sup>**

**7.5.5.2.1 Definition of DAC<sup>2</sup>:** A diagnosis by *urodynamic investigation*, generally (but not always) with relevant *symptoms* and *signs* manifest by the absence of an observed detrusor contraction during voiding studies resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span.

#### 7.5.5.2.2 Subtypes

**7.5.5.2.2.1 Neurogenic detrusor acontractility<sup>2</sup>**

**7.5.5.2.2.2 Non-neurogenic detrusor**

**accontractility<sup>2</sup>**

**7.5.6 Outlet factor (urethral/sphincter dysfunction)**

**7.5.6.1 Bladder outlet obstruction (BOO)<sup>2</sup>**

**7.5.6.1.1 Definition of BOO<sup>2</sup>:** A diagnosis based on *urodynamic investigations (pressure-flow studies ± imaging)*, generally (but not always) with relevant *symptoms* and/or *signs*, manifest by an abnormally slow UFR with evidence of abnormally high detrusor voiding pressures and abnormally slow urine flow during voiding cystometry with or without an abnormally high PVR.

**7.5.6.1.2 Possible sites/causes of BOO:** Can be:

**5.4.1.2.1 Functional<sup>2</sup>:** Bladder neck obstruction, detrusor sphincter dysfunction, pelvic floor overactivity. *NEW*

**5.4.1.2.2 Mechanical<sup>2</sup>:** Urethral stricture, meatal stenosis. Video UDS can sometimes be required to ascertain the cause/site.

**7.5.7: Alternate presentations of voiding dysfunction**

**7.5.7.1 Acute retention of urine<sup>2</sup>:** An individual is unable pass any urine despite having a full bladder, which on examination is painfully distended, and readily palpable and/or percussible. *CHANGED*

**7.5.7.2 Chronic retention of urine<sup>2</sup>:** Generally (but not always) painless and palpable or percussible bladder, where there is a chronic high PVR. The patient experiences slow flow and chronic incomplete bladder emptying but can be asymptomatic. Overflow incontinence can occur.

**7.5.7.3 Acute on chronic retention<sup>2</sup>:** An individual with chronic retention goes into acute retention and is unable to void.

**7.5.7.4 Retention with overflow<sup>2</sup>:** Involuntary loss of urine directly related to an excessively full bladder in retention.

#### 7.6 PFRD—OTHER DIAGNOSES

**7.6.1 POP<sup>1,3</sup> (see 3.7)**

**7.6.1.1 Definition:** A diagnosis by *symptoms and clinical examination, assisted by any relevant*

*imaging*, involves the identification of descent of one or more of the anterior vaginal wall (central, paravaginal or combination cystocele), posterior vaginal wall (rectocele), the uterus (cervix) or the apex of the vagina (vaginal vault or cuff scar) after hysterectomy. The presence of any such sign should correlate with relevant POP symptoms.

#### 7.6.2. Recurrent UTIs<sup>1</sup> (see 3.6.3)

**7.6.2.1 Definition:** A diagnosis by *clinical history* assisted by *the results of diagnostic tests* involves the determination of the occurrence of at least three symptomatic and medically diagnosed UTI over the previous 12 months.

#### 7.6.3 Anorectal incontinence (see 3.10.10):

**7.6.3.1 Definition:** a diagnosis is by *symptoms and clinical examination* assisted by the results of *investigations* (anorectal manometry) and *imaging* (endoanal ultrasonography). At times, endoscopic evaluation may be required. **NEW**

**7.6.3.2 Sphincteric anorectal incontinence:** Anal sphincter defects or weakness are present. **NEW**

**7.6.3.3 Urge anorectal incontinence:** Incontinence is due to involuntary anorectal spasms. **NEW**

**7.6.3.4 Artefactual anorectal incontinence:** Ineffective, inflammatory or neoplastic etiology is identified. **NEW**

## 9 | SECTION 8: CONSERVATIVE (NONSURGICAL) MANAGEMENT<sup>51-53</sup>

**8.1 Conservative management<sup>13</sup>:** Restricted to non-surgical and nonpharmacological treatments.

### 8.2 Lifestyle interventions

**8.2.1 Indications:** Lifestyle intervention may be optimized to manage the chronic incontinence in:

**8.2.1.1 Nonsurgical:** Women who are not candidates for surgical treatment. **NEW**

**8.2.1.2 Surgery not preferred:** Women who prefer not to undergo surgical treatment. **NEW**

**8.2.1.3 Urinary catheter not possible:** Women who are also not candidates for nonsurgical catheter treatment. **NEW**

### 8.2.2 Types of lifestyle interventions (urinary incontinence)

**8.2.2.1 Skin protection:** Protective dermal emollients to reduce dermatitis on the vulva, legs and feet. **NEW**

**8.2.2.2 Pads:** Adequate, preferably reusable, large pads or adult diapers.<sup>13</sup>

**8.2.2.3: Urethral plugs<sup>13,54</sup>:** Products to block the urethral meatus in women with stress urinary incontinence after fistula closure. **CHANGED**

**8.2.2.4 Vaginal lubricants<sup>13</sup>:** Pharmacological preparations aimed at reducing friction during coital or any other sexual activity and therefore alleviating dyspareunia, or at least reducing discomfort associated with clinical examination of the vagina or rectum. Pharmacological and natural plant-based oils may be used.

**8.2.2.5 UTI prophylaxis:** Prophylactic antibiotics/antibacterial (e.g. hexamine hippurate) to reduce the incidence of recurrent or postcoital UTI.

### 8.2.3. Types of lifestyle interventions (anorectal incontinence) Anorectal lifestyle interventions include:

**8.2.3.1: Dietary modification:** To minimize flatus and loose-liquid stool. **NEW**

**8.2.3.2: Skin protection:** Protective dermal emollients for the vulva, legs, and feet. **NEW**

**8.2.3.3: Pads:** Adequate, preferably reusable, large pads or adult diapers.<sup>13</sup>

**8.2.3.4: Vaginal lubricants<sup>13</sup>:** Pharmacological preparations aimed at reducing friction during coital or any other sexual activity and therefore alleviating dyspareunia, or at least reducing discomfort associated with clinical (per vagina or per rectum examination). Pharmacological and natural plant-based oils may be used.

### 8.3 Catheter insertion

Inserting a catheter when an acute lower urinary tract injury is diagnosed may result in closure of the fistula, or reduced size of the fistula before subsequent surgical intervention.<sup>52</sup>

**8.3.1 Bladder catheterization:** May be used for secondary prevention or nonsurgical treatment of bladder fistula.<sup>55</sup> **NEW**

**8.3.2 Ureteral catheterization (cystoscopic):** May be used for secondary prevention or nonsurgical treatment of ureteric fistula. Care must be taken to evaluate the healed ureter for secondary ureteric stenosis that may result in secondary obstructive nephropathy after fistula treatment. **NEW** Ureteric catheterization may be used during the repair of vesicovaginal and ureteric fistulas. It is not a treatment for ureteric fistulas.

### 8.4 Physical therapy

**8.4.1 Pelvic physiotherapy—General:** Assessment, prevention, and/or treatment of pelvic floor dysfunction, performed by a pelvic physiotherapist. The therapy aims at reducing symptoms of fistula and post-fistula treatment incontinence symptoms as well as improvement of pelvic floor function.<sup>56</sup> The role of continence nurses amongst other allied health professionals in performing some of these specialized therapies is acknowledged.

**8.4.2 Other therapies:** Covers many specialized therapies that can be used to train the pelvic floor including<sup>13</sup>:

**8.4.2.1 Therapeutic exercise<sup>13</sup>:** Consists of interventions directed toward maximizing functional capabilities.

**8.4.2.2 Cognitive behavioral therapy<sup>13</sup>:** Cognitive techniques used in association with behavior therapy principles.

**8.4.2.3 Bladder training<sup>13</sup>:** Consists of a program of patient education, along with a scheduled voiding regimen with gradually adjusted voiding intervals.

**8.4.2.4 Bowel habit training<sup>13</sup>:** Is aimed at establishing a regular, predictable pattern of bowel evacuation by patient teaching and adherence to a routine to achieve a controlled response to bowel urgency.

**8.4.2.5 Muscle training<sup>13</sup>:** Exercise to increase muscle strength, endurance, flexibility or relaxation.

**8.4.2.6 Coordination training<sup>13</sup>:** Is the ability to use different parts of the body together smoothly and efficiently.

**8.4.2.7 Biofeedback<sup>13</sup>:** The use of an external sensor to give an indication with regard to bodily processes, usually with the purpose of changing the measured quality.

**8.4.2.8 Electrical muscle stimulation<sup>13</sup>:** Is the use of electric potential or currents to elicit therapeutic responses. Current may be directed at motor or sensory functions.

In those fistula patients with flexure injuries, and/or foot drop, musculo-skeletal physiotherapy can be helpful in preparing the patient for surgery.

## 10 | SECTION 9: SURGICAL MANAGEMENT

### 9.1 General fistula surgical terminology

**9.1.1 Biological grafts<sup>9</sup>:** Any isolated healthy tissue for transplantation into fistulous area to augment or strengthen the repair.

**9.1.1.1 Autologous grafts<sup>9</sup>:** From patient's own tissues, for example, rectus sheath or fascia lata.

**9.1.1.2 Allografts<sup>9</sup>:** From post-mortem human tissue banks. Not often used in fistula surgery e.g. fascia lata.

**9.1.1.3 Xenografts<sup>9</sup>:** From other species, for example, modified porcine dermis, porcine small intestine, and bovine pericardium. Occasionally used in fistula surgery.

#### 9.1.2 Autologous grafts and flaps

**9.1.2.1 Labia majora fat-flap:** The use of labial fibro-adipose tissue underneath the labia majora (Figure 24). *NEW*

**9.1.2.2 Labia minora flap:** The use of labia minora to provide a skin flap to help reconstruct the vagina. *NEW*

**9.1.2.3 Buttock and perineal skin rotation flaps:** The use of skin flaps from the buttock/perineal area to

FIGURE 24 Labial fat-flap mobilized from the right labium (© J Goh)

provide interposition fat and blood supply as well as increased vaginal skin surface area. *NEW*

**9.1.2.4 Peritoneal grafts and flaps:** The use of peritoneum flap/graft to provide interposing tissue and blood supply as well as increased vaginal non-dermal surface area. It may be used at vaginal or abdominal surgery. *NEW*

**9.1.2.5 Omental flap:** The use of omentum to provide interposing fat and blood supply during abdominal surgery. *NEW*

**9.1.2.6 Muscle flap:** The use of muscle, for example, gracilis muscle or rectus abdominus muscle flap to provide tissue and blood supply. *NEW*

**9.1.2.7 Rectal advancement flap:** Mobilize/elevating a flap of the rectum above/below the fistula and using the flap to close over the fistula. *NEW*

**9.1.2.8 Singapore flap (pudendal thigh/groin vasculocutaneous flap):** For vaginal reconstruction (not dissimilar to 9.1.2.3).

**9.1.2.9 Colonic flaps:** For vaginal reconstruction of a large PFF in the presence of complete vaginal loss.

### 9.2 Fistula repair surgery

#### 9.2.1 Minor fistula surgery

**9.2.1.1 Cystoscopic cauterization of fistula:** Cauterization of the fistula under direct vision via cystoscopy. Used for tiny fistulas and may succeed. This is usually combined with prolonged catheter drainage. Theoretically, light (judicious) cautery of the fistula, allowing the bladder and vaginal tissues to heal (Figure 25). *NEW*

**9.2.1.2 Debridement of fistula:** Defined as removal of damaged tissue or foreign objects from a wound. May successfully be engaged as a primary therapy for small fresh RVaF and adjunctively for nonsurgical catheter treatment of VVaF.<sup>50</sup> *NEW*

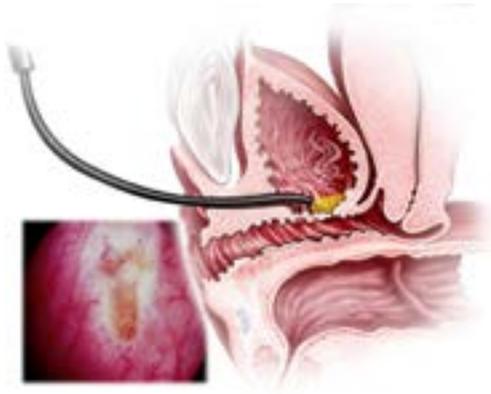

FIGURE 25 Light (judicious) fulguration of the fistula. (left) ©G Ghoniem (right) © Levent Efe

## 9.2.2 Major fistula repair surgery

Principles of all fistula surgery include:

**9.2.2.1 Patient counseling:** On the possibility of complications, including failure, and staged care. *NEW*

**9.2.2.2 Optimizing patient health:** Operating on patients who are in optimal health for wound healing. *NEW*

**9.2.2.3 Tissue handling:** Careful tissue handling during dissection and suturing. *NEW*

**9.2.2.4 Wide dissection** to well-mobilize the fistulized organs from each other. *NEW*:

**9.2.2.5 No tension:** Close the fistula defects under no tension. *NEW*

**9.2.2.6: Flaps and grafts:** Judicious use of autologous interposition flaps and grafts to assure adequate blood supply for wound healing. *NEW*

**9.2.2.7: Optimize functional result:** Attention paid to both form (close the hole) and function (restore normal function to the urinary, genital and anorectal tracts). *NEW*

**9.2.2.8 Intercurrent prolapse and incontinence surgery:** Including but not limited to judicious use of prolapse reconstructive and incontinence procedures for concurrent pelvic floor disorders during the fistula repair. *NEW*

**9.2.2.9 Bladder drainage:** Catheterization

## 9.3 Measuring outcome in PFF surgeries<sup>11</sup>

As per IUGA-ICS Report on outcome measures for pelvic floor surgery,<sup>11</sup> every study evaluating pelvic floor surgery should report.

**9.3.1 Perioperative data<sup>11</sup>:** That is, blood loss, operating time, length of hospital stay, return to normal activities, and complications.

**9.3.2 Subjective (patient-reported) outcomes<sup>11</sup>:** At its simplest level, this can be reported as the presence or absence of urinary/fecal incontinence. Patient satisfaction and quality of life can be measured by validated instruments that cover fistula, prolapse, urinary, bowel, and sexual function. Reproductive outcomes are also a consideration: for example, menstruating, able to conceive and carry a pregnancy to term.

**9.3.3 Objective outcomes<sup>11</sup>:** PFF-staging measurements tabulated with absolute values and percentages to allow other studies to compare results.

**9.3.4 Secondary outcomes<sup>11</sup>:** For example, LUTS, stress urinary incontinence or bowel and sexual dysfunction, in their studies whenever possible.

### 9.3.5 Surgery type:

**9.3.5.1 Primary surgery<sup>11</sup>:** Indicates the first procedure required for treating PFF in any compartment.

**9.3.5.2 Further surgery<sup>11</sup>:** Provides a term for any subsequent procedure relating to primary surgery. Further surgery is subdivided into:

**9.3.5.2.1.** Primary surgery in a different site/compartment.

**9.3.5.2.2.** Repeat surgery in the same site/compartment for PFF symptom recurrence.

**9.3.5.2.3.** Surgery for complications, for example, pain, infection, recurrent/persistent incontinence, or hemorrhage.

**9.3.5.2.4.** Surgery for non-PFF-related conditions usually prolapse, new onset urinary (e.g. stress urinary incontinence), or flatal/fecal incontinence.

### 9.3.6: Complications of PFF surgeries

TABLE 1 Total, new and changed definitions (compared with previous definitions in the ICS glossary)

Section	New definitions/descriptors	Changed definitions/descriptors	Total
Introduction, etiology	16	0	16
Classification	27	0	27
Symptoms	22	0	90
Signs	45	3	56
Investigations	11	0	71
Imaging	4	0	31
Diagnoses	37	0	64
Conservative management	10	1	29
Surgical management	16	0	32
Total	188 (45%)	4 (1%)	416

Complications related to PFF native tissue repair and surgeries using graft have been classified separately according to joint IUGA/ICS recommendation.<sup>10</sup> The system used in both documents utilizes specific category, time, and site taxonomy together referred as *CTS (Category, Time, Site) classification system*.

Classification is aided by on line calculators at either <http://www.ics.org/complication> or <http://www.ics.org/ntcomplication>.

## ACKNOWLEDGMENTS

No discussion on terminology should fail to acknowledge the fine leadership shown by the ICS over many years. The legacy of that work by many dedicated clinicians and scientists is present in all the Reports by the different Standardization Committees. It is pleasing that the ICS leadership has generously supported this initiative, including the funding of the majority of the figures, as a means of progress in this important and most basic area of PFF. This document was initiated at ICS Tokyo (SE, BH—September 2016) and formalized in London (June 2017—SE Chair) with LR as Co-chair (ICS Florence, September 2017) and JG as Co-chair from early 2019 with BH from October 2019. Working Group (WG) live meetings have been held in Florence (September 2017), Philadelphia (August 2018), and Gothenburg (September 2019). At Version 12 (early 2019), it had involved 11 rounds of review and writing by co-authors to form an interim draft. After some delays, formal editing, large sections of rewriting, and additions as well as formatting occurred (October–December 2019—JG, BH with help from LR) to create, for the first time, a “journal-ready” Version 13. There were a further two rounds of WG review, with the collation of comments and then the insertion of Figures to form Version 16 (JG, BH with help from LR). External review (8 experts—Version 17) was followed by website publication (Version 18). Sign-off has included ICS Standardization Steering Committee (Version 19) and ICS Board reviews (collation of comments V17–V19 and journal submission—JG, BH). Version 20 (post-Board review) will be submitted for NAU journal publication. We are extremely grateful for the eight expert external reviewers (Prof. Ganesh Dangal, Dr. Andrew Browning, Prof. Dirk De Ridder, Dr. Hannah Krause, Dr. Chris Payne, Dr. Tamsin Greenwell, Prof. Sayeba Akhter, Dr. Linda Ferrari). All of these colleagues provided excellent feedback. We thank the other colleagues who have provided comments on the website reviews including Prof. Hashim Hashim. This document has been greatly enhanced by the medical illustrations of Levent Efe, [www.leventefe.com.au](http://www.leventefe.com.au), who's ongoing work for ICS has been greatly appreciated. This document and all the **NEW** or **CHANGED** definitions will be uploaded

to the **ICS GLOSSARY** ([www.ics.org/glossary](http://www.ics.org/glossary)) where immediate electronic access to definitions and document download is available.

## DISCLOSURES

Sohier Elneil: Saluda Medical, Astellas, Bluewind Medical. Lauri Romanzi: No disclosures. Judith Goh: No disclosures. Bernard Haylen: No disclosures. Chi Chiung Grace Chen: No disclosures. Gamal Ghoniem: Cogentix Medical, Laborie. Munir'deen Aderemi Ijaiya: No disclosures. Soo Kwon: No disclosures. Joseph Lee: Astellas. BSCI. Sherif Mourad: Astellas, Ferring. Rajeev Ramanah: No disclosures. Mohan Regmi: No disclosures. Raheela Mohsin Rivzi: No disclosures. Rebecca Rogers: Astellas, royalties from Uptodate, Travel and stipend from IUGA, ACOG and ABOG. Jonathan Shaw: No disclosures. Vivian Sung: No disclosures.

## ENDNOTES

\* Total perineal defect: see Section 2.

† Total perineal defect<sup>12</sup>: A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance.

‡ Recto(colo)-ureteric fistula is created electively after ureteric diversion into the bowel for the management of PFF but can occur following colorectal surgery for cancer and inflammatory pathologies.

§ There are multiple classification systems published. Section 2.8 briefly mentions the more commonly used systems. Commonly used anatomical descriptions of PFF such as “urethral,” “mid-vaginal,” and “juxta-cervical” are terms from various published classification systems (see Goh et al.<sup>23,24</sup> for a more extensive review). There is currently no consensus on a classification for PFF and a comprehensive review on published classification systems was undertaken previously.<sup>23</sup> Below are commonly used PFF classifications.

\*\* Classification System A: The Francophone System,<sup>24,25</sup> developed in 1959, has been for use in urinary tract PFF and is used in Francophone (French-influenced) Africa. It divides the fistula into “simple,” “complex,” or complicated with significance placed on destruction of bladder neck, urethra, and scarring. It is the original classification system that was translated into English to create the basis for the Waaldijk classification system.

†† Classification System B: The Waaldijk System,<sup>26</sup> published in 1995, is based on whether the continence mechanism is impaired and on the extent of circumferential damage. In the original paper, the classification of the fistula was performed under anesthesia. Type I fistulas do not involve ‘the closing mechanism’ whilst Type II involves “the closing mechanism.” The definition of the “closing mechanism” is unclear. Type III are ureteric and “other exceptional fistulas.” There is a sub-classification according to the size of the fistula. Studies have been conducted to assess this system. Comparative study with other systems demonstrates the Waaldijk system to be less predictive of closure.

‡‡ Classification System C: The Goh System,<sup>27</sup> published in 2004, is based on fixed reference points. The external urinary meatus (or its site if the urethra is absent) is the reference point for genito-urinary

- fistulas and the hymen is the reference point for anorectal-vaginal fistulas. This system is based on distance from these fixed reference points, size of the fistula, presence of scarring, and other “special” circumstances such as radiation fistulas, circumferential fistulas, recurrent fistulas. Published studies using this system include intra- and interobserver concordances,<sup>28</sup> correlations with urinary incontinence after surgical closure and grade of fistula<sup>29</sup> and comparative studies with other systems.<sup>30</sup>
- <sup>§§</sup> Classification System D: The Panzi Hospital System,<sup>31</sup> published in 2018, is also known as the Panzi score. It is a descriptive and predictive scoring system based on retrospective review of surgical failure of fistula repair using characteristics from the Goh<sup>27</sup> and Waaldijk<sup>26</sup> systems. A scoring system was constructed by using the data obtained, correlating the score to likelihood of surgical outcomes. The score is based on whether the fistula is circumferential, the location and size of the fistula.
- <sup>\*\*\*</sup> About 1 in 4 women complains of ongoing urinary incontinence after successful fistula closure.<sup>29</sup> Urodynamic studies were performed in 149 women with post-fistula incontinence.<sup>34</sup> The most common diagnoses were urodynamic stress incontinence in 49%, mixed urodynamic stress incontinence and detrusor overactivity in 43%. Seven percent of women had a postvoid residual urine of 150 ml or more (which is high and significant, particularly in a partially destroyed bladder that has a maximum capacity of 150 ml).
- <sup>†††</sup> Women deemed incurable: In some facilities, this includes women with severe incontinence symptoms after successful fistula closure. These women also fall under “closed and Incontinent” category.
- <sup>††††</sup> It is important to take into consideration past history during examination and evaluation of the fistula e.g. radiation therapy. The signs will be documented according to anatomic findings.
- <sup>§§§</sup> Although the fistula is described from discrete anatomical sites, the fistula may involve 2 or more sites e.g. urethro-vesicovaginal fistula. A “vault/cuff fistula” is often a name given to a post-hysterectomy fistula from the bladder to the vagina. A “vault/cuff fistula” is a vesico-vaginal fistula.
- <sup>\*\*\*\*</sup> Urethro-vaginal fistula: There may be a common cavity made up of the anterior vaginal wall with a defect at or above the level of the bladder neck, indicative of total loss of the urethra (anterior and posterior walls) in the most extreme form – very difficult to cure. Lesser urethral deficiencies may involve variable degrees of loss of the urethra distal to the bladder neck, or congenital or acquired hypospadias.
- <sup>†††††</sup> Uretero-colonic fistula—This may be iatrogenic after ureteric diversion into the bowel for example, in the management of women with complex recurrent or persistent urinary fistula symptoms.
- <sup>††††††</sup> PFRD signs can result from neuropraxia of the sacral nerve roots (which control lower extremity function as well as bladder/bowel function), pelvic fibrosis, vaginal stenosis, cervical atrophy or stenosis, diastasis, or exposure of the pelvic bones.
- <sup>§§§§</sup> In such cases, it is common for intraoperative post-closure blue test to be negative, with clear urine pooling in the fornix, indicating persistence of an upper urinary tract (ureteric) fistula that may not have been diagnosed presurgery.
- <sup>\*\*\*\*\*</sup> Cystoscopy may also be used to:
- Evaluate suspected upper urinary tract fistula of the ureters through retrograde pyelography, to insert ureteric catheters at the time of repair of small lower urinary tract fistula that are in proximity to the ureters
  - To undertake ureteric catheter insertion for nonsurgical treatment of ureteric fistula.
  - To evaluate persistent fistula-related disorders of the lower urinary tract, such as poor bladder compliance and reduced bladder capacity, foreign bodies, bladder, and urethral diverticula, neurogenic bladder, and drainpipe urethra.
  - Ureteroscopy may be used to diagnose ureteric fistula and to assess for PFRD co-morbidities of ureteric fibrosis and stenosis or ureteric stones through direct visualization.
- <sup>†††††††</sup> Lower urinary tract symptoms (LUTS) may occur after closure of a lower urinary tract (bladder or urethra) fistula or may co-exist and persist after repair of an upper urinary tract (ureteric) or anorectal tract fistula. For persistent fistula-related disorders (PFRD) of the lower urinary tract, multi-channel urodynamics may be employed to evaluate complex bladder dysfunction symptoms that persist or occur de novo after successful PFF repair. It is understood that these may be aspirational investigations/technologies in many resource-constrained communities.
- <sup>††††††††</sup> Intravenous (antegrade) or retrograde pyelography may be used to evaluate for upper and lower urinary tract fistulas, urethral diverticulum, tumors, strictures, stenosis, stones, foreign bodies, hydronephrosis, hydro-ureter and other upper and lower urinary tract disease, for example, medullary sponge kidney.
- <sup>§§§§§§</sup> The diagnosis of urinary tract PFF may be defined by the anatomical location of the fistula (see Section 4), for example, urethra-vaginal fistula. Larger fistulas often occur over more than one anatomical site, for example, involving both urethra and bladder.
- <sup>\*\*\*\*\*</sup> The diagnosis of anorectal tract PFF may be defined by the anatomical location of the fistula (see Section 4) but larger fistulas may occupy more than one anatomical site.
- <sup>†††††††††</sup> The making of a WDI diagnosis is often, but not always, conditional. Of all categories, this is perhaps the most difficult diagnostic group and will be discussed further. Women in this category suffer with fistulas that are beyond the health system’s capacity to repair in an anatomically normal way, or who are unable or unwilling to undergo diversion of the urinary or anorectal tract for nonanatomic repair of their fistula. The categorization of women with fistula as “incurable” often occurs in the context of evaluation by a single clinician, usually but not always a fistula surgeon of variable level of expertise, working in an under-resourced environment with systems gaps that preclude achievement of a minimum acceptable standard of care for complex, elective reconstructive surgery.<sup>49</sup> The limitations to single-surgeon diagnosis for WDI include<sup>49</sup> (i) informed only by their skills and experience; (ii) criteria not standardized; (iii) patient is often excluded from the decision process; (iv) patient is often not adequately counseled on her health situation.
- <sup>††††††††††</sup> It could include those women who have their fistula closed but still remain incontinent despite repeated operations for ongoing incontinence.
- <sup>§§§§§§§§</sup> Limitations of WDI Diagnostic Criteria include but are not limited to (i) fistula complexity that precludes reconstruction of normal pelvic anatomy due to significant loss of tissue (bladder,

anorectum, vagina) with or without dense pelvic fibrosis and/or vaginal stenosis; (ii) socio-cultural and/or geopolitical constraints that preclude safe nonanatomic diversion and/or graft-based reconstructive surgery (bladder augmentation, intestinal or other graft source neo-vagina, etc); (iii) health systems constraints that preclude successful service provision of advanced, complex anatomic, or nonanatomic reconstructive surgery including staff (surgeon, anesthetic, nursing), facilities/equipment/infrastructure, accessibility, and affordability.

\*\*\*\*\* The labia majora fat flap has blood supply both proximally (inferior epigastric and clitoral vessels) and distally (pudendal vessels). The flap may be divided at proximal or distal ends whilst maintaining its blood supply.

## Abstract

**Introduction:** The terminology for female and male pelvic floor muscle (PFM) assessment has expanded considerably since the first PFM function and dysfunction standardization of terminology document in 2005. New terms have entered assessment reports, and new investigations to measure PFM function and dysfunction have been developed. An update of this terminology was required to comprehensively document the terms and their definitions,

Beth Shelly and Giuseppe Alessandro Digesu: Standardization Steering Committees ICS.

1217

and to describe the assessment method and interpretation of the finding, to standardize assessment procedures and aid diagnostic decision making.

**Methods:** This report combines the input of members of the Standardisation Committee of the International Continence Society (ICS) Working Group 16, with contributions from recognized experts in the field and external referees. A logical, sequential, clinically directed assessment framework was created against which the assessment process was mapped. Within categories and subclassifications, each term was assigned a numeric coding. A transparent process of 12 rounds of full working group and external review was undertaken to exhaustively examine each definition, plus additional extensive internal development, with decision making by collective opinion (consensus).

**Results:** A Terminology Report for the symptoms, signs, investigations, and diagnoses associated with PFM function and dysfunction, encompassing 185 separate definitions/descriptors, has been developed. It is clinically based with the most common assessment processes defined. Clarity and user-friendliness have been key aims to make it interpretable by clinicians and researchers of different disciplines.

**Conclusion:** A consensus-based Terminology Report for assessment of PFM function and dysfunction has been produced to aid clinical practice and be a stimulus for research.

#### KEYWORDS

clinical assessment, diagnosis, muscle dysfunction, pelvic floor

## 1 | INTRODUCTION

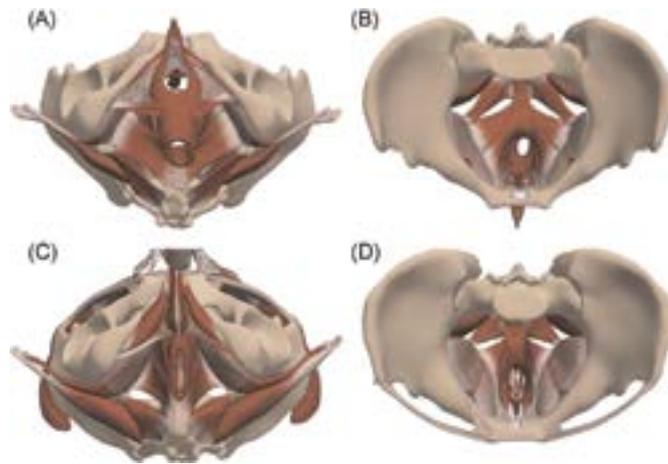

The current terminology used in the assessment and diagnosis of pelvic floor muscle (PFM) function and dysfunction is both diverse and variably defined, with no current consensus which captures, defines, and describes all terms. This document lists and describes terms which are used in the neuro-myo-fascial assessment and diagnosis of the PFM to aid teaching and standardization of terminology in this field. The terminology covers the assessment of both structure and function of the PFM. The pelvic floor structures defined in this document include muscular tissues in the pelvic floor and their neural connections, and the fascial (connective tissue) layers surrounding the PFM fibers/fascicles. In this document, assessment of the PFM is presented according to the perineal and pelvic regions of PFM. While PFM anatomy nomenclature varies according to texts, the following structures are considered to be the muscles that make up the perineum and the pelvic floor/levator ani.<sup>1</sup> The perineal region is divided into the anterior and posterior triangles. The anterior urogenital triangle comprises the superficial urogenital muscles (bulbospongiosus/

bulbocavernosus, ischiocavernosus, and the superficial transverse perinei), and the deep urogenital muscles (external urethral sphincter and deep transverse perinei). The posterior (anal) triangle comprises the external anal sphincter. The levator ani is comprised of pubococcygeus (which includes puborectalis, pubovisceralis, pubovaginalis, etc.), iliococcygeus, and ischiococcygeus/coccygeus (considered vestigial). The female and male perineal and PFM, inferior and superior views, are illustrated in Figure 1 (see page 3).

When referencing this document, the reader is asked to keep the term in context with PFM assessment. The PFM terms included apply to adult females and males presenting with different types of pelvic floor disorders. Assessment techniques are undertaken externally (*per perineum* [PP], and internally (*per vaginam* [PV] or *per rectum* [PR]). Where the definition or description of the term requires modification to differentiate between female (*f*) and male (*m*) assessment, this is indicated.

The search strategy used for this document was performed according to International Continence Society (ICS) Standardisation Steering Committee guidelines. The working group of multinational and

**FIGURE 1** (A) Muscles of the female perineum and pelvic floor inferior view (reprinted with permission from Primal pictures<sup>2</sup>). (B) Muscles of the female perineum and pelvic floor superior view (reprinted with permission from Primal pictures<sup>2</sup>). (C) Muscles of the male perineum and pelvic floor inferior superior view (reprinted with permission from Primal pictures<sup>2</sup>). (D) Muscles of the male perineum and pelvic floor superior view (reprinted with permission from Primal pictures<sup>2</sup>)

multidisciplinary committee members applied expert opinion to identify existing terms that refer to PFM assessment. Existing published ICS Standardization of Terminology documents were searched and terms added to cover all published terms or in common clinical use that refer to the assessment of PFM function and dysfunction. Inclusion of the final list of terms was achieved via a consensus process, which took place between 2017 and 2019. The final list of terms serves as a reference for future refinement and testing for clinical utility. This document is not a clinical protocol or guideline for how to perform a PFM assessment, it defines and describes terms which may be used in a clinical assessment of PFM function. As such, this document does not include within its scope other important considerations when undertaking a PFM assessment. These include but are not limited to competency of the assessor, clinical reasoning required for diagnostic decision making, protocol when conducting a sensitive examination of an intimate body part, appropriate informed consent, and ethical and legal considerations.<sup>3</sup> Further, only a brief, introductory-level description of how to undertake the test is provided, not

a detailed description of the exercise protocol using that tool, with the reader directed to other texts for more detailed description.

The number of total, new, and changed ICS definition terms relevant to PFM assessment are shown in Table 1 (see below). If a term does not currently exist in an ICS Standardisation of Terminology document, it is indicated here as a “**NEW**” term. When a term appears in an existing ICS Standardisation of Terminology document, the term definition and description is reproduced here with reference to the original terminology document, to present a complete framework of PFM assessment. When a modification to the existing term occurs, the word “**CHANGED**” is used. If the change is a significant alteration from the existing term, a footnote is used to explain the reason for modification, and a reference to the original term cited. Several of the terms related to ultrasound imaging have been drawn from the AIUM/IUGA practice parameter for the performance of Urogynecological ultrasound examinations document.<sup>4</sup> Similarly, terms in the algometry section already exist in the field of pain science, and terms related to muscle

**TABLE 1** Total, new, and changed ICS definition terms

Section	New definitions/descriptors	Changed definitions/descriptors	Unchanged definitions/descriptors	Total
Introduction and symptoms	1	1	0	2
Signs	31	15	12	58
Investigations	80	18	17	115
Diagnoses	7	3	0	10
Total	119 (64%)	37 (20%)	29 (16%)	185

Abbreviation: ICS, International Continence Society.

function exist in the field of exercise physiology, and so forth. These terms are labeled **NEW** for the purposes of this document however we acknowledge that these terms are already published and may be in widespread use.

There is a plethora of existing terms and conceptual and operational definitions related to PFM function and dysfunction.<sup>5</sup> Saltiel et al.<sup>5</sup> observed inconsistency and redundancy in PFM function terminology and suggested that a further consideration of PFM function terms relevant to research and to clinical practice is required.<sup>5</sup> A mapping of PFM function terms to the WHO International Classification of Functioning, Disability and Health (ICF) framework has been recently proposed,<sup>6</sup> leading to a list of the most frequently used terms.<sup>7</sup> In this paper, we define the assessment term, describe the application of the test and interpretation of its finding within a framework of diagnostic decision making and clinical reasoning. This follows the usual order of assessment undertaken by a clinician or researcher (referred to in this paper as an “assessor”), leading to a presumed diagnosis and formulation of a treatment plan, to help guide clinical practice. This process includes the use of a patient’s history, patient-reported symptoms/outcomes, and information gained from clinical signs and the results of investigations. It is important to recognize that neuro-musculo-skeletal structures beyond the PFM muscles (e.g., intra- and extra-pelvic muscles, the bony pelvis and pelvic girdle joints, and central nervous system factors) may impact on PFM function, however, terminology relating to the assessment of these structures and systems is beyond the scope of this paper.

We hope the terminology sited within this framework provides greater clarity and aids standardization of the usage of these terms. Where possible, the sequence of the terminology follows this order: the region of assessment, the type of evaluation being undertaken, the name (“term”) of the test/assessment being undertaken, the definition of that term, the description of how that assessment method is undertaken, how the assessment is rated and the terminology used to describe the finding.

#### **Limitations**

Normative data of PFM structure and function are lacking for the majority of PFM terms, which hinders the ability to rate or interpret the finding as “normal” or “abnormal.” In addition, due to the lack of known validity, reliability, and responsiveness to change and diagnostic test accuracy (sensitivity, specificity) of many of the commonly used PFM clinical assessment methods, investigations, and diagnoses, the clinical utility of these terms remains unknown. Therefore, this document is not intended to be an evidence-based recommendation of which tests should be included in a PFM assessment; rather our aim is to define and describe currently used terms, which subsequent

research may recommend for or against using in PFM assessment. Evidence to support or abandon the use of any of these terms and assessment methods is eagerly awaited. In the meantime, we advise assessors to exercise great caution in their interpretation of clinical findings, especially those measured with visual observation, digital palpation, and outputs of some of the available assessment tools, as despite their widespread clinical usage, these tests can yield subjective and highly variable findings. Due to the abundance and variety of terms used in the literature related to methods and techniques of measurements, word count has necessitated that this document describes only the most frequently published, or methods and techniques using that particular tool in common clinical usage.

With these limitations in mind, we recommend rating of PFM symptoms as present or absent; if present, a severity and/or bother scale can be added to aid reassessment in response to an intervention. Some of the signs and investigations terms have rating scales associated with their method and these should be used; if not, we recommend that assessors employ linear measurements (mm/cm) or specify ISI international units of measurement (e.g., s = seconds) where applicable to aid objectivity of the assessment method. If “normal” observations or values are not known, we recommend avoidance of the term “abnormal” or suggestion of pathology or disorder, as this cannot be confirmed with current knowledge. When using assessment methods which measure on a continuous scale but lack reference data of a “normal” value, the terms “increased”/“elevated”/“higher”/“faster,” or “decreased”/“reduced”/“lower”/“slower” may be used as this is the limit of our certainty at this point in time. Nevertheless, we acknowledge the subjectivity of these relative rating terms.

## **2 | SECTION 1: SYMPTOMS**

This section lists symptoms a patient may use to describe a sensation which could be related to a disorder of PFM structure or function. We recommend the assessor accurately documents the term the patient uses to describe the symptom, rather than an assessor-interpreted term, as symptoms may be used as a patient-reported outcome. A patient-reported outcome is any report of the status of a patient’s health condition that comes directly from the patient, without interpretation of the patient’s response by an assessor.<sup>8,9</sup>

PFM-related symptoms are divided into sensory and motor categories. PFM-related symptoms may coexist with symptoms of pelvic floor disorders such as urinary incontinence, voiding dysfunction, fecal incontinence, defecatory dysfunction, sexual dysfunction, or pelvic

organ prolapse, as well as coexist with other disorders of neuro-musculo-skeletal structures in the pelvis or spine<sup>i</sup>: the assessor should document the patient's symptoms and identify which of these s/he considers to be related to the PFM. Examples are provided of words a patient may use to describe their symptoms to the assessor. These words are not specific to neural or myofascial structures in the PFM—they are generic and may be used by a patient to describe altered sensation in any body part—and are therefore not different to standard definitions of these terms in English dictionaries. For this reason, definitions are not provided for these terms in this document, as they are not PFM-specific. The likely exception is the term “wind,” which is defined below. In addition to documenting the patient's symptom (term) and any other descriptors the patient uses to describe the symptom, the assessor documents the perceived location, frequency of occurrence, severity, distress, bother or impact of these symptoms to the patient.

**1.1 PFM sensory symptoms:** Patient terms may include numbness, reduced feeling, decreased sensation, tingling, pins and needles, sensitivity/hypersensitivity, or increased or unusual sensation in the region the patient perceives to be related to the PFM. Terms used to describe painful symptoms may include pain, tender, ache, burning, or discomfort in the region the patient perceives to be related to the PFM; use of existing descriptors in published scales<sup>10</sup> is recommended.

**1.2 PFM motor symptoms:** Patient terms may include loose, lax, gaping, sagging, open, weak, bulging, heaviness, full, loss of control, or difficulty to relax, tight, tense, narrow, or constricted. A patient may describe “wind” as a noise or passage of gas.

**1.2.1 Vaginal wind:** An involuntary passage of odorless air through the vagina, which is often audible and/or sensible, and usually associated with a change in posture (**CHANGED**).<sup>11,12,ii</sup> This may occur when legs are abducted and a change of position occurs and during times of low estrogen (e.g., breast-feeding).

**1.2.2 Anal wind<sup>iii</sup>:** Complaint of involuntary loss of flatus (gas). (**NEW**)

Following the assessment of a patient's symptom(s), the assessor will formulate provisional differential diagnoses which will be refined following the clinical examination.

### 3 | SECTION 2: SIGNS

Signs are elicited from the clinical examination, which includes visual observation, physical inspection, and simple tests.<sup>iv</sup> The majority of PFM clinical signs are

tested using digital palpation. The term “palpation” (latin origin: *palpare*) means to touch gently or to use the fingers or hands to examine.<sup>14</sup> Palpation allows the assessor to feel the texture, size, consistency, and location of certain body parts with the hands, or in the case of PFM assessment, with the fingers or finger-tips.<sup>v</sup> Due to the inherent subjective nature of visual and digital assessment, many of these characteristics and properties of the PFM are more accurately assessed using investigations. While some terms will be defined in signs, the measurement of that term may be better done in investigations. If an assessor does not have access to investigations, findings from signs may be used to guide practice, however, subsequent research may cast doubt on the certainty of findings from signs.

There are several aspects for the assessor to be aware of during the clinical assessment which apply to all measured aspects of PFM function, as variations in the examination conditions or maneuvers may alter the results of the test and reduce the certainty of the finding. These are listed in Box 1 (see page 6). We recommend all of these aspects should be reported by assessors to enable reproducibility of assessment. Akin to published checklists for exercise prescription,<sup>17</sup> checklists of clinical assessment may improve completeness and quality of research reports.

This section divides the clinical examination into an external PP assessment and an internal PV or PR assessment. The order of examination for PP assessment is visual observation before digital palpation. The full description of each term appears in the subsequent tables and text. Not all tests may be applicable for each patient; the decision to perform a test should be based upon clinical judgment.

#### 2.1 External assessment per perineum

**Visual observation:** All terms related to the visual observation per perineum under different PFM states (at rest, on contraction, and with raised intra-abdominal pressure [IAP]) are listed and defined in Table 2 (see page 7).

**Digital palpation:** All terms related to digital palpation *per perineum* under different PFM states (at rest, on contraction, and with raised IAP) are listed and defined in Table 3 (see page 8).

#### 2.2 Internal assessment per vaginam (PV) or per rectum (PR) by digital palpation

**Resting state:** The following terms (in Tables 4 (see page 9) and 5 (see page 10)) are used to define, describe and rate PFM assessment in the resting state *per vaginam* (PV) or *per rectum* (PR) by digital palpation. Terms related to muscle tone are expanded upon in subsequent text to provide greater explanation of the term definitions and descriptions.

**Box 1 Checklist of PFM clinical assessment, applicable to signs and investigations**

Aspect to standardize	Details to record
1. Patient's body position for the PFM assessment	<ul style="list-style-type: none"> <li>• Lying or upright</li> <li>• If lying, hip/knee flexion, supine, side-lying, or lithotomy</li> <li>• Number of pillows, +/- support from assessor's body</li> <li>• Bladder empty or not</li> </ul>
2. Testing of left and right sides of PFM. Symmetry: A measure of comparability of resting tone or shape between left and right sides of the muscle. If examining in side-lying, there will be a gravity effect and the dependent side may have a different feel to the upper side and appear as asymmetrical. This may affect assessor perception of PFM resting tone	<p>Record if symmetry/asymmetry is present at rest and on activity (contraction/relaxation). Rate as:</p> <ul style="list-style-type: none"> <li>• Symmetry between left and right (on a particular aspect/parameter)</li> <li>• Asymmetry present. Identify what aspect/parameter is asymmetrical, e.g., tone, L&lt;R<sup>15</sup></li> </ul>
3. Amount of pressure (light/moderate/strong) applied during digital palpation tests. Particular care is required when undertaking a PFM assessment in the presence of pelvic floor pain, however, even in an asymptomatic individual, the assessor may provoke pain or discomfort due to undue pressure applied during palpation or application of an instrument	<ul style="list-style-type: none"> <li>• If discomfort or pain is provoked, note pain location, intensity, duration (transient or persistent), if it reproduces the pain the patient complains of, and if referral of pain occurs to other locations</li> </ul>
4. Number of digits (and which digit) used during digital palpation	<ul style="list-style-type: none"> <li>• For single digit examination (<i>PV</i> or <i>PR</i>), usually the index finger is used</li> <li>• For two-digit examination (<i>PV</i>), usually the index and middle digits are used</li> </ul>
5. Orientation (e.g., lateral placement or posterior midline) and depth of examining finger(s) during internal digital palpation examination <sup>vi</sup>	<ul style="list-style-type: none"> <li>• The examining finger must be as close as possible to the PFM tissue to assess PFM response</li> <li>• When performing a <i>PV</i> examination, assessor decision as to which side or midline to examine will be determined by lumen capacity, presence of tenderness or defect and presence of firm stool within the rectum</li> <li>• When performing a <i>PR</i> examination, external anal sphincter and puborectalis strength should be assessed separately</li> <li>• Record depth of insertion of examining finger for differential assessment of perineal versus levator ani muscle layers. Further identification of individual muscles is not possible in all individuals</li> </ul>
6. Instruction to perform a maximum voluntary contraction (MVC)	<ul style="list-style-type: none"> <li>• Provide details of the instruction (wording, number of repetitions, and rest between repetitions) to ensure the test can be reproduced as an MVC</li> </ul>
7. Contraction of muscles other than those of the pelvic floor	<ul style="list-style-type: none"> <li>• if this is perceived to influence the PFM assessment, an attempt to minimize this should be made unless the purpose is to assess function of the other muscle.</li> <li>• List specific muscle, such as abdominal, hip adductor, etc.</li> </ul>

Abbreviations: L, left; MVC, maximum voluntary contraction; PFM, pelvic floor muscle(s); *PR*, *per rectum*; *PV*, *per vaginam*; R, right.

TABLE 2 External assessment *per perineum*: Visual observation

Test	Rating
<i>Tests of visual observation per perineum at rest</i>	
<b>2.1.1 Perineal skin assessment:</b> Assessment of the perineal skin to note presence of: scars, lesions (e.g., fissure), trophic changes/atrophy, color, erythema, swelling, and other conditions which could affect the function of the PFM (NEW)	<ul style="list-style-type: none"> <li>• Normal skin</li> <li>• Altered (detail the observation including extent of alteration)</li> </ul>
<b>2.1.2 Perineal body length (f):</b> Distance from posterior margin of vestibule to anterior anal verge <sup>18</sup>	<ul style="list-style-type: none"> <li>• State if &lt; or &gt;3 cm<sup>19,20</sup></li> </ul>
<b>2.1.3 Perineal body position at rest:</b> Relationship of the position of the perineal body to ischial tuberosities <sup>3</sup> (NEW). Palpate ischial tuberosity and visually estimate the relationship	<ul style="list-style-type: none"> <li>• <b>2.1.3.1 Descended perineum:</b> Perineal body rests below the plane of the ischial tuberosities<sup>21</sup> (NEW)</li> <li>• Normal: At or slightly above the level of the ischial tuberosities</li> <li>• Elevated: Significantly indrawn perineum at rest</li> </ul>
<b>2.1.4 Introital gaping:</b> Opening, or noncoaptation of vagina at rest. (NEW) If the introitus is not visible at rest the labia may need to be parted	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<b>2.1.5 Keyhole deformity at anus:</b> Characteristic posterior midline furrow deformity. This complication is seen when the anus is inspected by gently retracting the buttocks laterally. The anus is no longer slit-like, but appears in shape like a keyhole <sup>22</sup> (NEW)	<ul style="list-style-type: none"> <li>• Present</li> <li>• Note location of deformity with reference to a clock-face (where 12 o'clock is anterior/ventral)</li> <li>• Absent</li> </ul>
<b>2.1.6 Anal gaping:</b> Noncoaptation of anal mucosa at rest <sup>11</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Note location of deformity with reference to a clock-face</li> <li>• Absent</li> </ul>
<i>Tests of visual observation per perineum with a PFM contraction</i>	
<b>2.1.7 Voluntary contraction of the PFM:</b> Self-initiated activation of the PFM. (CHANGED) <sup>23</sup> Contraction of the bulbospongiosus/bulbocavernosus, ischiocavernosus, transverse perineal muscles may be observed <sup>9</sup> . The assessor may need to gently move the external genitalia (parting of the labia, lifting of the scrotum to one side) to effectively visualize the perineal response	<ul style="list-style-type: none"> <li>• Present</li> <li>• Uncertain</li> <li>• Absent</li> <li>• Response can be further described according to perineal movement observed: <ul style="list-style-type: none"> <li>• <b>2.1.7.1 Perineal elevation:</b> Inward (ventrocephalad) movement of the vulva (f), perineum, and anus<sup>11,24</sup> = normal finding</li> <li>• No change</li> <li>• Sex-specific changes on perineal elevation: <ul style="list-style-type: none"> <li>• f: closure of the urethral meatus (“wink”); a clitoral “nod”</li> <li>• m: Closure of the anus, cephalad testicular lift and penile retraction (the shaft of the penis draws in)<sup>25–27</sup></li> </ul> </li> <li>• <b>2.1.7.2 Perineal descent:</b> Dorsocaudal movement of the perineum, or anus 1 cm or greater beyond resting level (CHANGED)<sup>24</sup></li> </ul> </li> </ul>
<b>2.1.8 Relaxation of the PFM:</b> Return of the perineum to its original resting position following the voluntary contraction (NEW)	<p>If present, rate as:</p> <ul style="list-style-type: none"> <li>• Yes: Full relaxation visible directly after instruction; normal finding<sup>15</sup></li> <li>• Partial or delayed relaxation<sup>15</sup></li> <li>• <b>2.1.8.1 Nonrelaxing PFM:</b> No relaxation visualized of the PFM (CHANGED)<sup>23d</sup>.</li> </ul>
<i>Tests of visual observation per perineum with an increase in intra-abdominal pressure (IAP)</i>	
<b>2.1.9 Perineal movement with a sustained increase in IAP:</b> Direction of perineal movement during a sustained effort <sup>e</sup> . (NEW). As there may be a difference in PFM response to	<ul style="list-style-type: none"> <li>• Perineal elevation (see 2.1.7.1)<sup>f</sup></li> <li>• No change</li> <li>• Perineal descent (see 2.1.7.2)<sup>f</sup></li> </ul>

(Continues)

TABLE 2 (Continued)

Test	Rating
<p>bearing down versus valsalva,<sup>28</sup> it is important to state exact test instruction depending on the test, as the observed response may vary</p> <ul style="list-style-type: none"> <li>• <b>2.1.9.1 Valsalva:</b> Forceful exhalation against a closed mouth, glottis, and nose.<sup>28</sup> (NEW) Valsalva has been shown to result in an increase in IAP and usually an increase in PFM activation<sup>28</sup></li> <li>• <b>2.1.9.2 Bearing down (as if defecating):</b> A strain or push, which results in an increase in IAP which exerts a downward pressure, usually accompanied by PFM relaxation (NEW)</li> </ul>	<ul style="list-style-type: none"> <li>• <b>2.1.9.3 Excessive perineal descent with bearing down:</b> Movement of the perineum 3 cm or more below resting position<sup>29b</sup> (NEW)</li> </ul>
<p><b>2.1.10 Perineal movement with rapid increase in IAP:</b> direction of perineal movement during a rapid increase in IAP such as coughing, lifting, throwing. (NEW) Clarify if the patient is instructed to contract PFM before cough to differentiate voluntary (learned) response from an involuntary response (un-learned)</p>	<ul style="list-style-type: none"> <li>• Perineal elevation (see 2.1.7.1)<sup>23i,j</sup></li> <li>• May be due to:</li> <li>• Voluntary contraction (see 2.1.19)—precontraction may be a learned response<sup>k</sup></li> <li>• <b>2.1.10.1 Involuntary contraction:</b> A contraction which occurs reflexively or automatically, without volition or conscious control. Observe this response before instructing in a voluntary pre-contraction to differentiate from the voluntary pre-contraction response. (CHANGED)<sup>23</sup></li> <li>• No change</li> <li>• Perineal descent<sup>l</sup></li> </ul>

Abbreviations: *f*, female; IAP, intra-abdominal pressure; *m*, male; PFM, pelvic floor muscles.

<sup>a</sup>Visual observation of the exact position may be influenced by variations in adipose tissue over the ischial tuberosities.<sup>21,29–31</sup>

<sup>b</sup>As the levator ani are likely to be co-contracting with the superficial PFM, the observed response is unlikely to be due to the superficial PFM layer alone, as the levator ani contraction is likely to be contributing to the observed response.

<sup>c</sup>These movements may be observed alongside perineal elevation and may be better visualized in standing than supine. These observations to be checked against movement of the scrotum and the whole penis.

<sup>d</sup>The term “nonrelaxing PFM”<sup>23</sup> was previously used as a diagnosis, however, this term describes a sign, and is not recommended to be used as a diagnosis. This sign may be combined with symptoms to inform a clinical diagnosis.

<sup>e</sup>The term “involuntary relaxation” is not recommended to define perineal movement as it not possible to determine if the downward PFM movement is related to voluntary muscle relaxation or passive elongation of noncontractile tissue.

<sup>f</sup>Some patients will not allow full relaxation during assessment for fear of releasing gas or urine, therefore may voluntarily contract during this test.

<sup>g</sup>Modification: The word “excessive” has been removed from the previous definition<sup>24</sup> as some downward movement of the perineum is normal with coughing or bearing down such as in defecation.

<sup>h</sup>Adipose tissue at the ischial tuberosities will affect the measurement.<sup>29</sup>

<sup>i</sup>Perineal elevation with cough is expected but not always present.

<sup>j</sup>Messelink et al.<sup>23</sup> described the response of perineal elevation to a rapid increase in IAP as the test for an involuntary contraction. However, it is not possible to say if this is an involuntary or reflex activation of muscle spindles resulting in a contraction, or a voluntary pre-contraction of the PFM before increased IAP. Strategies may differ or be combined.<sup>28</sup>

<sup>k</sup>This manoeuvre is also called “the knock.”<sup>32</sup>

<sup>l</sup>A small degree of descent may be normal.<sup>33</sup>

TABLE 3 External assessment *per perineum*: Digital palpation

Test	Rating
<i>Tests of digital palpation per perineum at rest</i>	
<p><b>2.1.11 Sensation:</b> Test for presence, absence or altered quality of sensation in dermatomal distributions especially S2-4. May include light touch, blunt, sharp, pain, cold, vibration modalities (NEW)</p>	<ul style="list-style-type: none"> <li>• Allodynic, anesthetic, dysesthetic, hyperalgesic, hyperesthetic, hypoalgesic, hypoesthetic, paresthetic, neuralgic<sup>34</sup></li> </ul>
<p><b>2.1.12 Perineal scarring:</b> Presence of scar tissue on perineum (NEW). Using a finger-tip, attempt to slide the scar in all directions. Assess for adhesion or lack of skin mobility over underlying tissue<sup>a</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Degree of healing</li> <li>• Location of scar in relation to vulva/scrotum or anus</li> <li>• Location of adhesion</li> <li>• Extent/magnitude of scar mobility<sup>35</sup></li> <li>• Absent</li> </ul>

TABLE 3 (Continued)

Test	Rating
<p><b>2.1.13 Tone:</b> state of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement.<sup>24</sup> The recommended position of the examining digit(s) is to place the palmar surface of the examining finger on the ischiocavernosus, bulbospongiosus (<i>f</i>)/bulbocavernosus (<i>m</i>) or transverse perineal muscle belly at the thickest portion of the muscle belly, <i>per perineum</i>. Pressure or stretch is applied perpendicular to the muscle fibers to assess tone. Tone is described in more detail in 2.2.3</p>	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Decreased tone (see 2.2.3.4)</li> <li>• Increased tone (see 2.2.3.5)</li> </ul>
<p><b>2.1.14 Tenderness:</b> Sensation of discomfort with or without pain; discomfort elicited through palpation of any tissue indicates unusual sensitivity to pressure or touch.<sup>24</sup> May be generalized within a muscle</p> <p><b>2.1.14.1 Tender point:</b> Area of localized tenderness occurring in muscle, muscle-tendon junction, bursa, or fat pad (CHANGED)<sup>24b</sup></p>	<ul style="list-style-type: none"> <li>• Note location of pressure application</li> <li>• Note location of pain (where pressure applied, or if pain referral present, note location of pain referral)</li> <li>• Rate severity of pain on a numeric rating scale (NRS) 0–10<sup>36</sup></li> </ul>
<p><b>2.1.15 Pudendal nerve neurodynamics:</b> Neurodynamic assessment evaluates the length and mobility of the nerve to assess neurogenic origin of pain<sup>37</sup> (NEW). Tension is applied to the nerve or specific component of the nerve by lengthening the nerve or by distracting imposing tissues.<sup>37</sup></p>	<ul style="list-style-type: none"> <li>• Positive: If pain, sensation of burning or stabbing are experienced in the distribution of the nerve. This assessment can be uncomfortable in asymptomatic individuals, however, reproduction of patient's pain is suggestive of a neurogenic origin of pain</li> <li>• Negative</li> </ul>
<p><b>2.1.16 Cotton swab test (<i>f</i>):</b> A test for vestibular tissue sensitivity. (NEW) The test is performed with a cotton swab moistened with water or lubricating gel. Gentle pressure is applied to the following areas of the vaginal vestibule<sup>d</sup> in random order: 12:00, and quadrants 12–3:00, 3:00–6:00, 6:00–9:00, 9:00–12:00<sup>e</sup></p>	<ul style="list-style-type: none"> <li>• Positive if gentle pressure reproduces patient's pain</li> <li>• Report location of pain and severity on NRS 0–10<sup>36</sup></li> <li>• Negative</li> </ul>
<p><i>Tests of digital palpation per perineum for sacral reflex function</i></p>	
<p><b>2.1.17 Sacral reflex testing:</b> a measure of the involuntary function of sacral nerves. (CHANGED)<sup>12f</sup> Tests are described below.</p>	<ul style="list-style-type: none"> <li>• Present: Observation of anal sphincter contraction. Indicative of intact spinal reflex arcs (S2–S4 spinal segments) with afferent and efferent nerves through the pudendal nerve<sup>38</sup></li> <li>• Absent: No sphincter activity</li> </ul>
<p><b>2.1.17.1 Bulbocavernosus reflex (<i>f</i>):</b> A reflex contraction of the anal sphincter and bulbocavernosus in response to squeezing the clitoris (CHANGED)<sup>12</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<p><b>2.1.17.2 Bulbospongiosus reflex (<i>m</i>):</b> A reflex contraction of the striated muscles of the pelvic floor (anal sphincter) including bulbospongiosus muscles that occurs in response to various stimuli in the perineum or genitalia. Most commonly tested by placing a finger in the rectum and then squeezing the glans penis<sup>39</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<p><b>2.1.17.3 Anal reflex:</b> A reflex contraction of the anal sphincter in response to a painful pin prick delivered to the perianal skin<sup>12</sup> (CHANGED)<sup>g</sup></p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<p><i>Tests of digital palpation per perineum with PFM contraction<sup>h</sup></i></p>	
<p><b>2.1.18 Voluntary contraction of the PFM:</b> Self-initiated activation of the PFM (same term as 2.1.7). Each of the bulbospongiosus/bulbocavernosus, ischiocavernosus, and transverse perinei muscles may be palpated separately. The assessor may need to gently move the</p>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> <li>• Uncertain</li> </ul>

(Continues)

TABLE 3 (Continued)

Test	Rating
external genitalia (parting of the labia, lifting of the scrotum to one side) to effectively palpate the perineal response	

Abbreviations: *f*, female; *m*, male; NRS, numeric rating scale; PFM, pelvic floor muscles.

<sup>a</sup>Adherent skin could impact function of PFM beneath the scar.

<sup>b</sup>Tender points (2.1.15.1) differ from trigger points (see 2.2.3) therefore the terms should not be used interchangeably.<sup>40</sup>

<sup>c</sup>This test is also referred to as the "Q Tip test." "Cotton swab" is preferred to avoid proprietary names.

<sup>d</sup>Excessive pressure could provoke underlying structures (such as the PFM) misleading the report of pain to vestibular tissues.

<sup>e</sup>Examination tip: In patients with high irritability, it is recommended to test the most severe pain area last to avoid an amplified response due to carry-over irritation as the test progresses.<sup>41,42</sup> In addition if an area provokes increased pain, it is important to wait for the pain to subside before testing other locations.

<sup>f</sup>This term is listed as a modification of the term in Rogers et al.<sup>12</sup>

<sup>g</sup>In contrast to the bulbocavernosus reflex the anal reflex is a nociceptive reflex and the correct stimulus is painful. If a single stimulus does not activate the reflex, several pricks in a fast sequence should be delivered. It is often difficult to elicit in the elderly, and it should not be declared absent if only a single stimulus is used. A "voluntary" movement away from the (painful) stimulus (pin prick) can usually be interpreted correctly. The patient should be told that painful stimuli are going to be delivered, and usually they can "keep still" and only the reflex contraction of the anal sphincter is observed. It is often absent even in patients without a neural lesion.

<sup>h</sup>Some of the tests performed in the external examination section may be repeated during the internal examination.

TABLE 4 Tests of digital palpation *per vaginam/per rectum*, resting state

Test	Rating
<b>2.2.1 Sensation:</b> test for presence, absence, or altered quality of light touch sensation as for 2.1.12	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> <li>• Altered: increased or decreased</li> </ul>
<b>2.2.2 Presence of scarring:</b> Presence of scar tissue along vaginal walls or apex. (NEW). Using a finger-tip, attempt to slide the scar in all directions. Assess for adhesion or lack of mucosal/vaginal wall mobility over underlying tissue <sup>a</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Location of adhesion</li> <li>• Degree of healing</li> <li>• Extent/magnitude amount of scar mobility</li> <li>• Absent</li> </ul>
<b>2.2.3 Tone:</b> see 2.1.13. The recommended position of the examining digit(s) is to place the palmar surface of the examining finger on the levator ani, <i>PV</i> , or <i>PR</i> . Pressure or stretch is applied perpendicular to the muscle fibers to assess tone Further details regarding terminology and assessment of muscle tone are provided in text section 2.2.3	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Decreased tone (see 2.2.3.4)</li> <li>• <b>Increased tone (see 2.2.3.5)</b></li> </ul>
<b>2.2.4 Fasciculation:</b> individual brief twitches in a muscle. They may occur at rest or after muscle contraction and may last several minutes <sup>24,43</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> </ul>
<b>2.2.5 Tenderness:</b> See 2.1.15 and 2.1.15.1	See 2.1.15 and 2.1.15.1
<b>2.2.6 Pudendal nerve provocation test:</b> Palpation of the pudendal nerve to reproduce patient's pain if entrapment is suspected. The nerve may be palpated at the ischial spine, sacrospinous and sacrotuberous ligaments, or pudendal canal <sup>44,45</sup> (NEW)	<ul style="list-style-type: none"> <li>• Positive (pain response)</li> <li>• Negative</li> </ul>
<i>Per rectum only</i>	
<b>2.2.7 Digital rectal examination (DRE)<sup>b</sup>:</b> Palpatory examination of the anorectal tissues <sup>c</sup> (CHANGED) <sup>39</sup>	

TABLE 4 (Continued)

Test	Rating
<b>2.2.8 Palpable anal sphincter gap (PR):</b> a clear “gap” in the anal sphincter on digital examination indicates an anal sphincter tear ( <b>CHANGED</b> ) <sup>11d</sup>	<ul style="list-style-type: none"> <li>• Present</li> <li>• Absent</li> <li>• Note location</li> </ul>

Abbreviations: NRS, numeric rating scale; PR, *per rectum*.

<sup>a</sup>Adherent skin could impact function of PFM beneath the scar.

<sup>b</sup>Despite the name (DRE), the purpose of the examination is usually to assess anal canal tissue, not rectal tissue.

<sup>c</sup>DRE may be less useful in male urinary dysfunctions where the urethral sphincter, inaccessible to DRE, has a more important role.<sup>46</sup>

<sup>d</sup>An assessment can be made of a palpable anal sphincter gap to assess if there has been previous obstetric or surgical damage.<sup>11</sup>

TABLE 5 Tests of digital palpation *per vaginam* only with the PFM in a resting state

Test	Rating
<b>2.2.9 Flexibility of the vaginal opening:</b> The capacity of the vaginal opening to expand in response to stretching. ( <b>NEW</b> ) Assessed by separating index and middle finger in the medio-lateral direction. <sup>47</sup> Digital assessment of the vaginal opening is likely to represent the width of the levator hiatus <sup>3</sup>	<ul style="list-style-type: none"> <li>• Estimate the number of finger widths between the muscle bellies</li> <li>• Can be converted to cm width for the recording from that assessor</li> </ul>
<b>2.2.10 Levator injury/avulsion:</b> A discontinuity of the levator muscle at its attachment to the inferior pubic ramus. ( <b>NEW</b> ) Discontinuity may represent a partial tear, full tear, or thinning. Test for levator injury/avulsion: palpation of levator tissue, by placing finger(s) between the side of the urethra and the edge of the muscle measured on each side. The test is performed at rest and confirmed by asking the patient to contract and feeling for the edge of the contractile tissue of the levator muscle	<ul style="list-style-type: none"> <li>• Absent: Palpable PFM contraction next to the urethra on the inferior pubic ramus</li> <li>• Present: A distance of &gt;3.5 finger widths between the two sides of puborectalis muscle insertion on PFM contraction<sup>24b</sup></li> <li>• Rate number of finger widths palpable in the gap.</li> <li>• Several rating scales exist<sup>48,49</sup></li> </ul>

Abbreviation: PFM, pelvic floor muscles.

<sup>a</sup>Levator hiatus may be better measured with instruments (see Section 3).

<sup>b</sup><3.5 cm may represent a partial avulsion, however, digital palpation cannot reliably determine this distance of discontinuity

**2.2.3 Muscle tone**

Tone exists on a continuum, from hypotonicity (low tone) to hypertonicity (high tone). Normal tone may overlap with abnormally decreased muscle tone or abnormally increased muscle tone at either end of the tone spectrum, as illustrated in Figure 2. Tone is a dynamic physiological state modulated by many inputs: spinal cord, cortex, brainstem relays, stretch reflexes and cutaneous receptors, visceromotor reflex pathways, emotions, and pain (anticipation or experience of pain).

We recommend terms to indicate alterations to normal tone are differentiated according to the presence or absence of a neurological disorder, as illustrated in Figure 3 (see page 12). Abnormal tone related to a neurological disorder (hypotonicity, hypertonicity, dystonia) should not be used when describing PFM tone in a patient who does not have a diagnosed neurological disorder.

**Physiological basis of muscle tone**

Muscle tone has two components: the physiological contractile component, created by the activation of

motor units, and the noncontractile viscoelastic, or biomechanical component. The active component (EMG activity) of tone is the component that is related to the neural drive, therefore it is subject to variation and ongoing adjustment. The viscoelastic component is independent of neural activity and reflects the

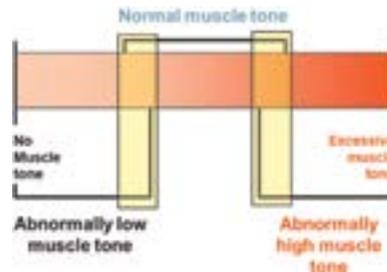

FIGURE 2 Spectrum of muscle tone (adapted from Allen and Widener 2009, with permission<sup>50</sup>)

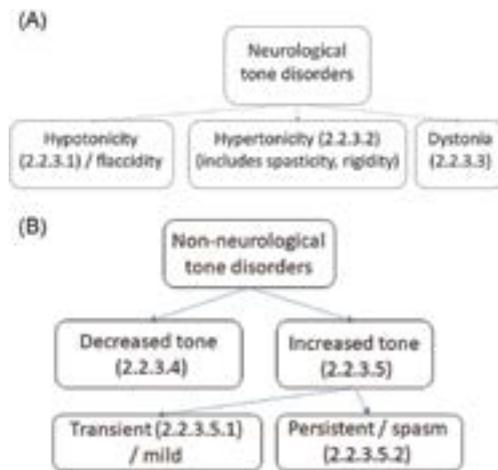

FIGURE 3 Terms for disorders of tone due to a neurological disorder (A) and a nonneurological disorder (B)

passive physical properties of the viscoelastic tension of the muscle tissues (e.g., the extensibility of actin-myosin cross-bridges); noncontractile cytoskeleton proteins and connective tissues surrounding the entire muscle (epimysium), muscle fascicle (perimysium), and muscle fiber (endomysium) as well as the osmotic pressure of the cells. Alterations in either the active or passive component can affect the resting tone; digital palpation cannot differentiate between these elements however investigations that combine EMG with another measure that assesses passive properties can identify specific components.

A localized area of increased tone within a muscle may be referred to as a taut band.<sup>51</sup> A trigger point is considered to be a tender nodule within a taut band.<sup>51</sup> The trigger point is considered by some authors to be part of the active component of tone<sup>51</sup> given the local disturbance in electrical activity, and by others as a separate category distinct from the active or passive components of tone.<sup>52</sup> Given the uncertainty about the characterization of a trigger point,<sup>53,54</sup> we propose describing palpatory findings by use of the terms “tender point” (2.1.15.1) and “increased tone” (2.2.3.4) if both observations coincide at the tested site, or use only “tender point” (2.1.15.1) or “increased tone” (2.2.3.4) if only one of those signs is observed at the tested site.

#### Assessment and rating

Tone can be assessed by application of digital site-specific compression and/or overall muscle stretch.

Digital palpation is inherently subjective and may be limited by pain provocation.

Several scales to quantify resting PFM tone in the absence of a neurological disorder have been proposed using either a 3-point,<sup>55,56</sup> 6-point,<sup>48</sup> or 7-point<sup>57</sup> scale.

#### Definitions and descriptions

**2.2.3.1 Hypotonicity:** A decrease in muscle tone in a patient **with** a neurological disorder. It may be due to a lower motor neuron or a muscle disorder. The term flaccidity<sup>58</sup> is often used interchangeably. (NEW)

**2.2.3.2 Hypertonicity:** An increase in muscle tone in a patient **with** a neurological disorder. It may be due to an upper motor neuron or extrapyramidal lesion, which in turn may lead to spasticity<sup>58</sup> or rigidity.<sup>58</sup> (NEW)

**2.2.3.3 Dystonia:** A disorder characterized by abnormalities of muscle tone and movements/postures in a patient **with** a neurological disorder.<sup>59</sup> It is often due to damage to the basal ganglia or other brain regions that control movement. (NEW)

**2.2.3.4 Decreased PFM tone:** A decrease in resting muscle tone in a patient **without** a neurological condition (CHANGED)<sup>43</sup>

**2.2.3.5 Increased PFM tone:** An increase in muscle resting tone in a patient **without** a neurological disorder. (CHANGED).<sup>43</sup> Increased tone may occur without patient report of pain.

**2.2.3.5.1 Transient increased muscle tone:** Increased muscle tone that decreases with verbal instruction, reassurance, or gentle pressure (NEW). Transient increase in tone may occur at any time during the examination.

**2.2.3.5.2 Muscle spasm:** Persistent contraction of muscle that cannot be reduced voluntarily.<sup>11,24,43</sup> Spasms may occur at irregular intervals with variable frequency and extent, and over time may lead to increased viscoelastic stiffness and shortening in the muscular and connective tissues.<sup>vii,viii</sup>

**Resting state per vaginam (PV) only (f):** Terms related to digital palpation of the vaginal tissues with the PFMs in a resting state are listed in Table 5.

**PFM contraction:** The following terms in Table 6 (see page 13) are used in the definition and the ratings of digital assessment *per vaginam/per rectum* of the PFMs during contraction.

**PFM contraction per vaginam (PV) only (f):** Terms related to digital palpation *per vaginam* only (f), on PFM contraction are listed in Table 7 (see page 14).

**PFM response to intra-abdominal pressure per vagina morper rectum**

**2.2.22 Direction of PFM movement during sustained increase in IAP:** As per 2.1.9. Specify task instruction, as response may differ depending on wording. Rate as elevation, no change, descent (normal finding), excessive descent.

TABLE 6 Tests of digital palpation *per vaginam/per rectum* on PFM contraction

Test	Rating
<p><b>2.2.11 Voluntary contraction of the PFM:</b> Self-initiated activation of the PFM (same term as 2.1.7). A contraction is felt as a tightening, lifting, and squeezing action under the examining finger. Technique:</p> <ul style="list-style-type: none"> <li>The recommended position of the examining digit(s) to assess levator ani contraction (PV) unilaterally is to place the palmar surface of the examining finger on the lateral levator ani muscle belly surface or “edge,” which may be identified by asking the patient to contract then relax</li> <li>The recommended position of the examining digit to assess anal sphincter and puborectalis muscle function (PR) is to place the palmar surface of the well-lubricated examining finger at the anal verge initially, wait for relaxation of EAS, then insert gently along the posterior wall of the anal canal.<sup>60</sup> Once anal sphincter function is assessed the examining digit remains pressed against the posterior wall and is inserted slowly into the rectum, passing over puborectalis at the anorectal junction</li> </ul>	<p>Presence of contraction may be rated as:</p> <ul style="list-style-type: none"> <li>No contraction</li> <li>correct contraction (cephalad and ventral movement)</li> <li>Contraction only with help from other muscles</li> <li>Uncertain</li> <li>Straining<sup>51</sup></li> </ul> <p>Absent: <b>2.2.11.1 Noncontracting PFM:</b> During palpation there is no palpable voluntary or involuntary contraction of the PFM<sup>23a</sup></p>
<p><b>2.2.12 Digital muscle test (DMT):</b> A test to evaluate PFM strength (NEW).</p> <p><b>2.2.12.1 Strength:</b> Force-generating capacity of a muscle. Usually expressed as a maximum voluntary contraction measurement (MVC).<sup>24</sup> A manual muscle test (MMT) evaluates the strength of a muscle by moving the muscle through its full-range of motion against gravity and then against gravity with resistance.<sup>14</sup> However, because joint range of motion is not being assessed in the pelvic floor and PFM examination is performed with a digit, not a hand, the term DMT is preferred. There are more than 25 published DMT scales<sup>62,63</sup> which provide grade of strength ranging from absence, to weakness to increasing strength</p>	<ul style="list-style-type: none"> <li>Commonly used scales include: ICS scale: absent, weak, normal (we propose the word “moderate” instead of normal), or strong<sup>23</sup></li> <li>modified Oxford grading scale 0–5<sup>64</sup></li> <li>Brink scale<sup>65</sup> grades 3 components (pressure, displacement, and time) on a scale of 1–4</li> <li>many others<sup>62,63</sup></li> </ul>
<p><b>2.2.13 Direction of pelvic floor movement:</b> Direction of pelvic floor movement during voluntary PFM contraction palpated PV (on the posterior vaginal wall) or PR (NEW)</p>	<ul style="list-style-type: none"> <li>Pelvic floor elevation: normal finding</li> <li>Pelvic floor descent: palpation of downward movement of the PFM during attempted PFM contraction</li> <li>No change</li> </ul>
<p><b>2.2.14 Endurance:</b> Muscular endurance refers to the ability of a muscle or muscle group to perform repeated contractions or to maintain a contraction for a predetermined period of time<sup>66,67</sup> (CHANGED)<sup>24</sup></p>	<p><b>2.2.14.1 Fatigue:</b> A decreased capacity to perform a maximum voluntary muscle action or a series of repetitive contractions. (NEW) Fatigue may occur due to central or peripheral mechanisms.<sup>68</sup> A fatigued muscle is unable to continue working even when the type of activity is changed<sup>b</sup></p>
<p>Record the time at which fatigue starts to occur, or the number of contractions in a row before onset of fatigue</p>	
<p><b>2.2.14.2 Sustained contraction endurance test:</b> the number of seconds the patient can hold near maximal or maximal PFM contraction (NEW)</p>	<ul style="list-style-type: none"> <li>Record number of seconds contraction is sustained at near maximal or maximal intensity</li> </ul>
<p><b>2.2.14.3 Repeatability of contraction:</b> The ability to repeatedly develop near maximal or maximal force determined by assessing the maximum number of repetitions the patient can perform (CHANGED)<sup>24c</sup></p>	<ul style="list-style-type: none"> <li>Record number of contractions in a row</li> </ul>
<p><b>2.2.15 Number of rapid contractions performed:</b> The number of repeated, quick MVCs performed (NEW). This can be measured in two ways, according to the instruction:</p>	<p>Use the rating appropriate to the instruction:</p>

(Continues)

TABLE 6 (Continued)

Test	Rating
<p>1. Number of contractions repeated within a specific duration (i.e., a 10-s period<sup>b</sup>)</p> <p>2. The elapsed time to perform a pre-specified number of contractions (e.g., 10 s<sup>69</sup>) A contraction should comprise an ascending and a descending phase with the PFM force returning to the resting state in between. If the maximal force declines, the assessment ceases</p>	<ul style="list-style-type: none"> <li>Record the number of contractions repeated and the duration allowed to perform them</li> <li>Specify the exact number of contractions to be repeated and record the number of seconds to completion.</li> <li>Qualitative descriptions can include quality and extent of contraction and relaxation phases</li> </ul>
<p><b>2.2.16 Relaxation postcontraction:</b> Return of the PFM to its original resting tone following the voluntary contraction (<b>CHANGED</b>)<sup>23d</sup>. The patient is able to relax the PFMs on demand, after a contraction has been performed. Relaxation is felt as a termination of the contraction</p>	<ul style="list-style-type: none"> <li>Yes: Relaxation felt directly after instruction: normal finding</li> <li>Partial or delayed relaxation</li> <li>No: Absent = nonrelaxing PFM (see 2.1.8.1)</li> </ul>
<p><b>2.2.17 Co-ordination:</b> The ability to use different parts of the body together smoothly and efficiently.<sup>24</sup> In the pelvic floor, co-ordination may be an action between PFMs and organ function (e.g., PFM relaxation during voiding), PFMs and an external environmental event (e.g., movement of a limb) and PFMs and a rise in IAP (e.g., PFM contraction before a cough). Co-ordination is an aspect of motor control.</p>	<ul style="list-style-type: none"> <li>Present</li> <li>Absent. If absent, describe pattern of incoordination. e.g., paradoxical contraction: the inability to maintain PFM relaxation when it is expected; or lack of PFM contraction when it is expected</li> </ul>
<p><b>2.2.17.1 Co-contraction:</b> Contraction of two or more muscles at the same time.<sup>24</sup> Co-contraction of muscles can be synergistic (e.g., resulting in an augmentation of motor activity) or it could be counterproductive to normal function (e.g., contraction of antagonistic muscles resulting in abnormal movement or training other muscles instead of the targeted ones, e.g., training of gluteal muscles instead of the PFM).<sup>24</sup> Activation or inhibition of PFM contraction may be task-dependent</p>	<ul style="list-style-type: none"> <li>If present, identify which muscles are co-contracting, and whether the co-contraction is synergistic or counter-productive<sup>e</sup></li> </ul>

Abbreviations: DMT, digital muscle test; EAS, external anal sphincter; *f*, female; IAP, intra-abdominal pressure; *m*, male; MVC, maximum voluntary contraction; PFM, pelvic floor muscles; *PR*, *per rectum*; *PV*, *per vaginam*.

<sup>a</sup>This term is referring to a sign and not recommended to be used as a diagnosis. This sign may be combined with symptoms to inform a clinical diagnosis.

<sup>b</sup>Endurance training can delay the onset of fatigue.<sup>70</sup>

<sup>c</sup>Modification from Bo et al.<sup>24</sup>: removal of “at a given percentage of 1 RM” as definition already states “near maximal or maximal force.”

<sup>d</sup>This can only be graded if the patient is able to generate a PFM contraction.

<sup>e</sup>Antagonistic contraction has not been included in this document as there is not a muscle whose action counteracts the action of the PFM.

TABLE 7 Tests of digital palpation *per vaginam* only (*f*), on PFM contraction<sup>a</sup>

Test	Rating
<p><b>2.2.19 Urethral lift:</b> Elevation of the urethra in a cephalad direction.<sup>15</sup> (<b>NEW</b>) Index finger is placed along the line of the urethra (on the anterior vaginal wall)</p>	<ul style="list-style-type: none"> <li>Yes: Urethral lift palpable</li> <li>No: No urethral lift palpable</li> </ul>
<p><b>2.2.20 Levator closure:</b> Movement of right and left muscle bellies closer together during a PFM contraction (palpated on the lateral vaginal wall).<sup>15</sup> (<b>NEW</b>) May be tested unilaterally if bi-digital assessment is uncomfortable for the patient</p>	<ul style="list-style-type: none"> <li>Yes: Levator closure movement palpable</li> <li>Partial/uncertain: Some closure movement palpable, but could be un-certain, or asymmetrical</li> <li>No: No levator closure movement palpable</li> </ul>
<p><b>2.2.21 Levator hiatus size:</b> The size of the levator hiatus measured during maximal contraction by a digital examination<sup>71b</sup> (<b>NEW</b>)</p>	<ul style="list-style-type: none"> <li>With 2 fingers in the vagina, distance measured in centimeters (converted approximately from finger widths) during PFM contraction</li> <li>LH transverse: The distance between the left and right muscle bellies just inferior to the pubic bone</li> <li>LH sagittal: The distance between the back of the pubic symphysis and the midline raphe of the puborectalis<sup>71</sup></li> </ul>

Abbreviations: LH, levator hiatus; *PV*, *per vaginam*.

<sup>a</sup>These tests are likely to produce more accurate results if measured using ultrasound imaging.

<sup>b</sup>This test was performed in patients with POP; the same technique may be uncomfortable in women with pelvic floor pain or increased tone.

Following the assessment of a patient's clinical signs, the assessor will formulate a provisional differential diagnosis which will be refined following the results of the investigations.

## 4 | SECTION 3: INVESTIGATIONS

An investigation is part of the differential diagnostic decision-making process. A PFM investigation is the measurement of the morphometry or function of the PFMs using mechanical or technological methods. The findings may be considered more accurate than findings from a clinical evaluation which relies on digital palpation. Some points to note regarding PFM investigations that should be considered in clinical and research application and interpretation of the finding: all devices are different and may not give the same information of a specific PFM physiological parameter or function. In addition, device specifications and analysis software options influence both the availability and measurement of PFM parameters,<sup>72,73</sup> the size and shape of a probe/sensor/electrode/transducer also influence the interpretation of findings<sup>72–74</sup> and raw values may need to be normalized. New devices to measure PFM properties may become available in the near future which do not fit the existing categories entirely, and new categories may need to be added to this living document.

**3.1 Dynamometry:** An investigation that measures both muscle power and force (**CHANGED**). Both active (contractile) and passive (noncontractile) forces can be detected.

**3.1.a Intra-vaginal PFM dynamometry:** Measurement of PFM resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina<sup>75</sup> (**CHANGED**).

Several PFM dynamometers have been developed to assess the PFM function in women.<sup>76–84</sup> Different configurations have been proposed in terms of the number, shape and the sizes of the branches, the force vector recorded (i.e., antero-posterior, latero-lateral or multi-directional forces) and the device specifications (e.g., configuration of strain gauges to avoid a lever-arm effect—the influence of the force location in regard to the gauges). In some dynamometers, the branches can be separated at a constant speed either manually or with a motorized unit to assess the passive properties during dynamic stretches.<sup>81,85</sup> Elastometry is a type of

intra-vaginal PFM dynamometer used for this specific application of evaluating the passive properties during dynamic stretches.<sup>81</sup>

Table 8 (see page 16) describes the most frequent parameters measured with intra-vaginal dynamometers as well as their definitions, specifications and findings. Parameters can be assessed at different fixed vaginal apertures or during stretching (i.e., while imposing an elongation to the tissues by separating the speculum branches).<sup>81,84</sup> The parameters measured with the dynamometer alone reflect the summative contribution of the active and passive components of tone. When combined with EMG, it enables the assessment of the differential contributions of tone components,<sup>86</sup> that is, during passive stretch of the PFM, concurrent EMG activity detects any electrogenic contributions. The passive component can then be identified when the EMG remains negligible.<sup>86,87</sup>

**3.2 Myotonometry:** An investigation that measures muscle tone characteristics by applying a mechanical impulse to the tissue.<sup>89–91</sup> (**NEW**) The device elicits oscillations of muscle after a probe applies a brief mechanical impulse with quick release under constant preload to the skin over the muscle belly. Myotonometry has been used externally on the perineum to measure superficial PFM stiffness. It cannot be used intra-vaginally to measure levator ani function as the probe must be perpendicular to the muscle and therefore cannot be used to interpret levator ani function. Table 9 (see page 17) describes the most frequent parameters measured with myotonometry that can be computed from the oscillation curve as well as their definitions, specifications and findings.<sup>92</sup> It should be noted that the tissues that lie between the probe and the muscle (e.g., skin, adipose tissues, connective and fascial tissues) can also influence the measurements.

**3.3 Manometry: An investigation that measures pressure**<sup>24,75</sup>

**3.3.1 Pelvic floor manometry:** Measurement of resting pressure or pressure rise generated during contraction of the PFM using a manometer connected to a sensor, which is inserted into the urethra, vagina or rectum.<sup>24</sup>

**3.3.1.a Intra-urethral manometry:** Manometry performed via the urethra. One example is the urethral pressure profile that is undertaken as part of a urodynamic investigation.<sup>94</sup> (**NEW**)

**3.3.1.b Intra-vaginal manometry:** Manometry performed via the vaginal canal. (**NEW**)

TABLE 8 Parameters and findings evaluated with intravaginal dynamometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<p><b>3.1.1 Passive forces:</b> The average forces in N recorded at rest<sup>84</sup> (NEW)</p> <p>Specify:</p> <ul style="list-style-type: none"> <li>– Opening (distance between the two branches e.g., minimal opening, selected opening or maximal opening)</li> <li>– While stretching (dynamic opening)</li> </ul>	The finding is the resting forces of the PFMs which are indicative of PFM tone, i.e., the summative contribution of the active and passive components of tone
<p><b>3.1.2 Maximal aperture:</b> The maximal vaginal opening in mm or cm of the dynamometer branches, without provoking a pain response<sup>86</sup> (NEW)</p>	This aperture can be used to evaluate the flexibility <sup>1</sup> of the PFMs
<p><b>3.1.3 Viscoelastic stress relaxation during a static (sustained) stretch:</b> The percentage loss in passive force during the application of a steady stretch over a prolonged period (e.g., 1 min)<sup>85,88</sup> (NEW)</p>	Higher percentage of force decline is indicative of an enhanced viscoelastic stress relaxation response and muscle relaxation. This could be useful in quantifying tissue relaxation following stretching or lower force decline associated with strength training <sup>88</sup>
<i>(b) Parameters assessed at rest during dynamic stretching</i>	
Dynamic stretches are applied by repeatedly separating the speculum branches at a constant speed until maximal vaginal aperture (lengthening phase) and then, closing back to the minimal aperture (shortening phase)	
<p><b>3.1.4 Stiffness:</b> The resistance to deformation. Passive elastic stiffness is defined as the ratio of the change in the passive resistance or passive force (<math>\Delta F</math>) to the change in the length displacement (<math>\Delta L</math>) or <math>\Delta F/\Delta L</math> (N/mm)<sup>24,43,75b</sup>. Passive elastic stiffness should be computed for specific vaginal apertures<sup>81,84</sup></p>	The higher the N/mm value, the stiffer the muscle. This is a physiological property of muscle which contributes to the overall measurement of tone
<p><b>3.1.5 Compliance:</b> the reciprocal of muscle stiffness (mm/N)<sup>43</sup> (NEW)</p>	The higher the mm/N, the more compliant the tissue
<p><b>3.1.6 Hysteresis:</b> The area between the lengthening and shortening curves (N × mm). It corresponds to the loss of energy associated with lengthening of viscoelastic tissues<sup>85</sup> (NEW)</p>	Increased area indicates higher energy dissipated
<i>(c) Parameters evaluating contractile properties</i>	
<p><b>3.1.7 Maximal strength:</b> Peak force in N generated during a MVC. (NEW). The resting forces recorded before the effort are usually subtracted from the peak value<sup>78</sup></p> <p>Specify:</p> <ul style="list-style-type: none"> <li>– The length of hold for the MVC, e.g., 10 s contraction duration</li> <li>– How the peak score was obtained, e.g., peak during a single MVC, best of or average of 3 contractions</li> </ul>	Higher peak value indicates higher muscle strength
<p><b>3.1.8 Speed of contraction:</b> Rate of force development measured as the mean slope of the ascending curve in N/s during a fast MVC<sup>79</sup> (NEW)</p>	Higher rate of force (steeper slope) is indicative of a faster generation of force
<p><b>3.1.9 Speed of relaxation:</b> Rate of force reduction measured as the mean slope of the descending curve in N/s during PFM relaxation<sup>86</sup> (NEW)</p>	Lower values are indicative of slower relaxation
<p><b>3.1.10 Number of rapid contractions:</b> See section 2.2.16 for definition and rating. A contraction must comprise an ascending and a descending phase with the amplitude of the PFM forces returning to the resting state post contraction<sup>79</sup></p>	Higher number of contractions are suggestive of higher speed of contraction but also better motor control, as the task requires alternation between MVC and complete rest

TABLE 8 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.1.11 Normalized area under the force curve:</b> The area under the force curve divided by maximal force and multiplied by 100 (in % × prescribed s) during a sustained MVC <sup>79</sup> (NEW)	Higher normalized area is indicative of better muscle endurance

Abbreviations: MVC, maximum voluntary contraction; N, Newtons; PFM, pelvic floor muscles.

<sup>a</sup>See section 2.2.9 for definition.

<sup>b</sup>Using the dynamometer alone, the stiffness value will reflect the summative contribution of the active and passive components of tone. If dynamometry is combined with EMG, the passive contribution can be identified.<sup>86</sup>

**3.3.1.c) Intra-anal manometry<sup>ix</sup>:** Manometry performed via the anal canal. (NEW)

Pelvic floor manometric tools traditionally have measured pressure in mmHg, hPa, or cmH<sub>2</sub>O, however, new and future devices may provide output using different units. It should be specified whether the device is calibrated to zero/atmospheric pressure before insertion.<sup>24</sup> The most common parameters assessed with pelvic floor manometry (intra-vaginal and intra-anal) and their findings are described in Table 10 (see page 18).

Several common parameters are illustrated in Figure 4 (see page 19).

**3.3.2 Anorectal manometry<sup>x</sup>:** Is a pressure test to assess the structure and physiological function of the anorectal complex (CHANGED).<sup>11</sup> Water perfused and solid-state pressure transducers are used in combination with a balloon positioned in the anal canal.<sup>23</sup> The most commonly used PFM parameters and findings are described in Table 11 (see page 20).<sup>xi</sup>

TABLE 9 Parameters and findings evaluated with myotonometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.2.1 Oscillation frequency:</b> Characterizes the intrinsic tension of the muscle in its passive or resting state in the absence of voluntary contraction. <sup>93</sup> (NEW) Measured in Hz	A higher oscillation frequency (Hz value) indicates higher muscle tone <sup>92,93</sup>
<i>(a) Biomechanical properties</i>	
<b>3.2.2 Stiffness:</b> As defined in 3.1.4 for dynamometry. However, the method of application of the force is different to that described in 3.2.2; with this device, an external sensor applies a deformation perpendicular to the tissue	A higher N/m value indicates higher muscle stiffness.
<b>3.2.3 Logarithmic decrement:</b> Characterizes elasticity and dissipation of mechanical energy. Measured as $1n(D = \ln[a1/a3])$ . <sup>93</sup> It indicates the ability of the tissue (including muscle) to recover its shape after being deformed (NEW)	Elasticity is inversely proportional to decrement, therefore, if the decrement of a muscle decreases, the muscle elasticity increases. The smaller the decrement value, the smaller will be the dissipation of mechanical energy and the higher the elasticity of a tissue
<i>(b) Viscoelastic properties</i>	
<b>3.2.4 Mechanical stress relaxation time:</b> The time for a muscle to recover its shape from deformation after a voluntary contraction or removal of an external force (NEW). Measured in milliseconds <sup>92</sup>	The longer the time the more relaxation has occurred in the tissue
<b>3.2.5 Creep:</b> The gradual elongation of a tissue over time when placed under a constant tensile stress. (NEW): Measured by the ratio of relaxation time to deformation time (Deborah number)	The higher the creep, the less elasticity the tissue has and the more likely is permanent stretch or deformation

Abbreviations: Hz, hertz; N/m, newtons/meter.

TABLE 10 Parameters and findings evaluated with pelvic floor manometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<p><b>3.3.1.1 Resting pressure:</b> The pressure recorded at rest in mmHg, hPa or cmH<sub>2</sub>O. For greater accuracy, a mean resting pressure may be calculated over a specified period to account for fluctuations<sup>95,96</sup> (NEW)</p> <p>Resting pressure may be influenced by PFM tone (i.e., summative contribution of the active and passive components)</p>	Higher resting pressure may be a surrogate measure of increased PFM tone. However, the value should be interpreted with caution as the measurement is not limited to pressure originating from the PFMs (e.g., intra-abdominal pressure, vaginal tissue scarring, rectal contents may contribute to resting pressure)
<i>(b) Parameters evaluating contractile properties</i>	
<p><b>3.3.1.2 Peak pressure during a maximum voluntary contraction:</b> highest pressure recorded during a PFM MVC in mmHg, hPa or cmH<sub>2</sub>O (NEW)</p> <p>As the pressure measured does not confirm its origin, it is important to ensure the validity of intra-vaginal measurement: (1) perform vaginal palpation before using the manometer to ensure the patient is able to correctly contract her PFMs; (2) observe the cranial movement of the vaginal probe during measurement of the muscle contraction, and (3) ignore contractions associated with elevated intra-abdominal pressure (e.g., Valsalva maneuver), hip muscle contraction or any movement of the pelvis<sup>97,98a</sup></p> <p>Specify:</p> <ul style="list-style-type: none"> <li>- The length of hold for the MVC, e.g., 3 s/5 s/10 s contraction duration</li> <li>- How the peak score was obtained, e.g., peak during a single MVC/best of or average of 3 contractions<sup>99-106</sup></li> </ul>	Maximal pressure is often used as a surrogate of muscle strength, e.g., higher pressure being related to higher strength
<p><b>3.3.1.3 Time to peak pressure:</b> Time in seconds from onset of muscle contraction to maximal pressure (NEW)</p>	Shorter time to peak is indicative of a faster generation of pressure
<p><b>3.3.1.4 Speed of contraction:</b> Rate of pressure rise measured as the mean slope of the ascending curve in hPa/s during a fast MVC (NEW)</p>	Higher rate of force (steeper slope) is indicative of a faster generation of pressure
<p><b>3.3.1.5 Speed of relaxation:</b> Rate of pressure reduction measured as the mean slope of the descending curve in hPa/s during PFM relaxation (NEW)</p>	Lower values are indicative of a slower relaxation
<p><b>3.3.1.6 Number of rapid contractions:</b> See 2.2.16 and 3.1.10 for definitions and ratings</p>	See 3.1.10 for interpretation
<p><b>3.3.1.7 Time to return to baseline pressure:</b> Time in seconds from maximal pressure to relaxation state (NEW)</p>	Longer duration suggests slower relaxation
<p><b>3.3.1.8 Duration of a sustained contraction:</b> The length of time in seconds that a contraction can be sustained during MVC or at a specific % of MVC. (NEW). Specify if it is a maximal contraction or a % of MVC, e.g., 60%<sup>96,99,101,102,105</sup> and the threshold used to indicate that the target is no longer maintained</p>	A shorter duration suggests a lower endurance. Duration of contraction could be used as an indication of endurance, e.g., longer contraction being related to better endurance
<p><b>3.3.1.9 Area under the pressure curve during a sustained contraction:</b> The area under the pressure curve in hPa multiplied by time in s during a sustained MVC or at a specific percentage of MVC. This represents the total work performed. (NEW). Specify the duration of the contraction, e.g., 10 s, 30 s, etc.<sup>95,100</sup></p>	Higher area under the pressure curve above resting pressure reflects better muscle endurance

Abbreviations: MVC, maximum voluntary contraction; PFM, pelvic floor muscles.

<sup>a</sup>It is not recommended to use intravaginal pressure manometry to assess the reflex contraction of the PFM during coughing.<sup>107</sup> Bo and Constantinou<sup>107</sup> explained that pressure measurement is a summation of signals including PFM and intra-abdominal pressure caused by the cough itself and therefore, it is unlikely that the PFM reflex can be assessed in isolation using pressure manometry. In contrast, ano-rectal manometry can be used to assess a reflex during an involuntary PFM contraction<sup>108</sup> if the transducer is located in the anus, caudal to the puborectalis/ano-rectal junction; therefore it is not impacted directly by intra-abdominal pressure.

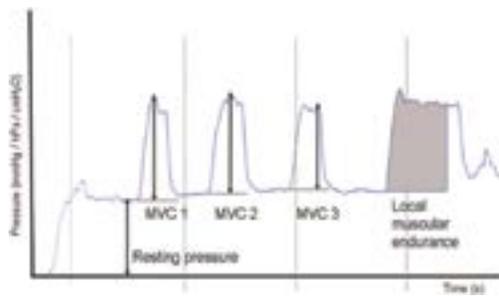

FIGURE 4 Graphical illustration of pelvic floor muscle manometry readings (modified from Ingeborg H Braekken, with permission)

**3.3.2.9 Vector manometry:** A three-dimensional pressure profile of the anal canal. (CHANGED).<sup>11</sup> Measures of total anal canal pressure and symmetry are made. The vector volume is the volume of the 3D shape generated and provides a value which reflects the overall length and symmetry of the sphincter.

**3.3.2.10 High resolution manometry:** Complete definition of the intra-anal pressure environment using a catheter with a large number of pressure sensors spaced less than 0.5 mm apart along the length of the catheter.<sup>11</sup>

**3.3.2.11 Ambulatory anorectal manometry:** Is a test performed using solid-state catheters in ambulant subjects an over an extended period of time (CHANGED).<sup>11</sup>

**3.4 Electromyography (EMG):** Is the recording of electrical potentials generated by the depolarization of muscle fiber membranes.<sup>24</sup> Investigators reporting PFM EMG studies should state the position of the patient, the recording equipment<sup>23</sup> and conditions used as summarized in Box 2 (see page 21). Nerve conduction studies, for example, pudendal nerve testing, are beyond the scope of this document.

Important considerations when interpreting EMG signals: Baseline and contractile sEMG amplitude is affected by properties of the electrode, configuration of electrodes, recording system, and patient/individual characteristics. Raw amplitude cannot be compared between individuals because the signal's amplitude is affected by many factors (e.g., cutaneous/mucosal tissue thickness, vaginal lubrication, positioning/direction of electrodes with respect to the muscle and muscle fibers, and properties of the detection system<sup>114–116</sup>). As a consequence, normalization of the sEMG amplitude is considered critical when comparing data across individuals.<sup>117</sup>

**3.4.a Artifact:** Extraneous information in the EMG signal from sources other than the target muscle, such as the environment (e.g., electromagnetic radiation) or

other body functions. Artifact examples include movement or contact quality artifact, heart rate, skin electrode shear, and electrode bridging (CHANGED).<sup>24</sup>

**3.4.b Crosstalk:** Muscle activity from nearby muscles that can contribute to the recorded EMG amplitude and be misinterpreted as PFM activation.<sup>24,xiii</sup>

**3.4.1 Intramuscular EMG:** Is a recording of motor unit action potentials using needle (concentric or monopolar) or wire electrodes inserted into muscles<sup>75,119</sup> (CHANGED).<sup>24</sup> This is not typically used in clinical assessment. The electrodes can be inserted to assess the superficial (e.g., bulbocavernosus) and deep layers (e.g., levator ani) of the PFMs as well as the urethral and anal sphincters.<sup>120</sup> This assessment as a rule focuses on the motor units to investigate motor unit physiology and pathophysiology. Parameters evaluated with concentric needle EMG can be used to differentiate between normal, denervated, reinnervated and myopathic muscle<sup>121,122</sup> Quantitative EMG includes analysis such as the multi-motor unit potential analysis<sup>122</sup> and the interference pattern analysis (turns/zero crossing or amplitude).<sup>122</sup>

**3.4.2 Surface electromyography (sEMG):** Is a recording of motor unit action potentials using surface electrodes placed on the skin or mucosa close to the muscle of interest. Recordings are also used in assessment of the activation pattern/“behavior” (sometimes referred to as kinesiological electromyography) of a particular muscle during a defined activity.<sup>121</sup> sEMG requires electrodes placed on the skin of the perineum or inside the urethra, vagina or rectum (CHANGED).<sup>12,24</sup> Parameters and findings evaluated with sEMG are described in Table 12 (see page 22). Several common parameters are illustrated in Figure 5 (see page 23).

**3.5 Imaging:** Refers to the process of creating images using high-energy modalities to allow visualization of body tissues. Imaging provides tissue-specific evaluation to identify if morphological properties (e.g., trauma or deficit) are present, which may relate to an individual's presenting symptoms.<sup>24,75</sup> In this document, we focus on ultrasound and MRI assessment and the terms related to PFM morphology and function, as well as the influence of other structures on PFM support and contractility investigated using these tools. It is not within the scope of this document to describe imaging of organ structures.

**Ultrasound imaging:** Pelvic floor ultrasound imaging measures PFM morphology and function via trans-abdominal, trans-perineal, trans-vaginal and trans-anal placement of the transducer (CHANGED).<sup>12,43</sup> This investigation applies diagnostic techniques taken in B-mode that use high-frequency sound waves to image internal structures. The image is formed by the differing reflection signals produced when a beam of

TABLE 11 Parameters and findings evaluated with anorectal manometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<b>3.3.2.1 Functional anal length:</b> The length (mm) of the anal canal over which resting pressure exceeds that of the rectum. <b>(CHANGED)</b> <sup>11</sup> The length of the canal is measured either by station pull-through or continuous pull-through <sup>11</sup>	Functional anal canal length has been shown to be shorter in females with fecal incontinence and longer in females with chronic constipation <sup>109</sup>
<b>3.3.2.2 Maximum resting pressure:</b> The highest pressure (in mmHg, hPa, or cmH <sub>2</sub> O) along the anal canal measured in the axial plane at a specific point <b>(CHANGED)</b> <sup>11</sup>	Internal anal sphincter (IAS) (smooth muscle) is responsible for 55%–85% of the anal pressure, and is variable along the length of the anal canal with the proximal two-thirds being more reliant on IAS tone to maintain adequate resting pressures. Low anal resting pressure is associated with passive fecal soiling. High anal resting pressure may be a feature of constipation <sup>110</sup>
<i>(b) Parameters evaluating contractile properties</i>	
<b>3.3.2.3 Maximum pressure during MVC/maximum squeeze pressure:</b> Is the anal canal pressure (in mmHg, hPa or cmH <sub>2</sub> O) measured during maximum voluntary contraction (MVC) in a specific location <b>(CHANGED)</b> <sup>11</sup>	The pressure increment above resting pressure during these maneuvers is primarily a representation of EAS function. Range of normative values varies according to the particular measurement device in a laboratory. <sup>11</sup> Decreased voluntary anal sphincter contraction is associated with fecal incontinence especially fecal urgency <sup>110</sup>
<b>3.3.2.4 Duration of sustained contraction MVC/endurance squeeze pressure:</b> Is the length of time (in seconds) the individual is able to maintain the pressure during the MVC <b>(CHANGED)</b> <sup>11</sup>	Shorter duration suggests a lower endurance. To assess the endurance squeeze pressure, measurements are taken during a 5–10 s squeeze. By calculating fatigability, the fatigue rate (using reduction of the mean pressure over 1-s periods throughout the endurance squeeze) can be derived <sup>11</sup>
<b>3.3.2.5 Number of rapid contractions:</b> See 2.2.16 and 3.1.10 for definitions and ratings	See 3.1.10 for interpretation.
<b>3.3.2.6 Involuntary maximum squeeze pressure:</b> The pressure (in mmHg, hPa, or cmH <sub>2</sub> O) created involuntarily by the PFM during a maximal cough <sup>108</sup> <b>(CHANGED)</b> <sup>11a</sup>	<ul style="list-style-type: none"> <li>• Present; numerical values of pressure change may be used to further quantify</li> <li>• Absent; associated with fecal incontinence<sup>111</sup></li> </ul>
<b>3.3.2.7 Balloon expulsion pressure:</b> The anal canal pressure (in mmHg, hPa, or cmH <sub>2</sub> O) during straining with a filled balloon in the rectum <sup>11</sup>	<ul style="list-style-type: none"> <li>• Increase from resting pressure suggests paradoxical contraction (see 4.3.1) and is associated with evacuation dysfunctions</li> <li>• No change</li> <li>• Decrease from resting pressure (normal)</li> </ul>
<b>3.3.2.8 Rectoanal inhibitory reflex (RAIR):</b> The relaxation response in the IAS following rectal distension (in mmHg, hPa, or cmH <sub>2</sub> O). <sup>11</sup> It is elicited by rapid inflation to first sensation of a balloon positioned in the distal rectum during anal manometry at the level of the proximal high-pressure zone	<ul style="list-style-type: none"> <li>• Present: a drop of at least 25% of resting pressure has to occur with subsequent restoration to at least two-thirds of resting pressure for the RAIR to be deemed present. This reflex is thought to underlie the sampling response that allows rectal contents to be sensed by the anal mucosa, thus ensuring continence of flatus and stool<sup>11,112</sup></li> <li>• Absent: seen in Hirschsprung disease, fecal incontinence, constipation, and after anorectal surgery<sup>110</sup></li> </ul>

Abbreviations: IAS internal anal sphincter; MVC, maximum voluntary contraction; PFM, pelvic floor muscles.

<sup>a</sup>This contrast with vaginal manometry where the source of pressure during an involuntary contraction cannot be assumed to be the levator ani contraction.

## Box 2 EMG system specifications

### Recommendations for reporting EMG studies (based on the recommendations of the International Society of Electrophysiology and Kinesiology<sup>113</sup>).

Reports on surface EMG should include:

- electrode material (e.g., Ag/AgCl)
- electrode geometry (discs, bars, rectangular)
- number and size (e.g., diameter, radius, width, length)
- interelectrode distance
- use of gel or paste
- skin/mucosal preparation (e.g., alcohol applied to cleanse skin, skin abrasion, shaving of hair, etc.)
- electrode location, orientation over muscle with respect to tendons, motor point (if known) and muscle fiber direction.
- type of ground electrode used, location

Reports on intramuscular wire electrodes should include:

- wire material (e.g., stainless steel)
- if single- or multistrand
- if single or bipolar wire
- interelectrode distance
- insulation material
- length of exposed tip
- method of insertion (e.g., hypodermic needle)
- depth of insertion/method of insertion guidance
- location of insertion in the muscle
- type of ground electrode used, location

Amplifiers should be described by the following:

- type (monopolar, differential, double differential, etc.)
- pre-amplification at the level of the electrode
- input impedance
- Common Mode Rejection Ratio (CMRR)
- actual gain range used

Filtering of the raw EMG should be specified by<sup>xii</sup>:

- low and/or high pass filter properties (e.g., cut-off frequencies, order)
- filter types (e.g., Butterworth, Chebyshev, Notch, etc.)
- notch filter

sound waves is projected into the body and bounces back at interfaces between those structures. Ultrasound evaluation may be undertaken as:

**3.5.1.a** Two-dimensional (2D) ultrasound: The transducer sends and receives ultrasound waves in one

anatomical plane. The reflected waves are used to generate gray scale images of structures in the field of view in this anatomical plane.

**3.5.1.b** Three-dimensional (3D) ultrasound: Creates volume data from multiple 2D images which are gathered by reflected waves at a variety of angles. Software integrates this information to create a single static 3D image.

**3.5.1.c** Four-dimensional (4D) ultrasound: Is similar to 3D US, but the image is repeated at intervals over time. This technique requires the use of a 3D/4D transducer and enables real-time visualization of 3D images.

**3.5.1.d** Tomographic ultrasound: Is viewing US imaging in sections. It allows the depiction of arbitrarily defined planes from volume data obtained in 3D or 4D US.<sup>134,135</sup>

Measurements are best understood by referring to anatomical planes of the body, that is, coronal (frontal), sagittal, and axial (horizontal or transverse) planes.

**3.5.1.1 Trans-abdominal pelvic floor ultrasound:** A 2D imaging technique to scan pelvic floor structures, using a convex transducer is placed in the supra-pubic region. (**NEW**) It can be oriented longitudinally to measure bladder base displacement in the mid-sagittal or parasagittal plane or oriented transversely to measure bladder base symmetry and displacement in the transverse plane. Trans-abdominal pelvic floor ultrasound is primarily used in clinical settings rather than for research purposes due to limitations measuring the image (no bony landmarks in view and difficulties for operator to keep transducer in plane—operator error is high). Artifact in measurement may also occur with incorrect PFM contraction when abdominal muscle contraction occurs (which pushes the transducer ventrally) and varying levels of bladder fullness (adherence to a fluid intake protocol may mitigate this limitation). Poor agreement between transverse and sagittal findings suggests measurement in the two planes evaluate displacement at different locations during a PFM contraction.<sup>136</sup> Table 13 (see page 25), describes the parameters and anatomical landmarks evaluated in the mid-sagittal plane, during different activity states of the PFM: rest, contraction and bearing down.

Parameters and findings evaluated with trans-abdominal imaging in the transverse plane—during different activity states of the PFM (rest, contraction, and bearing down)—are described in Table 14 (see page 26).

**3.5.1.2 Introital pelvic floor ultrasound:** 2D/3D/4D imaging technique to scan pelvic floor structures using an endocavity<sup>xvi</sup> transducer placed against the vaginal introitus/vulva or perineum.<sup>4</sup> (**NEW**) The transducer may be oriented ventrally/anteriorly to assess the pelvic floor structures (prolapse, levator ani muscle anatomy and function, and periurethral area), or oriented posteriorly to assess the anal sphincter structures.

TABLE 12 Parameters and findings evaluated with sEMG

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters assessed at rest</i>	
<p><b>3.4.2.1 Baseline muscle activity:</b> The amount of microvolts generated by activation of motor units in the target muscle during rest<sup>24,75a,b</sup></p>	<p><b>3.4.2.1.1 Inconsistent resting baseline:</b> The variation of baseline between contractions, between sets, or between days<sup>24,75</sup></p> <p><b>3.4.2.1.2 Elevated resting activity:</b> An increase in the active component of muscle tone; (the passive/viscoelastic component is not captured by sEMG) (NEW)</p>
<i>(b) Parameters evaluating contractile properties</i>	
<p><b>3.4.2.2 Signal amplitude:</b> Microvolts (μV) a muscle generates<sup>24</sup></p> <p>Specify: MVC contraction duration (s)—how the signal was processed. Signals are usually rectified and filtered to measure amplitude,<sup>114</sup> i.e., average rectified value or root-mean-square<sup>114</sup></p> <p><b>3.4.2.3 Peak amplitude:</b> The highest sEMG amplitude achieved measured in microvolts.<sup>24,75</sup> Specify the duration (s). Measured during an MVC or functional activities such as postural tasks or incontinence provocative activities<sup>123,124c</sup></p> <p><b>3.4.2.4 Normalization of the amplitude:</b> The value obtained during a specific task as a percent relative to the electrical activity detected during a MVC<sup>113,117</sup> (NEW)</p>	<p>sEMG amplitude reflects muscle activation.<sup>117</sup></p> <p>Increase in sEMG amplitude is related to the recruitment of motor units and increased firing rate.<sup>118</sup> The amplitude of the signal should not be interpreted as a direct force measurement because the relationship between force and EMG is generally not linear and is affected by type of contraction (concentric/isometric/eccentric), speed of contraction.). During strength training, early gains in force output are mainly related to an increase in motor unit recruitment and discharge frequency which will result in a higher signal amplitude. Later gains explained by hypertrophy<sup>24</sup> are not reflected in increased sEMG amplitude</p>
<p><b>3.4.2.5 Time to peak muscle activation:</b> Time in ms or s from onset of muscle activity to peak activity (NEW)</p> <p><b>Rate of change:</b> The mean slope of the ascending curve in μVs during a fast MVC. (NEW)</p>	<p><b>3.4.2.5.1 Slow recruitment:</b> A longer time to peak muscle activation in s or a slower rate of change<sup>125</sup> (CHANGED)<sup>24d,e</sup></p>
<p><b>3.4.2.6 Reaction time:</b> The latency (time in ms) between a stimulus (or the command) and the onset of muscle activation<sup>126</sup> (NEW)</p> <p><b>3.4.2.7 Time from command to peak:</b> Time in ms from stimulus to peak activity (NEW) This term encompasses both the reaction time and the time to peak muscle activation</p>	<p><b>3.4.2.6.1 Slow reaction time:</b> A longer time to initiate muscle activation (NEW)</p>
<p><b>3.4.2.8 Time to return to baseline muscle activity:</b> Time in s from peak activity to resting activity (NEW)</p> <p><b>Rate of change:</b> The mean slope of the descending curve in uV/s during a fast MVC</p>	<p><b>3.4.2.8.1 Slow de-recruitment:</b> Slow relaxation of the muscle contraction<sup>24</sup></p>
<p><b>3.4.2.9 Rate of change of amplitude during sustained contraction:</b> The change in sEMG amplitude divided by the duration of the contraction: <math>EMG_{final} - EMG_{initial} / \text{time}(s)</math>.<sup>127</sup> (NEW). The contraction could be sustained or intermittent at different % of MVC<sup>127</sup></p>	<p>A higher rate of change will be indicative of lower endurance</p>
<p><b>3.4.2.10 Timing of muscle activity:</b> Onset of the activation in milliseconds can be assessed in relation to onset of activation in other muscles, provocative activities or other aspects of a task (NEW)</p>	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Delayed: delayed activation of the PFM relative to the onset of a cough or a postural perturbation has been found in women with stress urinary incontinence<sup>124</sup></li> </ul>

TABLE 12 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.4.2.11 Duration of a sustained contraction:</b> The duration in seconds that a contraction could be sustained at a specific % of MVC <sup>127</sup> (NEW)	A shorter duration suggests lower endurance
<b>3.4.2.12 Power spectrum:</b> The distribution of frequency components of the sEMG signals, measured in Hz <sup>114</sup> (NEW)	The median frequency of the sEMG power spectrum shifts to lower frequencies as a muscle fatigues due to altered muscle fiber recruitment and other changes in the contractile properties <sup>128,129</sup>

Abbreviations: MVC, maximum voluntary contraction; PFM, pelvic floor muscles; sEMG, surface electromyography; uV microvolts.

<sup>a</sup>The recording of resting activity is highly susceptible to contamination by ambient noise. A low proportion of noise in the signal (or higher signal-to-noise ratio) is necessary for accurate assessment.

<sup>b</sup>Unlike many other skeletal muscles,<sup>130,131</sup> the PFM are thought to have a level of constant EMG activity to maintain continence and support of pelvic/abdominal contents.

<sup>c</sup>Advanced EMG techniques are needed to prevent inaccurate interpretation from artifacts and muscle crosstalk.

<sup>d</sup>Slow recruitment could be a sign of PFM dysfunction if it leads to leakage during coughing and sneezing when a quick muscle contraction is needed to counteract increased intra-abdominal pressure.<sup>24,75</sup>

<sup>e</sup>The definition for this term used in Bo et al.<sup>24</sup> is the definition this document calls “slow reaction time.”

<sup>f</sup>This may also be considered in the motor control domain.

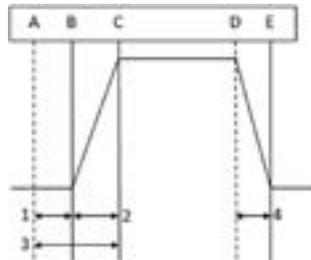

FIGURE 5 Parameters measured using electromyography. Parts of the EMG tracing: A = signal to contract, B = onset of muscle activity, C = peak muscle recruitment, D = signal to relax, E = return to baseline; 1 = Reaction time, 2 = Time to peak activation, 3 = Time from command to peak, 4 = Time to return to baseline muscle activity

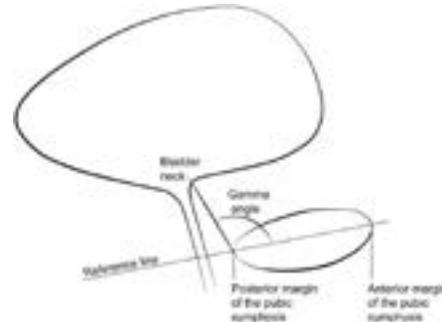

FIGURE 7 Perineal ultrasound parameter (gamma angle) assessed in the mid-sagittal plane using a reference line drawn from the anterior to the posterior margin of the pubic symphysis

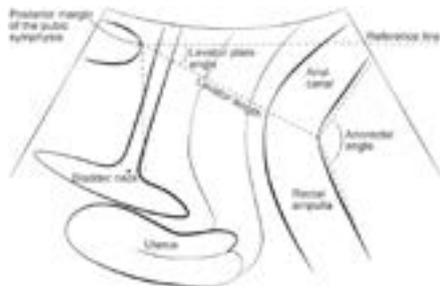

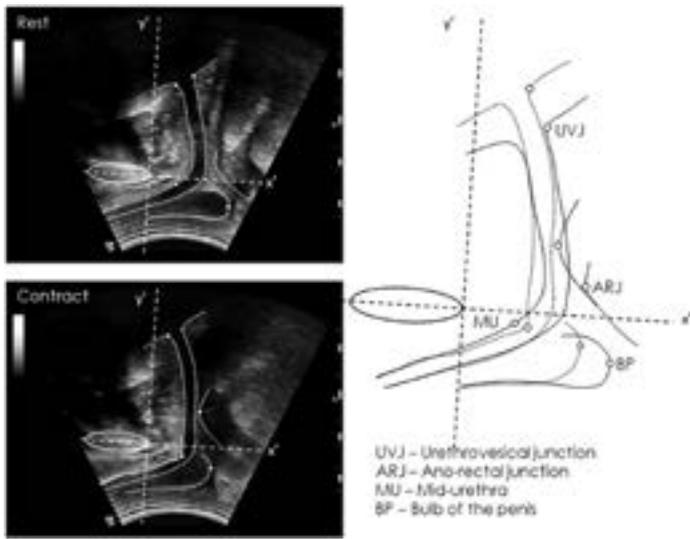

FIGURE 6 Perineal ultrasound parameters and anatomical landmarks assessed in the mid-sagittal plane using a horizontal reference line drawn from infero-posterior margin of the pubic symphysis

**3.5.1.3 Perineal pelvic floor ultrasound:** 2D/3D/4D imaging technique to scan pelvic floor structures using a convex transducer placed against the perineum/vulva.<sup>4</sup> (NEW) The transducer may be oriented longitudinally/sagittally (for bladder neck/urethra, prolapse, and levator ani muscle assessment), or oriented transversely (for assessment of anal canal, sphincters). The terms transperineal and translabial ultrasound are both used to refer to perineal ultrasound. Parameters and findings evaluated with perineal and introital pelvic floor ultrasound—during different activity states of the PFM or actions (rest, contraction, and bearing down)—are presented in Table 15 (see page 26).

**3.5.1.4 Endovaginal pelvic floor ultrasound:** an endocavity transducer is inserted into the vagina (rotational mechanical probe or radial electronic probe)<sup>4</sup> to

**FIGURE 8** Parameters and anatomical landmarks assessed in the mid-sagittal plane using a two-dimensional transducer oriented longitudinally/sagittally in men (reproduced with permission from Stafford et al.<sup>132</sup>). The sketch overlays two images illustrating the anatomy at rest (continuous lines) and during maximal pelvic floor contraction (dotted-lines)

assess pelvic floor morphology. **(NEW)** It can be used to evaluate bladder neck/urethra, levator ani muscle, anal canal, and sphincters during different activity states of the PFM (rest, contraction and bearing down), as described in Table 16 (see page 29).

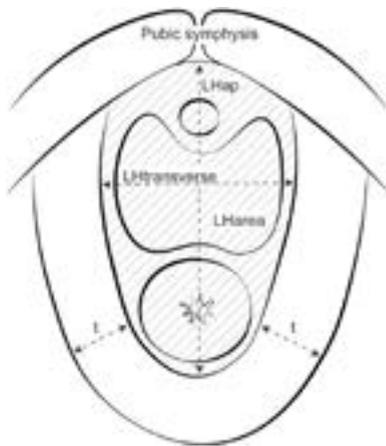

**3.5.1.5 Endoanal ultrasound (EAUS):** An endocavity transducer is inserted into the anus (linear array 3600 3D transducer or radial array 3600 3D transducer).<sup>4</sup> **(NEW)** It can be used to assess the external anal

sphincter (EAS) and internal anal sphincter (IAS). Parameters and findings evaluated with endoanal ultrasound imaging—during different activity states of the PFM (rest, contraction, and bearing down)—are described in Table 17 (see page 30).

**3.5.1.6 Ultrasound elastography:** A noninvasive imaging technique that allows quantification of mechanical and elastic tissue properties following application of physical stress.<sup>174</sup> **(NEW)**. Elastography imaging uses either compression/strain elastography or shear-wave elastography.<sup>156,175–179</sup> The primary differences between elastography techniques relate to the type or source of applied stress, and the methods of detecting displacement of the examined structures. Comparison between the elastography types and B-mode ultrasound is shown in Figure 11 (see page 31).

Parameters and findings evaluated with ultrasound elastography imaging are described in Table 18 (see page 31).

**3.5.2 Magnetic resonance imaging (MRI):** Is a noninvasive diagnostic technique that produces computerized images of internal body tissues and is based on nuclear magnetic resonance of atoms within the body induced by the application of radio waves.<sup>184</sup> **(NEW)** This technique can be applied for many purposes in urology/gynecology/gastroenterology including the assessment of PFM injury, morphometry and positioning of the PFMs and related organs as well as anorectal functioning. Considering that MRI is rarely used in clinic to assess PFM morphometry and function, only a brief overview is provided in Table 19 (see page 32) and further details are available in other standardization documents.<sup>11,150</sup>

**FIGURE 9** Levator hiatal dimensions measured using perineal ultrasound. LHap, levator hiatus antero-posterior diameter; LHarea, levator hiatus area; LHtransverse, levator hiatus transverse diameter; t, pubovisceral thickness

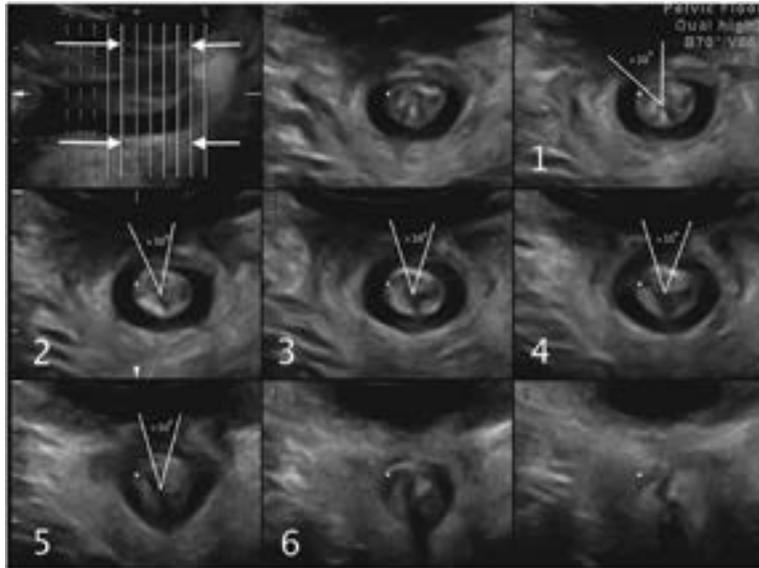

FIGURE 10 Assessment of the integrity of the anal sphincter complex assessed with tomographic ultrasound imaging plane (reproduced with permission from Guzman Rojas et al.<sup>135</sup>)

**3.6 Algometry:** A test to assess the pain response to application of blunt pressure. It is used to evaluate the pain threshold and pain tolerance. **(NEW)** Responses may reflect increased sensitivity (allodynia, hyperalgesia, hyperpathia) or loss of sensation. Algometry does not

provide objective information regarding pathology or neurophysiological function, as do other more sophisticated quantitative sensory testing methods.

Parameters and findings evaluated with algometry are described in Table 20 (see page 33).

TABLE 13 Parameters and findings evaluated with trans-abdominal ultrasound imaging in the mid-sagittal plane

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.5.1.1.1 Bladder base displacement<sup>a</sup>:</b> A marker is placed at the point of greatest displacement (mm or cm) of the infero-posterior bladder wall at rest and at maximal contraction or bearing down.<sup>137</sup> Direction and displacement of the bladder base movement from rest to final position. <b>(NEW)</b>. The bladder base is the most infero-posterior aspect of the bladder wall</p>	<p><i>PFM contraction:</i> Displacement from rest of the bladder base during (attempted) PFM contraction<sup>138</sup>:</p> <ul style="list-style-type: none"> <li>• Elevation (normal response): Movement of the bladder base in a cephalad and ventral direction toward the pubic bone infers contraction of the levator ani/puborectalis</li> <li>• No change</li> <li>• Descent: Movement of the bladder base caudal and posterior away from the pubic bone infers elevated intra-abdominal pressure—PFMs may be active but this cannot be confirmed</li> </ul> <p><i>Bearing down:</i> Displacement of the bladder base during sustained increased intra-abdominal pressure:</p> <ul style="list-style-type: none"> <li>• Elevation</li> <li>• No change</li> <li>• Descent</li> </ul>

Abbreviation: PFM, pelvic floor muscles.

<sup>a</sup>Factors that may compromise the measurement of bladder base displacement include: the lack of bony landmark as a fixed starting point and the fact that movement of the bladder base does not always reflect movement of the bladder neck.<sup>137</sup>

TABLE 14 Parameters and findings evaluated with trans-abdominal ultrasound imaging in the transverse plane

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.1.2 Symmetry of the bladder base:</b> Equal curvature of bladder base with probe placed in the transverse plane ( <b>NEW</b> )	<i>Rest:</i> Symmetrical or asymmetrical. Asymmetry can be related to unilateral increased tone, unilateral decreased tone, operator error in probe position, or asymmetry of passive support (e.g., unilateral ligament damage/trauma) <sup>1</sup>
<b>3.5.1.1.3 Bladder base displacement<sup>b</sup>:</b> See 3.5.1.1.1. Movement of the bladder base (in mm or cm) is used as a surrogate measure for activity of the PFM	<p><i>PFM contraction:</i> Displacement of the bladder base during attempted PFM contraction:</p> <ul style="list-style-type: none"> <li>Elevation (normal response): Movement of the bladder base in a cephalad/ventral direction. No change</li> <li>Descent: Movement of the bladder base in a caudal/dorsal direction</li> </ul> <p><i>Bearing down:</i> Displacement of the bladder base during sustained increased intra-abdominal pressure:</p> <ul style="list-style-type: none"> <li>Elevation</li> <li>No change</li> <li>Descent (normal response)</li> </ul>

Abbreviation: PFM, pelvic floor muscles.

<sup>a</sup>This finding must be correlated with findings of other tests and signs (especially digital vaginal/rectal palpation) to determine reason for asymmetry.

<sup>b</sup>Factors that may affect the measurement of bladder base displacement include: the lack of boney landmark as a fixed starting point and the fact that movement of the bladder base does not always reflect movement of the bladder neck.<sup>137</sup>

TABLE 15 Parameters and findings evaluated with perineal and introital ultrasound imaging assessed in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally/sagittally

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters and anatomical landmarks assessed in the mid-sagittal plane using a 2D/4D transducer oriented longitudinally (f)</i>	
<b>Bladder neck parameters:</b> Measurement of bladder neck position	<i>Rest:</i> Quantification of bladder neck position at rest from the horizontal and vertical distances from the PS <sup>140,146</sup> . Resting position of the bladder neck was found to be higher after PFM training <sup>145</sup>
<b>3.5.1.3.1 Bladder neck position:</b> Refers to the bladder neck position relative to the pubic symphysis (PS). <sup>139</sup> The position is analyzed in a horizontal (x-axis) and vertical position (y-axis) relative to a horizontal reference line (measured in mm or cm) ( <b>NEW</b> ) Specify if using: the infero-posterior margin (Figure 6 on page 23), <sup>140a</sup> the lowest margin, <sup>141</sup> or the central axis (line drawn from the anterior to the posterior margin) of the PS (Figure 7 on page 23) <sup>142</sup> ; the middle of the proximal urethra for the internal meatus, <sup>143</sup> the anterior bladder neck <sup>144</sup> or equidistant points along the urethra from bladder neck to external urethral meatus <sup>145</sup>	<p><i>PFM contraction:</i> Cranio-ventral displacement of the bladder neck<sup>18</sup> measured as: a decrease in x-value and increase in y-value. The ventro-cranial displacement of the bladder neck is measured as displacement = <math>\sqrt{(\Delta x^2 + \Delta y^2)}</math>.<sup>143,146</sup> The higher the value, the greater the ventro-cranial displacement of the bladder neck (bladder neck lift), which reflects the lifting action of the PFM<sup>143,147-149</sup></p> <p><i>Bearing down:</i> On bearing down with the instruction to relax the PFM, the dorso-caudal displacement is measured at the point of maximal displacement during the manoeuvre.<sup>146</sup> As the proximal urethra descends, the x-value increases and the y-value decreases. The higher the value, the greater the dorso-caudal displacement of the bladder neck (bladder neck descent or mobility).<sup>18,143,149</sup> Higher mobility is observed in incontinent women</p>
<b>3.5.1.3.2 Angle <math>\gamma</math> (Gamma)/Pubo-urethral angle:</b> Is the angle (in degrees) between the bladder neck and a line drawn from the anterior to the posterior margin of the pubic symphysis <sup>150</sup> ( <b>NEW</b> ) (see Figure 7)	<p><i>Rest:</i> Quantification of the angle at rest<sup>151</sup></p> <p><i>PFM contraction:</i> A change of the angle <math>\gamma</math> from rest to a maximal PFM contraction. A reduction of the angle is expected as the bladder neck displaces ventrally and caudally.</p> <p><i>Bearing down:</i> Method to assess bladder neck descent/mobility.<sup>150</sup> A larger angle indicates a greater descent of the bladder neck,<sup>140</sup> which has been related to incontinence</p>

TABLE 15 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.3.3 Perineal body:</b> Should appear as a triangular shaped, slightly hyperechoic (white) structure anterior to the anal sphincter <sup>11</sup>	Indicates if the integrity of the perineal body is normal or compromised.
<b>3.5.1.3.4 Levator plate angle:</b> The angle (in degrees) between a horizontal reference line at the level of the infero-posterior margin of the PS intersecting a line from the infero-posterior margin of the PS to the anorectal angle <sup>146,152</sup> <b>(NEW)</b> (see Figure 6)	<p><i>Rest:</i> Quantification of the levator angle at rest. Elevated levator plate angle may be indicative of increased tone in the PFM<sup>148</sup></p> <p><i>PFM contraction:</i> An increase of the levator plate angle in comparison to the angle at rest. Levator plate excursion is calculated by subtracting the angle at rest from the angle during contraction<sup>148</sup></p> <p><i>Bearing down:</i> A decrease of the levator plate angle in comparison to the angle at rest. Levator plate excursion is measured as per contraction, smaller angle is expected<sup>146</sup></p>
<b>3.5.1.3.5 Levator hiatus length:</b> The distance (mm or cm) between the infero-posterior margin of the pubic symphysis to the anorectal angle, representing the levator hiatus antero-posterior diameter in the mid-sagittal view <sup>147,152</sup> <b>(NEW)</b> (see Figure 6)	<p><i>Rest:</i> Quantification of the levator hiatus? at rest. Smaller levator plate length could be suggestive of high tone in PFM<sup>148</sup></p> <p><i>PFM contraction:</i> A reduction of the levator hiatus It has been demonstrated to reflect a PFM contraction<sup>139,151</sup></p> <p><i>Bearing down:</i> An increase of the levator plate length is expected</p>
<b>3.5.1.3.6 Anorectal angle:</b> The angle (in degrees), formed by the longitudinal axis of the anal canal and the posterior rectal wall <sup>11</sup>	<p><i>Rest:</i> Quantification of the anorectal angle at rest. Smaller anorectal angle could be suggestive of increased tone in the PFM<sup>148</sup></p> <p><i>PFM Contraction:</i> A reduction in the anorectal angle during a PFM contraction. The excursion of the anorectal angle is calculated as the angle during contraction of the levator ani muscle minus the angle at rest. Larger excursion could be suggestive of stronger activation of the PFM<sup>148,153,154</sup></p> <p><i>Bearing down:</i> Widening of the anorectal angle is expected.<sup>154</sup> If absent, PFM dyssynergia may be present</p>
<i>(b) Parameters and anatomical landmarks assessed in the mid-sagittal plane using a 2D transducer oriented longitudinally/sagittally (m)</i>	
Displacement or position (in mm or cm) of anatomical landmarks are assessed to interpret activation of individual PFM <sup>25,27</sup>	For the displacement of the anatomical landmarks described below, the displacement during contraction and cough are measured in relation to the resting position values. <sup>25,155</sup> Movement of these landmarks has been correlated with activation of levator ani (puborectalis) <sup>25</sup>
<b>3.5.1.3.7 Urethro-vesical junction:</b> The point of maximal inflection of a line drawn along the dorsal border of the urethra and the bladder neck <sup>25,27</sup> <b>(NEW)</b>	<b>For 3.5.1.3.7 and 3.5.1.3.8:</b>
<b>3.5.1.3.8 Anorectal junction:</b> The ventral-most point of a line drawn along the ventral aspect of the rectum at the anorectal junction <b>(NEW)</b>	<p><i>Rest:</i> The position of these landmarks in the caudo-cranial and antero-posterior planes can be quantified relative to the dorsal pole of the PS at rest (see Figure 8 on page 24). Lower resting position has been observed in incontinent men<sup>155</sup></p> <p><i>PFM contraction:</i> Cranio-ventral displacement is expected<sup>25,156</sup></p> <p><i>Cough:</i> Caudal-dorsal motion can be observed during the pressurization phase of cough due to levator ani muscle lengthening (probable eccentric contraction, but this cannot be confirmed from US imaging) during the phase when intra-abdominal pressure increases. This is followed by cranial-ventral displacement that occurs due to PFM shortening (concentric contraction)</p>
<b>3.5.1.3.9 Bulb of the penis:</b> the dorsal-most point on a line drawn around the bulb of the corpus cavernosum penis <b>(NEW)</b>	<p><i>Contraction:</i> Cranio-ventral displacement is expected due to bulbocavernosus shortening<sup>25,27,155</sup></p> <p><i>Cough:</i> Cranio-ventral displacement is expected due to bulbocavernosus shortening<sup>27</sup></p>
<b>3.5.1.3.10 Mid-urethra:</b> A point on the ventral border of the membranous urethra that undergoes the greatest dorsal movement during contraction. This point is located within 2.5 mm either side of a line drawn between the	<p><i>PFM contraction:</i> Dorsal displacement is expected due to striated urethral sphincter shortening<sup>25,27</sup></p> <p><i>Cough:</i> Dorsal displacement of the mid-urethra due to striated urethral sphincter shortening<sup>25,27</sup></p>

dorsal pole of the pubic symphysis and the most dorsal aspect of the bulb of the penis (NEW) (see Figure 8)	
(c) Parameters and anatomical landmarks assessed in the axial plane using the 4D transducer oriented longitudinally (f)	
<p><b>3.5.1.3.11 Hiatal dimensions:</b> Cross-sectional area of the pelvic floor/levator hiatus, including antero-posterior and transverse distances<sup>24</sup> Measured in the plane of minimal hiatal dimensions.<sup>18</sup> A transverse view is obtained and the plane of minimal hiatal dimensions is identified by moving the field of view cranially and caudally until the distance between the hyperechogenic posterior aspect of the PS and the hyperechogenic anterior border of the pubovisceral muscle is at a minimum<sup>157</sup></p>	
<p><b>3.5.1.3.11.1 Levator hiatus antero-posterior diameter:</b> The distance (in mm or cm) delineated from the PS (anteriorly) to the edge of the puborectalis muscle (posteriorly) (NEW)</p>	<p>Findings below apply to all measurements of hiatal dimensions. <i>Rest:</i> Quantification of the levator hiatus diameters/area at rest. Smaller diameter/area has been observed in women with pelvic pain and is may suggest increased tone in the PFM.<sup>148</sup> Conversely, a larger hiatus has been observed in women with pelvic organ prolapse</p>
<p><b>3.5.1.3.11.2 Levator hiatus left-right/latero-lateral/transverse diameter:</b> Latero-lateral diameter of the levator hiatus (in mm or cm) in the plane of minimal hiatal dimensions. (NEW) The diameter from right to left is measured at the widest part, and perpendicular to the antero-posterior diameter.<sup>11,149</sup></p>	<p><i>PFM contraction:</i> A reduction of the area/diameter is expected during a maximal PFM contraction. Hiatus reductions during contraction can be calculated as the percentage of change from baseline (i.e., levator hiatus narrowing = (levator hiatus at rest – levator hiatus at contraction)/levator hiatus at rest × 100)<sup>148</sup></p>
<p><b>3.5.1.3.11.3 Levator hiatus area:</b> Defined and measured as the area (in mm<sup>2</sup> or cm<sup>2</sup>) bordered by the pubovisceral muscle, PS and inferior pubic ramus in the plane of minimal hiatal dimensions<sup>149</sup> (NEW)</p>	<p><i>Bearing down:</i> An increase in the levator hiatus diameter/area is expected on bearing down with the instruction to relax the PFM.<sup>157</sup> The difference (or percentage of change) between the diameter at rest and on bearing down determines the degree of hiatal distension.<sup>11</sup> Higher distension has been observed in women with pelvic organ prolapse<sup>158</sup></p>
<p><b>3.5.1.3.12 Maximal levator ani muscle thickness:</b> Is the maximum diameter of the levator ani muscle measured in two locations bilaterally (in mm or cm). (NEW) (see Figure 9 (see page 24)). This is usually located 1–1.5 cm above the minimal levator hiatus dimension. Measured perpendicular to the presumed levator ani fiber direction<sup>149,157</sup></p>	<p>Provides morphologic measurements of the muscle diameter and area at rest.<sup>157</sup> <i>Rest:</i> Increased thickness has been observed after PFM training.<sup>159</sup> Increased thickness may be indirectly related to strength<sup>159</sup></p>
<p><b>3.5.1.3.13 Levator ani muscle cross-sectional area:</b> Is the area (in mm<sup>2</sup> or cm<sup>2</sup>) delineated by tracing the outline of the levator ani muscle at the level of maximal muscle thickness (NEW)</p>	
<p><b>3.5.1.3.14 Integrity of the anterior/medial fibers of the levator ani:</b> To assess if a disruption or disconnection of the insertion is present, direct the patient to perform a PFM contraction, and identify the plane of minimal hiatal dimensions at maximal PFM contraction. Use this plane for tomographic ultrasound imaging of the puborectalis component of the levator ani, with an interslice interval of 2.5 mm<sup>4</sup> (NEW)</p>	<p><b>3.5.1.3.14.1 Complete avulsion<sup>b</sup></b> is diagnosed when the 3 central slices show a loss of integrity or defect in the anterior/medial fiber of the levator ani muscle on the inferior pubic ramus resulting in a levator-urethra gap<sup>7</sup>(NEW). A gap of more than 2.5 cm has been suggested as an indicator of avulsion<sup>160</sup><b>3.5.1.3.14.2 Partial avulsion:</b> Is diagnosed when at one or two of the 3 central slices show a loss of integrity/defect of the medial fiber of the levator ani muscle (CHANGED)<sup>24</sup></p>
<p><b>3.5.1.3.15 Urethral sphincter volume:</b> Ultrasound imaging of the urethral sphincter (morphometry of the rhabdosphincter).<sup>18</sup>(NEW) The internal sphincter volume (in mm<sup>3</sup> or cm<sup>3</sup>) including the longitudinal smooth muscle and the lumen is seen as a hypoechoic (black) core whereas the external sphincter volume or the circular striated muscle of the rhabdosphincter is seen as a hyperechoic (white) ellipsoid structure<sup>161–163</sup></p>	<p>Smaller sphincter volume is related to urinary incontinence severity<sup>164</sup> and urethral pressure.<sup>163</sup> PFM training results in increased sphincter volume<sup>165</sup></p>

TABLE 15 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(d) Parameters and anatomical landmarks assessed with tomographic ultrasound imaging plane using the 4D transducer oriented transversely</i>	
<p><b>3.5.1.3.16 Integrity of the anal sphincter complex:</b> assessment of the internal and external anal sphincter to identify presence/absence of a defect (measured in degrees). <b>(NEW)</b> Using tomographic ultrasound imaging, the anal canal is visualized in the mid-sagittal plane and a set of 8 transverse slices is placed to encompass the entire external anal sphincter by locating one slice cranial to the external anal sphincter (at level of puborectalis, Slice 1) and another caudal to the internal anal sphincter (at level of subcutaneous part of external anal sphincter, Slice 8), leaving six slices to delineate the entire muscle (Slices 2–7) (see Figure 10 on page 25). Interslice interval is varied depending on external anal sphincter dimensions<sup>133,166</sup></p>	<p><i>PFM contraction:</i> A “significant” defect is diagnosed if four out of these six slices show a defect in &gt;30° of the circumference of the external anal sphincter.<sup>4,166</sup></p>

Abbreviations: *f*, females; *m*, males; MVC, maximum voluntary contraction; PFM, pelvic floor muscles; PS, pubic symphysis.

<sup>a</sup>The horizontal reference line drawn from antero-posterior margin or the lowest margin of the PS may be influenced by the angle of the transducer.

<sup>b</sup>Synonyms are puborectalis/pubovisceralis defects or injury.

TABLE 16 Parameters and findings evaluated with endovaginal ultrasound imaging

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<i>(a) Parameters and anatomical landmarks assessed in the sagittal plane (2D)</i>	
<p><b>3.5.1.4.1 Levator plate position:</b> the distance (in mm or cm) between the levator plate and endovaginal probe<sup>167</sup> <b>(NEW)</b></p>	<p><i>Rest:</i> Quantification of the distance between the levator plate and the probe with the PFM at rest.</p> <p><i>PFM contraction:</i> A reduction of the distance between the levator plate and the probe is expected during a maximal PFM contraction; may be called levator plate lift. A greater levator plate lift ratio (lift/rest × 100) detected by dynamic endovaginal sonography has been associated with higher PFM strength as determined by the Modified Oxford Scale<sup>167</sup></p>
<p><b>3.5.1.4.2 Perineal body:</b> See 3.5.1.3.3. The depth (antero-posterior diameter) and height (supero-inferior diameter) of the perineal body can be measured in mm or cm in this plane<sup>11,168</sup></p>	<p><i>Rest:</i> Visibility of the structure and biometric measurements are identified at rest; indicate if the perineal body is visible or not visible<sup>168</sup></p>
<p><b>3.5.1.4.3 Anorectal angle:</b> See 3.5.1.3.6.</p>	<p><i>Rest:</i> Quantification of the anorectal angle at rest<sup>169</sup></p>
<i>(b) Parameters and anatomical landmarks assessed in the axial plane (3D)</i>	
<p><b>3.5.1.4.4 Hiatal dimensions:</b> measurements of the following parameters are taken in the place of minimal hiatal dimension,<sup>49</sup> as described in Table 17</p> <p><b>3.5.1.4.4.1: Hiatal antero-posterior diameter:</b> Antero-posterior diameter (in mm or cm) of the levator hiatus measured at the level of minimum dimension <b>(NEW)</b></p> <p><b>3.5.1.4.4.2 Hiatal transverse diameter:</b> The diameter (in mm or cm) from right to left is measured at the widest part, and perpendicular to antero-posterior diameter <b>(NEW)</b></p>	<p><i>Rest:</i> Quantification of the levator hiatus diameters/area at rest<sup>49</sup></p>

(Continues)

TABLE 16 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.4.4.3 Hiatal area:</b> Defined and measured as the area (in mm <sup>2</sup> or cm <sup>2</sup> ) bordered by the pubovisceral muscle, PS, and inferior pubic ramus in the plane of minimal hiatal dimensions (NEW)	
<b>3.5.1.4.4.5 Levator ani thickness:</b> Defined as the diameter of the levator ani muscle (in mm or cm) at the “9 o'clock” and “3 o'clock” positions <sup>49</sup> as described in Table 15 (NEW)	<i>Rest:</i> Provides morphologic measurements of the levator ani diameter.
<b>3.5.1.4.4.6 Levator plate angle:</b> The angle (in degrees) between the reference line and the plane of minimal levator hiatal dimensions/anorectal angle, identified via a multiplanar view <sup>169</sup> (NEW)	<i>Rest:</i> This angle quantifies the levator plate position in reference to the pubic bone and the perineal body <sup>169</sup>
<b>3.5.1.4.4.7 Levator ani deficiency:</b> Assessed from a 3D volume. Individual levator ani muscles are evaluated in their specific axial plane where the full length of muscle can be visualized <sup>170,171</sup> (NEW)	<i>Rest:</i> The muscles on each side for each subgroup are scored based on thickness and detachment from the pubic bone: <ul style="list-style-type: none"> <li>• 0 = no defect</li> <li>• 1 = minimal defect with &lt;50% muscle loss</li> <li>• 2 = major defect with &gt;50% muscle loss</li> <li>• 3 = total absence of the muscle</li> </ul> Significant levator ani deficiency is defined as a total score within the range of 12–18 <sup>170,171</sup>
<b>3.5.1.4.4.8 Perineal body:</b> This anatomical structure is visualized as an ovoid-shaped, mixed echogenicity structure. The width (latero-lateral diameter) (in mm or cm) of the perineal body can be measured in the axial plane <sup>168</sup>	as per 3.5.1.3.3

Abbreviations: PFM, pelvic floor muscles; PS, pubic symphysis

TABLE 17 Parameters and findings evaluated with endoanal ultrasound imaging

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<b>3.5.1.5.1 Anal sphincter defect (or pathology):</b> Assessment of the internal and external anal sphincters to identify presence/absence of a defect; observed in cross-sectional images of the anal sphincter. (NEW) This measure is obtained by a probe inserted into the anal canal to a depth of approximately 6 cm and gently withdrawn down the anal canal. The anal canal is divided into three levels of assessment in the axial plane referring to the following anatomical structures <sup>11,172,173</sup> : <ol style="list-style-type: none"> <li>i. Proximal or lower level: corresponds to the subcutaneous part of the external anal sphincter where the internal anal sphincter is absent</li> <li>ii. Middle level: corresponds to the superficial part of the EAS (concentric band of mixed echogenicity), the conjoined longitudinal layer, the IAS (concentric hypoechoic ring), and the transverse superficial perineal muscles</li> <li>iii. Distal or upper level: the hyperechoic sling of the puborectal muscle and the complete ring of the internal anal sphincter are visualized<sup>11</sup></li> </ol> The probe should be rotated so that the anterior aspect of the anal canal is superior (12 o'clock) and left lateral is oriented right (3 o'clock) on the screen. The acquisition of a three-dimensional data volume (3D ultrasound) of the anal sphincter is also possible	Indicate if defect is present or absent

Abbreviations: EAS, external anal sphincter; IAS, internal anal sphincter.

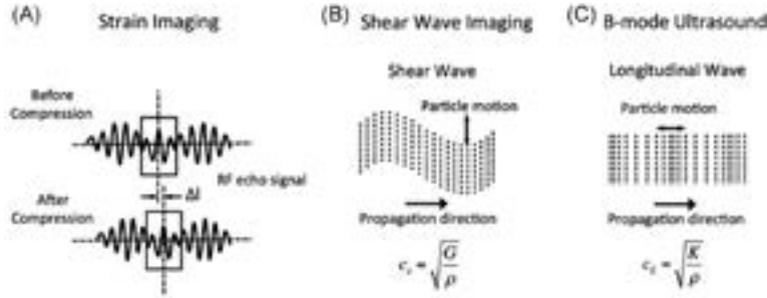

FIGURE 11 Ultrasound elastography physics, measurement methods (reproduced with permission from Sigrist et al.<sup>174</sup>). In strain imaging (A), tissue displacement is measured by correlation of radiofrequency echo signals between search windows (boxes) in the states before and after compression. In shear wave imaging (B), particle motion is perpendicular to the direction of wave propagation, with shear wave speed  $c_s$  related to shear modulus  $G$ . In B-mode ultrasound (C), particle motion is parallel to the direction of wave propagation, with longitudinal wave speed  $c_L$  related to bulk modulus  $K$

TABLE 18 Parameters and findings evaluated with ultrasound elastography imaging

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.5.1.6.1 Shear wave elastography (SWE):</b> Ultrasound elastography using shear waves generated by the US beam. (NEW). Different types are point SWE, 2D SWE, and transient elastography. 2D SWE uses an acoustic radiation force pulse sequence to generate shear waves, which propagate perpendicular to the ultrasound beam, causing transient displacements. The distribution of shear wave velocities at each pixel is directly related to the shear modulus in kilopascal (kPa), an absolute measure of the tissue's elastic properties. This technique is considered more objective than strain elastography<sup>180</sup></p>	<p>Higher values indicate stiffer tissue, as shear waves propagate faster in stiffer tissues. Stiffness measures include both active (muscle contraction) and passive (viscoelastic properties) components of the tissue</p>
<p><b>3.5.1.6.1.1 Perineal shear wave elastography:</b> Shear wave elastography applied per perineum. (NEW). Only 2D SWE has been applied to the PFM.<sup>156,175,179</sup> A linear transducer is placed against the perineum/vulva. Orientation is longitudinal (for assessing urethral sphincter), or aligned with the muscle fibers for specific PFM (e.g., puborectalis) assessment. A linear or curved transducer can be used. Stiffness is evaluated using quantitative shear modulus maps represented in a color-coded elastogram displaying shear-wave velocities in meters per second or tissue elasticity (shear elastic modulus) in kilopascals<sup>181</sup></p>	<p>Higher values indicate stiffer tissue. Measures may provide evidence of stiffer tissue at rest (e.g., high activation of PFM at rest) and should increase with contraction.<sup>156,175,179</sup> Quality of measurement depends on orientation of the transducer (parallel with muscle fibers), accuracy of movement of the transducer to follow the movement of the muscle during contraction. Measures are compromised if there are areas in the image where the measure is saturated (stiffness greater than the measurable scale) or unable to be quantified by the system</p>
<p><b>3.5.1.6.2 Strain elastography:</b> Ultrasound elastography which measures strain in one tissue area proportional to another. (NEW). Maps, or elastograms, are developed based on the relative differences in stiffness between the area of interest and the reference tissue. The assessor applies slight and constant vertical compression through the transducer along the major axis of the tissue. Elasticity is measured by means of the Young's modulus and is defined as the ratio between the pressure measured and the strain (deformation compared to the initial length) produced.<sup>182</sup> Soft tissue is more compressible than harder tissue and therefore has a higher</p>	<ul style="list-style-type: none"> <li>• <b>Qualitative analysis:</b> The different colors express different degrees of elasticity, usually varying from red (soft tissue) to blue (hard tissue) with intermediate colors representing intermediate degrees of stiffness<sup>182</sup></li> <li>• <b>Semi-quantitative analysis:</b> the target tissue is selected and labeled as the region of interest (ROI) A, and the reference tissue is labeled as ROI B. Elasticity of tissue expressed as a strain ratio: B/A. The higher the value of B/A, the stiffer the target tissue</li> </ul>

(Continues)

TABLE 18 (Continued)

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p>strain (displacement) for the same applied stress (force). The results of strain elastography can only be expressed qualitatively or semi-quantitatively<sup>180,182</sup></p>	
<p><b>3.5.1.6.2.1 Pelvic floor strain elastography:</b> strain elastography to assess deep PFM elasticity<sup>176,177</sup> and periurethral elasticity as an estimate of urethral mobility<sup>183</sup> (NEW)</p> <ul style="list-style-type: none"> <li>To assess deep PFM: A perineal transducer is placed perpendicular to the skin in the sagittal plane to identify levator ani muscle. The levator ani muscle is selected on screen and labeled as the target tissue (region of interest [ROI] A), and the adjacent anal canal is selected and labeled as reference tissue (ROI B)<sup>176</sup></li> <li>To assess urethral support tissues: an endovaginal transducer is placed parallel to the urethral meatus. The target tissue is the tissue between the urethra and the vagina (para-urethral tissue) (ROI A), and the reference tissue is set at the level of the posterior tissue of the bladder neck (ROI B)</li> </ul>	<p>The higher the value of B/A, the stiffer the target tissue. A 4-point elasticity score has been used to represent levator ani muscle elasticity<sup>176,177</sup></p>

Abbreviations: PFM, pelvic floor muscles; ROI, region of interest; SWE, shear wave elastography.

TABLE 19 Parameters and findings evaluated with pelvic floor MRI

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.5.2.1 Levator ani defects:</b> Is damage to muscle fibers ranging from disruption of a single fascicle, to complete disruption of the muscle origin (CHANGED)<sup>24a</sup></p> <p>There is no universally accepted system for the diagnosis and evaluation of the extent of the injury. Essentially, abnormalities are judged to have occurred when the morphology of the pubococcygeal portion of the levator ani muscle deviates from what is seen in normal nulliparous women<sup>24</sup></p>	<p>Levator ani damage on MRI can be diagnosed when one or more of the following is present: absence of pubococcygeal muscle fibers in at least one 4-mm section, or two or more adjacent 2-mm sections in both the axial and the coronal planes<sup>24</sup></p> <p>Defect severity may be further scored in each muscle from 0 (no defect) to 3 (complete loss). A summed score for the two sides (0–6) is assigned and grouped as minor (0–3) or major (4–6)<sup>11</sup></p>
<p><b>3.5.2.2 Levator ani position in the pelvis:</b> Location of the levator ani in the sagittal plane in relation to defined landmarks and reference points/lines<sup>126</sup> (NEW)</p>	<p>May be normal, elevated, or descended<sup>24</sup></p>
<p><b>3.5.2.3 Hiatal dimension:</b> See 3.5.1.3.11</p>	<p>See 3.5.1.3.11</p>
<p><b>3.5.2.4 MR defecography:</b> Demonstrates the anatomy of the anorectum as well as disorders of rectal evaluation. Barium paste is inserted before defecation over a translucent commode (CHANGED)<sup>29</sup></p>	<p>This assessment focusses on anorectal function. When dyssynergia is diagnosed (see definition 4.3.1) this confirms PFM involvement<sup>11</sup></p>

Abbreviations: MRI, magnetic resonance imaging; PFM, pelvic floor muscles.

<sup>a</sup>The term levator injury is also used synonymously.<sup>11,185</sup>

TABLE 20 Parameters and findings evaluated with algometry

Parameters, specifications (units of measure) and measurement processes	Outputs and interpretation of findings
<p><b>3.6.1 Algometer/Algesiometer:</b> An instrument for measuring the pain response to a pressure stimulus. <b>(NEW)</b> An algometry device measures pressure applied in Newtons or kg/cm<sup>2</sup>, with an associated patient-reported pain response</p> <ul style="list-style-type: none"> <li>To assess vulval or vestibular pressure pain response, the assessor uses an algometer<sup>186</sup> or a syringe with a pre-loaded or pre-set amount of pressure, called a vulvalgesiometer<sup>187</sup> or a cotton swab<sup>188</sup> against the vulval tissue and delivers the pressure</li> <li>To assess intra-vaginal pressure pain response, the assessor mounts a digital palpometer (sensor) to the palpating digit, covered by examination glove, and connected to an algometry device. The device applies a pre-set amount of pressure to the tissue.<sup>188–190</sup> To assess pressure/pain in pelvic floor tissues, the assessor applies a pre-set amount of pressure (usually in the range of 0.5–2 N<sup>188,191,192</sup>), starting at a low pressure and assesses pain response to that pressure, or applying increasing amounts of pressure and instructing the patient to state when the pressure reaches the patient's threshold</li> </ul> <p>Algometry tests:</p> <ul style="list-style-type: none"> <li><b>3.6.1.1 Pressure pain threshold (PPT):</b> The minimum intensity of a pressure stimulus that is perceived as painful.<sup>193</sup> (i.e., point at which a sensation changes from one of pressure to one of pain) <b>(NEW)</b></li> <li><b>3.6.1.2 Pressure pain tolerance (PPTol):</b> The highest intensity of painful pressure stimulus that an individual is able to tolerate<sup>193</sup> <b>(NEW)</b></li> </ul>	<p>Results may be expressed as the pressure applied when the patient reports detection or tolerance of pain, or a specific pressure applied and the patient rating of pain at that pressure. A finding of pain with a low applied pressure may suggest allodynia, and a finding of pain with a moderate applied pressure may suggest hyperalgesia</p> <p>Variability in readings can be caused by: anatomical test site (muscle belly vs. tendon<sup>194</sup>; mucosa vs. tendon,<sup>191</sup> coexistence of other pain disorders<sup>195</sup>; left vs. right,<sup>196</sup> stage in menstrual cycle,<sup>197</sup> sex and gender,<sup>198</sup> rate of pressure increase during test, dimensions of the pressure applicator</p>

## 5 | SECTION 4: DIAGNOSES

**Diagnosis:** The act or process of identifying or determining the nature and cause of a disease or injury through evaluation of patient history, examination, review of investigations, and the opinion derived from such an evaluation.<sup>199</sup>

**(CHANGED)** The diagnostic process aims to identify the most specific disorder possible. Overarching diagnoses are used when there is less certainty about the presenting disorder. Diagnoses that are specific to the PFM may coexist with and be used in addition to other pelvic floor diagnoses the patient presents with, for example, voiding dysfunction, pelvic organ prolapse. The diagnoses proposed below may change as evidence emerges to support or refute these terms as diagnostic terms. In some healthcare settings, clinicians are required to assign a code for the presenting diseases, disorders, injuries, and other related health conditions, using the International Classification of Diseases (ICD) coding system.<sup>200</sup> Not all terms below have a

corresponding ICD diagnostic code. As advised by ICD, “codes that describe symptoms and signs, as opposed to diagnoses, are acceptable for reporting purposes when a related definitive diagnosis has not been established (confirmed) by the provider.”

**4.0. PFM disorder/dysfunction:** An alteration of normal PFM function. **(NEW)** Any departure from normal function of the PFM that is of bother to the patient and has an associated sign and/or a finding from an investigation that suggests a departure from normal structure or function. If a specific disorder can be diagnosed, the following terms may be used.

### 4.1 Disorder of increased PFM tone

**4.1.1 Pelvic floor tension myalgia:** A condition of pain and increased PFM tone **(NEW)**.<sup>xv</sup> If the location can be confirmed as the levator ani, then the term can be levator ani tension myalgia. Criteria for diagnosis of pelvic floor tension myalgia are described in Table 21 (see page 34).

**4.1.2 Pelvic floor myofascial pain syndrome:** A pelvic floor pain syndrome of myofascial origin.

TABLE 21 Criteria for diagnosis of pelvic floor tension myalgia

Assessment	Findings
Symptoms	<ul style="list-style-type: none"> <li>• May relate to sensation of pain: pain, tender, ache, discomfort</li> <li>• May relate to sensation of increased tone: tight, tense, narrow or constricted</li> </ul>
Signs	<p>Tenderness or tender point on palpation of PFM<sup>s</sup> per perineum, per vaginam, or per rectum as well one or more of the following signs:</p> <ul style="list-style-type: none"> <li>• Lack of perineal and/or PFM descent with sustained increased intra-abdominal pressure</li> <li>• Absent, partial or delayed relaxation of perineum and/or PFM after contraction</li> <li>• Nonrelaxing PFM</li> <li>• Hypertonicity, or increased PFM tone, on a continuum from transient increase in tone to spasm</li> <li>• Fasciculation</li> <li>• Reduced flexibility of the vaginal opening</li> </ul>
Investigations	<p>Muscle tenderness as assessed by digital algometry (palpometry)</p> <p>Finding of increased tone from any tool which measures tone (dynamometry, myotonometry, manometry, EMG, ultrasound or MRI)</p> <ul style="list-style-type: none"> <li>• if EMG reveals an inconsistent or elevated resting baseline, or slow de-recruitment, this suggests increased myoelectrical activity, which may be termed overactivity in the PFM<sup>b</sup></li> </ul>

Abbreviations: EMG, electromyography; MRI, magnetic resonance; PFM, pelvic floor muscles.

<sup>a</sup>When assessing sensory changes *PV* or *PR*, the clinician needs to determine whether s/he is detecting sensory change in the mucosa (mucosal sensitivity), or the underlying muscle (muscle tenderness) by differentiating the depth and firmness of palpation.

<sup>b</sup>The previously proposed term “overactive PFM”<sup>23</sup> has been used to refer to increased tone in a muscle, however if the source of the increased tone (contractile or noncontractile component of tone) cannot be determined, this term is not recommended.

TABLE 22 Criteria for diagnosis of pelvic floor myofascial pain syndrome

Assessment	Findings
Symptoms	Presence of pain
Signs	<p>Tender point in a taut band (localized increased tone) of skeletal muscle<sup>53,54</sup></p> <p>Patient pain recognition on tender point palpation</p> <p>Referral pattern</p> <p>Local twitch response</p> <p>The paired criteria of tender points in taut bands and predicted or recognized pain referral form the most frequently cited combination of diagnostic criteria</p>
Investigations	<p>There is no consensus regarding objective laboratory tests for myofascial trigger point diagnosis however MR elastography and ultrasound elastography have been reported to investigate myofascial taut bands<sup>202</sup> and trigger points<sup>203</sup> in the trapezius muscle</p>

Abbreviation: MR, magnetic resonance

Assessment	Findings
Symptoms	Pain, tender, ache, discomfort
Signs	Muscle tenderness or tender point on palpation of PFM <sup>s</sup> <sup>a</sup> and normal tone in PFM <i>per perineum, per vaginam, or per rectum</i>
Investigations	<p>Muscle tenderness as assessed by digital algometry (palpometry)</p> <p>Finding of normal tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound, or MRI)</p>

Abbreviations: EMG, electromyography; MRI, magnetic resonance imaging; PFM, pelvic floor muscles; *PR*, per rectum; *PV*, per vaginam.

<sup>a</sup>When assessing sensory changes *PV* or *PR*, the clinician needs to determine whether s/he is detecting sensory change in the mucosa (mucosal sensitivity), or the underlying muscle (muscle tenderness) by differentiating the depth and firmness of palpation.

TABLE 23 Criteria for diagnosis of pelvic floor myalgia

TABLE 24 Criteria for diagnosis of decreased PFM tone

Assessment	Findings
Symptoms	Loose, lax, gaping, sagging, open, weak, bulging, full, loss of control
Signs	Hypotonicity, decreased PFM tone, anal or introital gaping, excessive flexibility of the vaginal opening, palpation of an anal sphincter gap or levator avulsion.  Deficit in PFM contractile function: absence of voluntary PFM contraction, decreased strength (weakness), decreased sustained and repeated endurance, lack of perineal or PFM elevation, no urethral lift, partial or uncertain levator closure, small to no change in levator hiatus on contraction
Investigations	Any tool which measures tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound, or MRI)  – If EMG reveals a reduced signal amplitude or peak microvolts, or shorter duration of sustained contraction this suggests decreased myoelectrical activity, which may be termed “underactivity” in the PFM <sup>a</sup>

Abbreviations: EMG, electromyography; MRI, magnetic resonance imaging; PFM, pelvic floor muscles.

<sup>a</sup>The previously proposed term “underactive PFM”<sup>2,3</sup> has been used to refer to decreased tone in a muscle, however, if the source of the decreased tone (contractile or noncontractile component of tone) cannot be determined, this term is not recommended.

TABLE 25 Criteria for diagnosis of vaginismus

Assessment	Findings
Symptoms	Pain, tight, tense, narrow, or constricted
Signs	Transient increased tone—inability to maintain relaxation with attempted vaginal penetration ( <i>f</i> )  Increased PFM tone
Investigations <sup>a</sup>	Assessment of resting tone (measured by dynamometry, myotonometry, manometry, EMG, ultrasound or MRI)  Increased activation of PFM shown by perineal or peri-anal EMG during attempted vaginal penetration

Abbreviations: *f*, female; EMG, electromyography; MRI, magnetic resonance imaging; PFM, pelvic floor muscles.

<sup>a</sup>Investigations may be in-conclusive, as PFM tone values may overlap in conditions such as dyspareunia and vaginismus, therefore the PFM resting tone and response to attempted penetration may not exclusively diagnose vaginismus.

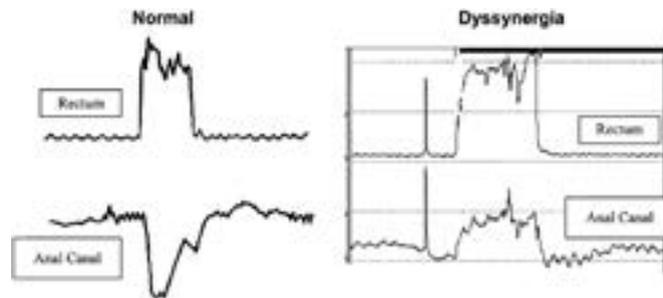

FIGURE 12 A normal and abnormal (dyssynergic) pattern of defecation (reproduced with permission from Rao<sup>206</sup>). A normal pattern consists of a rise in the intrarectal pressure coordinated with relaxation of anal sphincter pressure. In contrast, a dyssynergic pattern is associated with a paradoxical increase in anal sphincter pressure. Typical patterns for a normal and dyssynergic pattern of defecation as measured during anorectal manometry with a pressure sensor in the rectum and a pressure sensor in the anal canal

(NEW) this diagnosis has trigger points as a hallmark feature.<sup>53</sup> However there is no consensus of the definition and diagnostic criteria associated with trigger

points.<sup>53,54</sup> The criteria most consistently used for diagnosis amongst researchers and expert clinicians are shown in Table 22 (see page 34).

TABLE 26 Criteria for diagnosis of anismus

Assessment	Findings
Symptoms	Pain, tender, ache, discomfort during attempted defecation or anal penetration
Signs	Perineal and/or PFM elevation with sustained increased IAP (bearing down) or attempted penetration Increased PFM tone
Investigations	Balloon expulsion test MR defecography EMG: PFM activation during defecation suggesting poor motor control <sup>207</sup>

Abbreviations: EMG, electromyography; IAP, intra-abdominal pressure; MR, magnetic resonance; PFM, pelvic floor muscles.

4.2 Disorder of PFM pain

4.2.1 Pelvic floor myalgia: A condition of PFM pain. (NEW). Criteria for diagnosis of pelvic floor myalgia are described in Table 23 (see page 34).

4.3 Disorder of decreased PFM tone: A condition which results from a reduction in PFM tone, due to either the contractile or the noncontractile components of tone.<sup>xvi</sup> (NEW) Criteria for diagnosis of decreased PFM tone are described in Table 24 (see page 35).

4.4 Disorder of PFM coordination

4.4.1 PFM dyssynergia:<sup>xvii</sup> Paradoxical PFM or sphincter contraction: a dysfunction of coordination between the PFM and a functional activity, such as a PFM contraction when relaxation is functionally required. (NEW) These dyssynergias may share similar symptoms and signs.<sup>xviii,xix</sup>

4.4.1.1 Vaginismus: Spasm of vaginal musculature that interferes with vaginal penetration (CHANGED).<sup>12,xx</sup> Criteria for diagnosis of vaginismus are described in Table 25 (see page 35).

Vaginismus may also be termed genito-pelvic pain/penetration disorder, which includes fear or anxiety as a component of the disorder.<sup>204,205</sup>

4.4.1.2 Anismus: Spasm of the EAS with attempted defecation or anal penetration (CHANGED).<sup>11,xxi</sup> This dyssynergia is shown in Figure 12 (see page 35).

Criteria for diagnosis of anismus are described in Table 26.

4.5 Pudendal neuralgia: Pudendal neuralgia is a chronic and severely disabling neuropathic pain syndrome caused by mechanical or nonmechanical injury of the pudendal nerve.<sup>208</sup> (NEW) The Nantes criteria list five essential diagnostic criterion including three symptoms, one sign and one investigation.<sup>209</sup> These criteria are described in Table 27 (see below).

Assessment	Findings
Symptoms	Pain in the distribution of the pudendal nerve and its referral areas, primarily the genitalia including the vulvovaginal, anorectal, and distal urethral areas Worse in the sitting position Pain does not wake the patient at night, no numbness of the perineum The patient may also have associated pelvic floor symptoms <sup>208</sup>
Signs	Nantes criteria <sup>209</sup> sign: No loss of sensation in the pudendal distribution on objective testing Other signs include: <ul style="list-style-type: none"> <li>• Tenderness to palpation anywhere along the length of the pudendal nerve</li> <li>• Increased tone and tenderness of the obturator internus or piriformis muscles (depending on the location of the nerve irritation)</li> <li>• Positive pudendal nerve neurodynamic test</li> <li>• Positive pudendal nerve provocation test</li> </ul>
Investigations	As per Nantes criteria <sup>209</sup> : may be confirmed by relief of patient's pain after a pudendal nerve block with or without guided imaging <sup>a</sup>

<sup>a</sup>Pudendal nerve blocks are technically difficult to perform accurately and lack of pain relief after the procedure does not rule out the condition.<sup>208</sup>

TABLE 27 Criteria for diagnosis of pudendal neuralgia

## 6 | CONCLUSION

This report has drawn together the most frequently published methods of PFM assessment that appear in the published literature. This process has highlighted the plethora of terms in current use. We have attempted to provide the most precise yet clinically meaningful definitions and descriptions of these terms, and where available, provided an explanation of the finding from the assessment method. We hope this will provide clinicians and researchers with clarity and standardization in the recording of PFM function and dysfunction. It is anticipated that some of these terms will be discarded over time and new terms will emerge, and a revision of this document will be required in the future. It is important to remember that visual observation and digital palpation are subjective forms of assessment, and the assessor must be aware that conclusions of PFM function or dysfunction based on these clinical observations may be uncertain. At present, PFM tone and involuntary action remain less well understood than properties such as strength. Where available, the use of quantitative assessment tools (investigations), may strengthen the certainty of the finding. In some instances, it may not be possible to identify a specific classification of PFM disorder, beyond the first level of diagnosis of “PFM disorder.”

## 7 | AREAS FOR FURTHER RESEARCH

A core outcome set for PFM assessment would be valuable, however, this requires knowledge of the clinimetric properties of the many assessment methods currently used in clinical practice and research, and a comparison of these properties amongst the assessment methods; such knowledge is lacking. There is an urgent need for a report to compile the validity, reliability, and responsiveness of PFM assessment methods, especially for the more subjective methods of visual observation and digital palpation. The clinimetric properties of some aspects of the more objective methods of PFM assessment (simple and sophisticated tools) has been undertaken, however many gaps in testing remain. Whether any of these assessment methods provide diagnostic test accuracy of PFM function and dysfunction is unknown. Future research in this area is required.

### ACKNOWLEDGMENTS

We thank the following individuals for their contributions to this document: Paul McCrory, Neurologist, Ph.D., Melbourne, Australia; Paul Hodges, Physiotherapist, Ph.D., Brisbane, Australia; Ryan Stafford, Ph.D., Brisbane, Australia; Dawson Kidgell, Neuromuscular Physiologist, Ph.D., Melbourne, Australia; Ashlyn Frazer, Human

Physiologist, Ph.D., Melbourne, Australia; Hans Peter Dietz, Urogynaecologist, Ph.D., Sydney, Australia; Irmina Nahon, Physiotherapist, Ph.D., Canberra, Australia; Patricia Neumann, Physiotherapist, Ph.D., Adelaide, Australia; Shaza Kadah, Physiotherapist, Ph.D. student, Melbourne, Australia. This document has involved 20 rounds of reviews of individual sections and 12 rounds of full manuscript review by working group members, with cochair checking, collation, and feedback of all comments. Additional multiple rounds of development and refinement were undertaken by the cochairs in-between section and full working group reviews. The process was subject to live Meetings in Florence (September 2017), Philadelphia (2018), and Gothenburg (2019). Comprehensive and constructive review was undertaken by expert external reviewers, and we thank them for their considered input: Bert Messelink, David Vodusek, Chantale Dumoulin, Margaret Sherburn, Paul Hodges, and MJ Strauhal. A further round of revisions was undertaken in response to the external review. Following ICS website publication, there was a further round of review to address membership comments. Version 12 will be submitted for website and NAU journal publication.

### CONFLICT OF INTERESTS

Mohammad S. Rahnama'i: Consultant for Bioness, Dr. Pflieger, Astellas and Janssen. Marijke Slieker-ten Hove: KOL Indiba. The remaining authors declare that there are no conflict of interests.

### ENDNOTES

<sup>i</sup>For complete assessment, include as indicated: posture, abdominal, spinal, functional.

<sup>ii</sup>“Vaginal flatus” is the term used by Sultan<sup>11</sup>, however, Neels<sup>13</sup> distinguishes vaginal “wind” from vaginal “flatus”; assigning the term flatus to wind that is passed through the vagina due to an enterovaginal fistula. This type of “vaginal wind” will not be odorless. The term ‘vaginal flatus’ is more likely to be used by the clinician, not the patient.

<sup>iii</sup>This symptom is called “flatus incontinence” by Sultan et al.<sup>11</sup>

<sup>iv</sup>Included in the physical examination may be the use of simple tools, such as a pin, cotton wool, reflex hammer, and so forth.

<sup>v</sup>When assessing sensory changes *PV* or *PR*, the clinician needs to determine whether s/he is detecting sensory change in the mucosa (mucosal sensitivity), or the underlying muscle (muscle tenderness) by attempting to differentiate the depth and firmness of palpation.

<sup>vi</sup>Depth of insertion of examining finger has been described for *per vaginam* assessment.<sup>16</sup>

<sup>vii</sup>Terms such as short or elevated PFM may not be discernible via digital palpation and are therefore not recommended as sign terms.

<sup>viii</sup>If the spasm is painful, this is usually described as a muscle cramp.

<sup>ix</sup>This term refers to simple manometry that measures pressure in the anal sphincter. This is differentiated from sophisticated anorectal manometry—see Section 3.3.2.

<sup>x</sup>This investigation is termed “anal manometry” in Sultan et al.<sup>11</sup>

<sup>xi</sup>This is not an exhaustive list of anorectal manometry parameters.

<sup>xii</sup>Clinical EMG devices mainly offer preset filter settings.

<sup>xiii</sup>Reducing the size of electrode and the inter-electrode distance may increase the system selectivity and reduce crosstalk.<sup>118</sup>

<sup>xv</sup>An endocavity probe consists of an elongated probe used to perform endovaginal or endorectal examination.

<sup>xv</sup>This term was first used by Sinaki et al.,<sup>201</sup> however, in their case series, they did not assess PFM tone or tension. Nevertheless, they proposed the cause of the pain was “habit contraction or chronic spasm of the PFM.” We propose that this term should be used only when both pain and increased tone are present.

<sup>xvi</sup>It may be impossible to distinguish between the two subsets of this condition without access to an investigation which is able to separate the measurement of the contractile from the non-contractile components of tone. Even so, the certainty of the contribution from the contractile component of tone recorded by sEMG needs to consider the limitations of sEMG findings (noise, cross-talk, etc.).

<sup>xvii</sup>Dyssynergia may be similar to the condition termed “overactive pelvic floor muscles” as described by Messelink et al.<sup>23</sup>: “A situation in which the pelvic floor muscles do not relax, or may even contract when relaxation is functionally needed for example during micturition or defecation. This condition is based on symptoms such as voiding problems, obstructed defecation, or dyspareunia and on signs like the absence of voluntary pelvic floor muscle relaxation.”

<sup>xviii</sup>PFM-related symptoms reported by patients may be secondary to more bothersome functional symptoms such as inability to void, defaecate or allow vaginal entry.

<sup>xix</sup>Difficulty voiding may be due to paradoxical contraction of the urethral sphincter, as occurs in conditions such as detrusor sphincter dyssynergia or voiding dysfunction, however, there is no hallmark PFM-related symptom that the patient reports.

<sup>xx</sup>As stated in Rogers et al.,<sup>12</sup> there is often (phobic) avoidance and anticipation/fear/experience of pain, along with variable involuntary PFM contraction. Patients with vaginismus could present with severe fear avoidance without vulvar pain or fear avoidance with vulvar pain. Structural or other physical abnormalities must be ruled out/addressed. There is controversy of whether or not this term should be retained, with the Diagnostic and Statistical Manual of Mental Disorders 2013 proposal to replace dyspareunia and vaginismus with the term “Genito-Pelvic Pain/Penetration Disorder (GPP/PD),”<sup>204</sup> and the lack of consensus on this term.<sup>205</sup>

<sup>xxi</sup>Anismus is the PFM component of dyssynergic defecation. Diagnosis of dyssynergic defecation includes functional constipation criteria, prolonged transit, and ineffective motility to expel feces.<sup>206</sup>

## Abstract

**Introduction:** In the development of terminology of the lower urinary tract (LUT), due to its increasing complexity, the terminology for male LUT surgery needs to be updated using a male-specific approach and via a clinically-based consensus report.

**Methods:** This report combines the input of members of the Standardization Committee of the International Continence Society in a Working Group with recognized experts in the field, assisted by many external referees. Appropriate core clinical categories and a subclassification were developed to give a numeric coding to each definition. An extensive process of 14 rounds of internal and external review was developed to exhaustively examine each definition, with decision-making by collective opinion (consensus).

**Results:** A Terminology Report for male LUT and pelvic floor surgery, encompassing 149 separate definitions/descriptors, has been developed. It is clinically-based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in male LUT surgery. Figures have not been included to avoid any preference or bias towards a specific procedure.

**Conclusions:** A consensus-based Terminology Report for male LUT surgery has been produced aimed at being a significant aid to clinical practice and a stimulus for research.

## KEYWORDS

lower urinary tract dysfunction, male surgery, terminology

On behalf of the Standardization Steering Committees ICS and the ICS Working Group on the Terminology for Male Lower Urinary Tract Surgery

Luis Abranches-Monteiro and Rizwan Hamid are equal first authors (production and content)

## 1 | INTRODUCTION

The surgical procedures for the lower urinary tract (LUT) vary widely in indications. Even surgeries intended for the treatment of oncological and stone diseases have functional implications that can lead to the need for additional surgeries. Prostate surgeries and other therapies applied to prostate disease have been subject to recent developments and multiple variations with local preferences in technical details and terminologies.

Some procedures have their rationale and origins decades ago, with subtle differences among them. Traditional names and definitions were adopted long before current standardization approaches, leading to historical, conceptual, and practical puzzles and misunderstandings. For many years, a number of different terms have been used to describe surgical procedures even within the same surgical teams in a hospital.

With a plethora of new techniques being introduced the terminology for standardization of names for surgical procedures is becoming more important to facilitate clear communication amongst professionals. Most of these procedures are undertaken by urologists who have their own jargon with imprecise but widely accepted terms. However, nowadays, LUT dysfunctions are treated by various other professionals, so a standardized terminology is required for effective communication and research. Invasive procedures may have a diagnostic or therapeutic intention and often, the same procedure can aim both objectives simultaneously.

No document is available to standardize these terms in a comprehensive methodology encompassing open, laparoscopic and robotic, endoscopic surgeries, and minimally invasive therapeutic options. In general, LUT male surgery classification can be based on etiologies: oncologic, stone disease, and functional procedures. The latter is the focus of this report.

The International Continence Society (ICS) has provided leadership in terminology for LUT dysfunction over decades employing combined or generic reports.

The current report acknowledges that a male-specific terminology for invasive LUT procedures is required for surgical procedures in functional urology. It is envisaged that this report will result in

- (i) greater coherency and user-friendliness,
- (ii) greater specificity of surgical procedures,
- (iii) more accurate communication for clinical and research purposes.

Hence, in a functional and anatomical classification it will be divided into the following sections:

- I. urethra
- II. prostate
- III. bladder neck
- IV. bladder
- V. urinary diversions and reconstructions
- VI. vesico-ureteric junction and ureter

Some procedures involving the lower ureter will also be discussed as they happen to have an effect on LUT (dys)function.

The document reviews old but still existing procedures and also the latest approaches with clear worldwide acceptance. Historical practices and methods are defined for the sake of completeness and also because patients may present persistent complaints following historical treatments. Regular updates will be needed and considered in the initial document structure. The report is definitional with additional explanation when judged necessary.

The description of the procedure will be limited to the relevance of terms and expressions. Whenever possible, aliases and synonyms will be commented, and an historical explanation will be given. For example, Millin's prostatectomy versus retropubic transcapsular prostate adenectomy. Terminology is aligned with previous ICS definitions.

TABLE 1 Total, new, and changed definitions (compared with previous male-inclusive Reports)<sup>1,2</sup>

Section	New definitions/descriptors	Changed definitions/descriptors	Total
I. Urethra	29	0	29
II. Prostate	36	0	36
III. Bladder Neck	5	0	5
IV. Bladder	23	0	23
V. Urinary Diversion/reconstruction	34	0	34
VI. Vesicoureteric junction/ureter	22	0	22

Origin: Where a term's existing definition (from one of multiple sources used) is deemed appropriate, that definition will be included and duly referenced. A large number of terms in male LUT invasive procedures, because of their long-term use, have now become generic, as apparent by their listing in medical dictionaries (Table 1).

Able to provide explanations: Where a specific explanation is deemed appropriate to explain a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (*Footnote [FN] 1,2,3...*). Wherever possible, evidence-based medical principles will be followed.

## 2 | SECTION I: URETHRA PROCEDURES

### 2.1 | Urethral assessment or enlargement

#### 2.1.1 | Urethral calibration

Measurement of the diameter of the (distal) urethral lumen with special urethral sounds. **NEW**

#### 2.1.2 | Urethral dilatation

Distension of a stenotic segment with semi-rigid, rigid dilators, or balloon distention. **NEW**

#### 2.1.3 | Urethroscopy

Endoscopic visualization of the inner wall of the urethra (mucosa), usually done with a flexible or rigid cystoscope. **NEW**

#### 2.1.4 | Meatotomy

Incision of the meatus to enlarge the distal urethra to the caliber of the urethral lumen. **NEW**

#### 2.1.5 | Meatal skin flap technique

After meatotomy, a flap is mobilized from the prepuce or distal penile skin and sutured to the edge of the opened *fossa navicularis*. **NEW**

#### *Graft technique*

After meatotomy, skin, buccal mucosa, or any other suitable tissue is used as a free patch or a tube and sutured into the edge of the fossa navicularis or to substitute the urethra at this level. **NEW**

### 2.1.6 | Meatoplasty

Reconstruction of the meatal segment of the urethra for cosmetic or functional purpose. **NEW**

## 2.2 | Urethral incision

### 2.2.1 | Urethrotomy

Incision of an urethral stricture.

#### *Blind urethrotomy*

(without visual guidance): Opening of the stricture with the use of a special instrument (Otis urethrotome) to perform the incision without direct visualization. **NEW**

#### *Endoscopic urethrotomy*

(direct vision): Opening of the stricture with a cold incision (Sachse urethrotome using mechanical effect) or energy (LASER) under urethroscopy. **NEW**

## 2.3 | Transurethral resection of the urethra

Mono- or bipolar electric ablation of intraluminal tissue of the penile or bulbar urethra using a resectoscope and a resection loop or LASER, mostly done for urethral tumors. **NEW**

## 2.4 | Sphincterotomy

Transurethral incision of the external urethral sphincter with a mono- or bipolar electric hook or a LASER in patients with fibrotic sphincter stenosis or patients with detrusor-sphincter-dyssynergia. **NEW**

## 2.5 | Urethroplasty

Open surgical reconstruction of the posterior (proximal to the external urethral sphincter) or anterior (distal to the external urethral sphincter) urethra. This involves

incision/removal or substitution of the strictured part of the urethral segment followed by urethral reconstruction. **NEW**

### 2.5.1 | End-to-end repair

Open surgery for reconstruction of the urethra. After excision of the fibrotic urethral segment, the healthy proximal and distal urethra ends are reconnected by a primary tension-free anastomosis. **NEW**

### 2.5.2 | Substitution urethroplasty

Open surgery usually done for the reconstruction of bulbar urethral strictures with a stricture length  $\geq 1.5$  cm or penile urethral strictures. After incision of the fibrotic urethral segment, tissue from another part of the body, for example, buccal mucosa, lingual mucosa, or skin (graft/local flap/free flap—see below) are used to cover the incised area. The tissue may be placed dorsally/ventrally or combined (ventral and dorsal grafts). Substitution urethroplasty may be accomplished as a single-stage or as part of a multi (usually two-) stage procedure. **NEW**

#### *Urethroplasty with graft*

The use of free graft for urethral reconstruction usually in urethral stricture disease, in any part of the urethra. **NEW**

#### *Urethroplasty with flap*

The use of flaps for urethral reconstruction of penile urethra stricture disease, local rotational flaps such as preputial skin or local genital skin (e.g., Orandi flap). Flaps are often used in recurrent urethral stricture disease involving the penile urethra and navicular fossa. **NEW**

#### *Staged urethroplasty*

Usually two stage but occasionally additional stages are required in the treatment of urethral stricture. <sup>FN 1</sup>**NEW**

### 2.6 | Perineal urethrostomy

Surgical creation of a neomeatus in the perineum. <sup>FN 2</sup>**NEW**

### 2.7 | Sling surgery

A synthetic, biological, or composite sling placed ventrally of the urethra to treat stress urinary incontinence. **NEW** (*sling already defined*)

### 2.7.1 | Reposition sling

The sling pulls in and up the bulbous urethra. **NEW**

### 2.7.2 | Compressive sling

The sling compresses the urethra against the pubis. **NEW**

#### *Adjustable slings*

The pressure on the urethra can be readjusted over time. **NEW**

#### *Non-adjustable slings*

These cannot be adjusted once inserted in place. **NEW**

### 2.8 | Artificial urinary sphincter

Use of a prosthetic device, encircling the urethra which creates occlusion to restore continence. The cuff can be placed in the bulbar urethra or in the bladder neck to restore continence.<sup>3,4</sup> There are a number of different devices available using two or three components with different techniques of implantation. **NEW**

### 2.9 | Bulking agents

Endoscopic injection of inert substance into proximal urethral wall to achieve continence by coaptation. **NEW**

### 2.10 | Botulinum toxin to external sphincter

Endoscopic injection of toxin into the external sphincter complex. **NEW**

### 2.11 | Urethral diverticulectomy

Excision of a pseudo diverticulum (out-pocketing) of urethral mucosa. **NEW**

### 2.12 | Urethral prosthesis or stent

Placement of a temporary or permanent synthetic tube splint device in a stenotic urethral segment to avoid restenosis of the urethra or to keep the external sphincter open in detrusor-external sphincter dyssynergia.<sup>5,6</sup> **NEW**

### 2.13 | Urethral fistulectomy

Excision of a fistulous segment between the urethral lumen and the exit of the fistula (skin, bowel) and repair/reconstruction of the fistula openings. **NEW**

## 3 | SECTION II: PROSTATE PROCEDURES

Partial removal of the prostate (transition zone) for the treatment of benign diseases (e.g., benign prostatic obstruction) or complete removal of the prostate and adjacent tissues for the treatment of malignant diseases (e.g., prostate cancer). The routes to the prostate may be through the urethra, abdomen (transperitoneal), retroperitoneal space (extraperitoneal), perineum or vessels (arteries). The systematics of prostate operations is shown in Figure 1.

### 3.1 | Transurethral procedures of the prostate

Various prostate operations through the urethra to widen the proximal prostatic urethra by removal or compression of the transition zone. Tissue removal may be immediate or delayed. **NEW**

#### 3.1.1 | Transurethral procedures with immediate tissue ablation

Transurethral operations with removal of prostate tissue during the operation using different energy sources (electric current, LASERS,<sup>7</sup> or highly focused waterjet) and tissue removal techniques (fragmented, en bloc, or by vaporization), with or without suprapubic trocar to aid bladder irrigation. The resection is limited to the proximal prostatic urethra (resection margin: verumontanum). **NEW**

#### 3.1.2 | Transurethral resection procedures

Usually done in small to intermediate volume prostates but can be dependent on the experience and resection speed of the operating surgeon.

##### *Transurethral resection of the prostate (TURP)*

Fragmented prostate tissue removal using a resection loop and monopolar (m-TURP) or bipolar electric current (b-TURP).<sup>8</sup> **NEW**

*Holmium LASER resection of the prostate (HoLRP).* Fragmented prostate tissue removal by using the pulsed 2140 nm wavelength holmium LASER. **NEW**

*Thulium LASER resection of the prostate (ThuRP or TmLRP).* Fragmented prostate tissue removal by using the continuous wave thulium LASER with a wavelength between 1940 and 2013 nm. **NEW**

*Aquablation of the prostate.* Robot-assisted, fragmented prostate tissue removal by using a powerful waterjet stream (hydrodissection) under transrectal ultrasound control of the prostate.<sup>9</sup> **NEW**

### 3.1.3 | Transurethral vaporization procedures

Usually done in small to intermediate volume prostates ( $\leq 80 \text{ cm}^3$ ).

##### *Bipolar transurethral electrovaporization of the prostate (B-TUVP)*

Prostate tissue removal by vaporization using high-frequency bipolar electric current.<sup>10</sup> **NEW**

*“GreenLight” LASER vaporization of the prostate (GreenLight-VAP).* Prostate tissue removal by vaporization using the 532 nm wavelength KTP (kalium [potassium] titanyl phosphate) or LBO (lithium borat) LASER.<sup>11</sup> **NEW**

*Holmium LASER vaporization of the prostate (HoLAP).* Prostate tissue removal by vaporization using the pulsed 2140 nm wavelength holmium LASER. **NEW**

*Thulium LASER vaporization of the prostate (ThuVAP).* Prostate tissue removal by vaporization using the continuous wave thulium LASER with a wavelength between 1940 and 2013 nm. **NEW**

*Diode LASER vaporization of prostate (D-VAP).* Prostate tissue removal by vaporization using the diode LASER with a wavelength of 940, 980, 1318, or 1470 nm (depending of the used semiconductor).<sup>8</sup> **NEW**

### 3.1.4 | Transurethral vaporesction procedures

Usually done in small to intermediate volume prostates ( $\leq 80 \text{ cm}^3$ ).

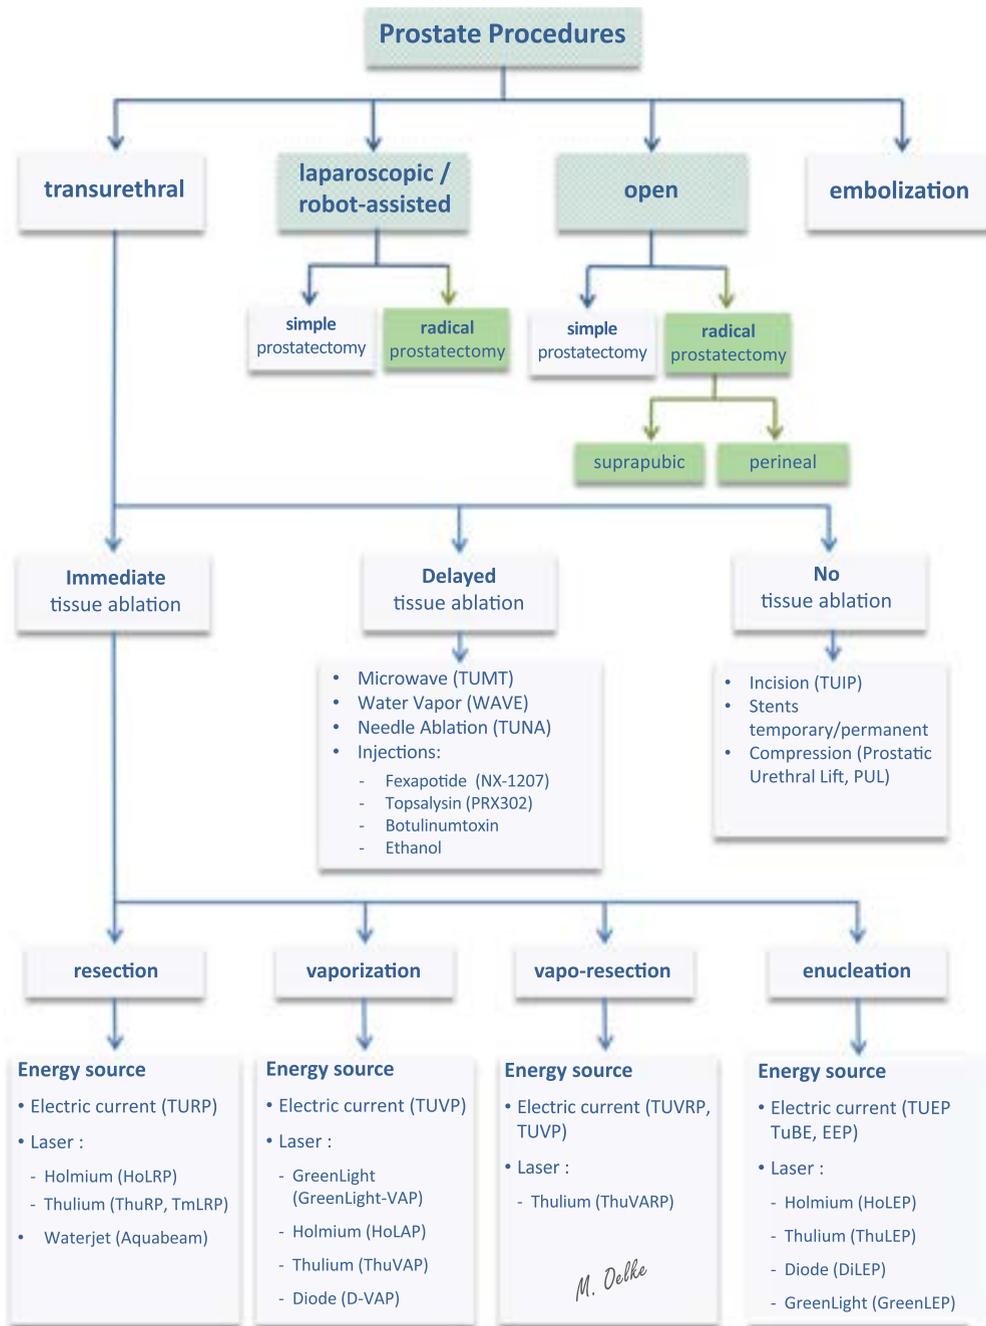

FIGURE 1 Classification of prostate operations for benign (blue) or malignant diseases (green). Abbreviations and systematics are explained in the text

*Transurethral vaporesction of prostate (TUVRP, TUVVP)*

Fragmented prostate tissue removal by electric resection and simultaneous vaporization using a broad resection loop (combination of TURP and b-TUVP). **NEW**

*Thulium vaporesction of the prostate (ThuVARP)*. Fragmented prostate tissue removal by resection and simultaneous vaporization using the continuous wave Thulium LASER with a wavelength between 1940 and 2013 nm. **NEW**

### 3.1.5 | Transurethral enucleation procedures

Usually done in large volume prostates (>80 cm<sup>3</sup>) but can also be done in small or intermediate volume prostates.

*Transurethral enucleation of prostate (TUEP, TUBE, or EEP)*

En bloc removal of the transition zone by using monopolar or bipolar electric current and specifically designed hooks or loops to approach the surgical capsule and blunt peeling of the prostatic adenoma with the shaft of the resectoscope afterwards. **NEW**

*Holmium LASER enucleation of the prostate (HoLEP)*. En bloc removal of the transition zone and separation of the tissue between the adenoma and surgical capsule by using the pulsed 2100 nm wavelength holmium LASER.<sup>12,13</sup> **NEW**

*Thulium LASER enucleation of the prostate (ThuLEP)*. En bloc removal of transition zone by using the thulium LASER with a wavelength between 1940 and 2013 nm to approach the surgical capsule and blunt peeling of the prostatic adenoma. The thulium LASER vapo-enucleation (ThuVEP) technique is identical.<sup>14</sup> **NEW**

*Diode LASER enucleation of prostate (DiLEP)*. En bloc removal of transition zone by using the diode LASER with a wavelength of 940, 980, 1318, or 1470 nm (depending of the used semiconductor) to approach the surgical capsule and blunt peeling of the prostatic adenoma with the shaft of the resectoscope.<sup>15</sup> **NEW**

*“GreenLight” LASER enucleation of the prostate (GreenLEP)*. En bloc removal of the transition zone using the 532 nm wavelength KTP (kalium [potassium] titanyl phosphate) or LBO (lithium borat) LASER to approach

the surgical capsule and blunt peeling of the prostatic adenoma with the shaft of the resectoscope. **NEW**

### 3.1.6 | Transurethral procedures with delayed tissue removal

Transurethral prostate operations using different energy sources or molecules which cause tissue damage during the operation and delayed desquamation (sloughing) of prostatic tissue during the next weeks or months, thereby reducing benign prostatic obstruction over time. <sup>FN 4</sup> **NEW**

*Transurethral microwave therapy (TUMT)*

Destruction and secondary ablation of prostate tissue by transurethral delivery of high-energy microwaves through an intraurethral antenna. Tissue is destroyed by being heated up to temperatures above cytotoxic thresholds (>45°) causing coagulation necrosis.<sup>16</sup> **NEW**

*Convective water vapor energy (WAVE) ablation of the prostate*

Destruction and secondary ablation of tissue by transurethral application of water vapor thermal energy injected into the prostate by needles.<sup>17</sup> **NEW**

*NX-1207 injections of the prostate*

Destruction and secondary ablation of prostate tissue by transurethral (or transrectal) injection of fexapotide trifluate (NX-1207).<sup>18</sup> <sup>FN 5</sup> **NEW**

*PRX302 injections of the prostate*

Destruction and secondary ablation of prostate tissue by transurethral (or transrectal) injection of topsalysin (PRX302).<sup>19</sup> <sup>FN 6</sup> **NEW**

*Transurethral needle ablation of the prostate (TUNA)*

Destruction and secondary ablation of prostate tissue by insertion of needles into the prostate and application of radiofrequency thermal energy causing a coagulation necrosis.<sup>20</sup> <sup>FN 7</sup> **NEW**

*Botulinum toxin injections of the prostate*

Destruction and secondary ablation of prostate tissue by transurethral (transrectal, transperineal) injection of 100–300 U onabotulinumtoxinA (Botox) or 300–600 U abobotulinumtoxinA (Dysport).<sup>21</sup> <sup>FN 8</sup> **NEW**

*Ethanol injections of the prostate*

Destruction and secondary ablation of prostate tissue by transurethral injection of dehydrated 95–98% ethanol.<sup>22,23</sup> <sup>FN 9</sup> **NEW**

### 3.1.7 | Transurethral procedures without tissue removal

Immediate relief of benign prostatic obstruction by incision or compression of prostatic tissue without tissue removal. Minimally-invasive procedures aim to reduce morbidity compared with operations with immediate tissue removal (see Section 1.1). **NEW**

#### *Transurethral incision of the prostate (TUIP)*

Diathermic incision of the transition zone at the 5 and 7 o'clock positions until the prostate capsule from the ureteral orifices until the verumontanum. TUIP works best in small volume prostates ( $\leq 30 \text{ cm}^3$ ). Some surgeons incise unilaterally to reduce the risk of retrograde ejaculation. **NEW**

#### *Prostatic stents*

Transurethral implantation of metallic prostate stents of different shapes and materials. Prostate stents may be implanted temporarily (removable) or permanently (non-removable). The latest development is the iTIND system made out of nitinol which is transurethral inserted into the prostatic urethra where it expands and incises the prostatic tissue at the 5 and 7 o'clock positions, similar to TUIP. The iTIND device is removed 5 days later.<sup>24</sup> **NEW**

#### *Prostatic urethral lift (PUL)*

Transurethral implantation of small anchors (made of nitinol, stainless steel, and a polyester suture) through the entire anterior prostate which compress prostatic tissue against the anatomic prostate capsule to widen the proximal anterior prostatic urethra. PUL works best in small to intermediate volume prostates ( $\leq 60\text{--}80 \text{ cm}^3$ ).<sup>25</sup> **NEW**

## 3.2 | Open or laparoscopic/robot-assisted procedures of the prostate

### 3.2.1 | Suprapubic open prostatectomy (prostate adenectomy, open enucleation of prostate)

Removal of the prostatic adenoma (transitional zone) after lower abdominal wall incision, either through the bladder (Freyer; Hryntschak)<sup>26,27,28</sup> or anterior prostatic capsule (Millin). These operations are usually done in large volume prostates ( $>80 \text{ cm}^3$ ). **NEW**

### 3.2.2 | Laparoscopic/robot-assisted adenectomy (enucleation of prostate)

Extraperitoneal or transperitoneal enucleation of prostate with laparoscopic or robotic armamentarium. The enucleation of the prostate adenoma is similar to open enucleation of the prostate and can be done by the transvesical (Freyer; Hryntschak) or transcapsular approach (Millin). These operations are usually done in large volume prostates ( $>80 \text{ cm}^3$ ). **NEW**

#### *Open suprapubic radical prostatectomy*

Radical removal of the entire prostate and seminal vesicles via an open, extraperitoneal approach for the treatment of prostate cancer. **NEW**

#### *Open perineal radical prostatectomy*

Radical removal of the entire prostate and seminal vesicles via a perineal approach for the treatment of prostate cancer. **NEW**

#### *Laparoscopic radical prostatectomy (LRP) or robot-assisted radical prostatectomy (RARP)*

Radical removal of the entire prostate and seminal vesicles via a minimally-invasive abdominal extraperitoneal or transperitoneal or even transperineal approach by using trocars and laparoscopic armamentarium for the treatment of prostate cancer. **NEW**

## 3.3 | Prostatic artery embolization (PAE)

Destruction and secondary ablation of prostate tissue by uni- or bilateral embolization of prostatic arteries with microspheres. Tissue damage is done during the operation but desquamation (sloughing) of prostatic tissue occurs only during the next weeks or months, thereby reducing benign prostatic obstruction over time. PAE belongs to the secondary ablative procedures, is performed in local anesthesia and is a minimally-invasive procedure which aims to reduce morbidity compared to operations with immediate tissue removal (see Section 1.1).<sup>29</sup> **NEW**

## 4 | SECTION III: BLADDER NECK PROCEDURES

Widening of the bladder neck with the intent of relieving bladder outlet obstruction, usually caused by primary bladder neck hypertrophy or secondary neck stenosis.<sup>1</sup>

#### 4.1 | Endoscopic bladder neck incision

Transurethral incisions of bladder neck tissue at the 5 and/or 7 o'clock positions using a metal hook with electric current or a LASER beam. An additional incision can be made at the 12 o'clock position if the bladder neck is still incompletely opened. Some surgeons only incise unilaterally to reduce the risk of retrograde ejaculation. **NEW**

#### 4.2 | Endoscopic bladder neck resection

Transurethral resection of bladder neck tissue using a metal loop with electric current. **NEW**

#### 4.3 | Open/laparoscopic/robot-assisted bladder neck incision with Y-V plasty

Complete incision through the anterior bladder neck tissue in Y-shape and resuturing the tissue in V-shape after open or laparoscopic approach of the retropubic space.<sup>2</sup> **NEW**

#### 4.4 | Open/laparoscopic/robot-assisted bladder neck resection

Complete removal of the entire bladder neck via an open or laparoscopic approach and reconnection of the prostatic urethra to the bladder. **NEW**

#### 4.5 | Botulinum toxin to bladder neck

This involves injection of botulinum toxin mixed with normal saline to the bladder neck for relief of functional obstruction. <sup>FN 12</sup>**NEW**

### 5 | SECTION IV: BLADDER PROCEDURES

#### 5.1 | Urethrocystoscopy

Direct visualization of the inner wall (mucosa) of urethra and bladder. It implies a form of endoscopic method. **NEW**

##### 5.1.1 | Flexible urethrocystoscopy

Direct visualization of the bladder and urethra using a hand operated flexible scope, a thumb lever allows the scope to be deflected as required to visualize the entire bladder. Can be performed under local or general

anaesthesia predominantly for diagnostic purposes or can be combined with tissue ablation. **NEW**

#### 5.1.2 | Rigid urethrocystoscopy

Direct visualization of the bladder and urethra using a rod-lens telescope optical system as well as a rigid sheath. Usually performed under local, regional, or general anaesthesia for diagnostic or therapeutic purposes. **NEW**

#### 5.2 | Transurethral bladder biopsy

Removal of sample of bladder tissue or lesion by the endoscopic, transurethral route, by means of mechanical or diathermic instrument with diagnostic intent. **NEW**

#### 5.3 | Transurethral resection of the bladder

Removal of bladder tissue or lesion by endoscopic transurethral route with both, diagnostic and therapeutic intent. Different energy sources can be used (electric energy, LASER). **NEW**

#### 5.4 | Cystodiathermy

Selective cauterization of areas of the bladder using different energy sources through an endoscope with therapeutic intent. **NEW**

#### 5.5 | Bladder distension

Infusion of fluid usually saline, under anaesthesia with the intent to stretch or distend the bladder walls in excess of usual physiological capacity. **NEW**

#### 5.6 | Bladder wall injections

Injection of a pharmaceutical agent into the bladder wall (to the suburothelial space or detrusor), using a needle inserted through the endoscope. **NEW**

#### 5.7 | Bladder instillations

This involves instillation of a chemical substance via a urethral catheter mostly under local anaesthesia. Usually there are multiple instillations spread over a period of

time. EMDA treatment (electromotive drug administration) aims to increase drug concentration in the vesical wall by iontophoresis and electrophoresis to overcome the urothelial barrier. **NEW**

## 5.8 | Cystectomy

Removal of the urinary bladder using a transabdominal open/laparoscopic/robot-assisted approach. Cystectomies are most frequently done for the treatment of bladder cancer but can also be a valid option for treatment resistant bladder pain syndromes or small capacity bladder where minimally invasive treatments have failed. **NEW**

### 5.9 | Partial cystectomy

A segment of urinary bladder (e.g., bladder dome) is excised. **NEW**

#### 5.9.1 | Supratrigonal cystectomy

The entire bladder except the trigone and bladder neck is excised. **NEW**

#### 5.9.2 | Total cystectomy

The entirety of the organ (urinary bladder) is removed. Usually for benign conditions. **NEW**

#### 5.9.3 | Radical cystectomy

The entirety of the urinary bladder is removed along with adjacent organs or structures (prostate/seminal vesicles). **NEW**

### 5.10 | Bladder diverticulectomy

Excision of a bladder pseudodiverticulum using a transvesical or extra vesical approach, by abdominal open, laparoscopic or robotic assisted techniques. **NEW**

### 5.11 | Bladder psoas-hitch

Fixation of bladder wall to the psoas muscle aponeurosis with the intent of reducing tension of a ureter to bladder

anastomosis in case of shortened/strictured distal ureter.<sup>30</sup> **NEW**

### 5.12 | Boari flap

Use of a segment of bladder wall to create a tube, which is then anastomosed to the remaining ureter with the intent of substituting the terminal ureter in case of shortened/strictured distal ureter.<sup>30</sup> **NEW**

### 5.13 | Cystolithotomy

Surgical removal of a bladder stone through the abdomen and the bladder wall. **NEW**

#### 5.13.1 | Percutaneous cystolithotripsy/cystolitholapaxy

Minimally invasive fragmentation of the bladder stone by ultrasonic or pneumatic lithotripsy or LASER and removal of the stone fragments via a thin suprapubic channel and an abdominal access sheath. **NEW**

#### 5.13.2 | Transurethral cystolithotripsy/cystolitholapaxy

Fragmentation of a bladder stone via the transurethral route with urethral removal of fragments. Different energy sources can be used, from direct mechanical to LASER impulses. **NEW**

#### 5.13.3 | Open, laparoscopic, or robot-assisted bladder stone removal

Complete removal of a bladder stone (without fragmentation) by a suprapubic open or laparoscopic or robotic approach. **NEW**

### 5.14 | Fistula repair

Excision and closure of an abnormal passage between two epithelial surfaces.

#### 5.14.1 | Vesico-cutaneous fistula repair

Excision of a fistula between bladder and skin. **NEW**

### 5.14.2 | Enterovesical fistula repair

Excision of a fistula between the bladder and an intestinal segment, usually with reconstruction of the intestinal tube and bladder wall. **NEW**

### 5.14.3 | Rectourethral fistula repair

Excision of a fistula between the rectum and (prostatic) urethra, often associated with prostatectomy and temporary artificial anus. **NEW**

### 5.15 | Cystorrhaphy

Suture of a laceration, injury, or rupture in the urinary bladder. **NEW**

## 6 | SECTION V: URINARY DIVERSIONS AND RECONSTRUCTIONS

Urinary diversion is any surgical procedure that alters the usual passage of urine from the kidneys. It may or may not involve the addition of bowel into the urinary tract, either to reroute the urine or replace/augment the native urinary tract. All urinary diversions and reconstructions can be done as an open procedure, laparoscopically, or robot-assisted. **NEW**

### 6.1 | Incontinent diversion

Rerouting of the urine from the urinary bladder, with or without removal of all or part of the urinary bladder. Reconstruction often involves addition of an isolated intestinal segment (stomach/small intestine/colon). Egress of urine is cutaneous and requires containment. Common incontinent diversions include ileal/colonic conduits, ileovesicostomy and ureterostomy. **NEW**

#### 6.1.1 | Ileal conduit

A rerouting of the urine from the ureters through an isolated segment of terminal ileum to a premarked site on the skin. It is in most parts of the world the most common diversion performed after cystectomy. **NEW**

### 6.1.2 | Sigmoid or colon conduit

A segment of sigmoid or colon is used for the urinary diversion where the ileum cannot be used or its appearance as a stoma onto healthy skin in the usual position is not possible. It is usually performed in cases of pelvic irradiation, regional enteritis, or short bowel syndrome. **NEW**

### 6.1.3 | Vesicostomy

A method of creating a communication between the bladder and the skin. This procedure is indicated in children with vesicourethral dysfunction (myelomeningocele, posterior urethral valve) who are unable to void or cannot catheterize through the urethra. **NEW**

### 6.1.4 | Ileovesicostomy

A communication from the bladder through an isolated segment the ileum to the skin. This method is typically employed with high spinal lesion patients who cannot perform intermittent catheterization. **NEW**

### 6.1.5 | Cutaneous ureterostomy

Direct anastomosis of the ureter to the skin. Can be loop or end cutaneous ureterostomy. **NEW**

### 6.2 | Continent urinary diversion

Re-routing of the urine from the urinary bladder. Reconstruction usually involves an isolated intestinal segment (stomach/small intestine/colon). Continence mechanisms may utilize existing sphincters (anal, urethral or ileocaecal valve) or be created by tunneling a bowel segment through the bladder/neobladder which requires catheterization. Egress of urine can therefore be via the anus (ureterosigmoidostomy) via the urethra (neobladder) or via a continent catheterisable channel (e.g. Mitrofanoff, Kock pouch, Mainz I). **NEW**

#### 6.2.1 | Orthotopic

Reconstructed bladder reservoir (entirely or partially constructed from bowel; usually terminal ileum) anastomosed to

the native urethra, usually utilizing the urethral sphincter as a continence mechanism. Diversion may be supratrigonal or total substitution—See 3.2 for more details on bladder substitution reconstructions.<sup>31</sup> **NEW**

### 6.2.2 | Heterotopic

Reconstructed urine storage organ (neobladder), which is attached directly to the ureter(s). Created entirely from bowel (usually terminal ileum), this neobladder resides outside the pelvis, and requires a catheterisable continent channel to the skin. **NEW**

#### *Ileal reservoir*

This neo-bladder is made entirely of ileum. It is opened at the anti-mesenteric border and stitched back in a detubularised manner. **NEW**

#### *Ileocaecal reservoir*

This neo-bladder is constructed from terminal ileum and caecum incorporating the ileo-caecal valve. Again, this isolated piece is de-tubularized to be stitched back together to decrease the peristalsis and increase capacity of the reservoir. **NEW**

#### *Pouches using large bowel*

*Indiana pouch.* Utilizes a segment of terminal ileum, caecum, and ascending colon. The ureteric implantation along the tinea coli and plication sutures of the ileal stoma conduit for improvement of continence. **NEW**

*Charleston pouch.* Utilizes the same bowel segments of Indiana pouch with the addition of the appendix as the cutaneous catheterisable stoma. **NEW**

*Mainz II pouch.* Also known as sigma-rectum pouch. Hence the pouch is created from a segment of rectum and sigmoid colon. The Mainz-II can also be utilized to convert a uretero-sigmoidostomy or colonic conduit. **NEW**

*Lundiana pouch.* Utilizes the ileocaecal segment with an instussuscepted ileal nipple, including the ileocaecal valve as efferent segment. **NEW**

#### *Small bowel pouches*

*Studer pouch.* Utilizes a segment of terminal ileum of approximately 54 cm length 25 cm proximal from the ileocaecal valve. The ureteric implantation site is

located at the proximal end of a closed ileum segment (chimney usually at the right side with a length of 14 cm), whereas the rest of the ileum is opened at the anti-mesenteric border and stitched back to a plate which is then formed to a neobladder and anastomized to the urethra. **NEW**

*Mansoura pouch.* Construction of a detubularized W-shaped ileal reservoir in which two serous lined troughs and two tapered ileal segments are used, one for reflux prevention and the other as a continent outlet. **NEW**

## 6.3 | Cystoplasty

A reconstructive procedure involving the addition of a detubularized bowel segment usually to the native bladder. The bladder is bivalved (as a clam) and the isolated piece of bowel is interposed between with the intention of increasing capacity, reducing bladder pressure or treating refractory detrusor overactivity. The outlet of this may be the native urethra (utilizing the intrinsic continence of the external urethral sphincter) or a created abdominal stoma (emptied via catheterization). **NEW**

### 6.3.1 | Ileocystoplasty

The piece of bowel used is terminal ileum at least 30 cm from ileo-caecal junction. **NEW**

### 6.3.2 | Gastrocystoplasty

An isolated piece of stomach is utilized to fashion an augmented bladder. **NEW**

### 6.3.3 | Colocystoplasty

Generally, sigmoid colon is used. **NEW**

### 6.3.4 | Ureterocystoplasty

The ureter is used to bridge the gap in a clammed bladder. This is only used if there is a mega ureter post severe long-standing dilatation of the upper tract with the ipsilateral non functioning kidney that will be removed at the same time or previously has been removed. This is mainly utilized in pediatric population. **NEW**

### 6.3.5 | Bladder auto-augmentation

Removal or incision of a portion of the detrusor leaving behind the exposed mucosa which bulges out, with the aim of reducing bladder pressures. **NEW**

## 6.4 | Supratrigonal/substitutional reconstruction

If an adequate reservoir capacity cannot be obtained using a bowel patch, then a substitution procedure is required. This reconstruction can include the trigone of the native urinary tract or consist of a reservoir created entirely from autologous tissue. These are described separately below. **NEW**

### 6.4.1 | Supratrigonal

The dome of the bladder is excised leaving the trigonal plate/bladder base, with attached ureters, to the native urethra. A reservoir (created from an isolated bowel segment) is then fashioned and anastomosed to the trigone. Although a number of bowel segments can be utilized, distal ileum is most commonly selected for reconstruction. A continent catheterisable stoma (usually catheterized via the anterior abdominal wall) can also be used in addition to this reconstructive technique. This technique usually spares the nerves maintaining sexual function. **NEW**

### 6.4.2 | Substitutional

This reconstruction does not utilize any part of the native bladder. Following cystectomy, a reservoir is constructed from bowel (usually terminal ileum) and the ureters are anastomosed to this, that is, orthotopic neobladder. The reservoir is then, in turn, anastomosed to the native urethra. **NEW**

## 6.5 | Continent stoma

### 6.5.1 | Appendicovesicostomy (Mitrofanoff)

Use of an isolated appendix on a vascularized pedicle as a catheterizable route of access to the bladder from the skin as an alternative to the urethra. **NEW**

### 6.5.2 | Yang–Monti catheterizable channel

A variant of the Mitrofanoff procedure in which a short segment of bowel is reconfigured into a long tube positioned between bladder and skin to permit intermittent catheterization. **NEW**

### 6.5.3 | Stapled continent conduit (Bejany and Politano)

A continent colonic urinary reservoir with a tapered distal ileal segment with a gastrointestinal anastomosis stapler with a catheterizable abdominal stoma. **NEW**

### 6.5.4 | The gastroileal reservoir (Lockhart)

A continent urinary diversion where segment of stomach and proximal ileum is used to construct the reservoir. **NEW**

## 6.6 | Continent heterotopic urinary diversion

### 6.6.1 | Ureterosigmoidostomy—Sigma rectum pouch (Mainz pouch II)

Modification that involves detubularizing the recto-sigmoid colon and reconfiguring the detubularized segment into a spherical shape, while maintaining bowel continuity.<sup>32</sup> **NEW**

## 6.7 | Suprapubic catheter

This involves insertion of a catheter via suprapubic route.

### 6.7.1 | Seldinger technique

The catheter is inserted into the bladder from the suprapubic route by seldinger technique through a specially designed kit. After ensuring the bladder is full a needle is inserted from suprapubic skin directly into the bladder. Once aspiration of urine is confirmed the tract is dilated with a trocar and the catheter is inserted via a specially designed sheath. This process can be aided by

direct endoscopic visualization or under ultrasound guidance. **NEW**

### 6.7.2 | Open/laparoscopic/robot-assisted technique

This involves insertion of a catheter into bladder via the suprapubic route under direct visualization of the bladder puncture. This entails incising skin, subcutaneous tissues, and sheath of the anterior abdominal wall. It is ensured the bladder is as full as possible and under direct vision the catheter is inserted into the bladder. **NEW**

### 6.7.3 | Button cystostomy

This procedure involves insertion of a gastrostomy button normally used for enteral nutrition into the bladder, using an endoscopic technique. Button cystostomy results in a continent device that permits urine drainage by suprapubic route, as well as suprapubic catheter, resulting more cosmetically acceptable, with less obstacles for sports activities, swimming, improving quality of life especially in children and young adults. **NEW**

## 7 | SECTION VI: VESICO-URETERIC JUNCTION AND URETER PROCEDURES

### 7.1 | Vesicoureteric junction operations

#### 7.1.1 | Ureteral reimplants

##### *Ureteroneocystostomy*

Direct reimplantation of the ureter into the bladder, primarily for disease involving the lower third portion of the ureter. **NEW**

**Intravesical** (*Politano–Leadbetter*) *technique*. A ureteroneocystostomy in which the ureter is excised from its attachment to the bladder and reattached intravesically in a more medial and superior position with a new submucosal tunnel.<sup>33</sup> **NEW**

**Extravesical** (*Lich–Gregoir*) *techniques*. An ureteroneocystostomy where the ureter is mobilized extravesically along the course of the ureter and the detrusor and then divided in the direction of the ureter. The ureter is then anastomosed to the bladder mucosa and the divided detrusor sutured to cover the ureter, creating a submucosal ureteral tunnel.<sup>34</sup> **NEW**

**Ureteral advancement** (*Glenn–Anderson*) *reimplantation technique*. The submucosal tunnel is made from the original ureteral meatus to the bladder neck—with or without incision of detrusor proximally from the original ureteral orifice—allowing the ureter to follow its natural course without the risk of folding or obstruction of the ureter.<sup>35</sup> **NEW**

**Cross-trigonal** (*Cohen*) *technique*. A submucosal ureteral tunnel is created transtrigonally, allowing the new ureteral orifice to be created around the contralateral ureteral orifice. **NEW**

**Intra–extra vesical technique** (*Paquin*). A type of ureteroneocystostomy in which the ureter is excised from its attachment to the bladder and reattached in a more posteromedial position. **NEW**

### 7.1.2 | Ureterocele incision/resection

This involves endoscopic resection/incision of the ureterocele. **NEW**

### 7.1.3 | STING (subtrigonal injection of inert substance) procedure

This entails injection of an inert substance via endoscopic technique at the vesico-uretric junction to treat reflux. Teflon was initially used but other inert substances can be used alternatively. **NEW**

### 7.1.4 | Ureter procedures

##### *Ureteroscopy*

Upper urinary tract endoscopy performed with a semi rigid or flexible endoscope passed through the urethra, bladder, and then directly into the upper urinary tract. **NEW**

##### *Unilateral/bilateral retrograde pyelography*

Evaluation of the ureter by injection contrast on either side and undertaking live fluoroscopy to delineate the anatomy of the ureter. **NEW**

##### *Endoluminal stents (ureteral stenting)*

Threading a thin tubular catheter into segments of the ureter, either down into the bladder internally, or to an external collection system, through the skin (percutaneously), or through the bladder via a cystoscope. Stents consist of an elongated body portion and a retention module. **NEW**

### *Ureterolysis*

Mobilization and freeing of the ureter by surgical displacement of the ureters from the surrounding disease/adhesions, or from retroperitoneal fibrosis process with lateral/intraperitoneal transposition and/or omental wrapping of the involved ureter. **NEW**

### *Ureterolithotomy*

Open, laparoscopic or robot-assisted removal of a calculus lodged in the ureter through a direct incision of ureter over the calculus. **NEW**

### *Endoureterotomy*

Endoscopic incision of a benign ureteral lesion or ureteroenteric strictures. **NEW**

### *Ureteroureterostomy*

An end-to-end anastomosis of the segments of the same ureter, with excision of the intervening injured, tumor, or scarred ureter. Transperitoneal ureteroureterostomy is a special urinary reconstruction with side-to-end anastomosis of the injured ureter from one side across the peritoneal cavity under the mesentery of the intestine to the healthy ureter on the opposite side. **NEW**

## 7.1.5 | Ureteroplasty

Any surgical reconstruction of the ureter. **NEW**

### *Graft ureteroplasty*

Use of buccal mucosa, preputial skin, and bladder mucosa to graft partially obliterated or defective ureter. **NEW**

### *Flap ureteroplasty*

Use of bladder mucosa or bowel to substitute partially obliterated or strictured ureter. **NEW**

### *Ileal ureteric replacement*

A segment of ileum is used to replace the damaged ureter. **NEW**

## 7.1.6 | Anastomosis to a bowel segment

### *The Bricker technique*

Spatulating and anastomosing each ureter to the serosa of the bowel segment separately. **NEW**

### *Wallace I (66) surgical technique*

Both ureters are spatulated to the same length. Their medial walls are anastomosed together, and the free

edges of the newly conjoined ureters are then anastomosed to the proximal end of an open bowel segment. **NEW**

### *Wallace II (69) technique*

Head-to-tail anastomosis: Blood supply is protected by suturing the apex of one ureter to the end of the other. The posterior medial walls are sutured together, and then the ends and lateral walls are sutured to the bowel segment. **NEW**

## FOOTNOTES

**FN 1:** The first stage involves incising the penile urethra ventrally, excising the stricture segment completely and applying an inlay graft (often oral mucosa graft). A period of at least 4–6 months is required to allow adequate vascularization of the graft before the final stage of the repair requiring tubularisation of the graft. Occasionally an intermediate stage is required with additional graft inlay.

**FN 2:** The word boutonnière is frequently used as a synonym.

**FN 3:** LASER energy aims to reduce the intra- and postoperative blood loss, even in larger prostates. Different LASER wavelengths are available, producing an array of resection, thermal vaporization, or enucleation of prostatic tissue. Enucleation techniques are a combination of blunt dissection and judicious use of electric or LASER energy to separate the prostate adenoma from the underlying surgical capsule. The adenoma tissue is pushed into the bladder and has to be retrieved by morcellation/resection at the end of the procedure.

**FN 4:** These procedures are also known as secondary ablative procedures, are minimally-invasive and aim to reduce morbidity compared to operations with immediate tissue removal (see Section 3.1.1). These procedures are usually done in small to intermediate volume prostates ( $\leq 60\text{--}80\text{ cm}^3$ ).

**FN 5:** The procedure is currently under clinical evaluation.

**FN 6:** The procedure is currently under clinical evaluation.

**FN 7:** The procedure is not in routine use anymore in most parts of the world.

**FN 8:** The procedure is no longer recommended because of the poor outcome results

**FN 9:** The procedure is no longer recommended because of the poor outcome results.

**FN 10:** Elderly men with multiple comorbidities may be unfit to undergo surgical management of benign prostatic obstruction and, therefore, are only suitable for minimal-invasive procedures without anesthesia.

**FN 11:** While the term “simple prostatectomy” has been used synonymously for open adenectomy or open enucleation of the prostate, it is misleading because only the hyperplastic adenomatous and not the entire prostate are removed. The nonhyperplastic peripheral and central prostatic zones as well as the anterior fibromuscular stroma are not removed and the prostatic capsule and seminal vesicles are also left in situ. In the era of prostatectomy for prostatic malignancy, use of the term “simple prostatectomy” should be discouraged to avoid confusion.

**FN 12:** This is still an experimental technique.

#### ACKNOWLEDGMENTS

No discussion on terminology should fail to acknowledge the fine leadership shown by the ICS over many years. The legacy of that work by many dedicated clinicians and scientists is present in all the reports by the different Standardization Committees. It is pleasing that the ICS leadership has accepted the need for this project.

This document was initiated at ICS Tokyo (BH, LA-M, RH—September 2016) and formalized in London (June 2017—LA-M, RH Co-Chairs). Working Group (WG) live meetings have been held in Florence (September 2017), Philadelphia (August 2018) and Gothenburg (September 2019). It has involved 14 rounds of full review, by coauthors, of an initial draft (LA-M, RH). Formal editing and formatting then occurred (December 2019, January 2020—MO, BH) to create Version 12. Following external review (four experts—Ricardo Pereira, Rui Almeida Pinto, Howard Goldman, and Tufan Tarcan). There have been a further two rounds to review the comments made. We thank the other colleagues who have provided comments on the website reviews. Sign-off has included Standardization Steering Committee (V14) and the ICS Board (V15). The document (V16) will be published in *Neurourology and Urodynamics*.

This document and all the **NEW** definitions will be uploaded to the **ICS GLOSSARY** ([www.ics.org/glossary](http://www.ics.org/glossary)) where immediate electronic access to definitions and document download is available.

#### AREAS FOR FURTHER RESEARCH

As this document was prepared, some difficulties arose on classifying the latest advances on prostatic procedures as they belong to entirely new approaches.

## Abstract

**Aims:** In 2016, the International Continence Society (ICS) Standardization Steering Committee appointed a working group to address the confusing plethora of synonyms currently used to describe single-use body worn absorbent incontinence products by recommending preferred terminology.

**Methods:** An online questionnaire was posted in 2016/17 inviting input from stakeholders internationally. The data were analyzed and conclusions progressively refined through working group discussions, an open meeting at the 2017 annual ICS conference, and a review of further iterations—including from the parent ICS Standardization Committee—until consensus was reached. Partway in, the International Organization for Standardization started

Mandy Fader and Alan Cottenden are Co-chairs of the Working Group.

Mandy Fader, Alan Cottenden, Chris Chatterton, Helena Engqvist, Sharon Eustice, Diane K. Newman, Joan Ostaszkiwicz, Mary H. Palmer and Tara Willson are members of the Working Group.

Bernard Haylen is Chair ICS Standardization Steering Committee.

a project with similar scope and the two organizations liaised to harmonize their conclusions while respecting each other's processes.

**Results:** A hundred people from 18 countries responded to the questionnaire. About a third (32.2%) of those declaring their nationality were from the UK and a further third (34.5%) from other English-speaking countries. Two-thirds (67.8%) lived in Europe; around a quarter (23%) in North America; and 9.2% in Australasia. Seven main design categories of products were identified and, while clear consensus was readily achieved in naming some of them, others required more work to determine the best term among multiple contenders.

**Conclusions:** The working group concluded that the seven product design categories should be called: (a) pads; (b) unbacked pads; (c) male pads; (d) male pouches; (e) pull-on pads (protective underwear); (f) all-in-ones (wrap-around pads, adult briefs); and (g) belted pads (belted products), in which the bracketed terms are judged acceptable (though not preferred) alternatives.

## 1 | INTRODUCTION

Not all bladder or bowel incontinence problems can be completely and permanently cured. The challenge for those whose symptoms persist is to discover how to deal with their incontinence to minimize its impact on their health and quality of life (QoL). And this usually includes managing urine and stool leakage using continence products. Even those whose incontinence is ultimately treated successfully may have to live with symptoms for a time—for example, while waiting for surgery, or for pelvic floor muscle training to yield its benefits—and they may use continence products temporarily during this waiting period. Others may use them as an adjunct to a treatment that reduces their leakage (eg, bladder training, toileting programs) without eliminating it. Still, others may use products intermittently, limiting their use to particular timeframes or activities associated with troublesome leakage. However, some use products permanently, either following treatment that has not been (completely) successful or because—depending on their frailty, severity of symptoms, and personal priorities—they are not candidates for treatment.

Successful management of incontinence with products is often referred to as “*contained incontinence*” and can bring substantial benefits to QoL even though a cure has not been achieved.<sup>1</sup> A wide variety of such products exists but by far the most common are *single-use* (as opposed to reusable/washable) *body worn* (that is, worn on the body as opposed to bed and chair protectors) *absorbent products*. The ICS defines absorbent products as “... those that have been specifically developed to help manage leakage or soiling,

such as absorbent pads and pants, absorbent bed sheets and chair covers”<sup>2</sup> and they come in a range of different designs. The purpose of this report is to recommend terms for single-use body worn absorbent products. The primary purpose of such products is to absorb and thereby contain urine, however, some designs may also be used to contain faeces either alone or in combination with urine. There are a very small number of products made from absorbent materials that are designed specifically to contain faeces alone; these are not included within the scope of this report.

The names used to describe absorbent products can vary considerably among—and even within—countries and cultures. This has resulted in a confusing plethora of synonyms in the clinical/academic literature,<sup>3–14</sup> as well as the literature provided by product suppliers, and information available on the internet or through other media such as magazines. Standardized terminology, providing preferred terms that all are encouraged to use, would facilitate understanding and communication among users, caregivers, clinicians, researchers manufacturers, and government agencies. To that end, the ICS appointed an international working group of experts in the field of containment with continence products to consult widely across the international community of people concerned with these products to establish a standard terminology that enjoys widespread support. The guiding principles were to identify—and recommend—for each product design category, that term most widely acceptable internationally, favoring—where possible—terms which are most helpfully descriptive of a design's characteristic features and avoiding terms with child/toddler/baby connotations.

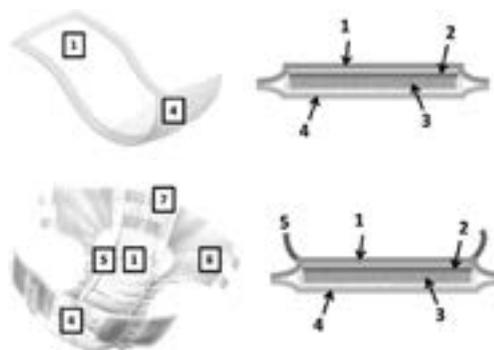

This report summarizes the recommendations of the working group. Further, detailed Supporting Information is available on-line on the ICS website (URL to be

determined), describing: the on-line questionnaire that was used to solicit the views of stakeholders internationally (Supporting Information, Appendix A, ICS website); the key characteristics and views of the respondents (Supporting Information, Appendices B and C, ICS website); and an International Continence Society members' consultation meeting on the topic at the 2017 annual ICS conference (Supporting Information, Appendix D, ICS website).

## 2 | METHODOLOGY

Drawing on their collective experience and the literature review conducted for the absorbent products section of the sixth International Consultation on Incontinence,<sup>1</sup> the working group created an online questionnaire (Supporting Information, Appendix A, ICS website) to solicit the opinions of stakeholders internationally. The questionnaire invited respondents to identify their interest in these products (such as product user, healthcare professional, or product manufacturer) and their nationality; express their preferences for a range of offered alternative names for each of seven different categories of single-use body worn absorbent incontinence products identified by the working group; suggest—with reasons—any other alternative names worthy of consideration; and comment on proposed descriptions for the defining features and main variant features for each of the seven design categories. The final questionnaire was posted on 12 December 2016 and closed for participation on 7 March 2017, by which time 100 people from 18 countries had responded. Almost a third (32.2%) of respondents who declared their nationality were from the UK and about a further third (34.5%) were from other English-speaking countries. Two-thirds (67.8%) lived in Europe; around a quarter (23%) in North America; and 9.2% in Australasia. Details of the characteristics and views of the respondents are given in Appendices B and C (Supporting Information, ICS website).

Drawing on the survey findings, the working group drafted a set of recommendations which were presented at an open meeting at the 2017 annual conference of the International Continence Society in Florence attended by 12 experts. This meeting focused on reaching agreement on rival terms when a clear consensus was not apparent, and a report of the meeting is provided in Appendix D (Supporting Information, ICS website). Part way into this project the International Organization for Standardization (ISO) embarked on a parallel project to standardize nomenclature relating to single-use absorbent body worn products for incontinence. ICS and ISO working groups shared their draft reports and recommendations to achieve as much alignment as they could while respecting each other's processes. The

**FIGURE 1** A (top), The design of a simple pad (left) and a transverse section through it (right) to show the layered construction. B (bottom), The design of a typical all-in-one product (left) and a transverse section through it (right) to show the layered construction. 1: Topsheet; 2: Backsheet; 3: Absorbent core; 4: Acquisition and distribution layer (ADL); 5: Standing gathers (leg cuffs); 6: Fasteners; and 7: Elastication

terminology adopted in the ISO standard currently under preparation is expected to be very similar to that described here. To complete the ICS project, working group members were invited to comment on drafts of the final report before it was deemed completed.

## 3 | PRODUCT DESIGN FEATURES

Although single-use (disposable) body worn absorbent incontinence products come in a variety of generic designs, they share many design features in common, as illustrated in Figure 1 and described in the following sections. These terms were used in describing the various proposed product categories in the on-line questionnaire (Supporting Information, Appendix A, ICS website), along with an invitation to respondents to identify any omissions, errors, or preferences for changes. In fact, terms and descriptions for design features turned out to be far less contentious than those for product categories, necessitating only very minor changes to draft text to arrive at the wording below.

### 3.1 | Topsheet

The *topsheet* in an absorbent incontinence product is the layer of fabric which lies against the wearer's skin. It is made from a water-permeable material that allows urine to pass readily through to the acquisition and distribution layer (ADL) and the absorbent core beneath.

FIGURE 2 Examples of pads

**3.2 | Acquisition and distribution layer**

Absorbent incontinence products often have an ADL between the topsheet (above) and the absorbent core (below). The ADL is designed to allow urine to enter the product rapidly, and spread it over a large area of absorbent core. It is not intended to absorb urine itself.

**3.3 | Absorbent core**

The *absorbent core* of an absorbent incontinence product is where urine is captured and stored. It is made from (a) material(s) which absorb(s) urine readily and retains it under pressure, such as when the wearer changes posture or position.

FIGURE 3 An example of an unbacked pad

**3.4 | Backsheet**

The *backsheet* in an absorbent incontinence product is a layer of waterproof material which forms the outside surface of the product, away from the wearer's body. It may be breathable.

**3.5 | Fasteners**

*Fasteners* (Tabs) enable the front and back regions of all-in-ones and belted pads to be secured to one another, helping to hold the product in the intended shape and enable a close fit to the wearer. Fasteners/tabs are most commonly faced with an adhesive (which usually allows them to be undone and refastened to achieve the desired fit) or a hook and loop fastening system.

TABLE 1 Total, new, and changed definitions (from those currently in the ICS Glossary)

Section	New definitions/descriptors	Changed definitions/descriptors	Total
Introduction & methodology	4	0	4
Product design features	7	0	7
Terms for product design categories	7	0	7
Total	18	0	18

Abbreviation: ICS, International Continence Society.

TABLE 2 The defining features and main variant features of pads

Defining features	Waterproof-backed absorbent products that are held in place using separate, close-fitting (regular or specially designed) underwear
Main variant features	<ul style="list-style-type: none"> <li>• Products may be used by either sex, but some are intended (by their color, style, shape, or the placing of absorbent material, for example) just for men or just for women.</li> <li>• Products come with different absorption capacities.</li> <li>• Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit, comfort, and prevent leakage.</li> <li>• Products may have an adhesive strip on the back or adhesive wings to the sides to help secure them in underwear.</li> <li>• Products may have a wetness indicator.</li> <li>• Products may or may not be suitable for containing fecal incontinence (FI) as well as urinary incontinence (UI).</li> </ul>

**TABLE 3** The defining features and main variant features of unbacked pads

Defining features	Absorbent products without a waterproof backing used either (a) inside another product such as a category 6 product to supplement its absorption capacity or to reduce the frequency with which it needs to be changed (the unbacked pad may be changed with relative ease, without necessarily needing to also change the outer product), or (b) on its own, secured using separate, close-fitting, underwear which itself includes waterproofing in the pad area
Main variant features	<ul style="list-style-type: none"> <li>• Products may be used by either sex.</li> <li>• Products may be rectangular or contoured to better fit the wearer.</li> <li>• Products come with different absorption capacities.</li> <li>• Products may or may not be suitable for containing FI as well as UI.</li> </ul>

**FIGURE 4** Examples of *male pads*

**FIGURE 5** An example of a *male pouch*

**3.6 | Elastication**

*Elastication* is often used to give an incontinence product the desired shape and to achieve a close fit with the wearer. It is commonly used in the waist belts of all-in-ones (wrap-arounds, adult briefs), pull-on pads (protective underwear), and belted pads (belted products). In pull-on pads, it may be used across much of the area of the product. It is used along the edges of the crotch region in many different designs.

**3.7 | Leg cuffs**

*Leg cuffs* (standing gathers) refer to a particular kind of elasticsation which may be used longitudinally on a

product near the edges of the crotch region to promote close contact with the groin on either side of the body.

**4 | RECOMMENDED TERMS FOR PRODUCT DESIGN CATEGORIES**

Single-use body worn absorbent products can be divided into seven distinct categories according to their main (defining) features. A recommended name for each design category is given below, along with descriptions of its defining—and main variant—features.

**TABLE 4** The defining features and main variant features of *male pads*

Defining features	Waterproof-backed absorbent products for men that are designed to cover the penis and scrotum, and are held in place using separate, close-fitting (regular or specially designed) underwear
Main variant features	<ul style="list-style-type: none"> <li>• Products come with different absorption capacities.</li> <li>• Longitudinal elastic side barriers and leg cuffs at the sides may be included to improve fit and comfort and prevent leakage.</li> <li>• Products may have an adhesive strip on the back to help secure them in underwear.</li> </ul>

**TABLE 5** The defining features and main variant features of *male pouches*

Defining features	Waterproof-backed absorbent products for men, fashioned into a pocket into which the penis—and sometimes the scrotum, too—is placed. They are held in place using separate, close-fitting (regular or specially designed) underwear
Main variant features	<ul style="list-style-type: none"> <li>• Products come with different absorption capacities.</li> <li>• Products may have an adhesive strip on the back to help secure them in underwear.</li> <li>• Products may have a hook and loop fastening system or adhesive tape to secure the product round the penis.</li> </ul>

**FIGURE 6** Examples of *pull-on pads* (protective underwear)**FIGURE 7** Examples of *all-in-ones* (wrap-around pads, adult briefs)

#### 4.1 | Pads

We recommend that products of the kind shown in Figure 2 should be called *pads*—waterproof-backed absorbent products that are held in place using separate, close-fitting (regular or specially designed) underwear. The defining features of pads and the main variant features are described in Table 1, while the construction of a simple variant is shown in Figure 1A. Although the online questionnaire found clear international consensus in favor of pad, two alternative names (insert and liner) were popular in some countries, but never more popular than pad (Supporting Information, Appendix C: Figure C-1 and Table C-1, ICS website). Accordingly, use of these two terms—and others favored by small groups of respondents—is discouraged Table 2.

#### 4.2 | Unbacked pads

We recommend that products of the kind shown in Figure 3 should be called *unbacked pads*—absorbent products without a waterproof backing. They comprise an absorbent core held in an envelope of water-permeable material and their defining features and main variant features are described in Table 3. The online questionnaire found clear international consensus in favor of booster pad. However, in Asia, it is common to use such pads, not so much to boost the absorption capacity of another product as to reduce the frequency with which it needs to be changed. An unbacked pad may be changed relatively easily without the need to also change the outer product. It is also known that pads (Section 4.1) may be used as “booster” pads and this term may, therefore, be confusing. Accordingly, unbacked pads are favored, a term which was also accepted

**TABLE 6** The defining features and main variant features of *pull-on pads* (protective underwear)

Defining features	Products in which the absorbent core, waterproof backing, and the means to hold it in place are combined in a single design resembling regular underwear. Elastic linings around the waist and hips help give a close fit
Main variant features	<ul style="list-style-type: none"> <li>• Products may be used by either sex, but some are intended (by their color, style, or the placing of absorbent material, for example) just for men or just for women.</li> <li>• Products come with different absorption capacities, and fit different body sizes.</li> <li>• Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit and comfort and prevent leakage.</li> <li>• In some designs, side seams can be torn away for easy removal.</li> <li>• Products may have wetness indicators.</li> <li>• Products may or may not be suitable for containing FI as well as UI.</li> </ul>

**TABLE 7** The defining features and main variant features of *all-in-ones* (wrap-around pads, adult briefs)

Defining features	One-piece products in which the absorbent core and the means to hold it in place are combined in a single design, secured using adjustable adhesive tabs or a hook and loop fastening system at the sides
Main variant features	<ul style="list-style-type: none"> <li>• Products may be used by either sex, but some are intended (by their color, style, or the placing of absorbent material, for example) just for men or just for women.</li> <li>• Products come with different absorption capacities, and to fit different body sizes.</li> <li>• Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit and comfort and prevent leakage.</li> <li>• Products may have wetness indicators.</li> <li>• Products may or may not be suitable for containing FI as well as UI.</li> </ul>

**FIGURE 8** Example of a *belted pad* (belted product)

internationally (Supporting Information, Appendix C: Figure C-2 and Table C-2, ICS website).

### 4.3 | Male pads

We recommend that products of the kind shown in Figure 4 should be called *male pads*—waterproof-backed absorbent products for men that are designed to cover the penis and scrotum, and are held in place using separate, close-fitting (regular or specially designed) underwear. Although they are shaped differently, they generally include a series of material layers similar to those shown in the pad in Figure 1A. The defining features of male pads and the main variant features are described in Table 4. The online

questionnaire found a clear international consensus in favor of male pad. Guard pad was quite a popular alternative in some countries but it was more popular than male pad in only one (Canada), though only marginally (Supporting Information, Appendix C: Figure C-3 and Table C-3, ICS website) Accordingly, the use of the term guard pad for men—and others favored by small groups of respondents—is discouraged.

### 4.4 | Male pouches

We recommend that products of the kind shown in Figure 5 should be called *male pouches*—waterproof-backed absorbent products for men, fashioned into a pocket into which the penis—and sometimes the scrotum, too—is placed. Although they are shaped differently, they generally include a series of material layers similar to those shown in the pad in Figure 1A. The defining features of male pouches and the main variant features are described in Table 5. The online questionnaire found clear international consensus in favor of pouch and no other term emerged as a popular alternative (Supporting Information, Appendix C: Figure C-4 and Table C-4, ICS website). We subsequently made the minor modification of “pouch” to “male pouch” to improve alignment with the conclusions of the parallel ISO project.

**TABLE 8** The defining features and main variant features of *belted pads* (belted products)

Defining features	One-piece products in which the absorbent core, waterproof backing, and the means to hold it in place are combined in a single design, secured by means of an adjustable belt with adhesive tabs or a hook and loop fastening system
Main variant features	<ul style="list-style-type: none"> <li>• Products may be used by either sex, but some are intended (by their color, style, or the placing of absorbent material, for example) just for men or just for women.</li> <li>• Products come with different absorption capacities, and to fit different body sizes.</li> <li>• Longitudinal elastic side barriers and leg cuffs on either side of the crotch may be included to improve fit and comfort and prevent leakage.</li> <li>• Products may have wetness indicators.</li> <li>• Products may or may not be suitable for containing FI as well as UI.</li> </ul>

**TABLE 9** Recommended, acceptable alternative and “retired” terms for the seven categories of single-use body worn absorbent products for incontinence

Design category #	Recommended term	Acceptable alternative term(s)	“Retired “ term(s)
1	Pads	...	Inserts, liners, shields, slips
2	Unbacked pads	...	Booster pads
3	Male pads	...	Guard pads for men; shields, leafs
4	Male pouches	...	...
5	Pull-on pads	Protective underwear	Pant-designs, pull-ups, underwear designs, up-and-gos
6	All-in-ones <sup>a</sup>	Wrap-around pads <sup>a</sup> , adult briefs	Briefs, diapers, slips
7	Belted pads	Belted products	Flexes, undergarments

<sup>a</sup>All-in-one is not a helpfully descriptive term but is in common use. The use of the term Wrap-around pad (currently uncommon) is encouraged.

#### 4.5 | Pull-on pads (protective underwear)

We recommend that products of the kind shown in Figure 6 should be called *pull-on pads*—products in which the absorbent core, waterproof backing, and the means to hold it in place are combined in a single design resembling regular underwear, with protective underwear as an acceptable alternative. Although they are shaped differently and have no need of fasteners, they generally include a series of material layers similar to those shown in the all-in-one in Figure 1B. The defining features of pull-on pads (protective underwear) and the main variant features are described in Table 6. The terms protective underwear and pull-up were each supported by about the same number of respondents in the questionnaire, but protective underwear was favored over pull-up (or equal to it) in all countries except the UK and Ireland (Supporting Information, Appendix C: Figure C-5 and Table C-5, ICS website). However, protective underwear is not a usefully descriptive term, and pull-up has child/toddler connotations. Thus, the term, Pull-on pads, is proposed as being descriptive of the key characteristic of the design while avoiding child/toddler connotations, with protective underwear as an acceptable alternative.

#### 4.6 | All-in-ones (wrap-around pads, adult briefs)

We recommend that products of the kind shown in Figure 7 should be called *all-in-ones*—one-piece products in which the absorbent core and the means to hold it in place are combined in a single design, secured using adjustable adhesive tabs or a hook and loop fastening system

at the sides, for the time being. Although in common use this term does not provide a helpful description of the product and we, therefore, encourage the use of the alternative more descriptive term, *wrap-around pads*. *Adult brief* is also an acceptable alternative but lacks helpful description and is, therefore, not encouraged. The construction of a typical all-in-one product is shown in Figure 1B, while the defining features of all-in-ones and their main variant features are described in Table 7. The online questionnaire revealed a diversity of views on what category 6 products should be called. Respondents from four countries favored diaper, but many others were against the term because of its connotations to infants. Slip and wrap-around were favored in the Netherlands but enjoyed little support elsewhere. Adult brief was favored by Canada, the United States, and Norway but, again, there was little support elsewhere. All-in-one was favored by Australia, Belgium, and the UK and had the highest number of respondents favoring it (note: the UK was strongly represented—about a third of respondents) (Supporting Information, Appendix C: Figure C-6 and Table C-6, ICS website). In conclusion, we recommend that these products should be called *all-in-ones*. However wrap-around pads and adult briefs are acceptable as alternatives.

#### 4.7 | Belted pads (belted products)

We recommend that products of the kind shown in Figure 8 should be called *belted pads*—one-piece products in which the absorbent core, waterproof backing, and the means to hold it in place are combined in a single design, secured by means of an adjustable belt with adhesive tabs or a hook and loop fastening system, with belted products as an acceptable alternative. Although they are shaped and secured differently, belted pads generally include a series

of material layers similar to those shown in the all-in-one product in Figure 1B. The defining and main variant features of belted pads (belted products) are described in Table 7. The online questionnaire found clear international consensus in favor of belted products, which was the (joint) top choice in most countries (Supporting Information, Appendix C: Figure C-7 and Table C-7, ICS website). However, “product” is rather vague, and we recommend that “pad” should be used instead, with belted product as an acceptable alternative Table 8.

#### 4.8 | Summary

The recommended terms for the seven categories of single-use body worn absorbent products for incontinence are gathered in Table 9, along with acceptable alternatives and retired terms; that is, terms recommended for discontinuation.

#### ACKNOWLEDGMENTS

We are pleased to acknowledge Jenny Ellis’ excellent work in administering the project and—with Dominic Turner—creating a viable online questionnaire. We are grateful, too, to Helena Engqvist who gathered all the diagrams and much of the written content for the questionnaire. The working group had no virtual or physical meetings but—by email—contributed actively to the editing of around 20 drafts of questionnaires and reports. We are grateful to Pierre Conrath (at the time, External Relations and Sustainability Director at EDANA [the International Association Serving the Nonwovens and Related Industries]) for useful advice on developing the on-line questionnaire on which the study was based.

Goldman,<sup>2</sup> Martin Huser,<sup>2</sup> Alfredo L. Milani,<sup>2</sup> Paul A. Moran,<sup>1,2</sup> Gabriel N. Schaer,<sup>1,2</sup> and Mariëlla I.J. Withagen<sup>2</sup>

<sup>1</sup>Standardization and Terminology Committees IUGA & ICS

<sup>2</sup>Joint IUGA / ICS Working Group on Female POP Terminology

**Introduction:** The terminology for female pelvic floor prolapse (POP) should be defined and organized in a clinically-based consensus Report. **Methods:** This Report combines the input of members of two International Organizations, the International Urogynecological Association (IUGA) and the International Continence Society (ICS), assisted at intervals by external referees. Appropriate core clinical categories and a sub-classification were developed to give a coding to definitions. An extensive process of fourteen rounds of internal and external review was involved to exhaustively examine each definition, with decision-making by collective opinion (consensus). **Results:** A Terminology Report for female POP, encompassing over 230 separate definitions, has been developed. It is clinically-based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in all the different specialty groups involved in female pelvic floor dysfunction and POP. Female-specific imaging (ultrasound, radiology and MRI) and conservative and surgical managements are major additions and appropriate figures have been included to supplement and clarify the text. Emerging concepts and measurements, in use in the literature and offering further research potential, but requiring further validation, have been included as an appendix. Interval (5-10 year) review is anticipated to keep the document updated and as widely acceptable as possible. **Conclusion:** A consensus-based Terminology Report for female POP has been produced to aid clinical practice and research. *NeuroUrol. Urodynam.* 35:137–168, 2016. © 2016 Wiley Periodicals, Inc., and The International Urogynecological Association

**Key words:** female; pelvic organ prolapse; standardization report; terminology report

### INTRODUCTION

**Prolapse** (Latin: *Prolapsus* – “a slipping forth”) refers to a falling, slipping or downward displacement of a part or organ. **Pelvic organ** refers most commonly to the uterus and/or the different vaginal compartments and their neighboring organs such as bladder, rectum or bowel. **Pelvic organ prolapse (POP)** is thus, primarily, a definition of anatomical change. Some such changes may well be considered within the range of normality for certain women. A **diagnosis of POP** ideally demands clear clinical evidence, starting with a woman having symptoms related to the “downward displacement” of a pelvic organ.

There is currently no single document encompassing all elements required for diagnoses in the area of female POP. Such a report would require a full outline of the terminology for symptoms, signs, clinical assessments, functional investigations for female POP, the imaging associated with those investigations, the most common diagnoses and terminology for the different conservative and surgical treatment modalities.

There will be a need to reference considerably the 2010 IUGA-ICS Joint Terminology Report on Female Pelvic Floor Dysfunction<sup>1</sup>. An original aim of that report<sup>1</sup> had been to provide a general terminology, forming a “backbone” or “core” terminology to which more specific terminologies can be attached. Reference can also be made to three other published Standardization Reports<sup>2–4</sup> and 6 joint IUGA-ICS Female Terminology Reports<sup>5–10</sup> subsequent to the 2010 Report<sup>1</sup>, three published<sup>5–7</sup>, three<sup>8–10</sup> advanced in development.

In terms of the previous standardization document on female POP<sup>4</sup>, now 20 years old, there has been much discussion and debate<sup>11–14</sup> on the possible need to update its classification POP-Q, or at least to present it in a refreshed version. The POP Working Group has opted for the latter, with major upgrades to symptoms, signs, investigations and diagnoses, but a conservative approach to the classification itself (apart from adding a validated simplified version), due to the longevity of its use and the lack of any validated, clearly superior alternative classification. Female-specific imaging (ultrasound, radiology and MRI) and conservative and surgical managements are major additions and appropriate figures have been included to supplement and clarify the text. Emerging concepts and measurements, in use in the literature and offering further research potential, but requiring further validation, have been included as an Appendix. This Report acknowledges that POP is often not a diagnosis in isolation but may be associated with POP-related and unrelated voiding, defecatory and/or sexual dysfunctions and/or other diagnoses of pelvic floor dysfunction.

This Terminology Report is inherently and appropriately a definitional document, collating the definitions of those terms, i.e. “words used to express a defined concept in a particular branch of study”<sup>15</sup>, here POP. Emphasis has been on comprehensively including those terms in current use in the relevant peer-reviewed literature. The aim is to assist clinical practice and research. Some new and revised terms have been included. Explanatory notes on definitions have been referred, where possible, to the “Footnotes” section.

Like all the other joint IUGA-ICS female-specific terminology reports, every effort has been made to ensure this Report is:

**(1) User-friendly:** It should be able to be understood by all clinical and research users.

**(2) Clinically-based:** Symptoms, signs and validated assessments/investigations should be presented for use in forming workable diagnoses for POP and associated dysfunctions. Sections 1-5 will address symptoms, signs, POP quantification, investigations for associated dysfunctions and current POP imaging modalities that may be used to make those diagnoses. A number of related radiological investigations including Magnetic Resonance Imaging (MRI) and Computerized Tomography (CT) have also been incorporated. Section 6 will address POP diagnoses, possible POP-related diagnoses and co-existing diagnoses. The scope of the Report will exclude more invasive investigations requiring an anesthetic. Sections 7 and 8 will list the terminology for evidence-based conservative and surgical treatments for POP.

**(3) Origin:** Where a term’s existing definition (from one of multiple sources used) is deemed appropriate, that definition will be included and duly referenced. A large number of terms in female pelvic floor prolapse and dysfunction, because of their long-term use, have now become generic, as apparent by their listing in medical dictionaries.

**(4) Able to provide explanations:** Where a specific explanation is deemed appropriate to describe a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (*Footnote [FN] 1,2,3...*). Wherever possible, evidence-based medical principles will be followed.

It is suggested that acknowledgement of these standards in written publications related to female POP, be indicated by a footnote to the section “Methods and Materials” or its equivalent, to read as follows: “Methods, definitions and units conform to the standards jointly recommended by the International Urogynecological Association and the International Continence Society except where specifically noted”.

#### SECTION 1: SYMPTOMS:

**Symptom:** Any morbid phenomenon or departure from the normal in structure, function or sensation, experienced by the woman and indicative of disease or a health problem<sup>16</sup>. Symptoms are either volunteered by, or elicited from the woman or may be described by the woman’s caregiver<sup>1–3</sup>.

<sup>1</sup>: In the era of advanced cellphone camera technology, a woman, at times, will bring photographic evidence of the prolapse at its worst. This can add to other clinical evidence, particularly if there is a discrepancy between symptoms and signs.

<sup>2</sup>: The more formal classification of constipation is as follows:

Rome II diagnostic criteria for constipation:

- At least 12 weeks, which need not be consecutive, in the previous 12 months, of two or more of:
  - (i) Straining in > 1 in 4 defecations.
  - (ii) Lumpy or hard stools in > 1 in 4 defecations.
  - (iii) Sensation of incomplete evacuation in > 1 in 4 defecations.
  - (iv) Sensation of anorectal obstruction/ blockage in > 1 in 4 defecations.
  - (v) Manual manoeuvres to facilitate > 1 in 4 defecations (e.g. digital evacuation, support of the pelvic floor).
  - (vi) Less than 3 defecations per week.
- Loose stools are not present and there is insufficient evidence for IBS (irritable bowel syndrome)

<sup>3</sup>: A symptomatic-based subdivision of Stage II (see Appendix A) was overlooked at this time in favor of maintaining the current strictly anatomical definition of the “sign of POP”.

### Pelvic Organ Prolapse (POP) Symptoms

**Prolapse symptoms<sup>1</sup>:** A departure from normal sensation, structure or function, experienced by the woman in reference to the position of her pelvic organs. Symptoms are generally worse in situations when gravity might make the prolapse worse (e.g. after long periods of standing or exercise) and better when gravity is not a factor e.g. lying supine. Again symptoms may be more noticeable at times of abdominal straining e.g. defecation.

#### A: Vaginal Prolapse Symptoms

**(i) Vaginal bulging<sup>1</sup>:** Complaint of a “bulge”, lump or “something coming down” or “falling out” through the vaginal introitus. The woman may state she can either feel the bulge by direct palpation or see it, perhaps aided with a mirror. FN1

**(ii) Pelvic pressure<sup>1</sup>:** Complaint of increased heaviness or dragging (pain or discomfort) in the suprapubic area and/or pelvis.

**(iii) Bleeding, discharge, infection<sup>1</sup>:** Complaint of abnormal vaginal bleeding, discharge or infection which may be related to ulceration of the prolapse.

**(iv) Splinting / Digitation<sup>1</sup>:** Complaint of the need to digitally replace the prolapse or to otherwise apply manual pressure, e.g. to the vagina, perineum or perianal area (splinting), or rectally (digitation) to assist voiding or defecation.

**(v) Low backache<sup>1</sup> (POP-related):** Complaint of low, sacral (or “menstrual-like”) backache associated temporally with vaginal POP and relieved when prolapse is reduced.

#### B: Urinary Tract Prolapse Symptoms

**(i) Urethral Prolapse:** Complaint of a “lump” at the external urethral meatus.

#### C: Anorectal prolapse symptoms

**(i) Anorectal prolapse:** Complaint of a “bulge” or “something coming down” towards or through the anus/rectum. The woman may state she can either feel the bulge by direct palpation or see it perhaps aided with a mirror. FN1

**(ii) Rectal prolapse:** Complaint of external protrusion of the rectum.

#### Effects of Pelvic Organ Prolapse on Bladder, Bowel and Sexual Function.

As demonstrated in Figure 1, higher stage utero-vaginal prolapse will usually cause anatomical distortion to surrounding organs, bladder and rectum most commonly. This can lead to abnormal function, most commonly difficulty with bladder and bowel emptying. Commonly, symptoms related to those surrounding organs are the most bothersome leading to the eventual diagnosis of the POP.

Figure 1. Utero-vaginal prolapse.

#### D: Potential prolapse-related lower urinary tract symptoms:

**(i) Hesitancy<sup>1</sup>:** Complaint of a delay in initiating micturition.

**(ii) Slow stream<sup>1</sup>:** Complaint of a urinary stream perceived as slower compared to previous performance (particularly prior to the development of POP) or in comparison with others.

**(iii) Intermittency<sup>1</sup>:** Complaint of urine flow that stops and starts on one or more occasions during voiding.

**(iv) Straining to void<sup>1</sup>:** Complaint of the need to make an intensive effort (by abdominal straining, Valsalva or suprapubic pressure) to either initiate, maintain or improve the urinary stream.

Neurourology and Urodynamics DOI 10.1002/nau

- (v) **Spraying (splitting) of urinary stream**<sup>1</sup>: Complaint that the urine stream is a spray or split rather than a single discrete stream.
- (vi) **Feeling of incomplete (bladder) emptying**<sup>1</sup>: Complaint that the bladder does not feel empty after micturition.
- (vii) **Need to immediately re-void**<sup>1</sup>: Complaint that further micturition is necessary soon after passing urine.
- (viii) **Post-micturition leakage**<sup>1</sup>: Complaint of a further involuntary passage of urine following the completion of micturition.
- (ix) **Position-dependent micturition**<sup>1</sup>: Complaint of having to take specific positions to be able to micturate spontaneously or to improve bladder emptying e.g. leaning forwards or backwards on the toilet seat or voiding in the semi-standing position.
- (x) **Splinting to micturate**<sup>1</sup>: as above A (iv).
- (xi) **Dysuria**<sup>1</sup>: Complaint of burning or other discomfort during micturition. Discomfort may be intrinsic to the lower urinary tract or external (vulvar dysuria).
- (xii) **(Urinary) retention**<sup>1</sup>: Complaint of the inability to pass urine despite persistent effort.
- (xiii) **Increased daytime urinary frequency**<sup>1</sup>: Complaint that micturition occurs more frequently during waking hours than previously deemed normal by the woman.
- (xiv) **Urgency**<sup>1</sup>: Complaint of a sudden, compelling desire to pass urine which is difficult to defer.

**E: Potential prolapse-related anorectal dysfunction symptoms**<sup>1,8</sup>

- (i) **Constipation**<sup>8</sup>: Complaint that bowel movements are infrequent and/or incomplete and/or there is a need for frequent straining or manual assistance to defecate. FN2
- (ii) **Feeling of incomplete bowel evacuation**<sup>1,8</sup>: Complaint that the rectum does not feel empty after defecation and may be accompanied by a desire to defecate again.
- (iii) **Straining to defecate**<sup>1,8</sup>: Complaint of the need to make an intensive effort (by abdominal straining or Valsalva) to either initiate, maintain or improve defecation.
- (v) **Sensation of anorectal blockage**<sup>8</sup>: Complaint suggestive of anorectal obstruction.
- (vi) **Splinting / Digitation**<sup>1,8</sup>: Defined above in A (iv).
- (vii) **Fecal (rectal) urgency**<sup>1,8</sup>: Complaint of a sudden compelling desire to defecate that is difficult to defer.
- (viii) **Post-defecatory soiling (NEW)**: Soiling occurring after defecation.

**F: Potential prolapse-related Sexual dysfunction symptoms**<sup>1,10,17</sup>

- (i) **Dyspareunia**: Complaint of persistent or recurrent pain or discomfort associated with attempted or complete vaginal penetration.
- (ii) **Obstructed intercourse**: Complaint that vaginal penetration is impeded. Possible causes include narrowing or a bulge.
- (iii) **Vaginal laxity**: Complaint of excessive vaginal looseness.
- (iv) **Libido – loss or decrease**: Complaint of loss or decrease of sexual desire

**G: Other Possible Associated Symptoms**<sup>1</sup>

- (i) **Urinary incontinence symptoms**<sup>1</sup>: Urinary incontinence (symptom); stress (urinary) incontinence; urgency (urinary) incontinence; postural (urinary) incontinence; nocturnal enuresis; mixed (urinary) incontinence; continuous (urinary) incontinence; insensible (urinary) incontinence; coital (urinary) incontinence.
- (ii) **Bladder storage symptoms**<sup>1</sup>: nocturia; overactive bladder syndrome.
- (iii) **Bladder sensory symptoms**<sup>1</sup>: Increased bladder sensation; reduced bladder sensation; absent bladder sensation.
- (iv) **Lower Urinary Tract Infection**<sup>1</sup>: Urinary tract infection (UTI); recurrent urinary tract infections (UTIs); other related history.

**H: More common POP-related symptoms:** Table I gives a consensus view of the authors of the more common POP-related symptoms

TABLE I. The symptoms that women with POP would more\* and most commonly\*\* describe.

<b>Potential prolapse-related symptoms</b>	
<u>Vaginal prolapse</u>	Bulge sensation /visualization**, pelvic pressure**, low (sacral) backache*
<u>Urinary tract</u>	Frequency**, recurrent UTI**, incomplete emptying/urinary retention <sup>1</sup> , slow stream <sup>1</sup>
<u>Ano-rectal</u>	Incomplete defecation**, digitation/splinting*, rectal urgency*, post-defecatory soiling
<u>Sexual</u>	Dyspareunia*, vaginal laxity*
<b>Other possible associated symptoms</b>	
<u>Urinary incontinence**</u>	Stress, urge, postural, nocturnal, coital
<u>Bladder storage*</u>	Urgency, nocturia,

## SECTION 2: SIGNS

**Sign:** Any abnormality indicative of disease or a health problem, discoverable on examination of the patient; an objective indication of disease<sup>16</sup> or a health problem.

**A: Signs of Pelvic Organ Prolapse:** All examinations for POP should be performed with the woman's bladder empty (and if possible an empty rectum). An increasing bladder volume has been shown to restrict the degree of descent of the prolapse<sup>18</sup>. The choice of the woman's position during examination, e.g. left lateral (Sims), supine, standing or lithotomy is that which can best demonstrate POP in that patient and which the woman can confirm as the maximal extent she has perceived e.g. by use of a mirror or digital palpation. The degree of prolapse may be worse after a lengthy time in the upright position. FN1

**(i) Pelvic organ prolapse (anatomical definition of the sign of POP):** The descent of one or more of the anterior vaginal wall, posterior vaginal wall, the uterus (cervix) or the apex of the vagina (vaginal vault or cuff scar after hysterectomy). **The presence of any such sign should be correlated with relevant POP symptoms**<sup>13,19-21</sup>, i.e., patient report of maximal prolapse. More commonly, this correlation would occur at the level of the hymen or beyond<sup>19-21</sup>.

**(ii) Pelvic organ prolapse – (POPQ) - (staging<sup>1,3,4</sup>):**

**Stage 0:** No prolapse is demonstrated.

**Stage I:** Most distal portion of the prolapse is more than 1cm above the level of the hymen.

**Stage II:** The most distal portion of the prolapse is situated between 1 cm above the hymen and 1cm below the hymen. FN3. See also Appendix.

**Stage III:** The most distal portion of the prolapse is more than 1cm beyond the plane of the hymen but everted at least 2cm less than the total vaginal length.

**Stage IV:** Complete eversion or eversion at least within 2 cm of the total length of the lower genital tract is demonstrated.

**(iii) Uterine/ cervical prolapse:** Observation of descent of the uterus or uterine cervix.

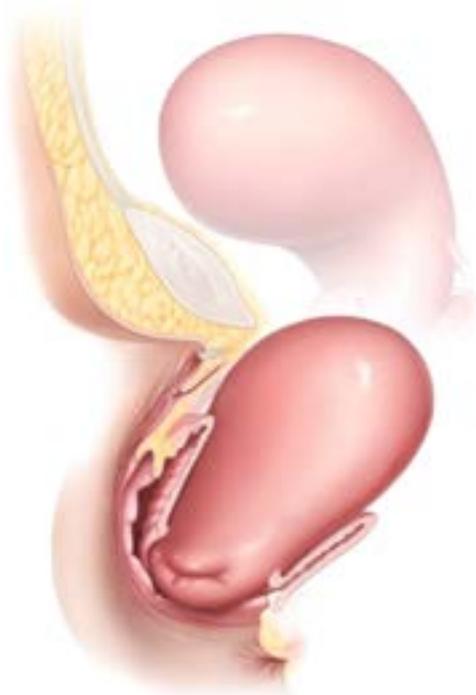

Figure 2. Uterine Prolapse.

**(iv) Anterior vaginal wall (compartment) prolapse:** Observation of descent of the anterior vaginal wall (compartment). Most commonly this might represent bladder prolapse (cystocele). Higher stage anterior vaginal wall prolapse will generally involve descent of uterus or vaginal vault (if uterus is absent). Occasionally, there might be an anterior enterocele (hernia of peritoneum and possibly abdominal contents), most commonly after prior reconstructive surgery.

142 Haylen et al.

Figure 3. Anterior vaginal wall (compartment) prolapse.

**(v) Posterior vaginal wall (compartment) prolapse:** Observation of descent of the posterior vaginal wall. Commonly, this would represent rectal protrusion into the vagina (rectocele). Higher stage posterior vaginal wall prolapse after prior hysterectomy will generally involve some vaginal vault (cuff scar) descent and possible enterocele formation. Enterocele formation can also occur in the presence of an intact uterus.

Figure 4. Posterior vaginal (compartment) wall prolapse.

**(vi) Vaginal vault (cuff scar) prolapse:** Observation of descent of the vaginal vault (cuff scar after hysterectomy).

Figure 5. Vaginal vault prolapse.

*Neurourology and Urodynamics* DOI 10.1002/nau

**B: Clinical Staging<sup>4</sup>:**

Each aspect of POP, uterine (cervical) prolapse, anterior vaginal wall (compartment), posterior vaginal wall (compartment), vaginal vault (cuff scar) prolapse can and should be subject to a clinical staging.

Figure 6. shows prolapse staging<sup>4</sup> – 0, I, II, III, IV. (uterine – by the position of the leading edge of the cervix).

**C: Supplementary Physical Examination Techniques**

(i) **Digital rectal-vaginal examination<sup>4</sup>:** While the patient is straining and the prolapse is maximally developed. The aim is to try to differentiate between a high rectocele and an enterocele.

(ii) **Q-tip (urethral) testing<sup>4</sup>:** Measurement of urethral axial mobility at rest and straining to assess degree of mobility.

**D: Clinical Assessment of Associations of POP**

(i) **Levator Defects / Trauma<sup>22</sup>:** Per-vaginal palpation for levator injury/defect/ “avulsion”.

(ii) **Uterine retroversion<sup>23,24</sup>:** (Turning backward) The axis of the uterus is directed backwards towards the hollow of the sacrum, away from its anteverted position overlying the bladder. Cervix is noted in/ towards the anterior fornix with fundus perhaps palpable in the posterior fornix. FN4

**E: Other Possible Signs.**

(i) **Urinary incontinence signs<sup>1</sup>:** Urinary incontinence; stress (urinary) incontinence; urgency (urinary) incontinence; extraurethral incontinence; stress incontinence on prolapse reduction (occult or latent stress incontinence)

(ii) **Other pelvic examinations/signs<sup>1</sup>:** Vulvar examination; urethral inspection/palpation (urethral mucosal prolapse, urethral caruncle; urethral diverticulum); vaginal examination; bimanual pelvic examination; pelvic floor muscle function (normal pelvic floor muscles, overactive pelvic floor muscles, underactive pelvic floor muscles, non-functioning pelvic floor muscles); examination for levator (puborectalis) injury; perineal examination (perineal elevation, perineal descent); rectal examination (anal sphincter tone and strength, anal sphincter tear, fecal impaction present/absent, other rectal lesions, anal lesions, other perianal lesions), vaginal atrophy.

(iii) **Other relevant examinations/Signs<sup>1</sup>:** Neurological signs, abdominal signs (bladder fullness/retention; abdominal masses or distension; scars from previous relevant surgery or trauma; renal tenderness or masses).

(iv) **Frequency volume chart / Bladder diary<sup>1</sup>**

(v) **Pad testing<sup>1</sup>**

**SECTION 3: PROLAPSE QUANTIFICATION****A: Pelvic Organ Prolapse Quantification (POP-Q)<sup>4</sup>**

(i) **Fixed Point of Reference.** The hymen is the fixed point of reference used throughout the POP-Q system of quantitative prolapse description.

<sup>4</sup>: The axis of the retroverted uterus is parallel to that of the vaginal axis with less impediment to uterine (cervical) descent. In contrast, the anteverted uterus is perpendicular to the vaginal axis with impediment to descent by the posterior vaginal wall and behind that the rectum.

**(ii) Defined Points.** The anatomic position of the six defined points (two on the anterior vaginal wall, two in the superior vagina, and two on the posterior vaginal wall) for measurement should be centimeters (cm) above or proximal to the hymen (negative number) or cm below or distal to the hymen (positive number) with the plane of the hymen being defined as zero (0). For example, a cervix that protruded 3 cm distal to the hymen would be + 3 cm. All points are measured on maximal straining (except total vaginal length).

**(iii) Anterior Vaginal Wall.**

(a) **Point Aa.** A point located in the midline of the anterior vaginal wall three (3) cm proximal to the external urethral meatus. By definition, the range of position of Point Aa relative to the hymen is -3 to + 3 cm.

(b) **Point Ba.** A point that represents the most distal (i.e., most dependent) position of any part of the upper anterior vaginal wall from the vaginal cuff or anterior vaginal fornix to Point Aa. By definition, Point Ba is at -3 cm in the absence of prolapse and would have a positive value equal to the position of the cuff (Point C) in women with total uterine prolapse or post-hysterectomy vaginal eversion.

(iv) **Superior Vagina.** These points represent the most proximal locations of the normally positioned lower reproductive tract. The two superior sites are as follows:

(c) **Point C.** A point that represents either the most distal (i.e. most dependent) edge of the cervix or the leading edge of the vaginal cuff (hysterectomy scar) after total hysterectomy.

(d) **Point D.** A point that represents the location of the posterior fornix in a woman who still has a cervix. It is included as a point of measurement to differentiate suspensory failure of the uterosacral-cardinal ligament “complex” from cervical elongation. When the location of Point C is significantly more positive than the location of Point D, this is indicative of cervical elongation which may be symmetrical or eccentric. Point D is omitted in the absence of the cervix.

**(v) Posterior Vaginal Wall.**

(e) **Point Ap.** A point located in the midline of the posterior vaginal wall three (3) cm proximal to the hymen. By definition, the range of position of Point Ap relative to the hymen is -3 to +3 cm.

(f) **Point Bp.** A point that represents the most distal (i.e., most dependent) position of any part of the upper posterior vaginal wall from the vaginal cuff or posterior vaginal fornix to Point Ap. By definition, Point Bp is at -3 cm in the absence of prolapse and would have a positive value equal to the position of the cuff in a women with total post-hysterectomy vaginal eversion.

**(vii) Other Landmarks and Measurements.**

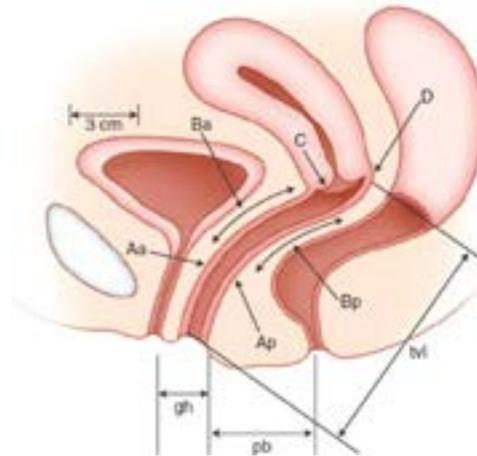

(g) The **genital hiatus (GH)** is measured from the middle of the external urethral meatus to the posterior margin of the hymen.

(h) The **total vaginal length (TVL)** is the length of the vagina (cm) from posterior fornix to hymen when Point C or D is reduced to its full normal position. (See Figure 40 - Appendix).

(i) The **perineal body (PB)** is measured from the posterior margin of the hymen to the mid-anal opening.

**(viii) Recording Measurements:** (NB: Intraoperative measurements with traction can be quite different from measurements made during Valsalva in clinic, both in regards to cervical location and the vaginal walls). Measurements directly after removing a vaginal pessary are unreliable and will tend to understage the degree of POP.

The position of Points Aa, Ba, Ap, Bp, C, and (if applicable) D with reference to the hymen should be measured (cm) and recorded.

**Figure 7.** The six sites (Aa, Ba, C, D, Bp and Bp), the genital hiatus (gh), perineal body (pb) and total vaginal length (tv) used cm above or proximal to the hymen (negative number) or cm below or distal to the hymen (positive number) with the plane of the hymen being defined as zero (0). Alternatively, a three by three grid can be used to organize concisely the measurements as noted in Figure 8.

Anterior wall	Anterior wall	Cervix or Cuff
Aa	Ba	C
Genital hiatus	Perineal Body	Total Vaginal Length
gH	pB	TVL
Posterior wall	Posterior wall	Posterior Fornix
Ap	Bp	D

Figure 8. Grid presentation of POP-Q measurements.

#### B: Simplified POP-Q<sup>25,26</sup>

This is based on the POP-Q with similar ordinal staging but with only four points measured instead of nine. There is no Stage 0; it is combined with Stage 1. It is undertaken in the dorsal lithotomy position with patient forcefully bearing down, performing Valsalva or coughing.

**(i) Four points used:**

- . Anterior vaginal segment: point Ba (estimated around 3cm proximal to hymenal remnants).
- . Posterior vaginal segment: point Bp (estimated around 3cm proximal to hymenal remnants).
- . Cervix point C
- . Apex/posterior fornix: point D (non-hysterectomized); point C (hysterectomized)

Figure 9. Simplified POP-Q.

**(ii) Staging:**

I, II, III, IV as for POP-Q above.

#### C: Additional available measurements awaiting further validation

These have been included as an Appendix after the References

**(i): Vaginal Anatomical Levels and Lengths.**

**(ii): Perineal measurements.**

**(iii): Vaginal measurements.**

SECTION 4: INVESTIGATIONS

**Urodynamics<sup>1</sup>:** Functional study of the lower urinary tract.

**Clinical sequence of testing<sup>1</sup>:** Urodynamic investigations generally involve a woman attending with a comfortably full bladder for free (no catheter) uroflowmetry and post void residual urine volume (PVR) measurement prior to filling and voiding (with catheter) cystometry.

**A: Assessment of Impact of Prolapse on Voiding Function**

POP can have a negative impact on voiding function, screening for which importantly involves a postvoid residual and ideally uroflowmetry. Voiding cystometry may clarify the cause of any voiding dysfunction.

**(i) Postvoid Residual<sup>1-3</sup>:** Volume of urine left in the bladder at the completion of micturition. **Conditions for PVR measurement:** PVR reading is erroneously elevated by delayed measurement due to additional urine production (1-14 ml/min). Ultrasonic techniques (transvaginal, translabial most accurately) allow immediate<sup>27</sup> (within 60 seconds of micturition) measurement and possible repeat measurement (Figure 10). A short plastic female catheter provides the most effective bladder drainage for PVR measurement by catheterization.

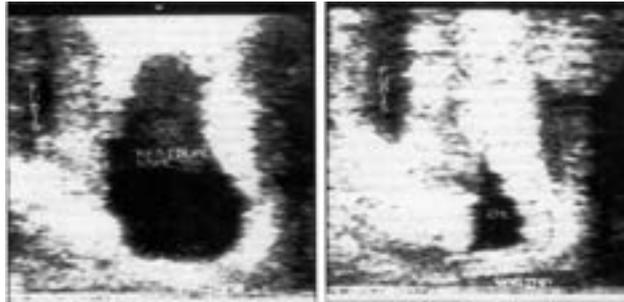

Figure 10. An image of postvoid residual of 65ml by transvaginal ultrasound, reducing to 4ml with a subsequent attempt at voiding.

**(ii) Uroflowmetry<sup>1-3</sup>:** Measurement of urine flow rates during micturition<sup>16</sup>

- . **Flow rate:** Volume of urine expelled via the urethra per unit time. It is expressed in ml/sec.
- . **Voided volume (ml):** Total volume of urine expelled via the urethra.
- . **Maximum (urine) flow rate (MUFR - ml/sec) - Q<sub>max</sub>:** Maximum measured value of the flow rate.
- . **Flow time (sec):** The time over which measurable flow actually occurs.
- . **Average (urine) flow rate (AUFR - ml/sec) - Q<sub>ave</sub>:** Voided volume divided by the flow time.

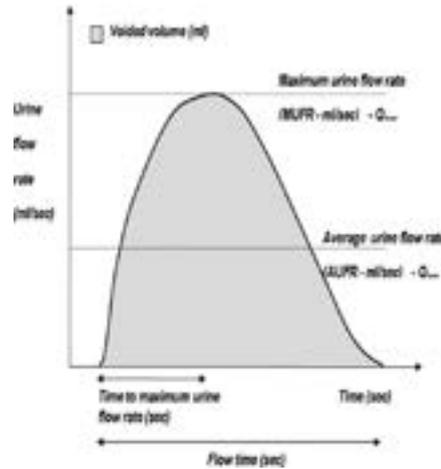

Figure 11. A schematic representation of urine flow over time.

The dependence of urine flow rates on voided volume<sup>23</sup> makes it desirable to reference raw urine flow rate data to established normative data.

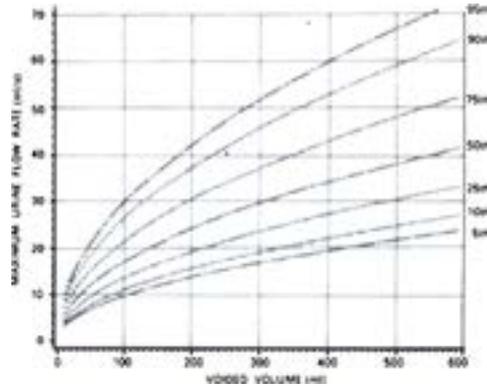

Figure 12. The Liverpool nomogram<sup>29</sup> for the maximum urine flow rate in women (under the 10<sup>th</sup> centile on repeat measurement can be regarded as abnormally slow<sup>30</sup>).

(iii) Pressure-Flow studies<sup>1-3;31</sup>

**Cystometry:** Measurement of the pressure/volume relationship of the bladder during filling and/or pressure flow study during voiding. Higher voiding detrusor pressures and slower urine flow during voiding may point an element of bladder outflow obstruction<sup>1-3,32</sup>, though other patterns of pressure-flow data are possible.

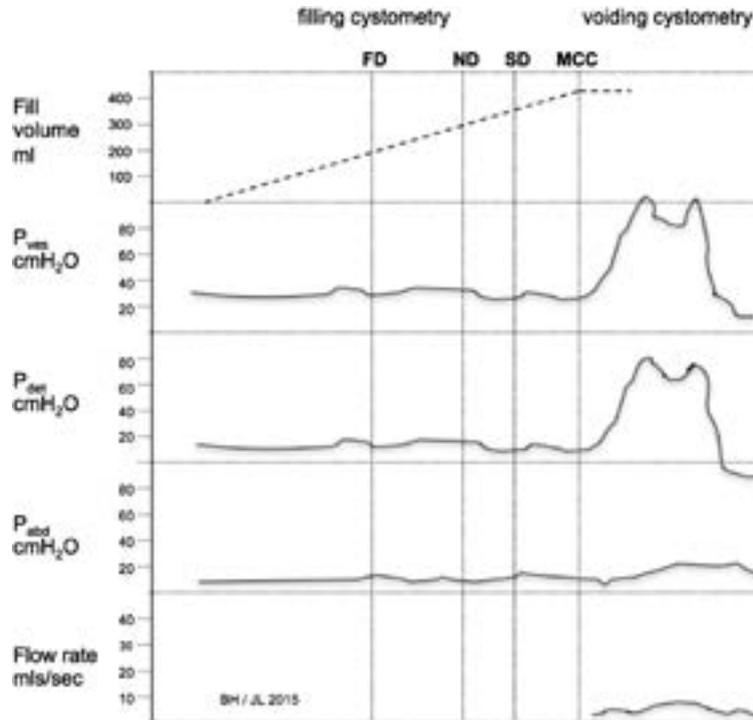

Figure 13. Filling and voiding cystometric trace, the latter part showing evidence of an element of bladder outflow obstruction. Normal bladder capacity, stable detrusor: no phasic activity seen. Voided with low urine flow rate and elevated detrusor pressure. Bladder outflow obstruction is thus demonstrated.

Neurology and Urodynamics DOI 10.1002/nau

**B: Assessment of Impact on Prolapse on Defecatory Function**

- (i) **Ultrasound Assessment:** See imaging section.
- (ii) **Radiological Assessment:** See imaging section.

**C: Other urodynamic investigations for intercurrent diagnoses<sup>1-3,31</sup>**

(i) **Filling cystometry:** The pressure/volume relationship of the bladder during filling can evaluate the presence of intercurrent diagnoses (ii-iv).

(ii) **Urodynamic stress incontinence<sup>1</sup>:**

Involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

(iii) **Detrusor Overactivity<sup>1</sup>:**

The occurrence of involuntary detrusor contractions during filling cystometry. These contractions, which may be spontaneous or provoked, produce a wave form on the cystometrogram, of variable duration and amplitude (Figure 14).

(iv) **Bladder Oversensitivity<sup>1</sup>:**

Increased perceived bladder sensation during bladder filling with: an early first desire to void; an early strong desire to void, which occurs at a low bladder volume; a low maximum cystometric bladder capacity. No abnormal increases in detrusor pressure are noted.

(v) **Detrusor underactivity<sup>1</sup>FN5 and Acontractile detrusor<sup>1</sup>FN6**

Can also be diagnosed at voiding cystometry.

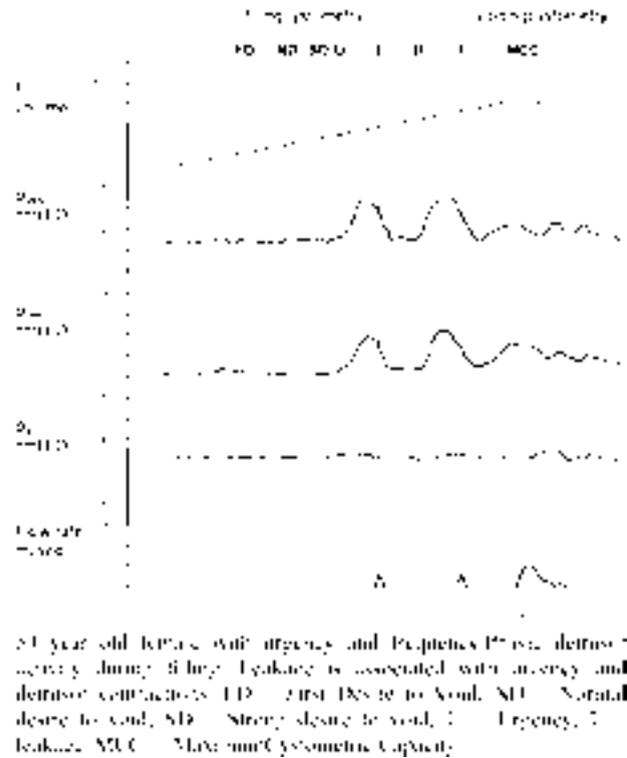

Figure 14. Cystometric trace showing detrusor overactivity<sup>1</sup>.

<sup>5</sup>: *Detrusor underactivity*: Detrusor contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span.  
<sup>6</sup>: *Acontractile detrusor*: The detrusor cannot be observed to contract during urodynamic studies resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span. The term “areflexia” has been used where there is a neurological cause but should be replaced by *neurogenic acontractile detrusor*.

## SECTION 5: PROLAPSE IMAGING

**Imaging may assist the clinical assessment of POP or intercurrent pelvic floor diagnoses. Use of any of the different imaging modalities is, however, entirely optional.**

**A: Prolapse-related ultrasound imaging – 2-D****(i) Modalities**

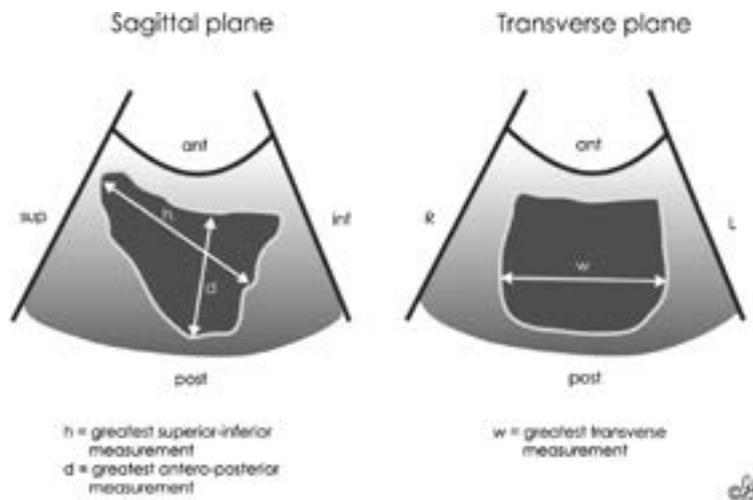

Transabdominal, perineal, introital and transvaginal ultrasound<sup>1</sup>.

- Transabdominal (T-A): curvilinear scanning applied to the abdomen.
- Perineal: curved array probe applied to the perineum. This term incorporates transperineal and translabial ultrasound.
- Introital: sector probe applied to the vaginal introitus.
- Transvaginal (T-V): intravaginal curvilinear, linear array, or sector scanning.

**(ii) Clinical applications:**

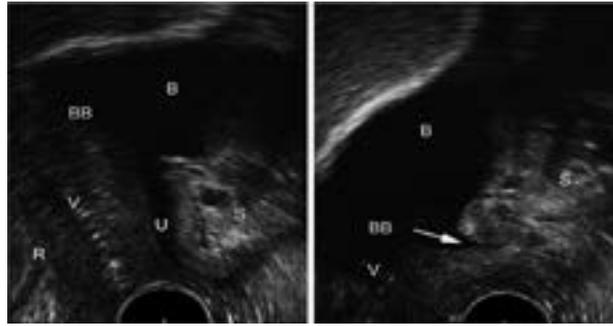

- Bladder neck descent/mobility. The position of the bladder neck at rest and on Valsalva.
- Urethral funnelling: i.e., opening of the proximal third of the urethra during coughing or on Valsalva.
- Post void residual: Several formulas have been described in the literature to measure the bladder volume by ultrasound<sup>33-35</sup>. An early formula  $[(h \times d \times w) \times 0.7]$  has been demonstrated to give reproducible results with a percentage error of 21%<sup>33</sup> (see Figure 15 for definitions of h,d,w).
- Bladder abnormalities: e.g., tumor, foreign body.
- Urethral abnormality: e.g., diverticulum.
- Intercurrent uterine and/or pelvic abnormality: dependent on probe range.
- Postoperative findings: e.g., bladder neck position and mobility, position of meshes, tapes, or implants.
- Descent of pelvic organs: visualization of descent of the bladder, uterine cervix, and rectum during coughing or on Valsalva.
- Assessment of voluntary pelvic floor muscle contractility.
- Pelvic floor/levator ani muscle defect (“avulsion”) and hiatal ballooning<sup>36</sup>.
- Ultrasound measurements of bladder and detrusor wall thickness, and ultrasound estimated bladder weight (UEBW) are potential noninvasive clinical tools for assessing the lower urinary tract. UEBW is higher in women with overactive bladder and detrusor overactivity<sup>37,38</sup>. FN7.

Figures 16 and 17 show examples of 2-D introital ultrasound in patients with POP symptoms.

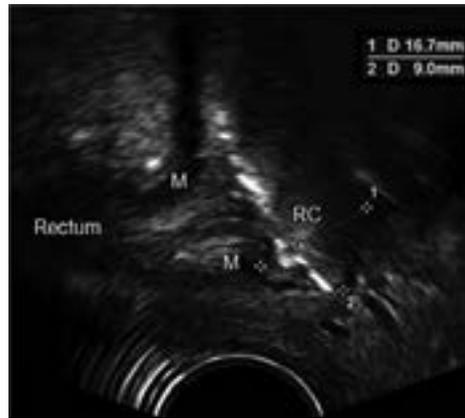

**Figure 15.** Ultrasound measurement of the bladder volume from Poston GJ et al. 1983<sup>33</sup>(redrawn).

<sup>7</sup>: Women with detrusor overactivity have a median UEBW of 48.0 g (95% CI 46-51), with urodynamic stress incontinence a median UEBW of 30 g (95% CI 29-31) and those who have associated detrusor overactivity and urodynamic stress incontinence have a median UEBW of 37.3 g (95% CI 33-41) ( $p < 0.001$ )<sup>37,38</sup>.

**Figure 16. (above):** 56 year old female with stage II cystocele and urodynamic stress incontinence. Left: at rest. Right: during Valsalva. B = Bladder, BB = bladder base, U = urethra, S = symphysis pubis, arrow = bladder neck during Valsalva, V = vagina, R = rectum. Arrow = bladder neck during Valsalva with bladder neck funnelling as a sign of urethral incompetence.

**Figure 17. (above):** 72 year old female with stage II rectocele. Measurement of rectocele (RC) width (1) and depth (2) during Valsalva. M = muscularis of rectum.

**B: Prolapse-related ultrasound imaging – 3-D**

**(i) Modalities: Endovaginal, transanal, and translabial/transperineal**

- Endovaginal ultrasound imaging may inadvertently compress tissues thus distorting the anatomy.
- Transanal ultrasound approach requires an expensive and dedicated transducer, and it is a more uncomfortable and embarrassing test for the woman. Its most common clinical indication is the assessment of sphincter integrity following obstetric trauma.
- Translabial/transperineal approach overcomes the limitations of endovaginal and transrectal techniques providing minimal pressure on local structures and it is least likely to alter surrounding anatomy.

**(ii) Evaluations:**

The following pelvic floor abnormalities/ surgical sequelae can be evaluated:

- (a) Trauma (injury/damage) of the levator ani muscle (LAM).
- (b) Excessive distensibility of the puborectalis muscle and levator hiatus (“ballooning”).
- (c) Pathologies of the anterior vaginal compartment like urethral diverticula.
- (d) Bladder tumours or foreign bodies (sling, mesh, bulking agents).
  - Polypropylene meshes: highly echogenic and thus easily identified in the coronal and axial plane, unless they are obscured by vaginal prolapse.
  - Periurethral bulking agents, used as a continence procedure, can also be depicted with 3D pelvic floor ultrasound. FN8

<sup>8</sup>: Synthetic implant such as macroplastique, are hyperechogenic whereas collagen injections are hypochoic and can be seen as spherical structures surrounding the bladder neck.

Figure 18 shows 3D ultrasound imaging of the pelvic floor anatomy.

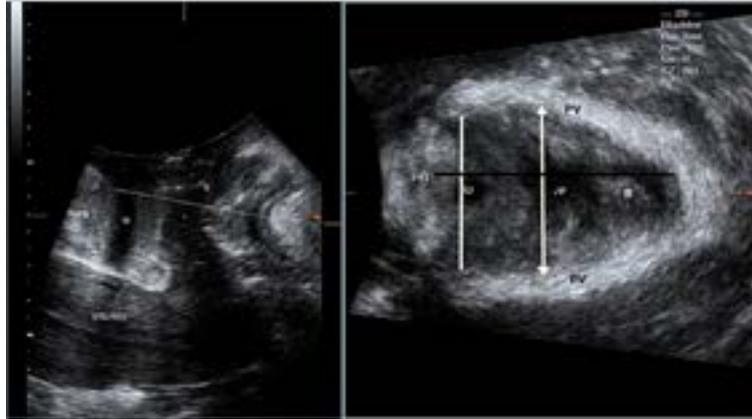

Figure 18. (above): 3D ultrasound image of levator ani muscle of an asymptomatic nulliparous woman at rest. 3D ultrasound image of the pelvic floor at rest showing the anatomy and the reference plane of measurements. Left: sagittal view; PB: pubic bone; U: urethra; V: vagina; ARA: anorectal angle; white line: plane of minimal hiatal dimensions (plane of all measurements). Right: axial view; PB: pubic bone; U: urethra; V: vagina; R: rectum; PV: pubovisceralis muscle; black line: antero-posterior diameter of the levator hiatus; white line: transverse diameter of the levator hiatus at the level of pubourethralis, white double-headed arrowed line: transverse diameter of the levator hiatus at the level of pubovaginalis.

#### (iii) 3D ultrasound imaging of the female urethra

3D ultrasound imaging of the rhabdosphincter overcomes the limits of MRI and two-dimensional (2D) ultrasound imaging that incorrectly measure the urethral sphincter volume using mathematical formulas based upon assumptions that the shape of the urethra is similar to that of an ellipse. Since the urethral shape is neither elliptical nor spherical, but rather an atypical geometric shape, equations should not be used<sup>39</sup>. FN9. Figure 19 shows 3D ultrasound imaging of the urethral sphincter

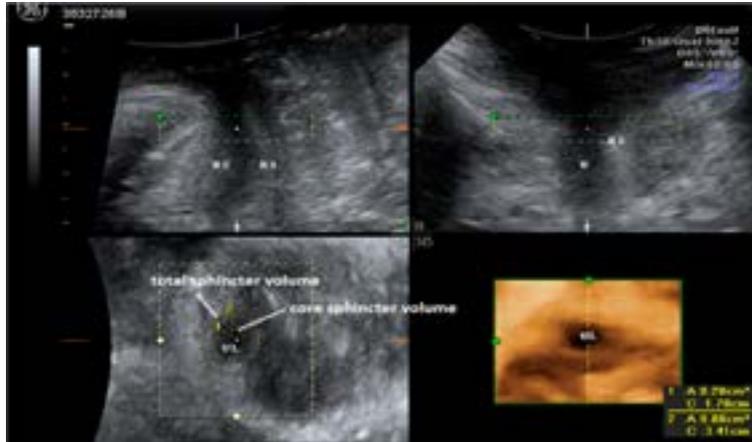

Figure 19. (above): 3D translabial image of the female urethra. The urethra lumen is shown clearly in the rendered volume image (bottom right). (U, urethra; UL, urethra lumen; RS, rhabdosphincter).

#### (iv) 3D ultrasound imaging of the levator ani trauma

The presence of levator ani trauma has been postulated to be associated to an increased risk of pelvic organ prolapse<sup>40</sup>. This can be evaluated using a tomographic ultrasound imaging assessment of the levator ani muscles (Figure 20).

<sup>9</sup>: The importance of precise structural assessment of the urethral sphincter using multiple axial cross-sectional areas at set distances can assist the evaluation of women with stress urinary incontinence. It has been suggested that it may predict the severity of incontinence as well as the outcome of continence surgery since a weak sphincter will have a lower volume compared to a competent/continent urethral sphincter<sup>39</sup>.

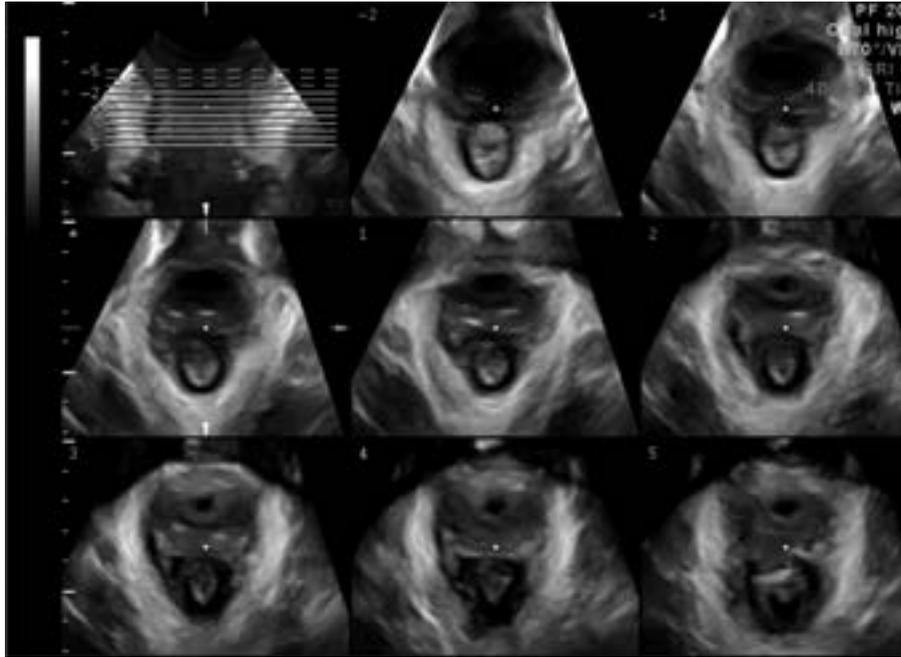

Figure 20. (above): Tomographic ultrasound imaging assessment of the levator ani muscles Intact LAM.

**(v) 3D ultrasound imaging of ballooning of the genital hiatus**

The presence of ballooning of the genital hiatus (= excessive distensibility of the levator hiatus) on Valsalva manoeuvre has also been associated to the severity of urogenital prolapse. An area of more than 25 cm<sup>2</sup>, 30 cm<sup>2</sup>, 35 cm<sup>2</sup> and 40 cm<sup>2</sup> has been defined as mild, moderate, marked and severe ballooning respectively (Figure 21)<sup>41</sup>.

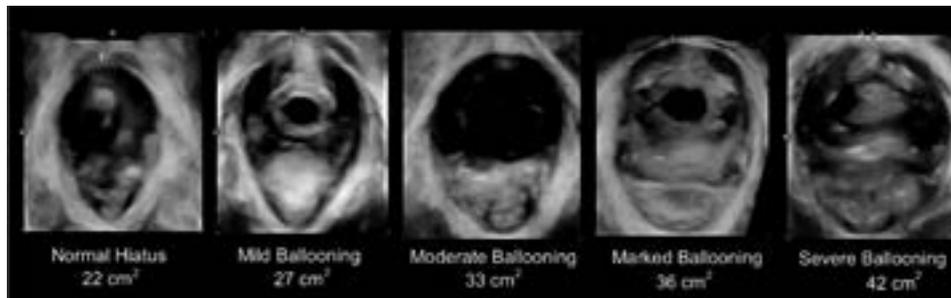

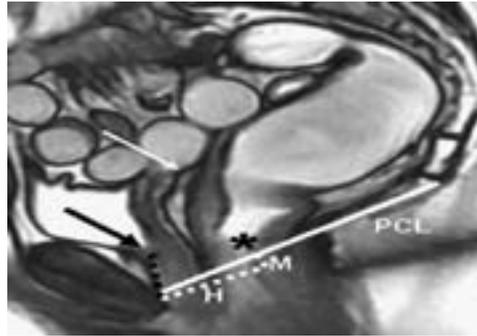

Figure 21. (above): Ballooning of the genital hiatus on Valsalva manoeuvre – levator defect.

**C: Magnetic resonance imaging (MRI) of the pelvic floor**

Magnetic resonance imaging (MRI) allows the detection of ligamentous and muscular pelvic floor structures in fine detail. Although it does not use ionising radiation, it is a high cost technique. Static MRI relies on static sequences and high spatial resolution images, to delineate the passive and active elements of the pelvic organ support system. Most commonly, images are acquired in axial, sagittal and coronal planes.

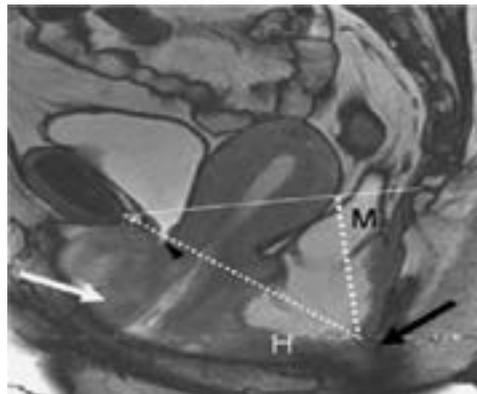

MRI has been proposed to be a useful method for diagnosing and staging POP. Several lines and levels of reference have been described in the literature. The most commonly used ones are either a line drawn from the inferior margin of the pubis symphysis to the last coccygeal joint (pubococcygeal line—PCL) or a line extending caudally along the longitudinal axis of the symphysis pubis in the sagittal plane, noted as midpubic line (MPL)<sup>42,43</sup> (Figures 22 and 23).

*Neurourology and Urodynamics* DOI 10.1002/nau

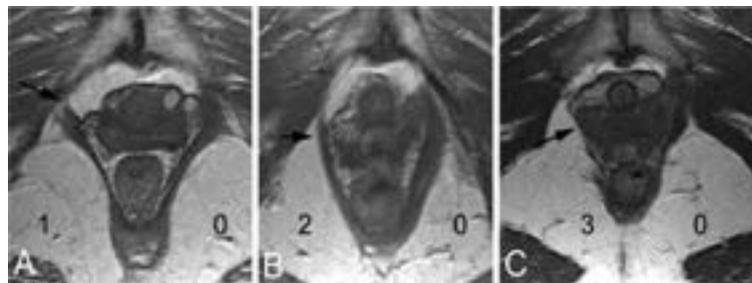

**Figure 22. (above):** Sagittal MRI image of the pelvic floor obtained at rest in a 50-year-old normal volunteer woman. The H line is drawn from the inferior border of the pubic symphysis to the posterior wall of the rectum at the level of the anorectal junction.

The M line is drawn perpendicularly from the PCL to the most posterior aspect of the H line. (PCL: pubococcygeal line, black arrow: bladder base, white arrow: vaginal vault, \*: anorectal junction, from Colaiacomo MC<sup>42</sup> et al. 2009).

**Figure 23. (above):** Severe uterine prolapse in a 41-year-old woman. Sagittal function MRI image obtained during defaecation shows the uterus moving downward inside the vagina and the cervix exits the vaginal introitus (white arrow). H and M lines are abnormally elongated. Urethral funnelling without hypermobility (arrowhead) and severe posterior compartment descent (black arrow) are also noted (from Colaiacomo<sup>42</sup> et al. 2009).

Other applications of MRI are the assessment of the LAM morphology (size, thickness volume) and detection of LAM injuries/defects/ (“avulsion”) (figure 24)<sup>44–46</sup>.

**Figure 24. (above):** Examples of grades of unilateral defects in the pubovisceral portion of the LAM in axial magnetic resonance images at the level of the mid urethra. The score for each side is indicated on the figure, and the black arrows indicate the location of the missing muscle (A. grade 1 defect; B. grade 2 defect; and C. grade 3 defect, from DeLancey, Levator Ani Impairment in Prolapse. *Obstet Gynecol* 2007).

**Introduction:** In the development of terminology of the lower urinary tract, due to its increasing complexity, the terminology for male lower urinary tract and pelvic floor symptoms and dysfunction needs to be updated using a male-specific approach and via a clinically-based consensus report.

**Methods:** This report combines the input of members of the Standardisation Committee of the International Continence Society (ICS) in a Working Group with recognized experts in the field, assisted by many external referees. Appropriate core clinical categories and a subclassification were developed to give a numeric coding to each definition. An extensive process of 22 rounds of internal and external review was developed to exhaustively examine each definition, with decision-making by collective opinion (consensus).

**Results:** A Terminology Report for male lower urinary tract and pelvic floor symptoms and dysfunction, encompassing around 390 separate definitions/descriptors, has been developed. It is clinically-based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in all the different specialty groups involved in male lower urinary tract and pelvic floor dysfunction. Male-specific imaging (ultrasound, radiology, CT, and MRI) has been a major addition whilst appropriate figures have been included to supplement and help clarify the text.

**Conclusions:** A consensus-based Terminology Report for male lower urinary tract and pelvic floor symptoms and dysfunction has been produced aimed at being a significant aid to clinical practice and a stimulus for research.

Carlos D'Ancona (Content) and Bernard Haylen (Production) are equal first authors.

**KEYWORDS**

lower urinary tract dysfunction, lower urinary tract symptoms, male, male urinary tract imaging, male urodynamics, terminology

**INTRODUCTION**

There is currently no single document addressing all elements required for diagnoses applicable to adult (fully grown and physically mature<sup>1</sup> – *new*) male lower urinary tract and pelvic floor dysfunction. Indeed, the diagnostic entities themselves may have not been all completely defined. The term “diagnosis” is defined as “the determination of the nature of a disease; **clinical:** made from a study of the symptoms and signs of a disease<sup>1</sup>; **laboratory:**” investigative options to be mentioned. Such a specific report would require a full outline of the terminology for all symptoms, signs, urodynamic investigations for male lower urinary tract (LUT) and pelvic floor (PF) dysfunction, the imaging associated with those investigations and the most common diagnoses.

It may have been possible in the past to combine all terminology for lower urinary tract function for men, women and children into one Report. The International Continence Society (ICS) has provided leadership in terminology for lower urinary tract dysfunction over decades employing combined or generic reports. The 1988<sup>2</sup> and 2002<sup>3</sup> Reports by the Committee on Standardization of Terminology are such examples. With the increasing specificity and complexity of the diagnoses in both sexes, combined reports, let alone attempting to cover “all patient groups from children to the elderly,”<sup>3</sup> may now be an anachronism. With evidence that the absence of specific female diagnoses as well as other female specific terminology, may not have been advantaged by a combined approach,<sup>4</sup> there occurred the development and 2010 publication of an International Urogynecological Association (IUGA)/ICS Joint Report on the Terminology for Female Pelvic Floor Dysfunction.<sup>5</sup> The 2002 Report<sup>3</sup> still provides the traditional core male terminology and some useful modifications, many of which are repeated in this document. The current report, with the large number of *new* and *changed* definitions, acknowledges that a male-specific update of terminology for LUT and PF symptoms and dysfunction is now timely.

It is hoped that some of the advantages noted in the female-specific document<sup>5</sup> might be seen here in this male document: (i) more comprehensive coverage of male-specific terminology; (ii) greater coherency and user-friendliness; (iii) greater specificity of male diagnoses; and (iv) more accurate communication for clinical and research purposes. It is also an aim in this document, to develop a general male terminology,

forming a “backbone” or “core” terminology, to facilitate an update of the other subcategories of male-specific terminologies. There have been seven other (IUGA-ICS) female PF-related terminology documents,<sup>6–12</sup> all published, following the production of the initial joint IUGA/ICS document on female pelvic floor dysfunction.<sup>5</sup> The authors of that document<sup>5</sup> have kindly permitted the template of that Report to be used as the basis for the current Report. Four other male terminology reports have been initiated: (i) male anorectal dysfunction; (ii) surgical management of male LUT dysfunction; (iii) sexual health in men with LUT/PF dysfunction and (iv) conservative management of male LUT/PF dysfunction, to follow the publication of this “core” report.

This Terminology Report is inherently and appropriately a definitional document, collating the definitions of those terms, that is, words used to express a defined concept in a particular branch of study,<sup>1</sup> here core male terminology. Emphasis has been on comprehensively including those terms in current use in the relevant peer-reviewed literature. The aim is to assist clinical practice and research. Explanatory notes on definitions have been referred, where possible, to the “Footnotes section.” Table 1 lists the number of definitions: (i) new; (ii) changed; (iii) total by section, compared with the previous male-inclusive Reports.<sup>2,3</sup>

As with its female terminology equivalent, qualities for a male-specific terminology report should be:

- (1) User-friendly: It should be able to be understood by all clinical and research users.
- (2) Clinically-based: Symptoms, signs, validated investigations and imaging should be presented for use in forming diagnoses. Sections 1-4 will address symptoms, signs, urodynamic investigations and current associated imaging modalities routinely used in the office, urodynamic laboratory, or imaging department to make those diagnoses. Readership is not assumed to be limited to medical specialists, accounting for a more extended “basic” physical examination (Section 2). Related radiological investigations, computerized tomography (CT) and magnetic resonance imaging (MRI) as well as a description of electromyography (EMG) has been included. This report limits terminology for neurogenic lower urinary tract dysfunction (LUTD) as this is covered by a separate ICS Report.<sup>13</sup>

**TABLE 1** Total, new and changed definitions (compared with previous male-inclusive Reports<sup>2,3</sup>)

Section	New definitions/descriptors	Changed definitions/descriptors	Total
Introduction & Symptoms	60	23	118
Signs	73	14	98
Investigations	23	25	106
Imaging	42	n/a	42
Diagnoses	14	9	26
Total	211 (54%)	71 (18%)	390

- (3) Section 5 will address the most common diagnoses of male lower urinary tract and pelvic floor dysfunction. The terms<sup>3</sup> “urodynamic observation” and “condition” (non-medical) have not been used in this report. The scope of the report will exclude (i) diagnostic pathology (blood, urine, histology); (ii) more invasive investigations requiring an anesthetic; (iii) evidence-based treatments for each diagnosis.
- (4) Origin: Where a term's existing definition (from one of multiple sources used) is deemed appropriate, that definition will be included and duly referenced. Many terms in male lower urinary tract and pelvic floor function, because of their long-term use, have now become generic, as apparent by their listing in medical dictionaries.
- (5) Able to provide explanations: Where a specific explanation is deemed appropriate to explain a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (*Footnote [FN] 1,2,3 ...*). Wherever possible, evidence-based medical principles will be followed.

As in earlier ICS Reports,<sup>2,3,5</sup> when a reference is made to the whole anatomical organ, the *vesica urinaria*, the correct term is the bladder. When the smooth muscle structure known as the *m. detrusor vesicae* is being discussed, then the correct term is detrusor.

It is suggested that acknowledgement of these standards in written publications related to male lower urinary tract and pelvic floor symptoms and dysfunction, be indicated by a footnote to the section “Methods and Materials” or its equivalent, to read as follows: “Methods, definitions and units conform to the standards recommended by the International Continence Society, except where specifically noted.”

## SECTION 1: SYMPTOMS

**Symptom:** Any morbid phenomenon or departure from the normal in structure, function, or sensation, possibly indicative of a disease or health problem. Symptoms are either

volunteered by, or elicited from the individual, or may be described by the individual's partner or caregiver<sup>2,3,5</sup>

**Complaint:** The description of the symptom.<sup>1</sup> (*NEW*)

**Main (Chief) Complaint:** The symptom that a patient states as the main reason for seeking medical advice.<sup>1</sup> (*NEW*) The degree of “bother (worry, concern)” for other symptoms can be variable.<sup>14</sup> (*NEW*)

**Lower urinary tract symptom (LUTS):** A symptom related to the lower urinary tract; it may originate from the bladder, prostate, urethra, and/or adjacent pelvic floor or pelvic organs, or at times be referred from similarly innervated anatomy, for example, lower ureter. (*NEW*)

### STORAGE SYMPTOMS

**1.1 Storage Symptoms:** Lower urinary tract symptoms occurring during the bladder storage phase. (*NEW*)

#### *General Storage symptoms*

**1.1.1 Increased urinary frequency:** Complaint that voiding occurs more frequently than deemed normal by the individual (or caregivers).<sup>3,5</sup> Time of day and number of voids are not specified. (*NEW*)

**1.1.2 Increased daytime urinary frequency:** Complaint that voiding occurs more frequently during waking hours than previously deemed normal by the individual (or caregivers).<sup>3,5</sup> <sub>FN1.1</sub> NB pollakiuria <sub>FN1.2</sub> (*CHANGED*)

**1.1.3 Nocturia:** The number of times urine is passed during the main sleep period. Having woken to pass urine for the first time, each urination must be followed by sleep or the intention to sleep. This should be quantified using a bladder diary.<sup>18</sup>

**1.1.4 Polyuria (global symptom):** Complaint that the urine excretion volume over 24 h is noticeably larger than the previous experience.<sub>FN1.4</sub> (*NEW*)

**1.1.4.1 Diurnal polyuria:** Complaint that daytime urine excretion volume is noticeably larger than the previous experience. (*NEW*)

**1.1.4.1 Nocturnal polyuria (symptom)<sup>18</sup>:** Complaint of passing large volumes of urine at night-time. (*NEW*)

### *Sensory symptoms*

**1.1.5 Bladder filling (sensory) symptoms:** Abnormal sensations experienced during bladder filling.<sup>1</sup> *(NEW)*

**1.1.5.1 Increased bladder filling sensation:** Complaint that the sensation of bladder filling occurs earlier or is more intense or persistent to that previously experienced.<sup>3,5</sup> *(CHANGED)* N.B. This differs from urgency by the fact that micturition can be postponed despite the desire to void.

**1.1.5.2 Urgency:** Complaint of a sudden, compelling desire to pass urine which is difficult to defer.<sup>3,5</sup> FN1.5, FN1.6

**1.1.5.3 Reduced bladder filling sensation:** Complaint that the sensation of bladder filling is less intense or occurs later in filling than previously experienced. *(CHANGED)*

**1.1.5.4 Absent bladder filling sensation:** Complaint of both the absence of the sensation of bladder fullness and a definite desire to void<sup>3</sup>

**1.1.5.5 Non-specific (atypical) bladder filling sensation (bladder dysesthesia):** Complaint of abnormal bladder filling sensation such as the perception of vague abdominal bloating, vegetative symptoms (nausea, vomiting, faintness), or spasticity. *(CHANGED)* FN1.7 It differs from normal bladder filling sensation or pain, pressure or discomfort of the bladder.

### *Incontinence symptoms*

**1.1.6 Urinary incontinence symptoms<sup>16</sup>:** Involuntary loss of urine experienced during the bladder storage phase FN1.8, FN1.9 *(NEW)*

**1.1.6.1 Urinary incontinence (symptom):** Complaint of involuntary loss of urine.<sup>3,5</sup> FN 1.9

**1.1.6.2 Urgency urinary incontinence (UUI)<sup>3,5</sup>:** Complaint of involuntary loss of urine associated with urgency.

**1.1.6.3 Stress urinary incontinence (SUI):** Complaint of involuntary loss of urine on effort or physical exertion including sporting activities, or on sneezing or coughing.<sup>3,5</sup> N.B. “*activity (effort)-related incontinence*” might be preferred in some languages to avoid confusion with psychological stress. FN1.10

**1.1.6.4 Mixed urinary incontinence (MUI):** Complaints of both stress and urgency urinary incontinence, that is, involuntary

loss of urine associated with urgency as well as with effort or physical exertion including sporting activities or on sneezing or coughing (stress).<sup>3,5</sup>

**1.1.6.5 Enuresis:** Complaint of intermittent (non-continuous) incontinence that occurs during periods of sleep.<sup>18</sup> *(CHANGED)*

**1.1.6.6 Continuous urinary incontinence:** Complaint of continuous involuntary loss of urine.<sup>3,5</sup> *(CHANGED)*

**1.1.6.7 Insensible urinary incontinence:** Complaint of urinary incontinence where the individual is aware of urine leakage but unaware of how or when it occurred.<sup>5</sup> *(CHANGED)*

**1.1.6.8 Postural urinary incontinence:** Complaint of urinary incontinence during change of posture or position, for example, from supine or seated to standing.FN1.12 *(NEW)*

**1.1.6.9 Disability associated incontinence:** Complaint of urinary incontinence in the presence of a functional inability to reach a toilet/urinal in time because of a physical (eg, orthopedic, neurological) and/or mental impairment. *(NEW)*

**1.1.6.10 Overflow incontinence:** Complaint of urinary incontinence in the symptomatic presence of an excessively (over-) full bladder (no cause identified). *(NEW)*

**1.1.6.11 Sexual arousal incontinence<sup>19</sup>:** Complaint of involuntary loss of urine during sexual arousal, foreplay and/or masturbation. *(NEW)*

**1.1.6.12 Climacturia<sup>19</sup>:** Complaint of involuntary loss of urine at the time of orgasm. *(NEW)*

### *Storage symptom syndrome*

**1.1.7 Overactive bladder (OAB, urgency) syndrome:** Urinary urgency, usually accompanied by increased daytime frequency and/or nocturia, with urinary incontinence (OAB-wet) or without (OAB-dry), in the absence of urinary tract infection or other detectable disease.<sup>3,5</sup> *(CHANGED)*

## VOIDING SYMPTOMS

**1.2 Voiding symptoms:** Lower urinary tract symptoms during the voiding phase (experienced during micturition). *(NEW)*

**1.2.1 Hesitancy:** Complaint of a delay in initiating voiding (when the individual is ready to pass urine). *(CHANGED)*

- 1.2.2. Paruresis (“bashful” or “shy bladder”):** Complaint of the inability to initiate voiding in public (i.e. voiding in the presence of other persons) despite there being no difficulty in private.<sup>20</sup>  
FN1.13 (NEW)
- 1.2.3 Episodic inability to void:** Complaint of occasional inability to initiate voiding despite relaxation and/or an intensive effort (by abdominal straining, Valsalva maneuver or suprapubic pressure). (NEW)
- 1.2.4 Straining to void:** Complaint of the need to make an intensive effort to either initiate, maintain or improve voiding or the urinary stream.<sup>3,5</sup> (CHANGED)
- 1.2.5 Slow (urinary) stream:** Complaint of a urinary stream perceived as overall slower than previous performance or in comparison with others.<sup>3,5</sup>
- 1.2.6 Intermittency:** Complaint of urine flow that stops and starts on one or more occasions during one voiding episode.<sup>3,5</sup>
- 1.2.7 Terminal dribbling:** Complaint that during the final part of voiding there is noticeable slowing of the flow to drops or a trickling stream. (CHANGED)
- 1.2.8 Spraying (splitting) of urinary stream:** Complaint that the urine passage is a spray or split rather than a single directional stream.<sup>3,5</sup> (CHANGED)
- 1.2.9 Position-dependent voiding:** Complaint of having to adopt specific positions to be able to void spontaneously or to improve bladder emptying, for example, needing to void in a seated position. (NEW)
- 1.2.10 Dysuria:** Complaint of pain, burning, other discomfort, or difficulty during voiding. Discomfort may be intrinsic to the lower urinary tract (eg, bladder or urethra), external, or referred from other adjacent similarly innervated structures, for example, lower ureter. FN1.14 (CHANGED)
- 1.2.11 Stranguria:** Complaint of voiding which is slow, difficult and spasmodic (at times “drop by drop”), usually associated with pain. (NEW)<sup>FN1.15</sup>
- 1.2.12 Hematuria:** Complaint of passage of visible blood mixed with urine. This may be initial (at the beginning), terminal (at the end) or total (throughout bladder emptying). (NEW)
- 1.2.13 Pneumaturia<sup>1</sup>:** Complaint of the passage of gas (or air) from the urethra during or after voiding. (NEW)
- 1.2.14 Fecaluria<sup>1</sup>:** Complaint of passage of feces (per urethram) in the urine. (NEW)
- 1.2.15 Chyluria (albiduria)<sup>1</sup>:** Complaint of passage of chyle (pale or white, milky cloudy) in the urine.<sup>1</sup> (NEW)
- 1.2.16 Urinary retention:** Complaint of the inability to empty the bladder completely.<sup>1</sup> (NEW)
- 1.2.16.1 Acute urinary retention (AUR):** Complaint of a rapid onset, usually painful suprapubic sensation (from a full bladder) due to inability to void (non-episodic), despite persistent intensive effort.<sup>FN1.16</sup> (NEW)
- 1.2.16.2 Chronic urinary retention (CUR):** Complaint of chronic or repeated inability to empty the bladder, despite the ability to pass some urine. This may result in the frequent passage of small amounts of urine or urinary incontinence and a distended bladder FN1.17 (NEW)

## POST-VOIDING SYMPTOMS

**1.3 Postvoiding Symptom:** Lower urinary tract symptom experienced after voiding has ceased. (NEW)

**1.3.1 Feeling of incomplete (bladder) emptying:** Complaint that the bladder does not feel empty after voiding has ceased.<sup>3,5</sup> (CHANGED)

**1.3.2 Need to immediately re-void (“Encore” or “Double” voiding):** Complaint that further voiding is necessary soon after passing urine (cessation of flow).<sup>3,5</sup> (CHANGED)

**1.3.3 Post-voiding incontinence:** Complaint of a further involuntary passage (incontinence) of urine or dribbling following the completion of voiding.<sup>3,5</sup>  
FN1.18. (NEW)

**1.3.4 Post-micturition urgency:** Complaint of persistent urgency post-voiding. (NEW)

*Voiding symptom syndrome (proposal for further research)*  
– *Underactive bladder syndrome:* FN1.19

**1.4 Lower Urinary Tract Pain and/or Other Pelvic Pain**

**1.4.1 Pain:** A variably unpleasant sensation.<sup>1</sup> It may be described as pressure or discomfort by the patient. Pain should be characterized by site, type, frequency, duration, precipitating, and relieving factors.<sup>FN1.20; FN 1.21</sup> (CHANGED)

**1.4.2 Bladder pain:** Complaint of suprapubic or retropubic pain, pressure or discomfort related to the bladder, and usually associated with bladder filling. It may persist or be relieved after voiding.<sup>3,5</sup> (CHANGED)

**1.4.3 Urethral pain:** Complaint of pain, pressure or discomfort felt in the urethra<sup>3,5</sup> before, during and/or after voiding and the man indicates the urethra as the site. (CHANGED)

- 1.4.4 Scrotal pain:** Complaint of pain, pressure or discomfort felt in and around the scrotum.<sup>3</sup> It may be localized to the testis, epididymis, cord structures, or scrotal skin.
- 1.4.5 Perineal pain:** Complaint of pain, pressure, or discomfort felt on the surface or in the depth of the tissue between the scrotum and the anus.<sup>3</sup>
- 1.4.6 Pelvic pain:** Complaint of pain, pressure, or discomfort related to the pelvis but not clearly related to the bladder, urethra, scrotum, or perineum.<sup>3</sup>
- 1.4.7 Ejaculatory pain:** Complaint of pain, pressure, or discomfort felt in the perineum, suprapubic region and/or penis during ejaculation, but may continue for a time afterwards. *(NEW)*<sub>FN 1.22</sub>
- 1.4.8 Anorectal pain symptoms:** Complaint of pain, pressure or discomfort particularly during defecation or straining to defecate but can occur at any time. *(NEW)*
- 1.4.8.1 Pain during straining /defecation:** Pain during defecation or straining to defecate.
- 1.4.8.2 Inflammatory anorectal pain:** Pain characterized by burning or stinging (inflammation, radiation, sepsis). *(NEW)*
- 1.4.8.3 Non-inflammatory anorectal pain:** Blunted anorectal pain (proctalgia fugax, Levator ani syndrome, pudendal neuralgia). *(NEW)*
- 1.4.9 Coccygeal pain (coccydynia):** Complaint of pain, pressure, or discomfort in the coccygeal region. *(NEW)*
- 1.4.10 Pudendal pain (neuralgia):** Complaint of pain, pressure, or discomfort in one or more of the areas innervated by the pudendal nerve (may be caused by inflammation or entrapment of the pudendal nerve and involving its dermatome). *(CHANGED)*
- 1.4.11 Chronic pelvic pain syndromes:** See ICS standard for terminology in chronic pelvic pain syndromes.<sup>23</sup> <sub>FN1.21</sub>
- 1.5 Urinary tract infection (UTI)**
- 1.5.1 Symptoms of acute urinary tract infection:** Symptoms such as increased bladder sensation, urgency, frequency, dysuria/stranguria, pain in the lower urinary tract with or without urgency urinary incontinence might suggest lower urinary tract infection. Confirmation of a UTI requires evidence of significant microorganisms and pyuria. <sub>(FN1.23, FN 1.24)</sub> *(CHANGED)*
- 1.5.2 Recurrent urinary tract infections (UTIs):** A history of at least two symptomatic and medically diagnosed UTI in the previous 12 months.<sub>FN1.25</sub> The previous UTI(s) should have resolved prior to a further UTI being diagnosed. *(CHANGED)*
- 1.5.3 Urethral discharge:** Of mucus, pus, or blood, from the urethral meatus. *(NEW)*
- 1.6 Symptoms of sexual dysfunction:** Abnormal sensation and/or function experienced by a man during sexual activity. *(NEW)*
- 1.6.1 Altered Libido:** Change in interest in sexual activity. *(NEW)*
- 1.6.1.1 Decreased libido:** Complaint of decreased interest in sexual activity in comparison to previous experience. *(NEW)*
- 1.6.1.2 Increased libido:** Complaint of increased interest in sexual activity in comparison to previous experience. *(NEW)*
- 1.6.2 Erectile dysfunction<sup>25</sup>:** Complaint of inability to achieve and sustain an erection firm enough for satisfactory sexual performance. *(NEW)*
- 1.6.3 Ejaculatory dysfunction:** Complaint of alteration of the emission of seminal fluids during ejaculation. *(NEW)*
- 1.6.3.1 Anejaculation:** Complaint of absence of seminal fluid emission. May be associated with the absence of the sensation of orgasm or anorgasmia. *(NEW)*
- 1.6.3.2 Delayed ejaculation:** Complaint of an increase in the time taken for ejaculation to occur. *(NEW)*
- 1.6.3.3 Premature ejaculation:** Complaint of a persistent or recurrent pattern of too rapid achievement of ejaculation during partnered sexual activity,<sup>1</sup> that is, before the individual wishes it. <sub>FN 1.26</sub> *(NEW)*
- 1.6.3.4 Decreased (low) semen volume\*\*:** Complaint of smaller amount of seminal fluid than normal or previously experienced <sub>FN1.27.</sub> *(NEW)*
- 1.6.3.5 Increased (high) semen volume:** Complaint of higher amount of seminal fluid than normal or previously experienced. *(NEW)*<sub>FN1.27</sub>
- 1.6.4 Hematospermia:** Complaint of the appearance of visible blood in the seminal fluid. Color of the seminal fluid may be red or brown. *(NEW)*
- 1.6.5 Penile pain with intercourse (male dyspareunia):** Complaint of any penile discomfort occurring during intercourse. May be caused by penile disease, vaginal anatomy (eg, vaginal tightening, scarring, or exposed mesh) and/or may relate to various positions with intercourse. <sub>FN1.28</sub> *(NEW)*

**1.6.6 Obstructed intercourse:** Complaint that vaginal intercourse is not possible due to perceived obstruction. Whilst this may be a partner issue, it can occur in cases of penile curvature (Peyronie's disease) or penile carcinoma. *(NEW)*

## 1.7 Symptoms of anorectal dysfunction<sup>5,10,27</sup>: FN1.29

**1.7.1 Anorectal incontinence (symptoms):** Complaint of involuntary loss of flatus or feces.<sup>5,10</sup> Can be further subdivided into:

**1.7.1.1 Flatal incontinence:** Complaint of involuntary loss of flatus (gas).<sup>5,10</sup>

**1.7.1.2 Fecal incontinence:** Complaint of involuntary loss of feces.<sup>5,10</sup>

- when feces is solid and/or
- when feces is liquid

**1.7.1.3 Fecal (rectal) urgency:** Complaint of a sudden, compelling desire to defecate that is difficult to defer.<sup>5,10</sup>

**1.7.1.4 Fecal (flatal) urgency incontinence:** Complaint of involuntary loss of feces (flatus) associated with fecal urgency.<sup>5,10,27</sup>

**1.7.1.5 Passive (insensible) fecal incontinence:** Complaint of involuntary soiling of liquid or solid stool without sensation or warning. *(NEW)*

**1.7.1.6 Overflow fecal incontinence:** Complaint of involuntary loss of stool due to an overfull rectum or fecal impaction. *(NEW)*

**1.7.1.7 Coital fecal incontinence:** Complaint of involuntary loss of stool occurring with intercourse.<sup>5,10</sup>

**1.7.1.8 Stress fecal incontinence (SUI):** Complaint of involuntary loss of feces on effort or physical exertion including sporting activities, or on sneezing or coughing. *(NEW)*

## 1.7.2 Anorectal sensory symptoms

**1.7.2.1 Diminished rectal sensation (rectal hyposensitivity):** Complaint of diminished or absent sensation of filling in the rectum. *(CHANGED)*

**1.7.2.2 Increased rectal sensation (rectal hypersensitivity):** Complaint of a desire to defecate (during rectal filling) that occurs earlier or more persistent to that previously experienced. *(NEW)*

**NB:** for 1.7.2.1 and 1.7.2.2, can be to (i) first sensation; (ii) urge sensation; (iii) maximum tolerated volume.

**1.7.2.3 Tenesmus:** Complaint of an urgent desire to evacuate the bowel, accompanied by

involuntary straining and the passage of little fecal matter.<sup>1</sup>

**1.7.3 Defecatory or post-defecatory symptoms:** Symptoms experienced during or following the act of defecation. *(NEW)*

**1.7.3.1 Constipation:** Complaint that bowel movements are infrequent and/or incomplete and/or there is a need for frequent straining or manual assistance to defecate. (Rome IV criteria<sup>28</sup>) FN1.30.

**1.7.3.1.1 Slow transit:** infrequent bowel motions due to delay in transit of bowel contents to reach rectum.

**1.7.3.1.2 Obstructed defecation:** Complaint of difficulty in evacuation due to a mechanical obstruction.

**1.7.3.2 Feeling of incomplete bowel evacuation:** Complaint that the rectum does not feel empty after defecation. May be accompanied by a desire to defecate again.<sup>5,10</sup>

**1.7.3.3 Straining to defecate:** Complaint of the need to make an intensive effort (by abdominal straining or Valsalva) or to use abdominal massage to either initiate, maintain, or improve defecation.<sup>5,10</sup>

## 1.7.3.4. Manual defecatory assistance

**1.7.3.4.1 Internal: Anorectal Digitation:** Complaint of the need to use of fingers in the rectum to manually assist in evacuation of stool contents by scooping, stretching and/or stimulation.<sup>5</sup> *(NEW)*

**1.7.3.4.2 External: Perineal pressure or buttock separation:** Complaint of the need to press on the perineum or separate the buttocks to assist defecation. *(NEW)*

**1.7.3.5 Post defecatory soiling:** Complaint of soiling occurring after defecation. *(NEW)*

**1.7.3.6 Rectal bleeding/mucus:** Complaint of the loss of blood or mucus per rectum.

**1.7.4 Anorectal prolapse:** Complaint of external protrusion (bulge) of the anus or rectum (differentiation on subsequent examination between rectal mucosal prolapse and full thickness rectal wall prolapse which includes muscle and serosal layers). *(CHANGED)*

## 1.8 Other Relevant History

Current medications, previous urological operations, radiotherapy, and catheterization should be noted.

### Footnotes for Section 1

1.1: Milsom et al.<sup>15</sup> first reported that frequency caused by an overactive bladder was arbitrarily defined as more than eight micturitions per 24 h, given that the normal voiding frequency in healthy individuals is typically under six micturitions per 24 h. It was higher than previously reported for healthy women using a frequency/volume chart (median 5.5 micturitions per 24 h).<sup>15–17</sup>

1.2: Pollakiuria: Complaint of abnormally (extraordinary<sup>1</sup>) frequent micturition (rarely used definition).

1.3: It is common to void during the night when sleep is disturbed for other reasons—eg, insomnia—this does not constitute nocturia.

1.4: Polyuria is more fully defined in the “Signs” section.

1.5: “Urgency” replaces “urge” as the “accepted” terminology for the abnormal rather than the normal phenomenon.

1.6: The use of the word “sudden,” defined as “without warning or abrupt,” used in earlier definitions<sup>2,3,5</sup> has been subject to much debate. Its inclusion has been continued.

1.7: This symptom generally occurs where there is some form of neurological disease.

1.8: “Continence” is defined as absence of involuntary leakage of bowel and bladder contents (i.e. normal voluntary control of bowel and bladder function).

1.9: In each specific circumstance, urinary incontinence should be further described by specifying relevant factors such as type, severity, precipitating factors, social impact, effect on hygiene, and quality of life, the measures used to contain the leakage, and whether or not the individual seeks or desires help because of urinary incontinence.

1.10: This change is to accommodate for ambiguity in some languages between stress and anxiety. This symptom would most commonly occur in men who have undergone (radical) prostatectomy. Men who had radical prostatectomy may experience activity-related incontinence and/or during sex.<sup>19</sup>

1.11: Small amounts of urine may be leaked without warning.

1.12: Men with post-prostatectomy incontinence do report this. It also happens in men after artificial sphincter placement. When they get up, they leak. Can be due to stress and without urge or other associated symptoms in the standing or upright position.

1.13: The term “pareuresis” is not in common usage, although the symptom is well-recognised.<sup>20</sup> Pareuresis is defined as the fear of being able to urinate in situations where other persons are present. Diagnostic and statistical manual of mental disorders. Arlington, VA: American Psychiatric Association; 2013.

1.14: Dysuria is a type of urethral pain but could be urethral in origin or referred there from a pathological process in bladder, lower ureter or prostate.

1.15: The symptom of “stranguria” is poorly understood, overlapping at times with urethral pain, dysuria, and pelvic pain.

1.16: The bladder is distended, palpable, and possibly tender. A significantly increased residual is present.

1.17: Non-neurogenic chronic urinary retention (CUR) in men (AUA consensus<sup>21</sup> supported by the current authors) can be defined as an elevated post-void residual of greater than 300 mL that has persisted for at least 6 months and is documented on two or more separate occasions. Evidence is not strong. CUR can be caused by different pathologies that create detrusor underactivity and/or result in chronic bladder outlet obstruction.<sup>21</sup>

1.18: May occur after clothing has been adjusted, due to some “pooling” of urine in the urethra if underwear, or clothing has caused some restriction during voiding or a urethral stricture or diverticulum.

1.19: Complaints of a slow urinary stream, hesitancy and straining to void, with or without sense of incomplete bladder emptying and dribbling, sometimes with storage symptoms: symptom grouping proposed to be suggestive of detrusor underactivity<sup>22</sup> (DU). Diagnosis of actual detrusor underactivity depends on urodynamic findings as discussed in Section 5 on Diagnoses.

1.20: It is often difficult to localize pain precisely, so descriptions as to location of the pain may be imprecise. For example, the term “bladder pain” does not necessarily indicate that the bladder is the cause. Pain thought to be arising from the bladder, or felt in the urethra, scrotum or perineum might be referred from the lower ureter, or bladder base or other pelvic organs.

1.21: The definitions of pelvic pain and especially chronic pelvic pain had been debated in several societies with a view to simplification and restructuring of the classification. The ICS has now published a report from chronic pelvic pain syndromes.<sup>23</sup>

1.22: Painful ejaculation (previously termed “odynorgasmia”), is a poorly characterized syndrome. It may be associated with urethritis, BPH, acute or chronic prostatitis, CPPS, seminal vesiculitis, seminal vesicular calculi or ejaculatory duct obstruction. Often, no obvious etiologic factor can be found.

1.23: Commonly suggested criteria for: (i) Bacteriuria are >100 000 CFU/mL on voided specimen or >1000 CFU/mL on catheterized specimen; (ii) Pyuria are >10 WBC/mm<sup>3</sup> in uncentrifuged urine. The presence of nitrites in the urine is supportive of a UTI involving a common organism (*E. Coli*, *Klebsiella*).

1.24: Those symptomatic patients with fewer colony counts may still harbor organisms detectable by mRNA analyses not widely available at present.<sup>24</sup> Testing for urinary microbiome is being explored but it is not widely available.

1.25: Recurrent urinary tract infections (UTIs) has not been consistently defined. They are far less common in men

than women but perhaps more significant. There is the difficulty of balancing the practical clinical definition and the scientific one. Records of diagnostic tests are often inaccessible over the medium to longer term. With a bias towards the former category, a definition might be the presence at least two symptomatic and medically diagnosed UTIs in 12 months. "Recur" strictly means to "occur again" or "be repeated."

1.26: This symptom must have been present for at least 6 months and must be experienced on almost all or all (approximately 75-100%) occasions of sexual activity. It causes clinically significant distress in the individual. It has been called early ejaculation, rapid ejaculation, rapid climax or premature climax. There is no uniform cut-off defining "premature," but a consensus of experts at the International Society for Sexual Medicine endorsed a definition of around 1 min after penetration. The International Classification of Diseases (ICD-10) applies a cut-off of 15 s from the beginning of sexual intercourse.

1.27: Mean semen volume is 3.9 mL (5<sup>th</sup> centile 1.5 mL; 95<sup>th</sup> centile 6.8 mL). Low semen volume is under 1.5 mL; high semen volume is over 6.8 mL.<sup>25,26</sup>

1.28: Dyspareunia ("hispareunia"), the symptom most applicable to male discomfort on sexual intercourse, will depend on many factors including a woman's introital relaxation and/or anatomical factors.

1.29. Symptoms of defecatory dysfunction are not uncommon in men, particularly those who have undergone anal sphincterotomies for fissure-in-ano.

1.30. Rome IV Criteria for 1.8.3.1 *Constipation*<sup>28</sup>: Complaint that bowel movements are (i) infrequent (<3/wk); (ii) need to strain; (iii) lumpy or hard stool bloating; (iv) sensation of incomplete evacuation; (v) sensation of anorectal obstruction or blockage abdominal pain, (vi) need for manual assistance, in more than one quarter of all defecation.

## SECTION 2: SIGNS

**Sign:** Any abnormality indicative of disease or a health problem, discoverable on examination of the patient; an objective indication of disease or a health problem.<sup>1</sup> (**CHANGED**)

**General principles of examination for male with symptoms of LUT/PF dysfunction**<sup>29</sup>: A comprehensive physical examination is done to seek potential influences on symptoms.<sup>FN2.1</sup> It should include abdominal examination, focussing on the suprapubic area to detect an enlarged bladder, or other abdominal mass, and digital examination of the rectum (prostate) as well as examination of the external genitalia, the perineum and lower limbs. The hernia orifices should also be evaluated. Penile lesions including meatal stenosis, phimosis, and penile cancer must be excluded.<sup>29-31</sup>

If a neurological diagnosis is suspected, then a focused neurological examination with evaluation of perianal crude and pinprick sensations need to be tested. Also, the anal muscle tone can be assessed with finger in the rectum and asking the patient to squeeze. (**NEW**)

### 2.1 General (visual) observations

**2.1.1 Mobility:** generalized muscle strength and ability to ambulate independently or with assistance. (**NEW**)

**2.1.2 Skin:** jaundice or pallor or skin irritation due to urinary loss. (**NEW**)

**2.1.3 Nutritional Status:** cachexia (possible underlying malignancy); obesity (possible endocrine abnormality<sup>29</sup> including metabolic syndrome). (**NEW**)

**2.1.4 Edema of genitalia and lower extremities:** Possible cardiac decompensation, renal failure, nephrotic syndrome, or pelvic and/or retroperitoneal lymphatic obstruction.<sup>29-31</sup> (**NEW**)

**2.2 Abdominal examination**<sup>3,5</sup>: Among numerous possible abdominal signs are:

**2.2.1 Bladder fullness/retention:** The bladder may be felt by abdominal palpation or detected by supra-pubic percussion.<sup>FN2.2</sup> (**CHANGED**)

**2.2.2 Other abdominal masses:** or distension (eg, ascites). (**NEW**)

**2.2.3 Scars:** Indicating previous relevant surgery, trauma, or evidence of previous radiotherapy. (**NEW**)

**2.2.4 Renal Area:** Examination for tenderness, masses. (**NEW**)

### 2.3 Lower Urinary Tract/Genital Examinations/Signs

#### 2.3.1 Genital skin:

**2.3.1.1** Excoriation, redness, irritation secondary to urinary incontinence and the effect of pads or diapers. (**NEW**)

**2.3.1.2** Mycotic infections (balanoposthitis, intertrigo, or scrotal): Moist, red pruritic skin usually in men with urinary or fecal incontinence, immune suppression or poorly controlled diabetes mellitus.<sup>32</sup> (**NEW**)

**2.3.1.3** Skin pigmentation: balanitis xerotica obliterans (BXO – syn. *lichen sclerosus*) and vitiligo may cause depigmentation (penile skin, scrotum, glans). (**NEW**)

**2.3.1.4** Cutaneous manifestations of sexually transmitted diseases: vesicles, ulcers. (**NEW**)

#### 2.3.2 Penile examination:

- 2.3.2.1 Foreskin abnormalities:**
- 2.3.2.1.1 Tumor or infection** (balanoposthitis, ie, inflammation of the glans penis and overlying foreskin<sup>1</sup>). (NEW)
- 2.3.2.1.2 Phimosis**<sup>33</sup>: Partial or complete inability to retract the prepuce due to adhesion between the glans and the prepuce or a preputial ring. FN2.3 (NEW)
- 2.3.2.1.3 Paraphimosis**<sup>33</sup>: Entrapment of the prepuce behind the glans. FN2.3 (NEW)
- 2.3.2.2 Position of the urethral meatus**<sup>31</sup>:
- 2.3.2.2.1 Hypospadias**: Refers to the urethral meatus sited on *ventral surface* of the penis, either congenital or acquired, proximal to its normal position on the tip of the glans. External urethral meatus may be on the glans penis (*glandular hypospadias*), sulcus (*coronal hypospadias*), shaft (*penile hypospadias*), scrotum (*scrotal hypospadias*), or perineum (*perineal hypospadias*). (NEW)
- 2.3.2.2.2 Epispadias**: Refers to the urethral meatus sited on *dorsal surface* of the penis, either congenital or acquired, proximal to its normal position on the tip of the glans. (NEW)
- 2.3.2.2.3 Neoplastic or inflammatory lesions** within the fossa navicularis.<sup>34</sup> (NEW)
- 2.3.2.2.4 Post-hypospadias/epispadias repair**: including post-urethroplasty urethral fibrosis: palpated near the meatus or in the penile shaft. (NEW)
- 2.3.2.2.5 Postoperative fistula**: Urine is visible at or near the incision lines. (NEW)
- 2.3.2.3 Urethral examination:**
- 2.3.2.3.1 Palpation**: along the ventral aspect of the penis and inferiorly into the perineum to detect fibrosis, lumps or tenderness along the shaft. (NEW)
- 2.3.2.3.2 Tenderness**: suggestive of urethral or periurethral inflammation, often secondary to a urethral stricture<sup>34</sup> or sexually transmitted disease. (NEW)
- 2.3.2.3.3 Meatal stenosis**: narrowing changes of the distal urethra; post-infection, post-surgery. (NEW)
- 2.3.2.4 Examination of the glans and shaft**
- 2.3.2.4.1 Penile plaque**: palpation of node or plaque in the tunica usually on the dorsal aspect (perhaps related to Peyronie's disease). (NEW)
- 2.3.2.4.2 Lichen sclerosus**: tight foreskin, cracking, and bleeding.
- 2.3.2.5 General examination**: redness, ulcers, warts, (NEW)
- 2.3.3 Scrotal examination**: (NEW)
- 2.3.3.1 Normal**: The scrotum is a loose sac containing the testes and spermatic cord structures. The epididymis is palpable applied to the posterior surface of the testis as a ridge although occasionally it is sited on the anterior surface. FN 2.4 (NEW)
- 2.3.3.2 Inflammation**: The epididymis may be swollen and tender, and if severe, the inflammatory process may involve the whole scrotal content (i.e. testis and epididymis [epididymo-orchitis]) and the scrotal skin as well. FN2.5 (NEW)
- 2.3.3.3 Cystic dilatations of the epididymis**: (epididymal cysts or spermatocele) and hydroceles (fluid collections between the visceral tunica albuginea and parietal layer of the testicular peritoneum)—usually benign. The examination of these structures would be generally non-tender and without pain (as opposed to 2.3.3.2). FN2.6 (NEW)
- 2.3.3.4 Inguinal bulge**: Examination and differentiation of hernia from hydrocele or cyst of spermatic cord or groin lymph nodes. (NEW) (use of transillumination may assist though ultrasound is generally diagnostic) FN2.7
- 2.3.4 Perineal examination**: this is generally performed with the patient in the lateral supine or in the lithotomy position. (NEW)
- 2.3.4.1 Perianal dermatitis**: Skin infection at the perineum around the anus, usually associated with fecal incontinence or diarrhoea. (NEW)
- 2.3.4.2 Fissures**: A break or tear in the skin of the perineum, anal sphincter or distal rectum usually associated with anal pain. (NEW)

- 2.3.5 Rectal and prostate examination:** Digital rectal examination (DRE) is recommended<sup>35–37</sup> as part of the physical examination. Generally done with the patient standing and bent over the examining table, or with the patient in the left lateral knees bent position, or in the lithotomy position. DRE is usually pain-free. (*NEW*)
- 2.3.5.1 Anal examination:** This can detect the following findings in the anal sphincter or distal rectum: (*NEW*)
- 2.3.5.1.1 Benign diseases:** hemorrhoids, fissure, anal sphincter injury, levator discomfort, or pain. (*NEW*)
- 2.3.5.1.2 Possible malignant diseases:** anal, distal rectal, and prostate carcinoma. (*NEW*)
- 2.3.5.1.3 Anal tone:** increased or decreased anal sphincter tone might suggest similar changes in the urinary sphincter and may indicate neurologic disease. (*NEW*)
- 2.3.5.1.4 Anal stricture:** a circumscribed narrowing or stenosis of the anal canal. (*NEW*)
- 2.3.5.2 Prostate gland characteristics:** size, symmetry, firmness, nodules, and its relation to the pelvic sidewall and rectum can be assessed.<sup>35–37</sup> The gland is about the size of a walnut and has a consistency similar to that of the contracted thenar eminence of the thumb.<sup>FN2.8.</sup> (*NEW*)
- 2.3.5.3 Nodularity and/or firmness –** May indicate possible abnormality requiring further investigation.<sup>37</sup> (*NEW*)
- 2.3.5.4 Prostate tenderness:** prostate palpation, as part of a DRE, is usually pain-free. Pain with prostatic palpation is variable though if present, it may be helpful in differentiating prostate/pelvic pain syndromes.<sup>34</sup> (*NEW*)
- 2.3.5.5 Rectal examination (circumferential):** this might lead to the detection of non-urological diseases such as rectal carcinoma, fistula and fecal impaction.<sup>FN2.9</sup> (*NEW*)
- 2.4 Focused neurological exam**<sup>3,5</sup>
- 2.4.1 Overall neurological status:** abnormalities of speech, gait as well as upper and lower extremity dexterity should be noted as they may indicate a neurological cause for the urological symptoms.
- Neuropathy may impact also on management options.<sup>38</sup> <sup>FN2.10</sup> (*CHANGED*)
- 2.4.2 Level of neurologic abnormality:** can occasionally be localized by the pattern of sensory or motor deficit noted during physical examination using a dermatome map.<sup>30</sup> (*NEW*)
- 2.4.3 Penile, scrotal, or perianal sensory deficits:** may indicate damage or injury to sacral roots or nerves. Reflex testing in the genital area may also be performed. The most important of these is the BSR.<sup>39</sup> (*NEW*)
- 2.4.4 Bulbospongiosus reflex (BSR)**<sup>39</sup> a reflex contraction of the striated muscle of the pelvic floor (anal sphincter) and the bulbo-spongiosus muscle that occurs in response to various stimuli in the perineum or genitalia. <sup>FN2.11</sup> (*NEW*)
- 2.4.5. Cremasteric reflex:** contraction of the ipsilateral cremaster muscle, drawing the testis upwards, when the upper inner aspect of the thigh is stroked longitudinally. (*NEW*)
- 2.5 Urinary Incontinence Signs**<sup>3,5,40,41</sup>: All examinations for the evaluation of urinary incontinence are best performed with the individual's bladder comfortably full.
- 2.5.1 Urinary incontinence**<sup>3,5</sup>: observation of involuntary loss of urine on examination.
- 2.5.2 Stress urinary incontinence (clinical stress leakage)**<sup>3,5</sup>: observation of involuntary leakage from the urethral orifice synchronous with effort or physical exertion, or on sneezing or coughing.
- 2.5.3 Urgency urinary incontinence**<sup>3,5</sup>: observation of involuntary leakage from the urethral orifice associated with the individual reporting a sudden, compelling desire to void. (*CHANGED*)
- 2.5.4 Extra-urethral incontinence**<sup>3,5</sup>: observation of urine leakage through channels other than the urethral meatus, for example, fistula. <sup>FN2.12</sup>
- 2.6 Pelvic floor muscle (PFM) function.**<sup>3,5,42,43</sup> The following signs of PFM function may be assessed via the perineum (visual or tactile examination) or per rectum (digital palpation) examination. Digital rectal examination (DRE) may be less useful in male urinary dysfunctions where the urethral sphincter, inaccessible to DRE, has a more important role.<sup>44</sup> (*NEW*)
- 2.6.1 Perineal examination**<sup>3,5,42,43</sup>—when the patient is asked to cough or bear down, the perineum should only show limited downward movement; ventral movement may occur because of the guarding actions of the pelvic floor muscles. (*CHANGED*)

**2.6.1.1 Perineal elevation**<sup>43,44</sup>: This is the inward (ventro-cephalad) movement of the perineum and anus. FN2.13 Look for testicular lift and penile retraction. These need to be checked against movement of the scrotum and the whole penis. Correct movement occurs with the PFM only: the shaft of the penis draws in and the testes lift in a cephalad direction. These movements may be better visualized in standing than supine position.<sup>45-47</sup> (NEW)

**2.6.1.2 Perineal descent**<sup>43</sup>: This is the outward (dorso-caudal) movement of the perineum and anus.

## 2.6.2 Examinations<sup>43</sup>

**2.6.2.1 PFM state at rest**; aspects to assess.

FN2.13

**2.6.2.1.1 Myalgia**: provoked by palpation. Levator muscle pain/tenderness may be elicited by palpation of these muscles via rectal examination.<sup>43</sup> FN 2.14 (NEW)

- **Tender point**: Tenderness to palpation at a specific soft tissue body site. (NEW)

**2.6.2.1.2 Tone**: state of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement. Muscle tone has two components, the contractile component and the viscoelastic component. Muscle tone may be altered in the presence or absence of pain. (CHANGED)

**2.6.2.1.3 Increased PFM tone (non-neurogenic hypertonicity)**: increased tone in a patient without an intercurrent neurological diagnosis. (CHANGED)

**2.6.2.1.4 Decreased PFM tone (non-neurogenic hypotonicity)**: decreased tone in a patient without an intercurrent neurological diagnosis. (CHANGED)

**2.6.2.1.5 Symmetry**: if examining in the left lateral, there will be a gravity effect and the dependent side will have a different feel to

the upper side and appear as asymmetrical. This may affect PFM tone. Not so common in men. (NEW)

**2.6.2.1.6 PFM injury**: for example, palpable anal sphincter gap though overall not common unlike women. (NEW)

**2.6.2.2 PFM contractile function**: Aspects to assess

**2.6.2.2.1 Voluntary contractility**<sup>43</sup>: the individual is able to contract the PFM on demand. A contraction is felt as a tightening, lifting, and squeezing action under/around the finger. (NEW)

**2.6.2.2.2 Strength**<sup>43</sup>: Force-generating capacity of a muscle. It is generally expressed as maximum voluntary contraction. (NEW)

**2.6.2.2.3 Endurance**<sup>43</sup>: the ability to sustain near maximal or maximal force, assessed by the time a patient is able to sustain a maximal static or isometric contraction. (NEW)

**2.6.2.2.4 Repeatability**<sup>43</sup>: the ability to repeatedly develop near maximal or maximal force, determined by assessing the maximum number of repetitions the patient can perform before detectable decline in force. Record number of contractions in a row. (NEW)

**2.6.2.2.5 Co-contraction**: contraction or activation of two or more muscles at the same time. Identify which muscles are co-contracting and whether the co-contraction is synergistic. (NEW)

**2.6.2.2.6 Relaxation ability**: return of the PFM to its original resting tone following the voluntary contraction. Also includes the ability to maintain PFM relaxation in anticipation of or during any type of touch. (NEW)

**2.6.2.3 PFM response to increased intra-abdominal pressure**: for example, strain/Valsalva/cough aspects to assess

### 2.6.2.3.1 Direction of contraction (elevation, descent)

## 2.6.3 Diagnoses related to PFM examinations

**2.6.3.1 Overactive pelvic floor muscles:** Pelvic floor muscles which do not relax, or may even contract when relaxation is functionally needed, for example, during voiding or defecation. *(CHANGED)*

**2.6.3.2 Underactive pelvic floor muscles:** Pelvic floor muscles which cannot voluntarily contract when instructed to do so or when required. *(CHANGED)*

## 2.7 Frequency-Volume Chart/Bladder Diary

### 2.7.1 Frequency-volume chart (FVC):<sup>3,5,18,48</sup>

The recording of the time of each micturition together with the volume voided for at least 24 h. Ideally a minimum of three days of recording (not necessarily consecutive) will generally provide more useful clinical data. It is relevant to discriminate daytime and nighttime micturition.

**2.7.2 Bladder diary:** Adds to the FVC above, the fluid intake, pad usage, incontinence episodes, the degree of incontinence and the circumstances at the time of the leakage. \*\* Signs where FVC or Bladder diary are important. Episodes of urgency and sensation might also be recorded, as might be the activities performed during or immediately preceding the involuntary loss of urine. Additional information obtained from the bladder diary involves: Severity of incontinence in terms of leakage episodes and pad usage.

**2.7.2.1 Daytime:**<sup>18</sup> the period between waking up with the intention of arising until going to bed with the intention of sleeping (awake hours). *(NEW)*

**2.7.2.2 Night-time:**<sup>18</sup> The individual's main daily period of sleep. It commences at the time of going to bed with the intention of sleeping and concludes when the individual decides to no longer attempt to sleep and rise for the next day. *(CHANGED)* FN2.15, FN2.16

**2.7.2.3 Main sleep period:**<sup>18</sup> The period from the time of falling asleep to the time of rising for the next day.

**2.7.2.4 Nocturnal:** Occurring or active at night.<sup>1</sup> For example, symptoms

and signs that occur at night.<sup>18</sup> *(CHANGED)*

**2.7.2.5 Daytime (urinary) frequency:**<sup>3,5</sup> Number of voids during daytime (awake hours including first void after waking up from sleep and last void before sleep)\*\*.

**2.7.2.6 Night-time (urinary) frequency:**<sup>18</sup> Total number of night-time voids irrespective of sleep.\*\*

**2.7.2.7 Nocturia:** The number of times an individual passes urine during their main sleep period, from the time they have fallen asleep up to the intention to rise from that period. This is derived from the bladder diary.<sup>18</sup>

**2.7.2.8 24-hour (urinary) frequency:**<sup>3,5,18,48</sup> Total number of daytime and night-time voids during a specified 24-hour period.\*\* *(CHANGED)*

**2.7.2.9 24-hour urine volume:**<sup>18</sup> Summation of all urine volumes during a specified 24 h period. The first void after rising is discarded and the 24-hour period begins at the time of the next void and is completed by including the first void, after rising, the following day.\*\* *(CHANGED)*

**2.7.2.10 Maximum voided volume:** Highest voided volume recorded during the assessment period. *(CHANGED)* This usually equals bladder capacity.\*\*

**2.7.2.11 Average voided volume:** Summation of volumes voided divided by the number of voids during the assessment period.\*\* *(CHANGED)*

**2.7.2.12 Mean maximum voided volume (functional capacity):** Mean maximum voided volume in everyday activities.\*\*

**2.7.2.13 Polyuria:** Excessive production of urine.<sup>1,3,5</sup> It has been defined as more than 40 mL urine/kg body weight during 24 h or 2.8 L urine for a man weighing 70 kg.<sup>48</sup>

**2.7.2.14 Nocturnal urine volume:**<sup>18</sup> Total volume of urine produced during the night. Volume measurement

begins after last void preceding sleep and concludes after the first day-time void (when the individual decides to no longer attempt to sleep).<sup>FN2.16</sup> \*\*

**2.7.2.15 Nocturnal (night-time) polyuria:**<sup>18,48</sup> \*\* Increased proportional production of urine during the night-time compared with the 24 h urine volume. <sup>FN2.17</sup> (**CHANGED**). Nocturnal polyuria index (NPI) is most commonly used definition (Night-time urine volume/24 h urine volume) × 100%.  
 - 33% in elderly, eg, >65 years;

- >20% in younger individuals
- 20-33% in “middle age”

Figure 1 (below): provides an example of a bladder diary.

**2.7.2.16 Pad Testing:** For individuals with urinary (fecal) incontinence symptoms, the quantification of the amount of urine (feces) lost over the duration of testing, by measuring the increase in the weight of the pads (weighed pre- and post-testing) used. This may give a guide to the severity of incontinence. Different durations from a short (1 h) test to a 24 and 48-hour tests have been used with provocation varying from normal everyday activities to defined regimens. <sup>FN2.18</sup>

**FIGURE 1** Bladder diary: This simple chart allows you to record the fluid you drink and the urine you pass over 3 days (not necessarily consecutive) in the week prior to your clinic appointment. This can provide valuable information. (i) Please fill in approximately when and how much fluid you drink, and the type of liquid. (ii) Please fill in the time and the amount (in mLs) of urine passed, and mark with a star if you have leaked or mark with a “PC” if you have needed to change your pad (Please find below an example of how to complete this form).  
 Frequency = 9; Nocturia = 1; Urine production/24hr = 1250 mL; maximum voided volume = 300 mL; average voided volume = 125 mL

### Footnotes for Section 2

2.1: There is little evidence from clinical trials that carrying out a clinical examination improves care, but general consensus suggests that it remains an essential part of assessment of men with urinary incontinence<sup>2</sup> or other LUTS.

2.2: A normal bladder in the adult cannot be palpated or percussed until there is at least a volume of 150 mL of urine. At larger volumes of about  $\geq 500$  mL, a distended bladder may be visible in thin patients as a lower midline abdominal mass. Percussion is better than palpation for diagnosing a distended bladder. The examiner begins by percussing just above the symphysis pubis and continues cephalad until there is a change in tone from dull to resonant.<sup>30</sup>

2.3: If phimosis is severe, this can cause voiding symptoms. Most penile cancers occur in uncircumcised men and arise on the prepuce or glans and may be associated with voiding symptoms.<sup>33</sup>

2.4: Scrotal abnormalities can help in elucidating lower urinary tract symptoms in men. For example, men with epididymitis may have associated urinary infection symptoms secondary to coliform bacteriuria.<sup>34</sup>

2.5: Isolated orchitis secondary to UTI is rare, however, mycobacterial infection, mumps, and BCG treatment may cause orchitis.<sup>34</sup>

2.6: If very large they may distort the scrotum and urethra and interfere with normal voiding. A hydrocele is sometimes secondary to testis tumor or inflammatory processes in the epididymis or orchitis.

2.7: The presence of hernias, cystic swellings in the scrotum, and testicular tumors should be excluded by careful clinical examination.

2.8: During the DRE, prostate size and consistency can be estimated, although DRE tends to underestimate true prostate size.<sup>35,36</sup>

2.9: In patients with recto-urethral fistulas, the fistula can occasionally be palpated in the anterior rectal wall. The site of the fistula at or above the anal sphincter can occasionally be noted along with the degree of induration of the anterior rectal wall. With large fistulas the urethra can be palpated, especially if there is a Foley catheter in place.

2.10: For example, a person with Parkinson's may be unable to perform intermittent catheterization because of tremor. A focused neurological exam is also recommended, especially in patients suspected of having neurogenic bladder dysfunction.<sup>38</sup> Decreased perineal sensation and anal sphincter tone may be signs of neuropathy.<sup>41</sup>

2.11: This reflex is most commonly tested by placing a finger in the rectum and then squeezing the glans penis. If a Foley catheter is in place, the BSR can also be elicited by gently pulling on the catheter. If the BSR is intact, tightening

of the anal sphincter should be felt and/or observed.<sup>39</sup> The BSR tests the integrity of the spinal cord-mediated reflex arc involving S2-S4 and may be absent in the presence of sacral cord or peripheral nerve abnormalities.<sup>39</sup>

2.12: If the patient has had previous urethral or bladder surgery or trauma, the examiner should ascertain whether urinary leakage occurs through a fistula in a scar, or at any other site in the penis, perineum, groins, or lower abdomen.

2.13: Normally there is inward (cephalad) movement of the perineum and anus.

2.14: This is all part of doing a DRE, assessing anal sphincters and puborectalis.

2.15: For the purposes of the nocturia terminology, night-time is therefore defined by the individual's sleep cycle, rather than the solar cycle (from sunset to sunrise). Thus, some shift workers may have their "night" period during the daylight hours, as it is the time of their main sleep period.<sup>18</sup>

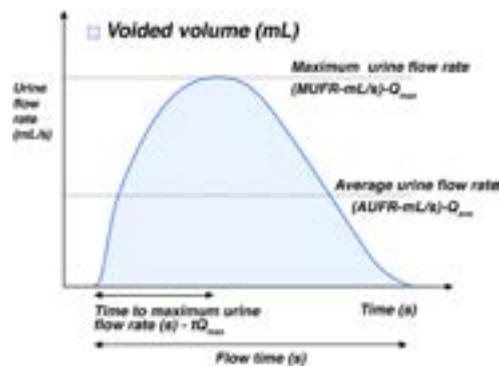

2.16: Volume measurement begins after the last void preceding sleep and concludes after the first daytime void. The first daytime void follows the individual's decision they will no longer attempt to sleep.<sup>18</sup>

2.17: There are several definitions in the literature that could be used to indicate nocturnal polyuria including:<sup>18</sup>

Nocturnal urine production based on body weight of greater than 10 mL/kg.<sup>49</sup>

1. Rate of nocturnal urine production  $>90$  mL/hr.<sup>50</sup> This is suggestive of nocturnal polyuria in men (about 450 mL per 8 h' sleep).<sup>51</sup> There are no studies looking at the rate of nocturnal urine production in women and this may well be different from that in men.
2. Nocturnal polyuria index is the most commonly used definition for nocturnal polyuria<sup>52</sup> (nocturnal urine volume/24-hour voided volume) based on nocturnal urine volume as part of total 24-hour urine volume (age dependent).
3. Nocturia index (nocturnal urine volume/maximum voided volume)<sup>53</sup>  $>1$ : nocturia occurs because maximum voided volume is smaller than nocturnal urine volume.  $>1.5$ : nocturia secondary to nocturnal urine over-production in excess of maximum bladder capacity, that is, nocturnal polyuria.

2.18: A pad test quantifies the severity of incontinence and may be the most objective measure of the incontinence. Severity of incontinence (quantified by pad weight) affects surgery outcomes. The 24-hour pad test and micturition diary are reliable instruments for assessing the degree of urinary loss and number of incontinent episodes, respectively. Increasing test duration to 48 and 72 h

**FIGURE 2** A schematic representation of urine flow over time and parameters of uroflowmetry

increases reliability but is associated with decreased patient compliance.<sup>54</sup> Overall, the 24-hour home test is the most accurate pad test for quantification and diagnosis of urinary incontinence because it is the most reproducible.<sup>55</sup> The 1-hour pad test may be used because it is easily done and standardized, however, there is no strict parallel with the 24-hour pad test and it may underestimate the weakness of the sphincter in the later part of the day.

## SECTION 3: URODYNAMIC INVESTIGATIONS

**Urodynamics:** Measurement of all the physiological parameters relevant to the function and any dysfunction of the lower urinary tract.<sup>56,57</sup> FN3.1, FN3.2. (NEW)

**Clinical sequence of testing:**<sup>3,5</sup> Urodynamic investigations generally involve an individual attending with a comfortably full bladder for free (no catheter) uroflowmetry and post-void residual (PVR) measurement prior to filling cystometry and pressure-flow study. (NEW)

### 3.1 Uroflowmetry

#### 3.1.1 Ideal conditions for free (no catheter)

**uroflowmetry:** All free uroflowmetry studies should be performed in a completely private uroflowmetry room. Most modern uroflowmeters have a high degree of accuracy ( $\pm 5\%$ ) though regular calibration is important (Figure 2).<sup>58</sup>

#### 3.1.2 Urine flow: Urethral passage of urine where the pattern of urine flow may be:<sup>2,3,5</sup>

**3.1.2.1 Continuous:** no interruption to urine flow.

**3.1.2.2 Intermittent:** urine flow is interrupted.

#### 3.1.3 Urine flow rate (UFR – unit: mL/s):

Volume of urine expelled via the urethra per unit time.<sup>2,3,5</sup>

**3.1.4 Voided volume (VV – unit: mL):** Total volume of urine expelled via the urethra during a single void.<sup>2,3,5</sup> (CHANGED)

**3.1.5 Maximum (urine) flow rate (MUFR – unit: mL/s) –  $Q_{max}$ :** Maximum measured value of the urine flow rate<sup>2,3,5</sup> corrected for artefacts.<sup>3,5</sup>

**3.1.6 Flow time (FT – unit: s):** Time over which measurable flow actually occurs.<sup>2,3,5</sup>

**3.1.7 Average (urine) flow rate (AUFR – unit: mL/s) –  $Q_{ave}$ :** Voided volume divided by the flow time.<sup>2,3,5</sup>

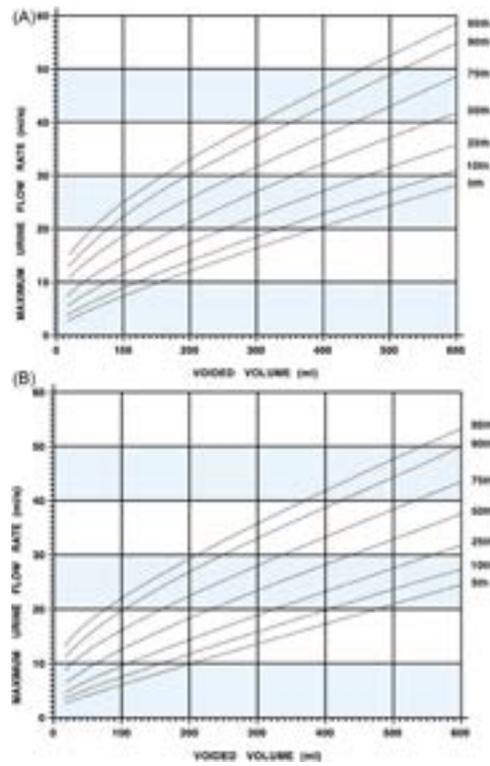

**3.1.8 Voiding time (VT – unit: s):** Total duration of micturition, including interruptions. When voiding is completed without interruption, voiding time is equal to flow time.<sup>2,3,5</sup>

**3.1.9 Time to maximum urine flow rate (tQ<sub>max</sub> – unit: s):** Elapsed time from the onset of urine flow to maximum urine flow.<sup>2,3,5</sup>

**3.1.10 Interpretation of the normality of free uroflowmetry:** Because of the strong dependency of urine flow rates in men on voided volume<sup>59,60</sup> and age,<sup>60</sup> they are best referenced to nomograms<sup>60–63</sup> where the cutoff for normality has been determined and validated. The individual should comment whether voiding was representative of his usual urine flow and whether he has diurnal variation in urine flow (Figure 3A, B). (NEW)

Figure 3A: the Liverpool nomograms<sup>60</sup> for the maximum urine flow ( $Q_{max}$ ) in men aged up to 50 years (mean 35 years). (NEW)

Figure 3B: the Liverpool nomograms<sup>60</sup> for the maximum urine flow rate ( $Q_{max}$ ) in men aged over 50 years (mean 60 years). (NEW)

**FIGURE 3** A and B, show the Liverpool nomograms<sup>60</sup> for the maximum urine flow rate in men (i) up to 50 years (mean 35 years) and (ii) over 50 years (mean 60 years). Equation for the maximum urine flow rate nomogram (divided by age as above) is:  $Sq\ Root\ (MUFR) = 2.37 + 0.18 \times Sq\ Root\ (Void\ volume) - 0.014 \times age$ . (Root mean square error: 0.727) (*NEW*). References to a specific urine flow rate as the lower limit of normal provided a specific volume has been voided require validation studies

The 25<sup>th</sup> percentile appeared to be most appropriate lower limits of normality for both urine flow rates to identify those men more likely to have voiding dysfunction (more commonly bladder outlet obstruction [BOO]).<sup>64</sup> Higher urine flow rate percentiles occurred in men with detrusor overactivity.<sup>64</sup> <sup>FN3.3</sup> Some racial differences in urine flow rates have been reported. <sup>FN3.4</sup> Ideally, abnormal uroflowmetry studies should be repeated. (*NEW*)

**3.2 Post-void residual (urine volume, PVR – unit: mL):** Volume of urine left in the bladder at the completion of voiding.<sup>2,3,5</sup>

**3.2.1 Conditions for PVR measurement:** PVR reading is erroneously elevated by delayed measurement due to additional renal input (1–14 mL/min) into the bladder. <sup>FN3.5</sup> Ultrasonic techniques allow immediate (within 60 s of micturition) measurement to minimize the error. Immediate insertion of a transurethral

catheter for bladder drainage can still provide an effective and accurate PVR measurement. All urethral catheters, however, may not be of equal drainage efficacy <sup>FN3.6</sup>. Ultrasound PVR measurement should ideally be repeated at least once if PVR is present. (*NEW*) An overdistended rather than “comfortably full” bladder might lead to a falsely elevated initial PVR, assessed further by repeat voiding/repeat PVR.

**3.2.2 Assessment of normality of PVR:** Upper limits in normal community dwelling men without LUTS are age dependent with studies reporting a cut-off value of 10–30 mL<sup>67–70</sup>. *There are no adequate currently available data from which to quote expected/typical ranges of PVR in men with symptoms of lower urinary tract dysfunction.* Such studies would need to reflect the accuracy of measurement, including whether the PVR measurement is “immediate”

(eg, by ultrasound) or by urethral catheterization (unless also “immediate”). In the absence of such studies, our consensus view is that a PVR (ultrasound) over 50 mL, following double voiding, might prompt the suspicion of voiding dysfunction. (*NEW*)

### 3.3 Cystometry – General<sup>2,3,5,56,57</sup>

- 3.3.1 Urodynamic studies:** These usually take place in a special clinical room (urodynamic laboratory) and involve (artificial) bladder filling with a specified liquid (ICS recommends physiological saline solution or X-ray contrast if video studies) at a specified rate.<sup>2,3,56,57</sup> FN3.7
- 3.3.2 Cystometry:** Measurement of the pressure-volume relationship of the bladder during filling.<sup>2,3,56,57</sup> FN3.7
- 3.3.3 Cystometrogram (CMG):** Graphical recording of the bladder pressure(s) and volume(s) over time.<sup>2,3,56,57</sup>
- 3.3.4 Conditions for cystometry including**
- 3.3.4.1 Pressures (zeroing);\***
- 3.3.4.2 Pressure transducers;\***
- 3.3.4.3 Catheter mounted transducers; \***
- 3.3.4.4 Initial bladder volume;\***
- 3.3.4.5 Fluid medium\*** FN3.7 \* Covered in references<sup>56,57</sup>
- 3.3.4.6 Temperature of fluid:** Fluid at room temperature is mostly used. It can be warmed to body temperature but without evidence that this influences results.<sup>71,72</sup> FN3.8 (*CHANGED*)
- 3.3.4.7 Position of patient:** Sitting (standing) position is more provocative for abnormal detrusor activity (ie, overactivity) than the supine position. At some point in the test, filling might desirably take place with the patient standing (in those patients able to do so).<sup>71,73</sup> FN3.9 (*CHANGED*) Many men will void standing.
- 3.3.4.8 Filling rate:** The filling rate, including any changes during testing, should be noted on the urodynamic report.<sup>3,56,57,71,73–76</sup> FN3.10. A medium fill rate (25–50 mL/min) should be applicable in most routine studies. Much slower filling rates (under 25 mL/min) are appropriate in men where there are concerns for poor compliance or with a bladder diary showing low bladder capacity or those

with neuropathic bladder. A higher filling rate is greater than 50 mL/min. (*CHANGED*)

#### 3.3.5 Intravesical pressure ( $P_{ves}$ - unit: cm H<sub>2</sub>O):

The pressure within the bladder (as directly measured by the intravesical catheter).<sup>2,3,56,57</sup>

#### 3.3.6 Abdominal pressure ( $P_{abd}$ - unit: cm H<sub>2</sub>O):

The pressure in the abdominal cavity surrounding the bladder. It is usually estimated from measuring the rectal pressure, though the pressure through a bowel stoma can be measured as an alternative. FN3.11 The simultaneous measurement of abdominal pressure is essential for interpretation of the intravesical pressure trace.<sup>2,3,5</sup> Artifacts on the detrusor pressure trace may be produced by a rectal contraction.<sup>2,3,56,57</sup> (*CHANGED*)

#### 3.3.7 Detrusor pressure ( $P_{det}$ - unit: cm H<sub>2</sub>O):

The component of intravesical pressure that is created by forces in the bladder wall (passive and active). It is calculated by subtracting abdominal pressure from intravesical pressure ( $P_{det} = P_{ves} - P_{abd}$ ).<sup>2,3,56,57</sup> FN3.12

### 3.4 Filling Cystometry<sup>2,3,56,57</sup>

- 3.4.1 Filling cystometry:** Pressure-volume relationship of the bladder during bladder filling. It begins with the commencement of filling and ends when a “permission to void” is given by the urodynamicist<sup>2,3,5,56,57</sup> or with incontinence (involuntary loss) of the bladder content (Figure 4).<sup>71</sup> (*CHANGED*)
- 3.4.2 Aims of filling cystometry:** To assess bladder sensation, bladder capacity, detrusor activity and compliance as well as to document (the situation of and detrusor pressures during) urine leakage. (*CHANGED*)
- 3.4.3 Bladder sensation during filling cystometry:** Usually assessed by questioning the individual in relation to the fullness of the bladder during cystometry.
- 3.4.3.1 First sensation of bladder filling:** The feeling when the individual first feels bladder filling.<sup>3,5,71,75</sup> FN3.13
- 3.4.3.2 First desire to void:** The first feeling that the individual may wish to pass urine.<sup>3,5</sup> FN3.13
- 3.4.3.3 Normal desire to void:** The feeling that leads the individual to pass urine at the next convenient moment, but voiding can be delayed if necessary.<sup>3,5</sup>

- 3.4.3.4 Strong desire to void:** The persistent desire to pass urine without the fear of leakage.<sup>3,5,71</sup> FN 3.13
- 3.4.3.5 Urgency:** Sudden, compelling desire to void which is difficult to defer.<sup>3,5</sup> FN1.4, FN1.5
- 3.4.3.6 Bladder oversensitivity<sup>5</sup>**—Increased bladder sensation during bladder filling with: (*NEW – male*)
  - earlier first desire to void;
  - earlier strong desire to void, which occurs at low bladder volume;
  - lower maximum cystometric bladder capacity (3.4.4.2);
  - no abnormal increases in detrusor pressure.
- 3.4.3.7 Reduced bladder sensation:** Bladder sensation perceived to be diminished during filling cystometry.
- 3.4.3.8 Absent bladder sensation:** No bladder sensation during filling cystometry, at least to expected capacity of 500 mL.
- 3.4.3.9 Pain:** the complaint of pain during filling cystometry is abnormal. Its site, character and duration should be noted.

**3.4.4 Bladder capacity during filling cystometry<sup>3,5,56,57</sup>**

**3.4.4.1 Cystometric capacity (units: mL):**

Bladder volume at the end of filling cystometry, when a “permission to void” is usually given by the urodynamicist. This endpoint and the level of the individual's bladder sensation at that time, for example, “normal desire to void,” should be noted. This endpoint might be higher than normal in men with reduced bladder sensation.

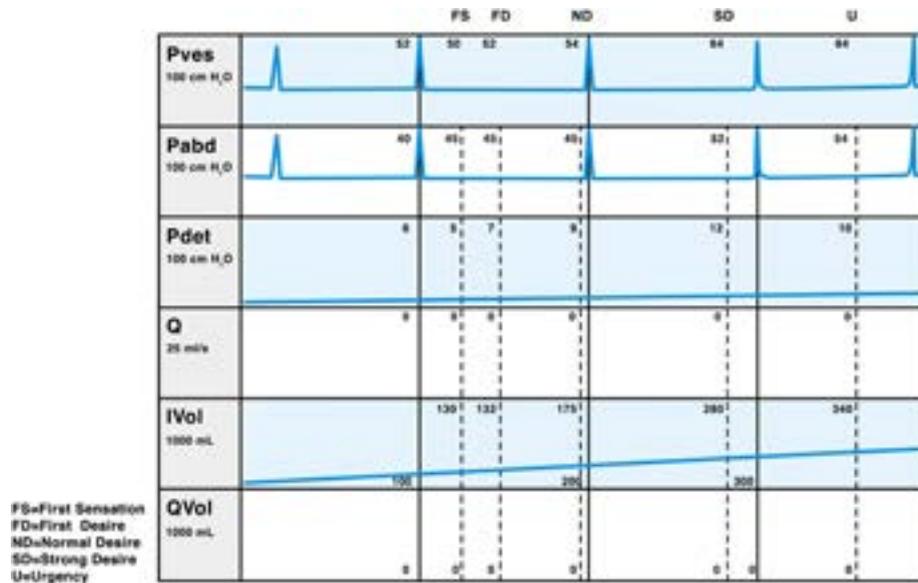

**3.4.4.2 Maximum cystometric capacity (units: mL):**

In individuals with normal sensation, this is the volume when one can no longer delay micturition during filling cystometry. FN3.14, FN3.15, FN3.16

**3.4.5 Detrusor function during filling cystometry**

**3.4.5.1 Normal detrusor activity/function:<sup>3,5</sup>**

There is little or no change in pressure with filling. There are no detrusor contractions, spontaneous or provoked with activities such as postural changes, coughing or hearing the sound of running water. FN3.17 (*CHANGED*)

**FIGURE 4** Normal filling cystometry on multichannel urodynamics. (first desire 132 mL, normal desire to void 175 mL, strong desire to void 280 mL, urgency 340 mL. Detrusor contraction is absent during filling cystometry). Cough artefacts and good subtraction of  $P_{abd}$  from  $P_{ves}$  to get  $P_{det}$  are demonstrated

**3.4.5.2 Detrusor overactivity (DO):**<sup>3,5</sup> The occurrence of detrusor contraction(s) during filling cystometry. These contractions, which may be spontaneous or provoked, produce a wave form on the cystometrogram, of variable duration and amplitude. The contractions may be phasic or terminal. They may be suppressed by the patient or uncontrollable (**CHANGED**). Symptoms, for example, urgency and/or urgency incontinence or perception of the contraction may (note if present) or may not occur.

**3.4.5.2.1 Idiopathic (primary) detrusor overactivity:** No identifiable cause for involuntary detrusor contraction (s). (**CHANGED**) (Figure 5)

**3.4.5.2.2 Neurogenic (secondary) detrusor overactivity:**<sup>3,5,13</sup> Detrusor overactivity and evidence (history; visible or measurable deficit) of a relevant neurological disorder. (**CHANGED**)

**3.4.5.2.3 Non-neurogenic (secondary) detrusor overactivity:**

An identifiable possible non-neurological cause exists for involuntary detrusor contraction(s) during bladder filling. For example, functional (obstruction); stone, tumor (eg, carcinoma in situ), UTI. FN3.18 (**CHANGED**)

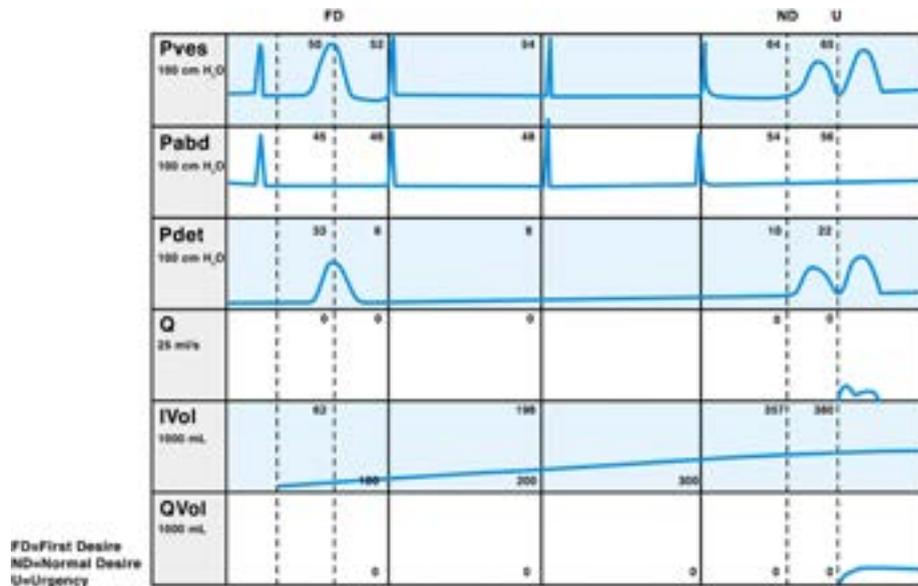

**3.4.6 Bladder (detrusor) compliance (unit: mL/cm H<sub>2</sub>O)**<sup>3,5,56,57,77-79</sup>

**3.4.6.1 Description:** Relationship between the change in bladder volume and simultaneous change in detrusor pressure as a measure for the distensibility of the bladder.<sup>3,5</sup>

**3.4.6.2 Calculation:** Divide the change of volume ( $\Delta V$ ) by the simultaneous change in detrusor pressure ( $\Delta P_{det}$ ) during filling cystometry – ( $C = \Delta V / \Delta P_{det}$ ). The compliance reflects the amount of fluid in the bladder to increase bladder pressure by 1 cm H<sub>2</sub>O and is expressed as mL per cm H<sub>2</sub>O.

**3.4.6.3.** Factors affecting the measurement of bladder compliance:

**3.4.6.3.1 Bladder filling speed:** The bladder should be filled at up to 50 mL/min if there is no

**FIGURE 5** Filling cystometry demonstrating detrusor overactivity: First desire to void occurred at 62 mL together a contraction; normal desire to void at 357 mL; urgency at 380 mL followed by a detrusor contraction There is also high pressure – slow flow during voiding

reason to suspect poor bladder compliance. Faster filling is more provocative and may artificially reduce bladder compliance. This artifact may settle when filling is interrupted or repeated with slower speed. *(CHANGED)*

#### 3.4.6.3.2 Contractile/relaxant properties of the detrusor (decreased compliance):

Properties of the bladder wall may reduce compliance, for example, pelvic radiation or chemotherapy or bladder overstretch. *(CHANGED)* Bladder outlet obstruction can result in detrusor muscle hypertrophy, intramural collagen and elastin deposition and contribute to reduced compliance. *(NEW)*

#### 3.4.6.3.3 Other factors affecting bladder compliance<sup>78</sup> (increased compliance):

Bladder diverticula (also pseudodiverticula) and vesico-ureteric reflux (high grade). *(NEW)*

#### 3.4.6.4 Starting point for compliance calculations:

Usually the detrusor pressure at the start of bladder filling and the corresponding bladder volume (usually zero).<sup>3</sup> Special attention should be made to ensure bladder is emptied at the commencement of measurement; incomplete emptying may artificially decrease bladder compliance. *(CHANGED)*

#### 3.4.6.5 End point for compliance calculations:

Detrusor pressure (and corresponding bladder volume) at cystometric capacity (allow time for pressure to settle after cessation of filling). Both points are measured excluding detrusor contraction. In the case of detrusor overactivity with leakage, both points should be measured or immediately before the start of any detrusor contraction (and therefore causes the bladder volume to decrease, affecting compliance calculations). Low compliance has been defined (in

women) as bladder compliance <10 mL/cm H<sub>2</sub>O (neurogenic) or <30 mL/cm H<sub>2</sub>O (non-neurogenic). Normal compliance is >30 mL/cm H<sub>2</sub>O (neurogenic) and 40 mL/cm H<sub>2</sub>O (non-neurogenic).<sup>79</sup> Recommended values in men have not been well-defined. <sup>FN3.19</sup> *(CHANGED)*

#### 3.4.7 Repeat Cystometry:

<sup>FN3.20</sup> The repetition of the urodynamic testing when abnormal bladder function, discrepancies between history and suspected urodynamic findings, technical errors and/or artifacts have been observed at immediate post-test analysis. *(CHANGED)*

#### 3.4.8 ICS Standard Urodynamic Test:<sup>57</sup>

Free uroflowmetry, postvoid residual, cystometry, and pressure-flow study are termed ICS standard urodynamic test (ICS-SUT).<sup>FN3.21</sup> *(CHANGED)*

### 3.5 Urethral function during filling cystometry (filling urethro-cystometry):

As filling urethro-cystometry is less well-explored in men than women, readers are referred to other reports for methodology.<sup>56,57,80</sup>

### 3.6 Urethral closure mechanism

#### 3.6.1 Normal urethral closure mechanism:

A positive urethral closure pressure is maintained during bladder filling, even in the presence of increased abdominal pressure, although it may be overcome by detrusor overactivity.

#### 3.6.2 Incompetent urethral closure mechanism:

Leakage of urine occurs during activities which might raise intra-abdominal pressure in the absence of a detrusor contraction.

##### 3.6.2.1 Urodynamic stress incontinence (USI):

Involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

##### 3.6.2.2 Subtype: Intrinsic sphincter deficiency (ISD):

Very weakened urethral closure mechanism.

#### 3.6.3 Leak point pressures:<sup>2,3,5,80,81,82</sup>

There are two types of leak point pressure measurement. The pressure values at leakage should be measured at the moment of leakage.

##### 3.6.3.1 Detrusor leak point pressure (DLPP – unit: cm H<sub>2</sub>O):

This is a static test. The pressure is the lowest value of the detrusor pressure at which leakage is

observed during cystometry in the absence of increased abdominal pressure. DLPP is a reflection of the resistance of the bladder outlet or urethral sphincter. High DLPP (eg, over 40 cm H<sub>2</sub>O<sup>80</sup>) may put patients at risk for upper urinary tract deterioration, or secondary damage to the bladder in the cases of known underlying neurological disorders such as spinal cord injury or MS.<sup>81</sup> There are no data on any correlation between DLPP and upper tract damage in non-neurogenic patients. (*CHANGED*)

**3.6.3.2 Abdominal leak point pressure (ALPP – unit: cm H<sub>2</sub>O):** This is a dynamic test. It is the intentionally increased abdominal pressure that provokes urinary leakage in the absence of a detrusor contraction.<sup>82</sup> The patient can achieve this by coughing (CLPP) or straining (Valsalva Leak Point Pressure – VLPP). The VLPP allows measuring the lowest pressure (measured by the bladder or abdominal pressure) that causes urine leakage.

### 3.7 Pressure-Flow Studies<sup>2,3,5,56,57</sup> FN3,24

**3.7.1 Pressure-flow studies:** Pressure-volume (urinary flow) relationship of the bladder during voiding.<sup>1–3,5,56,57</sup> It begins when the “permission to void” is given by the urodynamicist and ends when the man considers his voiding has finished. Measurements to be recorded should be the intravesical ( $P_{ves}$ ) and abdominal ( $P_{abd}$ ) pressures and calculate the detrusor pressure ( $P_{det}$ ) as well as the urine flow rate. FN3,22 (*CHANGED*)

**3.7.2 Detrusor pressure and other measurements during pressure-flow studies** (Figure 6)<sup>2,3,5,56,57</sup>

**3.7.2.1 Detrusor opening pressure (unit: cm H<sub>2</sub>O):** Detrusor pressure recorded immediately before the commencement of urine flow. (*CHANGED*)

**3.7.2.2 Flow delay (unit: s):** The time elapsed from initial rise in pressure to the onset of flow. This is the initial isovolumetric contraction period of micturition. It reflects the time necessary for the fluid to pass from the point of pressure

measurement to the uroflow transducer. FN3,23 (*CHANGED*)

**3.7.2.3 Urethral opening pressure ( $P_{det,uo}$  – unit: cm H<sub>2</sub>O):** Detrusor pressure recorded at the onset of measured flow (consider time delay – usually under 1 s).

**3.7.2.4 Maximum detrusor pressure ( $P_{det,max}$  – unit: cm H<sub>2</sub>O):** Maximum registered detrusor pressure during voiding.

**3.7.2.5 Detrusor pressure at maximum flow ( $P_{det,Qmax}$  – unit: cm H<sub>2</sub>O):** Detrusor pressure recorded at maximum urine flow rate.

**3.7.2.6 Detrusor pressure at end of flow ( $P_{det,ef}$  – unit: cm H<sub>2</sub>O):** Detrusor pressure recorded at the end of urine flow.

**3.7.2.8 Postvoiding detrusor contraction:** An increase in detrusor pressure ( $P_{det}$ ) following the cessation of urinary flow (*NEW*)

### 3.7.3 Detrusor function during voiding<sup>2,3,5,56,57</sup>

**3.7.3.1 Normal detrusor contractile function:** Normal voiding in men is achieved by an adequate continuous detrusor contraction that leads to complete bladder emptying within a normal time span. It depends on central initiation and stimulation of the reflexes involved. The amplitude of the detrusor contraction (detrusor contraction strength/power) tends to increase in response to any increased urethral resistance until the bladder is empty.<sup>83</sup> (*CHANGED*)

**3.7.3.2 Detrusor underactivity (DU):** Low detrusor pressure or short detrusor contraction time, usually in combination with a low urine flow rate resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span. (c.f. the term “hypocontractile detrusor” or detrusor hypocontractility describes a detrusor contraction of reduced strength). Detrusor underactivity can be of neurogenic<sup>13,84</sup> or non-neurogenic origin. (*CHANGED*)

**3.7.3.3 Acontractile detrusor:** The detrusor cannot be observed to contract (ie, no increase in  $P_{det}$ ) during urodynamic studies resulting in failure to void

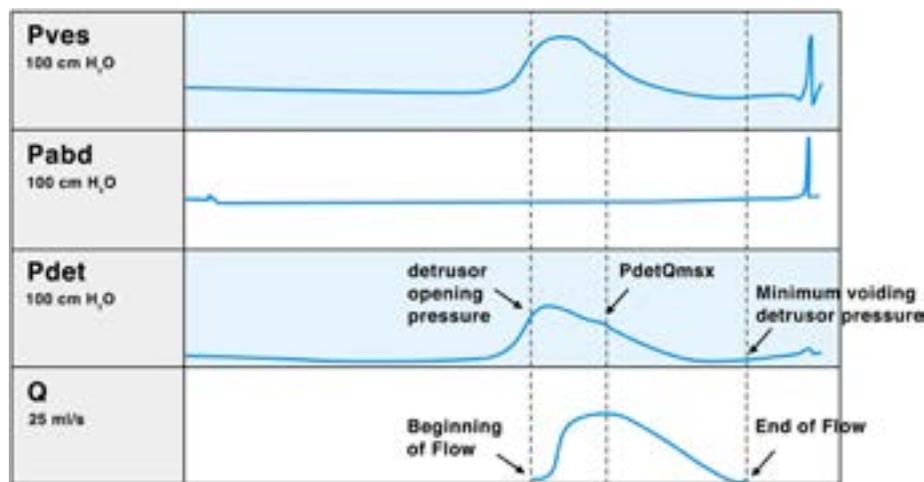

FIGURE 6 A schematic diagram of a pressure-flow study

(*CHANGED*). Limited voiding may occur by straining. The possibility of “inhibition” of a detrusor voiding contraction must be considered if the man subsequently voids normally post-cystometry. An acontractile detrusor can be of neurogenic or non-neurogenic origin. Neurogenic acontractile detrusor should replace the term “detrusor areflexia.”

**3.8 Urethral function during voiding:** This can be interpreted by the pressure-flow trace assisted at times by video cysto-urethrography (video-urodynamics – 4.3.4) and electromyography (EMG – 3.9) as available.

**3.8.1 Normal urethral function during voiding:**

Initiation of voiding begins with voluntary relaxation of the pelvic floor and striated sphincters (rhabdosphincter). The bladder then contracts with the bladder neck, the latter then opening due to its spiral arrangement of fibres. Voiding is prompted with the urethra being continuously relaxed to allow micturition at a normal detrusor pressure and urine flow, resulting in complete bladder emptying.<sup>85,86</sup>

FN3.24, FN3.25, FN3.26

**3.8.2 Abnormal urethral function during voiding:**

The urethral sphincter(s) do not relax completely or they are (temporarily) contracted during voiding, resulting in increased detrusor

pressure. Bladder emptying may be complete or incomplete (PVR present).

**3.8.2.1 Bladder outlet obstruction (BOO):**<sup>87,88</sup>

This is the generic term for obstruction during voiding. It is a reduced urine flow rate with a simultaneously increased detrusor pressure FN3.27. The Bladder Outlet Obstruction Index ( $BOOI = P_{det, Q_{max}} - 2Q_{max}$ ) will give a guide to the likelihood of obstruction being present.<sup>87</sup>

BOOI <20 cm H<sub>2</sub>O = non-obstruction;  
BOOI 20-40 cm H<sub>2</sub>O = equivocal;  
BOOI >40 cm H<sub>2</sub>O = obstruction)

(*CHANGED*)

**3.8.2.2 Dysfunctional voiding:** is characterized by an intermittent and/or fluctuating flow due to inadequate or variable relaxation generally of the sphincters during voiding in neurologically normal men (i.e. no historical, visible or measurable evidence of neurological disease). (*CHANGED*) Dysfunctional voiding may cause functional bladder outlet obstruction. This type of voiding may also be the result of an acontractile or underactive detrusor (voiding with abdominal straining). Video-urodynamics is required to diagnose primary bladder neck obstruction and/or rhabdosphincter discoordination.<sup>87</sup>

**3.8.2.3 Detrusor sphincter dyssynergia (DSD):**<sup>88</sup> Dyscoordination between

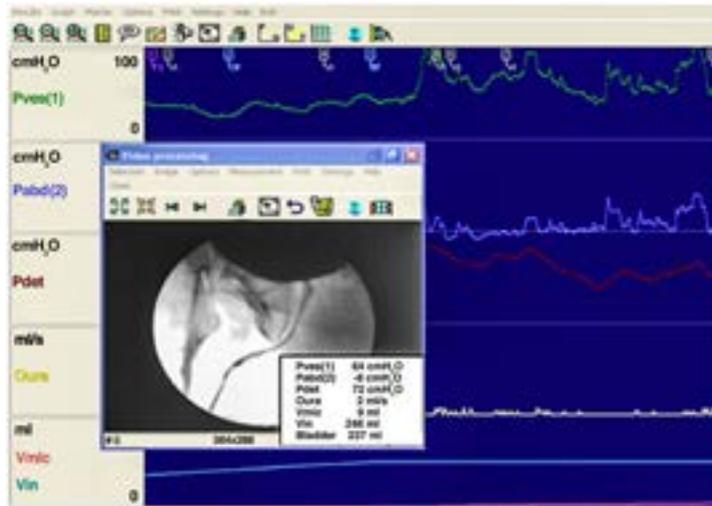

FIGURE 7 Primary bladder neck obstruction in non-neurogenic patient: Urodynamic trace plus imaging

detrusor and rhabdosphincter function during voiding due to a neurological abnormality (ie, detrusor contraction synchronous with contraction of the urethral and/or periurethral striated muscle). This is a feature of neurological voiding disorders. Neurological features should be sought.<sup>88</sup> Video-urodynamics (4.3.4) is generally valuable to conclude this diagnosis. DSD generally occurs due to a lesion above the sacral level 3 but below pons. Sphincter EMG might be

helpful where facilities for video-urodynamics are unavailable.

**3.8.2.4 Primary Bladder Neck Obstruction (non-neurogenic):** During voiding, the bladder neck smooth muscle fails to adequately open. The detrusor pressure increases to try to overcome the resistance of the bladder neck and allow urine to flow (Figure 7).

**3.8.3 Pressure-Flow Analysis** Graphical presentation of the results or calculations based on the pressure-flow measurement (passive urethral

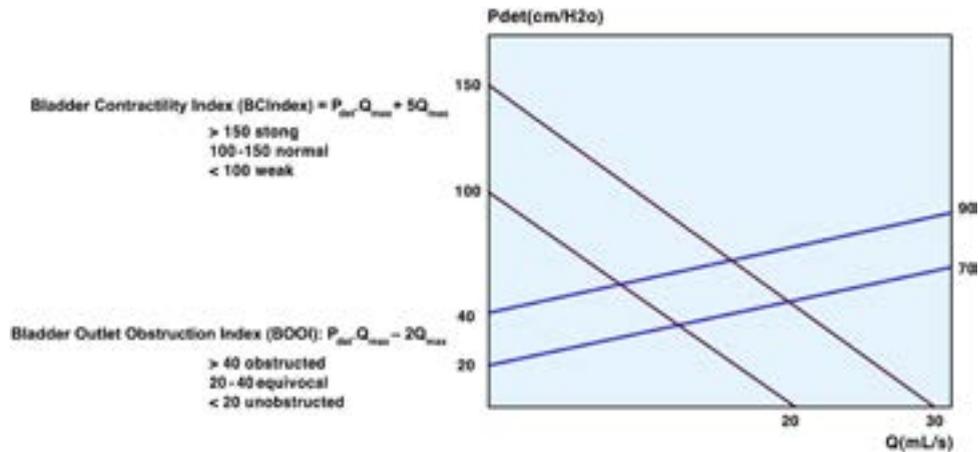

FIGURE 8 ICS Nomogram<sup>89</sup>

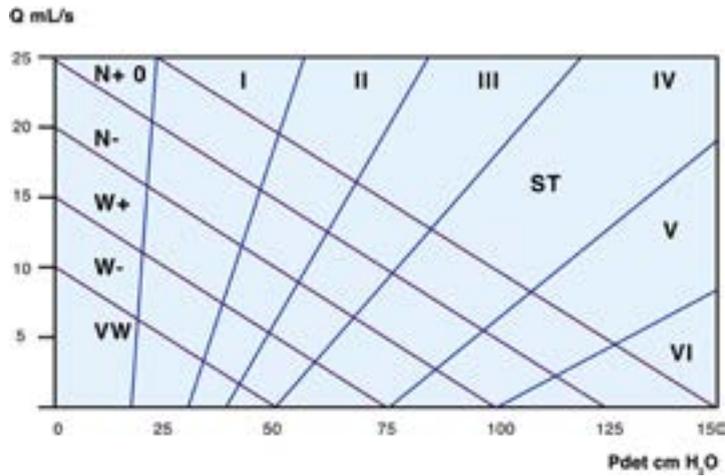

FIGURE 9 Schäfer Nomogram<sup>90,91</sup>

pressure relationship, PURR) have been developed into nomograms. Different nomograms use a variable amount of information of the pressure-flow plot. Figures 8–10 are available to assess bladder outlet obstruction in men<sup>89–92</sup>

**3.8.3.1 ICS Nomogram<sup>89</sup>:** Only  $P_{det}$  at  $Q_{max}$  is plotted into the nomogram (one point

determination of bladder outlet resistance). Depending on the position of this point on the nomogram, the patient can be categorised as “unobstructed,” “equivocal,” or “obstructed.” The calculation of BOOI is used to express bladder outlet resistance as a continuous variable. BOOI can be extracted from

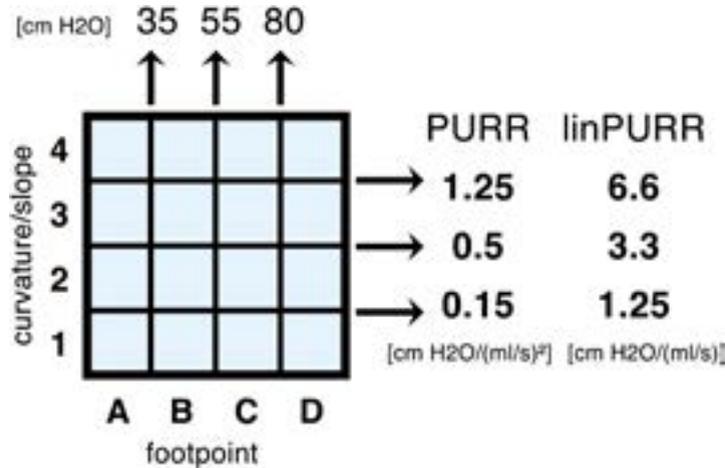

FIGURE 10 CHES Nomogram<sup>92</sup> for the two-dimensional classification of bladder outlet obstruction (assessment of compressive and/or constrictive BOO). The entire information of the pressure-flow plot is used to calculate the passive urethral resistance relation (quadratic PURR, ie, the lowest detrusor pressure for each urine flow during the recorded void; multiple point determination of bladder outlet resistance). The PURR footpoint (ie, crossing-point of the PURR with the pressure-axis) and PURR curvature (ie, PURR ascent) are used to determine bladder outlet resistance. In total, 16 different fields are generated by using the threshold values indicated in the figure. Only field A1 testifies “non-obstruction”; field A2 and B1 indicate “equivocal obstruction” and all other fields indicate different types of obstruction. The increase in the footprint (A to D) indicates compressive BOO whilst the increase in the curvature (1 to 4) indicates constrictive BOO. (NEW)

the nomogram by drawing a line between  $P_{\text{det.Qmax}}$  and the cutting point of the Y-axis (n.b. the line must be parallel to the lines drawn into the nomogram (ie, those for “unobstructed,” “equivocal,” or “obstructed”).<sup>FN3.28, FN3.29, FN3.30</sup> (NEW)

**3.8.3.2 Schäfer Nomogram**<sup>90,91</sup>:  $P_{\text{det.mu0}}$  (minimal urethral opening detrusor pressure) and  $P_{\text{det.Qmax}}$  (detrusor pressure at maximum urine flow) together with corresponding urine flow rates are plotted into the nomogram (2-point determination of the bladder outlet resistance). The line between the two points represents the linearized passive urethral resistance relationship (linPURR) and the location of the linPURR in the nomogram indicates the amount of bladder outlet resistance of the patient. The nomogram differentiates 7 grades of bladder outlet resistance (grades 0 and I=no bladder outlet resistance); grades II to VI indicate increasing grades of BOO. The length (endpoint) of linPURR indicates detrusor contraction strength that can be very weak (VW), weak (W), normal (N), or strong (ST). (NEW)

### 3.9 Electromyography (EMG)

**3.9.1 Purpose:** Reflects the activity of the striated musculature (peri-urethral, rhabdosphincter and pelvic floor). EMG is poorly standardized with variance in the type of needle, needle versus patch electrode, and electrode placement.<sup>93</sup> Perineal patch electrodes are often preferred for easier placement, patient tolerance and allow greater mobility. However, they measure all the above striated musculature. In contrast, needle electrodes can be placed in the area of interest and measure activity of defined muscles or muscle groups for example, rhabdosphincter. (NEW)

**3.9.2 Interpretation:** May be difficult due to artifacts introduced by other equipment. In the urodynamic setting, an EMG is useful as a gross indication of the patient's ability to control the pelvic floor. (NEW)

**3.9.3 Detrusor-sphincter dyssynergia (DSD):** Simultaneous contraction of the detrusor and (rhabdosphincter) urethral sphincters with the

evidence of a neurological disorder (either visible or measurable neurological deficit or a history of neurological disease). The classification of DSD can be divided into two groups continuous versus intermittent. DSD type and degree of SCI lesions seem to correlate.<sup>93,94</sup> (NEW)

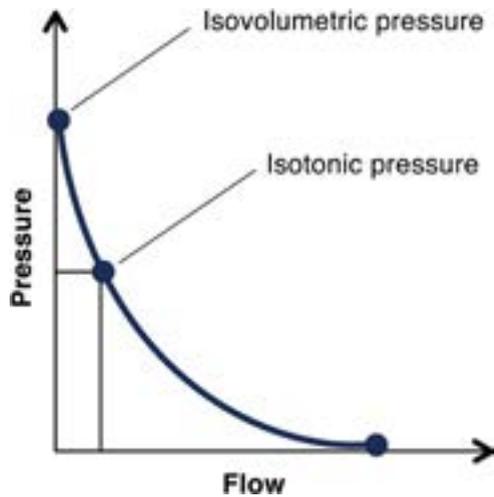

**3.9.3.1 Type 1 DSD** occurs in patients with incomplete neurological lesions. Type 1 – there is a progressive increase in external urinary sphincter (EUS) contraction activity that peaks at maximal detrusor contraction followed by sudden relaxation of the EUS as the detrusor pressure declines allowing urination (Figure 12). (NEW)

**3.9.3.2 Type 2 DSD** occurs more often in patients with complete lesions. Type 2 – occurs with continuous EUS contraction throughout the entire detrusor contraction resulting in urinary obstruction or inability to urinate.<sup>93,94</sup> (NEW)

**3.10 Ambulatory urodynamics:** A functional test of the lower urinary tract for which a transurethral catheter is placed in the bladder (and, in some protocols, another one in the rectum as is typical for a urodynamic study) performed outside the clinical setting, involving natural bladder filling by drinking and continuous recording of the bladder pressure ( $P_{\text{ves}}$ ) for a longer period of time (eg, 12 h). Ambulatory urodynamics can reproduce bladder function and urine loss during the individual's normal everyday activities. (CHANGED)

**3.11 Non-invasive urodynamics:** The penile cuff<sup>95</sup> and condom catheter<sup>96</sup> and urethral device<sup>97</sup> have been developed as non-invasive alternatives to pressure-flow studies. The principle of these tests is to interrupt the flow and measure the bladder pressure. The detrusor contraction is maintained and the urethral sphincter remains open; the column of fluid from the urethra to the bladder is sufficient to measure the bladder pressure (isovolumetric pressure). The external pressure on the urethra, which is needed to interrupt the flow, should be identical to the pressure in the bladder (ie, isovolumetric bladder pressure –  $P_{\text{ves, iso}}$ ). Therefore,  $P_{\text{ves, iso}}$  provides information on bladder pressure during voiding and, when urinary flow is also measured, it is able to distinguish between obstruction and non-obstruction (Figure 11). (NEW)

**3.12 Videourodynamics (Fluorourodynamics):** Functional test of the lower urinary tract in which filling

**FIGURE 11** Isometric and isotonic pressure are indirectly related to the condition of the muscles fibers (detrusor). The isometric contraction of the detrusor, that is contraction without length modification or without shortening of the muscle fibers. Isovolumetric pressure is established by the isometric contraction of the detrusor (no flow). Isotonic contraction is developing force with length modification and therefore, shortening the muscle fibers. In this case, the isotonic pressure is referring to the fact that it is being developed in the voiding phase

cystometry and pressure-flow studies (and possibly EMG) are combined with real-time imaging of the lower urinary tract (Figure 12). (see 4.3.3). (CHANGED)

**3.12.1 Bladder neck at rest:** Shut and competent on coughing and straining, possible exception post-prostatectomy.

**3.12.2 Bladder neck during voiding:** Bladder neck opens like a funnel.

**3.12.3 Bladder neck obstruction during voiding:** Bladder neck remains closed.

**Footnotes for Section 3**

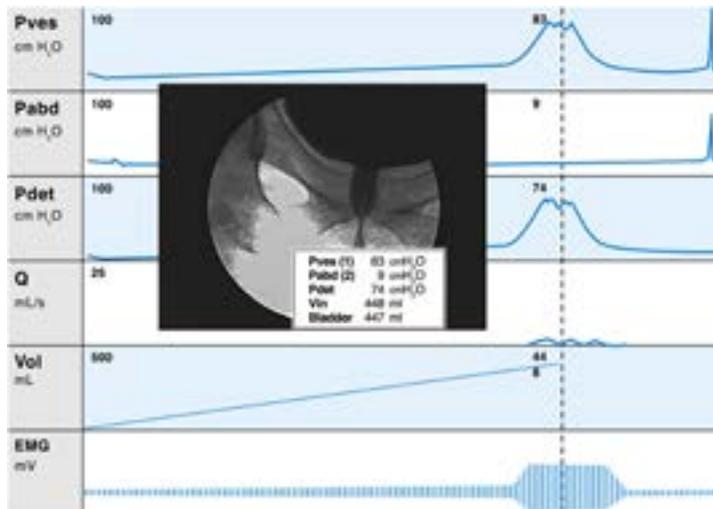

3.1: Urodynamics is the general term to describe all the measurements that assess the function or dysfunction of the LUT by the measurement of relevant physiological parameters.<sup>56,57</sup>

3.2: Urodynamic tests: Over the years, a variety of terms have been developed for the group of diagnostic tests that evaluate LUT function: uroflowmetry, post void residual (PVR), cystometry, pressure-flow studies, electromyography (EMG), urethral pressure profile (UPP), and videourodynamics (videocystourethrography – VCU) are the terms most frequently used in the scientific literature.<sup>56,57</sup>

3.3: Men with detrusor overactivity had the highest urine flow rates. Detrusor overactivity (previously “instability”) was present in 71% of men with centile rankings for the maximum urine flow rate over 50 mL/s.<sup>64</sup>

3.4: There is a notable difference between the available nomograms (Liverpool, Siroky, and Bristol), particularly between race and in older patients.<sup>60-63</sup>

3.5: These are figures for maximal diuresis in women in response to fluid loads of 500 mL and 1000 mL.

**FIGURE 12** Videourodynamics with EMG: During the voiding phase, high detrusor pressure, slow urine flow, increased electrical muscle activity and the image shows dilatation of the proximal urethra and narrowing of the membranous urethra (rhabdosphincter)

Equivalent male diuresis data is unavailable.<sup>65</sup> However, maximum diluting capacity of urine is generally regarded as 20 L/day which converts to 13.9 mL/min (exactly the same as female data<sup>65</sup>).

3.6: Not all catheters empty with similar efficacy. There is evidence in women that a less-compressible (silicone or plastic) catheter is much more effective than a more compressible (latex) catheter in draining the bladder.<sup>66</sup> Such evidence in men is unavailable.

3.7 Continuous fluid filling of the bladder via a transurethral (or other route, eg, cystostomy or Mitrofanoff) catheter, at least with intravesical and abdominal pressure measurement and display of detrusor pressure, including cough (stress) testing. Cystometry ends with “permission to void” or with incontinence of the total bladder content. The fluid type and temperature, filling method and rate, catheter sizes, pressure recording technique, and patient position should all be specified in the urodynamic protocol.

3.8: Body temperature fluid and room temperature fluid do not differently affect bladder sensory thresholds and do not unequally provoke detrusor overactivity or lower urinary tract irritation.<sup>71,72</sup>

3.9: Detrusor overactivity would have been missed in 76% of cases of cystometry was done in the supine position and 60% would have been missed if the study was done supine compared to seated<sup>71,73</sup>. The sitting or standing position is the most representative for daily life situations and is probably the least uncomfortable and/or embarrassing for the patient.<sup>73</sup>

3.10: Filling rate, especially when very fast and the volume infused is much larger than the functional bladder capacity, may influence the results or the representativeness of the cystometry. Evidence that filling rate should be changed during the cystometry is lacking. Diuresis, during cystometry, adds volume that is not recorded by the urodynamic system with automated filling volume recording, but that is relevant for interpretation of the results.

3.11: There is no specific evidence, but the position of the catheter-tip is usually above the bladder in a stoma, and bowel activity may much more likely cause artifacts in those cases, hampering measurement of absolute abdominal pressures, detrusor subtraction pressure, and therefore, the interpretation.

3.12: The urodynamic pressure is the excess pressure above atmosphere at the hydrostatic level of the upper edge of the symphysis pubis. This is valid for all pressures recorded with fluid-filled lines.

3.13: Values evaluated in healthy men<sup>75,76</sup> (mean  $\pm$  SD) are (i) First sensation of bladder filling: 222 mL  $\pm$  150 mL; (ii) First desire to void: 325  $\pm$  140 mL; (iii) Strong desire to void: 453  $\pm$  94 mL.

3.14: Maximum cystometric capacity that should be in healthy adult men, mean 552 mL (range 317-927 mL).<sup>76</sup>

3.15: Filling of more than 800 mL is seldom useful<sup>71</sup>.

3.16: Maximum bladder capacity under anaesthetic (“anatomical bladder capacity”) – the volume to which the bladder can be filled under deep general or spinal anaesthetic, without urinary leakage, is rarely reported in scientific literature but may be of relevance in interstitial cystitis.<sup>71</sup>

3.17: “Normo-active detrusor” as several studies have demonstrated detrusor overactivity during filling in healthy individuals.

3.18: UTI is a very uncommon cause of DO. Most centres do not do urodynamic studies in the presence of an active infection because of the risk of septicaemia.

3.19: Normal values of bladder compliance in men have not been well-defined. Bladder compliance in the volunteers was higher than usually considered normal in adults during cystometric bladder filling.<sup>76</sup> In 28 healthy volunteers, men with mean age of 24 years (range 19-28), the mean compliance was 56.1 mL/cm H<sub>2</sub>O (SD 37.3). Since no precise figures exist for normal compliance in men, a prospective study of a large normal population is needed.

3.20: There is no convincing evidence that the clinical diagnosis on the basis of the first cystometry is often changed on repetition of the test. There is no definite evidence that immediate repetition of an adequately performed urodynamic test “for confirmation” is required. The recommendation of immediate repetition of the test: (i) when doubt exists as to whether the test has answered the clinical question; (ii) when technical errors and artifacts have been observed at immediate post-test analysis.

3.21: Cystometry and pressure-flow study, free uroflometry and PVR are termed ICS standard urodynamic test (ICS-SUT). This may be supplemented with other tests such as EMG, imaging, continuous urethral pressure(s), and/or urethral pressure profile measurements. All tests are performed in the patient's preferred or most usual position: comfortably seated and/or standing if possible.<sup>56,57</sup>

3.22: Voiding physiology depends on central neural activation, bladder contractility and coordinated urethral relaxation throughout the process. There remains much to learn about these components including central activation and its potential grading, and its role and interactions in detrusor underactivity and dysfunctional voiding.

3.23: It is usually between 0.5 to 0.8 s depending on the individual's position and the distance to the uroflowmeter.

3.24: The first “event” in voiding is relaxation of the pelvic floor. This may mean a drop in intra-abdominal

pressure in the rectal line, and an associated increase in the detrusor pressure which does not imply a detrusor contraction.

3.25: As any other muscular contraction, detrusor contraction has an isometric and an isotonic component. The isometric component means that detrusor fibers do not shorten and intravesical pressure rises. The isotonic component produces changes in fiber length; there is shortening and a flow ensues. The first is represented externally as  $P_{ves}$  or  $P_{det}$  and the second by flow. In voiding cystometry, in the presence of flow, detrusor pressure is a function of these two variables, governed by urethral resistance to flow.

3.26: Voluntary interruption of voiding: If the need to interrupt the flow were to arise, contraction of the pelvic floor and urethral sphincters can do this, resulting in an isometric detrusor pressure rise. Urine in the proximal urethra is milked back into the bladder.

3.27: In men with symptoms of lower urinary tract dysfunction, urine flow (rate) and PVR are important markers of bladder outlet obstruction, but are also dependent on the central initiation and continuation of the detrusor contraction and pressure. In the original definition, only pressure and urine flow were included.

3.28: Voiding cystometry graphic presentation: It has been recommended to present pressure-flow studies with a plot of the flow rate (mL/s) on the X-axis and the synchronous detrusor pressure (cm H<sub>2</sub>O) on the Y-axis in addition to the time-based graphs but the axis can be reversed. These plots can be added a cut-off value or a range of normality and equivocal zones. These cut-off values are population specific, varying widely among male patients.

The relation between detrusor pressure and generated synchronous flow indicate “*urethral resistance*.” With computing, these plots can be drawn since the beginning to the end of flow. *Urethral resistance* is then appreciated graphically throughout the whole emptying phase. Most of these resistance points are considered to be driven by urethral muscular activity. The point of less calculated resistance should be taken as an approximation to the urethral resistance free of active muscular urethral and peri-urethral contractions. This concept of “*passive urethral resistance relation*” is then taken as an “anatomical obstruction” caused by fixed structures as the prostate or strictures.

*Pressure-flow plots as a measure of detrusor voiding contraction.* “*Detrusor contractility*” can be used for any method that diagnoses or aims to diagnose “intrinsic” detrusor muscle properties (eg, potential [maximum] force or velocity), by any method.

In a given group of patients the *detrusor contractility* can be calculated upon series of stop-flow or interrupted-

voiding tests and mathematical or graphical analysis methods of pressure, flow and or other parameters. Cut-off values or a continuous scale of contractility can then be drawn. Independently of the magnitude of the detrusor contraction, it can be fading before the total emptying leading to incomplete voiding; “unsustained contraction” or “fading contraction” may then be used.

3.29: “ICS Nomogram”<sup>®</sup> formerly known as Abrams-Griffiths Nomogram and “Abrams-Griffiths number” (now BOOI) is more commonly used.

3.30: Catheter flow should be compared with free flow to ascertain whether dysfunctional voiding might only occur during urodynamics due to catheter placement.

## SECTION 4: IMAGING

**4.1 Overview:** Imaging has become increasingly important in the assessment of male lower urinary tract and pelvic floor dysfunction. Table 2 indicates possible imaging modalities by site and the main goals from kidney to pelvic floor. (NEW)

Application of the individual imaging technique is dependent on the suspected abnormality, ability of the imaging technique to visualize this abnormality and image resolution. In case of competing imaging techniques, non-radiological techniques should be preferred to avoid radiation exposure. (NEW)

### 4.2 Ultrasound Imaging

**4.2.1 Ultrasound in the assessment of the lower urinary tract:** As noted in Table 2, ultrasound imaging has become a relevant imaging modality in all sites that might be subject to investigation of male lower urinary tract and pelvic floor dysfunction both in the office and in the urodynamic suite. (NEW)

#### 4.2.2 Modalities in current routine clinical use:

**4.2.2.1 Transrectal:** Linear array or sector scanning per rectum. (NEW)

**4.2.2.2 Transabdominal:** Curved or linear arrays applied to the abdomen. (NEW)

**4.2.2.3 Perineal:** Curved or linear array probe applied to the perineum (transperineal). (NEW)

**4.2.2.4 Scrotal:** Linear array probe applied to scrotum looking at testes, epididymes and intrascrotal abnormalities. (NEW)

#### 4.2.3 Current routine uses of ultrasound in male LUT/PF dysfunction

**4.2.3.1 Post-void residual (PVR):** Transabdominal<sup>98,99</sup> or transrectal<sup>100</sup> (see section

**TABLE 2** Imaging modalities by site and goal

Location	Imaging technique	Purpose
Upper Urinary Tract	<ul style="list-style-type: none"> <li>• Renal ultrasound</li> <li>• IVU with X-ray or CT</li> <li>• IVU with MRI</li> </ul>	detects the presence and degree of hydronephrosis, urothelial carcinoma/tumors, stones, other renal or ureteric abnormalities/ diseases.
Bladder	<ul style="list-style-type: none"> <li>• Ultrasound bladder scanner</li> <li>• Transabdominal ultrasound</li> <li>• Transrectal ultrasound</li> <li>• CT</li> <li>• MRI</li> </ul>	measurement of post-void residual (PVR), detrusor or bladder wall thickness, intravesical prostatic protrusion (IPP) or bladder weight (to help judge BOO) or calcification. Evaluate the presence of other diagnoses such as neoplasm, stones or foreign bodies.
Prostate	<ul style="list-style-type: none"> <li>• Transrectal ultrasound (3D, contrast-enhanced, Doppler)</li> <li>• Transabdominal ultrasound</li> <li>• MRI (T2-weighted, multiparametric, prostate segmentation, functional MRI).</li> </ul>	evaluate prostate volume, prostate anatomy, BOO. MRI: Evaluation for prostate cancer
Scrotum	<ul style="list-style-type: none"> <li>• Scrotal ultrasound</li> </ul>	Testis, epididymis, tunica vaginalis
Urethra	<ul style="list-style-type: none"> <li>• X-Ray (retrograde or antegrade urethrography)</li> <li>• MRI</li> <li>• Ultrasound</li> </ul>	evaluate congenital abnormalities, fistula, diverticula, (post-surgical) stricture, neoplasm
Ano-rectum	<ul style="list-style-type: none"> <li>• Endoanal ultrasound (10-13-16 Hz axial and sagittal array)</li> <li>• Defecography</li> <li>• MRI</li> </ul>	Anal sphincter integrity; peri-anal sepsis, pelvic floor coordination during defecation
Penis	<ul style="list-style-type: none"> <li>• Ultrasound</li> <li>• CT</li> <li>• MRI</li> </ul>	Peyronie's disease, corpora cavernosa rupture.
Lower urinary tract	<ul style="list-style-type: none"> <li>• Video-cystourethrography</li> <li>• Video-urodynamic</li> </ul>	Evaluate of the bladder during filling and/or voiding, vesico-ureteric reflux; bladder morphology – trabeculation, diverticulum; anatomical site; BOO; type of stress incontinence; urethral diverticulum; strictures, fistulae

**3.2.2)** ultrasound measurement of the bladder volume. The following formula shows the lowest transabdominal measurement error when compared with catheterization.<sup>99</sup> PVR calculation (by abdominal ultrasound) is done by multiplying the width (left to right borders), depth (anterior to posterior borders) and length (cranial to caudal borders) and multiplying this result with 0.52 (there are different multiplication factors available but 0.52 is the most common one) (Figure 13). *(NEW)*

$$\text{Volume} = (\text{width} \times \text{depth} \times \text{length}[\text{cm}]) \times 0.52[\text{mL}]$$

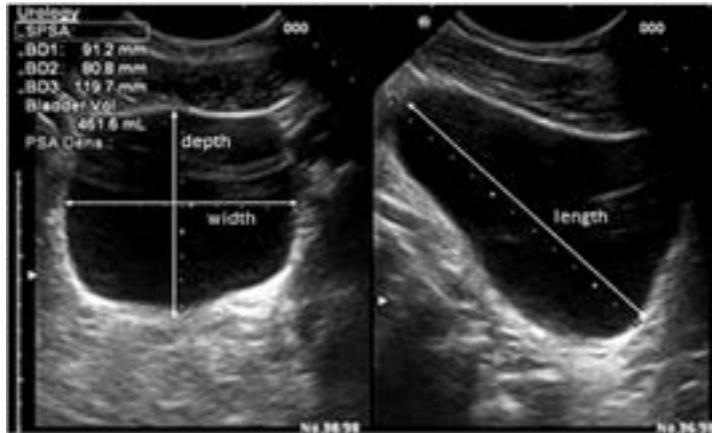

**4.2.3.2 Intercurrent abnormalities:** For example, prostate volume (transabdomi-

nal, intraabdominal, retroperitoneal, or intrapelvic tumor, hydronephrosis). *(NEW)*

**4.2.3.3 Bladder abnormalities:** For example, tumor, foreign body, overdistension, stones. *(NEW)*

**4.2.3.4 Detrusor wall thickness (DWT) or bladder wall thickness (BWT):** Transabdominal visualization of the anterior bladder wall with a (linear) high frequency ultrasound scanner for the detection of BOO if DWT is  $\geq 2$  mm in bladders filled with  $\geq 250$  mL (Figure 14) or BWT is  $\geq 5$  mm in bladders filled with 150 mL (Figure 14).<sup>101–105</sup> *(NEW)*

**4.2.3.5 Ultrasound-estimated bladder weight (UEBW):** can be calculated

**FIGURE 13** Determination of bladder (post-void residual) volume by transabdominal ultrasound imaging

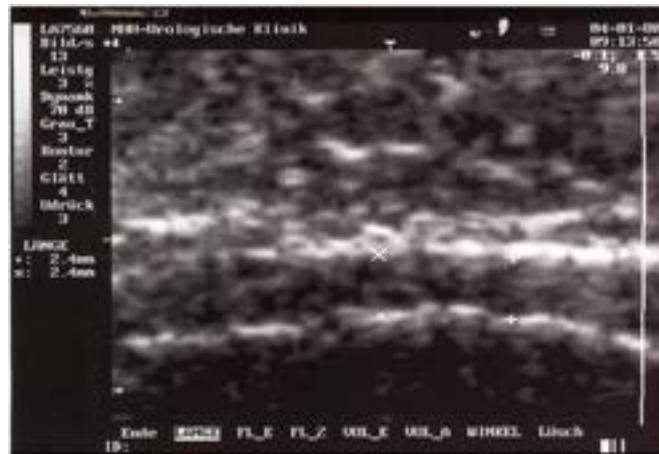

by measuring the urine volume in the bladder and BWT and applying the following formula (Figure 15).<sup>106,107</sup> (NEW)

**4.2.3.6 Intra-vesical Prostatic Protrusion (IPP):** Transabdominal measurement of the distance of the bladder base until the tip of the prostate in the bladder lumen<sup>108</sup> (Figure 16A and B). It is recommended to fill the bladder with 100-200 mL of fluid in order to receive representative measurements; bladder

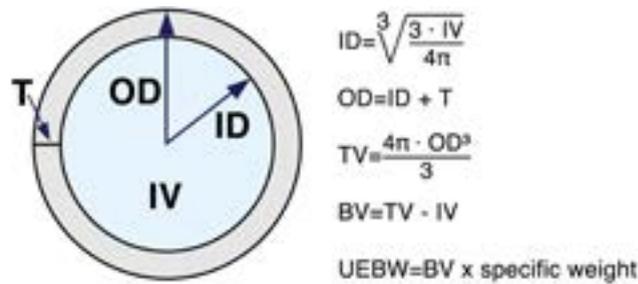

filling over 400 mL will lower IPP values.<sup>108</sup> The IPP measurement can be divided into three grades: grade I = 0-4.9 mm; grade II = 5-10 mm; grade III = >10 mm.<sup>109</sup> IPP grade III is associated with prostate-related BOO.

**4.2.3.7 Urethral abnormality:** For example, diverticulum, urethral stenosis, degree, and depth of spongiofibrosis. (NEW)

**4.2.3.8 Postoperative findings:** For example, post-prostatectomy (urethral shape), male sling position, artificial urinary

**FIGURE 14** Ultrasound measurement of detrusor wall thickness (DWT) at the anterior bladder wall with a linear 7.5 MHz ultrasound array in a bladder filled >250 mL; the hypoechoic detrusor (black bar) is sandwiched between the hyperechoic (white) mucosa (bottom) and adventitia (top).<sup>101,102</sup> DWT is measured from the inner border of the mucosa to the inner border of the adventitia as demonstrated in the figure, whereas BWT is measured from the outer border of the mucosa to the outer border of the adventitia

IV = inner volume; ID = inner radius; OD = outer radius; T=(bladder wall) thickness;  
 TV = total volume. Note again, "D" refers to "radius" not "diameter". Volume of  
 bladder wall itself should be  $\frac{4}{3}\pi$  times (Rt3-Rid3)

**FIGURE 15** UEBW<sup>106,107</sup> FN 4.1. IV = inner volume; ID = inner radius; OD = outer radius; T = (bladder wall) thickness; TV = total volume. Note again, "D" refers to "radius" not "diameter". Volume of bladder wall itself should be  $\frac{4}{3}\pi$  times (Rt3-Rid3)

sphincter –placement of cuff and reservoir, bulking agents. (NEW)

**4.2.3.9 Prostate ultrasound:** determination of prostate and transition zone volume, prostate shape and visualization of the prostate parenchyma for calcifications, cysts, abscesses, or enlargement (Figure 17). (NEW)

**4.2.4 Pelvic floor:** For example, anal sphincter defects (see below)

**4.2.5 3D and 4D Ultrasound:** research modalities at present FN 4.2

**4.2.6 Other assessments:** Synchronous ultrasound screening of the bladder and/or urethra and measurement of the bladder and abdominal pressure during filling cystometry and pressure flow study (Video-ultrasound-urodynamics). (NEW)

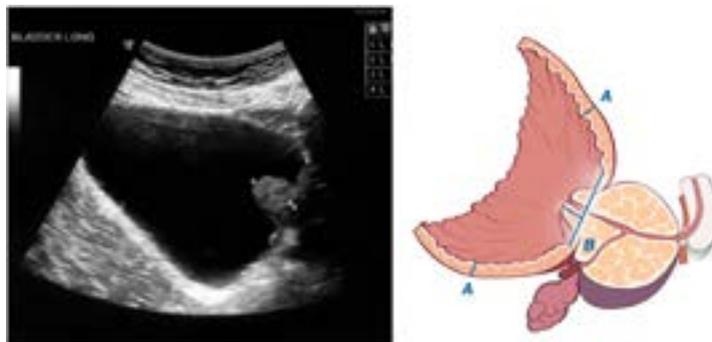

#### 4.2.7 Anal ultrasound (Endosonography<sup>110,111</sup>):

This is the gold standard investigation in the assessment of anal sphincter integrity. There is a high incidence of defecatory symptoms in men with anal sphincter defects (Figure 18). (NEW)

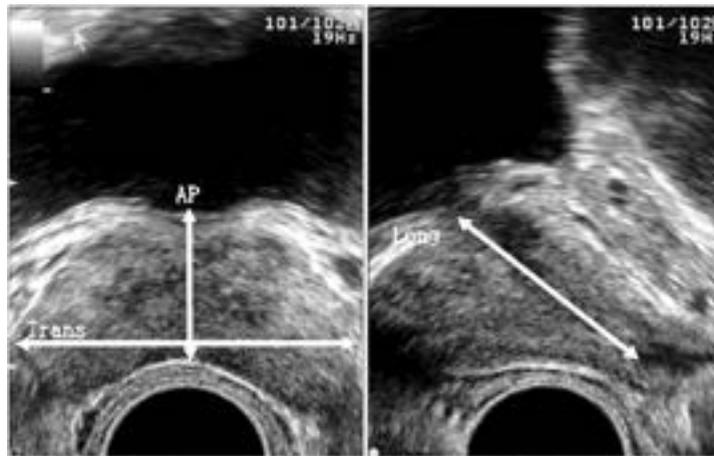

##### 4.2.7.1 Endoanal ultrasonography (EAUS)

##### or Anal Endosonography (AES):

Ultrasound of the anal canal performed with a pole-like ultrasound probe placed in the anal canal giving a 360 degree image of the anal canal. It is usually performed with the patient placed in the lithotomy, prone position or sometime left lateral. Two dimensional AES; three dimensional AES – three-dimensional reconstruction of the anal canal is performed using either axial or sagittal images. (NEW)

**FIGURE 16** A: Transabdominal ultrasound measurement of intravesical prostatic protrusion (IPP). B: How to measure IPP – base of bladder (line A) to the most cranial part of the prostate (line B)

**FIGURE 17** Prostatic volume by transrectal ultrasound

**4.2.7.2 Anal Canal** – The anal canal in adults is between 2.5 and 5 cm in length and begins as the rectum narrows, passing posteriorly between the levator ani. Three levels of assessment in the axial plane.<sup>111</sup> (NEW)

**4.2.7.2.1 Upper level:** the hyperechoic sling of the puborectalis muscle (PR) and the complete ring of the internal anal sphincter (IAS). (NEW)

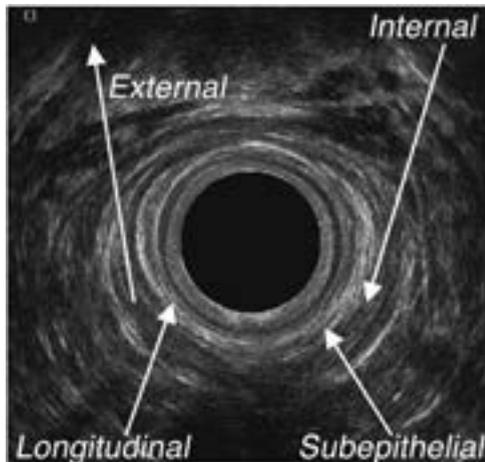

**4.2.7.2.2 Middle level:** corresponds to the superficial part of the EAS (concentric band of mixed echogenicity), the conjoined longitudinal layer, the IAS (concentric hypoechoic ring), and the transverse superficial perineal muscles. (NEW)

**4.2.7.2.3 Lower level:** corresponds to the subcutaneous part of the EAS where the IAS is absent. (NEW)

**4.2.7.3 Internal anal sphincter** – The caudal continuation of the circular smooth muscle of the rectum forms the internal anal sphincter, which terminates caudally in a clearly defined edge, at a variable distance from the anal verge. (NEW)

**4.2.7.4 Longitudinal muscle** – Comprises smooth muscle cells continuous with the outer layer of the rectal wall, and striated muscle from various pelvic floor muscles. The longitudinal muscle lies between the internal and external anal sphincters in the inter-sphincteric space. (NEW)

**4.2.7.5 External anal Sphincter** – It is made up of striated muscle and surrounds the longitudinal muscle forming the outer border of the inter-sphincteric space. The external sphincter is divided into

**FIGURE 18** Normal anal canal anatomy as seen on anal endosonography (AES)

deep, superficial and subcutaneous parts, with the deep and subcutaneous parts of the sphincter forming rings of muscle, between them elliptical fibres from the superficial part of the external anal sphincter run anteriorly from the perineal body to the coccyx posteriorly. (NEW)

- 4.2.7.6 Puborectalis** – is formed from the most anterior fibres of the pubococcygeus muscle, this forms a sling pulling the rectum forward. (NEW)

### 4.3 Radiography

#### 4.3.1 Modalities in current routine clinical use

- 4.3.1.1 Intravenous urography (IVU):** This provides an anatomical outline of the upper urinary tract, ureters and bladder as well as the evaluation of the kidney function and excretion of contrast media. IVU consists of at least 3–4 abdominal images: one plain x-ray, one almost immediately after injection to evaluate for renal vascular uptake, one image 7 min and one image 15 min after infusion of contrast media (and bladder emptying). The preliminary plain x-ray may show calcification in kidney, ureter, bladder, seminal vesicles or vasa. (NEW)

- 4.3.1.2 Retrograde urethrocytography and voiding cystourethrography:** Unidirectional or combined contrast imaging of the urethra in a patient in the 30 degree oblique position to visualize the lumen, mainly to diagnose urethral strictures or diverticula (Figure 19). It is also of use to diagnose and stage urethral trauma. (NEW)

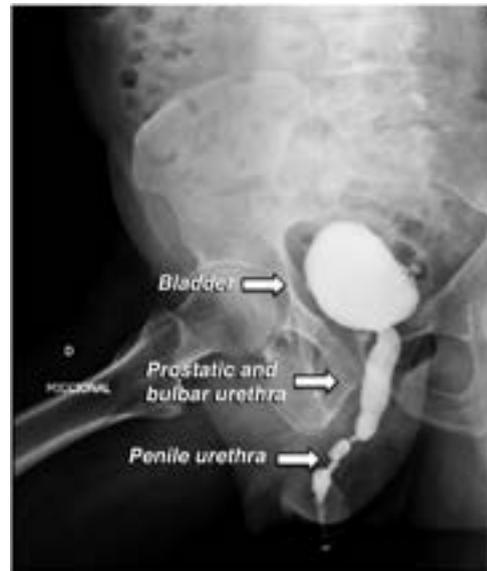

- 4.3.1.3 Voiding cystourethrography:** imaging of the bladder neck, urethra and prostate during voiding (Figure 20). The principal use is determining the site of any obstruction, for example, bladder neck or prostate. It can detect vesico-ureteric reflux, vesical or urethral fistulae, vesical or urethral diverticula and strictures. (NEW)

- 4.3.1.3.1 Videocystourethrography (VCU):** Synchronous radio-

**FIGURE 19** Retrograde urethrocytography of a patient with a penile urethral stricture

logical screening of the bladder and urethra during filling and voiding (Figure 21). The only difference between

**FIGURE 20** Voiding cystourethrography: Shows bladder diverticula, open bladder neck and prostatic urethra till stricture of penile urethra

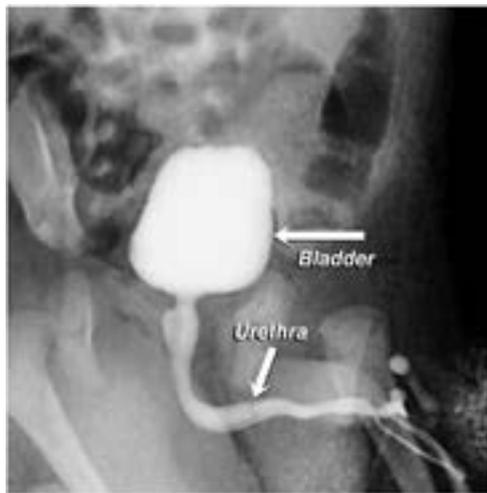

FIGURE 21 Example of Videocystourethrography

VCU and 4.3.1.3. is continuous image capture. (NEW)

**4.3.4 Videourodynamics<sup>112</sup>:** Videourodynamics refers to videocystourethrography with synchronous pressure and flow rate recordings. It is a dynamic study with function, during bladder filling and emptying. (NEW) See also Figure 12.

Video-urodynamics has two defining characteristics:

- It is a kinetic technique that records morphological and functional changes of the lower urinary tract as a function of time. This feature distinguishes this technique from the static images obtained by cystography.
- It is a technique that is applied simultaneously with conventional urodynamic studies.

Image acquisition for the urinary tract can be performed with X-rays (fluoroscopy) or by ultrasound. Although in a strict sense, the “video” prefix refers to the recording of the images and not to their acquisition.

**4.3.5 Defecography (Evacuation proctography):** This demonstrates the anatomy of the anorectum as well as disorders of rectal evacuation. Barium

paste is inserted rectally prior to defecation over a translucent commode. (NEW)

#### 4.4 Computerized Tomography (CT)

**4.4.1 CT Urogram (CT-U):** CT study of the urinary tract system using injected contrast, used to clarify diagnoses such as (i) tumors; (ii) renal disease; (iii) abnormal fluid collections/abscesses (iv) bladder diseases. (NEW)

**4.4.2 CT Kidneys, ureter, bladder (CT-KUB):** Non-contrast study aimed primarily at identifying stones but may identify other diseases. Aka “stone protocol.” (NEW)

#### 4.5 Magnetic Resonance Imaging<sup>113</sup>

**4.5.1 Magnetic resonance imaging (MRI) in male lower urinary tract and pelvic floor dysfunction:** MRI provides the opportunity to examine the soft tissue structures of the pelvic support apparatus. It is non-invasive, has excellent soft tissue contrast resolution without exposure to ionizing radiation and allows the study of function of pelvic floor structures under different dynamic conditions. Several anatomical landmarks used for pelvic measurements are also easily identified in MRI and most measurements are thus highly reproducible. T-weighting assists enhancement of fluid-filled structures. (NEW)

**4.5.2 Current possible measurements using MRI in male lower urinary tract and pelvic floor dysfunction.** FN4.2

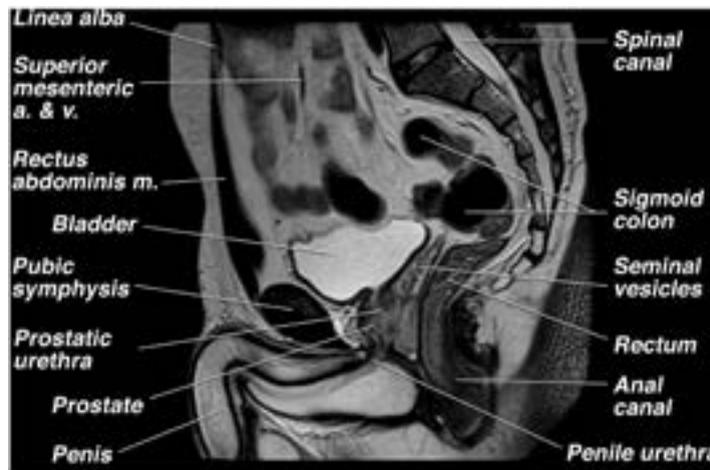

**4.5.2.1 Bladder abnormalities:** For example, tumor, foreign body, bladder wall abnormalities, intestine-vesical fistulae. (NEW)

**4.5.2.2 Urethral abnormality:** For example, diverticulum, recto-urethral fistulae. (NEW)

**4.5.2.3 Urethral sphincter length:**<sup>114</sup> prediction of post-prostatectomy incontinence. (NEW)

**4.5.2.4 Prostate abnormalities:** For example, benign enlargement, cancer, cysts, prostatic-rectal fistulae. (NEW)

**4.5.2.5 Intercurrent abnormalities:** For example, rectum – rectal dynamics are assessed during evacuation after adding ultrasound gel to the rectum. Anorectal and pelvic floor motion can be imaged

**FIGURE 22** MRI (sagittal) of male lower abdomen and pelvis

providing pelvic images at rest and when the subject strains. (*NEW*)

**4.5.2.6 Congenital abnormalities:** Detection of Mullerian duct remnants, aberrantly inserted ureters and duplicated pelvic structures. (*NEW*)

**4.5.2.7 Standardised MRI prostate imaging:** PI-RADS – prostate imaging reporting and data system (Figures 22–24).<sup>FN4,4, FN4,5</sup> (*NEW*)

#### Footnotes for Section 4

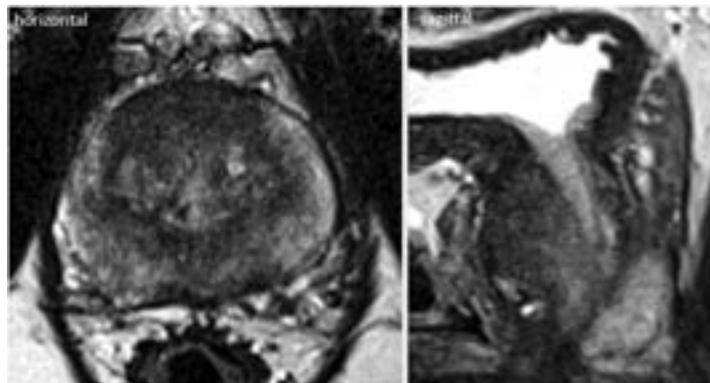

4.1: The “cut-off” value for obstruction has been suggested as 35 g (adult Asian men).<sup>106</sup>

4.2: The potential of 3D and 4D ultrasound in male lower urinary tract and pelvic floor dysfunction is

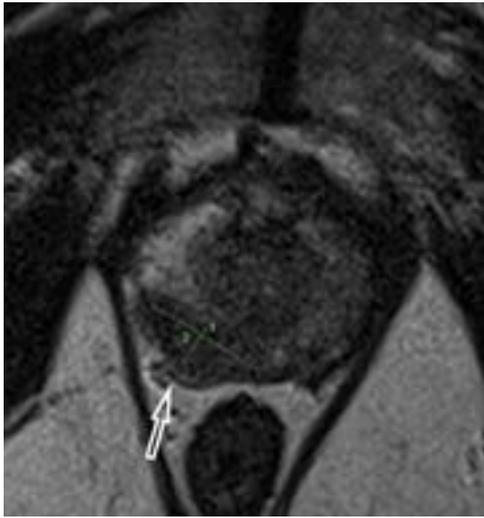

currently being researched with validated applications likely to be included in future updates of this Report and/or separate ultrasound reports.

4.3: Diagnostic ability may be enhanced by the use of 3D MRI. New techniques with high speed sequence of pictures allows for a functional MRI.

4.4: Prostate imaging has over the last 5 years become more standardised with the introduction of PI-RADS (Prostate Imaging Reporting and Data System), currently version 2. The recommended MRI prostate protocol consists of multiparametric study which consists at least of a diffusion sequence (DWI), high resolution anatomical sequences (T2 weighted) and dynamic contrast enhanced sequences (perfusion imaging). A score is given according to each sequence finding and an overall PI-RADS score is finally given based on a structured

**FIGURE 23** MRI of prostate showing low grade inflammatory changes in the peripheral zone

**FIGURE 24** MRI of prostate showing prostate cancer in the right posterolateral peripheral zone

reporting scheme. A score of 1–5 is given with one being benign and five being highly suspicious of malignancy. Ideally the MR studies are performed on a three Tesla strength MR scanner negating the need for an endorectal coil to achieve adequate resolution. MR spectroscopy imaging on the prostate is now rarely performed as it rarely adds value to the above multiparametric study.

## SECTION 5: DIAGNOSES (MOST COMMON)

This report, like previous ones,<sup>2,3,5</sup> highlights the need to base diagnoses for male lower urinary tract and pelvic floor dysfunction on the correlation between a man's symptoms, signs and any relevant diagnostic investigations. We include EMG and imaging as possible diagnostic investigations. The diagnoses are categorized according to three subgroups that reflect the function of the lower urinary tract, namely storage, voiding dysfunction and mixed storage and voiding dysfunction. *It should be noted that prevalence data for the relative frequency of the different male diagnoses are scarce.* <sup>FN5.1</sup> *More studies are required.* (NEW)

**STORAGE DYSFUNCTION (SD)** <sup>FN5.1</sup> Those diagnoses related to abnormal changes in bladder sensation, detrusor pressure or bladder capacity during filling cystometry. (NEW)

### 5.1 Bladder Factor

**5.1.1 Bladder Oversensitivity (BO)**<sup>5</sup> <sup>FN5.2 FN 5.3</sup> (NEW – Male)

**5.1.1.1 Definition:** Bladder oversensitivity, a clinical diagnosis made by *symptoms and urodynamic investigations*, most likely to occur in individuals with symptoms of increased daytime frequency and nocturia. A frequency-volume chart shows a clearly reduced average voided volume (by day and night). As noted in section (3.4.3.6), it can be defined as: increased perceived bladder sensation during bladder filling with specific cystometric findings of: (i) early first desire to void (3.4.3.2); (ii) early strong desire to void, which occurs at low bladder volume (3.4.3.4); (iii) low maximum cystometric bladder capacity (3.4.4.2); and (iv) no abnormal increases in detrusor pressure. Specific bladder volumes at which these findings occur vary in different populations. <sup>FN5.3</sup>

### 5.1.2 Detrusor Overactivity (DO) <sup>FN 5.1 FN5.4 FN5.5</sup>

<sup>FN5.6</sup>

**5.1.2.1 Definition:** As noted in section 3.4.5.2, this diagnosis by *symptoms and urodynamic investigations* is made in individuals with lower urinary tract symptoms (more commonly OAB symptoms – section 1.1.7) when detrusor muscle contractions occur during filling cystometry. (CHANGED)

#### 5.1.2.2 Subtypes

(i) **Idiopathic (primary) detrusor overactivity:** As noted in 3.4.5.2.1, no identifiable cause for the involuntary detrusor contraction(s). (CHANGED)

(ii) **Neurogenic (secondary) detrusor overactivity:**<sup>3,5,13</sup> As noted in 3.4.5.2.2, there is detrusor overactivity and evidence (history; visible or measurable deficit) of a relevant neurological disorder. (CHANGED)

(iii) **Non-neurogenic (secondary) detrusor overactivity:** As noted in 3.4.5.2.3, an identifiable possible non-neurological cause exists for involuntary detrusor contraction (s) during bladder filling. For example, functional (obstruction); stone, tumor (eg, carcinoma in situ), UTI. (CHANGED)

**5.1.3 Reduced compliance storage dysfunction (RCSD):** this diagnosis by *symptoms and urodynamic investigations* is made in individuals with lower urinary tract symptoms, more commonly storage symptoms, when there is a non-phasic (at times linear or exponential) rise in detrusor pressure during filling cystometry with generally reduced capacity indicating reduced compliance (section 3.4.6). (NEW)

**5.1.3.1 Reduced compliance (RCSD) incontinence:** urinary incontinence directly related to the RCSD. (NEW)

**5.2 Outlet Factor** (Urethra/Sphincter Dysfunction – decreased urethral resistance – incompetence /insufficiency)

**5.2.1 Urodynamic Stress Incontinence (USI)** <sup>FNS.7</sup>

**5.2.1.1 Definition:** As noted in section (3.6.2.1), this clinical diagnosis by *symptom, sign and urodynamic investigations* involves the finding of involuntary leakage during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor muscle contraction.

<sup>FNS.7–FNS.10</sup>

**5.2.1.2 Subtype: Intrinsic sphincter deficiency (ISD** (See 3.6.2.1.1): Very weakened urethral closure mechanism. (CHANGED)

**VOIDING DYSFUNCTION (VD)** Those diagnoses related to abnormally slow and/or incomplete bladder emptying manifest as an abnormally slow urine flow rate (3.1.10) and/or an abnormally high post-void residual (3.2.2), with confirmation by pressure-flow studies (including any related imaging). (NEW – Male)

**5.3 Bladder factor – (poor or absent detrusor activity)**

**5.3.1 Detrusor Underactivity (DUA)** <sup>FNS.11</sup>

**5.3.1.1 Definition of DU:** As per 3.7.3.2 A diagnosis based on *urodynamic investigations* generally (but not always) with relevant *symptoms, signs* manifest by low detrusor pressure or short detrusor contraction in combination with a low urine flow rate (3.1.10) resulting in prolonged blad-

der emptying and/or a failure to achieve complete bladder emptying within a normal time span, with or without a high postvoid residual (3.2.2) (c.f. “hypocontractile detrusor” – detrusor contraction of reduced strength) (CHANGED)

**5.3.2 Detrusor Acontractility (DAC)** <sup>FNS.11</sup>

**5.3.2.1 Definition of DAC:** As per 3.7.3.3. a diagnosis by *urodynamic investigation*, generally (but not always) with relevant *symptoms, signs* manifest by the absence of an observed detrusor contraction during voiding studies resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span. Voiding in men with DAC is usually achieved by straining or manual pressure on the bladder resulting generally in an abnormally slow urine flow rate (3.1.10) and/or an abnormally high postvoid residual (3.2.2) (CHANGED)

**5.3.2.2 Subtypes:**

- Neurogenic detrusor acontractility (See 3.7.3.3.1)
- Non-neurogenic detrusor acontractility (See 3.7.3.3.2)

**5.4 Outlet Factor (Urethral/Sphincter dysfunction)**

**5.4.1 Bladder Outlet Obstruction (BOO)** <sup>FN 5.1 FNS.12</sup>

**5.4.1.1 Definition of BOO:** A diagnosis based on *urodynamic investigations (pressure-flow studies ± imaging)*, generally (but not always) with relevant *symptoms* and/or *signs*, manifest by an abnormally slow urine flow rate (3.1.10) <sup>FNS.12</sup> with evidence of abnormally high detrusor voiding pressures and abnormally slow urine flow (3.8.2.1) during voiding cystometry with or without an abnormally high PVR. (3.2.2). <sup>FNS.13</sup> (CHANGED)

**5.4.1.2 Possible sites/causes of BOO:** Can be:

**5.4.1.2.1 Functional**

bladder neck obstruction, detrusor sphincter dysfunctions, pelvic floor overactivity. (NEW)

**5.4.1.2.2 Mechanical:** benign prostatic enlargement, urethral stricture, meatal stenosis). <sup>FNS.14–FNS.19</sup>

Imaging of the lower urinary tract especially video-urodynamics and EMG can be required to evaluate location/cause. *(NEW)*

#### 5.4.2 Alternate presentations of Voiding Dysfunction

**5.4.2.1 Acute retention of urine:** An individual is unable pass any urine despite having a full bladder, which on examination is painfully distended, and readily palpable and/or percussible. *(CHANGED)*

**5.4.2.2 Chronic retention of urine:** Generally (but not always) painless and palpable or percussible bladder, where there is a chronic high PVR. The patient experiences slow flow and chronic incomplete bladder emptying but can be asymptomatic. Overflow incontinence can occur. Some men with retention present with impaired renal function and/or hydronephrosis. *(CHANGED)*

**5.4.2.3 Acute on chronic retention:** An individual with chronic retention goes into acute retention and is unable to void. *(NEW)*

**5.4.2.4 Retention with overflow:** Involuntary loss of urine directly related to an excessively full bladder in retention. *(NEW)*

#### 5.5 MIXED STORAGE AND VOIDING DYSFUNCTION

##### 5.5.1 Bladder Outlet Obstruction and Detrusor Underactivity (BOO-DU)

**5.5.1.1 Definition:** Urodynamic BOO (3.8.2.1) occurring synchronous with urodynamic DU (3.7.3.2) in pressure-flow analyses. FN5.20 *(NEW)*

##### 5.5.2 Detrusor Overactivity and Bladder Outlet Obstruction (DO-BOO)FN5.1

**5.5.2.1 Definition:** Urodynamic DO (3.4.5.2) on filling cystometry in the presence of BOO (3.8.2.1) on pressure-flow studies. FN5.21 *(NEW)*

##### 5.5.3 Detrusor Overactivity with Detrusor Underactivity (DO-DU)

**5.5.3.1 Definition:** Urodynamic DO (3.4.5.2) on filling cystometry) in combination with urodynamic DU (3.7.3.2) on pressure-flow studies. This diagnosis is intended to supersede the old expression “detrusor hyperactivity with impaired contractility” (DHIC) and detrusor overactivity with impaired contractility (DOIC). It is most common in the elderly group. *(NEW)*

#### Footnotes for Section 5

5.1: Large series data on the relative frequency of diagnoses in men presenting with symptoms of LUT/PF dysfunction are scarce. The relative prevalence of six main diagnoses is known in women.<sup>4,5</sup> In a series of 504 consecutive men<sup>64</sup> aged 49-94 years, referred for urodynamic studies including videocystourethrography (VCU) and department review of results because of urological symptoms. The following diagnoses were made:

Detrusor overactivity (DO) 149 (29.6%)

DO plus obstruction (BOO) 124 (24.6%)

**i.e. Total DO (54.2%)**

Obstruction (BOO) alone 161 (31.9%)

**i.e. Total Obstruction (56.5%)**

Normal/ No Specific Dx 70 (13.9%) Some more recent diagnoses may not have been present in 1990.

5.2: Prevalence of Bladder Oversensitivity (BOS): In the EPIC study,<sup>115</sup> the prevalence rate for men who void with frequencies of greater than eight times per day is approximately 12%. The presence of bladder oversensitivity in urogynaecology patients is 10-13%.<sup>5</sup>

5.3: There should be no known or suspected urinary tract infection. Bladder oversensitivity is often a diagnosis after other more serious conditions such as lower urinary tract malignancy, including carcinoma-in-situ of the bladder, are excluded.

5.4: Prevalence of overall urinary incontinence in men by age:<sup>116</sup> 19-44 (4.8%); 45-64 (11.2%); 65-79 (21.1%); >80 (32.2%)

5.5: Prevalence of urgency (urinary) incontinence in men by age<sup>117</sup>: 19-44 (3.1%); 45-64 (7.8%); 65-79 (11.7%); >80 (18.1%)

5.6: Abnormal detrusor contractions can be, at times, observed during filling cystometry without the patient being symptomatic.

5.7: Prevalence of urodynamic stress incontinence (USI): Prevalence of stress (urinary) incontinence in men by age:<sup>115</sup> 19-44 (0.7%); 45-64 (3.8%); 65-79 (2.7%); >80 (N/A) or overall for men over 18 years<sup>117</sup> (1.4%).

5.8: Men, unlike women, do not develop significant urethral hypermobility (with radical prostatectomy a possible exception), and hence urodynamic stress incontinence is most often associated with intrinsic sphincter deficiency, rather than urethral hypermobility. Sphincter deficiency is most commonly a result of either pelvic trauma or post-prostatectomy, either transurethral or radical, or neurological disorder.

5.9 Prevalence for urinary incontinence after transurethral prostatectomy (TURP) for benign prostatic disease appears between 0.5% and 3%.<sup>118–122</sup>

5.10: Prevalence for post radical prostatectomy: The rates of post radical prostatectomy incontinence varies depending on the definition used and the duration of follow-up. However, the long-term incidence ranges between 4% and 8%.<sup>117–122</sup>

5.11: Prevalence of either detrusor underactivity (DU) or acontractility (DAC): In a study involving a review of urodynamic data of 1179 patients aged 65 and older, Jeong et al. reported the prevalence of DUA of 40.2 % in men.<sup>123</sup>

5.12: Urodynamic BOO can be diagnosed using the ICS Nomogram<sup>89</sup>. The formula used, known as the bladder outlet obstruction index (BOOI) is calculated by detrusor pressure at maximum flow ( $P_{det, Q_{max}}$ ) minus two times the maximum urinary flow ( $BOOI = P_{det, Q_{max}} - 2 Q_{max}$ ). A BOOI with a value of >40 defines BOO, less than 20 defines absence of BOO, and in between denotes equivocal BOO. Alternative classifications for BOO are the Schäfer grades (0–VI)<sup>90,91</sup> and CHES classification.<sup>92</sup>

5.13 The evidence in men regarding PVR and BOO is not clear. Urodynamic studies in adult male patients with clinical BPH demonstrated that approx. 30% of men with PVR  $\geq$  50 mL do not have BOO/BPO, independent on the magnitude of PVR<sup>124</sup> and, vice versa, 24% of men with urodynamically confirmed BOO/BPO have PVR <50 mL or even 0 mL.<sup>124–125</sup>

5.14: The level of obstruction can usually be diagnosed during voiding video cysto-urethrography. It may be aided by sphincter or pelvic floor EMG during voiding.

5.15: Bladder outlet obstruction from an enlarged prostate: BOO where the cause is benign prostatic enlargement (BPE) with clinical or imaging evidence.

5.16: Bladder outlet obstruction from the bladder neck: BOO where the cause is at the level of the bladder neck (clinical or radiological). The pelvic floor electromyogram (EMG) trace should be quiet during voiding in these patients.

5.17: Bladder outlet obstruction from pelvic floor muscular overactivity: Bladder outflow obstruction where the cause is at the level of the pelvic floor musculature (clinical, urodynamic or radiological). The pelvic floor electromyogram (EMG) trace may not be positive during voiding.

5.18: Bladder outlet obstruction from the rhabdosphincter (external urinary sphincter): BOO where the cause is at the level of rhabdosphincter (clinical, urodynamic or radiological). The pelvic floor electromyogram (EMG) trace may not be positive during voiding.

5.19: Bladder outlet obstruction from stenosis of bladder neck or urethra due to fibrosis: Bladder neck stenosis may occur secondary to prostate surgery for benign disease, radical prostate surgery, radiotherapy or trauma.

5.20: Currently, although many experts in this field agree that this entity exists, there is currently no consensus on its

definition because there is currently no consensus on defining detrusor underactivity. There is a Maastricht-Hannover Nomogram<sup>126</sup> may be used to diagnose reduced detrusor contractility in the presence of obstruction (or vice versa).

5.21: Up to 83%<sup>127</sup> of men with urodynamic BOO may have concomitant urodynamic DO. Both BOO-grade and advancing age were independent factors of DO in men. The more severe BOO, the higher the chance of DO.

## AREAS FOR FURTHER RESEARCH

In the preparation of this document, the following “gaps” in knowledge in male LUT/PF dysfunction have been noted compared to the equivalent for female LUT/PF dysfunction:<sup>5</sup>

- Post-void residuals in men with symptoms of LUT/PF dysfunction.
- Male diuresis data.
- Bladder compliance – normal and abnormal values in men.
- Additional large patient series for the prevalence data and the relative frequency of the most common male diagnoses.<sup>64</sup>

## ACKNOWLEDGMENTS/ADDENDUM

No discussion on terminology should fail to acknowledge the fine leadership shown by the ICS over many years. The legacy of that work by many dedicated clinicians and scientists is present in all the Reports by the different Standardization Committees and Working Groups. It is pleasing that the ICS leadership has accepted this vital initiative as a means of progress in this important and most basic area of Terminology and its Standardization.

This document has involved 22 rounds of full review, by co-authors, of an initial draft (BH) with the collation of comments and figures. Included in the review process were as follows: (i) 8 external expert reviewers; (ii) an open ICS website review; (iii) ICS Standardisation Steering Committee review and (iv) ICS Board of Trustees review. The process was subject to live Meetings in Tokyo (Sept 2016 – planning), and Working Group Meetings in Florence (September 2017), Copenhagen (March 2018) and Philadelphia (August 2018). There were also teleconferences in June, July and August 2018. The co-authors acknowledge the input and extensive comments by those external reviewers of

version 18: Craig Comiter, Dirk De Ridder, David Ginsberg, John Heesakkers, Michael Kennelly, Richard Millard, Victor Nitti, and Gommert van Koeveringe. Thanks to Dr Pascal Bou-Haidar for his assistance with the MRI section. Version 19 was subject to ICS website publication and an open public forum discussion at ICS Philadelphia. Thanks to those who provided formal, in particular Werner Schäfer, and informal comments. Version 22 was sent for ICS Board review. As there were no significant changes, Version 22 was submitted to Neurourology and Urodynamics in late October 2018 to appear in the Journal in early 2019.

## AUTHORS' DISCLOSURES

Carlos D'Ancona: Clinical trial – Ipsen. Bernard Haylen: No disclosures. Matthias Oelke: Speaker, consultant and/or trial participant for Apogepha, Astellas, Duchesnay, Glaxo Smith Kline, Ferring, Lilly & Pfizer. Grant from Astellas in 2012 on the investigation of detrusor underactivity. Luis Abranches-Monteiro: Trial participant: Ipsen, Allergan, Bayer, Lilly. Advisory Board: Astellas. Edwin Arnold: No disclosures. Howard Goldman: Medtronic: consultant, study support. Consultant: Allergan, Nuvectra, Axionics, NewUro. Study participant: Cook, Ipsen, Bioness. Rizwan Hamid: Consultant: Allergan, Wellspect. Speaker: Astellas, Allergan, Pfizer, Laborie. Travel/Research grants: Allegan, Astellas, Pfizer, Wellspect. Yukio Homma: Honorarium: Astellas, Pfizer, Kissei, Daiichi-Sankyo, Glaxo-Smith Kline, Nippon Shinyaku. Tom Marcelissen: No disclosures. Kevin Rademakers: No disclosures. Alexis Schizas: No disclosures. Ajay Singla: No disclosures. Irela Soto: No disclosures. Vincent Tse: Consultant: Astellas, Allergan, Ferring. Stefan de Wachter: Research grants: Medtronic, Astellas, Wellspect, Coloplast, Boston Scientific. Consultant: Medtronic, Astellas, Sander Herschorn: Consultant for Astellas, Allergan, Pfizer, Ipsen.

**Introduction:** The terminology for adult neurogenic lower urinary tract dysfunction (ANLUTD) should be defined and organized in a clinically based consensus Report.

**Methods:** This Report has been created by a Working Group under the auspices and guidelines of the International Continence Society (ICS) Standardization Steering Committee (SSC) assisted at intervals by external referees. All relevant definitions for ANLUTD were updated on the basis of research over the last 14 years. An extensive process of 18 rounds of internal and external review was involved to exhaustively examine each definition, with decision-making by collective opinion (consensus).

**Results:** A Terminology Report for ANLUTD, encompassing 97 definitions (42 NEW and 8 CHANGED, has been developed. It is clinically based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in all the different groups involved not only in lower urinary tract dysfunction but additionally in many other medical specialties.

**Conclusion:** A consensus-based Terminology Report for ANLUTD has been produced to aid clinical practice and research.

## KEYWORDS

adult, dysfunction, neurogenic, terminology, urinary tract

Rizwan Hamid, Marcus J. Drake, and Bernie Haylen belongs to Standardization Steering Committee ICS.

Jerzy B. Gajewski, Brigitte Schurch, Rizwan Hamid, Márcio Averbeck, Ryuji Sakakibara, Enrico Finazz Agrò, Tamara Dickinson, Christopher K. Payne, Marcus J. Drake, Bernie Haylen belongs to ICS SSC Working Group on Adult Neurogenic Lower Urinary Tract Dysfunction.

## 1 | INTRODUCTION

“Adult” refers to “a fully grown and physically mature individual”<sup>1,2</sup> “Neurogenic” refers to “originating in the nervous system.”<sup>2</sup> “Lower Urinary Tract (LUT)” refers to the bladder, urethra (and prostate in men).<sup>2</sup> “Dysfunction”

refers to abnormal or difficult function. “Adult neurogenic lower urinary tract dysfunction (ANLUTD)” refers to abnormal or difficult function of the bladder, urethra (and/or prostate in men) in mature individuals in the context of clinically confirmed relevant neurological disorder. There is currently no single document focusing on the definitions related to ANLUTD. Many ANLUTD symptoms and signs have been defined in core current terminology reports for lower urinary tract and pelvic floor dysfunction.<sup>3,4,5</sup> With the advantage of ongoing research into ANLUTD epidemiology, pathophysiology as well as pharmacological initiatives by generalist and specialist medical practitioners, it is timely to reconsider the different definitions.

## 2 | METHODOLOGY

This document was developed according to the published methodology of the International Continence Society Standardization Steering Committee.<sup>6</sup> This document aligns with the previous standardizations of the ICS on lower urinary tract dysfunction and is adapted to a group of patients with ANLUTD. Thus, ANLUTD can be diagnosed in the presence of neurological disease only. The intent is to supersede older terminology of “Neurogenic Bladder” or “Neurogenic Bladder Dysfunction”: these definitions are misleading, because the dysfunction(s) may involve not only the bladder but also the urethral sphincter competence or relaxation. Furthermore, using a single term to indicate a broad spectrum of dysfunctions is restrictive and unclear. For instance, there are many differences, in terms of investigations needed, treatment and prognosis, between a male patient with spinal cord injury (SCI) at cervical level and a female patient with Parkinson’s disease, both complaining of Lower Urinary Tract Symptoms (LUTS) and “labeled” as having a “Neurogenic Bladder.” Finally, these definitions could lead to the conviction that the dysfunction may be due to a problem of the bladder, whilst the primary defect is in the central or peripheral nervous system. The document contains some original standardization of LUTS-related definitions, some modified with designation “CHANGED” and some newly defined — “NEW.”

This Terminology Report is inherently and appropriately a definitional document, collating the definitions of those terms, that is, “words used to express a defined concept in a particular branch of study,”<sup>7</sup> here ANLUTD. Emphasis has been on comprehensively including those terms in current use in the relevant peer-reviewed literature. The definitions of those terms will be reviewed with all available evidence. The aim is to assist clinical practice and research. Some new and revised terms have been included. Explanatory notes on definitions have been referred, where

possible, to the “Footnotes” section. Like all the other joint ICS terminology reports, every effort has been made to ensure this Report is:

1. User-friendly: It should be able to be understood by all clinical and research users.
2. Clinically based: Refers to the relevant clinical practice.
3. Origin: Where a term’s existing definition (from one of multiple sources used) is deemed appropriate, that definition will remain and be duly referenced. A large number of these, because of their long-term use, have now become generic, as apparent by their listing in medical dictionaries.
4. Able to provide explanations: Where a specific explanation is deemed appropriate to describe a change from earlier definitions or to qualify the current definition, this will be included as Footnote to this paper. Wherever possible, evidence-based medical principles will be followed.

This document has involved 18 rounds of full review, by co-authors, of an initial draft (Version 1) completed 16.09.2014. Comments for each round of review were collated and debated as necessary in order to form a subsequent version. Live meetings on the document took place in Zurich and Tokyo.\*

This document covers symptoms, signs, urodynamic observations and definitions, clinical diagnoses, and treatment.

## 3 | RESULTS

### 1 ANLUTD SYMPTOMS:

Symptom: Any morbid phenomenon or departure from the normal in structure, function, or sensation, experienced by individual and indicative of disease or a health problem.<sup>2</sup> Symptoms are either volunteered by, or elicited from the individual or may be described by the patient’s caregiver.<sup>3,4,5</sup> LUTS are classified as neurogenic in the presence of a relevant neurological disease ONLY. Symptoms are a subjective indicator of, or change in disease as perceived by the patient, carer, or partner that may lead the patient to seek help from healthcare professionals. They are usually qualitative. In general, LUTS cannot be used to make a definitive diagnosis. LUTS in people with neurological disease can also indicate pathologies other than NLUTD, such as urinary infection.

\*14th International Neuro-Urology Meeting, Zürich 2016 and International Continence Society Meeting, Tokyo, 2016.

Three groups of LUTS are: storage, voiding, and post micturition symptoms.

- 1.1. Storage Symptoms** are experienced during the storage phase of the bladder, (CHANGED).<sup>†</sup>
- 1.1.1. Increased daytime urinary frequency:** Complaint that micturition occurs more frequently during waking hours than previously deemed normal.<sup>5</sup>
- 1.1.2. Nocturia** is waking to pass urine during the main sleep period.<sup>8</sup> (CHANGED)
- 1.1.3. Urgency** is the complaint of a sudden compelling desire to pass urine, which is difficult to defer.<sup>4</sup>
- 1.1.4. Urinary incontinence:** Complaint of involuntary loss of urine.<sup>5</sup> ‡
- 1.1.4.1. Stress Urinary Incontinence** is the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing.<sup>4</sup>
- 1.1.4.2. Urgency Urinary Incontinence** is the complaint of involuntary loss of urine associated with urgency.<sup>5</sup>
- 1.1.4.3. Mixed Urinary Incontinence** is the complaint of involuntary leakage associated with urgency and also with exertion, effort, sneezing, or coughing.<sup>5</sup>
- 1.1.4.4. Enuresis:** Complaint of intermittent incontinence that occurs during periods of sleep<sup>8</sup> (NEW).
- 1.1.4.4.1. Primary enuresis** has been present lifelong (NEW).
- 1.1.4.4.2. Acquired enuresis** is an enuresis developed in adults (NEW).<sup>§</sup>
- 1.1.4.5. Continuous (urinary) incontinence:** Complaint of continuous involuntary loss of urine<sup>5</sup>
- 1.1.4.6. Impaired cognition urinary incontinence:** Complaint of periodic urinary incontinence that the individual with cognitive impairment

<sup>†</sup>Some symptoms in NLUTD cannot be defined properly when there is a significant reduction in motor and/or sensory function. "Complaint" is intended to mean the patient (or sometimes caregiver) expresses the symptom is present, regardless of whether it also causes them bother.

<sup>‡</sup>Loss of urine can result from: (a) incontinence; (b) involuntary passing of urine; (c) incontinence that is not derived from an abnormality in the lower urinary tract or its innervation, but from immobility, cognitive disability, and decreased motivation impaired patient's mobility enhances likelihood of being incontinent.

<sup>§</sup>Mature CNS regulation ensures voiding (detrusor contraction with outlet relaxation) is under voluntary control. Abnormal voiding reflexes, or disinhibition, may result in the person passing urine without voluntary control. Confirming the precise underlying mechanism(s) is often not possible in routine clinical practice. Enuresis is considered different from urgency urinary incontinence.

reports to have occurred without being aware of it. (NEW)

- 1.1.4.7. Impaired mobility urinary incontinence:** Complaint of inability to reach the toilet on time for voiding because of physical or medical disability (NEW).<sup>||</sup>
- 1.1.4.8. Sexual activity urinary incontinence** is the individual report of urinary incontinence associated with or during sexual activity (NEW).<sup>¶</sup>
- 1.1.4.9. Other situational types of urinary incontinence** may exist, for example giggle incontinence, or incontinence associated with epileptic seizures, sphincter denervation in cauda equina and in the Onuf's nuclei lesions in Multiple system atrophy (NEW).
- 1.1.5. Bladder Sensation** can be defined, during history taking by following categories.
- 1.1.5.1. Normal:** the individual is aware of bladder filling and increasing sensation up to a strong desire to void.<sup>4</sup>
- 1.1.5.2. Increased:** Increased bladder sensation: complaint that the desire to void during bladder filling occurs earlier or is more persistent to that previous experienced. N.B. This differs from urgency by the fact that micturition can be postponed despite the desire to void.<sup>5</sup>
- 1.1.5.3. Reduced:** Reduced bladder sensation: complaint that the definite desire to void occurs later to that previously experienced despite an awareness that the bladder is filling.<sup>5</sup>
- 1.1.5.4. Absent:** the individual reports no sensation of bladder filling or desire to void.<sup>4</sup>
- 1.1.5.5. Non-specific bladder awareness:** the individual reports no specific bladder sensation, but may perceive, for example, abdominal fullness,

<sup>||</sup>This inability includes (any combination of) the individual's physical as well as social causes or reasons. Other signs or symptoms of LUTD should not be present, or should be reported by the professional (as primary or as accessory) (eg, "Urgency urinary incontinence" with "mobility impairment"; or "Mobility impairment urinary incontinence" with "stress urinary incontinence.")

<sup>¶</sup>Sexual activity urinary incontinence may be reported as a single symptom, but may also be reported in association with other LUTD. Sexual activity urinary incontinence is documented (in combination with other symptoms) as being the primary or the as the associated symptom (or vice versa) based on the individual's expression of predominance.

vegetative symptoms, urethral sensations or spasticity as bladder filling awareness or a sign of bladder fullness. (CHANGED).

**1.1.5.6. Abnormal sensations:** awareness of sensation in the bladder, urethra or pelvis, described with words like “tingling,” “burning,” or “electric shock,” in the setting of a clinically relevant neurologic disorder (eg, incomplete spinal cord lesion) (NEW).

**1.1.5.7. Bladder Pain:** Complaint of suprapubic or retropubic pain, pressure or discomfort, related to the bladder, and usually increasing with bladder filling. It may persist or be relieved after voiding.<sup>4</sup>

**1.2. Voiding symptoms:** A departure from normal sensation or function, experienced by a person during the act of micturition.<sup>2</sup> #

**1.2.1. Slow stream:** Complaint of a urinary stream perceived as slower compared to previous performance or in comparison with others.<sup>5</sup>

**1.2.2. Spraying (splitting)** of the urinary stream: Complaint that the urine passage is a spray or split rather than a single discrete stream.<sup>5</sup>

**1.2.3. Intermittent stream (Intermittency)** is the term used when the individual describes urine flow, which stops and starts on one or more occasions, during micturition.<sup>4</sup>

**1.2.4. Hesitancy:** Complaint of a delay in initiating micturition.<sup>5</sup>

**1.2.5. Straining to void:** Complaint of the need to make an intensive effort (by abdominal straining, Valsalva or suprapubic pressure) to either initiate, maintain or improve the urinary stream.<sup>5</sup>

**1.2.6. Terminal dribble** is the term used when an individual describes a prolonged final part of micturition, when the flow has slowed to a trickle/dribble.<sup>4</sup>

**1.3. Post Micturition Symptoms** are experienced immediately after micturition.<sup>4</sup>

**1.3.1. Feeling of incomplete emptying:** Complaint that the bladder does not feel empty after micturition.<sup>5</sup>

**1.3.2. Post micturition leakage:** Complaint of a further involuntary passage of urine following the completion of micturition.<sup>4,5</sup>

#Some symptoms in NLUTD cannot be defined properly when there is a significant reduction in motor and/or sensory function.

## 2 ANLUTD SIGNS

**Sign:** Any abnormality indicative of disease or a health problem, discoverable on examination of the patient; an objective indication of disease<sup>2</sup> or a health problem. Signs are observed by the physician including simple means to verify symptoms and quantify them.

Measuring the frequency, severity and impact of lower urinary tract symptoms by asking the patient to record micturitions and symptoms for a period of days provides invaluable information. The recording of “micturition events” can be in three main forms.\*\*

**2.1. Micturition Time Chart:** this records only the times of micturitions, day and night, for at least 24 h.<sup>4</sup>

**2.2. Frequency Volume Chart (FVC):** this records the volumes voided as well as the time of each micturition, day and night, for at least 24 h.<sup>4</sup>

**2.3. Bladder Diary:** this records the times of micturitions and voided volumes, incontinence episodes, pad usage, and other information such as fluid intake, the degree of urgency, and the degree of incontinence.<sup>4,9</sup> ††

## 3 ANLUTD URODYNAMIC OBSERVATIONS AND DEFINITIONS

### 3.1 Filling cystometry definitions

Bladder storage function should be described according to bladder sensation, detrusor activity, bladder compliance and bladder capacity. Storage abnormalities identified may or may not be the result of a clinically relevant neurologic disorder.

#### 3.1.1. Bladder sensation during filling cystometry

**3.1.1.1. Normal bladder sensation** can be judged by three defined points (as per ICS recommendations) noted during filling cystometry: First sensation of bladder filling, First desire to void and Strong desire to void, and evaluated in relation to the bladder volume at that moment and in relation to the patient's symptomatic complaints.<sup>4,7</sup>

**3.1.1.2. Reduced Bladder Sensation:** Bladder sensation perceived to be diminished during filling cystometry.<sup>5</sup>

\*\*Validated questionnaires are useful for recording symptoms, their frequency, severity and bother, and the impact of LUTS on QoL. The instrument used should be specified. Some instruments were not validated in NLUTD or are impossible to implement because of sensory or motor deficiency in NLUTD.

††Recommended minimum duration of 3 days.<sup>9</sup> Some information could be difficult or impossible to collect because of sensory or motor deficiency in NLUTD.

- 3.1.1.3. Absent Bladder Sensation:** The patient reports no bladder sensation during filling cystometry.<sup>5</sup>
- 3.1.1.4. Bladder oversensitivity:** Increased perceived bladder sensation during bladder filling with: an early first desire to void; an early strong desire to void, which occurs at low bladder volume; a low maximum cystometric bladder capacity and no abnormal increases in detrusor pressure.<sup>5</sup>
- 3.1.1.5. Abnormal sensations:** awareness of sensation in the bladder, urethra or pelvis, described with words like “tingling,” “burning,” or “electric shock,” in the setting of a clinically relevant neurologic disorder (eg, incomplete spinal cord lesion) (NEW).
- 3.1.1.6. Non-specific bladder awareness:** perception of bladder filling as abdominal fullness, vegetative symptoms, spasticity or other “non-bladder awareness,” in the setting of a clinically relevant neurologic disorder (eg, incomplete spinal cord lesion) (NEW).
- 3.1.1.7. Bladder Pain:** An unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder. (CHANGED).<sup>‡‡</sup>
- 3.1.2. Bladder capacity during filling cystometry**
- 3.1.2.1. Cystometric capacity** is the bladder volume at the end of the filling cystometry, when “permission to void or to empty the bladder” is usually given. The end point should be specified, for example, if filling is stopped when the patient has a normal desire to void. The cystometric capacity is the volume voided together with any residual urine.<sup>4§§</sup>
- 3.1.3. Detrusor function during filling cystometry**
- 3.1.3.1. Neurogenic detrusor overactivity** is an urodynamic observation characterized by involuntary detrusor contractions during the filling phase which may be spontaneous or provoked in the setting of a clinically relevant neurologic disease.<sup>4 |||</sup>
- Specific types of neurogenic detrusor overactivity include:
- 3.1.3.1.1. Phasic detrusor overactivity** is defined by a characteristic wave form, and may or may not lead to urinary incontinence.<sup>4 ¶¶</sup>
- 3.1.3.1.2. Terminal detrusor overactivity** is defined as involuntary detrusor contraction occurring near or at the maximum cystometric capacity, which cannot be suppressed, and results in incontinence or even reflex bladder emptying (reflex voiding) (CHANGED).<sup>##</sup>
- 3.1.3.1.3. Sustained detrusor overactivity** is defined as a continuous detrusor contraction without returning to the detrusor resting pressure (NEW).
- 3.1.3.1.4. Compound detrusor contraction** is defined as a phasic detrusor contraction with a subsequent increase in detrusor and base pressure with each subsequent contraction (NEW).
- 3.1.3.1.5. High pressure detrusor overactivity** is defined as a phasic, terminal, sustained or compound high maximal detrusor overactivity with the high detrusor pressure perceived by investigator to be potentially detrimental to the patient’s renal function and/or health and the value should be defined in the report (NEW).

<sup>‡‡</sup>The pain may be felt suprapubically or retropubically. It usually increases with bladder filling, and may persist after voiding. Bladder pain may or may not relate to clinically relevant neurologic disorder.

<sup>§§</sup>In certain types of dysfunction including neurogenic LUTD, the cystometric capacity cannot be defined in the same terms. In the absence of sensation, the cystometric capacity is the volume at which the clinician decides to terminate filling. The reason(s) for terminating filling should be defined in the report, for example, high detrusor filling pressure, large infused volume or pain. If there is uncontrollable voiding/bladder emptying, it is the volume at which this begins. In the presence of sphincter incompetence the cystometric capacity may be significantly increased by occlusion of the urethra, for example, by a Foley catheter balloon.<sup>4</sup>

<sup>|||</sup>Provoked contraction may be elicited by cough, change of position etc., or by urethral/sphincter to bladder reflex.

<sup>¶¶</sup>Phasic detrusor contractions are not always accompanied by any sensation, or may be interpreted as a first sensation of bladder filling, or as a normal desire to void. In neurogenic LUTD phasic detrusor contraction may elicit autonomic dysreflexia or abnormal bladder sensation.

<sup>##</sup>Terminal detrusor overactivity is typically associated with reduced bladder sensation, for example in the elderly stroke patient when urgency may be felt as the voiding contraction occurs. However, in neurogenic LUTD phasic detrusor contraction may elicit autonomic dysreflexia or abnormal bladder sensation and in complete spinal cord injury patients there may be no sensation whatsoever.

**3.1.3.1.6. Neurogenic Detrusor Overactivity Incontinence** is incontinence due to involuntary neurogenic detrusor overactivity (NEW).<sup>\*\*\*</sup>

**3.1.3.2. Leak point pressures:**

**3.1.3.2.1. Detrusor Leak Point Pressure (DLPP)** is defined as the lowest detrusor pressure at which urine leakage occurs in the absence of either a detrusor contraction or increased abdominal pressure.<sup>4</sup>

**3.1.3.2.2. Detrusor Overactivity Leak Point Pressure (DOLPP)** is defined as the lowest detrusor pressure rise with detrusor overactivity at which urine leakage first occurs in the absence of voluntary detrusor contraction or increased abdominal pressure (NEW).

**3.1.3.2.3. Detrusor Leak Point Volume (DLPV)** is defined as a bladder volume at which first urine leakage occurs, either with detrusor overactivity or low compliance (NEW).

**3.1.3.2.4. Abdominal Leak Point Pressure (ALPP)** is the intravesical pressure at which urine leakage occurs due to increased abdominal pressure in the absence of a detrusor contraction.<sup>4 †††</sup>

**3.1.3.2.5. Bladder compliance** during filling cystometry describes the relationship between change in bladder volume

and change in detrusor pressure.<sup>4 †††</sup>

### 3.2. Pressure Flow Study Definitions

**3.2.1. Detrusor function** during the voiding phase in people that can initiate voluntary voiding

**3.1.3.2.1. Normal detrusor function** is a voluntarily initiated continuous detrusor contraction that leads to complete bladder emptying within a normal time span, and in the absence of obstruction. For a given detrusor contraction, magnitude of the recorded pressure rise will depend on the degree of outlet resistance.<sup>4</sup>

**3.1.3.2.2. Neurogenic detrusor underactivity** is defined as a contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span in the setting of a clinically relevant neurologic disorder (NEW).

**3.1.3.2.3. Neurogenic acontractile detrusor** is one that cannot be demonstrated to contract during urodynamic studies in the setting of a clinically relevant neurologic lesion (NEW).

**3.1.3.2.4. Balanced bladder emptying** is a bladder emptying with physiological detrusor pressure and low residual as perceived by the investigator, and should be defined in the report (NEW).

<sup>†††</sup>Compliance is calculated by dividing the volume change ( $\Delta V$ ) by the change in detrusor pressure ( $\Delta p_{det}$ ) during that change in bladder volume ( $C = \Delta V / \Delta p_{det}$ ). It is expressed in mL/cm H<sub>2</sub>O. The normal value are not well defined however any report on compliance must include reference to the rate of filling and position of patient. A variety of means of calculating bladder compliance has been described. The ICS recommends that three standard points should be used for compliance calculations: the investigator may wish to define additional points. These points are measured excluding any detrusor contraction. The standards points are: (1) The detrusor pressure at the start of bladder filling and the corresponding bladder volume (usually zero). (2) The detrusor pressure at the bladder volume when the bladder pressure rises significantly and decreased compliance commences (Low compliance starting volume). (3) The detrusor pressure (and corresponding bladder volume) at cystometric capacity or immediately before the start of any detrusor contraction that causes significant leakage (and therefore causes the bladder volume to decrease, affecting compliance calculation).

<sup>\*\*\*</sup>Incontinence can occur with or without any sensation of urgency or awareness.

<sup>†††</sup>This test can be applied to both neurogenic and non-neurogenic patients with stress urinary incontinence.

**3.2.2.** Detrusor function during pressure flow studies in people that cannot initiate voluntary voiding.

**3.2.2.1. Initiated reflex bladder emptying** is an artificially elicited LUT reflex comprised of various manoeuvres (exogenous stimuli) performed by the patient or the therapist, resulting in complete or incomplete bladder emptying (NEW).<sup>§§§</sup>

**3.2.3** Sphincter function during pressure flow studies

**3.2.3.1. Detrusor-Sphincter Dyssynergia (DSD):** describes a detrusor contraction concurrent with an involuntary contraction of the urethral and/or periurethral striated muscle. Occasionally flow may be prevented altogether.<sup>¶¶¶¶</sup>

**3.2.3.2. Non-relaxing urethral sphincter** is characterized by a non-relaxing, obstructing urethral sphincter resulting in reduced urine flow.<sup>¶¶¶¶¶</sup>

**3.2.3.3. Delayed relaxation of the urethral sphincter** is characterized by impaired and hindered relaxation of the sphincter during voiding attempt resulting in delay of urine flow (NEW).<sup>###</sup>

#### 4 ANLUTD CLINICAL DIAGNOSES

Clinical diagnoses are the clinical manifestation of symptoms and signs, which are characterized by specific urodynamic findings and/or non-urodynamic evidence defined by the presence of urodynamic observations associated with characteristic symptoms or signs and/or non-urodynamic evidence of relevant pathological process.

<sup>§§§</sup>Spontaneous reflex bladder emptying is termed Detrusor Overactivity Incontinence

<sup>¶¶¶¶</sup>Neurological disease that impairs the ability of the PMC or its pathways to co-ordinate function of the LUT spinal centres, leading to detrusor contraction against a contracting outlet. Detrusor sphincter dyssynergia (DSD) typically occurs in patients with a supra-sacral lesion, and is uncommon in lesions of the lower cord. DSD is responsible for bladder outlet obstruction and occasionally flow may be prevented altogether.

<sup>¶¶¶¶¶</sup>Non-relaxing sphincter obstruction is found in individuals with a neurological lesion (sacral and infra-sacral lesions such as meningomyelocoele) and after radical pelvic surgery. It may relate to both smooth and striated muscle sphincter.

<sup>###</sup>This can occur in some patients with Parkinson's disease or muscular dystrophy

This depends on the extent of loss of neurological function and depends on which part(s) of the nervous system is affected. Neural lesions are described according to time of onset, risk of neurological progression, completeness, and neurological level.

**4.1. Spinal Shock Phase** is usually temporary following acute neurologic insult or SCI that is characterized by loss of sensory, motor and reflex activity below the level of injury. NLUTD in Spinal Shock: is usually a temporary complete painless urinary retention (NEW).

**4.2. Suprapontine Lesion (SPL)** is a neurological lesion above the pons (forebrain or midbrain). NLUTD in SPL: there is a reflex contraction of the detrusor with impaired cerebral regulation and central inhibition and usually synergistic voiding/bladder emptying (NEW).<sup>\*\*\*\*</sup>

**4.3. Suprasacral spinal cord/pontine lesion (SSL)** is a neurological lesion in suprasacral spine and/or pons. NLUTD in SSL: Detrusor overactivity (DO) and DO incontinence are common, with or without detrusor-urethral sphincter dyssynergia (DSD), often resulting in a significant post void residual (PVR) and "high pressure" bladder (NEW).<sup>††††</sup>

**4.4. Sacral Spinal Cord Lesion (SSCL)** is a neurological lesion in the sacral spinal cord. NLUTD in SSCL; findings include acontractile detrusor with or without decreased bladder compliance and usually with impaired sphincter activity. (NEW).<sup>\*\*\*\*</sup>

<sup>\*\*\*\*</sup>Lesions resulting from cerebral or brainstem lesion with preservation of the pontine micturition center (PMC), that is, cerebrovascular disease, degenerative disease, hydrocephalus, intracranial neoplasms, traumatic brain injury (the list is incomplete). This may lead to inability to initiate voiding, inappropriate timing of bladder emptying, detrusor overactivity (DO), and DO incontinence.

<sup>††††</sup>Lesion persists after resolution of the spinal shock. Bladder sensation may be somewhat preserved (incomplete lesions) but voluntary control of the micturition reflex arc is lost. Altered function of the sympathetic spinal centre in the thoraco-lumbar spinal cord may alter blood pressure control. Complete SSL above T6 may be associated with autonomic dysreflexia when there is residual sympathetic nucleus function; this should be included in the description of the lesion.

<sup>\*\*\*\*</sup>There is a loss of parasympathetic control of the detrusor and a somatic denervation of the external urethral sphincter. Sensory impairment is typically associated with a complete lesion. Some afferent pathways remain intact due to potential preservation of hypogastric afferents. Some patients may have stress urinary incontinence (SUI) due to sphincter deficiency (loss of Onuf's nuclei).

- 4.5. Infrasacral (cauda equina and peripheral nerves) Lesion (CEPNL)** is a neurological lesion affecting the cauda equina and/or peripheral nerves. NLUTD in CEPNL: acontractile detrusor and/or SUI may be present. In diabetic neuropathy, detrusor overactivity can be seen in combination with the above (NEW).<sup>§§§§</sup>
- 4.6. Mixed Neuronal Lesion** is resulting from lesions of the neural pathway at different levels of the central nervous system concurrently (NEW)
- 4.7. Autonomic Dysreflexia** is a syndrome resulting from upper thoracic or cervical spinal cord injury above T6, elicited by a stimulus in the field of distribution of the autonomous sympathetic nucleus, characterized by unregulated sympathetic function below the lesion and compensatory autonomic responses (NEW).<sup>|||||</sup>
- 4.7.1. Asymptomatic Autonomic Dysreflexia:** increase of blood pressure without any other symptoms (NEW).<sup>¶¶¶¶</sup>
- 4.8. Neurogenic Overactive Bladder** is characterized by urgency, with or without urgency urinary incontinence, usually with increased daytime frequency and nocturia in the setting of a clinically relevant neurologic disorder with at least partially preserved sensation (NEW).<sup>####</sup>
- 4.9. Voiding dysregulation** is urination in situations which are generally regarded as socially inappropriate, such as while still fully dressed, or in a public setting away from toilet facilities (NEW).
- 4.10. Involuntary voiding** is both a symptom and a diagnosis of sporadic bladder emptying

<sup>§§§§</sup>The peripheral nerves and the lower spinal centres are often grouped under the term “lower motor neurones,” as damage to these structures causes loss of contractile function. Elsewhere, the neurological lesions are termed “upper motor neuron lesions,” where the consequences are impaired co-ordination and reflex function. This is a considerable simplification, and anatomically inaccurate, so the committee considers categorization into lower versus upper motor neuron lesions should no longer be supported.

<sup>|||||</sup>It is potentially a medical emergency characterized by hypertension, bradycardia, severe headaches, and flushing above, with pallor below the cord lesion, and sometimes convulsions.<sup>10</sup>

<sup>¶¶¶¶</sup>This can happen during routine urodynamic bladder studies or bowel program.<sup>11</sup>

<sup>####</sup>These symptom combinations in case of preserved sensation, are suggestive of urodynamically demonstrable detrusor overactivity, but can be due to other forms of LUTD. These terms can be used if there is no proven infection or other obvious non neurological disease.

when awake, without intention to void (NEW).<sup>\*\*\*\*\*</sup>

- 4.11. Urinary retention** is an inability to properly empty the bladder and can be divided into acute, chronic, complete and incomplete (NEW).

**4.11.1. Acute retention** of urine is defined as an acute event of painful, palpable or percussable bladder, when the patient is unable to pass any urine when the bladder is full.<sup>5 †††††</sup>

**4.11.2. Chronic retention** of urine is defined as a non-painful bladder, which remains palpable or percussable after the patient has passed urine. Such patients may be incontinent.<sup>4‡‡‡‡‡</sup>

**4.11.3. Complete urinary retention** is an inability to empty any amount of bladder volume (or the requirement for use of a catheter, consciously or unconsciously due to anatomical or functional bladder outlet obstruction, detrusor underactivity or both (NEW).

**4.11.4. Incomplete urinary retention** is impaired bladder emptying due to anatomical or functional bladder outlet obstruction, detrusor underactivity or both, when the voided volume is smaller than Post Void Residual.

**4.11.5. Post void residual (PVR)** is defined as the volume of urine left in the bladder at the end of micturition.<sup>4</sup>

<sup>\*\*\*\*\*</sup>Usually the voiding reflex is preserved, and there is only lack of proper inhibition of the voiding reflex. If that happens when asleep it is called Acquired Enuresis.

<sup>†††††</sup>Although acute retention is usually thought of as painful, in certain circumstances pain may not be a presenting feature, for example, when due to prolapsed intervertebral disc, post-partum, or after regional anaesthesia such as an epidural anaesthetic. The retention volume should be significantly greater than the expected normal bladder capacity. In patients after surgery, due to bandaging of the lower abdomen or abdominal wall pain, it may be difficult to detect a painful, palpable, or percussable bladder.<sup>4</sup>

<sup>‡‡‡‡‡</sup>The ICS no longer recommends the term “overflow incontinence” This term is considered confusing and lacking a convincing definition. If used, a precise definition and any associated pathophysiology, such as reduced urethral function, or detrusor overactivity/low bladder compliance, should be stated. The term chronic retention, excludes transient voiding difficulty, for example, after surgery for stress incontinence, and implies a significant residual urine; a minimum figure of 300 mls has been previously mentioned.<sup>4</sup>

## 5 ANLUTD TREATMENTS DEFINITIONS

- 5.1 Bladder Reflex Triggering** comprises various manoeuvres performed by the patient or the therapist to elicit reflex bladder emptying by exteroceptive stimuli (relating to, being, or activated by stimuli received from outside of the bladder).<sup>4</sup> §§§§§
- 5.2 Bladder Expression** refers to various compression manoeuvres aimed at increasing intravesical pressure to facilitate bladder emptying with or without obvious sensation from the bladder. (CHANGED).<sup>¶¶¶¶¶</sup>
- 5.3 Catheterization** is a technique for bladder emptying employing a catheter to drain the bladder or a urinary reservoir.<sup>4</sup>
- 5.3.1. Indwelling catheterization;** an indwelling catheter remains in the bladder, urinary reservoir or urinary conduit for a period longer than one emptying.<sup>4</sup> ¶¶¶¶¶
- 5.3.2. Intermittent Catheterization (IC)** is defined as drainage of the bladder or a urinary reservoir with subsequent removal of the catheter mostly at regular intervals. (CHANGED)
- 5.3.2.1. Clean IC (CIC):** use of a clean technique. This implies ordinary hand and genitals washing techniques and use of disposable or cleansed reusable catheters. (CHANGED)
- 5.3.2.2. Aseptic IC:** This implies genital antiseptic preparation and the use of sterile (single-use) catheters and instruments/ gloves in a designated clean area. (NEW)
- 5.3.2.3. Sterile IC:** Complete sterile setting, including genital skin antiseptics, sterile gloves, forceps, gown and mask (NEW).<sup>#####</sup>
- 5.3.2.4. No-touch technique IC:** This was introduced as an easier way for the patient to perform self-intermittent catheterization with a ready-to-use catheter (pre-lubricated catheter, usually a hydrophilic catheter). A pull-in aid or special packages

§§§§§The most commonly used manoeuvres are; suprapubic tapping, thigh scratching, and anal/rectal manipulation.

¶¶¶¶¶The most commonly used manoeuvres are; abdominal straining (Valsalva's manoeuvre) and exerting manual suprapubic pressure (Crede's manoeuvre).

¶¶¶¶¶Indwelling catheterization may be performed transurethral, suprapubic or trans-conduit.

#####Usually performed in the surgical theatre or during diagnostic procedures.

are used to handle the catheter without directly touching the sliding surface of the hydrophilic catheter (NEW).<sup>\*\*\*\*\*</sup>

## 5.4 Electrostimulation

- 5.4.1. Direct electrical neurostimulations** a direct stimulation of the nerves or neural tissue to effect function of the end organ. It is done through electrodes implanted directly or near the nerve or neural tissue (NEW).<sup>+++++</sup>
- 5.4.2. Electrical neuromodulation** is the stimulation of the nerves or neural tissue to modulate function and induce therapeutic response of the LUT (NEW).<sup>#####</sup>
- 5.4.3. Transcutaneous electrical nerve stimulation (TENS)** is electrical stimulation of the nerves through intact skin to modulate function and induce therapeutic response of the LUT (NEW).<sup>§§§§§</sup>
- 5.4.4. Pelvic electrical stimulation** is the application of electrical current to stimulate the pelvic viscera or their nerve supply (NEW).<sup>¶¶¶¶¶</sup>

## 4 | CONCLUSIONS

Standardized terminology is an important aspect on research and communication in NLUTD. The International Continence Society (ICS) continues to have a key role in standardizing terminology related to lower urinary tract and pelvic organ dysfunction.

\*\*\*\*\*The ICS Working Group recognizes that there is a lack of uniformity and consensus on the classification of aseptic technique in previously published studies, especially with regard to genital hygiene. Thus, it is strongly recommended that all aspects related to the technique of intermittent catheterization are described as completely as possible in the context of clinical research, including the environment in which catheterization is performed, the type of lubricant, the catheter characteristics, the use of gloves, as well as the genital hygiene mode.

+++++For example, stimulation of the anterior sacral roots, that is, Brindley's stimulator.

#####It is done through electrodes implanted directly on or near the nerves or neural tissue: Sacral Neuromodulation (SNM), Pudendal Nerve Stimulation (PNS), Percutaneous Tibial Nerve Stimulation (PTNS), Spinal cord stimulation (SCS), Deep brain stimulation (DBS).

§§§§§This is done by skin surface electrode(s), as touch plate(s) or superficial needle(s). Long-term or chronic electrical stimulation is delivered below the sensory threshold. Maximal electrical stimulation is using a high-intensity stimulus (just below the pain threshold). This can be done intermittently.

¶¶¶¶¶The aim of electrical stimulation may be to directly induce a therapeutic response or to modulate lower urinary tract, bowel, or sexual dysfunction through transvaginal or transrectal stimulation.

**Introduction:** The terminology for nocturia and nocturnal lower urinary tract function is reviewed and updated in a clinically and practically-based consensus report.

**Methods:** This report has been created by a Working Group under the auspices and guidelines of the International Continence Society (ICS) Standardisation Steering Committee (SSC). All relevant definitions were updated on the basis of research over the last 16 years since the publication of the first nocturia standardization document in 2002. An extensive process of 16 rounds of internal and external reviews was involved to examine each definition exhaustively, with decision-making by collective opinion (consensus).

**Results:** A clinically-based terminology report for nocturia and nocturnal lower urinary tract function, encompassing five key definitions divided into signs and symptoms has been developed. Clarity and user-friendliness have been key aims to make it interpretable by healthcare professionals and allied healthcare practitioners involved in the care of individuals with nocturnal lower urinary tract function.

**Conclusion:** A consensus-based terminology report for nocturia and nocturnal lower urinary tract function has been produced to aid clinical practice and research.

enuresis, International Continence Society, nocturia, nocturnal polyuria, terminology

## 1 | INTRODUCTION

In 2002, the International Continence Society (ICS) defined nocturia as the complaint that the individual has to wake at night one or more times to void.<sup>1</sup> Since that original

publication, several studies have been conducted looking at the epidemiology, pathophysiology and treatment of nocturia, leading to a wealth of new information.<sup>2,3</sup> The time has now come to review the terminology in the original publication since it has been established that nocturia may not be a

Hashim Hashim, Marco H. Blanker, Marcus J. Drake, Jens Christian Djurhuus, Jane Meijlink, Vikky Morris, Peter Petros, Jian Guo Wen, and Alan Wein: ICS Terminology Working Group on Nocturia and Nocturnal Lower Urinary Tract Function.

Marcus J. Drake and Jane Meijlink: Standardisation Steering Committee ICS. At time of publication, Marcus Drake was an ICS Trustee.

complaint and that people can get up at night to void for various reasons which may or may not be pathological.<sup>4</sup> Nocturia can also occur as a clinical entity in its own right due to non-medical reasons such as a baby crying, or a partner snoring, causing the individual to wake up at night to pass urine. In these latter scenarios, nocturia would have been excluded in the 2002 definition as the person would have not woken up to void due to a complaint, but rather due to a convenience void.

Nocturia may also be present as part of other conditions which may or may not be directly related to the urinary tract, for example, heart failure or sleep apnea. Therefore, patients can present to and consult not only urologists but also other clinicians such as gynecologists, geriatricians, neurologists, sleep experts, endocrinologists, cardiologists, immunologists, rheumatologists, and/or general practitioners. Each specialist is likely to approach nocturia in a different way depending on the presentation. However, it is important that all healthcare providers speak the same “language” and refer to the same condition using specific definitions, in order to avoid confusion and any misunderstandings.

The ICS therefore formed a new working group to revise and update the 2002 standardization document on nocturia and make new recommendations on terminology based on the published literature over the last 16 years. This terminology report is inherently and appropriately a definitional document, collating the definitions of those terms, that is, “words or phrases used to describe a thing or to express a concept, especially in a particular kind of language or branch of study,”<sup>5</sup> here nocturia and nocturnal lower urinary tract function. Emphasis has been on comprehensively including those terms in current use in the relevant peer-reviewed literature. The definitions of those terms will be reviewed with all available evidence and aim to assist clinical practice and research. Some new and revised terms have been included. Explanatory notes on definitions have been referred, where possible, to the “footnotes” section. This document does not address the epidemiology, pathophysiology or treatment of nocturia or any of its sub-categories, as that is not the main aim of the Standardisation Steering Committee (SSC) or the nocturia working group, is beyond the scope of this article, and is covered in several other publications.<sup>2,3,6–11</sup>

Like all other joint ICS terminology reports, every effort has been made to ensure this report is:

*User-friendly:* It should be understandable by all clinical and research users.

*Clinically-based:* The definitions should be applicable to clinical practice.

*Original:* Where a term's existing definition (from one of multiple sources used) is deemed appropriate, that definition will remain and be duly referenced.

*Able to provide explanations:* Where a specific explanation is deemed appropriate to describe a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (*Footnote [FN] 1,2,3...*). Wherever possible, evidence-based medical principles will be followed.

It is suggested that acknowledgement of these standards in written publications related to nocturia and nocturnal lower urinary tract function be indicated by a footnote to the section “Methods and Materials” or its equivalent, to read as follows: “Methods, definitions and units conform to the standards recommended by the International Continence Society Nocturia and Nocturnal Lower Urinary Tract Function Terminology Standard 2018, except where specifically noted”.

Relevant ICS 2002 and 2010 definitions are highlighted for ease of reference and comparison. The 2018 definitions (Table 1) will be added if there are any changes to the previous definitions.

## 2 | GENERAL DEFINITIONS

### 2.1 | Symptom(s)

**2002:** The subjective indicator of a disease or change in a condition as perceived by the patient, carer or partner, and may lead him/her to seek help from healthcare professionals. Symptoms may either be volunteered or described during the patient interview. They are usually qualitative. In general, Lower Urinary Tract Symptoms (LUTS) cannot be used to make a definitive diagnosis. LUTS can also indicate pathologies other than lower urinary tract dysfunction (LUTD), such as urinary tract infection.<sup>12</sup>

**2010:** Any morbid phenomenon or departure from the normal in structure, function, or sensation; experienced by the person and indicative of disease or a health problem. Symptoms are either volunteered by, or elicited from the person, or may be described by the person's caregiver.<sup>13,14</sup>

**2018:** The previous definitions have not been changed.

### 2.2 | Sign(s)

**2002:** Signs are observed by the physician including simple means, to verify symptoms and quantify them. For example, a classic sign is the observation of leakage on coughing. Observations from frequency/volume charts, pad tests and validated symptom and quality of life questionnaires are examples of other instruments that can be used to verify and quantify symptoms.<sup>12</sup>

**2010:** Any abnormality indicative of disease or a health problem, discoverable on examination of the

**TABLE 1** Definitions of terms related to nocturia and nocturnal lower urinary tract function (2018)

Term	Definition
Main sleep period (new)	The period from the time of falling asleep to the time of intending to rise for the next “day.”
First morning void (changed)	The first void after the main sleep period.
Enuresis (changed)	Symptom: complaint of intermittent incontinence that occurs during periods of sleep. If it occurs during the main sleep period, then it could be qualified by the adjective “nocturnal.” Sign: Intermittent incontinence (“wetting”) that occurs during periods of sleep (while asleep). If it occurs during the main sleep period then it could be preceded by the adjective “nocturnal.”
Night-time (changed)	Commences at the time of going to bed with the intention of sleeping and concludes when the individual decides they will no longer attempt to sleep and rise for the next “day.” It is defined by the individual’s sleep cycle, rather than the solar cycle (from sunset to sunrise).
Night-time frequency (changed)	The number of voids recorded from the time the individual goes to bed with the intention of going to sleep, to the time the individual ends their main sleep period with the intention of rising.
Nocturia (changed)	Symptom: The number of times urine is passed during the main sleep period. Having woken to pass urine for the first time, each urination must be followed by sleep or the intention to sleep. This should be quantified using a bladder diary. Sign: The number of times an individual passes urine during their main sleep period, from the time they have fallen asleep up to the intention to rise from that period. This is derived from the bladder diary.
Nocturnal polyuria (changed)	Symptom: Passing large volumes of urine during the main sleep period. This should be quantified using a bladder diary. Sign: Excessive production of urine during the individual’s main sleep period. This should be quantified using a bladder diary.
Nocturnal urine volume (changed)	Sign: Total volume of urine produced during the individual’s main sleep period including the first void after the main sleep period. This should be quantified using a bladder diary.
24-h voided volume (changed)	Sign: Total volume of urine passed during a 24-h period excluding the first morning void of the period. The first void after rising is discarded and the 24-h period begins at the time of the next void and is completed by including the first void, after rising, the following day.
24-h polyuria (not changed)	Excessive excretion of urine resulting in profuse and frequent micturition. Defined as >40 mL per kg body weight per 24-h.

patient; an objective indication of disease or a health problem.<sup>14</sup>

These can be quantified by a questionnaire or bladder diary.

**2018:** The previous definitions have not been changed.

*Nocturnal:* Refers to “Done, occurring, or active at night.”<sup>5</sup> Therefore, “nocturnal” will refer to signs and symptoms that occur during the night-time.

*Night-time (Changed):* For the purposes of the nocturia 2018 terminology, night-time will be defined by the individual’s sleep cycle, rather than the solar cycle (from sunset to sunrise). Thus, some shift workers may have their “night-time” period during the daylight hours, as it is the time of their main sleep period. It commences at the time of going to bed with the *intention* of sleeping and concludes when the individual decides they will no longer attempt to sleep and rise for the next “day.”

*Main sleep period (New):* The period from the time of *falling asleep* to the time of *intending to rise* for the next “day.”

*Frequency:* The frequency is the number of times an event occurs during a stated period.

### 3 | NOCTURNAL SYMPTOMS

#### 3.1 | Nocturia

**2002:** The complaint that the individual has to wake at night one or more times to void.<sup>1</sup>

**2010:** Complaint of interruption of sleep one or more times because of the need to micturate.<sup>14</sup> Each void is preceded and followed by sleep.

**2018:** The number of times urine is passed during the main sleep period. Having woken to pass urine for the first time, each urination must be followed by sleep or the intention to sleep. This should be quantified using a bladder diary.<sup>a</sup>

#### 3.2 | Core reasons for change

The 2002 and 2010 definitions of nocturia have caused much debate and controversy, including the fact that getting up once at night to void may not be bothersome and is therefore not a “complaint.” Furthermore, it can be difficult to determine the “reason for waking” and to confirm that waking was indeed in order to pass urine. What clinicians and researchers wanted

was to define a clinical condition. Also, the previous ICS definitions of nocturia did not take into account the voiding episodes at night during the main sleep period of several groups of people, including but not limited to:

1. those who need to void multiple times in the night after falling asleep, often several times in a row, small amounts at a time, and may not be able to get back to sleep again,
2. those whose bladder does not empty fully, and who consequently need to void again several times soon after going to sleep,
3. those who suffer from insomnia or have difficulty going back to sleep due to causes other than their bladder problem,
4. those who wake up and then are unable to sleep due to painful or sensitive bladders.

Furthermore, while various studies have been published on nocturia, only few have critically discussed the definition of nocturia. In fact, nocturia has not been defined at all in many studies. The new definition reflects the fact that nocturia is first a symptom, which may or may not be a complaint (ie, of an abnormality), with mixed and multiple etiologies and a prevalence in the general population which is well described for men and women of different ages worldwide.<sup>2,15,16</sup>

Night-time frequency can sometimes be confused with nocturia. However night-time frequency includes voids when an individual goes to bed, with the intention of sleeping, but cannot sleep and needs to void at least once before falling asleep (2002 nocturia document). For example, if an

individual goes to bed at 10 pm and passes urine three times before falling asleep at 11pm, then the three episodes are not part of nocturia, as nocturia starts when the person falls asleep but these are part of night-time frequency (Figure 1).

Another, scenario that may cause confusion is if an individual wakes up at, for example, 3 am from sleep and could not sleep although they want to sleep, and passes urine at 4 and 6 am, and then decides to end his/her sleep period at 7 am, then these voids are part of nocturia episodes.

In other words, nocturia episodes begins when the individual falls asleep and ends with the intention of getting up for the day. These, and other scenarios, will be highlighted by careful analysis of the bladder diary, which is a mandatory first-line investigation tool for the management of patients with LUTS (Figure 2). This document aims is to generalize the definitions to apply to all groups of patients with the symptom of nocturia.<sup>b</sup>

### 3.3 | Analysis of bladder diary

1. Nocturia by 2002/2010 definition: 1 (the only void that was preceded and followed by sleep was the one at 23.00). It could also be argued that nocturia could be three episodes as the voids at 1.00am and 3.00am were preceded and followed by sleep but the return to sleep was delayed. This depends on whether the definition is strictly applied or not. Either way, the definition misses out on nocturia episodes.
2. Nocturia by 2018 definition: 4 (the total number of voids after falling asleep at 22.30 and before the individual decides to get up for the day at 08.00).

	Scenario				
	1	2	3	4	5
<b>Time</b>					
10pm	Bed & Sleep	Bed	Bed	Bed	Bed
11pm		X	X	X	X
12am		Sleep	Sleep	Sleep	Sleep
1am					
2am	Wake to void X Sleep after Void	Wake to Void X Sleep after Void	Wake to Void X	Wake to Void X	Wake to Void X Sleep after Void
3am				X	
4am	Wake to Void X Sleep after Void	Wake to Void X Sleep after Void	X Sleep after Void	X Sleep after Void	Wake to Void X
5am					X Intention to Sleep but not able to
6am					
7am	Wake & Rise for the day	Wake & Rise for the day	Wake & Rise for the day	Wake & Rise for the day	Rise for the day

**FIGURE 1** Different scenarios highlighting difference between the different definitions of night-time frequency (NF), previous nocturia definition (N2002), and new nocturia definition (N2018). (X denotes micturition)

Night-time	
Time	Voided volume (mL)
Time of falling asleep: 22.30	
23.00	100 (woke up to void and went back to sleep)
01.00	150 (woke up to void but could not sleep after void although wanted to sleep)
03.00	100 (voided again and then fell asleep)
06.00	200 (woke up to void but could not sleep after void although wanted to sleep)
08.00	100 (decision to get up for the day)

**FIGURE 2** Example of nocturia using a single night extracted from a bladder diary<sup>c</sup>

**3.4 | Nocturnal polyuria (NP)**

**2002:** Not defined as a symptom.

**2010:** Not defined as a symptom.

**2018:** Passing large volumes of urine during the main sleep period. This should be quantified using a bladder diary.

**3.5 | Core reasons for change**

The previous standardization reports have not highlighted nocturnal polyuria as a symptom, but looked at it as a sign. However, we know from clinical practice that patients can report passing large volumes of urine at night, especially relative to the day, and hence we have defined the symptom of nocturnal polyuria.

**3.6 | Enuresis**

**2002:** Any involuntary loss of urine. If it is used to denote incontinence during sleep, it should always be qualified with the adjective “nocturnal.”<sup>1</sup>

**2010:** Complaint of involuntary loss of urine which occurs during sleep.<sup>14</sup>

**2018:** Complaint of intermittent incontinence that occurs during periods of sleep. If it occurs during the main sleep period, then it could be qualified by the adjective “nocturnal.” The patient has to be asleep when enuresis happens and is usually unaware of it. If the patient is woken from sleep and then leaks or has incontinence then this would be classified according to the pathophysiology of incontinence while awake, for example, stress urinary incontinence, urgency urinary incontinence, mixed urinary

incontinence, etc. The timing of leakage, whether during sleep or after being woken up and then leaking, is established when taking a detailed clinical history from the patient by asking them, for example, “Does the wetting/leakage occur while you are asleep and unaware of it or do you get woken up and then leak?”<sup>d</sup>

**3.7 | Core reasons for change**

Enuresis is a symptom reflecting several different pathologies, previously believed to be a complete emptying of the bladder, but later identified as both complete and incomplete emptying of the bladder. The International Children’s Continence Society (ICCS) defined nocturnal enuresis as both a symptom and a condition of intermittent incontinence that occurs during periods of sleep.<sup>17–19</sup> Previously it was wetting in discrete portions while asleep after the age of five. To ensure consistency between the ICCS and the ICS definitions, the ICS has adapted the ICCS definition.

**4 | NOCTURNAL SIGNS**

**4.1 | Nocturia**

**2002:** Not specifically defined.

**2010:** Not specifically defined.

**2018:** The number of times an individual passes urine during their main sleep period, from the time they have fallen asleep up to the intention to rise from that period. This is derived from the bladder diary.

In order to capture the frequency of nocturia, a bladder diary is needed on which the patient indicates the time of

falling asleep, the time when they decided they would no longer attempt to sleep, and all intervening voids. A bladder diary is needed to ascertain nocturnal urine production, with complete recording of all volumes voided during the main sleep period. Measurement of the frequency of nocturia begins after sleep and concludes before the first void following intention of getting up for the day.<sup>c</sup> The individual can also note why they went to void, for example, due to urgency, pain, etc.

#### 4.2 | Nocturnal polyuria (NP)<sup>3–5</sup>

**2002:** Nocturnal urine volume output greater than 20% of the daily total urine output in the young and 33% in the elderly, with the value for middle age probably falling somewhere in the middle. Increased proportion of a 24-h urine output occurring at night (normally during the 8 h while the patient is in bed).<sup>12</sup>

**2010:** Excess (over 20–30%—age dependent) proportion (nocturnal voided volume/total 24 h voided volume  $\times$  100%) occurs at night (or when patient is sleeping).<sup>14</sup>

**2018:** Excessive production of urine during the individual's main sleep period. The definition used by the health-care provider to quantify “excessive” will need to be highlighted in both clinical and research settings and should be derived from a bladder diary.

#### 4.3 | Core reasons for change

There have been numerous ways of classifying nocturnal polyuria.<sup>20</sup> From clinical practice, we have learned that the 20% and 33% numbers (the nocturnal polyuria index) are not well supported, as they were not based on normal distributions and were not properly validated. They also assumed that the index person is 70 kg and sleeps 8 h a day, irrespective of gender or age. Regardless of what definition is applied, the diagnosis of NP includes a differential diagnosis encompassing congestive heart failure, diabetes mellitus, obstructive sleep apnea, peripheral edema, excessive night-time fluid intake and “normal” ageing. Other factors which have been implicated in the causation of nocturnal polyuria are an abnormality in nocturnal secretion or action of arginine vasopressin (AVP) (this describes the classical nocturnal polyuria syndrome) and any edema-forming state (in addition to congestive heart failure, chronic renal disease, nephrotic syndrome, hypoalbuminemia, liver failure), co-morbidities such as autonomic nervous system dysfunction, Alzheimer's disease, multisystem atrophy, stroke, and Parkinsonism. Hence the need for standardization!

Terms that can be used to define urine production at night include:

1. 24-h urine production rate (mLs/h): volume of urine produced per hour in a 24 h period.
2. nocturnal urine production rate (mLs/h): nocturnal urine volume/length of time of main sleep period (mLs/h).
3. nocturnal urine production rate index: nocturnal urine production rate/24-h urine production rate.

Absolute and normal values are yet to be defined for the above terms, but will be dependent on fluid input, the population defined, and the gender. There are several definitions in the literature that could be used to indicate nocturnal polyuria<sup>f</sup> including:

1. Nocturnal urine production based on body weight of greater than 10 mLs/kg.<sup>21</sup>
2. Rate of nocturnal urine production >90 mLs/h.<sup>22</sup> This figure is suggestive of nocturnal polyuria in *men* only (about 450 mLs per 8 h sleep).<sup>23</sup> There are no studies looking at the rate of nocturnal urine production in women and this may well be different from that in men.
3. Nocturnal polyuria index is the most commonly used definition for nocturnal polyuria<sup>20</sup> (nocturnal urine volume/24-h voided volume)<sup>1</sup> based on nocturnal urine volume as part of total 24-h urine volume. It is age dependent; however the age groups have not been clearly defined:
  - a. 33% in elderly, for example, >65.
  - b. >20% in younger individuals.
  - c. 20–33% in “middle age.”
4. Nocturia index (nocturnal urine volume/maximum voided volume).<sup>24</sup>
  - a. >1: nocturia occurs because maximum voided volume is smaller than nocturnal urine volume.
  - b. >1.5: nocturia secondary to nocturnal urine overproduction in excess of maximum bladder capacity, that is, nocturnal polyuria.

One confounding issue is that if one uses an amount or volume as the indicator for nocturnal polyuria, then even with a normal distribution of day and night output, virtually all people with 24-h polyuria will have nocturnal polyuria. If one uses a percentage of total 24-h urine output, and if the normal circadian rhythm is preserved, they will not all have nocturnal polyuria. Whatever definition is used, it has to be clearly indicated in both clinical practice and research settings (Figure 3).

#### 4.4 | Enuresis

**2002:** Not defined as a sign in previous terminology documents.

**2010:** Not defined as a sign in previous terminology documents.

Daytime		Night-time	
Time	Voided volume (mL)	Time	Voided volume (mL)
Time of waking up: 07.00	200	Time of falling asleep: 22.30	
08.15	175	23.00	150
12.00	375	01.00	275
16.30	325	03.00	400
18.30	225	06.00	350
22.00	225	Woke up at 08.30 next morning and voided 200 mL.	

- > Maximum voided volume: 400 mL.
- > Daytime frequency: 6 times (200, 175, 375, 325, 225, 225)
- > Nocturia episodes: 4 times (150, 275, 400, 350)
- > 24-hour urine volume: 175+375+325+225+225+150+275+400+350+200=2700
- > Nocturnal urine volume: 150+275+400+350+200=1375
- > NPI:  $1375/2700 = 50.9\%$  i.e. nocturia due to nocturnal polyuria
- > Ni:  $(150+275+400+350+200)/400 = 3.4$  i.e. nocturia due to nocturnal polyuria
- > NBCI (Actual nightly voids (ANV) minus Predicted nightly voids (PNV = Ni-1) (24):  $3-(3.4-1) = 0.6$  i.e. nocturia is probably *not* due to reduced bladder capacity.
- > 24-hr urine production rate (mL/hr) =  $2700/24 = 112.5$  mL/hr
- > Nocturnal urine production rate (mL/hr) =  $1375/10 = 137.5$  mL/hr
- > Nocturnal urine production rate index =  $137.5/112.5 = 1.22$

**FIGURE 3** Example of Nocturnal Polyuria using a one-day bladder diary<sup>c</sup>

**2018:** Intermittent incontinence (“wetting”) that occurs during periods of sleep (while asleep).

NB. As in the symptoms section previously, this occurs while the patient is asleep and has not been woken up from sleep and then leaks. If it occurs during the main sleep period then it could be preceded by the adjective “nocturnal.”

#### 4.5 | Core reasons for change

Previous definitions were not available for enuresis as a sign. Enuresis as a symptom has been defined as a complaint of intermittent incontinence that occurs during periods of sleep. As a sign, enuresis could be related to or be a manifestation of several different pathologies that the healthcare provider

would need to investigate, for example, high pressure urinary retention, overactive bladder, or neurogenic causes. Depending on the severity, it could be “wetting” the underclothes, outer clothes, or the bed.

#### 4.6 | Nocturnal urine volume

**2002:** The total volume of urine passed during the night, including the first morning void.<sup>1</sup>

**2010:** Cumulative urine volume from voids after going to bed with the intention of sleeping to include the first void at the time of waking with the intention of rising (excludes last void before sleep).<sup>14</sup>

**2018:** Total volume of urine produced during the individual's main sleep period, including the first void after the main sleep period.

Volume measurement begins after the last void preceding sleep and concludes after the first morning void. The first morning void follows the individual's decision they will no longer attempt to sleep.

#### 4.7 | Core reasons for change

Wording of previous definitions has been confusing. The new definition is practical and takes into account the fact that if an individual does not empty his/her bladder before falling asleep, then for pragmatic reasons it would be reasonable to include any volume produced after the last void before falling asleep as part of nocturnal urine produced. Alternatively, it would be best to advise individuals who are filling out a bladder diary or frequency/volume chart to void before going to sleep to make assessment of volumes passed easier by the healthcare provider when analyzing the diary or chart.

#### 4.8 | 24-h voided volume

**2002:** Total volume of urine voided during a 24 h period (1st void to be discarded; 24 h begin at the time of the next void).<sup>1</sup>

**2010:** Summation of all urine volumes voided in 24 h.<sup>14</sup>

**2018:** Total volume of urine passed during a 24-h period excluding the first morning void of the period. The first void after rising is discarded and the 24-h period begins at the time of the next void and is completed by including the first void, after rising, the following day.

#### 4.9 | Core reasons for change

Previous definitions needed further clarification to avoid confusion with regard to when the 24-h period begins and when it ends. The new definition clarifies this matter.

#### 4.10 | 24-h polyuria

**2002:** 24-h urine output >40 mL/kg, in men and women, causing daytime urinary frequency and nocturia occasioned by a general increase in urine output, outstripping even normal bladder capacity.<sup>1</sup>

**2010:** Excessive excretion of urine resulting in profuse and frequent micturition. It has been defined as over 40 mL/kg body weight during 24 h or 2.8 L urine for an individual weighing 70 kg.<sup>14</sup>

**2018:** The previous definitions have not been changed.

#### 4.11 | Core reasons for change

Since there was no new research or information on defining polyuria, the working group has decided to retain the previous definitions as volumes passed daily vary considerably, and are influenced by environmental, physiological, and pathological factors; which can affect the amount of fluid loss by other means, such as perspiration, and the amount of fluid intake.

### 5 | CONCLUSION

This standardization document on nocturia and nocturnal lower urinary tract function aimed to update previous standardization documents with emphasis on pragmatism and practicality when coming up with new definitions. These new definitions can be used both clinically and in research, allowing better communication and understanding between healthcare providers and researchers.

This document has involved 16 rounds of full review by co-authors of an initial draft (Version 1) completed on 3 October, 2014. Comments for each round of review were collated and debated as necessary in order to form a subsequent version. Live meetings on the document took place at the ICS annual meetings in Brazil (2014) and Tokyo (2016). The document was then sent to six experts for comments before the final version was produced. The document was also subject to general ICS membership review and reviews by the SSC and ICS Board.

#### ACKNOWLEDGEMENTS

No discussion on terminology should fail to acknowledge the fine leadership shown by the ICS over many years. The legacy

of that work by many dedicated clinicians and scientists is present in all the reports by the different Standardisation Committees.

1. Bernard T. Haylen, University of New South Wales, Sydney. N.S.W. Australia: Chair of SSC at the time of publication.
2. Stergios Doumouchtsis, Epsom and St Helier University Hospitals NHS Trust, United Kingdom: SSC mentor.
3. Jeffrey Weiss, SUNY Downstate College of Medicine, New York, USA: Input into an early version (version 4) of the document.

#### External Reviewers

1. Paul Abrams, Bristol Urological Institute, Southmead Hospital, United Kingdom

3. Philip van Kerrebroeck, University Hospital Maastricht, Maastricht, The Netherlands
4. Dudley Robinson, King's College Hospital, London, United Kingdom
5. Ruud Bosch, University Medical Centre Utrecht, Utrecht, The Netherlands
6. Karel Everaert, Ghent University Hospital, Ghent, Belgium

#### ENDNOTES

- <sup>a</sup> The first nocturia episode must be preceded by sleep. Subsequent nocturia episodes must be followed by the intention of getting back to sleep. The quality of life impact of nocturia is not an element in its definition but will be appropriately evaluated during its assessment by fully validated quality of life questionnaires.
- <sup>b</sup> Definition of nocturia does not take into account whether this is bothersome or not, whether it is affecting quality of life or whether it needs treatment. The aim is to have a global pragmatic definition, rather than defining or suggesting a clinical pathological entity. For the healthcare provider, it is prudent that they state the cause of nocturia when reporting it clinically or for research purposes for each individual, in other words it has to be reported why the nocturia occurred, for example, due to urgency, pain, habit, etc.
- <sup>c</sup> A 3-day bladder diary is the standard of care for the assessment of patients with lower urinary tract symptoms including nocturia and nocturnal polyuria.
- <sup>d</sup> Enuresis can be primary (has been present lifelong) or acquired (developed in adults).
- <sup>e</sup> The frequency with which a person passes urine during their main sleep period can be used as an indicator of the severity of their nocturia. It is known that this does not necessarily correspond with the quality of life impact of nocturia. The first void after the main sleep period follows the individual's decision that they will no longer attempt to sleep.

<sup>f</sup> The working group recognizes the limitations and difficulties that exist in defining nocturnal polyuria. It believes that there is not enough data in the literature to make a recommendation to adopt a new definition of nocturnal polyuria as a "sign" or to recommend one method of calculation over the other. Further research is needed into this field before adopting one of the methods of calculation as every definition above has limitations. However, the working group believes that the way forward for new research is to have an absolute number based on rate of urine production during the main sleep period or when the patient has gone to sleep, relative to the urine production rate in 24 h, for the various age groups and both genders. Ultimately, the definition will be used to aid treatment of a bothersome condition and the treatment will target the cause rather than the definition. The definition should also be easily usable in research. Whichever definition is used, the healthcare provider or researcher should specify exactly which parameter and method of calculation they have used to diagnose nocturnal polyuria.

**Aims:** Terms used in the field of chronic pelvic pain (CPP) are poorly defined and often confusing. An International Continence Society (ICS) Standard for Terminology in chronic pelvic pain syndromes (CPPS) has been developed with the aim of improving diagnosis and treatment of patients affected by chronic pelvic pain syndromes. The standard aims to facilitate research, enhance therapy development and support healthcare delivery, for healthcare providers, and patients. This document looks at the whole person and all the domains (organ systems) in a systematic way. **Methods:** A dedicated working group (WG) was instituted by the ICS Standardisation Steering Committee according to published procedures. The WG extracted information from existing relevant guidelines, consensus documents, and scientific publications. Medline and other databases were searched in relation to each chronic pelvic pain domain from 1980 to 2014. Existing ICS Standards for terminology were utilized where appropriate to ensure transparency, accessibility, flexibility, and evolution. Consensus was based on majority agreement. **Results:** The multidisciplinary CPPS Standard reports updated consensus terminology in nine domains; lower urinary tract, female genital, male genital, gastrointestinal, musculoskeletal, neurological aspects, psychological aspects, sexual aspects, and comorbidities. Each is described in terms of symptoms, signs and further evaluation. **Conclusion:** The document presents preferred terms and definitions for symptoms, signs, and evaluation (diagnostic work-up) of female and male patients with chronic pelvic pain syndromes, serving as a platform for ongoing development in this field. *NeuroUrol. Urodynam.* © 2016 Wiley Periodicals, Inc.

**Key words:** bladder pain syndrome; chronic pelvic pain syndromes; comorbidities; condition; disease; domain; female genital pain; gastrointestinal pain; Hunner lesion; hypersensitive bladder; interstitial cystitis; lower urinary tract pain; male genital pain; musculoskeletal pain; neurological aspects; phenotype; psychological aspects; sign; sexual aspects; symptom; syndrome

## INTRODUCTION

This is the first International Continence Society (ICS) published Standard of Chronic Pelvic Pain Syndromes (CPPS). Global standardization of terms and clear definitions are essential for scientific and clinical progress. Furthermore, meaningful coding of diseases, nationally and internationally, depends on accepted terminology. Inappropriate and unclear coding and definitions have negative effects not only on diagnosis, but also on the patient's ability to obtain appropriate treatment, reimbursement, and social benefits. The International Continence Society (ICS) has led the way in the development of Standards for terminology of lower urinary tract function and dysfunction,<sup>1</sup> and the need for a Standard in CPPS was identified by the ICS Standardisation Steering Committee (SSC).

Chronic pelvic pain (CPP) is the most common indication for referral to women's health services, and accounts for 20% of all outpatient appointments in secondary care.<sup>2</sup> This leads to a substantial burden on limited health care resources. For example, \$881.5 million are spent per year on its outpatient management in the USA, while an estimated £158 million are spent annually on management in the United Kingdom National Health Service.<sup>2</sup> CPPS are multifactorial and multidisciplinary conditions, and terminology can vary according to which specialist is looking at the patient. This document is an endeavour to look at the whole person and to consider all the domains involved. Each domain is described separately.

Pain in the pelvic area potentially includes urologic, gynecologic, gastrointestinal, musculoskeletal, neurologic and/or rheumatologic etiology, with psycho-social aspects, and hence must be regarded as a multidisciplinary issue. A taxonomy of the relevant elements of CPP was provided by the International Association for the Study of Pain (IASP).<sup>3,4</sup> Complementing the taxonomy, the European Association of Urology (EAU) Guidelines on Chronic Pelvic Pain provide a comprehensive overview of basic science pertaining to pelvic pain, clinical workup and management of CPPS.<sup>5</sup> This ICS Standard should be seen as complementary to other CPPS standards and guidelines. Its aims are to:

1. Describe the nine clinical domains involved in CPPS (summarized in Tables I–XI).
2. Define terminology.
3. Develop an evaluation guideline for each domain.
4. Establish a process for evolving terminology in response to scientific and clinical development and patient need.

This Standard for CPPS Terminology should facilitate future research and therapy development, improve cost effectiveness, and ensure access by the patient to appropriate treatment, reimbursement, and social benefits.

## METHODS

The CPPS Standard was developed according to the published methodology of the ICS Standardisation Steering Committee (SSC).<sup>6</sup> The Working Group (WG) and Chairperson were selected by an independent SSC sub-committee following an open advertisement. The WG comprised a multi-disciplinary group of health care providers, a basic science researcher, and a patient advocate. Activities of the WG and contributions of individual members were recorded in an open forum on the ICS website. The WG developed an outline of proposed content at an open workshop at the ICS annual scientific meeting in Beijing (2012). Successive iterations of the draft standard involved electronic communications, teleconferences, and face-to-face meetings. The WG reviewed documents that provided historical and research insight into the multidisciplinary approach to the evaluation of female and male CPPS.

A literature review covered the period 1980–2015 and extracted sources from electronic database searches, including MEDLINE and Cochrane. In addition, cross-referencing was done for existing relevant guidelines and consensus documents, notably:

- The EAU Guidelines on Chronic Pelvic Pain,<sup>5,7</sup> which place CPP in the clinical context.
- The American Urological Association (AUA) guidelines for the diagnosis and the treatment of IC/BPS.<sup>8,9</sup>
- The International Continence Society (ICS) joint/ICS joint report on the terminology for female pelvic floor dysfunction,<sup>10</sup> which covers terminology for female sexual dysfunction, genital pain, and pudendal neuralgia.
- The IASP Taxonomy, which classified pain on the basis of "organ + pain + syndrome" and applied it to pain of urogenital origin.<sup>3</sup>
- In 2008, the International Society for the Study of Bladder Pain Syndrome (ESSIC) published diagnostic criteria, classification, and nomenclature for bladder pain syndrome (BPS).<sup>11</sup>
- The East Asian IC Study Group/Society of Interstitial Cystitis of Japan (SICJ) guidelines, which revived the concept of hypersensitive bladder.<sup>12</sup>
- The Functional Gastro-Intestinal Disorder Society (FGIDS) Rome III Diagnostic Criteria<sup>13</sup> for gastro-intestinal disorders.

## RESULTS

The WG identified the following nine domains, each of which are considered in terms of symptoms, signs, and further evaluation.

### I. Lower Urinary Tract Domain

- A. Bladder.
- B. Urethra.

**II. Female Genital Domain**

- A. Vulva, vestibule, and clitoris.
- B. Intra-abdominal female genital pain.
- C. Pelvic floor muscle pain.

**III. Male Genital Domain**

- A. Prostate.
- B. Scrotum.
- C. Epididymis.
- D. Testicle.
- E. Penis.
- F. Urethra.
- G. Sexual Pain.

**IV. Gastro-Intestinal Domain**

- A. Anorectum.
- B. Colorectum.

**V. Musculoskeletal Domain**

- A. Pelvic muscle pain.
- B. Coccyx pain syndrome.
- C. Pelvic Joint, ligament, or bony pain.

**VI. Neurological Domain**

- A. Complex Regional Pain Syndrome (CRPS).
- B. Somatic neuropathic pain.
- C. Pain following mesh surgery.

**VII. Psychological Domain**

- A. Worry, anxiety, and fear.
- B. Depression and depressed mood.
- C. Catastrophizing.

**VIII. Sexual Domain**

- A. Sexual desire disorder.
- B. Sexual arousal disorder.
- C. Orgasmic disorder.
- D. Sexual pain disorder.

**IX. Comorbidities**

- A. Allergies.
- B. Chronic pain and fatigue syndromes.
- C. Systemic autoimmune syndromes/disease.
- D. Extraintestinal manifestations of inflammatory bowel disease.

**TAXONOMY**

**A. Pain**—A subjective phenomenon described as an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage.<sup>14</sup>

- a. Nociceptive pain: arises from actual or threatened damage to non-neural tissue and is due to the activation of nociceptors.
- b. Somatic pain: arises from bone, joints, muscles, skin, or connective tissue and is normally achy or throbbing and well localized.
- c. Visceral pain: arises from visceral organs, with involvement of the organ capsule with aching, and is localized. There is obstruction of hollow viscus, causing intermittent cramping, which is poorly localized.<sup>15</sup>
  - i. Nociceptive: direct injury or lesion of an internal organ such as: bladder stone, surgical injury.
  - ii. Inflammatory: acute/chronic inflammation of an internal organ such as urinary tract infection, pelvic inflammatory disease, colitis, endometriosis.
  - iii. Neuropathic: primary lesion of visceral nerves such as neuritis following mesh placement.

*Neurourology and Urodynamics* DOI 10.1002/nau

#### 4 Doggweiler et al.

- d. Centrally generated pain/deafferentation pain: may result from injury to either the peripheral or central nervous system, leading to burning pain below the level of the lesion. It can be sympathetic-nervous system maintained pain, which may result in chronic regional pain syndrome (CRPS). There is increased responsiveness of nociceptive neurons in the central nervous system to normal or sub-threshold afferent input.
- e. Hypersensitivity: increased nerve activity from a standardized stimulus with an expected tissue/clinical response. The underlying mechanism remains to be defined.
- f. Central sensitization:<sup>16</sup> nociceptor sensitization results in synaptic strengthening by incoming afferent volleys (sensitization) and is expressed as hyperalgesia (a form of non-associative learning characterized by an increase in responsiveness upon repeated exposure to a stimulus).<sup>17</sup>

**B. Pain Experience**—According to the most common views, pain constitutes the internal perception of bodily damage. It is unknown whether chronic pelvic pain syndromes (CPPS) are primarily an abnormal perception of a normal stimulus or a normal perception of an abnormal physiologic sensory stimulus.<sup>14 FN1</sup>

**C. Psychology of Pain**—Pain is modulated by cognitive factors and emotional experience, memory, attention, and context represented in descending modulation of pain, affecting pain experience from moment to moment and longer term. Pain has an impact on many aspects of daily life, affecting mood, sleep, relationships, and activities. Therefore, attention to the psychological aspects of pain is an important part of effective assessment and treatment.<sup>18,19</sup>

**D. Neurobiology of Pain**—Alterations in gut and bladder motility, visceral perception and central processing of pain and motor function due to abnormalities in the visceral and central nervous systems may account for the symptoms.<sup>18 FN2</sup>

**E. Chronic Pelvic Pain**—Chronic pelvic pain is characterized by persistent pain lasting longer than 6 months or recurrent episodes of abdominal/pelvic pain, hypersensitivity or discomfort often associated with elimination changes, and sexual dysfunction often in the absence of organic etiology.<sup>20</sup>

#### F. Symptoms and Signs of Chronic Pelvic Pain Syndromes

- a. Symptoms: The subjective indicator of a disease or change in condition/syndrome/phenotype as perceived by the patient, caregiver or partner which may lead him/her to seek help from healthcare professionals.<sup>21</sup> The main symptom in CPPS is pain and will be described in relation to its domain and its perception. Complaint: what the patient describes when prompted by the physician.
- b. Signs are observed by the physician including simple means to verify symptoms and quantify them. To evaluate and discover all the signs, a full evaluation of the pelvis and body is necessary as multiple intra and extra-pelvic domains (organ systems) are commonly involved. It is necessary to attempt to identify all of the pain generators.<sup>11,21</sup>

#### G. Condition, Disease, Syndrome

- a. A condition is defined by the presence of observations associated with characteristic symptoms or signs and/or evidence of relevant pathological processes.<sup>7</sup>
- b. A disease is a disordered or incorrectly functioning organ, part, structure, or system of the body resulting from the effect of genetic or developmental errors, infection, poisons, nutritional deficiency or imbalance, toxicity, or unfavourable environmental factors; illness; sickness; ailment.
- c. A syndrome is a complex of concurrent symptoms and signs that is collectively indicative of a disease, dysfunction or disorder in the absence of obvious pathology. (NEW) Example: Interstitial Cystitis/Bladder Pain Syndrome (IC/BPS) is one of the Chronic Pelvic Pain Syndromes.<sup>1 FN3</sup>

#### H. Characteristics

- a. Duration of pain: Six months or more of persistent pain.<sup>FN4</sup>
- b. Location of pain: Pelvis, lower abdomen, low back, medial aspect of thigh, inguinal area, perineum.
- c. Perception of pain: Patients may describe the pain as sharp, burning, aching, shooting, stabbing, pressure or discomfort, sexual pain (dyspareunia).<sup>22 FN5</sup>
- d. Modality of pain (7): Persistent and/or continuous, recurrent and/or episodic and/or cyclic (related to menstrual cycle).

<sup>FN1</sup>Diagnosis is often based on the presence of clinical symptoms. The diagnosis of CPP is confirmed by applying symptom-based criteria and pursuing further diagnostic evaluation to exclude organic disease. Validation of symptom-based criteria is a process; it is not carved in stone and is easy to change as new data on its underlying pathophysiology emerge.<sup>3</sup>

<sup>FN2</sup>The brain-visceral axis and biopsychosocial model have been used to explain how intrinsic and extrinsic stimuli modulate disease expression.<sup>14,18</sup>

<sup>FN3</sup>This is an update of the ICS Standardisation Sub-committee report on the Standardisation of Lower Urinary Tract Function.<sup>1</sup>

<sup>FN4</sup>In different guidelines and standardisation documents, the duration varies from 6 weeks to 6 months.

<sup>FN5</sup>Some patients describe pain as an ache, soreness or simply discomfort, while cultural differences may influence perception of pain. For example, some patients describe an unpleasant sensation or pressure or discomfort, but do not consider these to be true pain. Memories, emotions, thoughts, expectations and culture are now believed to influence how people perceive pain.<sup>22</sup>

**I. Phenotype**—Subgroup of patients within a condition, disease, or syndrome that share similar expression of specific symptoms, signs and diagnostic parameters: Example: Irritable bowel syndrome has three phenotypes: constipation, diarrhea, or mixed constipation/diarrhea.<sup>5,23,24 FN6</sup>

Phenotyping is currently in its infancy with regard to evidence and will increase in importance in the future to aid in identifying specific patient pools for research and treatment.<sup>5,23</sup>

**J. Domain (organ system)**—Lower urinary tract, female genital, male genital, gastro-intestinal, musculoskeletal, neurological, psychological, sexual, and comorbidities are domains involved in chronic pelvic pain syndromes (CPPS).

Tables I–IX are a summary of the appropriate domain for domains I–IX and appear in the Symptoms section.<sup>25 FN7</sup>

## INDIVIDUAL PATIENT ASSESSMENT

### Section 1: Symptoms

The first and most important step is to obtain a thorough history of the patient's perception of her/his pain or discomfort. The common complaints are the most prevalent symptoms.

Ask about duration (at least 6 months), perception (identify inciting event and/or triggers), and modality (persistent/recurrent).

#### I. Lower Urinary Tract Domain (Table I)

##### A. Bladder

Common complaints include: increased urinary frequency day and night, urgency, hypersensitivity, pain, pressure, discomfort, pain with filling, hesitancy, intermittency, feeling of incomplete emptying. Pain/hypersensitivity related to the bladder provides an umbrella for hypersensitive bladder, interstitial cystitis/bladder pain syndrome, and interstitial cystitis with Hunner lesion.<sup>26–28</sup> Urgency: A compelling need to urinate which is difficult to defer (pain, pressure, discomfort).<sup>1,5,11,21,30–33 FN8 FN9</sup> The Working Group identified the following adjustments as applying more descriptively, for example, to Interstitial Cystitis/Bladder Pain Syndrome patients: a compelling need to urinate, due to pain or an unpleasant sensation, that is difficult to defer.<sup>FN10 FN11 FN12</sup>

As there are differences in symptoms as well as in the perception and experience of pain, the WG agreed to distinguish:

- a. Hypersensitive Bladder (HSB)(Japanese and East Asian guidelines). Hypersensitive bladder symptoms (increased bladder sensation, usually associated with increased urinary frequency day and night, with or without bladder pain) in the absence of pathology explaining the symptoms.<sup>29,30 FN13</sup>
- b. Interstitial Cystitis/Bladder Pain Syndrome (IC/BPS). Persistent or recurrent chronic pelvic pain, pressure or discomfort perceived to be related to the urinary bladder accompanied by at least one other urinary symptom such as an urgent need to void or urinary frequency.<sup>11</sup>
- c. Interstitial Cystitis (IC) with Hunner lesion has the same symptoms as IC/BPS.<sup>31 FN14 FN15</sup> Pain in IC/BPS and IC with Hunner lesion may be pain, pressure or discomfort, which may increase with bladder filling. Possible locations of perceived discomfort and pain are the pelvis, lower abdomen/suprapubic area, low back, medial aspects of the thigh, inguinal area, or multiple pain sites.<sup>11</sup> Descriptors/Perception of pain<sup>5</sup> include: "Sharp, burning, ache, shooting, stabbing, pressure, discomfort."

##### B. Urethra

Urethral pain is perceived to be in the urethra, usually when voiding, with increased day- and night-time frequency. It may be combined with a feeling of dull pressure, and sometimes radiates toward the groin, sacrum and perineum.<sup>1,7</sup> The terms "chronic urethritis" and "urethral syndrome" are no longer recommended.<sup>5,23</sup>

- i. Persistent or recurrent pain.
- ii. No history of current infection or other obvious pathology.
- iii. May be subsequent to a previous urinary tract infection.

<sup>FN6</sup>This has been adapted from the European Association of Urology Guidelines on Chronic Pelvic Pain.<sup>5</sup>

<sup>FN7</sup>Domains I–V involve intrapelvic organs, VI–IX involve overlying aspects including comorbidities.

<sup>FN8</sup>In the previous ICS LUTS document of 2002, urgency was defined as: the sudden complaint of a compelling desire to pass urine, which is difficult to defer.<sup>3</sup>

<sup>FN9</sup>This was a change from a previous definition in 1988 which stated that urgency may be associated with two types of dysfunction: (i) Overactive detrusor function (motor urgency), and (ii) Hypersensitivity (sensory urgency).<sup>30</sup>

<sup>FN10</sup>The change in definition in 2002 with introduction of the word "sudden" effectively restricted this term to overactive bladder syndrome and there was no mention of another sensation of urgency (urgent need to void) due to pain or hypersensitivity.

<sup>FN11</sup>The term hypersensitive bladder is a revival of an earlier ICS Document.<sup>30</sup>

<sup>FN12</sup>Hunner lesion is preferable to Hunnefs ulcer.

<sup>FN13</sup>There is currently global discussion as to whether Hunner lesion should/could be completely separated from IC/BPS and if so what it should be called. It is felt that more research is needed to provide sufficient evidence for such a step.<sup>31</sup>

<sup>FN14</sup>The term vulvodynia is no longer recommended.<sup>3</sup>

<sup>FN15</sup>The terms Dyesthetic vulvodynia and Essential vulvodynia are no longer recommended.<sup>3,34</sup>

**TABLE I. Lower Urinary Tract Domain**

Symptoms	Signs	Evaluation	Syndrome/disease
Increased daytime frequency Increased night-time frequency	Suprapubic tenderness Tenderness of the bladder	Questionnaires Voiding diary	Hypersensitive bladder Interstitial cystitis/bladder pain syndrome
Urgency	Tenderness of the pelvic floor muscles	Urine analysis	Interstitial cystitis/hunner lesion
Hypersensitivity		Optional: urine culture/cytology	
Pain, pressure, discomfort with bladder filling		Intravesical anesthetic challenge	
Hesitancy		Urodynamics	
Intermittency		Cystoscopy (biopsy)	
Feeling of incomplete bladder emptying			
Frequency/urgency painful urination	Tenderness of the urethra	Urine analysis	Urethral pain

**II. Female Genital (Table II)**

Common complaints: painful menstruation, abnormal bleeding, pain with intercourse (dyspareunia), discharge, burning, itching, stabbing pain, voiding/defecatory pain, abdominal/pelvic pain (unilateral or bilateral, persistent or cyclic).

Female genital pain is defined as pain perceived in the pelvis, pelvic organs, the vagina and/or the female external genitals.<sup>5,34</sup>

**A. Vagina (Vulva, Vestibule, and Clitoris)**

1. Pain in the vagina or the external genital organs (vulva, which includes the labia, clitoris and entrance to the vagina).<sup>5 FN14</sup>
2. Generalized vulvar pain syndrome.<sup>4</sup>
  - i. Diffuse vulvar pain perceived to be in the vestibule or beyond.
  - ii. Dyspareunia.
  - iii. Provocation of pain with touch, pressure or friction.<sup>3,34 FN15</sup>

3. Localized vulvar pain syndrome.<sup>4</sup>

Pain is usually provoked with touch, pressure, or friction; example: tight clothing, bicycle riding, tampon use, sexual activity.

- i. Vestibular pain syndrome—Pain localized to one or more portions of the vulvar vestibule.<sup>3,34 FN16 FN17</sup>
- ii. Clitoral pain syndrome—Pain localized to or perceived in the clitoris.

**B. Intra-Abdominal Female Genital**

1. Ovary
  - i. Unilateral or bilateral abdominal/pelvic pain.
  - ii. Persistent.
  - iii. Cyclic.
2. Pelvic Congestion Syndrome
  - i. Pressure, heaviness, dull aching pain in the pelvis and/or in the back.
  - ii. Dysmenorrhea.

**C. Pelvic Floor Muscle<sup>5</sup> (See Domain V Musculoskeletal Pain)**

- i. Urinary/defecatory dysfunction.
- ii. Dyspareunia (see also VIII sexual aspects).
- iii. Pain with sitting.
- iv. Bulging sensation.

**D. Female Sexual Pain (See Domain VIII)**

<sup>FN16</sup>The terms vulvar vestibulitis, vestibulodynia, and focal vulvitis are no longer recommended.<sup>34</sup>

<sup>FN17</sup>Differential diagnosis and treatable diseases: A history of infection (Pelvic Inflammatory Disease, sexually transmitted diseases, endometriosis, adenomyosis or fibroids, and Mullerian abnormalities should be excluded.

TABLE II. Female Genital Domain

Dyspareunia	Tenderness	Pain Mapping	Vaginal/vulvar/perineal pain
Sharp burning and/or stabbing Provocation of pain with touch	Erythema	Q-tip touch sensitivity test	
Dysmenorrhea Abnormal menstrual bleeding Dyspareunia	Tenderness: uterine, adnexal	Laboratory testing Pelvic ultrasound Laparoscopy/biopsy CT-scan	Intra-abdominal: Ovarian Pain Pelvic congestion Uterine pain Tubal pain
Itching, stabbing, burning pain Cyclic, (episodic or persistent)			

### III Male Genital Domain (Table III)

Male genital pain syndromes are often associated with symptoms suggestive of lower urinary tract and sexual dysfunction. Common complaints: genital pain, uncomfortable urination, dysuria, sensation of residual urine, increased daytime frequency, slow stream, urgency, dyspareunia.<sup>4,5</sup> Absence of infection, previous operations, or other obvious pathology.

#### A. Prostate

Persistent or recurrent prostate pain, associated with symptoms suggestive of urinary tract and/or sexual dysfunction. No proven infection or other obvious pathology is present to account for the symptoms.<sup>3,35</sup> FN18 FN19 FN20

Bladder, perineal, testicular, penile and/or groin pain.

- i. Perception of pain: variable.
- ii. Persistent or recurrent.
- iii. Dyspareunia or erectile dysfunction.
- iv. Voiding and post micturition symptoms (for example: hesitancy, intermittency, feeling of incomplete emptying).

#### B. Scrotum

Chronic scrotal pain (generic term used when site of pain is not clearly in the testis or epididymis).<sup>23</sup> FN21

- i. Persistent or recurrent episodic pain, unilateral or bilateral.
- ii. Spontaneous, or reproduced by digital pressure and physical activities.
- iii. Pain is not in the skin of the scrotum but perceived within its contents.
- iv. Lower urinary tract symptoms or sexual dysfunction.

#### C. Epididymis

Pain is specific/localized to the epididymis.<sup>FN22</sup>

- i. Persistent or recurrent episodic pain.
- ii. Spontaneous, or reproduced by digital pressure and physical activities.
- iii. Lower urinary tract symptoms or sexual dysfunction.

#### D. Testicle<sup>23</sup> FN23

- i. Persistent or recurrent episodic pain.
- ii. Spontaneous, or reproduced by digital pressure and physical activities.
- iii. Lower urinary tract symptoms or sexual dysfunction.

#### E. Penis

Pain within the penis that is not primarily in the urethra<sup>FN24</sup> and may be:

- i. Persistent or recurrent.
- ii. Spontaneous, or reproduced by digital pressure and physical activities.
- iii. Lower urinary tract symptoms or sexual dysfunction.

#### F. Urethra

(See Domain I Lower Urinary Tract)

FN18 Using the National Institutes of Health classification system, prostate pain syndrome may be subdivided into type A (inflammatory) and type B (non-inflammatory).<sup>35</sup> Nickel JC. Prostatitis and related conditions, orchitis and epididymitis. In: Campbell-Walsh, editor. Urology. Philadelphia: Elsevier; 2012.

FN19 Based on a more general definition, the term prostate pain syndrome (PPS) is used by the European Association of Urology (EAU) instead of the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) term chronic prostatitis/chronic pelvic pain syndrome.

FN20 The terms "Chronic Prostatitis" and "Prostatodynia" are no longer recommended.

FN21 It may be associated with a congestive epididymitis. Example: after vasectomy. It can result from a mechanical pressure more often than an inflammatory process.

FN22 It may occur at any age, but the majority of cases are in the mid to late thirties and it may be disabling and associated with anxiety about cancer.<sup>36</sup>

FN23 Pain is localized to the testis and could be explained by neural plasticity when subsequent to a trauma or disease and this phenomenon can result from the amplification of the pain messages at all levels of nervous system.<sup>22</sup> The previous terms "Chronic Orchitis," "Orchalgia," or "Orchiodynia" are no longer recommended.

FN24 The most common site for referral to the penis is from the bladder outlet.

TABLE III. Male Genital Domain

Symptoms	Signs	Evaluation	Syndrome/disease
Pain LUTS Dyspareunia Erectile dysfunction Persistent or episodic	Tenderness on rectal/genital examination Urethral discharge	Questionnaires Culture PSA/biopsy Cystoscopy/biopsy Ultrasound	Prostate pain
	Tenderness on physical examination Scars	Questionnaires Ultrasound	Scrotal pain Epididymal pain Testicular pain Penile pain

**G. Sexual Pain**

(dyspareunia; (see Domain VIII)

i. Penile

1. Prior to penetration (example: pain with erection).
2. With penetration.
3. Post coital.

ii. Perineal

1. During intercourse.
2. After intercourse.

iii. Orgasmic Pain (during ejaculation)

1. Penile.
2. Anorectal.
3. Pelvic.

**IV Gastro-Intestinal (Table IV)**

Common complaints: constipation, diarrhea and obstructive defecation, pain with defecation, bleeding, discharge, cramping abdominal pain, recurrent rectal pain, rectal pressure, burning sensation or aching episodes.<sup>37 FN25</sup>

**A. Anorectum (7) (4)**

1. Chronic Proctalgia—rectal pain, more than 20 min of duration per episode, for at least 3 months with symptom onset at least 6 months prior to diagnosis.
  - i. Persistent or recurrent rectal pain.
  - ii. Rectal pressure or aching episodes.
  - iii. In the absence of other causes of rectal pain.
2. Levator Ani Syndrome (the term may refer to the same syndrome as “pelvic floor muscle pain syndrome”/“tension myalgia of the PFM”—see Domain V).
  - i. Pain with sitting.
  - ii. Pain with defecation.
3. Proctalgia Fugax
  - i. Severe recurrent episodic pain localized in the anus or lower rectum.
  - ii. Duration seconds to minutes.
  - iii. No pain between episodes.

**Consider the Symptoms of the Following Treatable Diseases, as They Need to Be Excluded**

4. Anal Fissure<sup>38</sup>

- i. Bright red bleeding with bowel movements.
- ii. Anal pain or spasms that can last hours after bowel movements.<sup>38</sup>
- iii. Pain with sitting.

5. Abscess

- i. Pelvic rectal pain.

<sup>FN25</sup>Chronic Gastro-Intestinal pain includes syndromes and diseases that have obvious pathologies, but similar symptoms.

TABLE IV. Gastro-Intestinal Domain

Symptoms	Signs	Evaluation	Syndrome/disease
Pain with defecation Evacuation dysfunction Pain/pressure with sitting	Tenderness on rectal examination	Questionnaire Culture Colonoscopy/biopsy	Ano-rectal pain
Abdominal pain Nausea Constipation/diarrhea Persistent or episodic	Abdominal tenderness Bloating	Ultrasound CT/barium enema/MRI	Colo-rectal pain

- ii. Tenesmus<sup>39</sup> (persistent painful need to defecate despite an empty colon).
- iii. Pain with sitting.
- 6. Hemorrhoids<sup>40–42</sup>
  - i. Anal discomfort with engorgement.
  - ii. Pain and itching.
  - iii. Lump in perianal area.
  - iv. Pain with defecation.
  - v. Internal hemorrhoids—Painless bleeding, mucus discharge, incomplete evacuation.
  - vi. External hemorrhoids—Anal discomfort with engorgement, pain, and itching.
  - vii. Thrombosed External Hemorrhoids- Exquisitely painful lump in the perianal area. The pain tends to be acute at onset. Typically following straining at the time of bowel movement or physical exertion.
- 7. Anorectal Crohn’s Disease—May be asymptomatic, with possible anal pain during flare.<sup>43</sup>

**B. Colorectum (ROME III Criteria)**

Rome III Criteria are a standard for functional gastrointestinal disorders. The Rome III Criteria are a system developed to classify the **functional gastrointestinal disorders (FGIDs)** of the digestive system, in which symptoms cannot be explained by the presence of structural or tissue abnormality, based on clinical symptoms. Some examples of FGIDs include irritable bowel syndrome, functional dyspepsia, functional constipation, and functional heartburn.<sup>13</sup>

- 1. Irritable Bowel Syndrome (IBS) Functional (non-inflammatory)
  - i. Recurrent episodes of abdominal pain.
  - ii. Changes in frequency, form or consistency of the stool.
  - iii. Sensation of incomplete evacuation, straining, fecal urgency.<sup>44</sup>
  - iv. Sensation of nausea, fatigue, fullness, vomiting.
  - v. Recurrent abdominal pain or discomfort at least 3 days/month in the last 3 months associated with two or more of the following:
    - 1. Improvement of pain with defecation.
    - 2. Onset associated with change in frequency of stool.
    - 3. Onset associated with a change in the form (appearance) of stool.<sup>45</sup>

**Note: Consider the Symptoms of the Following Disease**

Inflammatory Bowel Disease (IBD)—Complaint of recurrent abdominal pain and discomfort of at least 3 days per month in the last 3 months. The majority of IBD patients experience periods of flares and remission.

- i. Abdominal and anal pain, diarrhea which may be associated with blood, suggestive of ulcerative colitis.
- ii. Abdominal pain, fatigue, prolonged diarrhea with crampy abdominal pain, weight loss, and fever, with or without gross bleeding. Irregular bowel habits, with possible blood in the stool, are suggestive of Crohn’s disease.<sup>45</sup>

**V. Musculoskeletal Domain (Table V)**

Musculoskeletal pain may originate from muscles, fascia, ligaments, joints, or bones.

TABLE V. Musculoskeletal Domain

Symptoms	Signs	Evaluation	Syndrome/disease
Abdomino-pelvic-perineal pain	Altered muscle tone Tension; muscle spasms and muscle compliance	Questionnaires Pain mapping	Pelvic muscle pain syndrome Coccyx pain syndrome
Pain at rest, with movement, with sitting, with sexual activity Pain with voiding or bowel evacuation Unilateral or bilateral pain Persistent or episodic	Stiffness muscle tightness Trigger point tenderness Tender taut band Twitch response, referred pain	Ultrasound	Pelvic joint, ligament or bony pain

Neurourology and Urodynamics DOI 10.1002/nau

## 10 Doggweiler et al.

Common complaints: abdominal/pelvic pain, pain with sitting or with movement or with change of posture, with sexual activity, unilateral or bilateral pain. Possible pain with voiding or bowel evacuation.

### A. Pelvic Muscle Pain<sup>10,46</sup> (See also Domain IV)

#### 1. Pelvic Floor Muscle Pain (Pelvic Floor Myalgia)<sup>FN26</sup>

- i. Pain in the muscles of the pelvic floor (perineal or levator ani).

#### 2. Intra-pelvic Muscle Pain

- i. Pain in the pelvic side wall muscles (obturator internus, piriformis, coccygeus).

#### 3. Anterior Pelvic/Lower Abdominal Muscle Pain

- i. Pain in the rectus abdominus, oblique or transverse abdominus muscles, described below the umbilicus.

#### 4. Posterior Pelvic/Buttock Muscle Pain

- i. Pain in the gluteal muscles.

### B. Coccyx Pain Syndrome

- i. Complaint of chronic or recurrent pain in the coccyx or sacro-coccygeal joint.

### C. Pelvic Joint, Ligament, or Bony Pain

#### 1. Joint pain

- i. Sacroiliac or pubic symphysis joint.

#### 2. Ligament pain

- i. Sacro-spinous or Sacro-tuberous ligament.

#### 3. Bony pain

- i. Pain described in or along the margins of the pubic ramus, ilium, ischial spine or ischial tuberosity.

### VI Neurological Aspects Domain<sup>47</sup> (Table VI)

Common complaints: Burning, throbbing, stabbing, electric shock-like sensation, tingling, stinging and/or paresthesia pain in the pelvis and/or perineal region.

### A. Complex Regional Pain Syndrome<sup>48</sup> (CRPS)

Sympathetic, centrally generated pain.

1. CRPS 1- Triggered by tissue injury with no underlying nerve injury.
2. CRPS 2- Associated with nerve injury.

- i. Burning pain.
- ii. Increased skin sensitivity.
- iii. Changes in skin temperature, color, and/or texture.

### Note: Consider Differential Diagnosis:

#### B. Somatic Neuropathic Pain—Nerve injury (stretching, blunt trauma, compression, entrapment, suture ligature).

##### 1. Sacral nerve (disease)<sup>49</sup>

- iv. Pudendal neuralgia is a disabling form of pelvic pain. It is related to a ligamentous nerve compression mechanism. This pain is associated with the second stage of labor, sacrospinous vault suspension, vaginal laceration repairs, prostatectomy, straddle injuries, prolonged motorcycle riding, and laser treatment to the vulva, scrotum and/or perineum.

1. Unilateral or bilateral.
2. Lancing burning pain in the clitoris, penis, urethra, labia, scrotum, perineum and/or anus.
3. Worse with sitting.
4. Relieved by standing or supine position.

##### 3. Thoracolumbar nerve (disease)<sup>50 FN27</sup>

<sup>FN26</sup>International Urogynecological Association (IUGA)/International Continence Society (ICS) joint report on the terminology for the conservative management of female pelvic floor dysfunction (under review).<sup>51</sup>

<sup>FN27</sup>Irritation of the thoracolumbar facet joints causes pain referred to the distribution of nerves T12, L1, and L2. This results in pain to the iliac crest and buttock. Frequently seen after abdominal and/or pelvic surgery.<sup>50</sup>

TABLE VI. Neurological Aspects Domain

Symptoms	Signs	Evaluation	Syndrome/disease
Characteristic sensation descriptions: burning, throbbing, stabbing, tingling, stinging, shooting, electric shock-like sensation paresthesia, atrophy, persistent or episodic	Tenderness (nerve distribution)	Questionnaires	Somatic neuropathic pain
	Referred pain	Quantitative sensory testing	Complex regional pain syndrome
	Possible skin change (color, temp, texture)	Pain mapping Nerve block imaging Ultrasound MRI	

- i. Ilioinguinal nerve.
  - 1. Pulling or throbbing that limits physical activity (groin, labia scrotum inner thigh).
- ii. Iliohypogastric nerve.
  - 1. Pulling or throbbing sensation that limits physical activity (suprapubic area and groin).
- iii. Genitofemoral nerve<sup>52</sup>
  - 1. Burning, paresthesia and pain (groin, labia or scrotum, medial thigh).
- iv. Obturator nerve
  - 1. Medial thigh or groin pain.
  - 2. Weakness with adduction of the thigh.

**C. Pain Following Mesh Surgery**<sup>34,53</sup>

- i. Pain during physical activity.
- ii. Dyspareunia.
- iii. Vaginal discharge.
- iv. Exposure of mesh in vagina or elsewhere.

**VII Psychological Aspects Domain** (Table VII)

Common complaints: worry, anxiety, low mood, frustration, sleep disturbance, helplessness, hopelessness, difficulty in concentrating, pain impairing enjoyment. These all have biopsychosocial aspects.<sup>54</sup>

The **biopsychosocial model** in pain medicine was introduced with the publication of the Gate Control Theory of Pain. It is suggested that in the perception of pain three different inputs are involved: the sensory-nociceptive, the affective-motivational and the cognitive-evaluation input. These could differ within individuals, but all of these are involved in the human experience of pain.<sup>55</sup>

Psychological distress as a biopsychological aspect is most often a consequence of persistent pain, although existing distress is likely to exacerbate the experience of pain and difficulties dealing with it. Findings support growing evidence that the negative affective, cognitive and psychosocial state of chronic pain is universal, regardless of a neuropathic, or nociceptive nature. Emotions, thoughts and behavior involve many different locations in the brain and multiple psychological processes are involved in neuromodulation of pain.<sup>18,54</sup>

**A. Worry, anxiety, fear:** Pain is interpreted as a message of something seriously wrong with the body at the point where the pain is felt, consistent with models of severe acute pain. Without an explanation for chronic pain, anxiety is likely to persist and results in attempts to avoid activities which exacerbate the pain or are expected to do so.

**B. Depression and depressed mood:** This is predominantly pain-related and concerns loss of valued activities and roles as a result of pain. Difficulty sleeping, difficulty concentrating, helplessness, and hopelessness about finding a solution to the pain or a way of living a worthwhile life despite pain are common.

**C. Catastrophizing:** a tendency to overattend (magnification) to pain stimuli, with overestimation of the threat value and underestimation (hopelessness and helplessness) of the capacity to deal with the threat.

TABLE VII. Psychological Aspects Domain

Symptoms	Signs	Evaluation	Syndrome/disease
Worry, anxiety, fear	Helplessness	Formal psychological assessment	Worry/anxiety/fear
Catastrophizing	Hopelessness	Asking the patient what is wrong and what worries her/him about pain	Depression
Persistent or episodic	Avoidance of certain activities	Questionnaires	

Neurourology and Urodynamics DOI 10.1002/nau

**VIII Sexual Aspects Domain** (Table VIII)

Common Complaints: Low sex drive, inability to become aroused, pain with intercourse, difficulty reaching orgasm.

Sexual dysfunction is a disturbance in the sexual response cycle or pain associated with sexual intercourse, and can take a heavy psychological toll; it is associated with depression, anxiety, and debilitating feelings of inadequacy.<sup>56</sup> It is appropriate to investigate for possible history of sexual/physical abuse.

Dyspareunia is a biopsychosocial phenomenon that can have physical and psychosocial implications for the individual as well for the relationship.<sup>57</sup> Decrease in self-esteem, depression, anxiety, fatigue, and the need to use pain medication and other medications increase the likelihood of one or more of the disorders.

Superficial or entry dyspareunia is often associated with provoked vaginal-vulvar pain syndrome. Deep or thrusting dyspareunia often occurs in association with lower urinary tract pain, musculoskeletal pain, gastrointestinal pain, as well as abdominal/pelvic pain.<sup>58,59</sup>

Female and male sexual function is adversely affected in most patients with chronic pelvic pain, resulting in more than one comorbid disorder. More than 50% of partners are significantly affected and develop sexual dysfunction.

**A. Sexual Desire Disorder**

The following definitions form part of the DSM IV TR<sup>60,61 FN28</sup>

1. Hypoactive Sexual Desire Disorder (HSDD)

- i. Low sex drive.
- ii. An absence of sexual fantasizing or erotic thoughts.
- iii. No longer feeling aroused or excited during sex.
- iv. A substantial decrease in sexual activity with partner, persisting for more than 6 months.

2. Sexual aversion disorder

- i. Persistent or recurrent aversion to, or avoidance of, sexual activity.
- ii. When presented with a sexual opportunity, the individual may experience panic attacks or extreme anxiety.

**B. Sexual Arousal Disorder**

- i. Persistent or recurrent inability to become sexually aroused.
- ii. Often characterized by inadequate vaginal lubrication for penetration (female).
- iii. Inability to achieve or maintain an adequate erection for penetration (male).
- iv. Symptoms present for more than 6 months.

**C. Orgasmic Disorder**

- i. Difficulty or delay in reaching orgasm, after sufficient sexual stimulation (female).
- ii. Premature or delayed ejaculation (male).
- iii. Present for more than 6 months.

**D. Sexual Pain Disorder**

1. Dyspareunia

- i. Female sexual pain: Burning, ripping, tearing, or aching sensation associated with penetration. The pain can be at the vaginal opening, deep in the pelvis, or anywhere between. It may also be felt throughout the entire pelvic area and the sexual organs and may occur only with deep thrusting.
- ii. Male sexual pain: Sexual activity may induce a central sensitization process characterized by hypersensitivity or hyperalgesia.

History should include duration of symptoms, identification of disorder, impact on quality of life, and partner relationship. Partner interviews may be very helpful as erectile dysfunction, delayed or premature ejaculation in males with hypoactive sexual desire disorder result in a 4–30 times increased risk of female partner desire, arousal or orgasmic disorder.

TABLE VIII. Sexual Aspects Domain

Symptoms	Signs	Evaluation	Syndrome/disease
Lack of desire, arousal, orgasm Dyspareunia Persistent or episodic	Depression Relationship issues	Questionnaires Laboratory (hormonal and complete metabolic panel) Doppler ultrasound	Sexual dysfunction

**IX Comorbidities** (Table IX)

Patients with chronic pelvic pain syndromes, and in particular those with interstitial cystitis/bladder pain syndrome (IC/BPS), have a higher prevalence of one or multiple comorbid syndromes and diseases than the general population. These include: allergies, non-cancer chronic pain, fatigue syndromes and systemic autoimmune diseases. The risk of a comorbidity in patients

<sup>FN28</sup> Minimal data are available utilizing DSM 5 criteria, DSM IV TR was thus utilized. The Diagnostic and Statistical Manual of Mental Disorders, published by the American Psychiatric Association, offers a common language and standard criteria for the classification of mental disorders.<sup>60</sup>

TABLE IX. Comorbidities

Symptoms	Signs	Evaluation	Syndrome/disease
Allergies	Fatigue	General medical evaluation	Allergies
Fatigue	Skin lesions	Laboratory	Chronic pain and fatigue syndrome
Widespread muscular and joint pain	Dry eye	Imaging	Systemic autoimmune diseases
Irritation of the eyes	Muscular skeletal tenderness		
Dryness			
Sleep disorder			

affected by IC/BPS is usually between two and ten times higher than in a healthy population. However, data from studies on comorbidities in chronic pelvic pain patients are difficult to interpret as the composition of study populations and methodology are highly variable. Information on the prevalence of comorbidities is therefore often obtained from studies on IC/BPS.<sup>62–66</sup>

#### A. Allergies

Allergies are a heterogeneous group of diseases with involvement of the airways, skin, and sometimes of other organs. Symptoms are caused by an immunologic reaction to some kind of trigger (e.g., inhaled allergens such as dust mite allergen, pet dander, pollen, mold, food, drugs). Nonallergic reactions to drugs or food may cause symptoms similar to allergic reactions.<sup>67</sup> Examples include allergic asthma, allergic rhinitis (hay fever), atopic dermatitis (eczema), allergic drug reactions and allergic food reactions (tingling mouth, swelling of the lips, tongue, face or throat), hives, anaphylaxis, and atopic dermatitis.<sup>68</sup>

#### B. Chronic Pain and Fatigue Syndromes

Chronic pain and fatigue syndromes are characterized by pain, often widespread; fatigue; sleep disturbances; and disability. The symptoms are usually medically unexplained, have no known pathophysiology or organic basis and show no abnormal laboratory or imaging investigations. The literature suggests that many of these conditions share demographic characteristics, clinical course and psychosocial profiles.<sup>69</sup> Examples are:

1. Fibromyalgia: symptoms are widespread musculoskeletal pain, fatigue, non-restorative sleep, psychological distress, and regions of localized tenderness.
2. Temporomandibular Joint Disorders: symptoms consist of complaints of facial, jaw, neck, or shoulder pain. The pain is experienced in or around the ear with chewing, speaking, or opening the mouth, with or without migraine.
3. Chronic Fatigue Syndrome: is defined as clinically evaluated, unexplained, persistent or relapsing fatigue plus four or more specifically defined associated symptoms (self-reported impairment in short term memory or concentration; sore throat; tender cervical or axillary nodes; muscle pain; pain in multiple joints without redness or swelling; headaches of a new pattern or severity; unrefreshing sleep).<sup>70</sup>

#### C. Systemic Autoimmune Syndromes/Diseases

Systemic or generalized autoimmune diseases are a heterogeneous group of diseases with multi-organ involvement and evidence indicating a role played by the immune system in the pathogenesis. Examples are systemic lupus erythematosus (SLE), Sjögren's syndrome, and rheumatoid arthritis (RA). Many patients can be diagnosed with more than one of these diseases, or also with fibromyalgia and irritable bowel syndrome.

1. Systemic Lupus Erythematosus (SLE). Most frequent symptoms are debilitating fatigue, arthritis, red skin lesions after sun exposure such as a red butterfly lesion of the face, pericarditis and pleuritis, glomerulonephritis. The prevalence is 10× higher in females than in males and 2× more frequent in non-white people.
2. Sjögren's Syndrome is a systemic autoimmune disease characterized by a functional disorder of the tear and salivary glands, with or without signs of inflammation. The most common symptoms are irritation of the eyes, a dry mouth, muscle and joint pain, (debilitating) fatigue and Raynaud phenomenon.
3. Rheumatoid Arthritis (RA) is a disease characterized by chronic symmetric polyarthritis resulting in painful swelling of the joints. Other symptoms are morning stiffness, rheumatoid nodules and typical changes on hand and wrist radiographs.

**D. Extraintestinal Manifestations of Inflammatory bowel disease (IBD)** include non-destructive arthritis of large joints or axial arthritis such as sacroiliitis, inflammation of the eyes (uveitis, scleritis), or inflammation of the skin (erythema nodosum, pyoderma gangrenosum).<sup>71</sup>

### Section 2: Signs

#### Generalized Physical Examination

A comprehensive physical examination should be performed, including palpation of the lower abdomen for bladder fullness and tenderness, and a complete pelvic exam to identify pain generators and referred pain patterns:

1. Observe posture, gait and protective behavior (avoiding sitting on flat surface or standing to avoid sitting, neck folding posture).
2. Standing: kyphosis, scars, hernia.
3. Supine: abduction/adduction of the hips, hyperaesthetic areas, scars, hernia.
4. Comprehensive pelvic examination for female and male.
5. Pain mapping (identification of pain generators/trigger points and referred pain).<sup>72</sup>

Neurourology and Urodynamics DOI 10.1002/nau

14 Doggweiler et al.

### **I Lower Urinary Tract**

#### **A. Bladder/Urethra**

1. Suprapubic tenderness.
2. Tenderness of the bladder.
3. Tenderness of the urethra.
4. Tenderness of the pelvic floor muscles and identification of trigger points.<sup>46</sup> (See Domain V).

### **II Female Genital<sup>5</sup>**

#### **A. Vulva, Vestibule, and Clitoris**

Generalized vulvar pain syndrome refers to a vulvar pain syndrome where the pain/burning cannot be consistently and precisely localized by point-pressure “mapping” via probing with a cotton-tipped applicator or similar instrument. Tenderness is diffuse and may affect all locations of the vulva.<sup>FN29</sup>

##### 1. Localized and Generalized Vulvar Pain Syndrome

- i. Tenderness, Q-Tip touch sensitivity test.<sup>72</sup>
- ii. Erythema (localized or generalized).
- iii. Fissures.
- iv. Ulcers.

#### **B. Intra-Abdominal Female Genital**

1. Uterus and Fallopian Tube
  - i. Uterine tenderness.
  - ii. Cervical discharge, cervical excoriation, tenderness, adnexal tenderness, erythema.
  - iii. Extrauterine tenderness, decreased uterine mobility, adnexal mass.
  - iv. Enlarged uterus, nonspecific tenderness.
  - v. Abdominal or pelvic scars, neuroma.
2. Ovary; adnexal mass, tenderness, abdomino-pelvic scar.
3. Pelvic Congestion Syndrome: Labia varicosities, non-specific abdominal tenderness.
4. Cervix: Erosion, Nabothian follicles, discharge, bleeding.

#### **C. Pelvic Floor Muscle** (See Domain V)

1. Perineal scarring, neuroma, dermal cutaneous allodynia.
2. Tenderness (local and/or referred to another pelvic location).
3. Vaginal discharge, mesh extrusion.<sup>53</sup>
4. Bulging.
5. Mass, radiation changes.

### **III Male Genital**

A comprehensive physical examination should be performed in standing (example: exclusion of varicocele) and supine positions, including observation and palpation with pain mapping (identification of pain generators) of the external male genitals, and rectal examination.<sup>FN30</sup>

#### **A. Prostate**

1. Prostate tenderness on rectal examination.
2. Possible urethral discharge.

#### **B. Scrotum**

1. Tenderness on physical examination.
2. Change in color.
3. Masses on palpation.
4. Scars post-vasectomy.
5. Allodynia (increased perception of pain).

#### **C. Epididymis**

1. Tenderness.

<sup>FN29</sup>The vulvar vestibule (part of the vulva which lies between the labia minora into which the urethral meatus and vaginal introitus open) may be involved, (but the discomfort is not limited to the vestibule and may include referred pain from the other CPPS domains).

<sup>FN30</sup>Tenderness might be graded as mild, moderate, or severe.

2. Masses, nodules.

#### D. Testicle

1. Tenderness.
2. Masses, nodules.

#### E. Penis

1. Tenderness.
2. Curvature.
3. Nodules/plaque.

#### F. Urethra

1. Tenderness.
2. Discharge.

### IV Gastro-Intestinal

#### A. Anorectum

1. Chronic Proctalgia—Identification of tenderness on rectal exam<sup>3</sup>
2. Levator Ani Syndrome—Identification of tenderness during posterior traction on the puborectalis.
3. Proctalgia Fugax—Usually there is no evident sign on physical examination.<sup>40</sup>
4. Anal Fissure—Identification of separation of the anoderm, sentinel tag at the external apex, exposed internal sphincter muscle, hypertrophic anal papilla at the internal apex.<sup>38</sup>
5. Abscess—Identification of fluctuant collections in the perianal tissues, drainage (fistula).<sup>39</sup>
6. Hemorrhoids—Identification of skin tags, thrombosis, prolapse on straining (reducible and irreducible).
  - i. Internal: Located proximal to the dentate line and covered by columnar epithelium.
  - ii. External: Located distal to the dentate line and covered by modified Squamous epithelium (anoderm)
  - iii. Thrombosed: Painful lump in the perianal area.<sup>41,42</sup>
7. Anorectal Crohn's Disease—Identification of skin tags, hemorrhoids, fissures, anal ulcers, strictures, abscess, fistula, severe proctitis.<sup>43</sup>

#### B. Colorectum (IBS, IBD)

1. Abdominal tenderness.
2. Watery or bloody diarrhea.
3. Rectal bleeding.
4. Weight loss.
5. Fever.

### V. Musculoskeletal

The musculoskeletal structures are examined for signs of tenderness and altered tension or abnormal movement.<sup>73–76 FN31</sup>

1. Muscle tone: State of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement. Muscle tone has two components: (i) the contractile component, created by a low-frequency activation of a small number of motor units; (ii) the viscoelastic component, which is independent of neural activity and reflects the passive physical properties of the elastic tension of the muscle fiber elements and the osmotic pressure of cells.<sup>46</sup> In normally innervated skeletal muscle, tone is comprised of both "active" (contractile) and "passive" (viscoelastic) components.<sup>46,77,78 FN32</sup>
  - a. Hypertonicity is a general increase in muscle tone that can be associated with either elevated contractile activity and/or passive stiffness in the muscle.<sup>5,77–79 FN33</sup>
  - b. Hypotonicity is a general decrease in muscle tone that can be associated with either reduced contractile activity and/or passive stiffness in the muscle.<sup>FN34</sup> As the cause is often unknown, the terms neurogenic hypotonicity and non-neurogenic hypotonicity are recommended.

<sup>FN31</sup> Varying reliability has been found from pelvic floor muscle (PFM) studies assessing pain and tension using digital palpation scales.<sup>73–76</sup> Patients who present with alteration in the musculoskeletal structure need to be referred to a Physical Therapist well trained in the treatment of CPPS.

<sup>FN32</sup> Muscle tone is evaluated clinically as the resistance provided by a muscle when a pressure/deformation or a stretch is applied to it.<sup>46,77,78</sup> Muscle tone may be altered in the presence or absence of pain. There is no single accepted or standardized way of measuring muscle tone, and there are no normative values.

<sup>FN33</sup> As "hypertonicity" can also be used to describe increased muscle tone of neurogenic origin, the term "increased tone" is preferred when the cause is non-neurogenic.

<sup>FN34</sup> As "hypotonicity" can also be used to describe decreased muscle tone of neurogenic origin, the term "decreased tone" is preferred when the cause is non-neurogenic.

16 Doggweiler et al.

2. Stiffness: Stiffness is the resistance to deformation.<sup>80,81 FN35</sup>
3. Compliance: Passive compliance is defined as the reciprocal of muscle stiffness.<sup>80,81 FN36</sup>
4. Tension: may have a similar meaning to tone and stiffness.<sup>FN37</sup>
5. Spasm: persistent contraction of striated muscle that cannot be released voluntarily.<sup>82 FN38</sup>
  - a. Contracture: is an involuntary tightening of a muscle. Clinically, a muscle cramp and contracture may appear similar, however contractures are electrically silent.<sup>83</sup>
6. Cramp: a muscle cramp is a painful involuntary muscle contraction that occurs suddenly and can be temporarily debilitating.<sup>83,84 FN39</sup>
7. Fasciculation: A fasciculation is a single, spontaneous, involuntary discharge of an individual motor unit.<sup>83 FN40</sup>
8. Tender point: tenderness to palpation at soft tissue body sites.<sup>46</sup>
9. Trigger point (TrP): a tender, taut band of muscle that can be painful spontaneously or when stimulated.<sup>85</sup> The taut band is electrically silent. Local or referred pain may be reproduced.<sup>1,86 FN41</sup>

**VI Neurological Aspects<sup>4</sup>**

1. Tenderness on palpation corresponding to the nerve distribution.
2. Pain mapping (reproduce pain on palpation).
3. Identify referred pain by palpation.
4. Possible skin changes (color, blistering, temperature).

**VII Psychological Aspects**

Observation by the provider may reveal:

1. Anxiety and/or depressed mood, and avoidance or reduction of activities which exacerbate pain, or are believed by the patient to carry a risk of increasing the pain or causing harm.
2. Expression of helplessness and hopelessness (feeling of despair and representing ‘the internal belief that one cannot manage one’s pain’).<sup>18,54</sup>

**VIII Sexual Aspects (59)**

A patient with sexual pain often has one or more other sexual dysfunctions including desire disorder, arousal disorder or orgasm disorder.

In most cases the physical examination will not identify the specific etiology of sexual dysfunction. However, a focused and comprehensive pelvic examination in females and males is mandated. In addition, assessment of the secondary sexual characteristics should be performed.<sup>60 FN42</sup> For the specific assessment, see the relevant Domains.

**Section 3: Further Evaluation**

**Pain Evaluation and Measurement (7)**

Pain rating(s) are essential in patient evaluation, including; Baseline and ongoing regular evaluation of severity, quality of life, questions about thoughts, emotions and behavior associated with the pain (questionnaires).

**Pain Measurement**

1. One of the most commonly used tools is the visual analogue scale (VAS)(85), which is a 10 cm line from “0” no pain to “10” extreme pain.<sup>5 FN43</sup>

0	1	2	3	4	5	6	7	8	9	10
No pain										Extreme pain
Not unpleasant										Extremely unpleasant

<sup>FN35</sup> Passive elastic stiffness is defined as the ratio of the change in the passive resistance or passive force ( $\Delta F$ ) to the change in the length displacement ( $\Delta L$ ) or  $\Delta F/\Delta L$ .<sup>81</sup> The term should only be used if stiffness is measured quantitatively such as with instruments like dynamometry or myotonometry.

<sup>FN36</sup> It represents the compressibility of a muscle, clinically assessed by pressing a finger into it (palpation) to determine how easily it is indented and how “springy” it is.

<sup>FN37</sup> Muscle tension can be increased or decreased due to exogenous factors such as the amount of pressure applied and endogenous factors such as thickness/ cross sectional area of the muscle itself, fluid present within the muscle (swelling, inflammation), position (e.g., standing vs. sitting) or increased neural activity.

<sup>FN38</sup> Occurs at irregular intervals with variable frequency and extent. Spasm over days or weeks may lead to a contracture.

<sup>FN39</sup> Pain is intense and localized. It tends to occur when the muscle is in the shortened position and contracting, is generated by the motor unit, and displays a high firing rate (20–150 Hz).<sup>83</sup> Muscle cramp either during or immediately after exercise is commonly referred to as “exercise- associated muscle cramping.”<sup>84</sup> However, cramps are not specific to exercise.

<sup>FN40</sup> The source generator is the motor unit or its axon, prior to its terminal branches. Fasciculations display an irregular firing pattern of low frequency (0.1–10 Hz).<sup>83</sup> Clinically, fasciculations are recognized as individual brief twitches. They may occur at rest or after muscle contraction and may last several minutes.

<sup>FN41</sup> An active TrP is said to have a characteristic “twitch” response when stimulated; however, the twitch response to palpation has been shown to be unreliable.

<sup>FN39</sup> The most reliable sign of a TrP is sensitivity to applied pressure.<sup>86</sup>

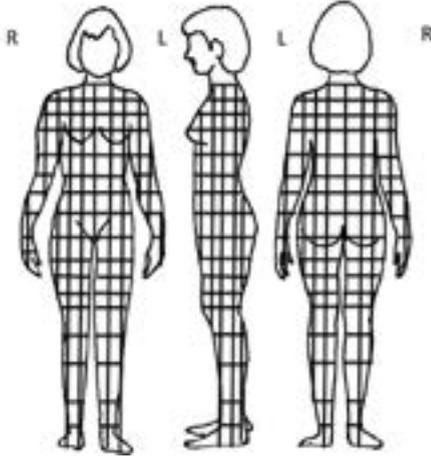

<sup>FN42</sup> Blood pressure, heart rate, peripheral pulses, edema, lower extremity strength, and vibratory sensation is almost always helpful.<sup>60</sup>

<sup>FN43</sup> A simple verbal rating scale can also be used, for example, “none,” “mild,” “moderate,” “severe.”

## 2. Pain Mapping Utilizing a Pain Body Chart<sup>87 FN44</sup>

**PAIN MAPPING**

**Instructions**  
Put highest intensity in each square that is applicable  
May use color codes for different pains

Pain evaluation involves additional pain mapping by identifying pain generators through diagnostic procedures.<sup>FN45</sup> These include EMG, Q-tip touch sensitivity testing,<sup>88,89</sup> trigger point injections, nerve blocks and imaging.<sup>88 FN46</sup>

### I Lower Urinary Tract

#### A. Questionnaires<sup>FN47</sup>

- a. Voiding diary with volume intake and output for 3 days at initial evaluation. Patient sensation at voiding might be recorded. At follow-up only the number of voids during day and night time is necessary. Morning volume might be recorded as a help to monitor highest functional capacity.<sup>90</sup>
- b. Basic symptom severity Questionnaires (condition specific):
  - i. The O’Leary–Sant Symptom Index.<sup>91</sup>
  - ii. International Prostate Symptom Score.<sup>92</sup>
- c. Visual Analogue Scale (VAS)<sup>87</sup> or a Likert scale for pain during the last 24 hr and over the last month (to fit with the voiding diary).<sup>FN48</sup>

#### B. Laboratory Testing

- a. Urine Dipstick (red blood cells, pH, leucocytes, nitrite).
- b. Urine Culture.<sup>FN49</sup>
- c. Urine Cytology in high risk patients.
- d. Investigations for Ureaplasma and Chlamydia are optional.

<sup>FN44</sup>Patients color the pain sites on the body chart.

<sup>FN45</sup>As pain is multidimensional, it can be helpful to assess separately pain intensity, pain distress, and interference of pain with activities of daily life.

<sup>FN46</sup>Kaufman Q-tip touch sensitivity test. This involves touching all four quadrants of the vulvar and vestibular Skene’s gland ostia to evaluate for vestibulodynia, using a visual analog scale to document the level of pain and sensitivity the patient is experiencing.<sup>89</sup>

<sup>FN47</sup>Many of the questionnaires have not been studied and validated in patients with CPPS. The main assessment is still a thorough history and a full and accurate physical examination followed by pain mapping and other studies as indicated.

<sup>FN48</sup>Separate scores for the average, mildest and worst pain might be obtained.

<sup>FN49</sup>If sterile pyuria, culture for tuberculosis, in high risk patients.

## 18 Doggweiler et al.

- e. C.T. Urogram for Hematuria.

**C. Intravesical Anesthetic Challenge**

An Anesthetic Challenge may be useful in pain mapping to identify the bladder and/or the urethra as a pain generator.<sup>93</sup> FN50

**D. Urodynamic Evaluation (1)**

- a. Flowmetry and Post-void Residual
- b. Filling Cystometry<sup>94,95</sup> FN51
- c. Pressure-Flow Study

It is recommended to perform filling cystometry and pressure flow study if the flowmetry suggests voiding dysfunction. The demonstration of pain may identify the bladder and/or urethra as a pain generator.

In males, bladder outlet obstruction might be a differential diagnosis<sup>96</sup> and it is recommended to perform flowmetry in all males and consider pressure-flow studies. In males with a peak flow below 20 ml/second. In females, flowmetry and post void residual urine volume should be considered, and pressure-flow study is optional.

**E. Cystoscopy**

Needs to be done for patients with hematuria<sup>97</sup> and to identify Hunner lesions.

- a. ESSIC standardized the procedure for cystoscopy and hydrodistension.<sup>11</sup> FN52

**Cystoscopic findings** by hydrodistension are important in subclassification of IC/BPS, see for example the ESSIC classification.<sup>11,31,98,99</sup> FN53

- i. Glomerulation
  - During cystoscopy with hydrodistension, glomerulations, with or without waterfall lesions (blood trickling downwards), may often be observed.<sup>100</sup> FN54
- ii. Hunner Lesion Figure 1

A Hunner lesion is not an ulcer, but an inflammatory infiltrate.<sup>11,101</sup> FN55

- i. Morphologic findings in Hunner Lesion

- 1. Inflammatory infiltrate on examination of biopsy taken with electro-resection or by cold cup biopsy.
- 2. Lymphocyte-like cells dominate in the infiltrate, but neutrophilic and eosinophilic granulocytes as well as plasma cells and mast cells are also found.
- 3. Perineural and perivascular arrangement of lymphocyte-like cell infiltrates
- 4. Granulation tissue.<sup>101–104</sup> FN56

**F. Differential Diagnosis (Confusable, treatable diseases):**

Criteria for diagnosis are needed as the target disease may be confused with other treatable diseases (confusable diseases) because of similar features.<sup>11</sup>

- a. Ketamine Cystitis

<sup>FN50</sup> A solution of lidocaine and sodium bicarbonate administered intravesically results in reduction of pain. Alkalinized lidocaine instillation has not been validated, but may be useful.<sup>93</sup>

<sup>FN51</sup> The NIDDK criteria excluded patients with detrusor overactivity at filling cystometry in order not to confuse the picture in clinical trials.<sup>94</sup> However, this does not mean that detrusor overactivity cannot coexist with interstitial cystitis/bladder pain syndrome. In the interstitial cystitis database, approximately 14% of IC/BPS patients had detrusor overactivity.<sup>95</sup>

<sup>FN52</sup> A rigid cystoscope is preferred to facilitate taking adequate biopsies. Glycine or corresponding filling fluid should be used to allow for coagulation after biopsies. Infusion height should be approximately 80 cm above the Symphysis Pubis. A dripping chamber is used and the bladder is filled until fluid dribbling stops. If necessary, a digital block is applied around the urethra to prevent leakage. Pre-distension inspection includes observation for radiating vessels, coagulum or fibrin deposits, white spots, hyperaemia, edema, cracks, scars or any other mucosal changes. Continuous inspection while filling the bladder is advised. When maximum capacity is reached, the distension is maintained for 1–3 min. The bladder is emptied and the color of the fluid checked for the degree of bleeding. The total volume drained is the measured maximum bladder capacity. During a second filling, the bladder is filled to approximately 1/3rd to 2/3rds of the bladder capacity to achieve optimal vision for inspection and biopsies. The bladder should not be filled to maximum capacity or distended again to avoid further provocation of changes with doubtful reproducibility.<sup>33</sup>

<sup>FN53</sup> The finding of a Hunner lesion is important because effective treatment is available.<sup>98,99</sup> The presence of Hunner lesions may be the diagnostic finding of the proposed disease "Interstitial Cystitis."<sup>31</sup>

<sup>FN54</sup> The significance of the presence of glomerulation remains to be determined.<sup>100</sup>

<sup>FN55</sup> A Hunner lesion is a distinct cystoscopic finding and typically presents as a circumscribed, reddened mucosal area with small vessels radiating towards a central scar, with a fibrin deposit or coagulum attached to this area. This site ruptures with increasing bladder distension, with petechial oozing of blood from the lesion and the mucosal margins in a waterfall manner. A rather typical edema may develop post-distension with varying peripheral extension. Usually, lesions are multiple but occasionally they may be single. It is not unusual for more lesions to be detected at re-inspection than seen at the initial phase of distension.<sup>11</sup>

<sup>FN56</sup> To a large extent, the detection rate and the findings on distribution of mast cells have been dependent on laboratory routines and staining as well as fixation techniques. Tryptase staining methods provide a stable result that is not sensitive to laboratory variations.<sup>103,104</sup>

Fig. 1. Hunner lesion.

Ketamine Cystitis is a new condition not previously described. Caused by recreational ketamine abuse, ketamine cystitis includes increased voiding, frequency, dysuria, bladder pain and hematuria.<sup>105,106 FN57</sup>

## II Female Genital

### A. Vulva, Vestibule and Clitoris

#### 1. Questionnaires

- i. Visual Analog Scale for pain.<sup>86</sup>
- ii. Female Sexual Function Index (FSFI).<sup>61</sup>
- iii. Female Sexual Distress Scale (FSDS).<sup>107</sup>

#### 2. Laboratory Testing

- i. Culture.
- ii. Biopsy.

#### 3. Diagnostic Testing

- i. Vulvoscopy, with or without biopsy.
- ii. Quantitative Sensory Testing (Q-tip touch sensitivity test).<sup>72,89,108</sup>

### B. Intra-abdominal Female Genital

#### 1. Questionnaires

- i. Visual Analog Scale(85) for pain.

#### 2. Laboratory Testing

- i. Culture.
- ii. Complete blood count.

#### 3. Laparoscopy (with or without biopsy)

#### 4. Ultrasound (US)

#### 5. MRI

#### 6. Venography (to rule out Pelvic Congestive Syndrome)<sup>109</sup>

### C. Pelvic Floor Muscle

#### 1. Questionnaires.

- i. Visual Analog Scale for pain.<sup>86</sup>
- ii. Pelvic Floor Distress Inventory (PFDI).<sup>110</sup>

<sup>FN57</sup>The molecular mechanism for ketamine-induced cystitis is unknown. The affected bladder exhibits a denudation of the urothelium with inflammatory cell infiltration. The upper urinary tract is also damaged in patients who use a higher dose and with a longer duration. Attention by both medical organizations and social workers for this increasing social phenomenon particularly among young people is now urgently needed.<sup>105,106</sup>

- 20 Doggweiler et al.
- iii. Prolapse and Incontinence Sexual Questionnaire (PISQ).<sup>111</sup>
2. Laboratory Testing
    - i. Wet Mount, Culture.
    - ii. Biopsy.
  3. Imaging References
    - i. Ultrasound (4D if available for visualization of mesh, where applicable).
    - ii. MRI (with or without defecography).
    - iii. Defecography.

### III Male Genital

#### A. Prostate Pain

1. Quantitative assessments.
  - i. Bladder diary.<sup>90,112</sup>
  - ii. CPSI (Chronic Prostatitis Symptom Index).<sup>113</sup>
  - iii. Visual Analog Scale for Pain (VAS).<sup>86</sup>
2. Laboratory Testing
  - i. Urinalysis (including post prostate massage).
  - ii. Urine Culture post prostate massage.
  - iii. Semen Culture.
3. Uroflowmetry, Post voiding residual volume, pressure flow study
4. Cystoscopy
5. Ultrasonography, with or without biopsy.

#### B. Scrotum, Epididymis, Testicle, Penis

1. Quantitative assessments
  - i. VAS for Pain.<sup>86</sup>
2. Ultrasonography

#### C. Urethra Pain

1. Quantitative assessments
  - i. Bladder diary.
  - ii. VAS for Pain.<sup>86</sup>
2. Laboratory Testing
  - i. Urinalysis (including post prostate massage, Ureaplasma/Chlamydia as appropriate).
3. Urethroscopy/Urethrography
4. Ultrasonography

#### D. Sexual Pain (See Domain VIII)

1. Questionnaires
  - i. VAS for Pain.<sup>86</sup>
  - ii. International Index of Erectile Function (IIEF).<sup>114</sup>

### IV Gastro-Intestinal (40)

1. Questionnaires
  - i. Rome III Criteria Questionnaire.<sup>115</sup>
  - ii. Colorectal Rectal Distress Inventory.<sup>116</sup>
2. Laboratory Testing
  - i. Culture.

*Neurourology and Urodynamics* DOI 10.1002/nau

- ii. Stool Evaluation for ova and parasites.
  - iii. Antibody testing.
  - iv. Biopsy.
3. Diagnostic Testing
- i. Anorectal Manometry (paradoxical contraction of the pelvic floor muscles when instructed to strain during defecation).
  - ii. Rigid or flexible endoscopy (Anorectal sigmoidoscopy) with or without biopsy.
  - iii. Anorectal/Pelvic US, 3D.
  - iv. Barium Enema.
  - v. CT Scan, Defecography, MRI defecography.

## V Musculoskeletal<sup>117</sup>

1. Questionnaires
- i. McGill Pain Questionnaire.<sup>118</sup>
  - ii. Pelvic Floor Distress Inventory (PFDI).<sup>110</sup>
  - iii. Female Sexual Function Index (FSFI).<sup>61</sup>
  - iv. Female Sexual Distress Scale (FSDS).<sup>107</sup>
2. Pain Location Drawing (Pain Mapping)
- i. Pain Chart body map.<sup>87</sup>
3. Evaluation of Muscle Tension There is no single tool which is able to measure all components of muscle tone. Some tools may be able to measure aspects of tone such as contractility, stiffness or elasticity. Instrumented methods may have a role in the valid and reliable evaluation of muscle tone, for example, surface electromyography, dynamometry, real-time ultrasound, elastometry, myotonometry.
- i. Pressure manometry is the measurement of resting pressure or pressure rise generated during contraction of the pelvic floor muscles using a pressure device (a manometer) inserted into the urethra, vagina or anus.<sup>119,120 FN58</sup>
  - ii. Surface electromyography (sEMG) refers to the bioelectrical activity generated by muscle fibres.<sup>121,122 FN59</sup>
  - iii. Dynamometry is the measurement of pelvic floor muscle resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina.<sup>123</sup>
  - iv. Real-time ultrasound measures pelvic floor muscle morphology and function via a non-invasive (trans-abdominal or trans-perineal) probe.<sup>124 FN60</sup>
  - v. Elastometry measures the elasticity of a tissue.<sup>125 FN61</sup>
4. Trigger point injection or needling has been used as a diagnostic test to identify pain generators.<sup>125 FN62</sup>
5. Imaging
- i. X-Ray.
  - ii. Ultrasound.
  - iii. MRI.

## VI Neurological Aspects

### A. Neuropathic Pain Questionnaires

1. VAS Pain Score.<sup>86</sup>
2. Pain DETECT (Validated for CPPS evaluation).<sup>129</sup>
3. Leeds Assessment for neuropathic symptoms and signs (not validated for chronic pelvic pain).<sup>130</sup>
4. Douleur Neuropathique 4 Questionnaire.<sup>131</sup>

<sup>FN58</sup>The tool has been used as an outcome measure in intervention studies of pelvic floor pain.<sup>119,120</sup> However, the tool has not been tested for reliability in this population.

<sup>FN59</sup>Pelvic floor muscle surface electrodes use either flat interface perineal electrodes or intra-vaginal/intra-anal probes to record sEMG either at rest or during a PFM contraction. Surface EMG is considered to be non-specific to the PFM. Because of the large surface area covered by the electrode, cross-talk from adjacent muscles often occurs.<sup>121,122</sup> It is therefore not considered reliable as a measure.

<sup>FN60</sup>Trans-perineal measures of ano-rectal angle and levator plate angle have been tested for reliability in a male pelvic pain population.<sup>124</sup>Therefore, this tool shows promise as an instrumented method to evaluate pelvic floor muscle changes in pelvic pain.

<sup>FN61</sup>It has recently been applied to measure the passive stiffness of puborectalis in asymptomatic women and shown to be reliable in this pilot study<sup>125</sup>However, it requires testing to establish application in a pelvic pain cohort.

<sup>FN62</sup>The taut band(s) of sarcomeres within the TrP can be identified by ultrasonography,<sup>126</sup> and magnetic resonance elastography.<sup>127</sup> A tissue compliance meter which measures stiffness in the taut band has been shown to confirm the hardness of the discrete band of muscle that harbors the tender region in peripheral skeletal muscle.<sup>128</sup>

22 Doggweiler et al.

### **B. Quantitative Sensory Testing**

1. 1Q-tip touch sensitivity.
2. Sensory pain mapping.<sup>72</sup>
3. Reflex evaluation.
4. Electromyography.

### **C. Nerve Blocks**

1. May/may not be done under Computed Tomography, Ultrasound or EMG guidance.<sup>132,133</sup>

### **D. Imaging**

1. Ultrasound
2. Magnetic resonance Imaging (MRI)

### **VII Psychological Aspects<sup>18,54</sup>**

The chief purpose of psychological assessment is to get a complete picture of the pain syndrome with all affected dimensions: somatic, affective, cognitive and behavioral, and the individual consequences for the patient. Direct questioning about the patient's view of what is wrong or what worries him/her is more helpful than questionnaires.<sup>FN63</sup>

1. Questionnaires
  - i. SF-12 or SF-36.<sup>134</sup>
  - ii. Brief Pain Inventory.<sup>135</sup>
  - iii. Catastrophizing Questionnaire can be considered in certain cases.<sup>136</sup>

### **VIII Sexual Aspects**

1. Questionnaires.
  - i. Female Sexual Function Index (FSFI).<sup>61</sup>
  - ii. Female Sexual Distress Scale (FSDS).<sup>107</sup>
  - iii. International Index of Erectile Function (IIEF).<sup>137</sup>
2. Laboratory Testing
  - i. Hormone Panel.
  - ii. Complete Metabolic Panel.
  - iii. Culture.
3. Imaging
  - i. Doppler US to assess blood flow.

It is also particularly important to work up the partner's potential sexual dysfunction. Early referral to a sexual counsellor is optimal.

### **IX Evaluation of Comorbidities**

If patients have symptoms and signs of comorbidities, evaluation should be undertaken according to relevant guidance, and may be appropriate to refer to the relevant specialist.

## **SUMMARY**

This first ICS Standard for Terminology in Chronic Pelvic Pain Syndromes aims to improve understanding of these syndromes and patient diagnosis. It is hoped that this will help develop the field, through facilitating phenotyping of patients, development of pertinent animal models and new preclinical development of therapeutic strategies.

Evaluation of patients based on the nine domains should be individualized, taking into consideration the patient's personal perception of pain, and also the biopsychosocial aspects of CPPS.

Discussions on nomenclature partly focused on the risk of inadequate patient care if diagnostic terminology is changed without taking into account the practical impact of its application on the patient's access to appropriate treatment, reimbursement, and social benefits.

This Standard for Terminology in CPPS will be reviewed in the future as continuing research, such as the Multidisciplinary Approach to the Study of Chronic Pelvic Pain (MAPP) Research Network, generates new insights.<sup>138-140</sup> Working with the guideline bodies, such as the AUA, East Asian IC Study Group/SIC, EAU, ESSIC, FGIDS, and IASP, the ultimate aim should be to achieve international consensus.

## **CONSULTANTS**

Ursula Wesselmann, Professor of Anesthesiology and Neurology, University of Alabama, Birmingham, AL, USA. Peter Rosier, Department of Urology, University Medical Center Utrecht, Utrecht, Netherlands. Fernando Cervero, Anaesthesia Research Unit,

<sup>FN63</sup> Early referral to a psychological healthcare provider should be considered. Patients with sexual dysfunction may need sexual counseling.

McGill University, Montreal, QC, Canada. Alain Watier, Gastroenterology, Sherbrooke, QC, Canada. Kari Bø, Professor of Physical Therapy, Norwegian School of Sport Sciences, Department of Sports Medicine, Oslo, Norway.

## An International Urogynecological Association (IUGA) / International Continence Society (ICS) Joint Report on the Terminology for Female Pelvic Organ Prolapse (POP)

Bernard T. Haylen,<sup>1,2\*</sup> Christopher F. Maher,<sup>1,2</sup> Matthew D. Barber,<sup>2</sup> Sérgio Camargo,<sup>2</sup> Vani Dandolu,<sup>2</sup> Alex Digesu,<sup>2</sup> Howard B. Goldman,<sup>2</sup> Martin Huser,<sup>2</sup> Alfredo L. Milani,<sup>2</sup> Paul A. Moran,<sup>1,2</sup> Gabriel N. Schaer,<sup>1,2</sup> and Mariëlla I.J. Withagen<sup>2</sup>

<sup>1</sup>Standardization and Terminology Committees IUGA & ICS

<sup>2</sup>Joint IUGA / ICS Working Group on Female POP Terminology

**Introduction:** The terminology for female pelvic floor prolapse (POP) should be defined and organized in a clinically-based consensus Report. **Methods:** This Report combines the input of members of two International Organizations, the International Urogynecological Association (IUGA) and the International Continence Society (ICS), assisted at intervals by external referees. Appropriate core clinical categories and a sub-classification were developed to give a coding to definitions. An extensive process of fourteen rounds of internal and external review was involved to exhaustively examine each definition, with decision-making by collective opinion (consensus). **Results:** A Terminology Report for female POP, encompassing over 230 separate definitions, has been developed. It is clinically-based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in all the different specialty groups involved in female pelvic floor dysfunction and POP. Female-specific imaging (ultrasound, radiology and MRI) and conservative and surgical managements are major additions and appropriate figures have been included to supplement and clarify the text. Emerging concepts and measurements, in use in the literature and offering further research potential, but requiring further validation, have been included as an appendix. Interval (5-10 year) review is anticipated to keep the document updated and as widely acceptable as possible. **Conclusion:** A consensus-based Terminology Report for female POP has been produced to aid clinical practice and research. *NeuroUrol. Urodynam.* 35:137–168, 2016. © 2016 Wiley Periodicals, Inc., and The International Urogynecological Association

**Key words:** female; pelvic organ prolapse; standardization report; terminology report

### INTRODUCTION

**Prolapse** (Latin: *Prolapsus* – “a slipping forth”) refers to a falling, slipping or downward displacement of a part or organ. **Pelvic organ** refers most commonly to the uterus and/or the different vaginal compartments and their neighboring organs such as bladder, rectum or bowel. **Pelvic organ prolapse (POP)** is thus, primarily, a definition of anatomical change. Some such changes may well be considered within the range of normality for certain women. A **diagnosis of POP** ideally demands clear clinical evidence, starting with a woman having symptoms related to the “downward displacement” of a pelvic organ.

There is currently no single document encompassing all elements required for diagnoses in the area of female POP. Such a report would require a full outline of the terminology for symptoms, signs, clinical assessments, functional investigations for female POP, the imaging associated with those investigations, the most common diagnoses and terminology for the different conservative and surgical treatment modalities.

There will be a need to reference considerably the 2010 IUGA-ICS Joint Terminology Report on Female Pelvic Floor Dysfunction<sup>1</sup>. An original aim of that report<sup>1</sup> had been to provide a general terminology, forming a “backbone” or “core” terminology to which more specific terminologies can be attached. Reference can also be made to three other published Standardization Reports<sup>2-4</sup> and 6 joint IUGA-ICS Female Terminology Reports<sup>5-10</sup> subsequent to the 2010 Report<sup>1</sup>, three published<sup>5-7</sup>, three<sup>8-10</sup> advanced in development.

In terms of the previous standardization document on female POP<sup>4</sup>, now 20 years old, there has been much discussion and debate<sup>11-14</sup> on the possible need to update its classification POP-Q, or at least to present it in a refreshed version. The POP Working Group has opted for the latter, with major upgrades to symptoms, signs, investigations and diagnoses, but a conservative approach to the classification itself (apart from adding a validated simplified version), due to the longevity of its use and the lack of any validated, clearly superior alternative classification. Female-specific imaging (ultrasound, radiology and MRI) and conservative and surgical managements are major additions and appropriate figures have been included to supplement and clarify the text. Emerging concepts and measurements, in use in the literature and offering further research potential, but requiring further validation, have been included as an Appendix. This Report acknowledges that POP is often not a diagnosis in isolation but may be associated with POP-related and unrelated voiding, defecatory and/or sexual dysfunctions and/or other diagnoses of pelvic floor dysfunction.

This Terminology Report is inherently and appropriately a definitional document, collating the definitions of those terms, i.e. “words used to express a defined concept in a particular branch of study”<sup>15</sup>, here POP. Emphasis has been on comprehensively including those terms in current use in the relevant peer-reviewed literature. The aim is to assist clinical practice and research. Some new and revised terms have been included. Explanatory notes on definitions have been referred, where possible, to the “Footnotes” section.

Like all the other joint IUGA-ICS female-specific terminology reports, every effort has been made to ensure this Report is:

**(1) User-friendly:** It should be able to be understood by all clinical and research users.

**(2) Clinically-based:** Symptoms, signs and validated assessments/investigations should be presented for use in forming workable diagnoses for POP and associated dysfunctions. Sections 1-5 will address symptoms, signs, POP quantification, investigations for associated dysfunctions and current POP imaging modalities that may be used to make those diagnoses. A number of related radiological investigations including Magnetic Resonance Imaging (MRI) and Computerized Tomography (CT) have also been incorporated. Section 6 will address POP diagnoses, possible POP-related diagnoses and co-existing diagnoses. The scope of the Report will exclude more invasive investigations requiring an anesthetic. Sections 7 and 8 will list the terminology for evidence-based conservative and surgical treatments for POP.

**(3) Origin:** Where a term’s existing definition (from one of multiple sources used) is deemed appropriate, that definition will be included and duly referenced. A large number of terms in female pelvic floor prolapse and dysfunction, because of their long-term use, have now become generic, as apparent by their listing in medical dictionaries.

**(4) Able to provide explanations:** Where a specific explanation is deemed appropriate to describe a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (*Footnote [FN] 1,2,3...*). Wherever possible, evidence-based medical principles will be followed.

It is suggested that acknowledgement of these standards in written publications related to female POP, be indicated by a footnote to the section “Methods and Materials” or its equivalent, to read as follows: “Methods, definitions and units conform to the standards jointly recommended by the International Urogynecological Association and the International Continence Society except where specifically noted”.

#### SECTION 1: SYMPTOMS:

**Symptom:** Any morbid phenomenon or departure from the normal in structure, function or sensation, experienced by the woman and indicative of disease or a health problem<sup>16</sup>. Symptoms are either volunteered by, or elicited from the woman or may be described by the woman’s caregiver<sup>1-3</sup>.

<sup>1</sup>: In the era of advanced cellphone camera technology, a woman, at times, will bring photographic evidence of the prolapse at its worst. This can add to other clinical evidence, particularly if there is a discrepancy between symptoms and signs.

<sup>2</sup>: The more formal classification of constipation is as follows:  
Rome II diagnostic criteria for constipation:

- At least 12 weeks, which need not be consecutive, in the previous 12 months, of two or more of:
  - (i) Straining in > 1 in 4 defecations.
  - (ii) Lumpy or hard stools in > 1 in 4 defecations.
  - (iii) Sensation of incomplete evacuation in > 1 in 4 defecations.
  - (iv) Sensation of anorectal obstruction/ blockage in > 1 in 4 defecations.
  - (v) Manual manoeuvres to facilitate > 1 in 4 defecations (e.g. digital evacuation, support of the pelvic floor).
  - (vi) Less than 3 defecations per week.
- Loose stools are not present and there is insufficient evidence for IBS (irritable bowel syndrome)

<sup>3</sup>: A symptomatic-based subdivision of Stage II (see Appendix A) was overlooked at this time in favor of maintaining the current strictly anatomical definition of the “sign of POP”.

### Pelvic Organ Prolapse (POP) Symptoms

**Prolapse symptoms<sup>1</sup>:** A departure from normal sensation, structure or function, experienced by the woman in reference to the position of her pelvic organs. Symptoms are generally worse in situations when gravity might make the prolapse worse (e.g. after long periods of standing or exercise) and better when gravity is not a factor e.g. lying supine. Again symptoms may be more noticeable at times of abdominal straining e.g. defecation.

#### A: Vaginal Prolapse Symptoms

**(i) Vaginal bulging<sup>1</sup>:** Complaint of a “bulge”, lump or “something coming down” or “falling out” through the vaginal introitus. The woman may state she can either feel the bulge by direct palpation or see it, perhaps aided with a mirror. FN1

**(ii) Pelvic pressure<sup>1</sup>:** Complaint of increased heaviness or dragging (pain or discomfort) in the suprapubic area and/or pelvis.

**(iii) Bleeding, discharge, infection<sup>1</sup>:** Complaint of abnormal vaginal bleeding, discharge or infection which may be related to ulceration of the prolapse.

**(iv) Splinting / Digitation<sup>1</sup>:** Complaint of the need to digitally replace the prolapse or to otherwise apply manual pressure, e.g. to the vagina, perineum or perianal area (splinting), or rectally (digitation) to assist voiding or defecation.

**(v) Low backache<sup>1</sup> (POP-related):** Complaint of low, sacral (or “menstrual-like”) backache associated temporally with vaginal POP and relieved when prolapse is reduced.

#### B: Urinary Tract Prolapse Symptoms

**(i) Urethral Prolapse:** Complaint of a “lump” at the external urethral meatus.

#### C: Anorectal prolapse symptoms

**(i) Anorectal prolapse:** Complaint of a “bulge” or “something coming down” towards or through the anus/rectum. The woman may state she can either feel the bulge by direct palpation or see it perhaps aided with a mirror. FN1

**(ii) Rectal prolapse:** Complaint of external protrusion of the rectum.

#### Effects of Pelvic Organ Prolapse on Bladder, Bowel and Sexual Function.

As demonstrated in Figure 1, higher stage utero-vaginal prolapse will usually cause anatomical distortion to surrounding organs, bladder and rectum most commonly. This can lead to abnormal function, most commonly difficulty with bladder and bowel emptying. Commonly, symptoms related to those surrounding organs are the most bothersome leading to the eventual diagnosis of the POP.

Figure 1. Utero-vaginal prolapse.

#### D: Potential prolapse-related lower urinary tract symptoms:

**(i) Hesitancy<sup>1</sup>:** Complaint of a delay in initiating micturition.

**(ii) Slow stream<sup>1</sup>:** Complaint of a urinary stream perceived as slower compared to previous performance (particularly prior to the development of POP) or in comparison with others.

**(iii) Intermittency<sup>1</sup>:** Complaint of urine flow that stops and starts on one or more occasions during voiding.

**(iv) Straining to void<sup>1</sup>:** Complaint of the need to make an intensive effort (by abdominal straining, Valsalva or suprapubic pressure) to either initiate, maintain or improve the urinary stream.

Neurourology and Urodynamics DOI 10.1002/nau

(v) **Spraying (splitting) of urinary stream**<sup>1</sup>: Complaint that the urine stream is a spray or split rather than a single discrete stream.

(vi) **Feeling of incomplete (bladder) emptying**<sup>1</sup>: Complaint that the bladder does not feel empty after micturition.

(vii) **Need to immediately re-void**<sup>1</sup>: Complaint that further micturition is necessary soon after passing urine.

(viii) **Post-micturition leakage**<sup>1</sup>: Complaint of a further involuntary passage of urine following the completion of micturition.

(ix) **Position-dependent micturition**<sup>1</sup>: Complaint of having to take specific positions to be able to micturate spontaneously or to improve bladder emptying e.g. leaning forwards or backwards on the toilet seat or voiding in the semi-standing position.

(x) **Splinting to micturate**: as above A (iv).

(xi) **Dysuria**<sup>1</sup>: Complaint of burning or other discomfort during micturition. Discomfort may be intrinsic to the lower urinary tract or external (vulvar dysuria).

(xii) **(Urinary) retention**<sup>1</sup>: Complaint of the inability to pass urine despite persistent effort.

(xiii) **Increased daytime urinary frequency**<sup>1</sup>: Complaint that micturition occurs more frequently during waking hours than previously deemed normal by the woman.

(xiv) **Urgency**<sup>1</sup>: Complaint of a sudden, compelling desire to pass urine which is difficult to defer.

**E: Potential prolapse-related anorectal dysfunction symptoms**<sup>1,8</sup>

(i) **Constipation**<sup>8</sup>: Complaint that bowel movements are infrequent and/or incomplete and/or there is a need for frequent straining or manual assistance to defecate. FN2

(ii) **Feeling of incomplete bowel evacuation**<sup>1,8</sup>: Complaint that the rectum does not feel empty after defecation and may be accompanied by a desire to defecate again.

(iii) **Straining to defecate**<sup>1,8</sup>: Complaint of the need to make an intensive effort (by abdominal straining or Valsalva) to either initiate, maintain or improve defecation.

(v) **Sensation of anorectal blockage**<sup>8</sup>: Complaint suggestive of anorectal obstruction.

(vi) **Splinting / Digitation**<sup>1,8</sup>: Defined above in A (iv).

(vii) **Fecal (rectal) urgency**<sup>1,8</sup>: Complaint of a sudden compelling desire to defecate that is difficult to defer.

(viii) **Post-defecatory soiling (NEW)**: Soiling occurring after defecation.

**F: Potential prolapse-related Sexual dysfunction symptoms**<sup>1,10,17</sup>:

(i) **Dyspareunia**: Complaint of persistent or recurrent pain or discomfort associated with attempted or complete vaginal penetration.

(ii) **Obstructed intercourse**: Complaint that vaginal penetration is impeded. Possible causes include narrowing or a bulge.

(iii) **Vaginal laxity**: Complaint of excessive vaginal looseness.

(iv) **Libido – loss or decrease**: Complaint of loss or decrease of sexual desire

**G: Other Possible Associated Symptoms**<sup>1</sup>

(i) **Urinary incontinence symptoms**<sup>1</sup>: Urinary incontinence (symptom); stress (urinary) incontinence; urgency (urinary) incontinence; postural (urinary) incontinence; nocturnal enuresis; mixed (urinary) incontinence; continuous (urinary) incontinence; insensible (urinary) incontinence; coital (urinary) incontinence.

(ii) **Bladder storage symptoms**<sup>1</sup>: nocturia; overactive bladder syndrome.

(iii) **Bladder sensory symptoms**<sup>1</sup>: Increased bladder sensation; reduced bladder sensation; absent bladder sensation.

(iv) **Lower Urinary Tract Infection**<sup>1</sup>: Urinary tract infection (UTI); recurrent urinary tract infections (UTIs); other related history.

**H: More common POP-related symptoms:** Table I gives a consensus view of the authors of the more common POP-related symptoms

TABLE I. The symptoms that women with POP would more\* and most commonly\*\* describe.

<b>Potential prolapse-related symptoms</b>	
<u>Vaginal prolapse</u>	Bulge sensation /visualization**, pelvic pressure**, low (sacral) backache*
<u>Urinary tract</u>	Frequency**, recurrent UTI**, incomplete emptying/urinary retention*, slow stream*
<u>Ano-rectal</u>	Incomplete defecation**, digitation/splinting*, rectal urgency*, post-defecatory soiling
<u>Sexual</u>	Dyspareunia*, vaginal laxity*
<b>Other possible associated symptoms</b>	
<u>Urinary incontinence**</u>	Stress, urge, postural, nocturnal, coital
<u>Bladder storage*</u>	Urgency, nocturia,

## SECTION 2: SIGNS

**Sign:** Any abnormality indicative of disease or a health problem, discoverable on examination of the patient; an objective indication of disease<sup>16</sup> or a health problem.

**A: Signs of Pelvic Organ Prolapse:** All examinations for POP should be performed with the woman's bladder empty (and if possible an empty rectum). An increasing bladder volume has been shown to restrict the degree of descent of the prolapse<sup>18</sup>. The choice of the woman's position during examination, e.g. left lateral (Sims), supine, standing or lithotomy is that which can best demonstrate POP in that patient and which the woman can confirm as the maximal extent she has perceived e.g. by use of a mirror or digital palpation. The degree of prolapse may be worse after a lengthy time in the upright position. FN1

**(i) Pelvic organ prolapse (anatomical definition of the sign of POP)<sup>1</sup>:** The descent of one or more of the anterior vaginal wall, posterior vaginal wall, the uterus (cervix) or the apex of the vagina (vaginal vault or cuff scar after hysterectomy). **The presence of any such sign should be correlated with relevant POP symptoms<sup>13,19-21</sup>**, i.e., patient report of maximal prolapse. More commonly, this correlation would occur at the level of the hymen or beyond<sup>19-21</sup>.

**(ii) Pelvic organ prolapse – (POPQ) - (staging<sup>1,3,4</sup>):**

**Stage 0:** No prolapse is demonstrated.

**Stage I:** Most distal portion of the prolapse is more than 1cm above the level of the hymen.

**Stage II:** The most distal portion of the prolapse is situated between 1 cm above the hymen and 1cm below the hymen. FN3. See also Appendix.

**Stage III:** The most distal portion of the prolapse is more than 1cm beyond the plane of the hymen but everted at least 2cm less than the total vaginal length.

**Stage IV:** Complete eversion or eversion at least within 2 cm of the total length of the lower genital tract is demonstrated.

**(iii) Uterine/ cervical prolapse:** Observation of descent of the uterus or uterine cervix.

Figure 2. Uterine Prolapse.

**(iv) Anterior vaginal wall (compartment) prolapse:** Observation of descent of the anterior vaginal wall (compartment). Most commonly this might represent bladder prolapse (cystocele). Higher stage anterior vaginal wall prolapse will generally involve descent of uterus or vaginal vault (if uterus is absent). Occasionally, there might be an anterior enterocele (hernia of peritoneum and possibly abdominal contents), most commonly after prior reconstructive surgery.

Figure 3. Anterior vaginal wall (compartment) prolapse.

**(v) Posterior vaginal wall (compartment) prolapse:** Observation of descent of the posterior vaginal wall. Commonly, this would represent rectal protrusion into the vagina (rectocele). Higher stage posterior vaginal wall prolapse after prior hysterectomy will generally involve some vaginal vault (cuff scar) descent and possible enterocele formation. Enterocele formation can also occur in the presence of an intact uterus.

Figure 4. Posterior vaginal (compartment) wall prolapse.

**(vi) Vaginal vault (cuff scar) prolapse:** Observation of descent of the vaginal vault (cuff scar after hysterectomy).

Figure 5. Vaginal vault prolapse.

*Neurourology and Urodynamics* DOI 10.1002/nau

**B: Clinical Staging<sup>4</sup>:**

Each aspect of POP, uterine (cervical) prolapse, anterior vaginal wall (compartment), posterior vaginal wall (compartment), vaginal vault (cuff scar) prolapse can and should be subject to a clinical staging.

Figure 6. shows prolapse staging<sup>4</sup> – 0, I, II, III, IV. (uterine – by the position of the leading edge of the cervix).

**C: Supplementary Physical Examination Techniques**

(i) **Digital rectal-vaginal examination<sup>4</sup>:** While the patient is straining and the prolapse is maximally developed. The aim is to try to differentiate between a high rectocele and an enterocele.

(ii) **Q-tip (urethral) testing<sup>4</sup>:** Measurement of urethral axial mobility at rest and straining to assess degree of mobility.

**D: Clinical Assessment of Associations of POP**

(i) **Levator Defects / Trauma<sup>22</sup>:** Per-vaginal palpation for levator injury/defect/ "avulsion".

(ii) **Uterine retroversion<sup>23,24</sup>:** (Turning backward) The axis of the uterus is directed backwards towards the hollow of the sacrum, away from its anteverted position overlying the bladder. Cervix is noted in/ towards the anterior fornix with fundus perhaps palpable in the posterior fornix. FN4

**E: Other Possible Signs.**

(i) **Urinary incontinence signs<sup>1</sup>:** Urinary incontinence; stress (urinary) incontinence; urgency (urinary) incontinence; extraurethral incontinence; stress incontinence on prolapse reduction (occult or latent stress incontinence)

(ii) **Other pelvic examinations/signs<sup>1</sup>:** Vulvar examination; urethral inspection/palpation (urethral mucosal prolapse, urethral caruncle; urethral diverticulum); vaginal examination; bimanual pelvic examination; pelvic floor muscle function (normal pelvic floor muscles, overactive pelvic floor muscles, underactive pelvic floor muscles, non-functioning pelvic floor muscles); examination for levator (puborectalis) injury; perineal examination (perineal elevation, perineal descent); rectal examination (anal sphincter tone and strength, anal sphincter tear, fecal impaction present/absent, other rectal lesions, anal lesions, other perianal lesions), vaginal atrophy.

(iii) **Other relevant examinations/Signs<sup>1</sup>:** Neurological signs, abdominal signs (bladder fullness/retention; abdominal masses or distension; scars from previous relevant surgery or trauma; renal tenderness or masses).

(iv) **Frequency volume chart / Bladder diary<sup>1</sup>**

(v) **Pad testing<sup>1</sup>**

**SECTION 3: PROLAPSE QUANTIFICATION****A: Pelvic Organ Prolapse Quantification (POP-Q)<sup>4</sup>**

(i) **Fixed Point of Reference.** The hymen is the fixed point of reference used throughout the POP-Q system of quantitative prolapse description.

<sup>4</sup>: The axis of the retroverted uterus is parallel to that of the vaginal axis with less impediment to uterine (cervical) descent. In contrast, the anteverted uterus is perpendicular to the vaginal axis with impediment to descent by the posterior vaginal wall and behind that the rectum.

(ii) **Defined Points.** The anatomic position of the six defined points (two on the anterior vaginal wall, two in the superior vagina, and two on the posterior vaginal wall) for measurement should be centimeters (cm) above or proximal to the hymen (negative number) or cm below or distal to the hymen (positive number) with the plane of the hymen being defined as zero (0). For example, a cervix that protruded 3 cm distal to the hymen would be +3 cm. All points are measured on maximal straining (except total vaginal length).

(iii) **Anterior Vaginal Wall.**

(a) **Point Aa.** A point located in the midline of the anterior vaginal wall three (3) cm proximal to the external urethral meatus. By definition, the range of position of Point Aa relative to the hymen is -3 to +3 cm.

(b) **Point Ba.** A point that represents the most distal (i.e., most dependent) position of any part of the upper anterior vaginal wall from the vaginal cuff or anterior vaginal fornix to Point Aa. By definition, Point Ba is at -3 cm in the absence of prolapse and would have a positive value equal to the position of the cuff (Point C) in women with total uterine prolapse or post-hysterectomy vaginal eversion.

(iv) **Superior Vagina.** These points represent the most proximal locations of the normally positioned lower reproductive tract. The two superior sites are as follows:

(c) **Point C.** A point that represents either the most distal (i.e. most dependent) edge of the cervix or the leading edge of the vaginal cuff (hysterectomy scar) after total hysterectomy.

(d) **Point D.** A point that represents the location of the posterior fornix in a woman who still has a cervix. It is included as a point of measurement to differentiate suspensory failure of the uterosacral-cardinal ligament “complex” from cervical elongation. When the location of Point C is significantly more positive than the location of Point D, this is indicative of cervical elongation which may be symmetrical or eccentric. Point D is omitted in the absence of the cervix.

(v) **Posterior Vaginal Wall.**

(e) **Point Ap.** A point located in the midline of the posterior vaginal wall three (3) cm proximal to the hymen. By definition, the range of position of Point Ap relative to the hymen is -3 to +3 cm.

(f) **Point Bp.** A point that represents the most distal (i.e., most dependent) position of any part of the upper posterior vaginal wall from the vaginal cuff or posterior vaginal fornix to Point Ap. By definition, Point Bp is at -3 cm in the absence of prolapse and would have a positive value equal to the position of the cuff in a women with total post-hysterectomy vaginal eversion.

(vii) **Other Landmarks and Measurements.**

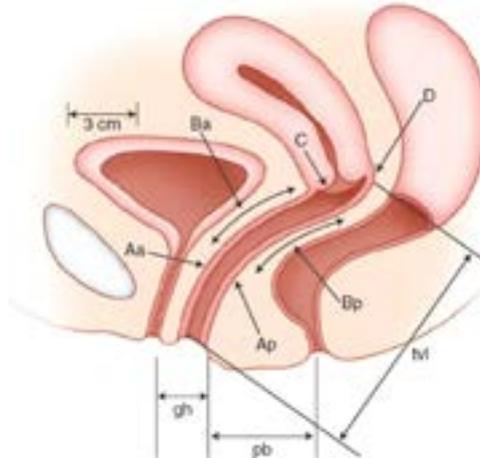

(g) The **genital hiatus** (GH) is measured from the middle of the external urethral meatus to the posterior margin of the hymen.

(h) The **total vaginal length** (TVL) is the length of the vagina (cm) from posterior fornix to hymen when Point C or D is reduced to its full normal position. (See Figure 40 - Appendix).

(i) The **perineal body** (PB) is measured from the posterior margin of the hymen to the mid-anal opening.

(viii) **Recording Measurements:** (NB: Intraoperative measurements with traction can be quite different from measurements made during Valsalva in clinic, both in regards to cervical location and the vaginal walls). Measurements directly after removing a vaginal pessary are unreliable and will tend to understage the degree of POP.

The position of Points Aa, Ba, Ap, Bp, C, and (if applicable) D with reference to the hymen should be measured (cm) and recorded.

**Figure 7.** The six sites (Aa, Ba, C, D, Bp and Bp), the genital hiatus (gh), perineal body (pb) and total vaginal length (tvL) used cm above or proximal to the hymen (negative number) or cm below or distal to the hymen (positive number) with the plane of the hymen being defined as zero (0). Alternatively, a three by three grid can be used to organize concisely the measurements as noted in Figure 8.

Anterior wall Au	Anterior wall Ba	Cervix or Cuff C
Genital hiatus gH	Perineal Body pB	Total Vaginal Length TVL
Posterior wall Ap	Posterior wall Bp	Posterior Fornix D

Figure 8. Grid presentation of POP-Q measurements.

#### B: Simplified POP-Q<sup>25,26</sup>

This is based on the POP-Q with similar ordinal staging but with only four points measured instead of nine. There is no Stage 0; it is combined with Stage 1. It is undertaken in the dorsal lithotomy position with patient forcefully bearing down, performing Valsalva or coughing.

**(i) Four points used:**

- . Anterior vaginal segment: point Ba (estimated around 3cm proximal to hymenal remnants).
- . Posterior vaginal segment: point Bp (estimated around 3cm proximal to hymenal remnants).
- . Cervix point C
- . Apex/posterior fornix: point D (non-hysterectomized); point C (hysterectomized)

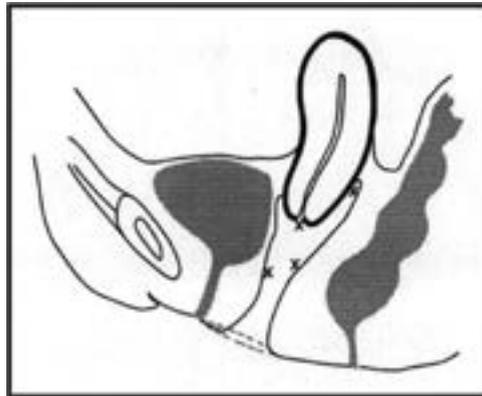

Figure 9. Simplified POP-Q.

**(ii) Staging:**

I, II, III, IV as for POP-Q above.

#### C: Additional available measurements awaiting further validation

These have been included as an Appendix after the References

**(i): Vaginal Anatomical Levels and Lengths.**

**(ii): Perineal measurements.**

**(iii): Vaginal measurements.**

## SECTION 4: INVESTIGATIONS

**Urodynamics<sup>1</sup>:** Functional study of the lower urinary tract.

**Clinical sequence of testing<sup>1</sup>:** Urodynamic investigations generally involve a woman attending with a comfortably full bladder for free (no catheter) uroflowmetry and post void residual urine volume (PVR) measurement prior to filling and voiding (with catheter) cystometry.

## A: Assessment of Impact of Prolapse on Voiding Function

POP can have a negative impact on voiding function, screening for which importantly involves a postvoid residual and ideally uroflowmetry. Voiding cystometry may clarify the cause of any voiding dysfunction.

**(i) Postvoid Residual<sup>1-3</sup>:** Volume of urine left in the bladder at the completion of micturition. **Conditions for PVR measurement:** PVR reading is erroneously elevated by delayed measurement due to additional urine production (1-14 mls/min). Ultrasonic techniques (transvaginal, translabial most accurately) allow immediate<sup>27</sup> (within 60 seconds of micturition) measurement and possible repeat measurement (Figure 10). A short plastic female catheter provides the most effective bladder drainage for PVR measurement by catheterization.

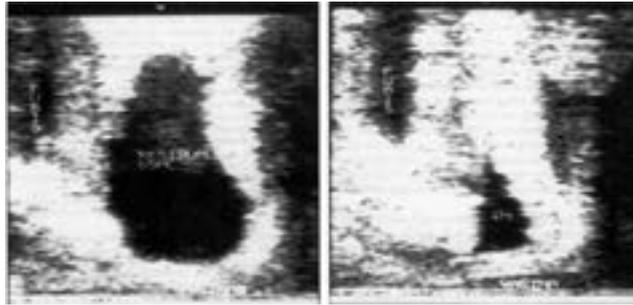

Figure 10. An image of postvoid residual of 65ml by transvaginal ultrasound, reducing to 4ml with a subsequent attempt at voiding.

**(ii) Uroflowmetry<sup>1-3</sup>:** Measurement of urine flow rates during micturition<sup>16</sup>

- . **Flow rate:** Volume of urine expelled via the urethra per unit time. It is expressed in ml/sec.
- . **Voided volume (ml):** Total volume of urine expelled via the urethra.
- . **Maximum (urine) flow rate (MUFR - ml/sec) - Q<sub>max</sub>:** Maximum measured value of the flow rate.
- . **Flow time (sec):** The time over which measurable flow actually occurs.
- . **Average (urine) flow rate (AUFR - ml/sec) - Q<sub>ave</sub>:** Voided volume divided by the flow time.

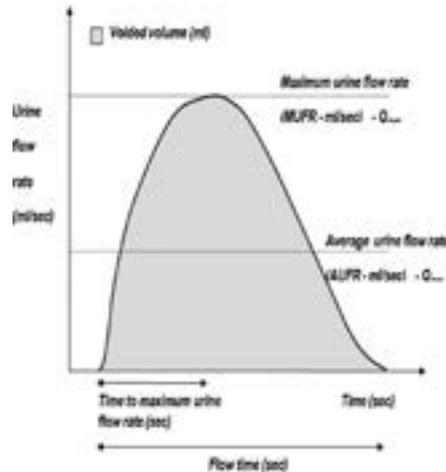

Figure 11. A schematic representation of urine flow over time.

The dependence of urine flow rates on voided volume<sup>28</sup> makes it desirable to reference raw urine flow rate data to established normative data.

Neurourology and Urodynamics DOI 10.1002/nau

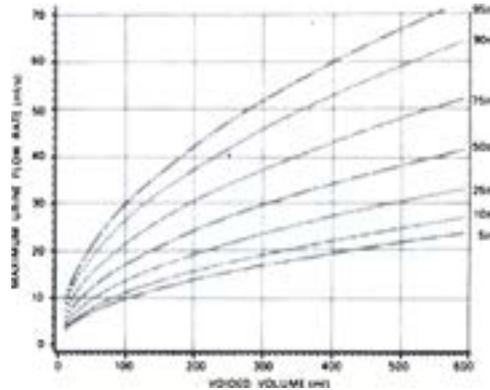

Figure 12. The Liverpool nomogram<sup>29</sup> for the maximum urine flow rate in women (under the 10<sup>th</sup> centile on repeat measurement can be regarded as abnormally slow<sup>30</sup>).

(iii) Pressure- Flow studies<sup>1-3,31</sup>

**Cystometry:** Measurement of the pressure/volume relationship of the bladder during filling and/or pressure flow study during voiding. Higher voiding detrusor pressures and slower urine flow during voiding may point an element of bladder outflow obstruction<sup>1-3,32</sup>, though other patterns of pressure-flow data are possible.

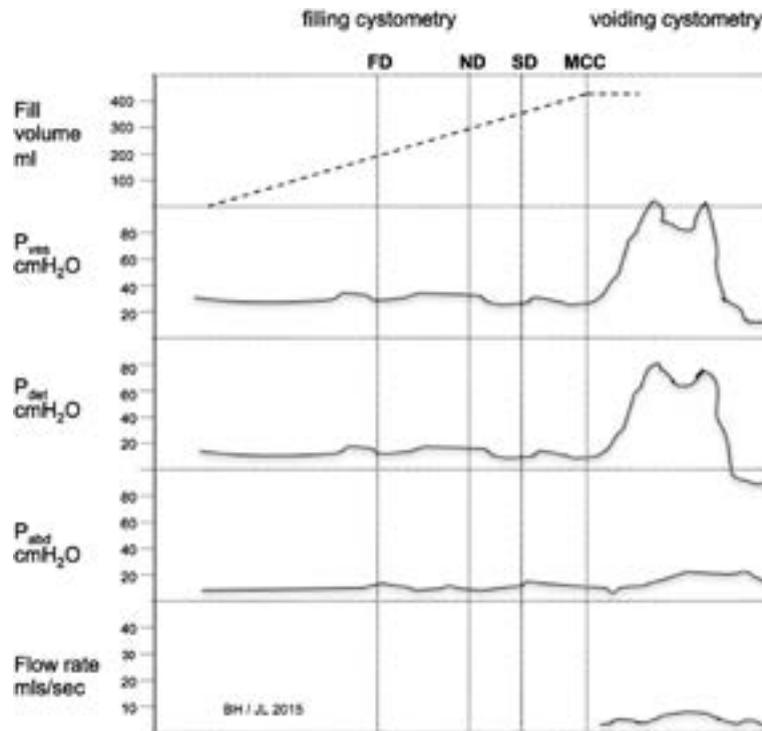

Figure 13. Filling and voiding cystometric trace, the latter part showing evidence of an element of bladder outflow obstruction. Normal bladder capacity, stable detrusor: no phasic activity seen. Voided with low urine flow rate and elevated detrusor pressure. Bladder outflow obstruction is thus demonstrated.

Neurourology and Urodynamics DOI 10.1002/nau

**B: Assessment of Impact on Prolapse on Defecatory Function**

- (i) **Ultrasound Assessment:** See imaging section.
- (ii) **Radiological Assessment:** See imaging section.

**C: Other urodynamic investigations for intercurrent diagnoses<sup>1-3,31</sup>**

(i) **Filling cystometry:** The pressure/volume relationship of the bladder during filling can evaluate the presence of intercurrent diagnoses (ii-iv).

(ii) **Urodynamic stress incontinence<sup>1</sup>:**

Involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction.

(iii) **Detrusor Overactivity<sup>1</sup>:**

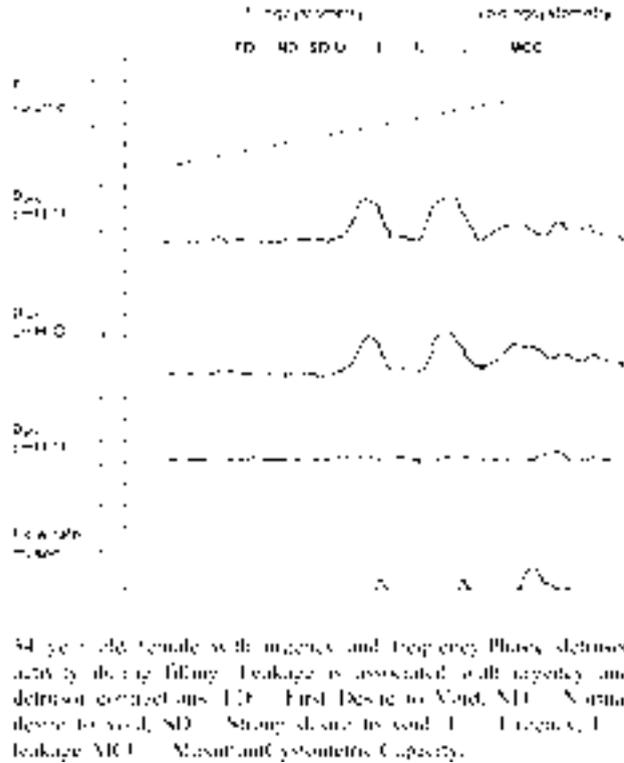

The occurrence of involuntary detrusor contractions during filling cystometry. These contractions, which may be spontaneous or provoked, produce a wave form on the cystometrogram, of variable duration and amplitude (Figure 14).

(iv) **Bladder Oversensitivity<sup>1</sup>:**

Increased perceived bladder sensation during bladder filling with: an early first desire to void; an early strong desire to void, which occurs at a low bladder volume; a low maximum cystometric bladder capacity. No abnormal increases in detrusor pressure are noted.

(v) **Detrusor underactivity<sup>3</sup>FN5 and Acontractile detrusor<sup>3</sup>FN6**

Can also be diagnosed at voiding cystometry.

**Figure 14.** Cystometric trace showing detrusor overactivity<sup>3</sup>.

<sup>5</sup>: *Detrusor underactivity:* Detrusor contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span.

<sup>6</sup>: *Acontractile detrusor:* The detrusor cannot be observed to contract during urodynamic studies resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span. The term “areflexia” has been used where there is a neurological cause but should be replaced by *neurogenic acontractile detrusor*.

## SECTION 5: PROLAPSE IMAGING

**Imaging may assist the clinical assessment of POP or intercurrent pelvic floor diagnoses. Use of any of the different imaging modalities is, however, entirely optional.**

**A: Prolapse-related ultrasound imaging – 2-D**

**(i) Modalities**

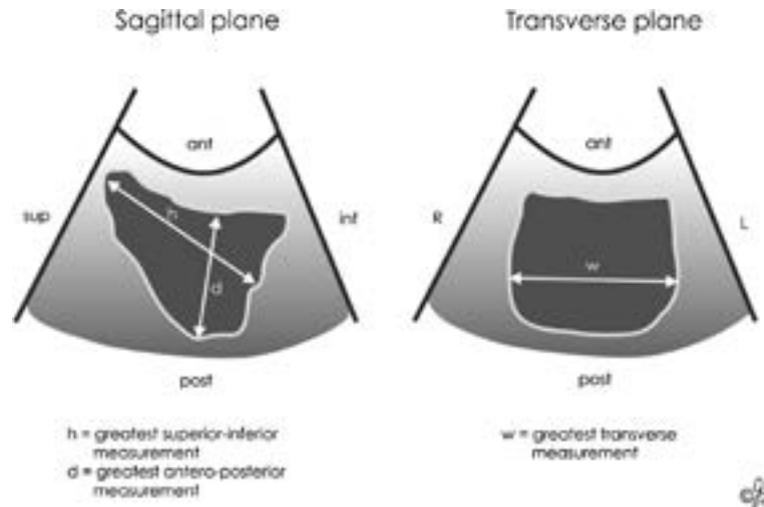

Transabdominal, perineal, introital and transvaginal ultrasound<sup>1</sup>.

- Transabdominal (T-A): curvilinear scanning applied to the abdomen.
- Perineal: curved array probe applied to the perineum. This term incorporates transperineal and translabial ultrasound.
- Introital: sector probe applied to the vaginal introitus.
- Transvaginal (T-V): intravaginal curvilinear, linear array, or sector scanning.

**(ii) Clinical applications:**

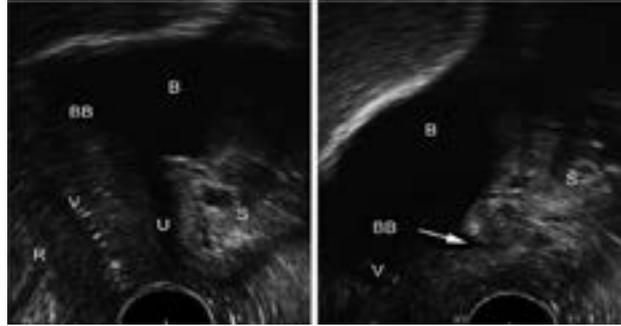

- Bladder neck descent/mobility. The position of the bladder neck at rest and on Valsalva.
- Urethral funnelling: i.e., opening of the proximal third of the urethra during coughing or on Valsalva.
- Post void residual: Several formulas have been described in the literature to measure the bladder volume by ultrasound<sup>33–35</sup>. An early formula  $[(h \times d \times w) \times 0.7]$  has been demonstrated to give reproducible results with a percentage error of 21%<sup>33</sup> (see Figure 15 for definitions of h,d,w).
- Bladder abnormalities: e.g., tumor, foreign body.
- Urethral abnormality: e.g., diverticulum.
- Intercurrent uterine and/or pelvic abnormality: dependent on probe range.
- Postoperative findings: e.g., bladder neck position and mobility, position of meshes, tapes, or implants.
- Descent of pelvic organs: visualization of descent of the bladder, uterine cervix, and rectum during coughing or on Valsalva.
- Assessment of voluntary pelvic floor muscle contractility.
- Pelvic floor/levator ani muscle defect (“avulsion”) and hiatal ballooning<sup>36</sup>.
- Ultrasound measurements of bladder and detrusor wall thickness, and ultrasound estimated bladder weight (UEBW) are potential noninvasive clinical tools for assessing the lower urinary tract. UEBW is higher in women with overactive bladder and detrusor overactivity<sup>37,38</sup>. FN7.

Figures 16 and 17 show examples of 2-D introital ultrasound in patients with POP symptoms.

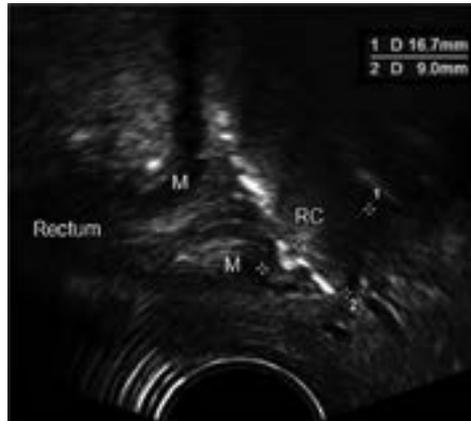

**Figure 15.** Ultrasound measurement of the bladder volume from Poston *et al.* 1983<sup>33</sup>(redrawn).

<sup>7</sup>: Women with detrusor overactivity have a median UEBW of 48.0 g (95% CI 46-51), with urodynamic stress incontinence a median UEBW of 30 g (95% CI 29-31) and those who have associated detrusor overactivity and urodynamic stress incontinence have a median UEBW of 37.3 g (95% CI 33-41) ( $p < 0.001$ )<sup>37,38</sup>.

**Figure 16. (above):** 56 year old female with stage II cystocele and urodynamic stress incontinence. Left: at rest. Right: during Valsalva. B = Bladder, BB = bladder base, U = urethra, S = symphysis pubis, arrow = bladder neck during Valsalva, V = vagina, R = rectum. Arrow = bladder neck during Valsalva with bladder neck funneling as a sign of urethral incompetence.

**Figure 17. (above):** 72 year old female with stage II rectocele. Measurement of rectocele (RC) width (1) and depth (2) during Valsalva. M = muscularis of rectum.

### **B: Prolapse-related ultrasound imaging – 3-D**

#### **(i) Modalities: Endovaginal, transanal, and translabial/transperineal**

- Endovaginal ultrasound imaging may inadvertently compress tissues thus distorting the anatomy.
- Transanal ultrasound approach requires an expensive and dedicated transducer, and it is a more uncomfortable and embarrassing test for the woman. Its most common clinical indication is the assessment of sphincter integrity following obstetric trauma.
- Translabial/transperineal approach overcomes the limitations of endovaginal and transrectal techniques providing minimal pressure on local structures and it is least likely to alter surrounding anatomy.

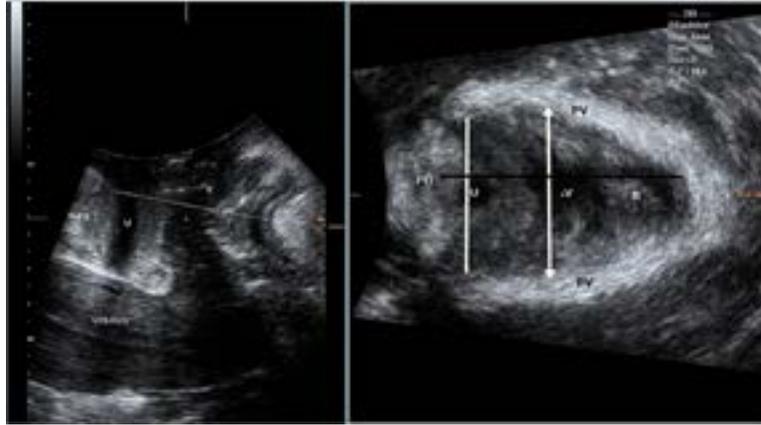

#### **(ii) Evaluations:**

The following pelvic floor abnormalities/ surgical sequelae can be evaluated:

- Trauma (injury/damage) of the levator ani muscle (LAM).
- Excessive distensibility of the puborectalis muscle and levator hiatus (“ballooning”).
- Pathologies of the anterior vaginal compartment like urethral diverticula.
- Bladder tumours or foreign bodies (sling, mesh, bulking agents).
  - Polypropylene meshes: highly echogenic and thus easily identified in the coronal and axial plane, unless they are obscured by vaginal prolapse.
  - Periurethral bulking agents, used as a continence procedure, can also be depicted with 3D pelvic floor ultrasound. FN8

<sup>8</sup>: Synthetic implant such as macropastique, are hyperechogenic whereas collagen injections are hypoechoic and can be seen as spherical structures surrounding the bladder neck.

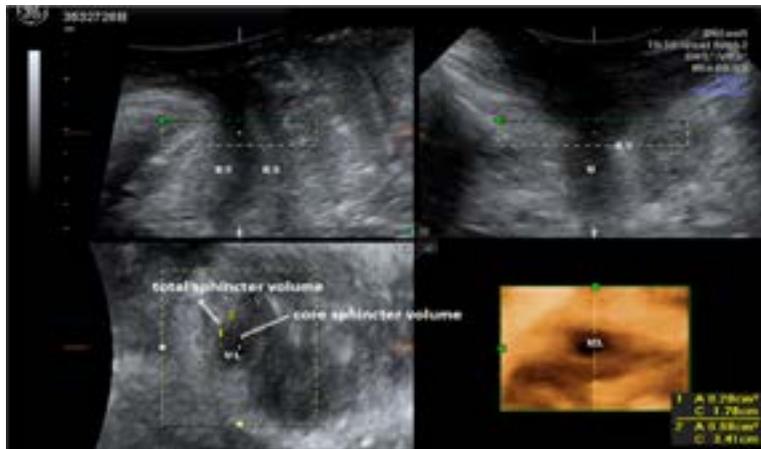

Figure 18 shows 3D ultrasound imaging of the pelvic floor anatomy.

**Figure 18. (above): 3D ultrasound image of levator ani muscle of an asymptomatic nulliparous woman at rest.** 3D ultrasound image of the pelvic floor at rest showing the anatomy and the reference plane of measurements. Left: sagittal view; PB: pubic bone; U: urethra; V: vagina; ARA: anorectal angle; white line: plane of minimal hiatal dimensions (plane of all measurements). Right: axial view; PB: pubic bone; U: urethra; V: vagina; R: rectum; PV: pubovisceralis muscle; black line: antero-posterior diameter of the levator hiatus; white line: transverse diameter of the levator hiatus at the level of pubourethralis, white double-headed arrowed line: transverse diameter of the levator hiatus at the level of pubovaginalis.

#### **(iii) 3D ultrasound imaging of the female urethra**

3D ultrasound imaging of the rhabdosphincter overcomes the limits of MRI and two-dimensional (2D) ultrasound imaging that incorrectly measure the urethral sphincter volume using mathematical formulas based upon assumptions that the shape of the urethra is similar to that of an ellipse. Since the urethral shape is neither elliptical nor spherical, but rather an atypical geometric shape, equations should not be used<sup>39</sup>. FN9. Figure 19 shows 3D ultrasound imaging of the urethral sphincter

**Figure 19. (above): 3D translabial image of the female urethra.** The urethra lumen is shown clearly in the rendered volume image (bottom right). (U, urethra; UL, urethra lumen; RS, rhabdosphincter).

#### **(iv) 3D ultrasound imaging of the levator ani trauma**

The presence of levator ani trauma has been postulated to be associated to an increased risk of pelvic organ prolapse<sup>40</sup>. This can be evaluated using a tomographic ultrasound imaging assessment of the levator ani muscles (Figure 20).

<sup>9</sup>: The importance of precise structural assessment of the urethral sphincter using multiple axial cross-sectional areas at set distances can assist the evaluation of women with stress urinary incontinence. It has been suggested that it may predict the severity of incontinence as well as the outcome of continence surgery since a weak sphincter will have a lower volume compared to a competent/continent urethral sphincter<sup>39</sup>.

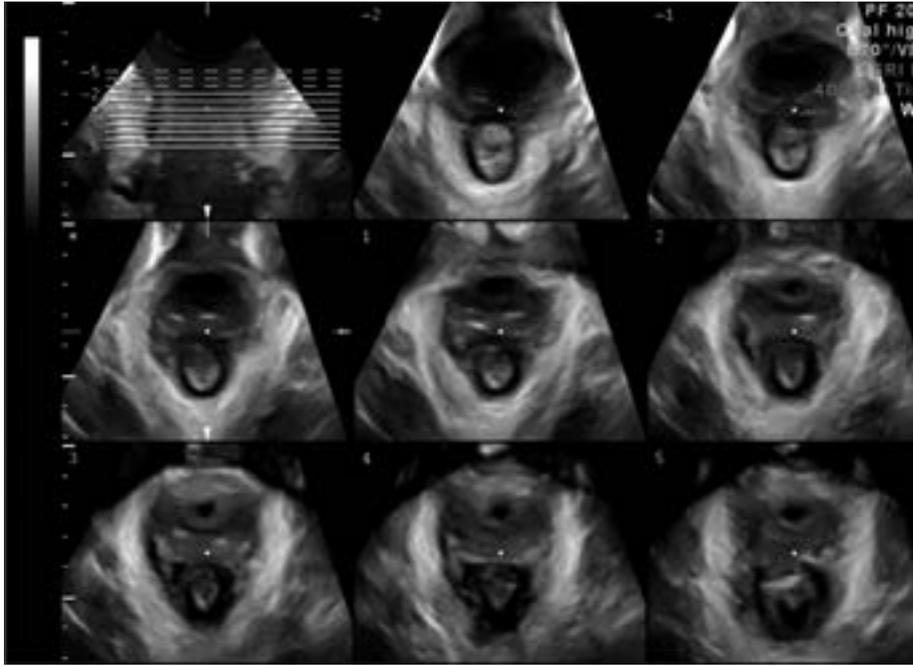

Figure 20. (above): Tomographic ultrasound imaging assessment of the levator ani muscles Intact LAM.

**(v) 3D ultrasound imaging of ballooning of the genital hiatus**

The presence of ballooning of the genital hiatus (= excessive distensibility of the levator hiatus) on Valsalva manoeuvre has also been associated to the severity of urogenital prolapse. An area of more than 25 cm<sup>2</sup>, 30 cm<sup>2</sup>, 35 cm<sup>2</sup> and 40 cm<sup>2</sup> has been defined as mild, moderate, marked and severe ballooning respectively (Figure 21)<sup>41</sup>.

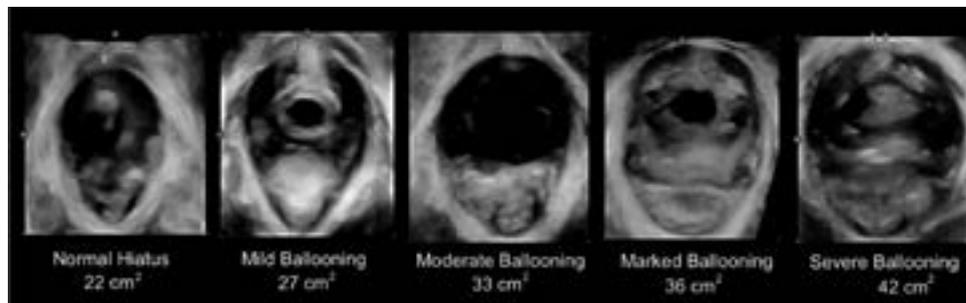

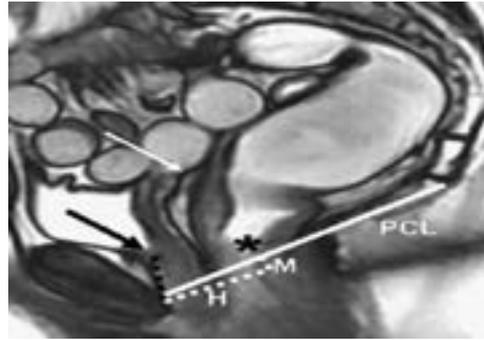

Figure 21. (above): Ballooning of the genital hiatus on Valsalva manoeuvre – levator defect.

**C: Magnetic resonance imaging (MRI) of the pelvic floor**

Magnetic resonance imaging (MRI) allows the detection of ligamentous and muscular pelvic floor structures in fine detail. Although it does not use ionising radiation, it is a high cost technique. Static MRI relies on static sequences and high spatial resolution images, to delineate the passive and active elements of the pelvic organ support system. Most commonly, images are acquired in axial, sagittal and coronal planes.

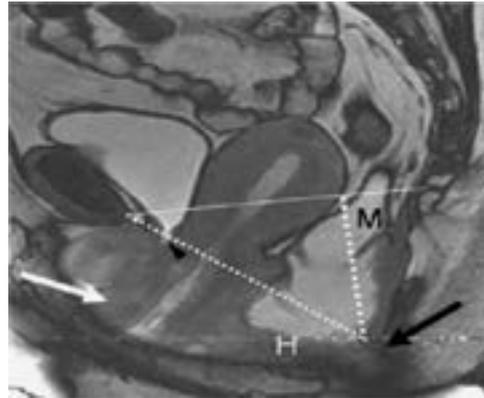

MRI has been proposed to be a useful method for diagnosing and staging POP. Several lines and levels of reference have been described in the literature. The most commonly used ones are either a line drawn from the inferior margin of the pubis symphysis to the last coccygeal joint (pubococcygeal line – PCL) or a line extending caudally along the longitudinal axis of the symphysis pubis in the sagittal plane, noted as midpubic line (MPL)<sup>42,43</sup> (Figures 22 and 23).

Neurourology and Urodynamics DOI 10.1002/nau

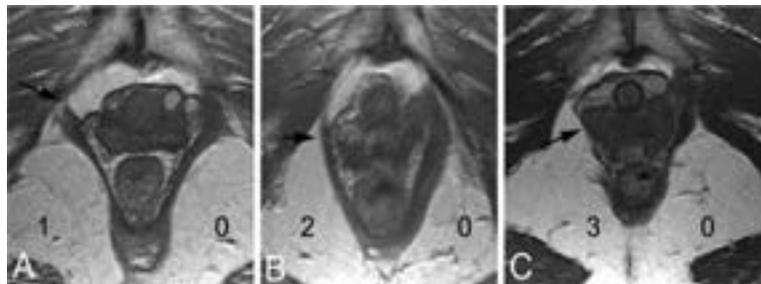

**Figure 22. (above):** Sagittal MRI image of the pelvic floor obtained at rest in a 50-year-old normal volunteer woman. The H line is drawn from the inferior border of the pubic symphysis to the posterior wall of the rectum at the level of the anorectal junction.

The M line is drawn perpendicularly from the PCL to the most posterior aspect of the H line. (PCL: pubococcygeal line, black arrow: bladder base, white arrow: vaginal vault, \*: anorectal junction, from Colaiacono MC<sup>42</sup> et al. 2009).

**Figure 23. (above):** Severe uterine prolapse in a 41-year-old woman. Sagittal function MRI image obtained during defaecation shows the uterus moving downward inside the vagina and the cervix exits the vaginal introitus (white arrow). H and M lines are abnormally elongated. Urethral funnelling without hypermobility (arrowhead) and severe posterior compartment descent (black arrow) are also noted (from Colaiacono<sup>42</sup> et al. 2009).

Other applications of MRI are the assessment of the LAM morphology (size, thickness volume) and detection of LAM injuries/ defects/ (“avulsion”) (figure 24)<sup>44–46</sup>.

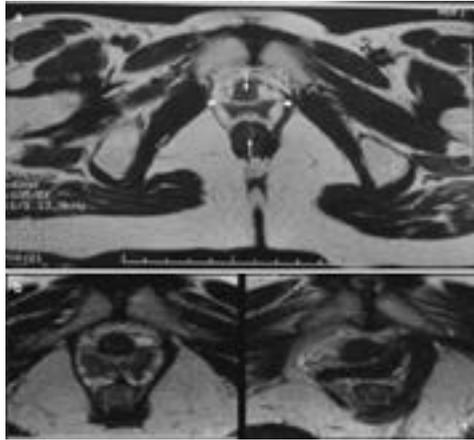

**Figure 24. (above):** Examples of grades of unilateral defects in the pubovisceral portion of the LAM in axial magnetic resonance images at the level of the mid urethra. The score for each side is indicated on the figure, and the black arrows indicate the location of the missing muscle (A. grade 1 defect; B. grade 2 defect; and C. grade 3 defect, from DeLancey. Levator Ani Impairment in Prolapse. *Obstet Gynecol* 2007).

Neurourology and Urodynamics DOI 10.1002/nau

**D: Current possible measurements using MRI in urogynecology****(i) Bladder neck and cervical descent / mobility:**

- Position of bladder neck and cervix at rest and on Valsalva
- Pubo-coccygeal line: A line extending from the inferior border of the pubic symphysis to last coccygeal joint (pubococcygeal line—PCL) Bladder neck or cervical descent > 2 cm below this line with straining indicates weakness of the pelvic floor. If alternative landmarks are used in scientific papers they should be clearly described.

**Figure 25. (above):** shows a number of possible measurements using MRI imaging. (a) Axial T2-weighted image of the pelvic floor of a healthy nulliparous Caucasian woman showing measurement of the anteroposterior diameter of the genital hiatus between the arrows from midurethra to mid-anus at the level of the lower border of the pubic symphysis. Transverse diameter (width) of the levator hiatus was measured between the stars at the point of maximum extension of the levator muscles at the level of the urinary bladder and proximal urethra. Reproduced from Am J Obstet Gynecol with permission from the Publisher. (b) An example of a unilateral levator defect of the pubococcygeus muscle (right image) seen on MRI imaging. Reproduced with kind permission from Mr. Olubenga Adekanmi; image reviewed by Professor John DeLancey.

**E: Computed tomography (CT) of the pelvic floor**

Computed tomography (CT) is not routinely recommended for imaging the pelvic floor mainly due to irradiation and poor soft tissue contrast. However multiplanar spiral CT may offer an accurate visualization of the pelvic floor soft and bony structures by reconstruction of axial images using 1 mm thick slices without gaps thus increasing the diagnostic accuracy of pelvic floor anatomical disorders (ie. LAM trauma) (Figures 26 and 27).

**Figure 26. (above):** Computed tomography (CT) of the LAM. Axial view of CT multiplanar 3-dimensional data volume, with 1 mm slice thickness without gaps, showing an intact pubovisceral muscle arising from the body of the pubic bone and forming a sling around the rectum (U: urethra, V: vagina, R: rectum, PM: pubovisceral muscle, PR: puborectalis muscle).

Neurourology and Urodynamics DOI 10.1002/nau

**Figure 27. (above):** Computed tomography (CT) of the LAM. Axial view of CT scan of a woman with bilateral injury of the pubovisceral muscle. Measurement of levator symphysis gap (LSG) is denoted bilaterally (U: urethra, V: vagina, R: rectum, PM: pubovisceral muscle).

#### **F: Associated POP-related Radiology<sup>8</sup>**

Defecography demonstrates normal anatomy of the anorectum as well as disorders of rectal evacuation. With barium paste inserted rectally prior to defecation, measurement of the anorectal angle is allowed with evidence of the presence, size or emptying of any rectocele.

Enteroceles, rectal intussusception and mucosal prolapse might be diagnosed as well as a spastic pelvic floor (anismus).

### **6: DIAGNOSES**

This Report highlights the need to base diagnoses for female pelvic organ prolapse on the **correlation between a woman's symptoms, signs and any relevant diagnostic investigations.**

#### **A: Pelvic Organ Prolapse**

Diagnosis by **symptoms and clinical examination, assisted at times by any relevant imaging (i.e. clinically evident):**

- (i) **Uterine/ cervical prolapse:** Clinically evident descent of the uterus or uterine cervix.
- (ii) **Anterior vaginal wall (compartment) prolapse:** Clinically evident descent of the anterior vaginal wall (compartment).
- (iii) **Posterior vaginal wall (compartment) prolapse:** Clinically evident descent of the posterior vaginal wall (compartment).
- (iv) **Vaginal vault (cuff scar) prolapse:** Clinically evident descent of the vaginal vault (cuff scar after hysterectomy).

Clinical staging (see Figures 6 and 28-30) assists in description.

**Figures 28–30:** Different types and stages of pelvic organ prolapse.

**Figure 28. (above):** Stage II Anterior vaginal wall (compartment) prolapse.

*Neurourology and Urodynamics* DOI 10.1002/nau

Figure 29. (above): Stage III Uterine prolapse.

Figure 30. (above): Stage IV Vaginal prolapse (complete eversion).

**B: Possible prolapse-related diagnoses:**

**(i) Voiding dysfunction:** A diagnosis by **symptoms and urodynamic investigations** is defined as abnormally slow and/or incomplete micturition, based on abnormal slow urine flow rates and/or abnormally high post void residuals, ideally on repeated measurement to confirm abnormality. (Voiding cystometry can be required to determine the cause of the voiding dysfunction). *FN10*

**(ii) Recurrent urinary tract infections (UTI):** A diagnosis by **clinical history** assisted by **the results of diagnostic tests** involves the determination of the occurrence of at least three symptomatic and medically diagnosed urinary tract infections (UTI) over the previous 12 months. One possible POP-related cause is a chronically elevated postvoid residual.

**(iii) Defecatory dysfunction:** A diagnosis by **clinical history** assisted, at times, by **the results of diagnostic tests** involving the confirmation of abnormal or difficult function in the initiation, passage or completion of defecation.

**(iv) Sexual dysfunction:** A diagnosis by **clinical history** (including specific questionnaires) involving the confirmation of abnormal function and/or difficulty with sexual intercourse.

<sup>10</sup>: It is acknowledged this definition may not encompass cases of (i) symptoms of voiding dysfunction without abnormality of voiding parameters; (ii) abnormality of voiding parameters without symptoms of voiding dysfunction.

**C: Intercurrent diagnoses:**

(i) **Urodynamic stress incontinence:** Involuntary leakage of urine during filling cystometry, associated with increased intra-abdominal pressure, in the absence of a detrusor contraction. In the circumstances where this diagnosis is only made when the POP is reduced, the additional term **“occult”** is appropriate.

(ii) **Detrusor overactivity:** The occurrence of involuntary detrusor contractions during filling cystometry.

(iii) **Bladder oversensitivity:** Increased perceived bladder sensation during bladder filling with: an early first desire to void; an early strong desire to void, which occurs at a low bladder volume; a low maximum cystometric bladder capacity. No abnormal increases in detrusor pressure are noted.

(iv) **Detrusor underactivity<sup>1</sup>FN5 and Acontractile detrusor<sup>1</sup>FN6**

**7: CONSERVATIVE TREATMENTS**

**Conservative:** restricted to non-surgical and non-pharmacological treatments.

**A: Lifestyle interventions:** Interventions that intentionally change the way a person lives in order to improve health status (e.g. weight loss and avoiding heavy lifting or coughing, e.g. by ceasing tobacco smoking), to avoid exacerbation of POP by decreasing intra-abdominal pressure.

**B: Devices**

**Device:** An object or instrument that has been invented/created for a particular purpose.

(i) **Pessary:** A device that is inserted into the vagina to provide structural support to one or more of descending vaginal compartments, i.e.; the uterus, anterior vaginal wall (and bladder), posterior vaginal wall (and rectum) and/or vaginal apex (with or without small intestine after a prior hysterectomy)<sup>47</sup>.

**Types of pessary:** Vaginal pessaries can be broadly divided into two types: support pessaries (ring, ring with support, Gehrung, Hodge) and space filling pessaries (doughnut, gellhorn, cube, inflatable pessaries).

Figure 31. Pessaries (clockwise from top left) donut, cube, ring with central support, gellhorn.

Figure 32. Shelf pessary.

158 Haylen et al.

The most frequently used pessaries are listed below, as shown in figure 31<sup>47</sup>.

- a. Ring pessary with or without central support
- b. Gellhorn pessary; round solid pessary with a central stem
- c. Donut pessary FN11
- d. Cuboid pessary FN12
- e. Shelf pessary: Similar to a Gellhorn but asymmetric

#### C: Physical Therapies<sup>9</sup>

**Pelvic physiotherapy:** Assessment, prevention and/or treatment of pelvic floor dysfunction, performed by a pelvic physiotherapist. The therapy aims at reducing POP symptoms and related bother as well as improvement of pelvic floor function. Pelvic physiotherapy covers many specialized therapies that can be used to train the pelvic floor: physical activity, cognitive behavioural therapy, bladder training, bowel habit training, muscle training (endurance, power), coordination training, biofeedback, and electrical muscle stimulation<sup>9</sup>. The role of continence nurses amongst other health professionals in performing some of these specialized therapies is acknowledged.

Other therapies: Refer to the terminology document of Bo et al<sup>9</sup>.

### 8: SURGICAL TREATMENTS

#### A: General POP Surgical Terminology

**(i) Prosthesis<sup>5</sup>:** A fabricated substitute to assist a damaged body part or to augment or stabilize a hypoplastic structure.

**(ii) Mesh<sup>5</sup>:** A (prosthetic) network fabric or structure; open spaces or interstices between the strands of the net. The use of this term would be for POP surgery with synthetic materials.

**(iii) Mesh kit<sup>5</sup>:** A set of articles or equipment utilized for POP surgery containing mesh with a system of trocars designed to achieve mesh fixation or allow mesh passage to or through specific areas within the pelvis.

**(iv) Implant<sup>5</sup>:** A surgically inserted or embedded prosthesis or graft. (*Explant:* a surgically excised prosthesis or graft).

**(v) Tape (Slings)<sup>5</sup>:** A flat strip of synthetic material. The use of this term would be for incontinence surgery with synthetic materials.

**(vi) Graft<sup>5</sup>:** Any tissue or organ for transplantation. This term will be used to refer to biological materials inserted.

Autologous grafts: From patient's own tissues e.g. rectus sheath or fascia lata. Allografts: From post-mortem tissue banks.

Xenografts: From other species e.g. modified porcine dermis, porcine small intestine and bovine pericardium.

Terminology for grafts has not been separated into the different applications for POP and continence surgery.

**(vii) Trocar<sup>5</sup>:** A surgical instrument with either a pyramidal, conical or needle-type cutting or dissecting point.

**(viii) Tissue<sup>6</sup>:** A collection of similar cells and the intercellular substances surrounding them.

**(ix) Native<sup>6</sup>:** Pertaining to birth - "in situ autologous".

#### B: Specific Surgeries

The following classification of surgical procedure subtypes is proposed when describing specific surgeries. It is acknowledged that more complex cases may require two or more procedures in addition to other non-POP related surgical interventions. Each surgical procedure should be described with respect to site specificity and either as primary surgery or further surgery<sup>7</sup>. All surgical procedures are primarily divided by surgical approach as follows:

##### I. Vaginal repairs:

- (i) Anterior vaginal wall repair with native tissue.
- (ii) Anterior vaginal wall repair with mesh or graft reinforcement.
- (iii) Posterior vaginal wall repair with native tissue.
- (iv) Posterior vaginal wall repair with mesh or graft reinforcement.
- (v) Vaginal vault repair involving uterus.
- (vi) Vaginal vault repair (post-hysterectomy).

##### II. Abdominal repairs:

- (i) Abdominal Repair with Mesh or Graft.
- (ii) Abdominal Repair without Mesh or Graft.

<sup>11</sup>: A more space occupying pessary.

<sup>12</sup>: A cuboid pessary does deliver 'support' by suction of the vaginal walls.

## III. Obliterative Procedures:

- (i) Colpocleisis.
- (ii) Total colpectomy.

**I: Vaginal Repairs (colporrhaphy):** (Greek: *kolpō* vagina + *raphē* suture)

**(i) Anterior vaginal wall repair with native tissue:** Repair the vagina by excision and suturing of the edges of any defect. Native tissue repair may be further sub-classified depending on the type of associated fascial repair:

- (a): Midline fascial plication: This represents perhaps the most common procedure currently performed for anterior wall prolapse [Fig 33 below]. FN13
- (b) Site specific repair: Paravaginal – bilateral vaginal reattachment of the lateral edge of damaged fascia to the Arcus Tendineus Fasciae Pelvis (Alt: White line).
- (c) Other site specific repair: Transverse, distal, combined.
- (d) Anterior enterocele repair.

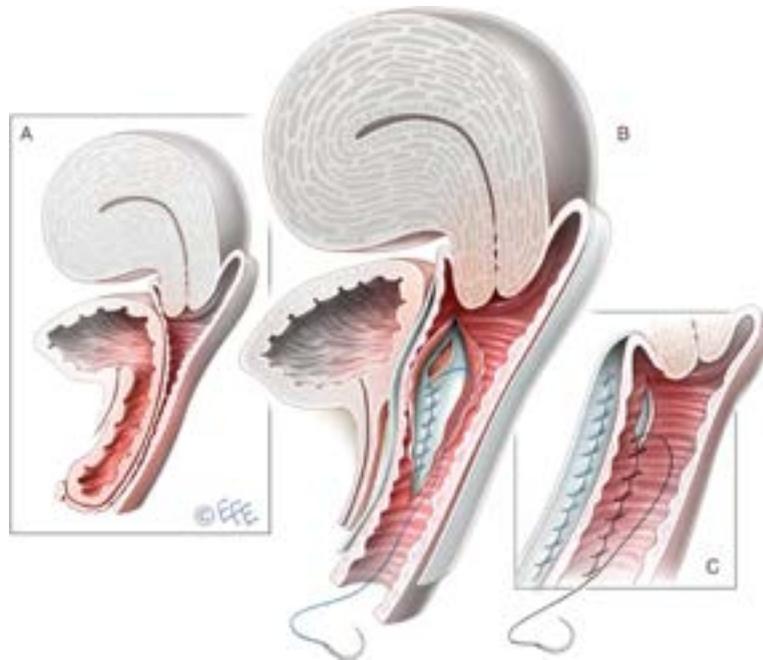

Figure 33. (above): Midline native tissue anterior vaginal repair.

**(ii) Anterior Vaginal Wall Repair with mesh or graft reinforcement** (a structural addition or inclusion used to give additional strength in function). It should be noted whether the graft is biologic, absorbable synthetic or permanent synthetic.

This may be further sub-classified into:

- (a) Mesh or graft placement **without** additional vault/uterine support with or without concurrent fascial plication.
- (b) Mesh or graft placement **with** additional vault/uterine support. This may be sub-divided into:
  - **Transobturator mesh kit:** Normally involves two needle passes through the obturator membrane bilaterally to retrieve and secure mesh arms through the area of the Arcus Tendineus Fasciae Pelvis (ATFP) and thus stabilize a central mesh support to the anterior vaginal wall.

<sup>13</sup>: It was first described by Kelly in 1913 and involves dissection under the full thickness of the vaginal epithelium followed by central plication of the pubocervical fascia over the bulging bladder with excision of the 'excess' vaginal wall skin. The Kelly-Kennedy plication suture (Alt: bladder neck buttress) is an extrapolation of midline fascial plication involving placement of sutures under the proximal urethra and bladder neck to try and treat or prevent stress incontinence.

160 Haylen et al.

- **Mesh kit with bilateral fixation to Sacrospinous Ligament [SSL]:** Anterior vaginal wall mesh or graft with concurrent vault/uterine suspension employing either bilateral iliococcygeal fixation or fixation to the SSL.

**(iii) Posterior vaginal wall repair with native tissue:** Repair the vagina by excision and suturing of the edges of any defect. Native tissue repair may be further sub-classified depending on the type of associated fascial repair:

- Midline fascial plication - This represents perhaps the commonest procedure currently performed for posterior wall prolapse and involves dissection under the full thickness of the vaginal epithelium followed by central plication of the pre-rectal fascia over the bulging rectum with excision of the 'excess' vaginal wall skin. [Fig 34 below]
- Site specific repair: Lateral (Uni- or Bilateral), Transverse (upper and/or lower), Combined
- Closure and/or excision of enterocele vaginally with or without concurrent posterior wall repair.

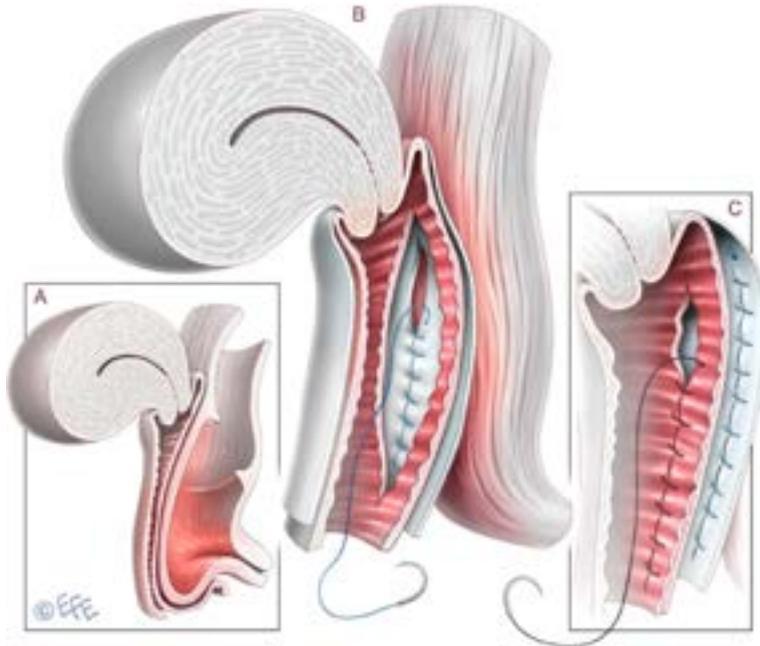

Figure 34. (above): Midline native tissue posterior vaginal repair.

**(iv) Posterior Vaginal Wall Repair with mesh or graft reinforcement** (a structural addition or inclusion used to give additional strength in function. It should be noted whether the graft is biologic, absorbable synthetic or permanent synthetic.

This may be further sub-classified into:

- Mesh or graft placement **without** additional vault/uterine support with or without concurrent fascial plication.
- Mesh or graft placement **with** additional vault/uterine support. This may be sub-divided into:
  - Mesh kit with bilateral mesh fixation to the SSL.
  - Mesh suspension kit with ischio-anal needle pass.
  - Posterior vaginal wall mesh/graft with concurrent vault/uterine suspension employing either bilateral iliococcygeal fixation or fixation to the SSL.
  - Transperineal mesh/graft insertion.

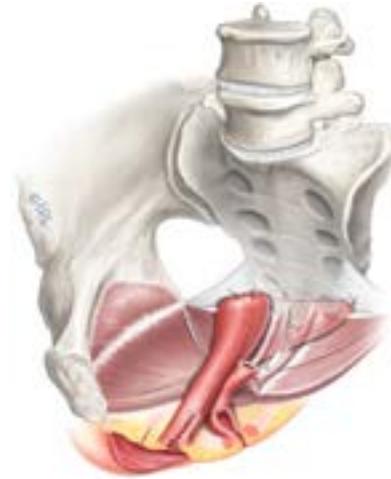

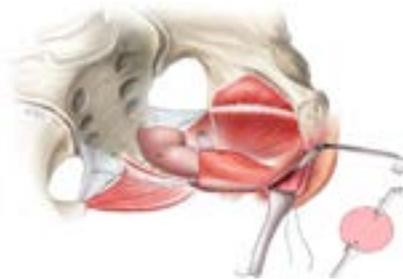

**Concurrent surgery performed in addition to vaginal posterior wall repairs:**

- Perineal Repair (alternatives; Perineorrhaphy, Perineoplasty).
- Levator ani muscle plication.
- Repair/closure of enterocele.
- Anal sphincter repair.

Neurourology and Urodynamics DOI 10.1002/nau

**(v): Vaginal Vault Repairs (involving uterus)****(a) Vaginal hysterectomy** – removal of the uterus and cervix vaginally.**(b) Vaginal hysterectomy with adjunctive McCall Culdoplasty** – Culdoplasty sutures incorporate the uterosacral ligaments into the posterior vaginal vault to obliterate the cul-de-sac and support and suspend the vaginal apex after vaginal hysterectomy.**(c) (Modified) Manchester Repair (Fothergill operation)** – This procedure combines anterior vaginal wall repair with amputation of the cervix and uterosacral ligament suspension with or without concurrent vaginal posterior wall repair. FN14**(d) Sacrospinous hysteropexy** - fixation of the uterus to the SSL. Variations of this technique to include:

- (a) Unilateral or bilateral procedure.
- (b) Anterior or posterior approach.
- (c) Permanent or absorbable suture and number of 'bites' taken.
- (d) Type of suture placement device employed.
- (e) Direct vision or with the use of a specific instrument (tactile feedback).

**(e) Laparoscopic assisted vaginal hysterectomy** with or without concurrent laparoscopic uterosacral ligament plication.**(vi) Vaginal Vault Repairs (Post-hysterectomy)****(a) Sacrospinous colpopexy** – Fixation of the vaginal vault to the SSL. Variations of this technique (as above a-e for sacrospinous hysteropexy).**Figures 35.** Sacrospinous colpopexy.**Figure 36.** Suture placement around junction of medial third and lateral two-thirds of ligament assisted by retraction (Miya speculum 7 o'clock; narrow Deaver 1 o'clock; Yankauer sucker not shown).

<sup>14</sup>: Its essential feature is suturing the cut cardinal/uterosacral ligament complex in front of the stump of the cervix hence pulling the cervix upwards and backwards, maintaining anteversion and creating anterior vaginal wall length. This procedure can be performed intra- or extra-peritoneally. Concurrent McCall culdoplasty or vaginal vault suspension techniques may be employed dependant on the extent of prolapse<sup>47</sup>.

162 Haylen et al.

**(b) Intraperitoneal uterosacral ligament (USL) vaginal vault fixation:** This is usually associated with posterior wall fascial wall reconstruction and possible concurrent excision and closure of enterocele.

**(c) Extraperitoneal USL vaginal vault fixation:** This is usually combined with posterior wall fascial reconstruction with or without enterocele closure and/or excision.

**(d) Mesh suspension kit with ischio-anal needle pass.** The graft is fixed to the vault and elevation achieved when the upper graft arms are retrieved back through the levator ani muscle bilaterally.

**(e) Vaginal Trachelectomy for Cervical Stump Prolapse** (previous subtotal hysterectomy) The cervical stump is removed in an identical fashion to the initial steps of a vaginal hysterectomy.

## II Abdominal Procedures

### (i) Abdominal Procedures with Mesh or Graft FN15

**(a) Open / Laparoscopic / Robotic Sacrocolpopexy** – Suspension of the vagina utilizing mesh or graft to the anterior longitudinal ligament usually at the level of the sacral promontory. (Fig 37 below)

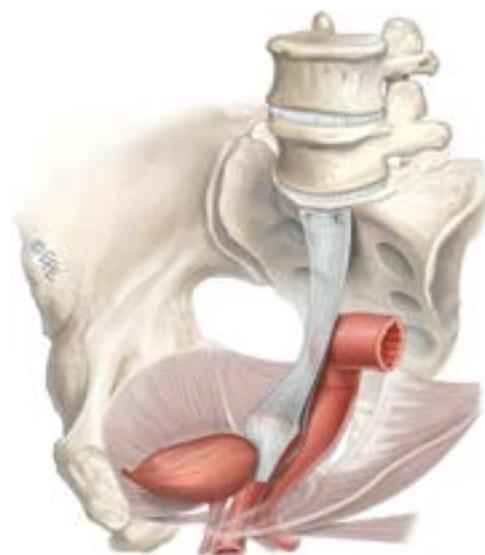

Figure 37. Sacrocolpopexy.

**(b) Open / Laparoscopic / Robotic Sacrocervicocolpopexy** – Suspension of the cervix (and usually vagina) utilizing mesh or graft to the anterior longitudinal ligament usually at the level of the sacral promontory. This procedure is commonly performed as an adjunct following subtotal hysterectomy for advanced utero-cervical prolapse.

**(c) Open / Laparoscopic / Open Sacrohysteropexy** – suspension of the cervix (with or without additional vaginal attachment) utilizing mesh or graft to the anterior longitudinal ligament usually at the level of the sacral promontory. Sacrohysteropexy is performed for women who are keen to preserve their uterus.

### (ii) Abdominal Procedures without Mesh or Graft

**(a) Open / Laparoscopic / Robotic paravaginal repair** – Extraperitoneal bilateral reattachment of the lateral edge of damaged fascia to the Arcus Tendineus Fasciae Pelvis (Alt: White line).

**(b) Laparoscopic / Robotic suture hysteropexy** – The plicated uterosacral ligaments are resutured to the cervix.

**(c) Open / Laparoscopic / Robotic closure of enterocele sac:**

- (a) Moschowitz procedure- Concentric purse string suture(s) are placed around the cul-de-sac to include the posterior vaginal wall, pelvic side-walls and serosa of the sigmoid.
- (b) Halban procedure- Obliteration of the cul-de-sac by using successive sutures placed sagittally between the uterosacral ligaments.
- (c) Uterosacral ligament plication (Fig 38 below) – transverse plication of the uterosacral ligaments to obliterate the cul-de-sac. Successive sutures are placed into the medial portion of one ligament, into the back wall of the vagina and into the medial border of the opposing ligament.

<sup>15</sup>: Variations in technique for all abdominal mesh/graft procedures: (i) Type of mesh or graft used; (ii) Shape of mesh /graft- single piece, 'DIY' two piece 'Y' mesh, Y mesh kit product; (iii) Points and length of attachment to vagina. (iv) Suture material employed / Metal stapling devices; (v) Peritoneal closure over mesh/graft.

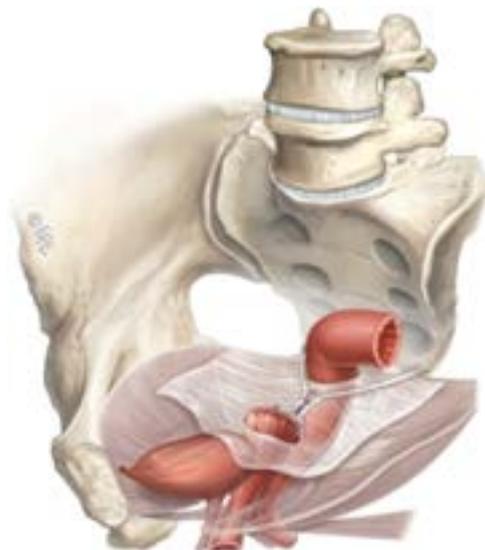

Figure 38. Uterosacral ligament plication.

**(d) Open / Laparoscopic / Robotic Burch Colposuspension** – Elevation or attachment of the upper paraurethral tissue adjacent to the bladder neck region to the iliopectineal ligament bilaterally. Although a recognized treatment for stress incontinence, this procedure will often correct associated anterior wall prolapse symptoms.

### III: Obliterative Procedures

**(i) Colpocleisis:** (Greek: kolpō + kleisis closure) – Operation for obliterating the lumen of the vagina. FN16

**(ii) Total colpectomy:** (Greek: kolpō + ektomē excision): Total excision of the vagina in a woman with no uterus and vaginal eversion. FN17

### C: Measuring Outcome in POP surgeries<sup>7</sup>

As per IUGA-ICS Report on outcome measures for POP surgery<sup>7</sup>, every study evaluating POP surgery should report.

**(i) Perioperative data:** i.e. blood loss, operating time, length of hospital stay, return to normal activities and complications.

**(ii) Subjective (patient-reported) outcomes:** At its simplest level this can be reported as the presence or absence of vaginal bulge. Patient satisfaction and quality of life can be measured by validated instruments that cover prolapse, urinary, bowel and sexual function.

**(iii) Objective outcomes:** POP-Q measurement generally and should be tabulated with absolute values and percentages to allow other studies to compare results.

**(iv) Secondary outcomes** (e.g. lower urinary tract symptoms, stress urinary incontinence or bowel and sexual dysfunction) in their studies whenever possible.

**(v) Surgery type and operated compartment:**

(a) **Primary surgery:** indicates the first procedure required for treating POP in any compartment.

(b) **Further surgery:** provides a term for any subsequent procedure relating to primary surgery. Further surgery is subdivided into:

- Primary surgery in a different (new) site/compartment.
- Repeat surgery in the same site/compartment for POP symptom recurrence.
- Surgery for complications e.g. mesh exposure, pain, infection or hemorrhage.
- Surgery for non-POP-related conditions usually urinary or fecal incontinence.

<sup>16</sup>: This is usually performed in a woman with a uterus who is no longer sexually active. It can be performed in the absence of a uterus in a woman with vaginal eversion instead of total colpectomy. The Le Fort's procedure involves denuding the vagina of skin both anteriorly and posteriorly, typically in a rectangular shape, avoiding the bladder neck and cervix. The cut edges are sewn together to achieve vaginal closure whilst leaving a bilateral epithelium-lined tunnel behind. The Labhardt procedure involves the removal of a 1 cm horse shoe shape of vaginal epithelium is removed over the posterior fourchette up to just under the urethra. By closing the incision and building up the perineum, an extremely high posterior repair almost closing the vagina is created.

<sup>17</sup>: The vagina is totally denuded of skin, typically in sections, whilst avoiding the bladder neck region. The prolapse is then reduced by a series of successive purse-string sutures and the epithelium at the entrance closed.

**D: Complications of POP surgeries<sup>5,6</sup>**

Complications related to POP native tissue repair and surgeries using prostheses/graft/mesh have been classified separately according to joint IUGA/ICS recommendation<sup>5,6</sup>. The sorting system used in both documents utilizes specific category, time and site taxonomy together referred as *CTS classification system*. Classification is aided by on line calculators at either <http://www.ics.org/complication> or <http://www.ics.org/ntcomplication>.

This document has involved 14 rounds of full review, by co-authors, of an initial draft (Version 1) completed on November 30, 2014. Comments for each round of review were collated and debated as necessary in order to form a subsequent version. Live meetings on the document took place in Washington, Rio, Nice and Montreal.

**ACKNOWLEDGEMENTS**

The assistance of Prof Steven Swift is gratefully acknowledged for the Simplified POP-Q section and other helpful input. Prof John DeLancey also contributed helpful input to Section 3 and the Appendix. We thank our invited external reviewers Prof Steven Swift, Prof Mark Vierhout, Prof Michele Meschia, Prof Doug Tincello and Prof Don Wilson for their constructive contributions. We also thank those who submitted constructive comments following IUGA and ICS website presentation of Version 12: Dr Kiran Ashok, Prof Phil Toozs-Hobson, Dr Kamil Svabik. Further helpful comments were received at an open forum at ICS Montreal from Beth Shelly, Julia Herbert, Kari Bo and Joe Lee. The talents of medical illustrator, Levent Efe were crucial to the development of this document ([levent@leventefe.com.au](mailto:levent@leventefe.com.au)).

#### APPENDIX - Concepts and available measurements awaiting further validation.

##### A: Subdivision of Stage II POP-Q:

An optional subdivision of Stage II into IIA (-1 to hymen) and IIB (hymen to +1) was considered at length. Stage IIA would then be defined as -1 to 0 (so the hymen, that is 0, is included in stage IIA) and stage IIB (>0 to +1), meaning the dependent part of prolapse beyond the hymen but no further than +1. It was felt that this might reflect a clinical difference between the two subdivisions in terms of symptoms. That change was not made at this time in part to maintain the current strictly anatomical definition of the “sign of POP”.

##### B: Vaginal Anatomical Levels and Lengths:

- (i) **Level I:** Uterine cervix (if present) and/or upper 2.5cm of vagina. Footnote *FN18*
- (ii) **Level II:** Mid-vagina from distal end of Level I to hymen. *FN19*
- (iii) **Level III (vaginal vestibule):** Vaginal entrance (Latin: “vestibulum” = “a space at the entrance of a canal”) from hymenal ring to just below the clitoris anteriorly (anterior vestibule), labia minora laterally and anterior perineum posteriorly (posterior margin of vestibule) *FN20*

<sup>18</sup>: Refinement of previous classification<sup>49</sup> reflecting the average length of non-gravid uterine cervix<sup>50</sup> and the average length of the supportive influence of the distal segment of the uterosacral ligaments on the posterolateral vaginal wall bilaterally<sup>51</sup>.

<sup>19</sup>: Mean length of Level II in women at posterior colporrhaphy found to be 5.0cm<sup>52</sup>

<sup>20</sup>: The outer edge of the vestibule is known as Hart’s line (see white line in Figure 39 with blue line demarcating anterior and posterior vestibule).

Figure 39. Anterior and posterior vestibule.

*Neurourology and Urodynamics* DOI 10.1002/nau

166 Haylen et al.

- (iv) **Posterior vestibule:** Posterior hymenal ring to anterior perineum (posterior margin of vestibule). FN21
- (v) **Total vaginal length<sup>4</sup>:** Posterior vaginal vault to hymen (cm), i.e. Levels I and II posteriorly.
- (vi) **Total posterior vaginal length<sup>52-54</sup>:** Posterior vaginal vault to posterior margin of vestibule (anterior perineum - cm), i.e. Levels I, II and III posteriorly.
- (vii) **Anterior vaginal length:** Anterior hymenal ring to the anterior vaginal vault (anterior cervicovaginal junction or anterior cuff post-hysterectomy)<sup>55</sup>.

Figure 40. Posterior vestibule.

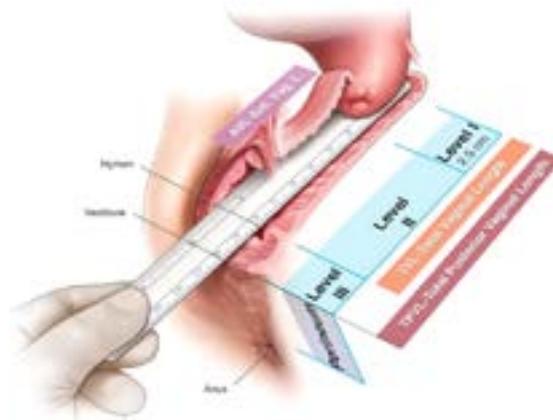

Figure 41. Vaginal Levels (I to III) and Vaginal lengths (Anterior, Total, Total Posterior).

**C: Additional available intraoperative measurements.**

**(i) Perineal measurements:**

**(a,b) Perineorrhaphy Width (PW) and Depth (PD)<sup>54</sup>:** Width and depth of the excised perineum

<sup>21</sup>: Mean length in women at posterior colporrhaphy was found to be 1.8cm<sup>52</sup>.

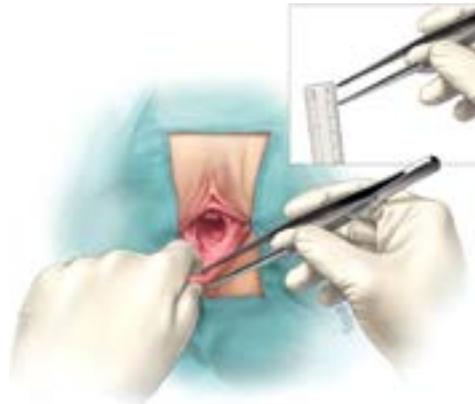

**Figure 42.** Perineorrhaphy width (PW) and perineorrhaphy depth (PD).

**(c) Perineal length (PL)<sup>54</sup>:** Distance from posterior margin of vestibule to anterior anal verge.

**Figure 43.** Perineal length.

**(d) Mid-perineal thickness (MPT)<sup>54</sup>:** Thickness (cm) of the mid-perineum in the midline.

**Figure 44.** Mid-perineal thickness.

**(e) Perineal Gap (PG)<sup>52-54</sup>:** Thinned out medial area (cm) between Moynihan forceps placed bilaterally where the labia minora meet the perineum.

*Neurourology and Urodynamics* DOI 10.1002/nau

Figure 45. Perineal Gap.

(f) **Perineorrhaphy Commencement Position (PCP): NEW** Where in Level III, the perineorrhaphy is commenced, e.g. hymen, mid-vestibule, posterior margin of vestibule.

(ii) **Posterior vaginal measurements<sup>53</sup>:**

(a) **Posterior Vaginal Vault Descent (PVVD)<sup>52,53</sup>:** Descent of the posterior vaginal vault towards the perineal gap obtained by subtracting the inferiorly displaced vaginal vault and the anterior perineum (second figure) from the total posterior vaginal length (TPVL - first figure – posterior vaginal vault to anterior perineum).

(b) **Mid-Vaginal Laxity (MVL) (Undisplaced)<sup>52,53</sup>:** Laxity of the vaginal mucosa (anterior traction) midpoint in the vagina super-posteriorly and in the midline with the vaginal vault held in an undisplaced position (similar to that after vault fixation)

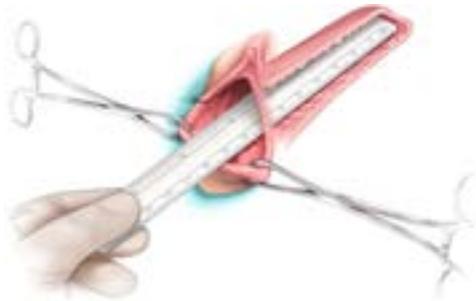

Figure 46. (left): Total posterior vaginal length (TPVL).

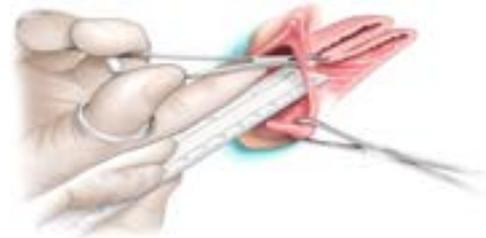

Figure 47. (right): Distance from vaginal vault (on traction) to anterior perineum. Posterior vaginal vault descent is the subtraction of this measurement from the TPVL.

(c) **Recto-vaginal Fascial Laxity (RVFL)<sup>52,53</sup>:** Laxity of the rectovaginal fascia (anterior traction) midpoint in the vagina super-posteriorly (mucosa opened) and in the midline with the vaginal vault held in an undisplaced position

Figure 48. (left): Mid-vaginal laxity (vault undisplaced).

Figure 49. (right): Recto-vaginal fascial laxity.

## An International Urogynecological Association (IUGA)/ International Continence Society (ICS) Joint Report on the Terminology for Female Anorectal Dysfunction

**Introduction:** The terminology for anorectal dysfunction in women has long been in need of a specific clinically-based Consensus Report. **Methods:** This Report combines the input of members of the Standardization and Terminology Committees of two International Organizations, the International Urogynecological Association (IUGA) and the International Continence Society (ICS), assisted on Committee by experts in their fields to form a Joint IUGA/ICS Working Group on Female Anorectal Terminology. Appropriate core clinical categories and sub classifications were developed to give an alphanumeric coding to each definition. An extensive process of twenty rounds of internal and external review was developed to exhaustively examine each definition, with decision-making by collective opinion (consensus). **Results:** A Terminology Report for anorectal dysfunction, encompassing over 130 separate definitions, has been developed. It is clinically based with the most common diagnoses defined. Clarity and user-friendliness have been key aims to make it interpretable by practitioners and trainees in all the different specialty groups involved in female pelvic floor dysfunction. Female-specific anorectal investigations and imaging (ultrasound, radiology and MRI) has been included whilst appropriate figures have been included to supplement and help clarify the text. Interval review (5–10 years) is anticipated to keep the document updated and as widely acceptable as possible. **Conclusion:** A consensus-based Terminology Report for female anorectal dysfunction terminology has been produced aimed at being a significant aid to clinical practice and a stimulus for research. *NeuroUrol. Urodynam.*

**Key words:** anorectal; fecal incontinence; female sexual dysfunction; female pelvic floor; imaging; terminology

### INTRODUCTION

The anatomical configuration of the anorectum is complex. The mechanisms that control continence and allow defecation are multifactorial and dependent on many factors such as the consistency of stool, bowel transit, rectal compliance and sensitivity, intact neurological function and integrity of the pelvic floor, and anal sphincters.

This document is being published simultaneously in *Neurourology and Urodynamics* (NAU) (DOI 10.1002/nu.23055) and the *International Urogynecology Journal* (IJU) (DOI 10.1007/s00192-016-3140-3), the respective journals of the sponsoring organizations, the International Continence Society (ICS) and the International Urogynecological Association (IUGA).

## 2 Sultan et al.

Historically, anorectal physiological investigations have quite often produced inconsistent results. Until the advent of imaging techniques such as endoanal ultrasound, the etiology of fecal incontinence was largely attributed to pudendal neuropathy.<sup>1</sup> We now better understand the contribution of vaginal delivery to anal sphincter trauma.<sup>2</sup> Imaging has taught us that training in clinical digital assessment can improve detection and repair of obstetric anal sphincter injuries and thereby minimize the risk of developing fecal incontinence.<sup>3</sup> Obstructive defecation is another common embarrassing problem and imaging techniques that attempt to capture the defecation process are often inconclusive.<sup>4</sup> Artificial contrast material replicating normal fecal consistency for defecating proctography is not available and magnetic resonance imaging requires an upright scanner.

When multiple conditions such as fecal incontinence, obstructive defecation, urinary incontinence, neurological diseases, medical conditions etc. co-exist, management becomes increasingly difficult and multidisciplinary assessment becomes important.<sup>5</sup> As the pelvic organs (bowel, bladder, and vagina) are in close proximity to each other, clinicians need to be aware of the impact of dysfunction and surgery of one organ may have on the neighboring structures. It is therefore important for clinicians and pelvic surgeons to have more global knowledge and adopt a holistic approach to pelvic floor dysfunction.

There is a need for standardized terminology in female anorectal dysfunction to accumulate accurate prevalence data, perform the appropriate investigations, institute management, and conduct audit and research. Lack of a unified definition of anal incontinence has resulted in variations in prevalence data from epidemiological data. "Pseudo incontinence" with mucoid leakage (usually caused by organic colonic disease, dietary sensitivity or fecal impaction) is often mistaken as fecal incontinence as questionnaires do not quite differentiate them.<sup>6</sup> There is indeed the need for a general terminology, forming a "backbone" or "core" terminology to which more specific terminologies can be attached.<sup>7</sup>

This Terminology Report is inherently and appropriately a definitional document, collating the definitions of those terms, that is, words used to express a defined concept, in a particular branch of study. Emphasis has been on comprehensively including those terms in current use in the relevant peer-reviewed literature. The aim is to assist clinical practice and research. Some new and revised terms have been included. Explanatory notes on definitions have been referred, where possible, to the "Footnotes section."

Similar to a previous report<sup>7</sup> the female-specific terminology report should be as follows:

**(1) User-friendly:** It should be able to be understood by all clinical and research users.

**(2) Clinically-based:** Symptoms, signs, and validated investigations should be presented for use in forming workable diagnoses. The first three sections will address symptoms, signs, and assessment tools. The next two sections will describe anorectal physiological investigations and currently used pelvic imaging modalities routinely used in the office or anorectal laboratory to make those diagnoses. A number of related radiological investigations as well as magnetic resonance imaging (MRI) have also been included. The value of electromyography and related nerve conduction, reflex latency, and sensory investigations will be outlined.

**(3) Origin:** Where a term's existing definition (from one of multiple sources used) is deemed appropriate, that definition will be included and duly referenced. A number of terms in female anorectal function and dysfunction, because of their long-term use, have now become generic, as apparent by their listing in medical dictionaries.

**(4) Able to provide explanations:** Where a specific explanation is deemed appropriate to explain a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (*Footnote [FN] 1,2,3 ...*). Wherever possible, evidence-based medical principles will be followed.

It is suggested that acknowledgement of these standards in written publications related to female anorectal dysfunction, be indicated by a footnote to the section "Methods and Materials" or its equivalent, to read as follows: "Methods, definitions and units conform to the standards jointly recommended by the International Urogynecological Association and the International Continence Society, except where specifically noted." It should be noted that the Working Group for this document was formed and started generation of this document prior to the Rosier statement.<sup>8</sup>

## SECTION 1: SYMPTOMS

**Symptom:** Any morbid phenomenon or departure from the normal in structure, function, or sensation, experienced by the woman and indicative of disease<sup>9</sup> or a health problem. Symptoms are either volunteered by, or elicited from the individual, or may be described by the individual's caregiver.<sup>7,10,11</sup>

### 1.1: Anorectal Incontinence Symptoms

**Anal incontinence (symptom<sup>7</sup>).** Complaint of involuntary loss of feces or flatus.

(i) **Fecal incontinence<sup>7</sup>:** Complaint of involuntary loss of feces.

(a) Solid

(b) Liquid

(ii) **Flatus Incontinence<sup>7</sup>:** Complaint of involuntary loss of flatus (gas).

(iii) **Double incontinence (NEW):** Complaint of both anal incontinence and urinary incontinence [<sup>FN1</sup>].

(iv) **Coital fecal (flatal) incontinence (NEW):** Fecal (flatal) incontinence occurring with vaginal intercourse (see related definition "Coital fecal urgency") [<sup>FN2</sup>].

<sup>FN1</sup> In regards to definition of various types of urinary incontinence, the interested reader can refer to (Haylen 2010).<sup>7</sup>

<sup>FN2</sup> A history of receptive anal intercourse has been shown to increase the risk of anal incontinence.<sup>12</sup>

- (v) **Passive fecal leakage (NEW)**: Involuntary soiling of liquid or solid stool without sensation or warning or difficulty wiping clean <sup>[FN3]</sup>.
- (vi) **Overflow fecal incontinence (NEW)**: Seepage of stool due to fecal impaction.

### 1.2: Anorectal Storage Symptoms

- (i) **Increased daytime defecation (NEW)**: Complaint that defecation occurs more frequently during waking hours than previously deemed normal by the woman.
- (ii) **Nocturnal defecation (NEW)**: Complaint of interruption of sleep one or more times because of the need to defecate.
- (iii) **Fecal (rectal) urgency<sup>7</sup>**: Complaint of a sudden compelling desire to defecate that is difficult to defer.
- (a) Fecal urgency warning time: time from first sensation of urgency to voluntary defecation or fecal incontinence.
- (iv) **Fecal (flatal) urgency incontinence<sup>7</sup>**: Complaint of involuntary loss of feces (gas) associated with (fecal) urgency.
- (v) **Tenesmus (NEW)**: A desire to evacuate the bowel, often accompanied by pain, cramping, and straining, in the absence of feces in the rectum.
- (vi) **Coital fecal urgency (NEW)**: Feeling of impending bowel action during vaginal intercourse.

### 1.3: Anorectal Sensory Symptoms

- (i) **Diminished rectal sensation<sup>7</sup>**: Complaint of diminished or absent sensation in the rectum.
- (ii) **Increased rectal sensation (NEW)**: Complaint of a desire to defecate (during rectal filling) that occurs earlier or more persistent to that previously experienced.

### 1.4: Defecatory and Post-Defecatory Symptoms

- (i) **Constipation<sup>7</sup> (Updated)**: Complaint that bowel movements are infrequent and/or incomplete and/or there is a need for frequent straining or manual assistance to defecate <sup>[FN4]</sup>.
- (a) Slow transit: infrequent bowel motions due to delay in transit of bowel contents to reach rectum.
- (b) Obstructed defecation: Complaint of difficulty in evacuation <sup>[FN5]</sup>.
- (ii) **Feeling of incomplete bowel evacuation<sup>7</sup>**: Complaint that the rectum does not feel empty after defecation and may be accompanied by a desire to defecate again.
- (iii) **Straining to defecate<sup>7</sup>**: Complaint of the need to make an intensive effort (by abdominal straining or Valsalva) to either initiate, maintain, or improve defecation.
- (iv) **Sensation of blockage (NEW)**: Complaint suggestive of anorectal obstruction.
- (v) **Digitation (NEW)**: Use of fingers in rectum or vagina to manually assist in evacuation of stool contents.
- (a) Rectal digitation: Use of fingers in rectum to physically extract stool contents to assist in evacuation.
- (b) Vaginal digitation: Use of thumb or fingers in the vaginal to assist in evacuation of stool.
- (vi) **Splinting (NEW)**: Support perineum or buttocks manually (usually with thumb or fingers) to assist in evacuation of stool content.
- (vii) **Post defecatory soiling (NEW)**: Soiling occurring after defecation.

<sup>FN3</sup> Soiling is a bothersome disorder characterized by continuous or intermittent liquid anal discharge. It should be differentiated from discharge due to fistulae, proctitis, hemorrhoids, and prolapse. Patients complain about staining of underwear and often wear protection.

- The discharge may cause inflammation of the perineal skin with excoriation, perianal discomfort, burning sensation, and itching.
- It often indicates the presence of an impaired internal sphincter function or a solid fecal mass in the rectum but could also be due to the inability to maintain hygiene due to hemorrhoids.

<sup>FN4</sup> Rome III criteria for functional constipation:

1. Must include two or more of the following:
  - a. Straining during at least 25% of defecations.
  - b. Lumpy or hard stools in at least 25% of defecations.
  - c. Sensation of incomplete evacuation for at least 25% of defecations.
  - d. Sensation of anorectal obstruction/ blockage for at least 25% of defecations.
  - e. Manual maneuvers to facilitate at least 25% of defecations (e.g., digitalevacuation, support of the pelvic floor).
  - f. Fewer than three defecations per week.
2. Loose stools are rarely present without the use of laxatives.
3. Insufficient criteria for irritable bowel syndrome.

\*Criteria fulfilled for the last 3 months with symptom onset at least 6 months prior to diagnosis.

<sup>FN5</sup> Difficulty evacuating stool, requiring straining efforts at defecation often associated with lumpy or hard stools, sensation of incomplete evacuation, feeling of anorectal blockage/obstruction or manual assistance to defecate (or inability to relax EAS/dyssynergic defecation).

### 1.5: Anorectal Prolapse Symptoms

(i) **Anorectal prolapse (updated)**: Complaint of a “bulge” or “something coming down” towards or through the anus/rectum. The woman may state she can either feel the bulge by direct palpation or see it aided with a mirror [FN6].

### 1.6: Anorectal Pain Symptoms (NEW)[FN7]

- (i) **Pain during straining/defecation**: Complaint of pain during defecation or straining to defecate.
- (ii) **Inflammatory anorectal pain**: Complaint of pain characterized by burning or stinging [FN8] (fissure, inflammation, sepsis).
- (iii) **Non-inflammatory anorectal pain**: Complaint of blunted anorectal pain, as opposed to sharp stinging or burning type of pain (proctalgia fugax, Levator ani syndrome, pudendal neuralgia<sup>13</sup>) See Section Pain Syndromes.

### 1.7: Anorectal Sexual Dysfunction Symptoms[FN9]

**Symptoms of sexual dysfunction**<sup>7</sup>. A departure from normal sensation and/or function experienced by a woman during sexual activity.

**Female sexual dysfunction**<sup>22</sup>. Complaint of dyspareunia or impairment of sexual desire, arousal, or orgasm.

- (i) **Receptive anal intercourse (NEW)**: Having a penis penetrating one's anus [FN10].
- (ii) **Other anal sexual practices with body parts**: Stimulation of the anus and/or rectum with bodily parts other than the penis (e.g., finger, fist) for sexual purposes by the recipient and/or a partner.
- (iii) **Other anal sexual practices with non-living objects**: Stimulation of the anus and/or rectum with non-living objects (e.g., dildo) for sexual purposes by the recipient and/or a partner.
- (iv) **Anodyspareunia (NEW)**: Complaint of pain or discomfort associated with attempted or complete anal penetration<sup>12</sup>[FN11].
- (v) **Anal laxity (NEW)**: Complaint of the feeling of a reduction in anal tone [FN12].

### 1.8: Miscellaneous Anorectal Symptoms

- (i) **Rectal bleeding/mucus**<sup>7</sup>: Complaint of the loss of blood/mucus per rectum [FN11].
- (ii) **Perianal itching/pruritus ani (NEW)**: Complaint of itchy anus [FN13].
- (iii) **Flaturia (NEW)**: Complaint of passage of gas per urethra.
- (iv) **Fecaluria (NEW)**: Complaint of passage of fecal material per urethra.
- (v) **Vaginal flatus/feces (NEW)**: Complaint of passage of flatus or feces per vagina.

## SECTION 2: SIGNS

**Sign**: Any abnormality indicative of disease or health problem, discoverable on examination of the patient: an objective indication of disease or health problem.<sup>7</sup>

### 2.1: Vaginal and Anorectal Inspection<sup>23</sup>

- (i) **Excoriation**: Perianal excoriation, skin rashes.
- (ii) **Soiling**: Perianal fecal soiling or vaginal fecal soiling.
- (iii) **Discharge**: Perianal or vaginal bloody or mucus discharge.
- (iv) **Gaping anus**: Non-coaptation of anal mucosa at rest.

<sup>FN6</sup> Anorectal prolapse can be due to hemorrhoidal, mucosal, rectal prolapse, or rectal intussusception. These definitions are further explained under “Signs.”

<sup>FN7</sup> This refers to pain localized to the anorectal region, and may include pain, pressure, or discomfort in the region of the rectum, sacrum, and coccyx that may be associated with pain in the gluteal region and thighs.

<sup>FN8</sup> Fissure pain during, and particularly after, defecation is commonly described as passing razor blades or glass shards See FN10.

<sup>FN9</sup> Receptive anal intercourse is associated with increased risk of both any female sexual dysfunction,<sup>14</sup> as well as with specifically female sexual arousal disorder with distress<sup>15</sup> (“a persistent or recurrent inability to attain [or to maintain until completion of the sexual activity] an adequate wetness and vaginal swelling response of sexual excitement”). The association of receptive anal intercourse with sexual dysfunction might be due to physiological and/or psychological processes. The psychological factors including emotional development problems,<sup>16</sup> poorer mood,<sup>17</sup> poorer intimate attachment<sup>18</sup> as well as general dissatisfaction are associated with women's receptive anal intercourse.<sup>19</sup> Physiologic factors could include that: (1) mechanical stimulation of the anus and rectum during anal intercourse increases hemorrhoid risk; (2) women with hemorrhoidectomy have impaired sexual function; and (3) persons with hemorrhoids who have not yet had hemorrhoidectomy “are more likely to have abnormal perineal descent with pudendal neuropathy.”<sup>20,21</sup> Thus, pudendal nerve dysfunction could be one mechanism leading to sexual dysfunction, and this might be the case even in the absence of diagnosed haemorrhoids.<sup>13</sup>

<sup>FN10</sup> A history of receptive anal intercourse has been shown to increase the risk of anal incontinence, rectal bleeding, and anal fissure.<sup>12</sup>

<sup>FN11</sup> Unlike dyspareunia (from coitus), it might be normal to experience pain or discomfort during receptive anal intercourse.

<sup>FN12</sup> This may be accompanied by a finding of decreased anal resting tone (in some cases, the result of anal intercourse)—see under Signs. Damage to the internal anal sphincter is the likely basis for the laxity. Unlike stool passage, receptive anal intercourse is not likely to elicit reflex relaxation of the internal sphincter.

<sup>FN13</sup> Pruritus ani has been classified into primary and secondary. The primary form is the classic syndrome of idiopathic pruritus ani. The secondary form implies an identifiable cause or a specific diagnosis.

(v) **Scars, sinuses, deformities, condylomata, papillomata, hematomata:**<sup>[FN14]</sup>.

(vi) **Deficient perineum/cloacal-like defect:** A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina.

(vii) **Anal fissures:** Longitudinal split in the skin of the anal canal, exposing the internal anal sphincter muscle. The majority of fissures are found in the mid-line posteriorly and there may be a skin tag associated with them.

(viii) **Hemorrhoids:** Abnormality of the normal cushion of specialized, highly vascular tissue in the anal canal in the submucosal space. Hemorrhoids can be divided into those originating above the dentate line which are termed internal and those originating below the dentate line which are termed external. Internal hemorrhoids are graded as follows:

Grade I - bleeding without prolapse.

Grade II - prolapse with spontaneous reduction.

Grade III - prolapse with manual reduction.

Grade IV - incarcerated, irreducible prolapse.

Grade II and Grade III hemorrhoids will become evident on asking the patient to bear down and grade IV hemorrhoids are obvious at the time of the examination. A proctoscopy is essential in examining for hemorrhoids unless they are completely prolapsed.

(ix) **Anorectal prolapse:** Full thickness eversion of the lower part of the rectum and anal canal. The exposed mucosa is red with circumferential folds around the central pit, which is the lumen of the rectum. Look for associated utero-vaginal prolapse, fistulas, sepsis, and ulcers.

(x) **Fistula in ano:** An anal fistula is an abnormal connection between the anal canal epithelium (or rarely rectal epithelium) and the skin epithelium. Patients may complain of pain, swelling, intermittent discharge of blood or pus from the fistula, and recurrent abscesses formation.

(xi) **Rectovaginal fistula:** Is a communication from the rectum to the vagina.

(xii) **Ano-rectal/vaginal/perineal fistula:** Is an abnormal communication from the anal canal to the vagina or perineal area.

## 2.2: Vaginal Examination

All examinations for pelvic organ prolapse should be performed with the woman's bladder empty (and if possible an empty rectum),<sup>7</sup> straining to maximally reveal the prolapse. All compartments should be examined for prolapse but of particular relevance to ano-rectal dysfunction is posterior vaginal wall prolapse.

(i) **Posterior vaginal wall prolapse:**<sup>7</sup> Observation of descent of the posterior vaginal wall. Commonly, this would represent rectal protrusion into the vagina (rectocele). Higher stage posterior vaginal wall prolapse after prior hysterectomy

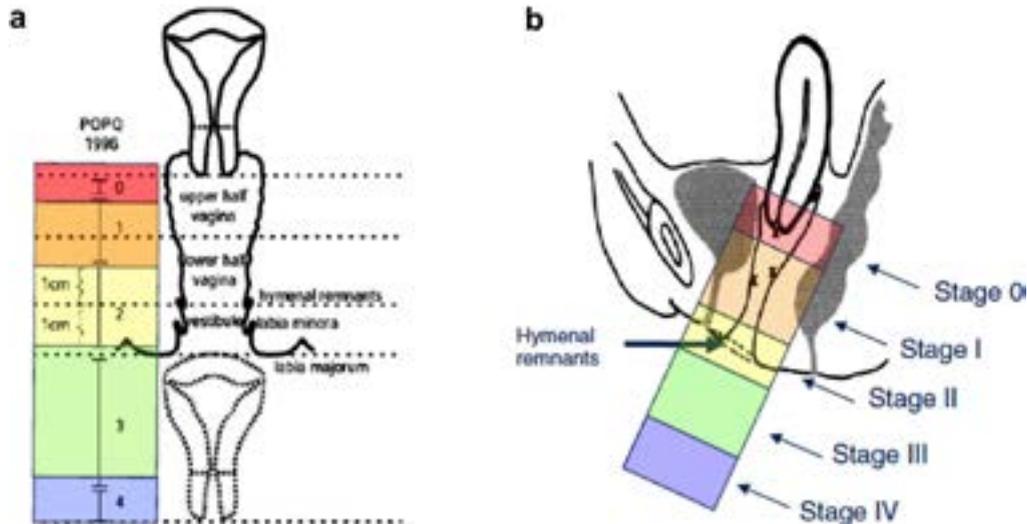

Fig. 1. Figure a and b shows prolapse staging—0, I, II, III, and IV (uterine by the position of the leading edge of the cervix).

<sup>FN14</sup>With perianal hematomas, the lump may be anywhere around the anal margin and may be multiple. Pilonidal sinuses are usually a small mid-line pit with epithelialized edges.

<sup>FN15</sup>Figure used from Pelvic floor dysfunction document<sup>7</sup> (Fig. 1a and b).

6 Sultan et al.

would generally involve some vaginal vault (cuff scar) descent and possible enterocele formation. Posterior vaginal wall prolapse can be a rectocele, enterocele, or a perineocele. Enterocele formation can also occur in the presence of an intact uterus.

- (ii) **Rectocele:** Bulge in posterior vaginal wall associated with herniation of anterior wall of the rectum.
- (iii) **Enterocele:** Bulge of upper wall of the vagina associated with herniation of the peritoneal sac and loops of small bowel.
- (iv) **Perineocele:** Bulge in the perineum associated with herniation of the anterior wall of the rectum.

### 2.3: Anorectal Examination

The patient lies in the left lateral position with hips flexed and ankles away from the examiner. Dorsal lithotomy position could also be used.

(i) **Perianal sensation/reflex:** In patients with possible neurogenic pelvic floor dysfunction there should be particular note of those neurological signs related to S2-4 but these should be complimented by a more general neurological examination as indicated. Specific to ano-rectal dysfunction, assessment of anal reflex, and perianal sensation should be performed.

(ii) **Digital rectal examination:** The gloved finger should be placed in the center of the anus with the finger parallel to the skin of the perineum in the midline. The finger should then be pressed gently into the anal canal but at the same time pressed backwards against the skin of the posterior wall of the anal canal and underlying sling of the puborectalis muscle. This overcomes most of the tone of anal sphincter and allows the finger to straighten and slip into the rectum. This will allow assessment of:

- (a) Resting anal tone, voluntary squeeze of the anal sphincter as well as the levator muscles, sustained squeeze over 5 sec and involuntary contraction elicited during a cough.
- (b) Obvious hemorrhoids can be palpated but grade II and grade III. Hemorrhoids are better assessed by proctoscopy. Painful examination may be associated with fistula in ano, fissure in ano, infection or pilonidal abscess.
- (c) Palpable anal sphincter gap. An assessment can be made of a palpable anal sphincter gap to assess if there has been previous obstetric or surgical damage. The perineal body can be assessed for deficiency.
- (d) Rectal contents. The contents of the rectum can be assessed. The feces may be hard or soft, the rectum may be empty or collapsed and sometimes ballooned out. This allows assessment of fecal impaction.
- (e) Confirmation of presence of rectocele, enterocele, or perineocele. Use of POP-Q for staging of prolapse [See <sup>FN15</sup>].
- (f) Bidigital examination may be carried out with the patient supine in a gynecological examining position. By inserting the index finger in the vagina and the middle finger in the rectum, the rectovaginal septum and any intervening small bowel loops can be palpated to differentiate a rectocele from an enterocele, during a Valsalva maneuver.
- (g) Rectal lesions such as carcinoma, intussusception or recto-vaginal fistula. If a mass is felt on a fingertip, the patient should be asked to strain, and this will often move the mass down to bring it within reach.
- (h) An assessment can be made of the rectovesico/recto uterine pouch to look for extra rectal masses.

### 2.4: Examination of Pelvic Floor Muscle Function<sup>7</sup>

Pelvic floor muscle function can be qualitatively defined by the tone at rest and the strength of a voluntary or reflex contraction as strong, normal, weak, or absent or by a validated grading symptom. Voluntary pelvic floor muscle contraction and relaxation may be assessed by visual inspection, by digital palpation (vaginal or anorectal) (circumferentially), electromyography, dynamometry, manometry, or ultrasound. Factors to be assessed include muscle strength (static and dynamic) (graded as strong, normal, weak or absent), voluntary muscle relaxation (graded as absent, partial, complete, delayed), muscular endurance (ability to sustain maximal or near maximal force), repeatability (the number of times a contraction to maximal or near maximal force can be performed), duration, co-ordination, and displacement.<sup>24</sup> Assessment can be made of each side of the pelvic floor separately to allow for any unilateral defects and asymmetry.<sup>23</sup> Assessment of displacement (perineal elevation or descent) of the pelvic floor can be made during cough or Valsalva. Normally, there is some downward movement of the pelvic floor muscles or there is a ventral movement (perineal elevation, inward (cephalad) and upward movement of vulva, perineum, and anus). Rectal examination observations can include:

- (a) Anal sphincter tone and strength: given the absence of a formal quantitative assessment via the rectal route, assessment of anal tone and strength on digital examination, can be graded using the same convention used when grading transvaginally—as strong, normal, weak, or absent or by a validated grading symptom.
- (b) Anal sphincter tear: may be recognized as a clear “gap” in the anal sphincter on digital examination.

### 2.5: Squeeze Pressure

Measurement of squeeze pressure involves the exertion of pressure, compressing the assessor's finger during digital palpation or using a mechanical device. The patient is asked to squeeze the PFM as hard as possible (maximum strength), to sustain the squeeze contraction (endurance), or to repeat squeeze contractions (repetitions). The measurement can be done in the anorectum using manual muscle testing with digital rectal palpation or pressure manometry in the vagina using manual

*Neurourology and Urodynamics* DOI 10.1002/nau

muscle testing with digital vaginal palpation or pressure manometry, or dynamometry. So far, not all quantitative assessments and scales of pelvic floor squeeze pressure have the same methodological qualities, like validity, reproducibility, and responsiveness.<sup>24–28</sup>

Pelvic floor muscle **spasm** was defined as persistent contraction of striated pelvic floor muscle that cannot be released voluntarily. If the contraction is painful, this is usually described as a cramp.<sup>29</sup> Spasm over days or weeks may lead to a contracture.

Pelvic floor muscle **tenderness**: sensation of discomfort with or without pain; discomfort of pelvic floor muscle elicited through palpation. Tenderness can be scored<sup>30</sup> during a digital rectal (or vaginal) examination of levator ani, piriformis and internal obturator muscles bilaterally, according to each subject's reactions: 0, no pain; 1, painful discomfort; 2, intense pain; with a maximum total score of 12.

Although not universally accepted, pelvic floor muscle **traction** is the use of a pulling force to examine or treat pelvic floor muscles, postulated to end pelvic muscle spasm or relieve pain.<sup>31</sup>

## 2.6: General Examination

Anorectal dysfunction may be associated with systemic disease and intestinal malignancy and a thorough medical examination should observe for signs relating to conditions such as anaemia, jaundice, lymphadenopathy, etc.

## 2.7: Neurological Examination

In patients with possible neurogenic pelvic floor dysfunction there should be particular note of those neurological signs related to S2-4 but these should be complimented by a more general neurological examination as indicated. Specific to ano-rectal dysfunction, assessment of anal reflex, and perianal sensation should be performed.

## 2.8: Abdominal Examination

A thorough abdominal examination should evaluate for the following:

- (i) Abdominal masses or distension.
- (ii) Scars indicating previous relevant surgery or trauma.
- (iii) Tenderness.

## SECTION 3: ASSESSMENT TOOLS AND QUESTIONNAIRES (NON INVASIVE)

### 3.1: Pictorial Stool Chart

It is a pictorial chart of stool consistencies. First described (but not published as a pictorial instrument) by Heaton et al.,<sup>32,33</sup> the "Bristol stool chart" seems to have widespread face validity and recognition and is useful in conversations with patients about their stool consistency, despite little validation work. It has not been validated as an outcome measure and a reported change in category may not represent sufficient degree of precision for use as a trial end point.

### 3.2: Bowel Diary

It is a recording of bowel actions. Bowel diaries have been widely used in diagnostic and intervention studies. Patient recall is less accurate than a diary.<sup>34,35</sup> Patients tend to underestimate symptom frequency, in one study by over 50%.<sup>36</sup> However, there are few published examples and no consensus on what should be included. Elements that might be included:

- Urgency,
- Fecal incontinence (amount, consistency),
- Flatus incontinence,
- Passive staining/soiling (tends not be discrete episodes),
- Pads (changes, degree of soiling),
- Straining/difficulty/time in the toilet,
- Unsuccessful attempts to defecate,
- Assistive measures (e.g., digital stimulation, manual evacuation, irrigation),
- Laxative or rectal evacuant use,
- Diet and fluids (type and/or timing).

Patients often need careful and detailed instructions on how to complete a diary, and still many are poorly completed. An incomplete diary is difficult to interpret and is liable to misinterpretation as a low bowel/event frequency.

3.3: Symptom Scores and Questionnaires

(i) **Fecal incontinence (FI)**

The International Consultation on Incontinence (ICI) chapter 5B<sup>37</sup> has reviewed FI questionnaires and found none with a grade A recommendation (validity, reliability, and responsiveness established with rigor). The ICI grades B (validity and reliability established with rigor, or validity, reliability, and responsiveness indicated) and C (early development—further work required) are noted where available in the text below.

The Cleveland Clinic Score,<sup>38</sup> often termed the “Wexner” score, was the first attempt to have a score based on both the frequency and consistency of FI and effect on lifestyle. In the original version it was physician-completed, although in subsequent literature it has also been completed by patients (grade C). The St Mark’s score<sup>39</sup> was an adaptation of the original Wexner score, adding scores for urgency and use of anti-diarrheals (grade C). This has been found to correlate reasonably well to patients’ global assessment of their bowel function.<sup>40</sup>

The Fecal Incontinence Quality of Life Scale<sup>41</sup> (grade B) and Fecal Incontinence Severity Index<sup>42</sup> (FISI) (grade B) were developed using items suggested by experts and then proposed to patients for ranking.

The international consultation on incontinence questionnaire—bowels (ICIQ-B)<sup>43</sup> has 23 items developed by literature review, expert opinion and in-depth qualitative interviews with patients, to include items of greatest importance to both clinicians and people with symptoms.<sup>44</sup> It has been validated up to the point of responsiveness to change, but further work is needed.

(ii) **Constipation**

There has been no exercise similar to the ICI Chapter 5B<sup>37</sup> which has graded constipation questionnaires.

The Patient Assessment of Constipation Quality of Life questionnaire<sup>45</sup> (PAC-QoL) and the PAC-SYM<sup>46</sup> are the best validated and most widely used tools for idiopathic constipation.<sup>47</sup> The PAC-SYM items were developed from the literature and patient focus group interviews. The validation process was robust and the instrument has 12 items grouped into three subscales (stool symptoms, rectal symptoms, and abdominal symptoms), each scored 0–4. It has also been validated for use with constipated older people in a care home environment<sup>47</sup> and opioid-induced constipation.<sup>48</sup>

The Cleveland Clinic constipation score gives a simple numerical total score<sup>49</sup> based on symptoms and physiological findings. Values allocated to symptoms and findings appear to be arbitrary. Validation has been limited.

Altomare has developed a scoring system specifically for the Obstructed Defecation Syndrome,<sup>50</sup> but this has not been formally validated. Table I shows utility of patient reported outcomes questionnaires for female anorectal dysfunction in clinical or research settings.

TABLE I. Patient Reported Outcome Questionnaires for Female Anorectal Dysfunction

Conditions	Tools	Clinical	Research
Bowel dysfunction	Bristol stool chart	R	R
Bowel dysfunction	Bowel diary	R	R
Fecal incontinence	Cleveland clinic score/	R	R
	Wexner	R	R
	St Marks score	R	R
	FI QoL	O	R
	FISI	O	R
	ICIQ-B	O	R
Constipation	PAC-QoL	R	R
	PAC-SYM	R	R
	Altomare	O	R

O, optional; R, recommended.

SECTION 4: ANORECTAL PHYSIOLOGICAL INVESTIGATIONS

Anorectal physiological assessment is a key part of the assessment of some patients with pelvic floor symptoms<sup>51,52</sup> providing a clinically meaningful, quantitative measure of a specific anorectal function. It is only in the context of the patient’s symptoms, thorough examination and radiological investigations that physiological measurements can be correctly interpreted.

4.1: Investigations to Exclude Organic Disease

(i) Anoscopy or proctoscopy is the inspection of the anal canal to identify anal fissure, fistula, or hemorrhoids as a cause of anal symptoms.

(ii) Rigid sigmoidoscopy is a bedside test to inspect the rectal mucosa, with no bowel preparation.

(iii) Flexible sigmoidoscopy refers to the inspection of the distal colonic mucosa, typically up to the splenic flexure, with a 60 cm flexible endoscope following enema preparation. Colonoscopy examines the entire colon following a full oral preparation to clear the bowel to allow this.

4.2: Anorectal Physiology Tests

Functional assessment tests of fecal incontinence and evacuatory disorders aim to qualify and quantify function, determine the etiology, guide management, and monitor progress.

#### 4.2.1 Manometry

Anal manometry is a test to assess the mechanical strength of the anal sphincters.<sup>53,54</sup> A range of methods is available, including water perfused, solid state, and micro-balloon systems. The length of the canal is measured either by station pull-through or continuous pull-through. Station pull-through involves inserting the catheter to 6 cm from the anal verge, withdrawing the catheter at 5–10mm intervals and measuring for 1–5 min at each “station” (see Fig. 2). Continuous pull-through involves withdrawing the catheter at a set speed by hand or by a mechanical puller. As normal values can differ substantially between laboratories according to the style of catheter used, each unit is encouraged to generate its own normal data.<sup>51,52</sup>

In patients with fecal incontinence the value of manometry is:

- (a) To define functional weakness of one or both sphincter muscles (as a compliment to anal endosonography).
- (b) To support findings of other tests and to monitor outcome and predict response to biofeedback training.
- (c) In cases where anal endosonography is not available, vector manometry may help identify anatomic defects of the anal sphincter complex.

In constipated patients the value of manometry is:

- (a) To exclude Hirschsprung's disease.
- (b) To identify and predict responses to biofeedback training (pelvic floor dyssynergia = failure to expel a water-filled balloon).

##### 4.2.1.1: Functional anal length

Functional anal canal length is defined as the length of the anal canal over which resting pressure exceeds that of the rectum by greater than 5 mmHg or, alternatively, as the length of the anal canal over which pressures are greater than half of the maximal pressure at rest.

##### 4.2.1.2: Maximum resting pressure

The maximum resting pressure is the maximum resting pressure generated in the anal canal at rest. Strictly speaking, it is defined as the difference between the intrarectal pressure and the highest recorded rectal pressure at rest. However, rectal contents may affect the accuracy of rectal pressure measurements. The internal anal sphincter (IAS) exhibits continuous tonic activity and is responsible for 55–85% of the resting anal canal pressure (see Fig. 2). Its contribution to resting tone is variable along the length of the anal canal with the proximal two thirds being more reliant on IAS tone to maintain adequate resting pressures.<sup>55,56</sup> The range of maximal resting pressure is typically between 60 and 120 cmH<sub>2</sub>O. The EAS has constant tonic activity contributing to the resting anal canal pressure.

##### 4.2.1.3: The maximum squeeze pressure

The maximum squeeze pressure is the maximum pressure generated in the anal canal during a voluntary contraction. Although the EAS contributes to the resting pressure the specific function of the EAS can be assessed during the *squeeze* and *cough* maneuvers. The pressure increment above resting pressures during these maneuvers is a direct representation of EAS function. The normal range, as stated above, varies according to measurement modality in each laboratory, but is approximately above 60 cmH<sub>2</sub>O.<sup>57,58</sup> Typically, higher values are obtained by automated pull-through rather than station withdrawal methodologies.<sup>51</sup>

##### 4.2.1.4: Involuntary maximum squeeze pressure

A common maneuver is a maximal cough to measure this involuntary increment, usually reported as a present or absent response, rather than numerically.

##### 4.2.1.5: Endurance squeeze pressure

The endurance squeeze pressure is the length of time the individual is able to maintain the pressure during a voluntary contraction. To assess the endurance squeeze pressure, measurements are taken during a 5–10 sec squeeze (normal  $\geq 5$  sec). Incontinent patients typically have fatigue rate of greater than two-thirds of initial pressure at the end of the sustained squeeze. By calculating fatigability, the fatigue rate (using linear regression on the mean pressure over one second periods throughout the endurance squeeze) can be derived.

##### 4.2.1.6: Rectoanal inhibitory reflex

The recto-anal inhibitory reflex (RAIR) a relaxation response in the IAS following rectal distension. A drop of at least 25% of resting pressure has to occur with subsequent restoration to at least two thirds of resting pressure for it to be deemed present. It is elicited by rapid insufflation and disinflation of 50 mls of air into a balloon positioned in the distal rectum during anal manometry at the level of the proximal high pressure zone.<sup>52</sup> This reflex is absent in Hirschsprung's disease: of greater physiological meaning, this reflex is thought to underlie the sampling response that allows rectal content to be sensed by the anal mucosa, thus ensuring continence of flatus and stool.<sup>59</sup>

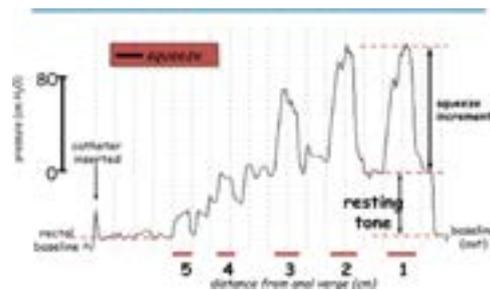

Fig. 2. Typical station pull through manometry trace on a patient, with explanations.

Neurourology and Urodynamics DOI 10.1002/nau

#### 4.2.1.7: Balloon expulsion pressure

The balloon expulsion pressure is the anal canal pressure during straining with a filled balloon in the rectum. Balloon expulsion can be performed on patients with evacuatory difficulty. An inappropriate increase in sphincter pressure on attempted voiding evacuation is usually reported as a present or absent response, rather than numerically. Such increased pressure is referred to as “anismus” or “paradoxical sphincter contraction.”

#### 4.2.1.8: Advanced manometric techniques

##### 4.2.1.8.1: Vector manometry

Vector manometry is a quantitative measure of radial symmetry and volume of the anal sphincter. It involves withdrawing (commonly using a mechanical puller) a radially arranged multi-channel anorectal manometry catheter through the length of the anal canal.<sup>60,61</sup> The following parameters are identified:

- Radial asymmetry index (RAI) is a quantitative measure of the radial symmetry and can be calculated at any level in the anal canal but most commonly refers to the level at which the highest resting pressure is generated. The principle is that an asymmetrical sphincter is more likely to have a sphincter defect.
- The vector volume is the volume of the 3D shape generated and provides a value which reflects the overall length and symmetry of the sphincter (Fig. 3).

##### 4.2.1.8.2: High resolution manometry

In this technique, a catheter with a large number of pressure sensors spaced less than 0.5 mm apart along the length of the catheter. This allows complete definition of the intra-anal pressure environment. The resulting data is displayed on a topographical three dimensional plot to allow easier pattern recognition. It is a measurement with the variables of pressure (displayed as the color), distance into the anal canal (y-axis) and time (x-axis). Normal ranges are slightly higher than measured with standard manometry, but the readings agree well with each other.<sup>62</sup>

##### 4.2.1.8.3: Ambulatory anorectal manometry

Using solid-state catheters, prolonged ano-rectal motor events have been recorded, including in ambulant subjects. The clinical applicability of these techniques has not been established.<sup>63–65</sup>

#### 4.2.2: Sensory measurements

##### 4.2.2.1: Assessment of rectal sensation to distension

Rectal sensation to distension is most commonly assessed by manually inflating an intrarectal domestic balloon at a rate of approximately 5 ml/second.<sup>56,66</sup> The following are elicited:

- Volume which elicits the first sensation of balloon expansion (threshold) [typical normal range 12–25 ml],
- Volume to get an urge to defecate (typical normal range 35–65 ml),
- Maximal tolerated volume (typical normal range 120–300 ml).

[normal ranges for the latter two sensations are highly variable due to lack of consensus on measurement technique especially of the nature and speed of inflation of the balloon]

The pressure required to elicit these sensations can also be measured using an electro-mechanical barostat and may be more reproducible. The barostat measures the volume and the pressure required to elicit these volumes sensations.<sup>67,68</sup> Typically distension thresholds with a barostat are higher, with larger volumes being required to elicit the same sensation. However, again, the published ranges vary widely between units: typically distension volumes 1.5 to 3 times are published for thresholds with a barostat compared to manual balloon inflation.

Distension sensitivity testing is of proven value in:

(a) Patients with fecal incontinence to help with biofeedback training by normalization of the initial sensation sensory thresholds.

(b) Identifying visceral hypersensitivity, poor rectal compliance, or rectal irritability if maximal tolerated volumes are low.<sup>51,52</sup>

There is no evidence to support use of the sensory thresholds for diagnosis and biofeedback training of patients with constipation. Compliance testing has also not proven valuable in identifying candidates for specific therapies.

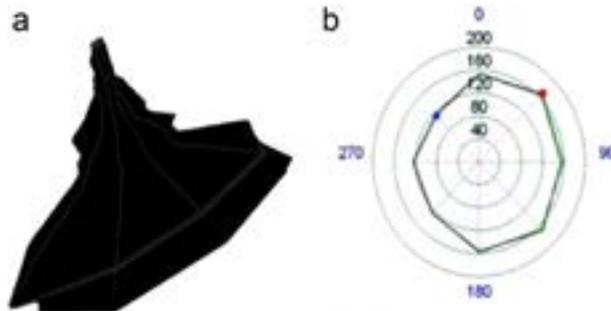

Fig. 3. Vector volume anal manometry trace. The left hand panel illustrates the shape of the contour curve at a fixed point, and the right hand figure shows the integrated whole across the length of the sphincter (from proximal to distal). It is evident that the greatest pressure is exerted in the distal canal.

#### 4.2.2.2: Mucosal electrosensitivity

This is test to measure anal and rectal sensory thresholds. Mucosal electrical stimulation is performed using a probe with two ring electrodes between which a small electrical potential is applied generating an alternating square wave with a variable frequency. Normal ranges have been established as anal electrosensation <10 mA, and rectal as <30 mA.<sup>69</sup> In general, prolonged anal electrosensation is suggestive of damage to the sensory fibers of pudendal nerve, and prolonged rectal electrosensation is suggestive of autonomic neuropathy.

#### 4.2.3: Rectal dynamics

##### 4.2.3.1: Rectal compliance

Rectal compliance is the term that describes the relationship between pressure and volume, reflecting the ability of the rectum to act as a reservoir and is assessed using a barostat, inflating the bag within the rectum prior to the recording inflation protocol, known as conditioning, has been shown to improve the precision of compliance testing.<sup>59</sup> Typically, compliance figures between 4 and 11 mmHg/ml are quoted as the normal range.

##### 4.2.3.2: Rectal impedance planimetry

These studies are the preserve of research institutions rather than clinical practice. The rationale is to calculate the diameter or cross sectional area of an intra rectal bag during a distension sequence. Impedance planimetry measures the cross sectional area which enables the circumferential wall tension to be calculated.<sup>70</sup>

##### 4.2.4: Attempted defecation and balloon expulsion

Patients with symptoms of prolapse and elderly patients with a history of constipation who present with passive incontinence should be thoroughly examined for the presence of a full thickness rectal prolapse. Patients are asked to strain as they would to pass stools whilst on a toilet or commode and given enough time to reproduce the prolapsing lump before examination.

Expulsion of a water-filled balloon can be used in the assessment of constipated patients. The ability to expel the balloon within 1 min may be a useful tool in demonstrating the absence of pelvic floor dyssynergia.

#### 4.2.5: Neurophysiology

##### 4.2.5.1: Single fiber EMG

A single fiber needle EMG technique is used to measure the muscle fiber density in the external sphincter and puborectalis. A raised fiber density indicates re-innervation in the muscles, which may occur following partial denervation. Calculating EAS fiber density is another method of assessing denervation and re-innervation of the EAS. It is used almost exclusively as a research tool. Conventional EMG can be used to quantify the re-innervation of the EAS by detecting prolongation in the duration of the motor unit potential.

##### 4.2.5.2: Concentric fiber EMG

Concentric needle EMG can be used to record activity in the external sphincter and puborectalis. The responses of these muscles to voluntary contraction, coughing, and straining can be displayed. The data are qualitative and compared to appearances in these muscles at rest. The muscles can also be studied at several sites to define areas of functioning muscle and identify sites of muscle injury (sphincter mapping) although this is has now been superseded by anal endosonography.

##### 4.2.5.3: Surface EMG

Electrodes placed on the skin of the perineum or inside the vagina or rectum. Surface recordings from the sphincter show increased activity with body actions and decreased activity in sleep. Needle EMG however is regarded as superior.<sup>71</sup> Some centers use surface EMG as an indicator of anal sphincter activity to provide feedback for patients undergoing behavioral biofeedback training for fecal incontinence or constipation.

##### 4.2.5.4: Pudendal nerve terminal motor latencies (PNTMLs)

The PNTML is a measurement of the delay between the electrical stimulation of the pudendal nerve and the EMG activity of the EAS. The pudendal nerve is stimulated as it passes over the ischial spine using a specially designed electrode attached to the index finger of the assessor in the rectum.<sup>71</sup> The surface EMG recording electrode which sits on the base of the assessor's index finger and measures external sphincter activity. The test does not reliably reflect the pudendal nerve damage. This may be because PNTMLs measure the speed of nerve conduction, which involves the fastest nerve fibers that are least susceptible to damage. The latencies are reported as normal if below 2.2 msec, but are also very operator dependent, with poor reproducibility and hence not recommended for general clinical use.<sup>72</sup>

### 4.3: Clinical Role of Anorectal Physiological Measurements

As can be seen from the above, the reliability, reproducibility, and clinical validity of these tests are unproven, owing to the variety of methodologies of measurement undertaken. Standardization in each individual laboratory, with normal ranges from each laboratory, is therefore the required standard. Table II shows the utility of anorectal physiology tests within clinical or research settings.

TABLE II. Anorectal Physiology Tests for Female Anorectal Dysfunction

Anorectal physiological tests	Conditions	Clinical	Research/optional
Anorectal manometry	Anal sphincter function	R	R
Defecography	Extent of rectal intussusception/rectocele	O	R
Neurophysiological testing	Preoperative before sphincteroplasty or SNM; or in	O	R
PTNML <sup>73</sup>	Patients with possible pudendal neuralgia		
CN-EMG	When USS or MRI equivocal		

O, optional; R, recommended.

Neurourology and Urodynamics DOI 10.1002/nau

SECTION 5: IMAGING

5.1: Ultrasonography (2D/3D/4D) of the Posterior Compartment Including Anal Sphincters, Pelvic Floor Muscles, and Prolapse (Endoanal, Transperineal, Transvaginal)

Ultrasound is increasingly being incorporated as an investigation of posterior compartment disorders<sup>7,74</sup> (Table III). An integrated multi-compartmental pelvic floor ultrasonography with a combination of different modalities has been described to assess pelvic floor dysfunction for a global and multi-compartmental perspective.<sup>75,76</sup>

Modalities in current routine clinical use:

- (a) **Endoanal:** intra-anal 360° sector scanning using rotational mechanical probe or radial electronic probe.
- (b) **Transperineal:** curved array probe applied in the perineum between the mons pubis and the anal margin. This term incorporates trans-labial ultrasound. Introital ultrasound is usually assumed to imply the placement of transducer with smaller footprints (such as end-firing endo-vaginal probe) within the introitus.
- (c) **Transvaginal:** intra-vaginal curvilinear, linear array, or 360° sector scanning.

5.1.1: Endoanal ultrasonography (EAUS)

The majority of current systems provide **2D & 3D Imaging** which give a 360° axial view of the anal canal and of the rectal wall.<sup>4,77,78</sup> Endoanal ultrasound can be performed with the patient placed in the dorsal lithotomy, left lateral or prone position. Irrespective of the position, the probe should be rotated so that the anterior aspect of the anal canal is superior (12 o'clock) and left lateral is right (3 o'clock) on the screen. The anal canal is divided into three levels of assessment in the axial plane referring to the following anatomical structures:

- **Upper level:** the hyperechoic sling of the puborectals muscle (PR) and the complete ring of the internal anal sphincter (IAS) are visualized (Fig. 4a),
- **Middle level:** corresponds to the superficial part of the EAS (concentric band of mixed echogenicity), the conjoined longitudinal layer, the IAS (concentric hypoechoic ring), and the transverse superficial perineal muscles (Fig. 4b),
- **Lower level:** corresponds to the subcutaneous part of the EAS where the IAS is absent (Fig. 4c).

The acquisition of a three-dimensional data volume (**3D ultrasound**) and the underlying techniques vary. Acquisition may be **“free-hand” (low resolution 3D)** or **“automatic computer-controlled” (high resolution 3D)**.<sup>79,80</sup>

5.1.2: Transperineal Ultrasonography (TPUS)

Conventional convex transducers (frequencies between 3 and 6 MHz and field of view at least 70°) provide 2D imaging of the pelvic floor.<sup>81,82</sup> Transperineal ultrasound is performed with the patient placed in the dorsal lithotomy position, with the hips flexed and abducted. If necessary, the patient can be examined standing, to maximise descent of pelvic organs, especially if the patient finds it difficult to produce an effective Valsalva maneuver. No rectal or vaginal contrast is used. Perineal ultrasound provides sagittal, coronal and oblique sectional imaging, with the mid-sagittal plane being the most commonly used as this gives an overall assessment of all anatomical structures (bladder, urethra, vaginal walls, anal canal, and rectum) between the posterior surface of the symphysis pubis (SP) and the posterior part of the levator ani (LA) (Fig. 5a and b). The imaging is usually performed at rest, on maximal Valsalva maneuver and on pelvic floor muscle contraction (PFMC). The access to the mid-sagittal plane allows the following evaluations<sup>83</sup>:

- Integrity of the perineal body: appearing as a triangular shaped, slightly hyperechoic structure anterior to the anal sphincter,
- Measurement of the anorectal angle (ARA): formed by the longitudinal axis of the anal canal and the posterior rectal wall,
- Dynamic assessment of the posterior compartment. During Valsalva it is possible to visualize descent of an enterocele, to assess the movement of the anterior rectal wall to detect a rectocele, and to evaluate movement of the PR and ARA to diagnose pelvic floor dyssynergy (Fig. 5c).

3D TPUS may be performed with volumetric probes (electronic curved array of 4–8 MHz). An advantage of this technique is the opportunity to obtain tomographic or multi-slice imaging, for example, in the axial plane, in order to assess the entire PR and its attachment to the pubic rami<sup>84</sup> (Fig. 6). It is also possible to measure the diameter and area of the levator hiatus (LH) and determine the degree of hiatal distension on Valsalva. Four dimensional (4D) imaging indicates real-time acquisition of volume ultrasound data.

TABLE III. Imaging Modalities for Female Anorectal Dysfunction

Conditions	Imaging techniques	Levels of evidence	Grade of recommendation
Fecal incontinence	Endoanal US	Level II	Grade B
	Static MRI	Level II	Grade B
	Defecating proctography	Level III	Grade C
Pelvic organ prolapse	Dynamic MRI	Level II	Grade B
	Transperineal US	Level II	Grade B
	Defecating proctography	Level II	Grade B
Obstructed defecation	Dynamic MRI	Level II	Grade B
	Defecating proctography	Level II	Grade B
	Transperineal US	Level III	Grade C
Perianal sepsis	Static MRI	Level II	Grade B
	Endoanal US	Level II	Grade B
	Fistulography	Level III	Grade C
Chronic pelvic pain	Static MRI	Level III	Grade C

Neurourology and Urodynamics DOI 10.1002/nau

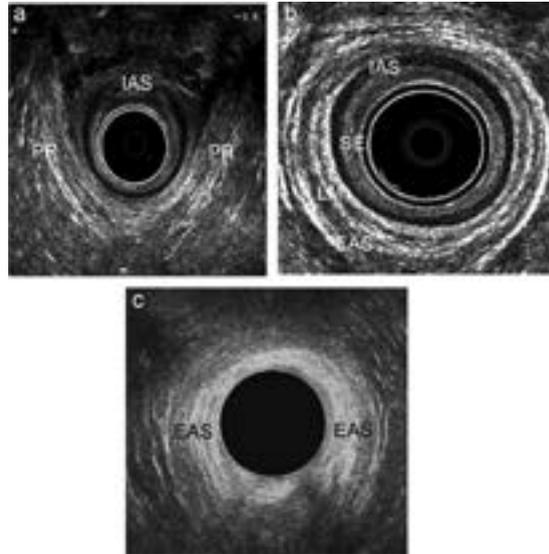

Fig. 4. Endoanal ultrasonography. (a) Upper level of the anal canal; (b) Middle level of the anal canal; (c) Lower level of the anal canal. PR, puborectalis; IAS, internal anal sphincter; EAS, external anal sphincter; LM, longitudinal muscle; SE, sub epithelium.

#### 5.1.3: Transvaginal Ultrasonography (TVUS)

Transvaginal ultrasound is performed with the patient placed in the dorsal lithotomy position. Currently, the transducers used for pelvic floor 3D TVUS are high multi-frequency (9–16 MHz), 360° rotational mechanical probe or radial electronic probe (Fig. 7a). The pelvic floor is divided into four levels of assessment in the axial plane referring to the following anatomical structures<sup>85</sup>: (not to be confused with Delancey's description of vaginal Levels of supports).

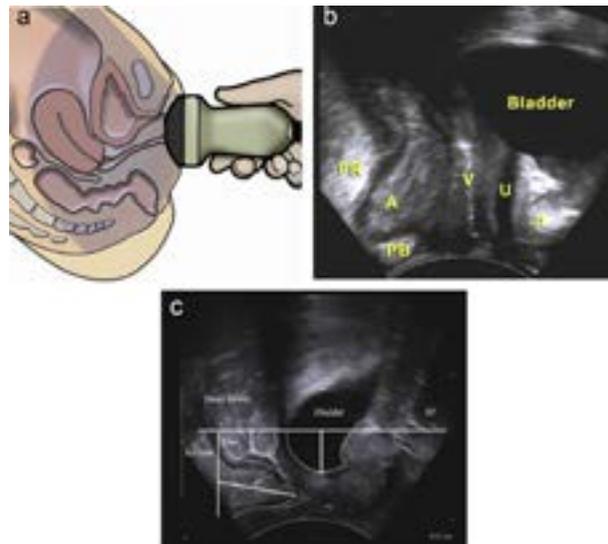

Fig. 5. 2D-Transperineal ultrasound. (a) Schematic drawing; (b) Pelvic organs at rest; (c) Pelvic organs descend below the symphysis pubis line after Valsalva maneuver (cystocele, enterocele, rectocele). PR, puborectalis muscle; A, anal canal; PB, perineal body; V, vagina; U, urethra; P/SP, symphysis pubis.

Neurourology and Urodynamics DOI 10.1002/nau

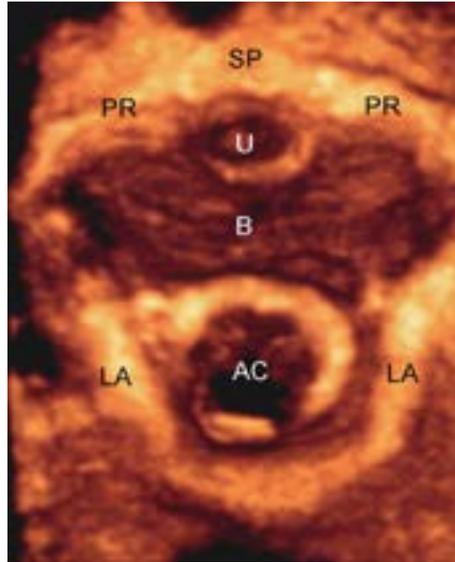

Fig. 6. 3D-Transperineal ultrasound. Axial image of the pelvic floor at rest showing the LA attachment to the pubic rami (PR). AC, anal canal; LA, levator ani; B, bladder; U, urethra; SP, symphysis pubis.

- **Level I:** at the highest level the bladder base is visualized on the screen at 12 o'clock position and the inferior third of the rectum at 6 o'clock position,
  - **Level II:** corresponds to the bladder neck, the intramural region of the urethra and to the anorectal junction. At this level the subdivisions of the LA (pubovaginalis, puboperinealis, puboanalis, puborectalis, and iliococcygeus) may be identified,
  - **Level III:** corresponds to the midurethra and to the upper third of the anal canal. At this level the LA is visualized as a multilayer hyperechoic sling coursing lateral to the vagina and posteriorly to the anal canal and attaching to the inferior pubic ramus (Fig. 7b). In the axial plane of minimal hiatal dimensions, identified as the minimal distance between the inferior edge of the SP and the anterior border of the LA at the ARA, the biometric indices (anteroposterior and transverse diameters, area) of the LH can be determined (Fig. 7c),<sup>86</sup>
  - **Level IV:** at the outer level, the perineal muscles (bulbospongiosus, ischiocavernosus, and superficial transverse perineii muscles), the perineal body, the distal urethra and the middle and inferior third of the anal canal are visualized. The anterior-posterior diameter of the urogenital hiatus (UGH), corresponding to the SP-perineal body distance, can be determined.<sup>87</sup>
- Transvaginal ultrasound may be also performed with electronic probes with linear array, which provide mid-sagittal image of the posterior compartment.<sup>76</sup> The main advantage of this technique is the dynamic assessment of the anorectal region, during Valsalva and pelvic floor muscle contraction (PFMC).

#### 5.1.4: Clinical applications of ultrasonography of the posterior compartment

##### 5.1.4.1: Fecal incontinence

Anal inspection and digital rectal examination can give information about internal and external anal sphincter function but are inaccurate for determining external anal sphincter defects <90 degrees and internal sphincter defects. Therefore, a sufficient diagnostic work-up should comprise at least rectal examination, anal inspection and endoanal ultrasonography.<sup>88</sup> EAUS has become the gold standard for morphological assessment of the anal canal.<sup>75</sup> The International Consultation on Incontinence (ICI)<sup>89</sup> has recommended EAUS as the first line imaging investigation for fecal incontinence to differentiate between those with intact anal sphincters and those with sphincter lesions (defects, scarring, thinning, thickening, and atrophy). Routine use of transperineal, transvaginal and translabial ultrasonography to image the anal sphincter complex are not recommended,<sup>89</sup> although research is ongoing. The operator should identify if there is a combined or isolated lesion of the IAS and EAS and report the number of defects, as well as the extent of the defect circumferentially (radial angle in degrees or in hours of the clock) and longitudinally (proximal, distal or full length).<sup>89-91</sup> Using 3D EAUS, two scoring systems have been proposed to define the severity of anal sphincter damage.<sup>92,93</sup>

EAUS has an important role in detecting undiagnosed anal sphincter injuries following vaginal delivery<sup>2</sup> and can be useful in the management of subsequent pregnancies following OASIS (119). It is also useful to evaluate the results of treatment (anterior sphincter repair, bulking agent injections).<sup>75,89</sup>

##### 5.1.4.2: Levator ani injuries

Levator avulsion is the disconnection of the muscle from its insertion on the inferior pubic ramus and the pelvic sidewall, whereas tears may occur in any part of the muscle. Avulsion is a common consequence of overstretching of the levator ani during the second stage of labor and it is detectable by 3D TVUS and 3D TPUS imaging as the lateral attachments of the levator ani to the

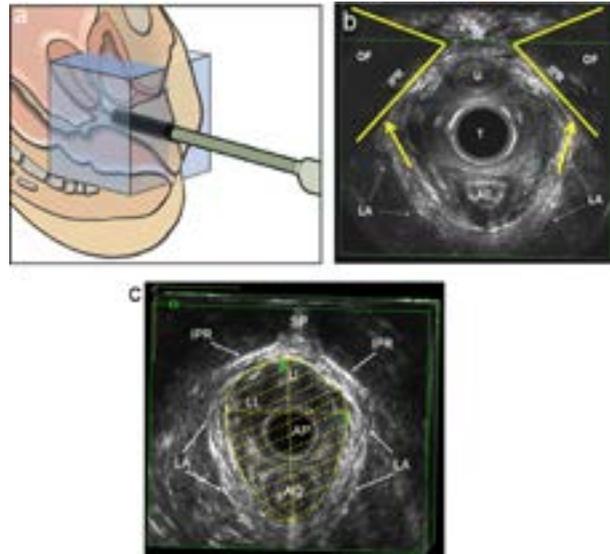

Fig. 7. 3D-Endovaginal ultrasound. (a) Schematic drawing; (b) Axial image of the pelvic floor at Level III, showing the LA attachment to the inferior pubic rami (IPR); and (c) the levator hiatus. AC, anal canal; LA, levator ani; B, bladder; U, urethra; SP, symphysis pubis; OF, obturator foramen; T, transducer; AP, anteroposterior diameter of the levator hiatus; LL, laterolateral diameter of the levator hiatus.

pubic bone are clearly visualized.<sup>94</sup> Defects are usually visualized most clearly on maximal PFMC. Tomographic ultrasound imaging is particularly useful. Levator ani injuries affect the size of the levator hiatus, with a hiatal enlargement to over 25 cm<sup>2</sup> on Valsalva maneuver defined as “ballooning,” and are related to symptoms and signs of prolapse.

#### 5.1.4.3: *Obstructed defecation syndrome (ODS)*

The term obstructed defecation syndrome (synonym: “outlet obstruction”) encompasses all pelvic floor dysfunctions, which are responsible for an incomplete evacuation of fecal contents from the rectum, straining at stool and vaginal digitations. During maximal Valsalva maneuver, dynamic TPUS and TVUS may be used to demonstrate.<sup>82,95</sup>

- **Rectocele:** herniation of a depth of over 10 mm of the anterior rectal wall,
- **Rectal intussusception:** invagination of the rectal wall into the rectal lumen, into the anal canal or exteriorized beyond the anal canal (rectal prolapse),
- **Enterocoele:** herniation of bowel loops into the vagina. It can be graded as small, when the most distal part descends into the upper third of the vagina, moderate, when it descends into the middle third of the vagina, or large, when it descends into the lower third of the vagina,
- **Dyssynergic defecation:** the ARA becomes narrower, the LH is shortened in the anteroposterior dimension, and the PR muscle thickens as a result of contraction.

#### 5.1.4.4: *Perianal abscesses and fistulas*

### 5.2: MRI for Anal Sphincters and Pelvic Floor (Static, Dynamic, Endocoil) Upright, Supine, Left Lateral Position

#### 5.2.1: *Static MRI*

Static MRI provides detailed information of the pelvic floor anatomy.<sup>96</sup> Current state-of-the-art MR imaging of the pelvic floor includes imaging at a magnetic field strength of 1.5 Tesla (T), using pelvic or phased-array coils and T2-weighted fast-spin echo (FSE) sequences. The spatial resolution can be enhanced by using endoluminal (endorectal, endovaginal) coils. In combination with T2-weighted FSE sequences, endoluminal coils provide improved signal-to-noise ratio (SNR) and high resolution images.<sup>97</sup> Based on T2-weighted turbo spin-echo sequences, muscles are relative hypointense, ligaments and fascia hypointense while fat and smooth muscle are hyperintense. The prominent pelvic floor structures of the posterior compartment visualized at MRI are (Fig. 8):

- Perineal body and superficial perineal muscles,
- Anal sphincters: the IAS is easily recognized as a circular hyperintense structure. It is approximately 2.9 mm thick on endoluminal MRI. The inter-sphincteric space is seen as a bright line on T2-weighted MRI. The EAS has a thickness of 4.1 mm on endoluminal imaging,
- Puborectalis muscle and levator ani,
- Superficial perineal muscles,
- Rectum and rectal support.

Neurourology and Urodynamics DOI 10.1002/nau

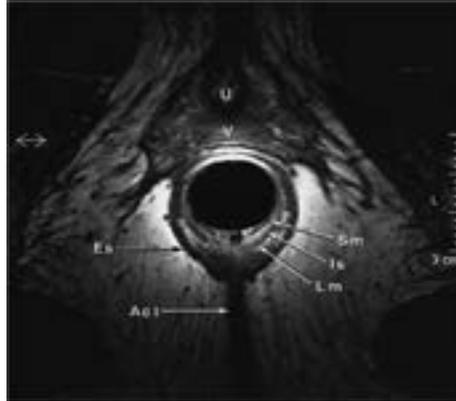

Fig. 8. Static MRI. Axial image of the anal canal. U: urethra; V: vagina; SM: submucosa; IS: internal sphincter; LM: longitudinal muscle; ES: external sphincter; ACL: anococcygeal ligament.

### 5.2.2: Dynamic MRI

With the development of fast multi-slice sequences MR imaging has gained increasing acceptance for dynamic imaging of pelvic floor. Because the posterior compartment is traditionally in the focus of interest, dynamic MR imaging of the pelvic floor is often called “MR defecography.”<sup>98</sup>

Dynamic pelvic imaging may be performed in an open-configuration MR system in the sitting position, or in a closed-configuration MR-system in the supine position. Both techniques are equally effective in identifying most of the clinically relevant abnormalities of the pelvic floor.<sup>98</sup> For evaluation of the posterior compartment of the pelvic floor, the rectum should be filled with a contrast agent (ultrasound gel or mashed potatoes, gadolinium-based MR contrast agent) to study the actual act of defecation.

The use of reference lines for image evaluation is helpful.<sup>99,100</sup> The most used reference line is the pubococcygeal line (PCL), which is defined on mid-sagittal images as the line joining the inferior border of the symphysis pubis to the last or second last coccygeal joint (Fig. 9a). The anorectal junction (ARJ) is defined as the cross point between a line along the posterior wall of the distal part of the rectum and a line along the central axis of the anal canal. To determine pathologic pelvic floor descent, the measurements are made on the images, which show maximal organ descent, usually during maximal straining or during evacuation (Fig. 9b). The anorectal angle (ARA) is defined as the angle between the posterior wall of the distal part of the rectum and the central axis of the anal canal and can be measured at rest, squeezing and straining. The extent of rectoceles and enteroceles are measured.

The degree of pelvic floor relaxation is measured with two reference lines (Fig. 9a): the H line which represents hiatal widening and extends from the inferior aspect of the symphysis pubis to the posterior wall of the rectum at the level of the ARJ and the M line which represents hiatal descent and extends perpendicularly from the PCL to the posterior end of the H line. Lesions of the pelvic musculofascial support result in widening of the hiatus and descent of the levator plate. Thus, the H and M lines tend to elongate

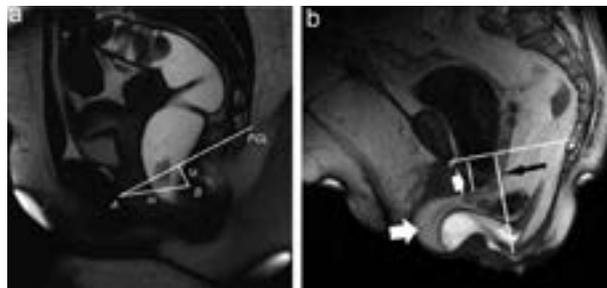

Fig. 9. Dynamic MRI. (a) Mid-sagittal steady state free precession T2-weighted image obtained at straining shows landmarks used in the HMO-system. The landmarks are the inferior aspect of the symphysis pubis (A) and the posterior wall of the rectum at the level of the anorectal junction (B). The H line (H) represents the anteroposterior hiatal width and extends from A to B. The M line (M) represents hiatal descent and extends perpendicularly from the pubococcygeal line (PCL) to the posterior end of the H line. (b) During Valsalva maneuver, there is a bladder descent below the PCL (small white arrow), with a perineal descent (black arrow) and a rectocele developing with a posterior vaginal wall prolapse (long white arrow).

Neurourology and Urodynamics DOI 10.1002/nau

with pelvic floor relaxation, widening the levator plate descent. Abnormal pelvic floor relaxation is present, when the H line exceeds 6 cm, and when the M line exceeds 2 cm in length.

### 5.2.3: Clinical applications of MRI of the posterior compartment

#### 5.2.3.1: Fecal incontinence

Endoanal ultrasound and endoanal magnetic resonance imaging (MRI) have been demonstrated to be comparable in the detection of external sphincter defects.<sup>101</sup> External phased array coil MRI can replace endoluminal MRI with comparable results.<sup>102</sup>

#### 5.2.3.2: Levator ani injuries

Abnormalities of the LA are identified on MRI as present or absent.<sup>103</sup> Defect severity is further scored in each muscle from 0 (no defect) to 3 (complete loss). A summed score for the two sides (0–6) is assigned and grouped as minor (0–3) or major (4–6).

#### 5.2.3.3: Obstructed defecation

During maximal Valsalva maneuver, dynamic MRI may be used to demonstrate:

- **Rectocele:** measured as the depth of wall protrusion beyond the expected margin of the normal anorectal wall. Based on sagittal MR-sections through mid of pelvis, rectoceles are graded as small (<2 cm), moderate (from 2 to 4 cm), and large (>4 cm),
- **Rectal intussusception:** the infolding of the rectal mucosa occurring during defecation. Depending on the location, an intrarectal intussusception, limited to the rectum, is distinguished from an intra-anal intussusception extending into the anal canal. The location of the intussusception may be anteriorly, posteriorly, or circumferentially. The intussusception either involves only the mucosa or the full thickness of the rectal wall,
- **Enterocoele:** defined as a herniation of the peritoneal sac, which contains omental fat (peritoneocoele), small bowel (enterocoele) or sigmoid (sigmoidocoele), into the rectovaginal or rectovesical space below the PCL. The largest distance between the PCL and the most inferior point of the enterocoele is measured with a perpendicular line. Depending on this distance, small (<3 cm), moderate (3–6 cm), and large (>6 cm) enterocoeles are distinguished,
- **Dyssynergic defecation:** different structural imaging findings can be seen on dynamic pelvic MRI, including prominent impression of the puborectal sling, narrow anal canal, prolonged evacuation, a lack of descent of the pelvic floor and thus a failure to increase the ARA.

In comparison with clinical examination (POP-Q), dynamic MRI has no additional value in the prediction of symptoms with increasing degree of POP.<sup>104</sup>

#### 5.2.3.4: Perianal abscesses and fistulas

## 5.3: Defecating Proctography

Evaluates in real time the morphology of rectum and anal canal in correlation with pelvic bony components both statically and dynamically by injection of a thick barium paste into the rectum and its subsequent evacuation.<sup>105</sup> Contrast administration into the bladder and vagina provides a more comprehensive assessment of the pelvic organs and has been labelled “**dynamic cystoproctography**.”<sup>104</sup>

At rest, the anal canal is closed and rectum assumes its normal upright configuration. The position of the pelvic floor is inferred by reference to the PCL (inferior margin of pubic symphysis to the sacro-coccygeal junction) (Fig. 10a). Perineal descent is measured from to this line to the ARJ, and may be up to 1.8 cm at rest. Some pelvic floor descent during evacuation is considered normal, and a descent of up to 3 cm from the rest position to anal canal opening is acceptable. The ARA is defined as the angle between the anal canal axis and the posterior rectal wall, and on average is around 90° (Fig. 10b). The puborectalis length (PRL) can be estimated by measuring the distance between the ARA and symphysis pubis.

A normal emptying phase at the proctogram is described by five elements:

- Increase in the ARA by around 20–30 degrees,
- Obliteration of the puborectalis impression and the PRL should increase by around 3–4 cm,
- Wide opening of the anal canal within a couple of seconds,
- Evacuation of rectal contents proceeding promptly and to completion,
- Lack of significant pelvic floor descent.

After evacuation is complete, the anal canal should close, the ARA recover and the pelvic floor return to its normal baseline position. Post toilet imaging may be required, particularly in those suspected of retained barium within rectoceles (Fig. 10c).

### 5.3.1: Clinical applications of defecating proctography

Assuming that posterior wall prolapse and rectocele can be considered the same anatomic entity, clinical examination is not accurate in diagnosing anatomical defects of posterior vaginal wall and enterocoeles compared to defecography as reference standard. Clinical examination overestimates the presence of the posterior wall defects (large false positive rates) but misses enterocoele in patients with primary POP (large false negative rates).<sup>106,107</sup> The major function of proctography is not merely to document evacuatory abnormalities, but also to classify those abnormalities into those potentially surgically relevant, those likely to benefit from behavioral biofeedback therapy alone, or indeed those which are incidental.<sup>108</sup>

#### 5.3.1.1: Pelvic floor descent

Pelvic floor descent, defined as the distance moved by the ARJ or ARA at rest to the point of anal canal opening, is considered abnormal if it exceeds 3 cm.<sup>105</sup>

#### 5.3.1.2: Intussusception and prolapse

Intussusception refers to infolding of the rectal wall into the rectal lumen. It may be described as intra-rectal, intra-anal or external to form a complete rectal prolapse.

#### 5.3.1.3: Rectocele

Rectocele diagnosis on evacuation proctography is defined as any anterior rectal bulge (Fig. 10c). The depth of a rectocele is measured from the anterior border of the anal canal to the anterior border of the rectocele. A distance of <2 cm is classified as small, 2–4 cm as moderate and >4 cm as large. Of more relevance however is barium trapping at the end of evacuation (defined as retention of >10% of the area, and this itself is related the size of the rectocele).

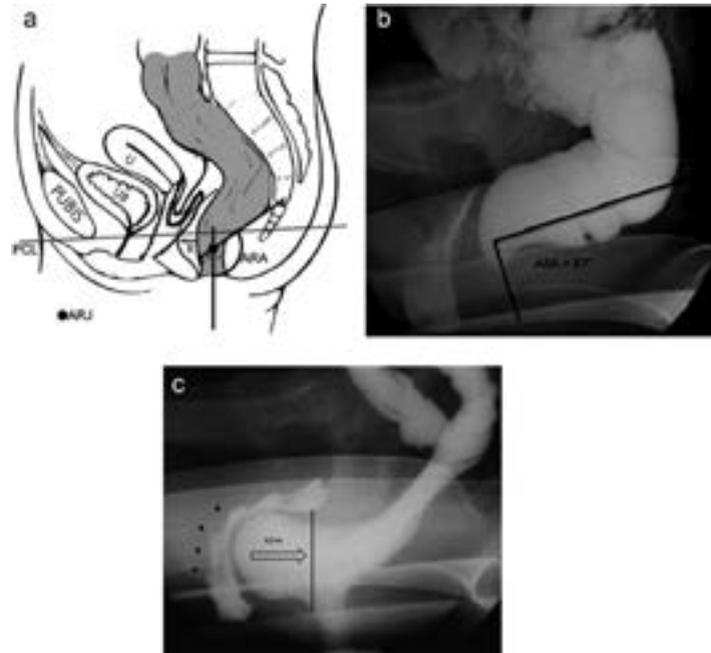

Fig. 10. Defecating proctography. (a) Schematic drawing; (b) Measurement of the anorectal angle at rest (ARA); (c) Image during Valsalva maneuver, showing the displacement of the anterior rectal wall (rectocele) with posterior vaginal wall prolapse (black arrows). PCL, pubococcygeal line; UB, urinary bladder; U, uterus; ARJ, anorectal junction; R, rectocele.

#### 5.3.1.4: Enterocele

An enterocele is diagnosed when small bowel loops enter the peritoneal space between the rectum and vagina. Diagnosis of an enterocele on proctography is only really possible if oral contrast has been administered before the examination.<sup>105</sup> Herniation of the sigmoid into the rectogenital space (sigmoidecele) is significantly less common than an enterocele.

#### 5.3.1.5: Dyssynergic defecation

Various proctographic abnormalities have been described including prominent puborectal impression, a narrow anal canal, and acute anorectal angulation. However these observations may be found in normal controls and are in themselves unreliable distinguishing features.

### 5.4: Contrast Enema

Contrast enema is used to identify colon pathology (benign and malignant lesions, diverticular disease, inflammatory conditions, congenital anomalies, intrinsic and extrinsic abnormalities).

#### 5.4.1: Single-contrast barium enema

Using an appropriate catheter, a barium-water mixture or a water-soluble solution of diatrizoate sodium (Gastrografin) is inserted into the colon with the patient in the prone position until the column of barium reaches the splenic flexure.

#### 5.4.2: Double-contrast or air-contrast barium enema

This procedure has become the routine study for evaluation of the bowel.<sup>108</sup> With the double-contrast examination, the colon is coated with a thin layer of contrast material and the bowel is distended with air so that the entire mucosal circumference is visualized.

### 5.5: Colonic Transit Studies (Radio-Opague Oral Markers, Pill Transit, Nuclear Medicine Scintigraphy)

Slow transit constipation can be distinguished by colonic transit studies.<sup>109,110</sup>

#### 5.5.1: Radiological transit (shapes) study

Segmental and total colonic transit time is assessed with the use of radio-opaque markers and sequential abdominal X-rays. There are different protocols. Most frequently used, utilizes a capsule containing 24 markers of 1 × 4.5 mm. Patient takes one capsule on day 0 by mouth and X-ray is performed on day 5 (Fig. 11). Patients who expel at least 80% markers on day 5 have normal colonic transit. Patients who retain 6 or more markers may have follow-up abdominal X-rays within several days. If remaining markers are scattered about the colon, the condition is slow transit or colonic inertia. If the remaining markers are accumulated in the rectum or rectosigmoid, this suggests functional outlet obstruction.

Fig. 11. Radiologic transit study. On day 5, the remaining markers are more than 80%, suggesting functional outlet obstruction.

#### 5.5.2: Nuclear transit study

Colon scintigraphy is performed at 6, 24, and 48 hr in ventral and dorsal projection after oral administration of methacrylate-coated capsule of non-resorbable <sup>111</sup>Indium-labeled polystyrene (<sup>111</sup>In-DTPA) micropellets.<sup>109</sup> The geometric center, as the sum of products of colon segment activity and colon segment number (1 = ascending colon, 2 = transverse colon, 3 = descending colon, 4 = rectosigmoid, and 5 = evacuated feces) dividing by the total counts is used to determine the velocity of colonic transit. Meals normally reach the cecum at 6 hr and are evacuated in 30 to 58 hr. Retention of radioactivity in the proximal colon at 48 hr, indicates slow colonic transit while retention in the rectum indicates anorectal dysfunction. Table III shows utility of various imaging modalities for female anorectal dysfunction.

### 6: DIAGNOSIS

#### 6: **DIAGNOSIS** (most common) [defined as prevalence >10%]

Diagnosis is based on symptoms, signs, examination, and any relevant diagnostic investigations

##### 6.1: Local (Fissures, Hemorrhoids)

Fissure: Is a break in the lining of the anal canal

Hemorrhoids: Abnormality of the normal cushion of specialized, highly vascular tissue in the anal canal in the submucosal space.

##### 6.2: Fecal Incontinence

Fecal incontinence: involuntary loss of solid or liquid stool and could be due to:

**6.2.1:** Anal sphincter disruption is due to discontinuity of the external anal sphincter, internal anal sphincter or both.

**6.2.2:** Hypocontractile/acontractile sphincter is due to neuropathy or atrophy.

**6.2.3:** Combined anal sphincter disruption and hypocontractile/acontractile sphincter.

**6.2.4:** Rectal overactivity due to exaggerated smooth muscle contraction of the rectum could also be associated with hypersensitivity.<sup>110,111</sup>

**6.2.5:** Overflow incontinence seepage of stool due to fecal impaction.

##### 6.3 Obstructed Defecation Syndrome

Obstructed defecation: incomplete evacuation of fecal contents from rectum due to physical blockage of the fecal stream during defecation attempts. It includes symptoms such as straining to defecate, sensation of blockage, digitation, and splinting. Constipation due to slow transit, irritable bowel syndrome, Hirschsprung's disease, megarectum, anismus are not within the remit of this standardization document. Associated features of obstructed defecation are:

**6.3.1: Rectocele:** Bulge in posterior vaginal wall associated with herniation of anterior wall of the rectum (See <sup>FN16</sup>).

**6.3.2: Enterocele/sigmoidocele:** Bulge of upper wall of vagina associated with herniation of peritoneal sac and small bowel (enterocele) or sigmoid colon (sigmoidocele).

**6.3.3: Intussusception:** Full thickness invagination of the upper rectum without extrusion through the anus leading to interruption of flow of the fecal stream.

<sup>FN16</sup> A transverse defect rectocele occurs simply by a detachment of the perineal body from the rectovaginal fascia. The hammock of rectovaginal fascia supporting the rectum remains intact but separates from the perineal body. A midline vertical defect is created by a midline separation of the rectovaginal fascia, and a separation of the rectovaginal fascia can occur from its lateral attachments. Rectoceles are more commonly situated in the mid to distal aspect of the posterior vaginal wall.

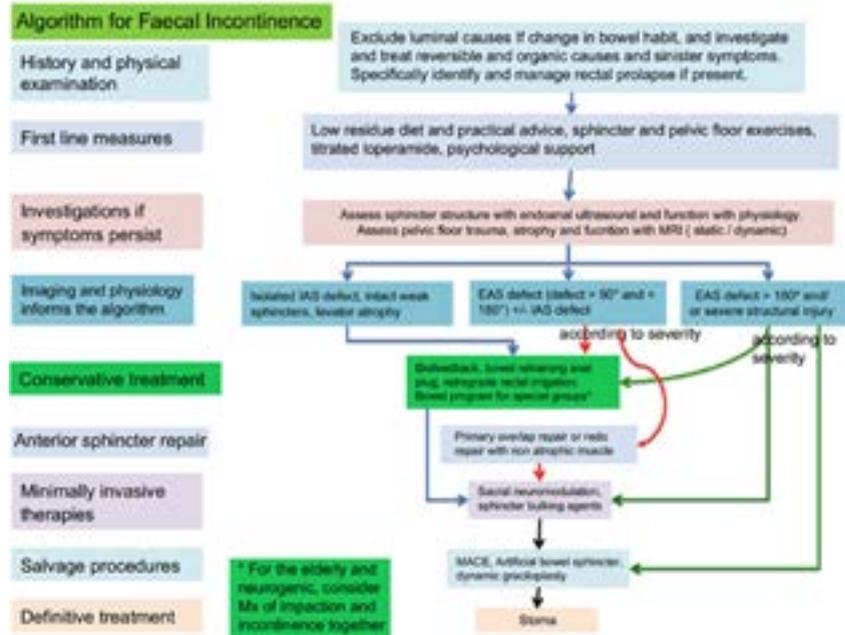

Fig. 12. (adapted from ref. [125]). Algorithm: fecal incontinence. IAS, internal anal sphincter; EAS, external anal sphincter; SNM, sacral neuromodulation; MACE, malone antegrade continence enema.

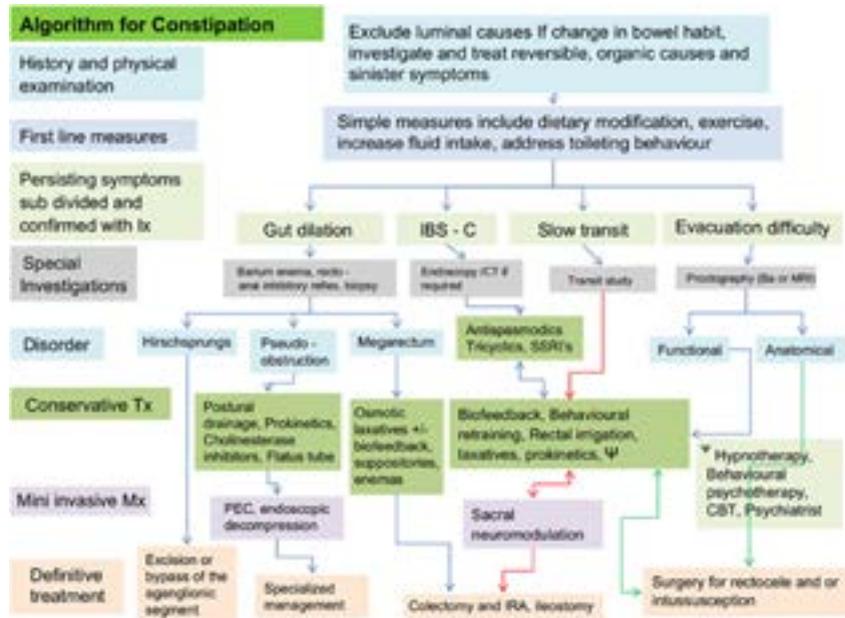

Fig. 13. (adapted from ref. [125]). Algorithm: constipation. IBS-C, irritable bowel constipation predominant; IRA, ileorectal anastomosis; J, hypnotherapy; behavioural psychotherapy; CBT, psychiatrist management; CBT, cognitive behavioural therapy; Ix, investigations; Mx, management; Tx, treatment.

**6.3.4: Internal mucosal prolapse:** Mucosal prolapse of the anterior, posterior, or circumferential mucosal layer.

**6.3.5: External rectal prolapse:** Full thickness rectal prolapse outside the anal canal

#### 6.4: Sepsis

##### 6.4.1: Abscess

Infection in a (non Crohn's) anal gland, located at the base of the dentate line, that initially forms an abscess, which can be located in one of the potential spaces surrounding the anus and rectum.

##### 6.4.2: Ano-rectal/vaginal/perineal fistula

Rectovaginal fistula is a communication from the rectum to the vagina and rarely the perineal area. An anovaginal/perineal fistula is an abnormal communication from the anal canal to the vagina or perineal area.

#### 6.5: Pain Syndromes

##### 6.5.1: Levator ani syndrome

Episodic rectal pain caused by spasm of the levator ani muscle. Proctalgia fugax (fleeting pain in the rectum) and coccydynia (pain in the coccygeal region) are variants of levator ani syndrome (See <sup>FN17</sup>).

##### 6.5.2: Proctalgia fugax

Definition: Proctalgia fugax (or Levator syndrome) is a severe, episodic, rectal and sacrococcygeal pain.<sup>112</sup> It can be caused by cramp of the pubococcygeus or levator ani muscles (See <sup>FN18</sup>).

##### 6.5.3: Pudendal neuralgia

Pudendal Neuralgia (PN) is a painful condition that is caused by inflammation of the pudendal nerve involving its dermatome.<sup>115</sup> It can affect both men and women (See <sup>FN19</sup>).

<sup>FN17</sup>Symptoms of levator ani syndrome are painful rectal spasm, typically unrelated to defecation, usually lasting >20 min. The pain may be brief and intense or a vague ache high in the rectum. It may occur spontaneously or with sitting and can waken the patient from sleep and occurs more often on the left. The pain may feel as if it would be relieved by the passage of gas or a bowel movement. In severe cases, the pain can persist for many hours and recur frequently. During clinical evaluation: a dull ache to the left 5 cm above the anus or higher in the rectum and a feeling of constant rectal pressure or burning. Physical examination can exclude other painful rectal conditions (e.g., thrombosed hemorrhoids, fissures, abscesses, scarring from previous surgery). Physical examination is often normal, although tenderness or tightness of the levator muscle, usually on the left, may be present. Occasionally the cause can be low back disorders. Coccydynia (coccygodynia) is complaint of pain and point tenderness of the coccyx (this is NOT anorectal pain).

<sup>FN18</sup>Proctalgia fugax most often occurs in the middle of the night and lasts for seconds to 20 min. During an episode, which sometimes occurs after orgasm, the patient feels spasm-like, sometimes excruciating pain in the anus, often misinterpreted as a need to defecate. Because of the high incidence of internal anal sphincter thickening with the disorder, it is thought to be a disorder of the internal sphincter or that it is a neuralgia of pudendal nerves. It tends to occur infrequently (once a month or less). Like all ordinary muscle cramps, it is a severe, deep rooted pain. Defecation can worsen the spasm, but may relieve it,<sup>113</sup> or provide a measure of comfort. The pain might subside by itself as the spasm disappears on its own, or may persist or recur during the same night. Patients with proctalgia fugax are usually asymptomatic during the anorectal examination, leaving no signs or findings to support the condition, which is based on symptoms by history taking, diagnostic criteria, described above, and the exclusion of underlying organic disease (anorectal or endopelvic) with proctalgia.<sup>114</sup>

<sup>FN19</sup>The condition is also known as pudendal neuropathy, pudendal nerve entrapment, cyclist's syndrome, pudendal canal syndrome, or Alcock's syndrome. The Nantes criteria<sup>13</sup> includes:

1. Pain in the anatomical region of pudendal nerve innervation.
2. Pain that is worse with sitting.
3. No waking at night with pain.
4. No sensory deficit on examination.
5. Relief of symptoms with a pudendal block.

Primary symptoms of PN include:

- a) Pelvic pain with sitting that may be less intense in the morning and increase throughout the day. Symptoms may decrease when standing or lying down. The pain can be perineal, rectal or in the clitoral/penile area; it can be unilateral or bilateral.
- b) Sexual dysfunction. In women, dysfunction manifests as pain or decreased sensation in the genitals, perineum or rectum. Pain may occur with or without touch. It may be difficult or impossible for the woman to achieve orgasm.
- c) Difficulty with urination/defecation. Patients may experience urinary hesitancy, urgency and/or frequency. Post-void discomfort is not uncommon. Patients may feel that they have to "strain" to have a bowel movement and the movement may be painful and/or result in pelvic pain after. Constipation is also common among patients with PN. In severe cases, complete or partial urinary and/or fecal incontinence may result.
- d) Sensation of a foreign object being within the body. Some patients will feel as though there is a foreign object sitting inside the vagina or the rectum.

It is important to note PN is largely a "rule out" condition. In other words, because its symptoms can be indicative of another problem, extensive testing by physical examination, assessment by touch, pinprick, bimanual pelvic palpation with attention to the pelvic floor muscles, in particular the levator and obturator muscles, tenderness of the bladder and sacrospinous ligaments are required to ensure that symptoms are not related to another condition. Maximum tenderness, or a trigger point can be produced by applying pressure to the ischial spine. Palpation of this area can reproduce pain and symptoms as a positive Tinel's sign.<sup>115</sup>

As PN is a diagnosis of exclusion, other conditions that should be excluded include coccygodynia, piriformis syndrome, interstitial cystitis, vulvodynia, vestibulitis, chronic pelvic pain syndrome, proctalgia, anorectal neuralgia, pelvic contracture syndrome/pelvic congestion, proctalgia fugax, or levator ani syndrome.

In addition to eliminating other diagnoses, it is important to determine if the PN is caused by a true entrapment or other compression/tension dysfunctions. In almost all cases, pelvic floor dysfunction accompanies PN. Electrodiagnostic studies will help the practitioner determine if the symptoms are caused by a true nerve entrapment or by muscular problems and neural irritation.

*Neurourology and Urodynamics* DOI 10.1002/nau

**First degree:** laceration of the vaginal epithelium or perineal skin only.  
**Second degree:** involvement of the perineal muscles but not the anal sphincter.  
**Third degree:** disruption of the anal sphincter muscles that should be further subdivided into:  
 3a: <50% thickness of external sphincter torn.  
 3b: >50% thickness of external sphincter torn.  
 3c: no internal sphincter also torn.  
**Fourth degree:** a third degree tear with disruption of the anal epithelium as well.  
**Button hole tear of rectum:** isolated tear of rectum without involvement of the anal sphincter.

Fig. 14. Classification of perineal trauma.<sup>119</sup>

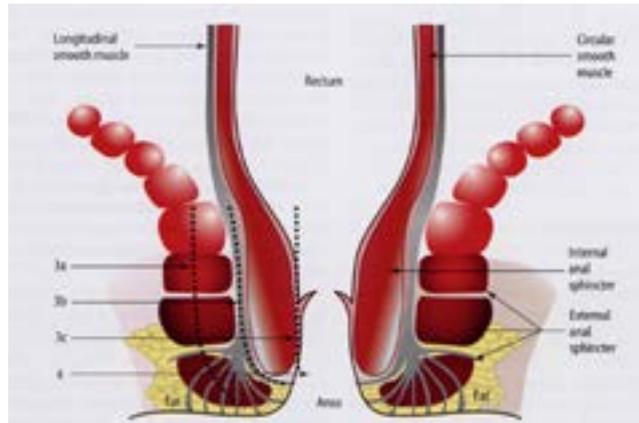

Fig. 15. Classification of 3rd and 4th degree tears (with permission from Springer<sup>116</sup>).

**6.6: Obstetric Anal Sphincter Injuries (OASIS)**

OASIS are reported to occur in 0.5–14% of vaginal deliveries (2.9–19% of primiparous vaginal deliveries).<sup>116</sup> It has previously been shown in a prospective study that about one third of OASIS can be diagnosed 8 weeks after delivery by endoanal ultrasound alone. As these were not identified clinically, the injuries were believed to be “occult.”<sup>12</sup> However, it has subsequently been proven that such injuries are not necessarily occult but in fact undiagnosed due to lack of expertise of midwives and doctors.<sup>3</sup>

Training in diagnosis and management of perineal trauma has been shown to be suboptimal<sup>117</sup> and dedicated hands-on courses have shown significant improvements in diagnosis and classification of OASIS.<sup>118</sup> Sultan therefore proposed a more descriptive classification of OASIS (Figs. 12 and 13)<sup>119</sup> that has now been accepted internationally to support consistency in reporting.<sup>120–122</sup> To avoid underestimation of the injury, if there is uncertainty regarding the full extent of the injury it should be classified as the greater degree, for example, if one is unsure as to whether an injury is a Grade 3a or 3b it should be classified as 3b (Figs. 14 and 15). This classification also has clinical relevance as it ensures increased vigilance for internal sphincter injuries that are best repaired soon after delivery<sup>123</sup> as persistent internal sphincter defects are associated with fecal incontinence.<sup>124</sup> Examination techniques to improve detection of these injuries and avoiding pitfalls in diagnosis have been described in detail.<sup>116</sup>

**AIMS:** The working group initiated by the ICS Standardisation Steering Committee has updated the International Continence Society Standard “Good Urodynamic Practice” published in 2002.

**METHODS:** On the basis of the manuscript: “ICS standard to develop evidence-based standards,” a new ICS Standard was developed in the period from December 2013 to December 2015. In July, a draft was posted on the ICS website for membership comments and discussed at the ICS 2015 annual meeting. The input of ICS membership was included in the final draft before ICS approval and subsequent peer review (for this journal).

**RESULTS:** This evidence-based ICS-GUP2016 has newly or more precisely defined more than 30 terms and provides standards for the practice, quality control, interpretation, and reporting of urodynamics; cystometry and pressure-flow analysis. Furthermore, the working group has included recommendations for pre-testing information and for patient information and preparation. On the basis of earlier ICS standardisations and updating according to available evidence, the practice of uroflowmetry, cystometry, and pressure-flow studies are further detailed.

**CONCLUSION:** ICS-GUP2016 updates and adds on to ICS-GUP2002 to improve urodynamic testing and reporting both for individual care and scientific purposes.

## KEYWORDS

clinical practice standard and quality, cystometry, incontinence, lower urinary tract dysfunction, pressure-flow study, urodynamic, uroflowmetry

## 1 | INTRODUCTION

The ICS Standardisation Steering Committee has initiated a working group (WG) to update the International Continence Society's Good Urodynamic Practice 2002<sup>1</sup> (GUP2002) with the aim of including new evidence and information on

urodynamic practice and urodynamic quality control and the revised ICS standard on urodynamic equipment.<sup>2</sup> Following the traditional ICS Standardisation style, while including the new method and structure,<sup>3</sup> changes of current standards are recommended and arguments provided for making these changes.

This report provides evidence-based specific recommendations for routine clinical urodynamic testing, and includes expert consensus where evidence is lacking.

Dr. Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper

Conclusions and recommendations are highlighted in the text and can be used for summary and express reading. We define “ICS standard” as: “Best practice, based on evidence, with the use of standard terms and standard techniques, evaluated and reported clinically or scientifically, in a complete and validated manner.” In individual cases and/or in research settings, the decision may be made not to adhere to this standard, but any deviation from the standard should be specified.

The ICS standard is particularly intended for evaluation of the function of the lower urinary tract (LUT) of adult persons without relevant neurological abnormalities and with intact “normal” anatomy of the LUT. Many of the recommendations in this document may, however, also be considered relevant, generalizable, or applicable for patients with neurological abnormalities, for Video-urodynamics or for urodynamics in research settings and/or also for patients with neobladders, augmented bladders, or diversions. The recommendations may also be helpful for performing urodynamics in children.<sup>4</sup>

## 2 | DEFINITIONS OF TERMS FOR URODYNAMIC TESTS

### 2.1 | Introduction and evidence base

Over the years, a variety of terms have been developed for the group of diagnostic tests that evaluate LUT function. The WG has constructed a table with terms and has provided their frequencies of use, both in PubMed (searching in title and abstract) and in Google (Table S1). Uroflowmetry, Post Void Residual (PVR), Cystometry, Pressure-flow study, Electromyography (EMG), Urethral Pressure Profile, and Video urodynamics are the terms most frequently used in the scientific literature. The ICS Standardisation of Terminology of LUT Function (ST2002)<sup>5</sup> (re-) introduced or used many of these terms, and the AUA-SUFU has also provided definitions of some terms.<sup>6</sup>

### 2.2 | Conclusions

Many terms have been introduced in earlier standardizations, without providing a precise definition.

A significant variety of synonyms are used for urodynamic tests and studies in the scientific literature as well as in lay texts and we conclude that the use of currently existing terms is not yet without variation in scientific literature.

### 2.3 | Discussion

Variations in the application of terms may bias communication, in science and also in communication with patients. The following terms are not really new and many were introduced earlier, sometimes long ago.

## 2.4 | Recommendation

For the purpose of uniformity, particularly in research we recommend and define the following as ICS standard terms:

**Urodynamics:** The general term to describe all the measurements that assess the function and dysfunction of the LUT by any appropriate method. Urodynamics allows direct assessment of LUT function by the measurement of relevant physiological parameters. (GUP2002 not changed).

**Invasive urodynamics:** Any test that is invasive, as it involves insertion of one or more catheters or any other transducers into the bladder and/or other body cavities, or insertion of probes or needles, for example for EMG measurement.

**Non-invasive urodynamics:** All urodynamics done without the insertion of catheters: for example, uroflowmetry, PVR, penile compression-release test, penile cuff, urethral connector, condom catheter, or sonography.

**Ambulatory urodynamics:** See the applicable ICS Standard.<sup>7</sup> (Not further discussed in this standard.)

**ICS standard urodynamics protocol (NEW):** a patient undergoing collection of a clinical history (should include (a) valid symptom and bother score(s) and medication list), relevant clinical examination, (3 days) bladder diary, representative uroflowmetry with post-void residual (PVR) and a complete ICS standard urodynamic test (see below), is referred to as having had the “ICS standard urodynamics protocol (ICS-SUP).”

**ICS standard urodynamic test (NEW):** Uroflowmetry and PVR plus transurethral cystometry and pressure-flow study (see below): all tests are performed in the patient’s preferred or most usual position: comfortably seated and/or standing, if physically possible. The patient(s) is reported as having had an ICS standard urodynamic test (ICS-SUT).

**ICS supplementary urodynamic tests:** ICS-SUT may be supplemented with EMG, with imaging, with continuous urethral pressure(s) and/or with urethral pressure profile measurement. Cystometry may be done via a suprapubic catheter (specify supplements).

**Recommendation:** The WG suggests all ICS-SUT-data as a minimum, and preferably complete ICS-SUP data should be specifically reported or summarized for the total cohort of patients in all research reports that contain (invasive) urodynamic results.

Furthermore, the WG suggests referring to the current manuscript when research is reported as “. . . according to ICS Standard Good Urodynamic Practices (ICS-GUP2016),” when complete ICS-SUT or SUP data are reported.

**Uroflowmetry:** A test that produces the [Citation from GUP2002]: “. . . flow rate of the external urinary stream as

volume per unit time in millilitres per second (mL/s).” ICS uroflowmetry minimally reports the maximum flow rate and the volume voided and PVR. (GUP2002, not changed.) Other characteristics such as flow pattern (specify) and other parameters may be added but should be specified.

**Post-void residual volume (PVR):** (GUP 2002) The remaining intravesical fluid volume determined directly after completion of the voiding. The technique (eg, ultrasound or catheter) used to measure the volume should be specified.

**Voided percentage (Void%):** The numerical description of the voiding efficacy or efficiency which is the proportion of bladder content emptied. Calculation:  $[(\text{volume voided}/\text{volume voided} + \text{PVR}) \times 100]$ . The WG suggests—solely for the purpose of standardization—that the term voided percentage with the abbreviation Void% is preferred. The relevance of the parameter is not discussed here.

**Cystometry:** Continuous fluid filling of the bladder via a transurethral (or other route, eg, suprapubic or mitrofanoff) catheter, at least with intravesical and abdominal pressure measurement and display of detrusor pressure, including cough (stress) testing. Cystometry ends with “permission to void” or with incontinence of the total bladder content. The fluid type and temperature, filling method and rate, catheter sizes, pressure recording technique, and patient position should all be specified.

**Cysto-urethrometry:** A cystometry is done with continuous urethral pressure measurement (specify technique).

**Pressure-flow study:** The intravesical and abdominal pressures are measured, from the moment of “permission to void,” while uroflowmetry is performed with a transurethral (or suprapubic) catheter in place. The position of the patient, the catheter sizes, and the pressure and flow recording technique should be specified.

**Pelvic muscle electromyography (EMG):** Pelvic muscle activity is judged with surface electrodes. ICS Standard: two skin electrodes on the perineal surface with an appropriate reference (=Pelvic muscle EMG). Other type, for example, vaginal probe: “vaginal EMG,” “anal EMG” or “needle EMG,” etc. and/or number and position of electrodes should be specified.

**Urethral pressure profile:** See ICS Standardisation of urethral pressure measurement.<sup>8</sup>

Urodynamics may be combined with imaging (specify). Invasive urodynamics performed with contrast fluid as the filling medium is Video urodynamics: X-ray (image amplifier) pictures or cine-loops are made at relevant moments. The contrast medium and report patient radiation dose should be specified. Video urodynamics is not further discussed in this document.

### 3 | PATIENT INFORMATION AND PREPARATION OF THE PATIENT FOR INVASIVE URODYNAMICS

#### 3.1 | Introduction and evidence base

Although evidence indicates that urodynamics is generally well tolerated, studies have examined pain and embarrassment, using a variety of questionnaire methods. Younger patients have been identified as a group that may experience more pain and apprehension<sup>9</sup> associated with depression, anxiety and/or bladder pain syndrome.<sup>10</sup> Effectiveness of patient information leaflets requires comprehensibility and communicative effectiveness.<sup>11–13</sup> However, reports analysing existing information conclude that this is of poor quality. Studies to develop a detailed explanatory leaflet, which were used in a double-blind randomized controlled trial to conclude that “leaflet” or “no leaflet” intervention had a disappointing satisfaction outcome.<sup>14,15</sup> Poor understanding of the test has been associated with lack of satisfaction with care and with, for example, the perception that the investigation in itself is therapeutic.<sup>16</sup>

#### 3.2 | Conclusions

Some evidence exists that information leaflets about urodynamic investigations are too difficult for patients to understand.

Young adults and patients with a bladder pain syndrome may have a relatively negative experience with urodynamic investigation.

Conflicting evidence exists about which precise information is helpful to give to patients before urodynamic testing to reduce distress.

#### 3.3 | Discussion

Effective communication is an expectation in modern healthcare, so that patients become actively engaged in the test and their care delivery. The WG has discussed that a leaflet with a minimum set of items would facilitate informed decision making. The WG is convinced that good information before and during the test increases a patient's acceptance and confidence, and will reduce confusion.

#### 3.4 | Recommendation

The WG suggests, although in the absence of good evidence, that an explanatory leaflet about urodynamic investigation with sufficient information, which uses clear, unambiguous wording will be appreciated by the majority of patients.

The WG suggests that a leaflet should include the items listed here below. The WG recommends that a leaflet that includes these items in an understandable manner for the

patient is referred to as the (NEW) ICS Standard Information Leaflet for Urodynamics.

## 4 | URODYNAMIC PRACTICE PROTOCOLS

### 4.1 | Introduction and evidence base

In an area where a minimum standard for urodynamic testing workload exists,<sup>17</sup> it was concluded on the basis of a postal survey that training had insufficient effect, and that practice significantly varied.<sup>18</sup> When 100 consecutive graphs from all men who underwent cystometry in one center were reviewed, “significant defects [in the pressures] were not uncommon”; furthermore,  $\pm 10\%$  of the transurethral catheters was reported to have been “falling out during voiding.”<sup>19</sup> Disappointingly, although willingness to change practice was observed, actual changes did not occur despite the distribution of a standard protocol for some of the elements of urodynamic testing.<sup>20</sup>

### 4.2 | Conclusions

Published evidence to support implementation of practice standards is scarce and the conclusion on the basis of simple implementation strategies toward the achievability of practice improvement is not very encouraging.

### 4.3 | Discussion

Implementation of standardized practice is a complex process that requires changing routine habits and beliefs while keeping an eye on context, for example, acceptability, adoption, appropriateness, feasibility, fidelity, and costs.<sup>21</sup> Furthermore, the quality of the practice guidelines or

standards for implementation is of importance.<sup>22</sup> Simple dissemination is not usually very effective and, as an example, for example, “blended” or “continuous quality improvement,” strategies may be required.<sup>23</sup>

## 4.4 | Recommendations

The WG recommends that departments develop urodynamic practice protocols on the basis of the ICS-GUP standards and facilitate specific training in, and evaluation of, urodynamic practice.

We recommend that centers should—ideally coordinated and together on a nationwide level—decide on individual accreditation and recertification (eg, required minimum number of tests) as well as the level of authority and autonomy to perform urodynamic tests.

## 5 | CLINICAL PRACTICE PRE-TESTING INFORMATION

### 5.1 | Introduction and evidence base

All guidelines on urinary incontinence recommend a clinical history, and validated symptom and/or bother scores are recommended in the majority of these.<sup>24–28</sup> Urinalysis and physical examination as the first step in the evaluation of a patient with urinary incontinence are considered routine. The GUP2002 has in this regard mentioned non-invasive urodynamics, frequency/voiding chart (FVC), or bladder diary (BD) uroflowmetry and PVR for all patients with LUT symptoms (LUTS). FVC and BD are mentioned in ST2002 and defined after that publication.<sup>29</sup> The test should be requested with the goal of answering a specific question (GUP2002). In order to formulate this question prior to urodynamics, as mentioned here above, a complete history, a list of medications taken must available as well as the results of the physical exam. Observation of the patient's gait, evaluation of sacral sensation and reflexes and identification of other neuro-urological findings are important. An abdominal exam and evaluation of the extremities for oedema are also helpful. In women, a systematic pelvic exam should include evaluation for prolapse,<sup>29</sup> vaginal wall masses, atrophy, pelvic muscle quality, and the ability to voluntarily contract them (as is standardized<sup>30</sup>), urinary leakage with strain, and any other details. In men, genital exam and a digital rectal prostate examination with an estimation of size is necessary. Prostate pain or abnormalities and degree of anal tone should be noted.

A (3-day) FVC or BD provides information that may obviate cystometry (eg, when excessive fluid intake is recognized) or may help to ensure and evaluate whether the cystometry, especially cystometric capacity, is representative of the patient's typical situation (“typical voided volumes”;

from GUP2002). Non-invasive urodynamic testing, that is, uroflowmetry plus PVR in men and women, should precede invasive urodynamics. This information gathering process serves as the foundation for determining treatment as well as formulating questions that can be answered with (invasive) urodynamics. A urinalysis to screen for infection or haematuria should be available.

When planning urodynamic tests, the physician should specifically instruct the patient whether or not to change any conservative measures or change or take medication before or after the test according to ((local) standards and/or guidelines and) the individual situation of the patient.

## 5.2 | Conclusion

We conclude that clinical practice guidelines and expert “first principles” agree that prior to invasive urodynamics, history, physical examination, and urinalysis should be completed.

The usefulness of a FVC-BD to help anticipate cystometric capacity and appropriate fill rate has never been formally investigated. It is, however, the WG's conclusion that the FVC-BD voided volumes should be considered relevant to evaluate the representativeness of the cystometry, as was recommended in GUP2002.

## 5.3 | Recommendation

The WG advises that apart from the clinical information (history, medication, and clinical examination), the information from the (3-day) FVC or BD, and the uroflowmetry and PVR are utilized while performing invasive urodynamics.

The WG advises specific instructions to the patient with regard to the continuation of usual LUT management (eg, medication) if the patient is on treatment, and—persisting or new onset—symptoms require urodynamic analysis.

# 6 | PRACTICE OF UROFLOWMETRY

## 6.1 | Introduction and evidence base

GUP2002 presents uroflowmetry as a first line screening for most patients with LUTS and has provided practice recommendations. ICI consultations and clinical practice guidelines have reconfirmed uroflowmetry as the first line test.<sup>5,7,28</sup> Data quality control is relevant and important<sup>31</sup> and ICS has updated equipment performance requirements.<sup>2</sup> Apart from technical quality, the clinical situation is relevant. Some papers concerning position during voiding of men<sup>32–39</sup> or women<sup>40–46</sup> have been published since GUP2002, with a

variety of primary outcomes related to different voiding positions (see Table S2). The results do not allow a very strong recommendation to be made, partly because test-retest variation inherently plays a role.<sup>47</sup> On the basis of these results and also on the basis of expert experience and plausibility, the WG concludes as follows.

## 6.2 | Conclusions

The WG concludes that it is useful, considering the representativeness of the test-result, for patients to be allowed to undergo uroflowmetry in their own preferred position.

## 6.3 | Discussion

Uroflowmetry and therefore flow rate, voided volume, and PVR are inherently sensitive to patient cooperation and emotion, and should only be clinically interpreted if the voiding has been representative with regard to both voided volume and the patient's opinion (eg, uroflowmetry may be abnormal if voiding was postponed for too long before the test). Furthermore, the interpretation can only be relevant if the test was done in a technically reliable manner, based on the examiner's opinion.

## 6.4 | Recommendations

The WG recommends permitting patients to undergo uroflowmetry in their preferred position and to strive for minimum physical discomfort and anxiety for the patient, as well as ensuring personal dignity.

The WG recommends checking if the voiding is representative, based on the patient's report and also on the association with the patient's FVC or BD volumes.

The position of the patient during voiding studies should be reported.

The WG recommends considering repetition of the uroflowmetry if the result has not been representative for the patient or if the result indicates abnormality. Particularly, if the voided volume and/or flow rate are unexpectedly low or the PVR is (much) larger than expected or explainable in both women and in men.

# 7 | PRACTICE OF CYSTOMETRY

## 7.1 | Introduction and evidence base

GUP2002 has specified catheters, pressures, pressures reference and quality checks for cystometry (and also for pressure-flow study). The WG has not found evidence that supports changes in these specifications. The WG has however studied and further specified six items in relation to the practice of filling cystometry. For each item we report

conclusions on the basis of the evidence and provide recommendations below.

## 7.2 | What determines filling rate?

The rate at which the bladder is filled during cystometry affects the results of the cystometry.<sup>48,49</sup> ST2002 has defined two different ranges of filling rate: maximum physiological filling rate as estimated by body weight in kilogram divided by four, thus typically in the range of 20–30 mL/min. The commonly applied filling rate in practice is often higher and, and this is (ST2002-) referred to as non-physiological filling rate. Neither ST2002 nor GUP2002 are however specific in the rate to select however GUP2002 has stated that the [citation] “typical voided volumes should be used for the control of subsequent invasive studies.”

The actual volumes in the bladder during cystometry may differ from the recorded filling volumes due to diuresis, which can add significantly volume, for example, up to 25% to the cystometry volume.<sup>50,51</sup> Cystometric capacity is most reliably determined by calculation of voided volume (mL) plus PVR (mL) immediately after pressure-flow study (ST2002). The WG has been unable to find evidence that stopping or slowing down the filling rate, for example, when urgency is perceived and/or when detrusor overactivity (DO) is observed, is of any relevance. GUP2002 has suggested that the investigator should stop filling and observe the pressure, when reduced compliance is thought to be a consequence of filling rate above physiological filling rate.

### 7.2.1 | Conclusions

Current ST2002 cystometry (pump-) non-physiological filling rate is frequently applied, but a recommended more specific value or range is lacking.

Filling rate, especially when very fast or to volumes that are very much larger than the person's usual (maximum) volumes, may influence the results or the representativeness of the cystometry. Evidence that filling rate should be changed during the cystometry is lacking.

Diuresis, occurring during cystometry, adds volume that is not recorded by the urodynamics system with automated filling volume recording, but that is relevant for interpretation of the results.

Correction of filled volume for diuresis in retrospect should be considered with regard to reporting of filling sensation parameters, compliance and cystometric capacity (=pressure-flow voided volume plus PVR; and assuming the diuresis to be constant).

### 7.2.2 | Discussion

A balance between a filling rate that is slow enough to mimic a representative bladder filling and fast enough to complete the cystometry in an efficient fashion is a pragmatic approach to achieving a representative result. The WG considered,

without specific evidence, but similar to practice in children's cystometry, that a filling rate in mL/min of roughly 10% of the largest voided volume (reported on a FVC or –BD; and PVR should be taken into account here) at a constant rate is a practical means to implement the above cited GUP2002 recommendation to use the person's typical voided volumes. This would, in a sensible manner, narrow the currently existing non-physiological fill rate-range and may also prevent too fast filling or filling to very unusual volumes. The WG suggests standardizing the filling in a fixed rate for the purpose of comparability in clinical cohort (management) research protocols where cystometric capacity, sensation, or compliance are outcome parameters.

The end of filling should relate to a “strong but not uncomfortable need to void.” The largest voided volume on the FVC-BD may be an indicator for this volume, however with as yet unknown specificity, and PVR should be taken into account. “Strong desire to void” (SDV) should be indicated on the urodynamic graph. Permission to void is given when the pump is stopped (ST2002) and end of filling should be regarded as the beginning of the voiding phase. A specific marker on the urodynamics graph to indicate permission to void must be used however, if there is a delay between halting the pump and permission to void.

### 7.2.3 | Recommendations

The WG recommends that the person doing the cystometry knows the FVC-BD results as well as the results of uroflowmetry and PVR, prior to performing invasive urodynamics.

The WG suggests that the ICS maximum physiological filling rate is standard and suggests that “non physiological filling rate” is standardized on the basis of the individual patient's typical voided volumes (including estimation of the PVR volume) to prevent too fast filling and/or too large volumes.

The WG recommends use of the maximum physiological rate when comparability is relevant (eg, this may be required in prospective research cohorts, before and after intervention).

Parameters during cystometry depending on bladder volumes should be corrected for diuresis if relevant for clinical management or for scientific purposes.

The WG recommends that “permission to void” should always be marked on the urodynamic graph to indicate the beginning of the pressure-flow study. Stopping the fill pump is a more or less automatic marker, but when there is a delay between stopping the filling and this permission, a specific marker should be used to allow correct interpretation of the graphs after the test.

## 7.3 | How is the patient instructed to report sensations?

Prior to filling cystometry, patients are typically informed (written and verbal) that they will be asked to report the sensations they experience during the test. The ST2002

recommends that three sensation parameters be recorded during cystometry: first sensation of filling (FSF), first desire to void (FDV) and SDV. In addition, the patient may report sensation(s) that are considered to represent “urgency” (ST2002) which can be marked specifically. These sensory parameters have been confirmed as applicable, consistent, and reproducible in healthy persons and in patients with overactive bladder (OAB) syndrome.<sup>52–54,57,58</sup> There is, however, conflicting data regarding the reliability and/or representativeness of bladder sensation reporting during cystometry.<sup>55–57,59,60</sup> The use of a visual analogue scale (VAS) to grade the level of sensation has been shown to correlate well with some of the standard sensation parameters.<sup>61</sup> Similarly, a keypad, allowing patients to indicate differing levels of sensation, had a good and reproducible association with filling volume.<sup>62</sup>

### 7.3.1 | Conclusions

The ST2002 expert-based recommendation for the assessment of sensations during cystometry is reasonable and applicable as is demonstrated in various study reports.

### 7.3.2 | Discussion

The WG has decided not to change the ICS standard in favor of the use of VAS. However, despite introduction of standard terms in 2002, few studies published have reported cystometry filling sensations and the WG feels the need to reintroduce these and to add practice recommendations. It should be noted that the WG has not evaluated the relevance of the filling sensation parameters.

FSF should, at the beginning of the cystometry, be separated from the (urethral) sensations caused by the catheterization. The explanation to the patient may be that FSF is “Tell me the moment when you perceive that your bladder is not empty anymore”; FDV is (if little or no chronic PVR exists) usually roughly associated with FVC-BD “typical voided” volumes and can be asked as “Tell me when you have the sensation that normally tells you to go to the toilet, without any hurry, at the next convenient moment.” SDV is “. . . the moment that you, without any pain or any fear of losing urine, will not postpone the voiding; you will visit the nearest restroom also, for example, while shopping.” SDV may however occur suddenly and include the fear of leaking (or actual urine loss) in specific patients and patients should report this also. Correlating the results of cystometry volume and sensations with FVC-BD may provide background information regarding day-to-day sensory findings and bladder volumes and may also limit the risk of overfilling.

Fear of leakage, pain, or other signs or symptoms during the test should be specifically marked on the urodynamic graph.

### 7.3.3 | Recommendations

The WG recommends marking FSF, FDV, and SDV, during cystometry as recommended by ST2002, on the basis of explicit verbal instructions and communication before and during the test specified in this GUP, and reporting the results.

## 7.4 | Fluid-filled external transducers and catheter system

Current ICS standard cystometry and pressure-flow study requires fluid-filled catheters with external pressure transducers to be leveled at the height of the upper edge of symphysis pubis. (GUP2002, ST2002). The urodynamic pressure is therefore the excess pressure above atmospheric pressure at the hydrostatic level of the upper edge of the symphysis pubis. Some studies that have compared fluid-filled catheters with microtip sensor catheters or air-filled catheters have shown that the results of the cystometry using these alternative systems are not interchangeable with the current ICS standard.<sup>63–65</sup>

### 7.4.1 | Conclusions

ICS standard urodynamic intravesical pressure ( $p_{ves}$ ), abdominal pressure ( $p_{abd}$ ) or other urodynamic pressure is the excess pressure above atmosphere at the hydrostatic level of the upper edge of the symphysis pubis. This is valid for all pressures recorded with fluid-filled lines.

The WG concludes that comparisons of micro-tip catheter systems (multicenter group averages) or air-filled catheters in vitro or in vivo (pairwise averages of two measurements) with ICS standard fluid-filled systems demonstrated that both systems give different results. The reports of these studies have concluded that systems are not interchangeable.

### 7.4.2 | Discussion

Fluid-filled external pressure systems referenced to the symphysis pubis are fundamentally different from the micro-tip or air-filled catheter systems, as the latter record pressure without a clear reference level. The use of ICS standard urodynamic pressures allows pressure related data to be comparable between patients and centers. Systematically obtained clinical evidence for the clinical reliability of micro-tip or air-filled catheter systems is scarce. Every urodynamic laboratory should be familiar with the potential artefacts of the specific system used for pressure measurement, and take the possibility of system- differences of up to 10 cm H<sub>2</sub>O into account.<sup>66</sup> The WG considers that the availability of alternative systems has consequences for multi-center studies. Also the WG has considered generalizability of pressure values published in studies using

other than fluid-filled external pressure systems is undecided.

ICS guidelines on equipment performance provide minimum system requirements for pressure responses and calibration.<sup>2,66</sup> Centers that utilize other pressure systems should provide reference values for their data.

#### 7.4.3 | Recommendations

ICS standard cystometry is performed with a fluid-filled system with external transducers at the reference level of the upper edge of the symphysis pubis.

Urodynamic laboratories should ensure that the equipment, including the catheters and transducers, meet the requirements as explained in the ICS guideline on equipment performance.<sup>2,66</sup>

Urodynamic laboratories should check the performance of their system at regular intervals and calibrate according to manufacturer recommendation, and as advised in the ICS guideline on equipment performance.<sup>66</sup>

### 7.5 | Transurethral catheter

ICS standard invasive urodynamics is done with the thinnest possible (6–7F) transurethral double or triple lumen catheter or a suprapubic catheter on the basis of ST2002 and GUP2002.

#### 7.5.1 | Discussion

The ICS recommendation, reiterated here above, is based on expert opinion and consensus. GUP2002 notes that the use of two separate catheters is “less convenient.” However, many studies since 2002 report the use of separate filling and pressure catheters and the removal of the filling catheter for stress provocation and/or for the pressure-flow study. Reported practice includes the range from 5 to 8F for the pressure recording catheter and usually  $\pm 10F$  for the filling catheter. The WG has no arguments for discarding the use of double catheter systems at present but has again (after GUP2002) discussed the need to re-catheterize if the test needs to be repeated and also the necessity to interfere with the patient at the moment of SDV, just before the voiding. However, the excess cost of the double or triple lumen catheter is a disadvantage. No head to head comparisons have been performed and no new evidence has been published on the spectrum of advantages and disadvantages of two catheter technique versus the recommendations in GUP2002.

Publications applying results of invasive urodynamics sometimes report a high rate of expelled catheters and it is the WG’s opinion that advice on catheter fixation, applicable for both intravesical (shown here for double lumen) and rectal catheters, will reduce that problem:

Men (left picture): Catheter is taped in the length of the penis over the catheter, without obstructing the meatus.

Women (right picture): Catheter is taped to the inner side of the labia or (similar in men and women) adjacent to the anus.

#### 7.5.2 | Recommendation

ICS standard invasive urodynamics is done with the thinnest possible double lumen catheter. However, on the basis of the lack of evidence for inferiority of two catheter techniques, this alternative is considered acceptable.

The WG recommends finding evidence with specific studies to direct practice standardization and harmonization for the catheters used for invasive urodynamics.

The WG recommends fixation of the catheters as adjacent as possible to the anus and the urethral meatus with tape, without blocking the urinary meatus.

### 7.6 | Abdominal pressure catheter placement: rectal versus vaginal

Flaccid filled balloon which may be punctured or slowly perfused open end catheters in the rectal ampulla are used to measure abdominal (“perivesical”) pressure (GUP2002). The WG has discussed that “slowly perfused open end” should not be used because rectal filling may cause a sensation of need to defecate and may influence the result of urodynamics, though there is no research evidence on this topic.

In a prospective, randomized trial comparing open (without balloon) vaginal versus open rectal abdominal pressure 6F catheters in women undergoing external sensor, fluid fill cystometry, the authors noted no differences in discomfort or patient acceptability, however it was reported that women declined randomization on the basis of a preference for a vaginal catheter. Set-up time, catheter events affecting signal quality (including during provocation), or alteration in patients with vaginal prolapse were also not different. The report states that despite quality control measures (catheter repositioning and flushing of air bubbles, checking signal quality during and at end of study) only 13% of graphs all had optimum quality and a significant number of catheters was lost during the tests.<sup>67</sup>

#### 7.6.1 | Conclusions

Although limited evidence suggests that women may prefer vaginal reference catheter placement, the WG concludes that this is insufficient to demonstrate that this is a reliable alternative to rectal catheterization.

### 7.6.2 | Discussion

After bowel resection with anal closure, the stoma may need to be considered as the route to measure abdominal pressure, especially in men. There is no specific evidence, but the position of the catheter-tip is usually above the bladder in a stoma, and bowel activity may much more likely cause artefacts in those cases, hampering measurement of absolute abdominal pressures and detrusor subtraction pressure, and therefore, the interpretation.

The WG considered that full (pre) filling or overfilling of rectal catheters with a balloon, as widely used, is a significant source of abdominal pressure measurement error. The catheter and balloon should be filled with water in a way that all air is replaced and without causing any excess pressure inside the balloon. Rectal balloon catheters should not be re-filled after insertion and therefore should be punctured to prevent over-filling and measurement error.

### 7.6.3 | Recommendations

Rectal placement of a fully fluid-filled open, or punctured balloon catheter, to measure abdominal pressure should be considered the ICS standard.

The WG recommends that vaginal or stoma placement of the abdominal pressure catheter is used alternatively only if rectal catheter placement is impossible.

## 7.7 | Patient positioning for cystometry and pressure-flow

It was noted on the basis of a literature review that DO was detected with a consistently higher rate in the upright position compared to supine position. DO would have been missed in 76% of cases of cystometry was done in the supine position and 60% would have been missed if the study was done supine compared to seated. Having the patient stand after being filled increased the chance of detecting DO by 21%.<sup>68</sup> In a prospective study, urodynamic stress incontinence was detected in 55% if the women were sitting but only 2% if supine, while DO was detected in 55% when seated but only in 9% when supine.<sup>69</sup> Combined diagnosis (DO plus USI) was observed seated in 18%, and zero when supine. Volumes at the time of reporting—ICS-standard—filling sensations and cystometric capacity were lower for seated cystometry.<sup>2</sup> Position during cystometry may also be relevant for the need to change the position for the optimal pressure-flow study (see below).

### 7.7.1 | Conclusions

The detection of DO, the detection of urodynamic stress incontinence, and bladder volumes at reported bladder filling sensation are influenced by the position of the patient. Sitting or standing position appears to have a higher sensitivity for detecting these abnormalities.

### 7.7.2 | Discussion

The sitting or standing position is the most representative for daily life situations and is probably the least uncomfortable and/or embarrassing for the patient. Furthermore, in the sitting position the intra-rectal as well as the intravesical catheter are at similar levels in the pelvic cavity (and similar to the transducer) which makes reliable (better balanced) pressure and subtraction more likely. Seated or standing (men) cystometry also allows a smooth transition from cystometry to pressure-flow study when SDV is reached, causing little movement artefact.

### 7.7.3 | Recommendations

ICS standard cystometry is done in the vertical position (standing or normally seated) whenever physically possible.

A pressure-flow study is done comfortably seated (women, some men) or standing if that is preferred position (men).

## 7.8 | Reliability and need for repeat cystometry for confirmation

In a prospective study of invasive urodynamics in healthy, asymptomatic female volunteers, poor reproducibility of sensory volume markers (FSF and FDV) as well as  $Q_{\max}$  and  $P_{\det Q_{\max}}$  between two cystometries done at the same session was reported.<sup>70</sup> Similarly, poor reproducibility of urodynamic results at short-term follow-up (1–5 months) was noted.<sup>71</sup> In another prospective study of immediate repeat cystometry in patients with neurogenic LUT dysfunction, the authors noted wide 95% limits of agreement for differences in same session test parameters (maximum cystometric capacity, compliance, storage  $p_{\det, \max}$ , DLPP,  $Q_{\max}$ , voiding  $p_{\det, \max}$ ,  $P_{\det Q_{\max}}$ ).<sup>72</sup> However, the study reported excellent reproducibility in the detection of DO. The authors suggested that one single urodynamic study may be inadequate to form the basis for clinical decisions in patients with spinal cord injury.<sup>73</sup>

In a later single-center study in women with symptoms and signs of urinary incontinence (without neurological abnormalities), the reproducibility of immediate repeat cystometry plus pressure-flow analysis was overall good to excellent, with intra-class correlations of around 0.75 and few differences in urodynamic diagnosis between the first and second run. Nevertheless, these authors suggested that repetition of urodynamic tests is justified to ensure diagnosis.

In elderly men, the immediate or longer interval test retest variation is less with regard to pressure-flow analysis. However, it is not reported whether differences in cystometry values have been observed.<sup>74–78</sup>

### 7.8.1 | Conclusions

Predominantly, single-center evidence suggests that immediate or longer term test- retest variation is sometimes large

for specific parameters (like sensation) but less with regard to pressure-flow variables, especially in elderly men.

There is no convincing evidence that the clinical diagnosis on the basis of the first cystometry is often changed on repetition of the test. There is no definite evidence that immediate repetition of an adequately performed urodynamic test “for confirmation” is required.

### 7.8.2 | Discussion

The WG considered that large test-retest variations may also reflect inadequately standardized methods of testing. Test retest data is scarce which was the reason to also include studies with patients with neurological abnormalities in the WG’s summary of the evidence. Measurement errors are a significant source of test-retest variation, but are seldom reported. The WG considers it prudent to repeat a technically adequate test when observations are not explainable in relation to the patient’s symptoms and signs, and especially when the urodynamic question is insufficiently answered and consequences for management are significant. Furthermore, the WG considers that some observations may be situational (eg, the inability to void during a test) and may not always be soluble.

### 7.8.3 | Recommendations

The WG does not recommend routine immediate repetition of invasive urodynamics “for confirmation” if the test was technically adequate, has been considered representative, and has answered the clinical question.

The WG recommends immediate repetition of the test when doubt exists as to whether the test has answered the clinical question.

The WG recommends repetition of a urodynamic test when technical errors and artefacts have been observed at immediate post-test analysis.

## 8 | PRACTICE OF PRESSURE-FLOW STUDIES AND AN UPDATE OF TERMS

### 8.1 | Introduction

An ICS subcommittee (ST1997) on standardization of terminology for pressure-flow studies revised and expanded diverse sections of the earlier ICS terminology.<sup>79,80</sup> ST1997 identified and defined five relevant parameters with the preferred abbreviations to depict pressure-flow studies.

For urodynamic practice: the “pressure-flow study” (as defined above) begins immediately after permission to void (ST2002) and ends when the detrusor pressure has returned to the baseline value and/or the flow rate to zero and/or the

patient considers the micturition completed. Note that pressure-flow analysis is only validated for voluntarily initiated micturitions and not for incontinence.

The WG considered that the relevance of instruction, position and privacy for the patient while performing pressure-flow study is equal to uroflowmetry and we refer to both the paragraphs here above for the practice of uroflowmetry and/or cystometry for the practice of pressure-flow study.

### 8.2 | Discussion

There is an inevitable delay between the fluid stream leaving the bladder and hitting the flowmeter which should be taken into account when a pressure-flow study is analysed (ST1997; GUP2002).<sup>2</sup> The delay between urethral meatus and flowmeter should be reduced by placing the flowmeter as close to the meatus as possible for every voiding position. Reducing the meatus to flowmeter distance may also result in more relaxed voiding because the patient may experience less concern about spattering.

### 8.3 | Recommendation

The WG recommends, especially for the purpose of pressure-flow analysis, a shortest possible meatus-to-flowmeter distance, adjusted to the voiding position, but recommends correcting for delay between pressure and flow.

### 8.4 | Discussion and suggested terms

Presentation of pressure-flow studies should be with a plot of the flow (-delay corrected) rate (mL/s) on the X-axis and the (delay corrected) synchronous detrusor pressure (cm H<sub>2</sub>O) on the Y-axis in addition to the time-based graphs (ST 1997).

ST1997 introduced “urethral function” and “urethral resistance (relation)” without precisely defining these as (new or standard) terms. The “(passive) urethral resistance relation” as a means of quantifying bladder outflow obstruction (in male patients with prostatic enlargement) was defined before ST1997.<sup>81,82</sup> New ICS terms are desirable to acknowledge the relevance of the anatomical structures adjacent to the anatomically defined urethra per se, to describe outflow conditions during micturition (with or without further specifying anatomy) and the WG suggests introducing a specific (ICS) standard to further detail terms and practice for pressure-flow study analysis.

The terms bladder outlet obstruction and bladder outflow obstruction are already frequently used. The WG introduces (**NEW**) **Bladder Outflow Obstruction (BOO)** (“outflow” to recognize what is measured) with the definition: a (specified) cut-off of bladder outflow resistance based on the pressure flow relation (ratio) that is considered clinically relevant (the WG does not define cut-off values

but advises that the term should be preferred for both genders and all ages).

ST1997 also stated that the urethral function during voiding can be overactive, without further definition or specification. There is a lack of terminology with regard to specific diagnosis of voiding dysfunction, also here the here above mentioned specific new ICS standard is needed.

The WG suggests already now: **(NEW) Normal voiding function:** flow rate (and pressure-rise) are within normal limits, begin more or less directly after permission to void and ends with an empty bladder.

Bladder outflow physical properties may vary during one course of voiding and the WG suggests that new terms are introduced when analysis methods and cut-off values or pattern descriptions are provided to describe (as introduced in ST1997) “overactive urethral function during voiding.” We conclude that no commonly agreed parameter or pattern description exists to clinically quantify or qualify “(over-) active urethral function” (if) outflow properties vary during a voiding.

“Underactive detrusor” and “acontractile detrusor” are defined in ST1997 and ST2002 as different from “normal detrusor” during micturition. GUP 2002 has also introduced that contraction during micturition may vary, or may be variable. Within this context, the WG discussed that voiding may be influenced by mental state and, although evidence is lacking in the neuro-gyneco-urological literature, anxiety in the test situation for the patient may plausibly influence initiation of the voiding reflex<sup>83–85</sup> and consequently affect detrusor function. The WG suggests **(NEW) “Situational inability to void”** and **“Situational inability to void as usual”** when in the opinion of the person performing the test, in communication with the patient, the attempted voiding has been not representative.

The WG here introduces the term **“detrusor voiding contraction”** for any analysis of combined pressure and flow ( $\pm$  other variables) that qualifies or quantifies the actual observed voiding. Following on to this: **“detrusor contractility”** is now suggested for any method that aims to quantify “intrinsic” detrusor muscle properties (eg, potential-maximum-force or velocity) by any method. We refer to, for example, stop-flow or interrupted-voiding tests and mathematical (extrapolation) or graphical analysis methods of pressure, flow and/or other parameters, such as, for example, the bladder working function.

Acknowledging the GUP2002, we suggest that the terms **“unsustained contraction”** (when waxing and waning) or **“fading contraction”** may be used when analysis methods and cut-off values or pattern descriptions are provided. We also acknowledge that no parameters to clinically demarcate normal, stable, or sustained detrusor contraction are available as yet.

## 8.5 | Recommendations

The WG has suggested some terms with the aim of improving communication with regard to pressure-flow analysis. However, the WG strongly recommends an updated ICS standard for pressure-flow analysis to ensure optimal ICS standardization of quantitative analysis (and standardization of diagnosis) of bladder outflow function as well as of detrusor voiding contraction diagnosis and/or detrusor contractility analysis for all patient groups.

## 9 | TECHNICAL AND CLINICAL QUALITY CONTROL DURING INVASIVE URODYNAMICS

### 9.1 | Introduction and evidence base

Quality control and standardization are an important part of urodynamics. Without training and standardization of equipment, and adherence to quality control and standards of urodynamic practice has been shown to be difficult.<sup>17</sup> The consequence is a large inter-site variability.<sup>18</sup> One national board has argued that maintaining expertise requires performing at least 30 urodynamic tests a year per urodynamicist and 200 tests in a department.<sup>19,20</sup>

A number of recommendations for control during urodynamics has been provided in the GUP2002 and a number are renewed or added, in the recently published “ICS guidelines on urodynamic equipment performance.”<sup>2</sup> Furthermore, an overview of common features errors and artefacts has been published.<sup>66,86</sup>

The WG has found no new evidence necessitating re-discussion of equipment requirements, labelling and scaling of traces in the graph and refers to earlier documents in this regard.<sup>1,2,5,79</sup>

Typical signal patterns, such as straining, rectal contractions, coughing and DO are important in quality control and everyone who performs or evaluates urodynamic tests should be able to recognize these during the test.<sup>66,87,96–100</sup> In diverse retrospective single and multicenter evaluations, it was demonstrated that the expert recognition and identification of specific patterns occurring in the urodynamic traces has required adaption or correction of the—initial—diagnoses.<sup>19,87–100</sup>

### 9.2 | Conclusions

Expert evidence confirms that prevention, recognition and management of errors and recognition of artefacts are important elements of urodynamic quality control. Systematic urodynamic quality management, including plausibility analysis, is relevant before, during and after the test as well as while reporting the results of the test.

### 9.3 | Discussion

The WG considers that regular calibration of pressure measurement systems should be documented in each urodynamic laboratory and that, in general, new technologies need to prove their usefulness as well as accuracy compared to existing standards before clinical application.

### 9.4 | Recommendations

The WG recommends that everyone performing or evaluating urodynamics should be able to recognize usual pressure patterns and be able to perform continuous quality control during the test.

The WG recommends that training and a process of continuous knowledge maintenance as the basis for performing urodynamic tests should be established.

#### *Terms related to the cystometry observations and evaluation.*

Adequate set-up of the system and continuous quality monitoring are mandatory and all patterns and features occurring during the test should be recognized. Typical patterns may lead to recognition of pathophysiology or explain the perceived dysfunction. However, when an error or an artefact is observed during the test,<sup>59</sup> the person performing the test should act accordingly and prevent continuation in case of an error. The WG explains here for clarity that artefacts are, like rectal activity, in analogy with, for example, scattering on ultrasound imaging, more or less unavoidable. Errors are usually preventable or correctable.

**Recommended terms to describe most common features, artefacts, and errors during invasive urodynamics:** A fluid-filled pressure measuring system shows patient movement and external manipulation of the catheter. This causes signals or signal patterns that should be recognized during the test and at (re-) evaluation of graphs. Prevention of fluid leaks and air bubbles in the pressure tubing system is needed (GUP2002). This already starts before beginning the test while setting up the equipment. However, the effects of fluid leaks and air in the system on the pressures should be recognized at the beginning of the test and during the test also and should be corrected (GUP2002). Furthermore, they should also be recognized and reported during post-test analysis, if recognition and correction during the procedure has failed, to prevent mis-diagnosis.<sup>66</sup>

Urodynamic laboratories should apply standard practice and therefore be aware of all potential features, errors, and artefacts that may occur when measuring with the fluid-filled system. Whoever is performing tests should be able to recognize artefacts and prevent, recognize, and correct errors.

The WG has listed terms here that are considered to be of use during the test and its evaluation. Many of the terms have been used in earlier ICS standardization documents, but usually not with precise definitions. While many terms refer to preventable or correctable problems, these features including artefacts should nevertheless also be recognized during evaluation after the test. The WG has opted for terms that are as descriptive as possible and is convinced that better definition and description of these errors and artefacts is a tool to improve practice. The features, patterns or events terms mentioned here should also be used in the ICS standard urodynamics report (see below).

**Initial resting pressure (NEW)** is the  $p_{ves}$  and the  $p_{abd}$  pressure at the beginning of the cystometry. To prevent reading measurements from a kinked catheter in an empty bladder with the catheter holes blocked with (insertion) gel and/or pushed against the bladder surface, the WG recommends (GUP2002) gentle flushing of both catheter channels and/or filling 20–30 mL of the bladder, before the initial resting intravesical pressures are considered to be “established.” Initial resting pressures should be within the physiological limits specified in previous manuscripts<sup>96,97</sup> and GUP2002.

**Dead signal (NEW):** A signal that is not showing small pressure fluctuations and is not adequately responding on straining, patient movements, or coughing is reported as a dead signal.

Previously (GUP2002): “In principle, a good  $p_{det}$  signal requires only that  $p_{ves}$  and  $p_{abd}$  show the same fine structure and quality of signals before filling, during filling, and after voiding.”

**Pressure drift (NEW):** Continuous slow fall or rise in pressure, that is physiologically inexplicable.

**Poor pressure transmission (NEW):** Poor pressure transmission has occurred when the cough/effort pressure peak signals on  $p_{ves}$  and  $p_{abd}$  are not nearly equal.

Note: The WG does not define a new limit for not “nearly equal.”

**Expelled catheter (NEW):** When a catheter is expelled, this is observed as a sudden drop in either  $p_{ves}$  or  $p_{abd}$ , usually below zero.

Earlier ICS description: “If a sudden drop or increase occurs in either  $p_{ves}$  or  $p_{abd}$  signal, the usual cause is movement, blockage, or disconnection of a catheter.”

Expelled catheter is usually simply visible during the test and should provoke correction or repetition of the test. However, this term should also be used in post-test evaluation.

**Catheter flush (NEW):** When one of the catheters is flushed during the test a steep pressure rise is observed in that pressure line for one or two seconds followed by an immediate fall to resting pressure.

A catheter flush is not always necessary after a carefully performed set-up but is suggested in GUP2002.

Flushing of the catheter measuring channel may be considered necessary to wash away entrapped air, or the gel used during insertion or urethral mucus, from the measuring hole. The rectal catheter can only be flushed when an open or a punctured balloon catheter is used, and flushing should definitely not be done if a closed balloon is used (which is not ICS standard). A catheter flush should be marked accordingly, but flushes are normally unnecessary after the cystometry has continued after the first milliliter of filling.

**Tube knock (NEW):** Tube knock is observable as high frequency, short duration spikes visible in  $p_{ves}$ ,  $p_{abd}$ , or both, and with spikes also usually visible in  $p_{det}$ .

**Pump vibrations (NEW):** Pump vibrations are visible as stable frequency oscillations of small but constant amplitude if the filling tube touches the pressure connecting tube (when a two catheter system is used) and the pump is switched on (switching of the pump can ascertain the situation).

**Cough pressure peak (NEW):** A cough pressure peak is recognizable during post-test evaluation as a phasic positive pressure change observed in  $p_{ves}$  and in  $p_{abd}$ .

**Urodynamic stress test (NEW):** The term urodynamic stress test is used for any physical effort of the person tested, to elevate abdominal pressure during cystometry, with the aim of examining (urodynamic) stress urinary incontinence.

ICS has defined urodynamic stress incontinence. Evidence is lacking (or conflicting) with regard to the preferred technique of urodynamic stress testing.

Note: The provocation method, the pressure measuring catheter(size) and method, the leak detection method as well as the absolute or relative (percentage of cystometric capacity) intravesical volume(s) while testing should be reported.

**Leak point pressure (NEW):** The leak point pressure (LPP) is the pressure (spontaneous or provoked) that has caused fluid to be expelled from the bladder at the moment that it is visible outside the urethra (may also be used for extra-urethral urine loss or stoma). This may refer to Abdominal, Cough or Valsalva LPP or Detrusor LPP.<sup>5,6,28,29</sup> Provocation and pressure recording site (“type of LPP”) should be reported.

Diverse methods of LPP measurement have been published with a variety of combinations of provocation or pressure recording site/type and/or technique. Detrusor LPP and Valsalva LPP were defined in ST2002. However, no ICS (or commonly agreed) standard technique or protocol is available and a variety of terms and techniques are used (counts in PubMed (April 2015): Cough LPP: 21; Valsalva LPP: 226; Detrusor LPP: 64; Abdominal LPP: 98; Overactivity LPP: 0).

**Cough associated detrusor overactivity (NEW):** Cough associated DO is reported when the onset of the DO

(with or without leakage) occurs immediately following the cough pressure peak.

No precise definition of cough associated detrusor activity is available. “Cough induced DO” is sometimes reported, although the precise (patho-)physiology and/or relevance remain speculative.

**Position change (NEW):** A change in patient position, either active or passive (eg, tilting), is visible on the cystometry trace by a lasting change of equal magnitude in both  $p_{ves}$  and  $p_{abd}$ .

Note: A position change should be (is readily) noted during the test. Position change should be followed by readjustment of the external pressure sensors height to the standard so that the  $p_{ves}$  and  $p_{abd}$ -values are similar to the pressure values before the position change. A position change should not affect  $p_{det}$ . The position change pattern should be recognized during post-test evaluation of the cystometry.

**Rectal contractions (NEW):** Rectal contractions are temporary phasic increases in  $p_{abd}$  without synchronous change in  $p_{ves}$  resulting in negative deflections of  $p_{det}$ .

Previously (GUP-2002), “Rectal contractions are usually of low amplitude and may or may not be felt by the patient.”

**Dropped  $p_{abd}$  at void (NEW):** A drop in  $p_{abd}$  during voiding is reported during the voiding time,  $p_{abd}$  decreases below the previous resting pressure (as a consequence of pelvic (and abdominal) muscle relaxation).

Note: The WG considers that this phenomenon will affect the pressure-flow analysis result, because it affects  $p_{det}$ . This observation should be differentiated from expelled catheter (that usually results in a much larger pressure drop).

**Straining (NEW):** Straining is observable as a temporary increase in both  $p_{ves}$  and  $p_{abd}$  pressure. Straining may be associated with (patient-active) position change (such as repositioning from leaning backwards to upright).

Note: A short abdominal strain peak may in retrospect be indistinguishable from a position change or a cough.

**After-contraction (NEW):** An after-contraction, is a continued or new detrusor pressure rise immediately after flow ended. It is important to note if this occurs with the complete emptying of the bladder.

Note: Cough checking of (intravesical) catheter position is always required after pressure-flow. To separate the after-contraction pattern from expelled catheter or catheter tip (with measuring hole) bending in the outlet when the bladder empties, this cough check is specifically important when a  $p_{ves}$  increment after voiding is observed.

Previously published description: a pressure increase after flow ceases at the end of micturition.

## 10 | THE URODYNAMIC GRAPHS AND THE URODYNAMICS REPORT

### 10.1 | Introduction and evidence base

A standard urodynamics protocol contains diverse elements. Results of clinical analysis and evaluations are documented when a (ICS Standard) Urodynamic Test is ordered. An ICS-SUT should be followed by a urodynamics report. The WG has not found evidence with regard to the standardization of such a report and no evidence regarding the elements that it should contain.

ICS (ST2002) has acknowledged urodynamic observations, but has not been specific in the definition of the type of observations relevant for diagnosis or for urodynamic conditions or the elements of urodynamic testing to be reported. Furthermore, the ST2002 has only mentioned (or standardized) a few of the possible observations, out of the many that can be the result of a complete ICS-SUT. Contemporary urodynamic equipment is able to provide lists test data and/or graphs, but here too no standard exists for these.

GUP2002 has standardized the layout of the urodynamic graph. The WG presents elements for qualitative reporting of the results of a ICS-SUT to ensure a descriptive and objective urodynamic diagnosis or establishment of a urodynamic condition.

### 10.2 | Discussion

While it will not be possible to cover all possibilities in one standard urodynamics report, the report may be customized, for example, relevant to the final diagnosis the urodynamic evidence has to be reported. However, when a test is done, all results and observations should be systematically reported. It is good clinical practice to integrate the urodynamics report with what is known about the patient from history and other examinations and tests.

On the basis of expert experience and consensus, the WG lists qualitative elements to be included in the urodynamics report of an ICS SUT without standardizing the numerical values.

### 10.3 | Recommendations

The WG recommends that, in addition to the GUP2002 standard urodynamic graph, a [cited form ST1997] “plot of detrusor pressure against flow rate during voiding” should be provided, according to the example in this ICS standard (ST1997).<sup>79</sup> For the “ICS standard urodynamic test,” the WG recommends both (NEW) an “ICS standard urodynamic (time-based) graph” as well as (NEW) an “ICS standard pressure-flow plot” to be required elements in the ICS standard urodynamics report. The WG recommends

development of an ICS standard urodynamics report template.

## 11 | CONCLUSION

The ICS Standardisation WG has updated the International Continence Society's Good Urodynamic Practice standard. This evidence-based ICS GUP2016 has defined terms and standards for the practice of urodynamics labs in general as well as for the (individual) practice of quality control during and after cystometry, and pressure-flow analysis. Furthermore, the WG has included recommendations for pretesting information and for patient information and preparation as well as recommendations for the urodynamics report. On the basis of earlier ICS standardisations and the available evidence, the practice of uroflowmetry, cystometry and pressure-flow study have been further detailed. The WG expresses the hope that implementation of this update of Good Urodynamic Practices will help to increase the quality of both individual clinical and research urodynamics.

## Good Urodynamic Practices: Uroflowmetry, Filling Cystometry, and Pressure-Flow Studies

Werner Schäfer,\* Paul Abrams, Limin Liao, Anders Mattiasson, Francesco Pesce, Anders Spangberg, Arthur M. Sterling, Norman R. Zinner, and Philip van Kerrebroeck

*International Continence Society Office, Southme Hospital, Bristol, BS10 5NB, United Kingdom*

This is the first report of the International Continence Society (ICS) on the development of comprehensive guidelines for Good Urodynamic Practice for the measurement, quality control, and documentation of urodynamic investigations in both clinical and research environments. This report focuses on the most common urodynamics examinations; uroflowmetry, pressure recording during filling cystometry, and combined pressure–flow studies. The basic aspects of good urodynamic practice are discussed and a strategy for urodynamic measurement, equipment set-up and configuration, signal testing, plausibility controls, pattern recognition, and artifact correction are proposed. The problems of data analysis are mentioned only when they are relevant in the judgment of data quality. In general, recommendations are made for one specific technique. This does not imply that this technique is the only one possible. Rather, it means that this technique is well-established, and gives good results when used with the suggested standards of good urodynamic practice. *Neurorol. Urodynam.* 21:261–274, 2002. © 2002 Wiley-Liss, Inc.

**Key words:** urodynamics; standardisation; uroflowmetry; cystometry; pressure-flow studies

### INTRODUCTION

A Good Urodynamic Practice comprises three main elements:

- A clear indication for and appropriate selection of, relevant test measurements and procedures
- Precise measurement with data quality control and complete documentation
- Accurate analysis and critical reporting of results

The aim of clinical urodynamics is to reproduce symptoms whilst making precise measurements in order to identify the underlying causes for the symptoms, and to quantify the related pathophysiological processes. By doing so, it should be possible to establish objectively the presence of a dysfunction and understand its clinical implications. Thus, we may either confirm a diagnosis or give a new, specifically urodynamic, diagnosis. The quantitative measurement may be supplemented by imaging (videourodynamics).

Urodynamic measurements cannot yet be completely automated, except for the most simple urodynamic procedure, uroflowmetry. This is not an inherent problem of the measurement itself, but is due to the current limitations of urodynamic equipment and the lack of a consensus on the precise method of measurement, signal processing, quantification, documentation, and interpretation. With the publication of this ICS Standardisation document on good urodynamic practice, it

© 2002 Wiley-Liss, Inc.

is expected that the necessary technological developments in automation will follow.

Urodynamics allows direct assessment of lower urinary tract (LUT) function by the measurement of relevant physiological parameters. The first step is to formulate the ‘urodynamic question or questions’ from a careful history, physical examination, and standard urological investigations. The patient’s recordings of micturitions and symptoms on a frequency volume chart, and repeated free uroflowmetry with determination of post-void residual volume provide important

---

Urodynamic techniques were performed according to the ‘Good Urodynamic Practice’ recommended by the International Continence Society.

noninvasive, objective information that helps to define the specific ‘urodynamic question’ or questions, prior to invasive urodynamics such as filling cystometry and pressure-flow studies.

Recommendations for good urodynamic practice are bullet pointed, inset, and printed in bold.

### RECORDING MICTURITIONS AND SYMPTOMS

A *Micturition Time Chart* records the time of each micturition. The usefulness of such a record is significantly enhanced when the voided volumes are recorded in a *Frequency Volume Chart*. The *Bladder Diary* adds to this the relevant symptoms and events such as urgency, pain, incontinence episodes, and pad usage. Recording for a minimum of 2 days is recommended. From the recordings, the average voided volume, voiding frequency, and if, the patient’s time in bed is recorded, day/night urine production and nocturia can be determined. This information provides objective verification of the patient’s symptoms, and furthermore, key values for plausibility control of subsequent urodynamic studies, for example, in order to prevent over-filling of the patient’s bladder.

### UROFLOWMETRY

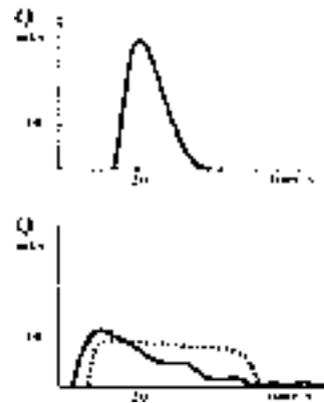

Uroflowmetry is noninvasive and relatively inexpensive. Therefore, it is an indispensable, first-line screening test for most patients with suspected LUT dysfunction. Objective and quantitative information, which helps one to understand both storage and voiding symptoms are provided by this simple urodynamic measurement.

Adequate privacy should be provided and patients should be asked to void when they feel a “normal” desire to void. Patients should be asked if their voiding was representative of their usual voiding and their view should be documented. Automated data analysis must be verified by inspection of the flow curve, artifacts must be excluded, and verification must be documented. The results from uroflowmetry should be compared with the data from the patient’s own recording on a frequency/volume chart. Sonographic estimation of post-void residual volume completes the noninvasive assessment of voiding function.

#### Normal Uroflow

Normal voiding occurs when the bladder outlet relaxes (is passive) and the detrusor contracts (is active). An easily distensible bladder outlet with a normal detrusor contraction results in a smooth arc-shaped flow rate curve with high amplitude. Any other shapes, such as curves that are flat, asymmetric, or have multiple peaks (fluctuating and/or intermittent), indicate abnormal voiding, but are not specific for its cause.

It is assumed that it is normal for the mechanical properties of a relaxed outlet to be constant, and that the properties can be defined by the dependency of the cross-sectional area of the

**Fig. 1.** Typical normal flow (top), constrictive flow (bottom, dotted line), compressive flow curve (bottom).

urethral lumen on the intraurethral pressure at the flow rate controlling zone (FRCZ). Typically, below the minimum urethral opening pressure (pmuo), the urethral lumen is closed. The lumen then opens widely with little additional pressure increase. With normal detrusor contractility and low intraurethral pressure, the normal flow curve is arc-shaped with a high maximum flowrate. (Fig. 1, top).

A normal flow curve is a smooth curve without any rapid changes in amplitude, because the shape of the flow curve is determined by the kinetics of the detrusor contraction, which arising from smooth muscle, does not show rapid variations. A decreased detrusor power and/or a constant increased urethral pressure will both result in a lower flowrate and a smooth flat flow curve. A constrictive obstruction (e.g., urethral stricture), with reduced lumen size results in a plateau-like flow curve. (Fig. 1, broken line).

A compressive obstruction with increased urethral opening pressure (e.g., benign prostatic obstruction) shows a flattened asymmetric flow curve with a slowly declining end part. (Fig. 1, bottom).

The same pattern may also originate from a weak detrusor in aging males and females. Fluctuations in detrusor contractility or abdominal straining, as well as variable outlet conditions, (e.g., intermittent sphincter activity) will lead to complex flow rate patterns.

Rapid changes in flowrate may have physiological or physical causes that owe to either changes in outlet resistance, for example, sphincter/pelvic floor contraction or relaxation, mechanical compression of the urethral lumen, or interference at the meatus, or to changes in driving energy, for example, abdominal straining. These intracorporeal causes lead to true flowrate changes. Rapid changes in flowrate may also be artifacts, when the flowrate signal is extracorporeally modified through interference between the stream and the collecting funnel, the flowmeter, movement of the stream across the

surface of the funnel, or patient movements. (see flow-curves in Figs. 3–8).

### Accuracy of Uroflowmeters

Uroflowmetry measures the flow rate of the external urinary stream as volume per unit time in milliliters per second, (ml/s). The ICS Technical Report [Rowan et al., 1984] made technical recommendations with respect to uroflowmetry, but did not compare different flowmeters by specific testing. There are, however, differences in the accuracy and precision of the flow rate signals that depend on the type of flowmeter, on internal signal processing, and on the proper use and calibration of the flowmeter. The desired and actual accuracy of uroflowmetry should be assessed in relation to the potential information that could be obtained from the urinary stream compared to the information actually abstracted for clinical and research purposes. Some relevant aspects of the physiological and physical information contained in the urinary stream are outlined here.

The desired clinical accuracy may differ from the technical accuracy of a flow meter. The ICS Technical report recommended the following standards: a range of 0–50 ml/s for  $Q_{\max}$  and 0–1,000 ml for voided volume, maximum time constant of 0.75 s; an accuracy of  $\pm 5\%$  relative to full scale, although a calibration curve representing the percentage error over the entire range of measurement should be made available. However, technical specifications from the manufacturers are rare and often not in accordance with ICS recommendations: this situation should be rectified.

Furthermore, as most flowmeters are mass flow meters (e.g., a weight transducer or rotating disk), variations in the specific gravity of the fluid will have a direct influence on the measured flow rate. For example, urine of high concentration may increase apparent flow rate by 3%. With X-ray medium, the flow rate may be overestimated by as much as 10%. These effects should be corrected by calibration software.

Thus, since the overall accuracy of flow rate signals will not be better than  $\pm 5\%$ , it would not be meaningful to report a maximum flow rate to a resolution better than a full milliliter per second (ml/s). Under carefully controlled research conditions, a better resolution may be possible by flowmeter calibration and instrument selection. However, such improvements in resolution may not be required for routine clinical applications. The dynamic properties of most flowmeters will be good enough for free uroflowmetry. When pressure flow data are analyzed, however, the limitation in signal dynamics should be taken into account because they will be different for pressure than for flow. Flow signals have a much slower response, and are less accurate than pressure signals.

### Problems in Urine Flow Rate Measurement

The problems in measurement, as well as the information that can be abstracted from the flow rate signal are rather dif-

ferent for free uroflowmetry compared to combined pressure/flow recordings.

In free uroflowmetry, the shape of the flow curve may suggest specific types of abnormality, but reliable, specific, and detailed information about the cause for abnormal voiding cannot be derived from a flow curve alone. Only when uroflowmetry is combined with intravesical and abdominal pressure recordings does it become possible, from the pressure–flow relationship, to analyze separately the contributions of detrusor contractility and bladder outlet function to the overall voiding pattern. (Figs. 3–8)

Urine flow rate measurement is affected by a number of important factors.

### Detrusor Contractility

As the voiding function reflects the interaction between the relaxed outlet and the contracting detrusor, variation of both will affect the flow. For steady outflow conditions, all variations in flowrate are related to changes in detrusor activity alone. The detrusor contraction strength varies neurogenically and myogenically, and can cause significant variability in urine flow rate measurements. (Fig. 5).

### Bladder Outflow Resistance

If detrusor, contractility is constant, then changes in outflow resistance will lead to changes in flow rate, for example, in patients with detrusor–sphincter dyssynergia (Figs. 3, 7, 8).

### Bladder Volume

As the bladder volume increases and the detrusor muscle fibers become more stretched, there is an increase in the potential bladder power and work associated with a contraction. This is most pronounced in the range from empty up to 150–250 ml bladder filling volume. It appears that at volumes higher than 400–500 ml, the detrusor may become overstretched and contractility may decrease again. Therefore,  $Q_{\max}$  is physiologically dependent on the bladder volume. This dependency will vary between individuals and with the type and degree of pathology, for example, in constrictive obstruction,  $Q_{\max}$  is almost independent of volume, and in compressive obstruction, the dependency becomes weaker with increasingly obstructed outlet conditions and lower flow rate.

### Technical Considerations

The flow rate signal is influenced by the technique of measurement and by signal processing. The external urinary stream should reach the flowmeter unaltered and with minimal delay. However, any funnel or collecting device, as well as the flowmeter, will inevitably introduce modifications to

the flow rate recording. Physically, the external urinary stream breaks into drops not far from the meatus. This fine structure of the stream has a high frequency, which can be assessed by drop spectrometry, and contains interesting information. For standard uroflowmetry, however, such high frequencies should be eliminated by signal processing.

For free uroflowmetry, all intracorporeal modulations of the flow rate are physiological artifacts and should be minimized, for example by asking the patient to relax and not to strain. Nevertheless, certain dynamic patterns of intracorporeal modulations can provide information about functional obstruction, for example, typical patterns of the detrusor-sphincter dyssynergia, or abnormal straining. This information may be lost by excessive filtering or during analog to digital A/D conversion with a filter speed of less than 10 Hz. The precise interpretation of dynamic variations in the flow rate signal is only possible when the flow rate is viewed together with the simultaneously recorded pressure signals. Thus, only in combined pressure–flow recordings can the details of the flow signal be fully understood.

For the determination of the ‘true’ maximum flow rate value, particularly during free flow, such high frequency signal variations are more likely to be misleading, and consequently they should be suppressed electronically.

#### Recommendations for Uroflowmetry

In order to facilitate the recording of urine flow rate and pattern recognition of flow curves, it is recommended that graphical scaling should be standardized as follows:

- one millimeter should equal 1 s on the x-axis and 1 ml/s and 10 ml voided volume on the y-axis.

With respect to the technical accuracy of uroflowmeters, it is meaningful for routine clinical measurements to read flowrate values only to the nearest full ml/s and volumes to the nearest 10 ml.

In order to make electronically-read  $Q_{\max}$  values more reliable, comparable, and clinically useful, we recommend internal electronic smoothing of the flow rate curve. It is recommended that:

- a sliding average over 2 s should be used to remove positive and negative spike artifacts.

If curves are smoothed by hand, the same concept should be applied. That is, when reading  $Q_{\max}$  graphically, the line should be smoothed by eye into a continuous curve so that in each period of 2 s, there are no rapid changes. Such a smoothed, clinically-meaningful maximum free flow  $Q_{\max}$  will be different (lower) from the peak value in the flow rate recording of electronic instruments currently available. (see Figs. 2, 5, 6, 8).

It is recommended that:

- only flow rate values, which have been ‘smoothed’, either electronically or manually, should be reported.

If a maximum flow value is determined electronically by simple signal peak detection without the recommended electronic smoothing, it should be labeled differently,  $Q_{\max,raw}$ . Such raw data has meaning only if a detailed specification of the type of flowmeter used is given.

The interpretation of any dynamic variation (signal patterns) in free flow will rely on personal experience, can be only descriptive, and in general will remain speculative.

For the documentation of the results of uroflowmetry, the following recommendations are made:

- Maximum (smoothed) urine flow rate should be rounded to the nearest whole number (a recording of 10.25 ml/s would be recorded as 10 ml/s);
- Voided volume and post void residual volume should be rounded to the nearest 10 ml (a recording of a voided volume of 342 ml would be recorded as 340 ml);
- The maximum flow rate should always be documented together with voided volume and post void residual volume using a standard format: VOID: Maximum Flow Rate/Volume Voided/Post Void Residual Volume.

For example, the automatically detected flows,  $Q_{\max,raw}$ , are 16.6 and 21.3 ml/s with voided volumes 86 and 182 ml, respectively. The smoothed  $Q_{\max}$  values are 8 and 17 ml/s and should be reported with voided volumes of 90 and 180, respectively, and the estimated residuals as VOID1 = 8/90/0 and VOID2 = 17/180/20 (see Figs. 2, 5, 6).

The adoption of these standards will aid the interpretation of uroflowmetry results. If data are not available, then a hyphen should be used, for example, if only the voided volume is known, VOID:—/340/— or if the voided volume was missing, VOID: 10/—/90.

- If a flow/volume nomogram is used, this should be stated and referenced.

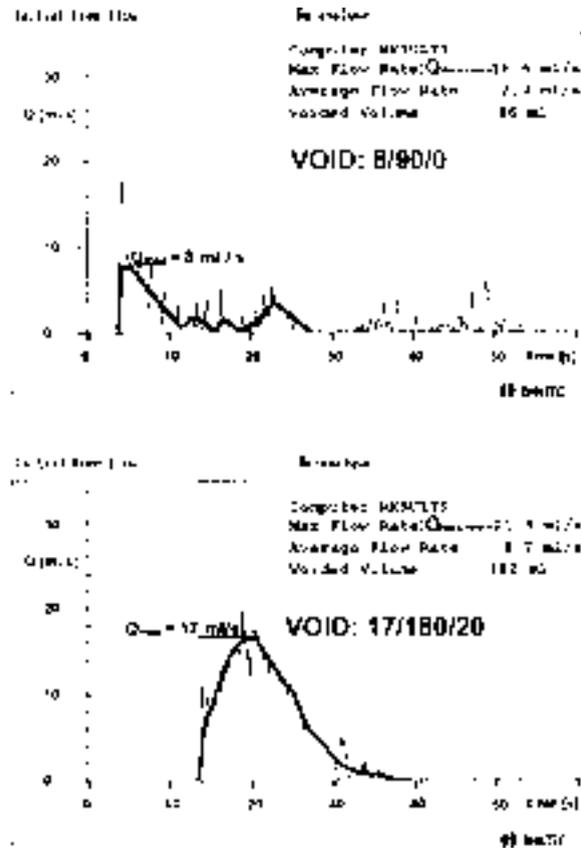

Uroflowmetry data from other than free flow, for example, measured in combination with intravesical pressure should be reported with an additional descriptive index, p, i.e.,  $Q_{\max,p}$  for pressure–flow recording.

### INVASIVE URODYNAMICS: FILLING CYSTOMETRY, PRESSURE–FLOW STUDY OF VOIDING

#### Introduction

Invasive urodynamic procedures should not be performed without clear indications and the formulation of specific urodynamic question(s). This process will usually be aided by the a priori completion of a frequency volume chart and free uroflowmetry. There are certain key recommendations, which will lead to the performance of a successful urodynamic study.

- A good urodynamic investigation should be performed interactively with the patient. It should be established by

**Fig. 2.** Exclusion of artifactual spikes in the flow curve,  $Q_{\max,raw}$ , and determination of a clinically relevant maximum flow rate,  $Q_{\max}$ , by manual smoothing. The results from uroflowmetry should be reported in the standard format:  $Q_{\max}/V_{void}/V_{res}$ .

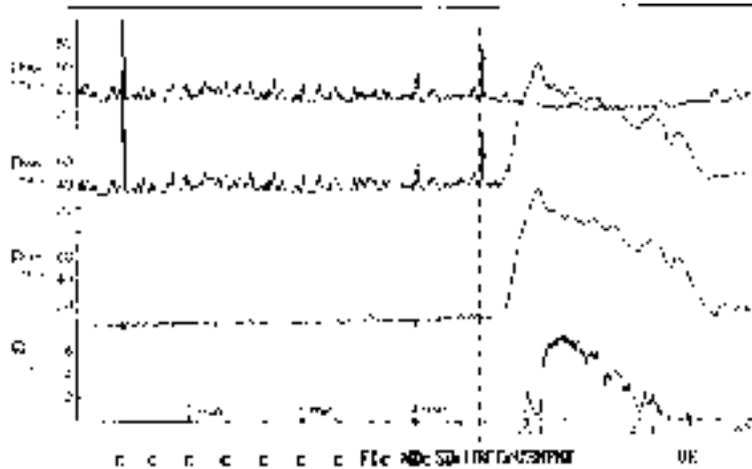

discussion with the patient that the patient's symptoms have been reproduced during the test;

- There should be continuous and careful observation of the signals as they are collected, and the continuous assessment of the qualitative and quantitative plausibility of all signals;
- Artifacts should be avoided, and any artifacts that occur should be corrected immediately. It is always difficult and is often impossible to correct artifacts during a retrospective analysis. Furthermore, it is more time consuming than if the signals are continuously observed and tested at regular intervals and artifacts recognized during the urodynamic study and corrected.

At present, ambulatory urodynamic monitoring has to rely on retrospective quality control and artifact corrections. However, in principle, the same quality criteria apply for ambulatory urodynamic monitoring as for standard urody-

namics [van Waalwijk et al., 2000]. This makes a consensus on quality even more important, because only when such criteria are precisely defined can they be implemented in an "automated intelligent" ambulatory system.

Quality control relies on pattern recognition and a knowledge of normal values as well as prior identification of useful information obtained from noninvasive urodynamics and all other sources relevant for the urodynamic question. Thus, before invasive urodynamics, a frequency volume chart should be completed and multiple free flows should be evaluated. Useful information obtained from noninvasive testing includes typical voided volumes and post-void residual volumes as well as the expected values for  $Q_{\max}$ . This information should be used for the control of subsequent invasive studies. Only by good preparation can it be assured that (a) the proper answers to the urodynamic questions will be obtained before the study is terminated and (b) necessary modifica-

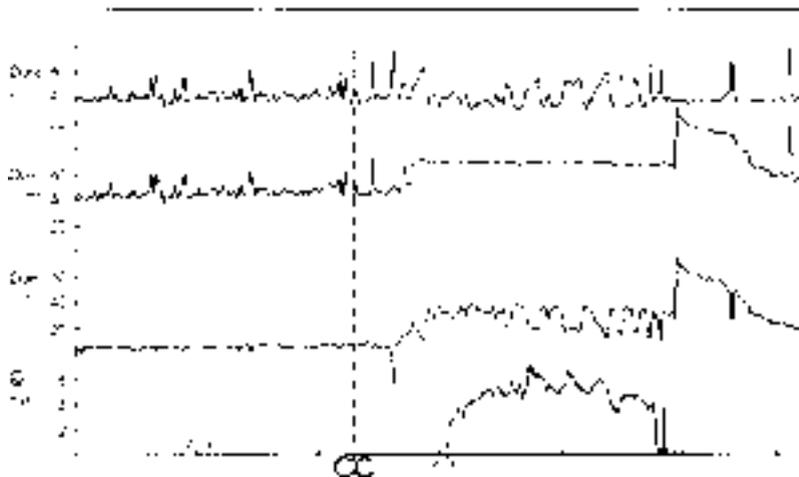

**Fig. 3.** Full recording of filling and voiding. Starting with initial values for  $p_{ves}$ ,  $p_{abd}$  of 32 cmH<sub>2</sub>O in the typical range for a standing patient with zero  $p_{det}$ ; testing signal quality with a vigorous cough at beginning, and regularly repeated (here less strong) coughs. Additionally, the pressure recordings show the typical pattern of a talking patient, while the  $p_{det}$  trace is unaffected; a weak contraction at first desire FD; another vigorous cough before voiding; beginning of flow shows dyssynergic sphincter activity as proven by decrease in flow with increase in  $p_{det}$ .

tions, additions, or repetitions of measurements will have been performed in order to derive the necessary information.

The effective practice of urodynamic requires: (a) a theoretical understanding of the underlying physics of the measurement, (b) practical experience with urodynamic equipment

and procedures, (c) an understanding of how to assure quality control of urodynamic signals, and (d) the ability to analyze critically the results of the measurements. Because urodynamic deals largely with mechanical measurements such as pressure and volume and their related changes in time, and

**Fig. 4.** Good recording quality until cystometric capacity CC is reached; at second cough before voiding the intravesical signal is lost (no response in  $p_{ves}$ , negative spike in  $p_{det}$ ). Dead  $p_{ves}$  — signal during voiding, which is “live” again only at second cough after voiding. Thus, pressure–flow study is lost. Careful observation of signals would have made it possible to interrupt the study immediately when signal failed and correct this problem before voiding starts.

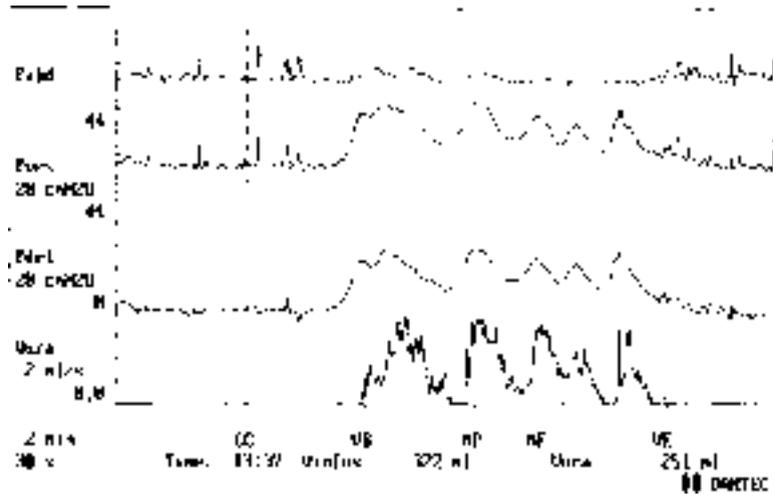

Fig. 5. Variable flowrate due to varying detrusor contraction strength. VOID: 7/250/70.

because many analytical models use mechanical concepts such as resistance to flow or contraction power, it is essential that the nature of these measurements and concepts, in particular for pressure and flowrate, are understood. Therefore, in addition to a comprehensive understanding of anatomy and physiology, some basic knowledge of biomechanics and physics is required.

The quality control of urodynamic measurements must be approached on a holistic basis. Different types and levels of data

quality and plausibility control should be used: (a) on a physical and technical level, (b) on a biomechanical level, and (c) on a pathophysiological clinical level. A common problem in urodynamics is that clinicians often proceed immediately to a clinical interpretation, i.e., to level c without a critical analysis of the potential pathophysiological information content, without considering the plausibility of the signals (level a), without considering the biomechanical context of the measurements (level b), and without taking into account the physical properties of the

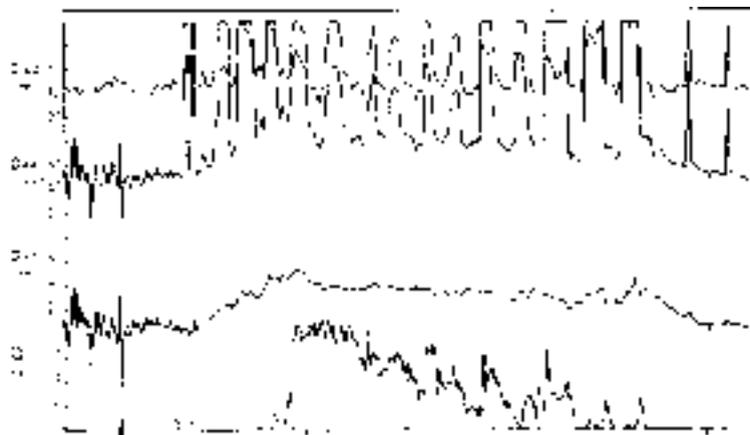

Fig. 6. The first part of the traces shows typical bi-phasic movement artifacts. The two coughs before voiding prove good recording quality. The typical picture of an unobstructed voiding: a weak detrusor contraction with  $p_{det}$  of 40 cmH<sub>2</sub>O and a  $Q_{max}$  of 9 ml/s is supported by vigorous straining, which causes some variability in flow (VOID: 9/380/100).

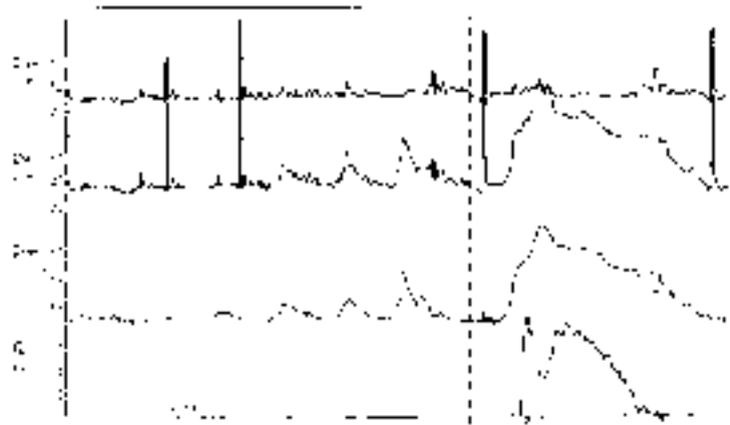

Fig. 7. A good recording showing the typical pattern of increasing detrusor overactivity and a dyssynergic event during voiding.

parameters, technical limitations, and accuracy of the signals. Therefore, it is recommended that:

- Invasive urodynamics should not be performed without precise indications and well-defined 'urodynamic questions' that are to be answered by the results of the urodynamic study.

**Measurement of Urine Flow Rate During Pressure-Flow Studies**

The usefulness of the concept of a FRCZ for data analysis requires that the recorded pressure and flow rate signal be synchronized with respect to the FRCZ [Griffiths et al. 1997]. Normally, no measurable time delay will exist between

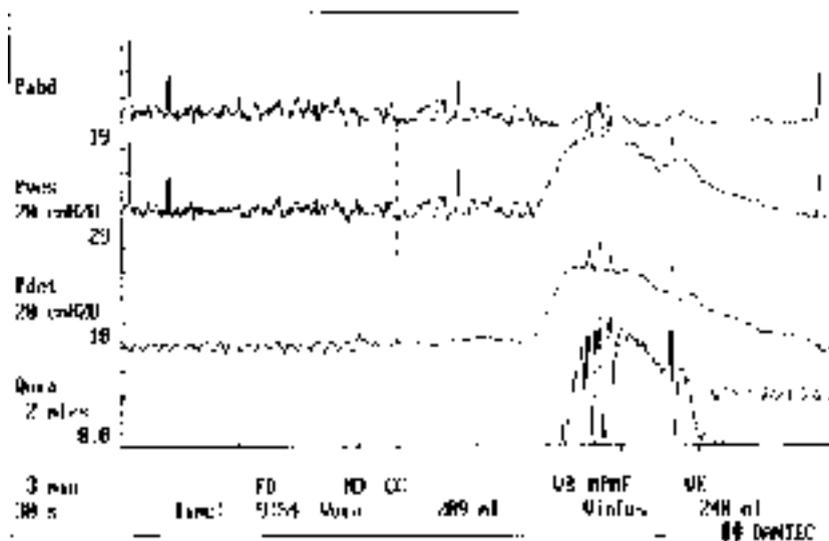

Fig. 8. High quality recordings allow detailed interpretation. The typical pattern of rectal activity becomes clearly visible in  $P_{det}$ . The flow artifacts can be identified as dyssynergic events and manually corrected from  $Q_{max,raw} = 11.2$  ml/s to  $Q_{max} = 9$  ml/s.

the intravesical pressure signal and the actual flow at the FRCZ. However, a significant delay is to be expected for the typical urodynamic flow rate recorded extracorporeally. This delay will vary with anatomy, pathology, flow rate, and the set-up for measurement. Our understanding of the actual dynamics of flow rate changes is limited, and the relatively slow response of most flow meters may not be sufficient to match the dynamics of the much-faster pressure signal. The actual time difference may be from 0.5 to 2 s; the time delay between urethral closure and the end of any flow recording may be much longer, particularly in prostatic obstruction and terminal dribbling than between the opening of the urethra and the start of a flow rate signal. Therefore, we recommend the use of more descriptive terminology for synchronizing pressure and flow values, such as  $p_{\text{det},Q_{\text{beg}}}$  for the pressure at which flow begins instead of  $p_{\text{det},\text{open}}$  and  $p_{\text{det},Q_{\text{end}}}$  when flow ends instead of  $p_{\text{det},\text{close}}$ . The time delay correction needs to be considered when analyzing pressure flow studies [Griffiths et al. 1997].

In average, the maximum flow rate  $Q_{\text{max}}$  recorded during PF studies, ( $Q_{\text{max},p}$ ), is lower than during free flow ( $Q_{\text{max}}$ ). This, however, is not due simply to a mechanical increase of outflow resistance by the intraurethral catheter, because such a difference is also found in suprapubic PF studies. A difference has also been reported between  $Q_{\text{max},p}$  during conventional and ambulatory urodynamics. This indicates more complex causes, possible psychogenic, but also physiologic, for example, that a difference in detrusor contraction strength may be involved, and that the fast filling rate used in clinical studies may lead to reduced contractility. This could also explain the difference in results between conventional and ambulatory studies.

#### Measurement of Intravesical and Abdominal Pressure

- It is recommended that there is strict adherence to the ICS standardization of zero pressure and reference height. Only then can pressure recordings be compared between patients and centers.

Zero pressure and reference height are concepts which are often confused in urodynamics. For example, by use of the misleading term “zero reference height”. As both are independent features of pressure, they must be considered separately, and both must follow recommended ICS methodology.

- Zero pressure is the surrounding atmospheric pressure.

Zero pressure is the value recorded when a transducer is open to the environment when disconnected from any tubes or catheters, or when the open end of a connected, fluid-filled tube is at the same vertical level as the transducer. Only then can a “set zero” or “balance” be performed.

- The reference height is defined as the upper edge of the symphysis pubis.

The reference height is the level at which the transducers must be placed so that all urodynamic pressures have the same hydrostatic component. It is often argued that it does not make a difference for the most relevant parameter,  $p_{\text{det}}$ , if the same error is introduced to  $p_{\text{ves}}$  and  $p_{\text{abd}}$ , as they tend to cancel each other out. This is not an acceptable argument. The hydrostatic pressure is real and important, and inevitably plays a role in any intracorporeal pressure recording. Many important aspects of quality and plausibility control, such as typical resting value ranges at different patient position, are based on the proper recording of pressures, and will not apply if pressures are not recorded according to ICS standards. Also, it is only meaningful to subtract one pressure from the other, for example ( $p_{\text{ves}} - p_{\text{abd}} = p_{\text{det}}$ ), when both are recorded to the same reference level.

#### Pressure Transducers

Urodynamic techniques were developed using external pressure transducers connected to the patient with fluid-filled lines, allowing easier compliance with the standards of correct zero and reference height. Catheter mounted pressure transducers, so-called microtip transducer catheters have become popular due to their apparent higher accuracy, better dynamic resolution, and their apparent independence from hydrostatic pressure. A catheter mounted pressure transducer is an advantage for dynamic recordings of urethral pressures during coughing (stress profiles) as well as for ambulatory urodynamics in mobile patients. Here only the application of catheter mounted pressure transducers for intravesical and abdominal pressure recordings will be discussed as urethral pressures are dealt with in a separate report [Lose et al., 2002].

All aspects of urodynamic pressure recording outlined in the preceding section are valid and independent of transducer type. It is impossible to define the precise position of an intravesical and a rectal catheter mounted pressure transducers at to place them at any common level, and impossible to position them at the standard level of the upper boarder of the symphysis pubis. It has become popular to circumvent this problem by setting the catheter mounted pressure transducers to zero pressure when inside the body at the start of pressure recording. This, however, means that both the standard zero pressure as well the reference level are ignored, so that such recorded pressure cannot be compared between patients or centers. The fact is, the initial intravesical and abdominal resting pressures are real, are different between patients, and depend significantly on patient's position. Thus, there are significant potential errors; by ignoring the correct atmospheric zero pressure, an error of up to 50 cmH<sub>2</sub>O, and as the reference height of the catheter mounted pressure transducers is usually undetermined, another potential error of 10 cmH<sub>2</sub>O is possible for a full bladder can occur. In addition, when a study starts with zero abdominal pressure then the commonly observed abdominal pressure decrease at pelvic floor relaxation during voiding will evidently result in negative abdominal pressure values, and thus in  $p_{\text{det}}$  being higher than  $p_{\text{ves}}$ .

The same problems of apparent independence from the existing hydrostatic pressure also applies to air-filled catheters and/or connection tubings. Due to the absence of a water column between the balloon-covered opening on the catheter and the external transducer, the reference height in an air-filled system will refer to the position of the sensing balloon on the catheter and not to the external transducer.

- It is recommended that for intravesical and abdominal pressure recording external transducers connected to fluid-filled tubings and catheters be used. If microtip or air-filled catheters are used, any deviation from standard zero and reference level should be minimized and taken into account at the time of data analysis.

### Urodynamic Catheters

Comparison between patients and urodynamic studies performed in different centers would be facilitated by the use of standard catheters. It is recommended that:

- For the measurement of intravesical pressure and for bladder filling, the standard catheter for routine urodynamics is a transurethral double-lumen catheter.

Only in small children and patients with severe constrictive obstruction (stricture) does suprapubic pressure recording have clear advantages. Intraurethral catheters should be as thin as possible, limited only by the practicality of insertion and by internal lumen sizes, which should be sufficiently large to avoid excessive damping of pressure transmission and to achieve the desired filling rate with standard pumps. A 6-Fr double lumen catheter is the smallest practical size at present.

The major advantage of a double lumen catheter is that the fill/void sequence can be repeated without the need for re-catheterization. Note that the use of a 6-Fr double lumen catheter can limit the infusion rate during cystometry to 20–30 ml/min, as a typical roller pump may not manage to transport a higher perfusion rate through such a small lumen. This can result in an incorrect filling volume being indicated by the machine, when the filling volume is calculated from the pump setting. For example, with a filling rate set at 60 ml/min and an actually achieved filling rate of 30 ml/min, the machine will show double the filling volume. Thus after voiding, a high calculated residual will occur. With some equipment, higher filling rates are possible; it is essential that any system should be critically tested to (a) measure the maximum filling rate that can be achieved by a particular catheter attached to an individual pump and (b) correct or calibrate the indicated infused volume.

The use of two separate tubes for filling and recording is less convenient. Removing the larger filling tube for voiding may appear to be an advantage because only a single small tube is left in the urethra. However, there are no data to suggest that, for example, in a compressive obstruction such as BPO, a 6-F catheter has detrimental influence on the pressure

or flow data. There are, however, data suggesting that results from a single study may be misleading. A double lumen catheter facilitates a second fill/void study to establish reproducibility. Re-introduction of the separate filling tube for a repeated study is more invasive and complicated.

- The use of a rectal balloon catheter is recommended for the measurement of abdominal pressure,  $p_{abd}$ .

Although there are various methods for the successful recording of abdominal pressures, a flaccid, air-free balloon in the rectal ampulla gives a suitable signal for  $p_{abd}$  to determine a meaningful  $p_{det}$  when  $p_{ves}$  is measured synchronously ( $p_{det} = p_{ves} - p_{abd}$ ). In females, vaginal recording may be more acceptable and provides comparable results. The recording of  $p_{abd}$  allows the measurement of any abdominal (i.e., perivesical) pressure component during changes in intravesical pressure. The role of the balloon is to maintain a small fluid volume at the catheter opening and to avoid fecal blockage, which can prevent or impair pressure transmission to the transducer. Additionally, as the rectal ampulla and the vagina are not homogeneously fluid filled spaces, the balloon prevents pressure artifacts arising from contact between the catheter opening and the wall tissue. The balloon serves this function best when it is filled only to 10–20% of its unstretched capacity. Overfilling and elastic distention of the balloon is the most common mistake in abdominal pressure recording. The resultant high balloon (not abdominal) pressure will produce a misleading pressure reading. Such an artificially-elevated balloon distention pressure can be avoided by making a small hole in the balloon, although this is unnecessary if the balloon is filled properly as described above. It is also possible to record reliable abdominal pressure with a very slowly perfused (<2 ml/min) open ended catheter. However, excessive fluid volume in the rectal ampulla may cause problems.

### Equipment: Minimum Requirements for Filling Cystometry and Pressure–Flow Studies of Voiding

The ICS has not yet specified definite technical standards in respect of minimum requirements for filling cystometry and pressure flow studies beyond the ICS Technical Equipment Report [Rowan et al. 1997] and the appendix to the ICS document on pressure flow [Griffiths et al., 1997], where a data exchange software standard is recommended. Some further aspects will be discussed in more detail here.

#### Equipment Recommendations

The minimum recommended requirements for a urodynamic system are:

- three measurement channels, two for pressure and one for flow;
- a display (on printer and/or monitor) and secure storage of three pressures ( $p_{abd}$ ,  $p_{ves}$ ,  $p_{det}$ ) and flow ( $Q$ ) as tracings against time;

- infused volume and voided volume may be shown graphically or numerically;
- on-line display of pressures and flow, with adequate scale and resolution; scales must be clearly given on all axes; no information should be lost electronically when tracings go off-scale on display;
- possibilities to record standard information about sensation and additional comments (event recording).

Meaningful plausibility assessment and quality control is possible only when the measured and derived signals are displayed continuously as curves over time, without delay (in real time), as the examination proceeds. Each displayed curve and number should be labeled according to ICS standards with clear scaling of amplitudes and the time axis. The following sequential position of tracings is suggested:  $p_{abd}$  at the top, then  $p_{ves}$ ,  $p_{det}$  and  $Q$  (see Figs. 3–8). It is least important when  $p_{abd}$  goes off-scale and is cut off (Fig. 6). Additional parameters such as EMG, bladder filling, and voided volumes can be displayed either as curves or digitally as numbers.

The following minimum technical specifications are recommended:

- Minimum accuracy should be  $\pm 1$  cmH<sub>2</sub>O for pressure and  $\pm 5\%$  full scale for flow and volume;
- Ranges of 0–250 cmH<sub>2</sub>O, 0–25(50) ml/s, and 1,000 ml for pressure, flow, and volume, respectively;
- The software must ensure that no information for pressures up to 250 cmH<sub>2</sub>O and for flow rates up to 50 ml/s is lost internally even when not displayed and that off-scale values are clearly identified;
- An analog/digital (A/D) frequency of 10 Hz per channel as the lower limit for pressure and flow;
- A higher frequency (minimum 20 kHz) is necessary for recording EMG;
- Calibration of all measurements should be possible.

The scalings should be kept unchanged as much as possible, because urodynamic data quality control is based on pattern recognition, and the recognition of patterns depend on scaling. Therefore, it is recommended that:

- During recording and for analysis, minimum scaling for pressure be of 50 cmH<sub>2</sub>O per cm, for flow 10 ml/s per cm, and for the time axis 1 min/cm or 5 s/mm during filling and 2 s/mm during voiding.

To enable a retrospective judgment of the curves, urodynamic measurements should be documented as curves over time with comments and explanations. It is usually insufficient to document urodynamic measurements by a few numerical values alone. The same amplitude of scaling should be used for all documentation, although the time axis may be compressed. Only if there is no relevant information to be lost by reducing resolution, for example, during filling, the time scale can be compressed.

For a print-out, maximum full scale deflections of 200 cmH<sub>2</sub>O, 50 ml/s, and 1,000 ml are sufficient for pressure, flow and volume, respectively. In most cases, half the maximum full scale will be sufficient to show all relevant parts of curves. Line resolution should be better than 0.10 mm.

During interventions, for example, interruption of bladder filling or manipulation of catheters, the continuation of both measurement and recording must always be possible.

On-line recording of comments should be possible, to complete the documentation.

### Calibration of Equipment

The need to calibrate pressure transducers, flowmeters, and pumps cannot be stated; simply “yes” if there is a need or “no” there is not. The specification of the manufacturer should be studied. Two aspects must be considered: the intended accuracy of the system and the investigator’s experience with the system. If a new system is installed or new transducers are being used, it is recommended that regular calibration be carried out. If experience with daily calibration shows that the potential error is small (e.g.,  $< 2$  cmH<sub>2</sub>O), then it will be sufficient to calibrate once a month. However, calibration should not be ignored and good urodynamic equipment makes it technically possible to perform a calibration. Calibration should not be confused with simple ‘zero balancing’, which is only one part of a calibration. In addition to setting the zero, it must be possible to check and adjust the amplitudes of all measurement channels, i.e., to calibrate all signals.

Calibration of a flowmeter can be achieved by pouring a precisely measured volume at a constant flow into the flowmeter, typically 400 ml in 20–30 s (at 15–20 ml/s) and checking the recorded volume. Special constant-flowrate bottles are available for flow calibration. Similarly, one can test a pump by measuring the time to deliver a known volume, for example, 100 ml into a measuring cylinder. It is recommended that pump calibration be performed with the filling catheter connected. Such a pump calibration can only be as good as the cylinder used, which needs to have good resolution and be accurate. Some measuring beakers that are usually available in clinics are not accurate.

### Pressure Signal Quality Control: Qualitative and Quantitative Plausibility

It is very important to observe and to test signals carefully and to correct any problems before starting the urodynamic study. If the signals are perfect at the beginning of the study, they usually remain so without the need for major intervention. If the signals are not perfect, remedial action must be taken. If a quality problem does not disappear at once, when filling commences, it will usually deteriorate further during the study.

Conscientious observation of the patient and of the signals, in particular  $p_{det}$ , during all parts of the study, together with

continuous signal testing, are the keys to high quality urodynamic. The first aim is to avoid artifacts and the second to correct the source of all artifacts immediately when they occur.

The following three criteria form the minimum recommendations for ensuring quality control of pressure recordings:

- Resting values for abdominal, intravesical, and detrusor pressure are in a typical range (see below);
- The abdominal and intravesical pressure signals are 'live', with minor variations caused by breathing or talking being similar for both signals; these variations should not appear in  $p_{det}$ ;
- Coughs are used (every 1 min. or, for example, 50 ml filled volume) to ensure that the abdominal and intravesical pressure signals respond equally. Coughs immediately before voiding and immediately after voiding should be included.

When standards are followed, i.e., with the transducer zeros set to atmospheric pressure, and the transducers placed at the level of the upper edge of the symphysis, a typical range for initial resting pressures values for  $p_{ves}$  and  $p_{abd}$  is (Schäfer, unpublished communications):

- supine 5–20 cmH<sub>2</sub>O.
- sitting 15–40 cmH<sub>2</sub>O.
- standing 30–50 cmH<sub>2</sub>O.

Usually both recorded pressures are almost identical, so that the initial  $p_{det}$  is zero, or close to zero, 0–6 cmH<sub>2</sub>O in 80% of cases and in rare cases up to 10 cmH<sub>2</sub>O [Liao et al., 1999].

All initial pressure values should be verified and patients' position should be documented on the urodynamics trace.

All negative pressure values, except when caused by rectal activity, should be corrected immediately. It should always be kept in mind that  $p_{abd}$  is recorded not to know the actual rectal pressure, but to eliminate the impact of (abdominal) pressure changes on  $p_{ves}$ . The principal aim is to determine the detrusor pressure,  $p_{det}$ , which is the pressure in the bladder without the influence of abdominal pressure. Therefore,  $p_{det}$  cannot be negative.

By talking to the patient during the study, the proper dynamic response in the pressure signals can be observed and is "automatically" documented (see Figs. 3, 4, 8).

### Problem Solving

If either detrusor or rectal contractions occur, the recorded pressures in  $p_{ves}$  and in  $p_{abd}$  will be different. Such changes can be identified and interpreted with sufficient accuracy and reliability only when the patient is observed and the relation between signal changes and patient sensation/activity are checked for plausibility and documented. Any pressure change caused by smooth muscle contractions will show a "smooth" pattern, (Figs. 5, 7, 8) i.e., there should be no rapid ("stepwise") changes (Fig. 4). If pressures increase or decrease step-wise, or with a constant slope over a long period of time,

a nonphysiological cause, such as catheter movement, should be considered.

If a sudden drop or increase occurs in either the  $p_{ves}$  or  $p_{abd}$  signal, the usual cause is the movement, blockage (Fig. 4), or disconnection of a catheter. When the patient changes position, sudden changes in resting values occur and are seen equally in both pressure signals. If  $p_{ves}$  (without change in  $p_{abd}$ ) increases slowly—as typical for a low compliance bladder—it is important to test for any other possible cause for a slow pressure increase. One cause could be a problem with the intravesical catheter measurement, for example, the hole for the pressure conducting lumen is slowly moving into the bladder neck region. This should be assessed by asking the patient to cough, if there is no other apparent artifact. Furthermore, it is recommended that bladder filling is stopped, if the filling rate was above a physiological limit of 10 ml/min. If the value of  $p_{ves}$  drops after filling is stopped, it is likely that 'low compliance' was, at least in part, related to fast filling.

There are several common problems that must be solved before the study is started or when observed during a study:

*Problem: Initial resting  $p_{det}$  is negative, for example, –5 cmH<sub>2</sub>O Possible explanations:*

- because  $p_{abd}$  is too high

*Solution: If  $p_{ves}$  is in the typical range, and both pressures are 'live', open the valve in the abdominal line and drain 1 or 2 drops from the rectal balloon filling volume. This will usually cause  $p_{abd}$  to fall to a proper value. If not, gently re-position the rectal balloon and/or make a small hole in the balloon.*

- because  $p_{ves}$  is too low

*Solution: This may be due to air bubbles trapped in the catheter, the catheter not being in the bladder, or the catheter being blocked/kinked. Gently flush through the  $p_{ves}$  line (max. 10 ml). It is very important to flush slowly while observing the pressure signal because pressures above 300 cmH<sub>2</sub>O may damage the transducer. If this does not solve the problem, add some more volume to the bladder via the filling lumen. If resistance to filling is high and it does not drain easily when opened, it will be necessary to check catheter position, and to re-position the catheter, if necessary.*

*Problem: Initial  $p_{det}$  too high, for example, 15 cmH<sub>2</sub>O*

*Possible explanations:*

*The key problem here is indicated by the measurement of 15 cmH<sub>2</sub>O. The situation is different from the clear statement that ' $p_{det}$  cannot be negative', as we do not have a definite upper limit for the normal maximum 'resting' value for  $p_{det}$ . Thus, we can only follow the present guidelines that in most tests, in an empty bladder  $p_{det}$  is between 0–5 cmH<sub>2</sub>O, and in some 90% it is between 0–10 cmH<sub>2</sub>O. For any higher value, stringent plausibility checking must be applied. If the patient has no detrusor overactivity, a  $p_{det}$  of 15 cmH<sub>2</sub>O is unlikely to be valid and there may be a signal problem. First*

check, if  $p_{abd}$  and  $p_{ves}$  are in the expected ranges. For example, if in a standing patient, initial  $p_{ves}$  is 30 cmH<sub>2</sub>O and  $p_{abd}$  is 15 cmH<sub>2</sub>O, then by experience the value of  $p_{abd}$  is too low (because  $p_{abd}$  is too low). If in a supine patient  $p_{abd}$  is 10 cmH<sub>2</sub>O and  $p_{ves}$  is 25 cmH<sub>2</sub>O, then the value of  $p_{ves}$  is too high (because  $p_{ves}$  is too high). Check the zero balance and proper signal response to coughing for both signals.

- because  $p_{abd}$  is too low  
Solution to  $p_{abd}$  being too low: Very slowly flush the rectal balloon with 1 or 2 ml.
- because  $p_{ves}$  is too high.  
Solution to  $p_{ves}$  being too high: This problem can be related to a misplaced catheter, a kink in the catheter, or contact with the bladder wall in an empty bladder, which occludes the eyehole(s) of the catheter. Proceed according to the solution for  $p_{ves}$  being too high, in the first example above.

If no signal problem can be identified, the clinical study may be started, but the  $p_{det}$  signal deserves particular attention. If compliance is normal and the bladder normal at filling, then it is very important to record and check, for some period after the micturition, the post-voiding resting value of  $p_{det}$ . Only if an elevated  $p_{det}$  is perfectly reproducible for repeated filling and voiding studies can it be accepted. However, it is most likely that a high resting  $p_{det}$  will not be reproducible and will be corrected by the measures described above.

In summary, if any resting value or cough response does not fit the usual values or patterns, it should be corrected before bladder filling is started. If this is not possible, the signals must be observed even more carefully and every effort made to reveal the potential source of error or artifact during the study.

### Retrospective Artifact Correction

In principle, a good  $p_{det}$  signal requires only that  $p_{ves}$  and  $p_{abd}$  show the same fine structure and quality of signals before filling, during filling, and after a voiding. (Figs. 3, 4, 7, 8) Both  $p_{ves}$  and  $p_{abd}$  must have the same zero and reference level. The most common mistake is to set (*balance*) the initial pressure values of  $p_{ves}$  and  $p_{abd}$  to zero with the catheters connected to the patient instead of setting zero to atmospheric pressure. This results in incorrect  $p_{ves}$  and  $p_{abd}$ . If this is done, urodynamic studies cannot be compared between centers and between patients. Although it may seem convenient and easy to start with a value of  $p_{det}$  as zero, this practice will lead to problems later in the test. As soon as pelvic floor relaxation occurs, which is particularly common during voiding, the value of  $p_{abd}$ , if starting at zero, becomes negative. With a negative  $p_{abd}$ ,  $p_{det}$  will be higher than  $p_{ves}$ , a conceptually meaningless result. Furthermore, it will then be impossible to correct a negative  $p_{abd}$ . Cough tests at regular intervals, particularly before voiding and after voiding, document the dynamic response of the pressure channels and are fundamentally important.

A typical physiological artifact that can be easily recognized is a rectal contraction. Rectal contractions are usually of low amplitude and may or may not be felt by the patient (Fig. 8). The value of  $p_{abd}$  shows a phasic rise with no change in the  $p_{det}$  signal—a potentially confusing fall in  $p_{det}$  results from the electronic subtraction, but this is, of course, an artefact. Usually rectal contractions are relevant only because they may be misinterpreted as detrusor overactivity (Fig. 8): they have no relevance to voiding.

Biphasic spikes as a response to cough tests are another example of artifacts that are easy to correct. However, any other artifacts such as a signal which is nonresponding (dead), has stepwise changes in pressure, or has negative pressures, often cannot be corrected or can be corrected only with a lot of speculation about the underlying causes of the problem. Studies with such artefacts, should be repeated see the next section).

Retrospective corrections require the same strategies for plausibility control as during recording, but then they are much more difficult and less successful to perform.

A few common artifacts (e.g., rectal activity, biphasic spikes at cough tests, or insufficient  $p_{abd}$  response during straining) can be accepted during the study as they can be corrected retrospectively. Usually, this is easier to do manually than through a computerized system.

### Urodynamic Computer Software

Computer applications should allow the easy use of even the most complicated analytical algorithms. However, most of the software offered by the urodynamic equipment industry is neither original nor validated. The software may, in fact, not do what the original developer(s) of the algorithm intended. Therefore, it is recommended that:

- When analytical urodynamic software is used to perform data analysis according to any published concept, the source of the software should be specified. It should also be clearly stated if the software has been validated, i.e., proven to provide results consistent with the algorithms to which the analyses are attributed.

### STRATEGY FOR REPETITION OF URODYNAMIC TESTS

- It is recommended that a urodynamic test should be repeated if the initial test suggests an abnormality, leaves the cause of troublesome lower urinary tract symptoms unresolved, or if there are technical problems preventing proper analysis.

It may not be necessary, however, to repeat a study, which beyond any doubt, confirms the expected pathology, for example, detrusor overactivity which correlates with the patient's symptoms. However, if the study is inconclusive, then the

consequences of not finding a clear answer to the urodynamic question(s) should be considered. If an invasive therapy is planned, the urodynamics should be repeated. Therefore, it is necessary to analyze the signals during the study and document the study immediately upon its conclusion. Only then is it possible to be sure that the urodynamic study is of a quality that answers the urodynamic question and provides an understanding about the patient's clinical problem. Therefore, it is recommended that:

- The urodynamic findings and the interpretation of the results should be documented immediately after the study is finished, i.e., before the patient has left the urodynamic laboratory. Doing so allows for a second test if required.

The analysis of a good study is easy and straight-forward. Indeed, an easy analysis actually is the key criterion for good urodynamics. A good study is one that is easy to read and one from which a any experienced urodynamicist will abstract the same results and come to the same conclusions. For computerized analyses, high data quality is even more important than for manual graphical data analysis. Efforts to achieve urodynamic data of high quality during the study will produce great benefits at the time of data analysis. The future development of urodynamic equipment and software should force investigators to conduct proper on-line data quality control. Analysis of ambulatory studies will remain problematic, as it is less easy to conduct on-line assessment of quality, and analysis is time consuming. Hence, it will be necessary to ask the patient to return, on another occasion, should the investigation require repeating, for whatever reason.

## CONCLUSIONS

This is the first report of the ICS Standardization committee of Good Urodynamic Practice. The authors are well aware that this is just a first step and many more will have to follow. Only the essential aspects are considered, but if these basic standards are followed, the quality of urodynamic studies will be significantly improved.

## ACKNOWLEDGMENTS

The Standardisation Committee is grateful for the extensive editing performed by Vicky Rees, ICS Administrator. The committee is also grateful for the detailed comments received from Linda Cardozo, Paul Dudgeon, Guus Kramer, Joseph Macaluso, Gerry Timm, and Alan Wein.

<sup>5</sup>Department of Medical Physics, Freeman Hospital, Newcastle upon Tyne, United Kingdom

<sup>6</sup>Department of Urology, Erasmus Medical Centre, Rotterdam, The Netherlands

<sup>7</sup>Department of Urology, University Medical Centre, Utrecht, The Netherlands

These guidelines provide benchmarks for the performance of urodynamic equipment, and have been developed by the International Continence Society to assist purchasing decisions, design requirements, and performance checks. The guidelines suggest ranges of specification for uroflowmetry, volume, pressure, and EMG measurement, along with recommendations for user interfaces and performance tests. Factors affecting measurement relating to the different technologies used are also described. Summary tables of essential and desirable features are included for ease of reference. It is emphasized that these guidelines can only contribute to good urodynamics if equipment is used properly, in accordance with good practice. *NeuroUrol. Urodynam.* © 2014 Wiley Periodicals, Inc.

**Key words:** urodynamics; specification; standardization

### INTRODUCTION

The International Continence Society (ICS) published a report on urodynamic equipment in 1987.<sup>1</sup> Since then, technology has changed dramatically, particularly in the application of computers to urodynamics. There is now the possibility that measurement accuracy may exceed clinical need, while new technologies being introduced to the market need benchmarks for assessment of their utility.

This article, developed under the auspices of the ICS Standardization Steering Committee, aims to:

- Summarize clinical performance requirements for urodynamic equipment.
- Relate these to specification and feature requirements.
- Develop technical specification ranges or limits from these requirements.
- Comment on different measurement technologies with respect to limitations and artefacts.
- Propose a set of tests/requirements for assessment of systems.

The readership is intended to be purchasers (to check features are actually necessary), designers (to state what is clinically required) and users (to check that equipment is actually performing). Included, therefore, are technical details, summary lists and some basic descriptions.

This document was developed according to the published methodology of the International Continence Society Standardization Steering Committee.<sup>2</sup> The group commissioned for this report developed an outline of proposed content and revised this in the light of a workshop held at the ICS Annual Scientific Meeting in Glasgow, UK in August 2011. The subsequent text was reviewed by manufacturers of urodynamic equipment before a final draft was discussed at a

workshop during the ICS meeting in Barcelona, Spain in August 2013.

The guideline contains the following sections, which include clinical requirements, measurement technologies and calibration techniques for each parameter. There are also tables for system requirements (features necessary for valid urodynamic measurements) and recommendations (features supportive of good practice).

- Uroflowmetry and voided volume.
- Infused volume.
- Pressure measurement (with special considerations of each parameter measured).
- EMG.
- User interface (recording, display and analysis).
- Standardized performance tests.

The ICS emphasizes that these guidelines can only contribute to good urodynamics if equipment is used properly. For that reason, they should not be assumed to be sufficient in isolation,

but only alongside training and practice carried out according to the ICS Good Urodynamic Practices document.<sup>3</sup>

The basic requirement of a standard urodynamic system is that it is able to measure at least two simultaneous pressures and, in real time, calculate detrusor pressure, defined as the simultaneous difference between intravesical and abdominal pressures. Furthermore a standard urodynamic system is usually capable of measuring the flow rate of the voided volume and regulating the rate of fluid infusion. In practice there are a number of other measurements, depending on the clinical demands and the urodynamic investigation being carried out, including urethral pressure or electromyography (EMG). Simultaneous recording of pressure measurements with imaging can be required. Other measurements, such as bladder wall thickness, detrusor perfusion, and sound recording are also being researched. This document, however, is limited to equipment performance for the measurement and recording of flow, volume, pressure and EMG only.

When new urodynamic equipment appears on the market, it is recommended that its function is tested with specific equipment in specialized centers. Such tests are described in the section Recommendations for Standardized Performance Tests. All urodynamic equipment should be calibrated and its performance should be tested with procedures that can be carried out by simple means that are readily available. These tests are described in the relevant sections below. When in use, correct calibration of the equipment should be verified regularly.

UROFLOWMETRY AND VOIDED VOLUME (see Tables I and II)

Clinical Requirements

**Accuracy.** The accuracy of flow measurement must be sufficient to capture physiological variation. We suggest equipment should be twice as accurate as test-retest variation in individual subjects as a minimum. Studies which have measured test-retest variation have found differences of 1.4–3.3 ml/sec.<sup>6,7</sup> Accuracy should therefore be approximately ±1 ml/sec for flow measurement over the clinically important range. In voided volume there should be a resolution of 2 ml or less in order to register leakage, while ± 3% error from true value is acceptable (range taken from market survey carried out by authors). This accuracy value must incorporate all variations due to hysteresis, linearity and temperature between 10 and 40°C.

**Range.** The range of flow measurement necessary is 0–50 ml/sec, with a volume range of 0–1,000 ml.<sup>3</sup> Accuracy should be maintained over this range. The expected clinical range for voiding time is between 14 and 54 sec,<sup>8</sup> while gaps between flows in the same void can occur. Equipment documentation should thus state after what time interval it automatically stops recording and should allow for flows at least 120 sec long.

TABLE I. Essential Requirements for Uroflowmetry

Parameter	Guideline value
Accuracy for flow rate	±1 ml/sec
Accuracy for voided volume	The greater of ±3% of true value or ±2 ml
Range for flow rate	0–50 ml/sec
Range for voided volume	0–1,000 ml
Maximum duration of flow recordable	≥120 sec
Minimum flow recordable	≤1 ml/sec
Bandwidth of flow measurement	0 to between 1 and 5 Hz

Neurourology and Urodynamics DOI 10.1002/nau

TABLE II. Desirable Features of Uroflowmetry Equipment

Documentation should state the minimum recordable volume change or flow rate
Equipment should allow the user to set the expected density of voided fluid
Equipment with load cells should not be damaged by loads less than 5 kg
Equipment should allow the user to reset the volume recorded to zero between voids during a test
Documentation should clearly state what filtering or integration is used in signal processing
Equipment should display the delay value used when synchronizing urine flow with pressure signals, preferably allowing modification of the value
An adjustable height urine collection funnel is recommended
In order to reduce flow artefacts, good delivery of the urine stream to the meter is recommended

TABLE III. Essential Requirements for Filling Volume Measurement

Parameter	Guideline value
Accuracy	The greater of 1–5% of true value or ±1 ml/min
Range	0–1,000 ml
Range of rate of infusion	0–100 ml/min, adjustable during filling
Sample rate of volume measurement	≥2 Hz

**Registering minimum flow.** It is important that a flowmeter registers clinically relevant low flow rates, for instance in the case of severe bladder outlet obstruction or terminal dribble. Not registering low flow rates may fail to trigger the autostart or terminate the reading prematurely resulting in inaccurate volume measurement and an incomplete clinical picture (especially in the case of uroflowmetry carried out alone). Flowmeters would be expected to measure at least down to the lowest level of accuracy, that is, a flow of 1 ml/sec. It is not essential that flowmeters should measure slower urine loss than this, for example as may occur during leakage, but the minimum recordable volume change or flow rate should be documented.

**Frequency response.** Flow is the result of relatively slow detrusor muscle contractions. The risetime constant of isometric contractions of strips of bladder muscle is in the order of 2 sec<sup>9</sup> and that of isovolumetric bladder contractions in patients is comparable.<sup>10</sup> Therefore the upper limit of the bandwidth of a flow measurement system (to –3 dB) need not be higher than 0.1 Hz and a sampling rate of 0.2 Hz should be adequate to record urine flow rate. However, a higher sampling rate would be desirable to allow the more common artefacts to be represented and recognized<sup>3</sup> and a measurement bandwidth from zero to between 1 and 5 Hz is recommended.

Measurement Technologies

Flow and voided volume information are interdependent, as one is normally calculated from the other. Currently, load cell

TABLE IV. Desirable Features of Filling Volume Measurement

Equipment should allow the user to calibrate infusion rate and/or filled volume
Equipment should alert the user to infusion tube or pump blockage
Systems measuring filled volume using a load cell should allow the user to set fluid density and to set filled volume when changing containers

(gravimetric) or rotating disc technologies are commonly used. The dipstick method of measuring flow uses a capacitive technique to measure urine depth in the collecting vessel.<sup>1</sup> However, although technically validated, no reports about its use and reliability in clinical practice have been published. Drop spectrometry,<sup>11</sup> which determines flow by counting the rate of drops of urine leaving the meatus, was technically too demanding and clinically unreliable.<sup>5</sup> We therefore describe only the load cell and the spinning disc methods.

**The load cell flowmeter.** Load cell (or gravimetric) flow meter technology is used by the majority of commercial flow meters,<sup>12</sup> and measures the weight of the fluid during voiding. Knowing the density of the fluid enables volume to be calculated, while flow is rate of change of volume. The weighing scale should be in a horizontal position for reliable measurement, which is a potential problem when the equipment is fixed to a urodynamic chair or videourodynamic unit. In practice, a load cell is more vulnerable to errors in its zero point than its sensitivity, and damage normally manifests as a fixed offset in voided volume. For this reason, and because it is not always convenient to empty the flowmeter between voids, a “Set zero volume” function should be available. Equipment should use load cells that will not be damaged by loads less than 5 kg.

**The spinning disk flowmeter.** In a spinning disk or momentum-flux flowmeter, the urine stream falls on a rapidly spinning disk and the flow rate is measured by the power needed to keep the rotation speed constant. The spinning disk flowmeter thus measures mass flow; as with the load cell, the density of the fluid is required in order to calculate volume flow. Volume voided is calculated by integration of the flow rate. The design of these flowmeters must allow effective cleaning.

#### Flow Signal Conditioning and Processing

Urine flow is not continuous; by the time the stream reaches the meter, it has broken into a series of droplets. Therefore a stage of low-pass filtering typically with a cut-off frequency of 1 Hz is added (market survey carried out by authors). Equipment documentation should therefore clearly state what filtering or integration is used, and guide the user as to the effects of this filtering on the display of flow parameters.

#### Calibration of Flowmeters

**Calibration.** Empty the flowmeter. Set volume to zero and fluid density to one on the recording device. Pour a known volume of water, of the order of 300 ml, into the flowmeter at an approximately constant flow rate of 15 ml/sec. For a spinning disk flowmeter, pour it at the funnel wall, not directly on the disk. Set the recording device to register the known volume. On a load cell flowmeter the process can equally well be carried out using a known weight instead of a known volume of water.

**Verifying calibration.** The calibration of the flow measurement system should be verified regularly, for example, once every 10 urodynamic measurements. This may be done by applying the appropriate calibration procedure as described above, but rather than setting the recording device to the known volume, the volume reading is verified. If the reading is more than 20 ml different from the poured volume, recalibration of the system is recommended.

An alternative, easy method to verify calibration is to pour the urine that is collected in the flowmeter into a measuring beaker and check the volume. Another method uses an easily

constructed constant flow bottle to verify the flow rate reading.<sup>13</sup>

If frequent recalibration is necessary, the flow transducer might need to be replaced. The effort and time involved for regular verification should be balanced with the risk that all the flow rate values measured since the previous verification test are incorrect. Verifying calibration may also be necessary after calibration, since in some equipment the process of calibration can alter the zero reading. In these cases it may be necessary to repeat the calibration cycle several times in a series of successive and increasingly accurate approximations.

#### Uroflow and Voided Volume Artefacts

**Liquid density error (load cell and spinning disk).** The volume flow rate is calculated by assuming the density of urine is approximately 1 g/ml. If using a denser contrast medium or if the patient is particularly dehydrated, the indicated flow rate will be proportionally high. A prompt or display of liquid density setting, and the capacity for the user to change this, is recommended.

**Momentum artefact (load cell).** The stream of urine has momentum that is registered as a force by a load cell. This is indicated as an abrupt change in volume and a brief surge at the start of flow. The size of the effect will depend on the amount and velocity of urine hitting the load cell, the resultant movement of liquid in the jug, and the filtering in the electronics. Momentum artefact can be reduced, for example by fitting a baffle and by a funnel spout that reaches into the jug. These slow the urine flow at the impact with the load cell, but cause a time delay in the flowmeter.

**Low flow (spinning disk).** In spinning disk flowmeters, flow is measured and integrated to give volume. Integration is sensitive to small input offsets that are equivalent to a low but constant flow into the device. These small input offsets must be identified and rejected. The corollary is that the signal produced by very low urine flow rates can be missed, and this can be a clinically important effect, masking a long, dribbling flow. See the section Registering minimum flow for recommendations.

**Time delay (all designs).** There is inevitably a delay between a change in bladder pressure and the corresponding change in flow rate being detected. This is caused by mechanical delays due to urethral compliance and due to the urine flowing down into the flow sensor, particularly when the collection funnel is dry. The low-pass filter in the flow meter electronics will introduce a further delay. A total delay of 0.4–0.6 sec has been shown to be normal.<sup>14</sup> This delay is of no importance for plain uroflowmetry, but is relevant when synchronous pressure measurements are made during voiding cystometry. Systems should display the delay value to the user, and possibly allow modification.

#### FILLED (INFUSED) VOLUME (see Tables III and IV)

This section clearly does not apply to ambulatory urodynamic equipment, where natural filling occurs during the test.

#### Clinical Requirements

**Accuracy.** Measurement of infused volume should be accurate to within  $\pm 5\%$ .<sup>3</sup> Accuracy of greater than 1% is unlikely to be clinically useful. However, for very low filling rates, for instance in children or in urethral pressure profiles, accuracy to only 1 ml/min will be required. These accuracy values must

4 Gammie et al.

incorporate all variations due to hysteresis, linearity and temperature between 10 and 40°C.

**Range.** Typically, even for repeated cystometry, the filled volume is unlikely to be more than 1,000 ml, so the measurable volume should be between 0 and 1,000 ml. The equipment should enable the disregarding of the weight of the bag or bottle used for fluid. For filling rate, the ICS defines the maximum physiological filling rate as body weight in kilogram divided by four, expressed as ml/min. This is routinely exceeded in clinical practice, and much lower rates are used in children. Nevertheless it is rare that more than 100 ml/min be infused, and faster rates will in any case be limited by catheter diameter. The filling rate is often reduced during the test if the patient shows signs of detrusor overactivity, so the rate must be adjustable during filling. The required range is therefore 0–100 ml/min.

**Frequency response.** If 100 ml/min is the maximum required filling rate, then for 5% volume accuracy a sample should be recorded faster than every 3sec. Considering other factors affecting accuracy, a frequency response of up to 1Hz will therefore be acceptable.

**Measurement Technologies**

Infused fluid is normally saline or contrast medium and the volume is either estimated by counting pump head revolutions or deduced from the decrease in bag weight. The section User Interface, Analysis and Post-Processing discusses how software might correct for residual volume and diuresis to estimate actual bladder volume.

**Infusion pump.** The infusion pump is normally of the peristaltic type where a series of rollers compress a flexible tube to drive the saline. This is susceptible to errors due in particular to variations in tube cross-section and downstream resistance. Equipment should therefore allow checking and calibration of infusion rate, often simply done by running the pumped fluid into a flowmeter. Many peristaltic pumps will turn even when the downstream tube is completely blocked, so equipment should register this error and alert the user. Because of this potential for error, load cell measurement of infused volume is advised.

**Load cell.** A load-cell arrangement measures actual infused volume by weighing the infusion bag. As with the flowmeter, contrast medium is denser than saline and will lead to over-indication of the filled volume if its density is not taken into account. Fluid density settings must therefore apply to both voided and filled volumes alike. In the case of voided volume, the effect of mixing contrast with saline or urine should be considered. Calibration is achieved by measuring known weights or volumes of fluid.

Where a load cell is used, there is a very obvious artefact generated when an empty fluid container is swapped for a full one. In terms of the unprocessed signal, the filled volume will increase by a few tens of ml as the container is removed, then return to approximately zero when the new bag is fitted.

Urodynamics systems should therefore have some means to correct this artefact.

It is known that filling with cooled fluid can promote detrusor contraction.<sup>17</sup> Equipment may therefore allow warming of the infused fluid to body temperature, though there is no conclusive evidence that this significantly affects the results of the cystometry. Historically, CO<sub>2</sub> gas has been used in place of saline to fill the bladder. Simultaneous pressure measurements are possible but it is not possible to measure flow rate or voided volume when using CO<sub>2</sub> gas infusion.

**MEASUREMENT OF PRESSURE (see Tables V and VI)**

Pressure in urodynamic studies is conventionally measured in centimeters of water (cmH<sub>2</sub>O), a unit based on the pressure exerted by a column of water of measured height. A unit of cmH<sub>2</sub>O is equivalent to 98.07 Pascals (Pa), the standard unit of pressure.

Since pressure signals are sensed, transmitted, and recorded in different forms, when quoting specifications for pressure measurement, values should be quoted for the entire system, that is, transducers, catheters and processing together. The type of catheter should be specified, for example, “measured using 7Fr water-filled double lumen catheter” and ideally also the internal diameter of the pressure measurement lumen.

**Clinical Requirements**

**Accuracy.** The accuracy of pressure measurement must be sufficient to capture physiological variation. We suggest equipment should be twice as accurate as test–retest variation in individual subjects. Studies which have measured this have found mean differences of 2.8 cmH<sub>2</sub>O<sup>7</sup> and 10 cmH<sub>2</sub>O<sup>6</sup>. This suggests systems should be accurate to between 1.5 and 5 cmH<sub>2</sub>O for p<sub>det</sub>, and thus between 1 and 2.5 cmH<sub>2</sub>O for p<sub>ves</sub> and p<sub>abd</sub> (rounding to the nearest 0.5 cmH<sub>2</sub>O). These accuracy values must incorporate all variations due to hysteresis, linearity, and temperature between 10 and 40°C, even in catheter-mounted transducers that are calibrated at room temperature then used at body temperature.

**Range.** An acceptable range for pressure measurement would be 0–250 cmH<sub>2</sub>O.<sup>3</sup> In addition it is useful for water-filled catheters to allow a certain amount, say 30 cmH<sub>2</sub>O, of negative pressure to be registered while the patient is temporarily lower than the level of the transducers. Certain events, such as flushing catheters, may apply a pressure significantly higher than the working range (called an overload pressure) to the transducer. Larger diameter syringes are safer in this regard, as they are less likely to generate high overload pressures. It is suggested that the application of pressures up to 5,000 cmH<sub>2</sub>O must not damage the transducer or alter the calibration in the working range by more than 1%.

**Frequency response.** Most clinically relevant pressure signal changes in urodynamics occur below 3 Hz frequency, including the majority of the power spectrum of a cough.<sup>18</sup> Even though a

TABLE V. Essential Requirements for Pressure Measurement

Parameter	Guideline value
Accuracy	The greater of ±3 % of true value or ±1 cmH <sub>2</sub> O
Range	–30–250 cmH <sub>2</sub> O (water-filled systems) 0–250 cmH <sub>2</sub> O (other systems)
Bandwidth of pressure measurement (whole system)	0 to ≥3 Hz, equal on both channels
Required feature when water filled catheters are used and patient positions are changed during the test	Equipment must allow reference levels to be reset

Neurourology and Urodynamics DOI 10.1002/nau

TABLE VI. Desirable Features of Pressure Measurement Equipment

Equipment should allow users to compare easily current pressure values with starting (baseline) pressures
The point in time at which baseline pressures are recorded should be able to be set by the user
Equipment should allow the user to see abdominal, intravesical and detrusor pressures concurrently
Equipment should record when calibration has been carried out to enable later checks on performance and use

cough has frequency components up to 14 Hz,<sup>19</sup> registering the equal transmission of this signal by both pressure lines is clinically more important than measuring its precise maximum pressure value. To adequately register the presence of a cough signal, therefore, the bandwidth of the whole system (including catheters) should be at least 3 Hz. A higher bandwidth, however, may allow the more common artefacts to be represented and recognized.

#### Pressure Measurement Technologies

In urodynamics, the pressures to be measured are in internal cavities with limited access: the bladder, vagina, rectum or stoma, or urethra. Therefore the transducer will be associated with a catheter and tubing to gain access to the measurement site. Three different transducer arrangements are in common use, all of which require the setting of zero pressure (by convention to atmospheric pressure) and calibration. Only with external transducers and water-filled catheters, however, can the reference height be consistently known, and thus  $p_{ves}$  and  $p_{abd}$  repeatedly and comparably measured.

**Water-filled catheter and external transducer.** This is recommended by the ICS.<sup>3</sup> A water-filled catheter or balloon is passed to the measurement site, with pressure transmitted along that catheter and connecting tubing to a transducer that is external to the patient. Even when set up correctly, a water-filled system is sensitive to being tapped or jostled, but responds reasonably well to fast changes in pressure.<sup>20</sup>

With a continuous column of liquid along the catheter, the pressure at the transducer is the same as that in the body *at the vertical level of the transducer*, regardless of where the catheter tip is. By convention the transducer is leveled to the pubic symphysis, an anatomical landmark for the bladder, and the zero point set to atmospheric pressure. The patient can move between supine, standing and sitting during the course of a test. Urodynamics equipment using water-filled measurement should therefore have the facility to move the transducers vertically in order to bring the transducers level with the symphysis pubis, if the patient is required to change position during the test. Alternatively, some other method of resetting the reference level is required.

**Catheter-tip transducers.** With catheter-tip transducers, the transducer is mounted in the tip of the catheter which is passed to the site of measurement. The pressure signal is converted to a voltage which is then amplified. A high measurement bandwidth (fast response) can be achieved with little or no movement artefact using catheter-tip transducers. However the transducer needs to be small, which makes it relatively difficult and expensive to manufacture.

The position of the catheter tip will affect the measurement. At the top of the bladder or rectum, the measured pressure will be typically 10 cmH<sub>2</sub>O lower than at the bottom; there is no easy way to correct for this positioning error. Systems should

therefore display clearly the pressure values at the start of the test so this artefact can be taken into account.

**Air-filled catheter and external transducer.** This arrangement is similar to the water-filled system with an external transducer, except that the catheter is filled with air, and a small balloon covers the opening at the end. The low density of air can be neglected, and the pressure is transmitted directly from the balloon at the catheter tip to the transducer. Therefore functionally, it is more similar to the catheter-tip transducer, suffering from the same uncertainty in positioning the catheter tip in the bladder or rectum. Again, therefore, it is important that the equipment allows the user to register the pressure readings at the start of the test.

There is little or no artefact due to knocking the line, but at the expense of a slowed frequency response. Air-filled catheters behave like an overdamped system, which can result in a delayed and diminished pressure response to rapidly changing pressures.<sup>20</sup>

#### Pressure Signal Conditioning and Processing

Signal conditioning would normally consist of two phases: low-pass filtering to remove high frequency artefacts, then subtraction of  $p_{abd}$  from  $p_{ves}$  to give  $p_{det}$ . The two processes are linear and can be applied in either order. However, the separate  $p_{abd}$  and  $p_{ves}$  traces are of interest, and therefore it is beneficial to filter them separately, that is, filtering before subtraction, which requires that the filters in the two channels be similar in frequency response.

Abdominal pressure signals such as a cough contain components at frequencies in excess of 10 Hz, and indeed there are some investigations, such as a cough urethral pressure profile, in which a faster frequency response is required. In this case, a higher sampling rate of approximately 100 Hz would be required if clinical precision demands this. Note that the entire system must also support the higher measurement bandwidth when required, which may exclude some arrangements.

#### Calibration of Pressure Transducers

During calibration two different pressures are set by exposing the catheter tip or sensor to two different well defined pressures. The calibration becomes more accurate when the pressure difference between the two pressures is larger (a pressure difference of at least 50 cmH<sub>2</sub>O is recommended). It may be necessary to go into some manufacturer-designed calibration routines or use one of the calibration devices available from some manufacturers. It is hoped that publication of this document will induce manufacturers to implement adequate means for calibration and include means for recording when calibration has been carried out. Calibration routines should be available for all measurement channels.

**Verifying calibration.** The calibration of pressure measurement systems should be verified regularly, for example, once every 10 urodynamic measurements for non-disposable transducers. This may be done by applying the appropriate calibration procedure as described in this section, but rather than setting zero level and the pressure reading at a defined height/depth, the pressure readings with the catheter at these levels are verified. If the pressure readings are more than 2 cmH<sub>2</sub>O different from the applied pressures, recalibration of the system is necessary. If frequent recalibration is necessary the transducer or catheter might need to be replaced. The effort and time involved for regular verification should be balanced with the risk that all the pressure values measured since the

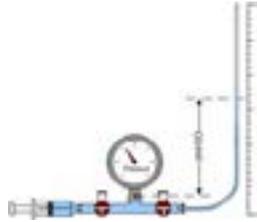

Fig. 1. Calibration of water-filled catheter by filling the line.

previous verification test are incorrect. Verifying calibration may also be necessary after calibration since in some equipment the process of calibration can alter the zero reading. In these cases it may be necessary to repeat the calibration cycle several times in a series of successive approximations.

**Calibration of water-filled catheters with external transducers.**

The external transducer is connected to the recording device. Open both three-way valves to the outside air to make sure that the transducer with air-filled dome cover is exposed to atmospheric pressure, and set the zero level at the recording device. Open the valves to the syringe and the line, and completely fill the system with bubble-free water until the water level in the line is a defined level above the transducer, at least 50 cm (Fig. 1). Set that level at the recording device.

Alternatively, a water-filled pressure measuring system may be calibrated by keeping the amount of water in the line constant and moving the line up and down (Fig. 2). With the water level at the level of the transducer, set the recording device to zero. Raise the line so that the water level is at a defined level, at least 50 cm above the transducer, and set that level at the recording device.

The transducer may also be calibrated by putting the line in a water-filled container, noting that the pressure measured reflects the height difference between the water level in the container and the transducer (not the end of the catheter).

**Calibration of catheter-tip transducers.** Mount the catheter on a tripod (Fig. 3). Set zero on the recording device, while holding the catheter tip in the air. Place the catheter tip in a container, and fill to at least 50 cm above the catheter tip. Note the height of the water level above the sensor and set that level at the recording device. (Note that lowering the holder and catheter into a prefilled container will raise the water level, so measure the height with the holder and catheter submerged).

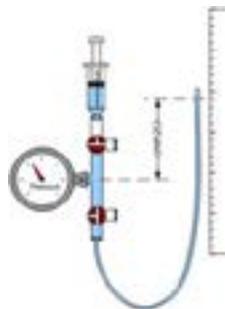

Fig. 2. Calibration of water-filled line by moving the line.

*Neurourology and Urodynamics* DOI 10.1002/nau

**Calibration of air-filled catheters.** Mount the catheter on a tripod (Fig. 3). Place the catheter balloon in a container and fill to at least 50 cm above the catheter balloon. Set zero on the recording device. Fill the balloon with air (repeatedly charging and discharging the balloon without properly emptying will result in a pressure rise inside the balloon and compromise the pressure measurement). Note the height of the water level above the balloon and set that level at the recording device. (Note that lowering the holder and catheter into a prefilled container will raise the water level, so measure the height with the holder and catheter submerged).

**Pressure Artefacts**

Since there is redundancy in having two pressure channels, most artefacts in urodynamic pressure measurements can be recognized and dealt with through proper quality control.

**Reference level errors.** Catheter-tip transducers and air-filled transducers will have an error due to their unknown and changing height within the bladder, which is difficult to correct. The same errors can occur in abdominal pressure measurements, resulting in potentially greater error when subtracting to obtain detrusor pressure. The trace display should therefore allow easy comparison of current pressure values with starting (referred to as “baseline”) values, in order to allow the operator to compensate for initial pressure offset. It is not recommended that this offset be set to zero in software at the start of the test, as this process changes one pressure reading from its real value.

**Air bubbles.** Air bubbles introduce two issues with water-filled catheters. First, the non-uniform density of fluids in the catheter will introduce an offset to pressure measurements. The size of the offset depends on the difference in height between the two ends of the bubble, which changes as the catheter is moved and as the measured pressure changes. Second, water is incompressible and pressure changes are transmitted without flow of water. Air bubbles are compressible; a change in pressure requires flow to compress or expand the air bubble. The bubble becomes a low pass filter that dampens the frequency response of the catheter. Note that this problem does not affect air-filled catheters to the same degree, because the opposition to flow offered by air is very low. Equipment should allow the operator to compare easily the size of pressure changes on all traces, in order for instance to test for the presence of air bubbles using a cough.

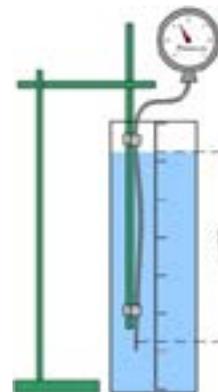

Fig. 3. Calibration of catheter-tip and air-filled transducers.

**Dislodged catheter.** A dislodged catheter that has moved from the measured body cavity can be identified by good quality control, since the measurement in the affected catheter will stop responding to coughs. If the catheter has moved significantly, the measurement may also show a dramatic offset from its baseline value. Again therefore, the trace display should allow comparison with baseline values during the test.

**Incomplete pressure transmission.** At the start of filling, it is sometimes the case that intravesical pressure is not recorded correctly, possibly due to the sensor touching the wall of an empty bladder. Equipment should therefore allow users to fill the bladder a small amount before baseline values for pressure are recorded, rather than automatically assigning baseline values at the start of filling.

**Incomplete cough cancellation.** With water-filled catheters, it is usual that the bladder line is of smaller diameter than the abdominal line. In these circumstances the characteristics of the two lines will be different, with the abdominal line usually having the faster frequency response. Therefore the complete cancellation of a cough in the detrusor trace may be difficult and any automatic processing should treat a symmetric biphasic wave on the detrusor trace as being of acceptable quality.

**Artefacts with separate lines.** With separate filling and measurement catheters, there will be a positive pressure offset in  $p_{ves}$  if the measuring catheter is not disengaged from its insertion position in the filling catheter hole (“piggy-back”) before filling commences, or if filling flow faces directly onto the measurement point. This artefact disappears if the infusion pump is stopped.

**Single Lumen Artefact.** If both filling and pressure measurements are done through the same lumen of a catheter, the positive pressure from the filling pump will add an offset to the value measured, and if a roller pump is used this offset is variable and confusing. Pressure measurements should therefore be made only when the pump is not running. Alternatively, if continuous measurements are required, calibration may be done when the pump is running, or users compensate by subtracting the offset, but only when the pump is running. This artefact disappears if the infusion pump is stopped.

**Dual-lumen artefact (pump).** Dual-lumen water-filled catheters are susceptible to a filling artefact in which the pressure generated by the infusion pump affects the pressure in the parallel measuring lumen, particularly at high filling rates. The effect is due to peristalsis from the pump interacting with the compliance of the thin catheter wall, and is manifested as a rhythmic signal from the pump rollers superimposed on the  $p_{ves}$  signal. This artefact too disappears if the infusion pump is stopped.

**Abdominal Pressure Special Considerations**

Catheters in the rectum, vagina, or an abdominal stoma give an approximation to the pressure surrounding the bladder. In particular, the use of rectal transducers in urodynamics makes the assumption that they give a good measure of resting abdominal pressure.<sup>22</sup> However, the rectal transducer will often measure rectal contractions. These will be manifested as positive waves on abdominal pressure and thus negative-going waves on resting detrusor pressure that may sometimes appear to be substantially below zero. Equipment should therefore allow the user to see all pressure traces concurrently and negative  $p_{det}$  readings should be displayed and not clipped to zero.

**Urethral Pressure—Special Considerations**

In some circumstances, it may be requested to quantify the pressure along the length of a dry urethra. Some authors report

making measurements using a solid-state catheter-tip transducer coated in an aqueous lubricating gel.<sup>23</sup> In the Brown and Wickham method,<sup>24</sup> a water-filled catheter is passed *per urethram* then withdrawn using a catheter puller, typically at 2–5 mm/sec. Meanwhile, continuous pressure measurements are made. Since the distal urethra is dry, the line must be perfused with saline, typically at 2–5 ml/min. Equipment that supports urethral pressure measurement should enable perfusion and withdrawal rates within these ranges. As systems perform differently at different rates and with different catheters, centers should maintain a consistent and clearly defined protocol when making urethral pressure measurements.

**EMG (see Table VII)**

Electromyography (EMG) measurements can contribute to the interpretation of urodynamics studies in that they document the relationship between pressure and/or flow as well as the activity of the pelvic floor and striated sphincter. Consequently EMG measurements, particularly when associated with the investigation of neuropathic disorders of the lower urinary tract, can be of critical importance. In the past, needle electrodes have been used to investigate individual muscle action potentials, usually inserted in the anal sphincter providing a record of motor unit activity of the group of muscles. While not exactly reflective of pelvic floor muscle activity, needle or wire electrodes remain the current gold standard of documenting skeletal muscle activity. However needle electrodes are invasive, technically difficult to insert and are not pleasant for the patient. Therefore in centers that use it, EMG measurement is limited to surface electrodes measuring the activation of the pelvic floor muscles.

All skeletal EMG signals have a relatively high bandwidth, typically from 10 Hz up to 1 kHz. The EMG amplitude from surface electrodes is comparatively low, nominally from 10 to 100  $\mu$ V, and depends greatly on skin cleaning, electrode placement and patient morphology in terms of the amount of fat between electrode and muscle to be monitored. Given the small signal amplitude, the amplifier properties are important. In particular, it should have a high input impedance in excess of 100 MOhms, and common-mode rejection ratio (CMRR) in excess of 80 dB.<sup>1</sup> A notch filter at mains frequency is recommended.

In most cases, the high bandwidth of the EMG is addressed by using a rectify-integrate (iEMG) or a root-mean-square circuit that gives a low-bandwidth estimate of the EMG amplitude or envelope. When displayed graphically this gives a line trace where in some cases, subtle or slow changes can be missed and filtering can lose the phase relationship with the pressure or flow signals. In fact, the original EMG can be deliberately under-sampled at typically 100 Hz, which loses some information content, but nevertheless gives a distinctive EMG appearance when displayed at the timescale of urodynamic traces.

**TABLE VII. Essential Requirements of EMG Measurement Equipment (Where Fitted)**

Parameter	Guideline value
Minimum impedance	100 MOhms
Minimum CMRR	80 dB
Required feature	EMG processing and display variable to suit clinical need

**USER INTERFACE (see Table VIII)**

**Operation**

Equipment should be designed such that operation is ergonomic and safe. Surfaces likely to come into contact with clinical materials should be easy to clean, while the physical layout should be stable and allow easy access. The equipment design should be such that technicians at the user's institution can carry out electrical safety checks without causing damage to the equipment.

**Recording**

Data should be recorded and stored in such a way that the study can be displayed in the same way at a later date, preferably on other equipment as well. Electronic marking of events is important for analysis of studies at a later date, as artefacts and real events can easily get confused if they are not permanently annotated on the original soft copy. The position of event markers should be adjustable after the test has finished, and the meaning of any abbreviations used for their labels should be clear. The ability to enter further diagnostic information such as post void residual volume and the results of related diagnostic tests may be useful in order to display all related information to clinicians. The ability to export in plain data format (.txt or .csv) should be available. Also required is the ability to integrate with popular electronic medical software and to export in the ICS standard format (.ics).<sup>25</sup> For data protection purposes, the system should store data securely, or allow the user's institution network to do so. Backing up of data onto remote systems or media and connection to the hospital data network should be facilitated. Data recovery in the event of power failure would be an advantage.

**Display**

The ICS suggests that urodynamic tests should be displayed on a 1 mm = 5 sec scale for filling and 1 mm = 2 sec for voiding.<sup>3</sup> This allows resolution of short scale events, easy visual comparison of multiple studies and prevents misinterpretation of traces due to scaling issues. Line thicknesses on screens and on printouts should allow the clear visualization of clinically important details, and these thicknesses should not represent values greater than the accuracies recommended above. A variable on-screen scale allows both visual summary of the whole test, as well as close inspection of detailed features, but default scales and layout should conform to ICS recommendations.<sup>3</sup> The system must allow for simultaneous display of all pressure traces. For those integrating fluoroscopy, temporal synchronization or embedding of the image are necessary features. For ambulatory equipment, the option of a real time display of pressure is helpful, in order to check the setting up of transducers.

**Analysis and Post-Processing**

Automated analysis is an optional extra which, if included, should not be affected by artefacts (e.g.,  $Q_{max}$  caused by knocking the flow meter,  $P_{max}$  from cough). If summary statistics and automated analysis are provided, the user should have the ability to check the values for feasibility and change the relevant ones if necessary. This implies that software should not filter or remove artefacts, but should be able to ignore them for analysis. Results of validation of any automated analyses should be available.<sup>26</sup> Established nomograms and calculated parameters may also be provided. A facility to estimate bladder volume using post-void residual, infused and voided volumes may be a useful tool, though inaccuracies in these measurements, along with any urethral infusion, diuresis, and leakage will confound calculation.<sup>27</sup>

**RECOMMENDATIONS FOR STANDARDIZED PERFORMANCE TESTS**

Testing of new technologies for pressure and flow rate measurement should be done by a specialized center prior to introduction to the market to ensure that they have sufficient accuracy, linearity, minimal hysteresis and temperature dependence, and an appropriate frequency response, as well as consistent performance throughout the lifetime of the system. These tests should be performed using all components of the system as they will be utilized clinically since, for example catheter size and length can affect the frequency response of a pressure measurement system. Potential users should utilize the results of these tests to determine if a new technology would provide sufficiently accurate measurements for their needs prior to purchase.

A single study can be utilized to test linearity and hysteresis by production of a linear increase in pressure or flow rate followed by a linear decrease in pressure or flow rate. For pressure, this can be accomplished using a fluid-filled pressure chamber in which the pressure can be tightly controlled. For flow rate, this can be accomplished using a controllable flow pump.

Frequency response can be determined by changing pressure or flow rate in a controllable manner such that different frequencies are tested. Two such standard tests for measuring the frequency response of a pressure measuring system are the pop test and the frequency ramp test.<sup>20</sup> For the pop test, a piece of latex, similar to a balloon, is tightly stretched over the top of an air-filled chamber in which pressure sensing catheters are placed. The chamber is then pressurized to a standard pressure and the latex bulges out in response. The latex is then popped with a pin or needle, dropping the pressure in the chamber to zero (equal to barometric pressure in the room) nearly instantaneously. This test is therefore sometimes called a step test because of the sudden drop to zero pressure. This test enables measurement of the response of a pressure sensing

**TABLE VIII. Essential Requirements of User Interfaces**

Parameter	Guideline
Access and cleaning	Equipment laid out ergonomically
Display	Should allow for later review with line thicknesses representing smaller values than recommended measurement accuracy
Data export	Text/spreadsheet format, ICS format and electronic patient record interface
Data storage	Backup facility and option for network connection required Secure data storage should be made possible
Image capture and display	Simultaneous recording and playback with pressure traces required, if images are used
Display scales	Clearly displayed and adjustable
Event marking	Required
Automated analyses	Relevant parameters should be controlled by user, not fixed

*Neurourology and Urodynamics* DOI 10.1002/nau

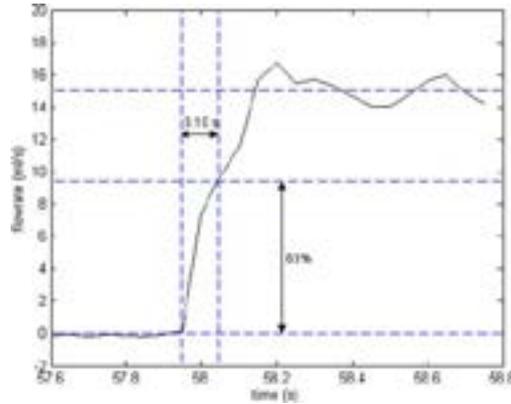

Fig. 4. Simple test for flow meter signal response. The rise time to 63% of final value should be less than 0.16 sec.

system to a sudden change in pressure. For the frequency ramp test the pressure in the pressure chamber is rapidly changed and a range of relevant sinusoidal frequencies are examined. Zero to 20 Hz is sufficient to assess urodynamic pressure measurement systems. Sophisticated software is required to characterize the pressure measurement system from the resultant data, but if done well, an accurate determination can be made and the system can be characterized by its resonant frequency and/or the  $-3$  dB frequency as illustrated with regard to a flowmeter step test (Fig. 4).<sup>28</sup> The resultant data from these tests can also be used to determine if the pressure sensing system constitutes an under- or over-damped recording system.<sup>20</sup> If the system is underdamped, the resonant frequency ought to be outside the working range of the system (greater than 20 Hz in this case). If the system is overdamped, it ought to have adequate slew rate to respond in a timely fashion to pressure changes within the working range of frequencies.

To test simply flowmeter frequency response, put the flowmeter under a running tap, and adjust the tap until the flowmeter indicates approximately 15 ml/sec. Intercept the stream for approx. 4 sec with a plastic cup. Then quickly remove the cup again, and record the flow signal for 4 sec more. Figure 4 shows a detailed recording of the time interval when the cup was removed, using a spinning disk flowmeter. Since we require a cutoff frequency of at least 1 Hz (see Table I), the time taken to rise from zero to 63% of the final value should be at most 0.16 sec.

A frequency ramp test can test new flow rate technologies by creating sinusoidal changes in flow rate whose frequencies change through the working range of flow rate frequencies, that is, 0–5 Hz as stated earlier.

Temperature dependence can be tested by performing the linearity and hysteresis test and the frequency response test at different temperatures within the working range of the system.

Disposable systems do not need to demonstrate lifetime consistency since they are marketed for single use only. Durable systems ought to be tested to ensure they have a consistent response throughout their recommended lifetime, which can be defined either according to time by utilizing an expiration date, or according to number of uses. Repetition of a simulated urodynamics test interleaved with periodic repetition of the

above benchmarking tests could determine the appropriate lifetime of a new technology, regardless of how lifetime is ultimately defined. Change of less than 1% throughout the lifetime of a system would be expected, after periodic recalibration has been undertaken.

#### SUMMARY

The review contained in this article allows clinical requirements for a standard urodynamics system to lead to technical recommendations. Equipment can be over-specified (e.g., more accuracy than is required) or under-specified (unable to achieve necessary performance). It is hoped that this document will be helpful to purchasers, users and manufacturers in avoiding these errors. Purchasers can use the lists of required features to check the suitability of equipment for urodynamics. Users can perform the tests described to check ongoing performance and calibration. Manufacturers can be guided by this technical summary of clinical need when introducing new designs or techniques. The document may also encourage the establishment of standard tests for urodynamic equipment, leading to both procurer and operator assurance, and also patient benefit.

#### ACKNOWLEDGMENT

The Standardization Steering Committee member responsible for overseeing adherence to the required development protocol was Marcus Drake.

**Aims:** The terminology in current use for sexual function and dysfunction in women with pelvic floor disorders lacks uniformity, which leads to uncertainty, confusion, and unintended ambiguity. The terminology for the sexual health of women with pelvic floor dysfunction needs to be collated in a clinically-based consensus report.  
**Methods:** This report combines the input of members of the Standardization and Terminology Committees of two International Organizations, the International Urogynecological Association (IUGA), and the International Continence Society (ICS), assisted at intervals by many external referees. Internal and external review was developed to exhaustively examine each definition, with decision-making by collective opinion (consensus). Importantly, this report is not meant to replace, but rather complement current terminology used in other fields for female sexual health and to clarify terms specific to women with pelvic floor dysfunction.

Eckhard Petri and Joseph Lee belongs to Standardization and Terminology Committees IUGA.

Kristene Whitmore belongs to Standardization and Terminology Committees ICS.

Rebecca G. Rogers, Rachel N. Pauls, RaneeThakar, Melanie Morin, Annette Kuhn, Eckhard Petri, Brigitte Fatton, Kristene Whitmore, Sheryl Kinsberg, and Joseph Lee belongs to Joint IUGA/ICS Working Group on Female Anorectal Terminology.

Dr. Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

**Results:** A clinically based terminology report for sexual health in women with pelvic floor dysfunction encompassing over 100 separate definitions, has been developed. Key aims have been to make the terminology interpretable by practitioners, trainees, and researchers in female pelvic floor dysfunction. Interval review (5-10 years) is anticipated to keep the document updated and as widely acceptable as possible.

**Conclusion:** A consensus-based terminology report for female sexual health in women with pelvic floor dysfunction has been produced aimed at being a significant aid to clinical practice and a stimulus for research.

**KEYWORDS**

female pelvic floor dysfunction, female sexual health, terminology

## 1 | INTRODUCTION

The terminology in current use for sexual function and dysfunction in women with pelvic floor disorders lacks uniformity, which leads to uncertainty, confusion, and unintended ambiguity. Comprehensive and precise description will aid this situation, leading to more accurate reporting. For example, many definitions are used to describe dyspareunia; few are specific as to the location or etiology of the pain. Women may be treated for sexual complaints from a large array of providers including physicians, psychologists, psychiatrists, or sex therapists. While other fields have standardized terminology regarding diagnoses of sexual dysfunction in women without pelvic floor dysfunction, these diagnoses and descriptions do not include descriptions of conditions commonly encountered by the urogynecologist or others who treat women with pelvic floor disorders, such as coital incontinence. More standardized terminology would aid inter-disciplinary communication and understanding, as well as educate our providers on standardized terminology used in other fields.

Existing published reports document the importance of including the assessment of sexual function. For example, while Haylen et al<sup>1</sup> offers definitions of symptoms, that document does not comment on how to further evaluate sexual function or incorporate it into the assessment of women with pelvic floor dysfunction. Assessment of how pelvic floor dysfunction treatment affects sexual health and how to measure changes in sexual health are important to the practice of urogynecology. Ideally, terminology should be consistent between practitioners who treat women with sexual dysfunction and those who treat pelvic floor disorders. Terminology presented in this document will align with current terminology documents and a literature terms analysis will be included in the process.

This report contains;

1. Definitions of sexual function relevant to the treatment of pelvic floor dysfunction and terminology developed to designate the anatomic location of the symptom.
2. Terminology currently accepted as standard outside the field of urogynecology will be referenced, as these terms will allow urogynecologists to communicate effectively with other practitioners providing care to women with sexual dysfunction and pelvic floor disorders.
3. Assessment of sexual dysfunction of women with pelvic floor disorders including the history and physical exam necessary to assess women reporting sexual difficulties which may or may not be related to their pelvic floor dysfunction including physical exam, imaging, nerve testing, as well as descriptions of how sexual dysfunction is related to other pelvic floor disorders, such as urinary and anal incontinence and pelvic organ prolapse.
4. Management of sexual dysfunction in women with pelvic floor disorders is described including conservative, surgical, and pharmacological management. Management of sexual dysfunction may be provided by different disciplines working in this field. Terminology related to the different types of therapy will be specified and distinguished. In addition, surgical and non-surgical management strategies are defined and described.
5. The working group consisted of stakeholders in sexual function including urogynecologists, sex therapists and physiotherapists and the document was vetted through the wider membership of IUGA and ICS. The working group includes optimal methods of reporting sexual function research in women with pelvic floor dysfunction. Currently no single document collates all elements required for diagnoses in the area of female sexual function in women with pelvic floor dysfunction in a comprehensive way. This report includes a full outline of the terminology for all

symptoms, signs, ordered clinical assessments, the imaging associated with those investigations, the most common diagnoses, and terminology for different conservative and surgical treatment modalities.

Like all the other joint IUGA-ICS female-specific terminology reports, every effort has been made to ensure this Report is:

1. User-friendly: Able to be understood by all clinical and research users.
2. Clinically-based: Symptoms, signs, and validated assessments/investigations are presented for use in forming workable diagnoses for sexual health and associated dysfunctions.
3. Origin: Where a term's existing definition (from one of multiple sources used) is deemed appropriate, that definition is included and duly referenced.
4. Able to provide explanations: Where a specific explanation is deemed appropriate to explain a change from earlier definitions or to qualify the current definition, this will be included as an addendum to this paper (*Footnote a,b,c...*). Wherever possible, evidence-based medical principles have been followed. This Terminology Report is inherently and appropriately a definitional document, collating definitions of terms. Emphasis has been on comprehensively including those terms in current use in the relevant peer-reviewed literature. Our aim is to assist clinical practice, medical education, and research. Some new and revised terms have been included. Explanatory notes on definitions have been referred, where possible, to the "Footnotes" section.

Acknowledgement of these standards in written publications related to female pelvic floor dysfunction, should be indicated by a footnote to the section "Methods and Materials" or its equivalent, to read as follows: "Methods, definitions and units conform to the standards jointly recommended by the International Continence Society and the International Urogynecological Association, except where specifically noted."

## 2 | OVERVIEW OF SEXUAL FUNCTION AND DYSFUNCTION

Over 40% of women will experience a sexual problem over the course of their lifetime. A sexual complaint meets the criteria for a diagnosis when it results in personal distress or interpersonal difficulties. With regard to sexual complaints that reach the level of a diagnosable sexual disorder, recent epidemiologic surveys place the prevalence of diagnosable sexual disorders at approximately 8-12%.<sup>2</sup>

### 2.1 | Normal sexual function and models of sexual response

"Normal" sexual function can be determined using a variety of standards and is therefore difficult to define. Multiple models have been developed to describe normal or healthy sexual function. In 1966, Masters and Johnson proposed a linear model of sexual response based on their observations of the physiologic changes that occurred in men and women in a laboratory setting. Their model consisted of four stages: excitement, plateau, orgasm, and resolution. Subsequently, Kaplan and Lief independently modified this model to include the concept of desire as an essential component of the sexual response. Basson introduced an intimacy-based circular model to help explain the multifactorial nature of women's sexual response and that desire is responsive as well as spontaneous. This model further allows for the overlap between desire and arousal and is ultimately the basis for the DSM 5 combined disorder, Female Sexual Interest, and Arousal Disorder (FSIAD).

#### 2.1.1 | Screening and diagnosis

Sexual concerns should be addressed routinely. Many women are hesitant to initiate discussions but still want their provider to open the dialogue about sexual problems. When a provider opens this dialogue, he/she acknowledges and prioritizes the role that sexual health plays in overall wellbeing. A variety of questionnaires can be used to help identify women who suffer from sexual problems. These questionnaires are a useful adjunct to the patient history and physical examination in the diagnosis of sexual disorders.

Once a sexual problem has been brought up and/or identified, it is important that it is adequately assessed. Though time is limited in the clinical setting, it is important to ask questions that help determine the true nature of problem. When the patient presents with low desire, a detailed description of her problem, including the onset, duration, and severity of her symptoms, should be obtained. Her level of distress should be determined. Open-ended questions allow the patient to provide information essential for accurate diagnosis and the development of an appropriate treatment plan. If there is not enough time to have a complete discussion, a return visit should be scheduled to specifically focus on her sexual concerns.

#### 2.1.2 | History and physical exam

A comprehensive medical and psychosocial history, preferably of both partners, is essential.<sup>3</sup>

A completed medical history can identify conditions that contribute to her symptoms. The gynecologic history is also a vital component in the diagnosis. Components of the sexual

history should include direct questions about sexual behavior, safe sex practices, and whether or not there is a history of sexual abuse. Sexual history taking should always be conducted in a culturally sensitive manner, taking account of the individual's background and lifestyle, and status of the partner relationship. A history of current medications should be taken. It should be noted in what way the additional pelvic floor symptoms interfere with sexual function. Medications as antihypertensive agents (alpha blockers, beta blockers, calcium channel blockers, antidiuretics) chemotherapeutics, drugs that act on the central nerve system and anti-androgens may interfere with sexual function.<sup>4</sup> A history and physical examination with special attention to atrophy, infections, scar tissue, and neoplasms should be performed. Motor and sensory neurological function should be assessed. Clinical signs of urinary and fecal incontinence should be noted and provocation tests such as a cough stress test performed. For women with pelvic neurological disease a detailed neurological genital exam is necessary, clarify light touch, pressure, pain, temperature sensation, anal and vaginal tone, voluntary contraction of vagina and anus as well as anal and bulbocavernosus reflexes.<sup>5</sup> Basic laboratory testing should be performed such as serum chemistry, complete blood count, and lipid profiles to identify vascular risk factor as hypercholesterolemia, diabetes, and renal failure.<sup>4</sup>

## 2.2 | Pelvic floor disorders and sexual dysfunction

The effects of pelvic floor disorders (PFDs) including urinary (UI) and anal incontinence (AI) and pelvic organ prolapse (POP) on sexual function remain debatable with some studies showing no and others a negative impact.<sup>6-8</sup> This variability can be attributed partly to the fact that the populations studied, as well as the methodology and the type of questionnaires used, are different between the studies. These discordant findings can also be attributed to the complexity of human sexual function which is subject to a host of influences. Despite conflicting published data, in general most PFDs are thought to negatively affect sexual health. Pelvic floor symptoms have been shown to be associated with low sexual arousal, and infrequent orgasm and dyspareunia.<sup>7</sup> Up to 45% of the women with UI and/or lower urinary tract symptoms (LUTS) complain of sexual dysfunction with 34% reporting hypoactive sexual desire, 23% sexual arousal disorder, 11% orgasmic deficiency, and 44% sexual pain disorders (dyspareunia or non coital genital pain).<sup>9</sup> Sexual function is related to women's self-perceived body image and degree of bother from pelvic organ prolapse (POP).<sup>10</sup> Genital body image and sexual health are related in women with stage 2 or greater POP<sup>11-13</sup> particularly in the domains of sexual desire and satisfaction. Women with anal incontinence (AI) have similar rates of sexual activity but poorer sexual function than

women without.<sup>12,14</sup> An estimated 16% to 25% of women with chronic pelvic pain experience dyspareunia often leading to sexual avoidance.<sup>15</sup> High pelvic floor muscle tone and sexual dysfunction are related.<sup>16</sup> In women with PFDs there is a positive association between pelvic floor strength and sexual activity and function.<sup>17</sup>

Resolution of symptoms after successful treatment of PFDs often improves sexual function and/or women's wellbeing as measured on pelvic floor condition specific measures. After surgery for stress urinary incontinence (SUI) sexual function was unchanged in 55.5% of women, improved in 31.9% and deteriorated in 13.1%.<sup>18</sup> The resolution of coital incontinence is closely correlated to patient's degree of sexual satisfaction and preoperative coital incontinence has been suggested as a prognostic factor for improvement of sexual function after surgery.<sup>19</sup> Most women who undergo surgery for POP report unchanged sexual function.<sup>20</sup>

## 3 | SYMPTOMS OF SEXUAL FUNCTION SPECIFIC TO PELVIC FLOOR DYSFUNCTION

### 3.1 | Symptom

Any morbid phenomenon or departure from the normal in structure, function, or sensation, experienced by the woman and indicative of disease or a health problem. Symptoms are either volunteered by, or elicited from the individual, or may be described by the individual's caregiver.<sup>1</sup> Sexual symptoms may occur in combination with other pelvic floor symptoms such as urinary, fecal, or combined incontinence or pelvic organ prolapse (POP) or pelvic pain.

### 3.2 | Vaginal symptoms

1. Obstructed intercourse: Vaginal intercourse that is difficult or not possible due to obstruction by genital prolapse or shortened vagina or pathological conditions such as lichen planus or lichen sclerosis.
2. Vaginal laxity: Feeling of vaginal looseness.<sup>1</sup>
3. Anorgasmia: Complaint of lack of orgasm; the persistent or recurrent difficulty, delay in or absence of attaining orgasm following sufficient sexual stimulation and arousal, which causes personal distress.<sup>3</sup>
4. Vaginal dryness (NEW): Complaint of reduced vaginal lubrication or lack of adequate moisture in the vagina.

### 3.3 | Lower urinary tract sexual dysfunction symptoms

1. Coital urinary incontinence: urinary incontinence occurring during or after vaginal intercourse<sup>a</sup>

2. Orgasmic urinary incontinence (NEW): urinary incontinence at orgasm
3. Penetration urinary incontinence (NEW): urinary incontinence at penetration (penile, manual, or sexual device)
4. Coital urinary urgency (NEW): Feeling of urgency to void during vaginal intercourse.
5. Post coital LUT symptoms (NEW): Such as worsened urinary frequency or urgency, dysuria, suprapubic tenderness.
6. Receptive urethral intercourse (NEW): Having a penis penetrating one's urethra (urethral coitus).<sup>b</sup>

### 3.4 | Anorectal sexual dysfunction symptoms<sup>28</sup>

1. Coital fecal (flatal) incontinence: Fecal (flatal) incontinence occurring with vaginal intercourse (see related definition "Coital fecal urgency").
2. Coital Fecal Urgency: Feeling of impending bowel action during vaginal intercourse.
3. Anodyspareunia: Complaint of pain or discomfort associated with attempted or complete anal penetration.<sup>28</sup>
4. Anal laxity: Complaint of the feeling of a reduction in anal tone.

### 3.5 | Prolapse specific symptoms

1. Abstinence due to pelvic organ prolapse: Non engagement in sexual activity due to prolapse or associated symptoms.<sup>c</sup>
2. Vaginal wind (Flatus): Passage of air from vagina (usually accompanied by sound).
3. Vaginal laxity: Feeling of vaginal looseness.<sup>d</sup>
4. Obstructed intercourse: vaginal intercourse is difficult or not possible due to obstruction by genital prolapse or shortened vagina or pathological conditions such as lichen planus or lichen sclerosis.

### 3.6 | Pain symptoms

1. Dyspareunia: Complaint of persistent or recurrent pain or discomfort associated with attempted or complete vaginal penetration.<sup>1,e</sup>
2. Superficial (Introital) dyspareunia: Complaint of pain or discomfort on vaginal entry or at the vaginal introitus.
3. Deep dyspareunia: complaint of pain or discomfort on deeper penetration (mid or upper vagina)
4. Vaginismus (NEW): recurrent or persistent spasm of vaginal musculature that interferes with vaginal penetration.<sup>f</sup>
5. Dyspareunia with penile vaginal movement: pain that is caused by and is dependent on penile movement.

6. Vaginal dryness: Complaint of reduced vaginal lubrication or lack of adequate moisture in the vagina.<sup>g</sup>
7. Hypertonic pelvic floor muscle: A general increase in muscle tone that can be associated with either elevated contractile activity and/or passive stiffness in the muscle.<sup>4,35,h</sup>
8. Non coital sexual pain (NEW): pain induced by non coital stimulation.<sup>i</sup>
9. Post coital pain (NEW): pain after intercourse such as vaginal burning sensation or pelvic pain.
10. Vulvodynia: vulvar pain of at least 3 months' duration, without clear identifiable cause, which may have potential associated factors.<sup>37</sup>

### 3.7 | Specific postoperative sexual dysfunction symptoms

- 1 De novo sexual dysfunction symptoms (NEW): new onset sexual dysfunction symptoms (not previously reported before surgery)
- 2 De novo dyspareunia (NEW): dyspareunia first reported after surgery or other interventions
- 3 Shortened vagina (NEW): perception of a short vagina expressed by the woman or her partner
- 4 Tight vagina (NEW):
  - Introital narrowing: vagina entry is difficult or impossible (penis or sexual device)
  - Vaginal narrowing: decreased vaginal calibre.
- 5 Scarred vagina (NEW): perception by the partner of a "stiff" vagina or a foreign body (stitches, mesh exposure, mesh shrinkage) in the vagina
- 6 Hispareunia: male partner pain with intercourse after female reconstructive surgery.<sup>j</sup>

### 3.8 | Other symptoms

1. Decreased libido or sexual desire (NEW): Absent or diminished feelings of sexual interest or desire, absent sexual thoughts or fantasies, and a lack of responsive desire.<sup>1,3</sup> Motivations (here defined as reasons/incentives) for attempting to become sexually aroused are scarce or absent. The lack of interest is considered to be beyond the normative lessening with lifecycle and relationship duration.
2. Decreased arousal (NEW): Persistent or recurrent inability to achieve or maintain sexual excitement. This may be expressed as lack of excitement, lack of lubrication, lack of vaginal and clitoral engorgement, or lack of expression of other somatic responses.<sup>1,3,k</sup>
3. Anorgasmia or difficulty in achieving orgasm (NEW): Lack of orgasm, markedly diminished intensity of

orgasmic sensations or marked delay of orgasm from any kind of stimulation.<sup>1,3</sup>

## 4 | SIGNS

### 4.1 | Sign

Any abnormality indicative of disease or health problem, discoverable on examination of the patient: an objective indication of disease or health problem.<sup>1</sup> Not all observed changes are associated with pathology from the point of view of the patient, and not all require intervention. The genital examination is often informative and in women with sexual dysfunction can often be therapeutic. A focused genital examination is highly recommended in presence of dyspareunia, vaginismus, neurological disease, genital arousal disorders, history of pelvic trauma, acquired or lifelong orgasmic disorder.<sup>4,1</sup> The internal examinations are generally best performed with the woman's bladder empty.<sup>1</sup> Examination should be performed and described including vaginal length, calibre and mobility, presence of scarring and/or pain and estrogenization, and whether or not there is vaginal or labial agglutination. The location of any vaginal pain should be noted. Pelvic organ prolapse should be evaluated at it may influence sexual function by both affecting body image and vaginal symptoms during sexual activity.<sup>39</sup> If the patient has had an operation in which a synthetic mesh is utilized then mesh may be felt in the vagina which may or may not be associated with symptoms.<sup>40</sup> Bimanual examination should be performed to make observations for any pelvic mass or unusual tenderness by vaginal examination together with suprapubic palpation. Examination of the pelvic floor muscles may elicit signs pertaining to female sexual dysfunction. If dyspareunia, vaginismus, or history of pelvic trauma are present, completing internal exams is difficult and may be impossible. Assessing for presence of vulvar pain via a gentle, introital palpation, or performing a “Q-tip touch test” of the introitus is recommended prior to any internal examination.

### 4.2 | Perineal/vulval/urethral inspection and/or examination

1. Vulval gaping: non-coaptation of vulva at rest, commonly associated with increased size of genital hiatus.
2. Deficient perineum/cloacal-like defect: A spectrum of tissue loss from the perineal body and rectovaginal septum with variable appearance. There can be a common cavity made up of the anterior vagina and posterior rectal walls or just an extremely thin septum between the anorectum and vagina.<sup>28</sup>

3. Urethral: Prolapse, caruncle, diverticulum.
4. Vulval agglutination: Labial lips fused.<sup>m</sup>

### 4.3 | Vaginal examination

1. Vaginal agglutination: defined as condition where the walls of the vagina are fused together above the hymen.
2. Vulvo-vaginal hypoesthesia: Reduced vulvo-vaginal sensitivity to touch, pressure, vibration, or temperature.<sup>4,34,35,n</sup>
3. Vulvo-vaginal hyperaesthesia: Increased vulvo-vaginal sensitivity to touch, pressure, vibration, or temperature
4. Pudendal neuralgia: elicited or described by the patient as burning vaginal and vulva pain (anywhere between the anus and the clitoris) with tenderness over the course of the pudendal nerve.<sup>1,o</sup>

### 4.4 | Examination of pelvic floor muscles<sup>1,p</sup>

1. Muscle tone: In normally innervated skeletal muscle, tone is created by “active” (contractile) and “passive” (viscoelastic) components clinically determined by resistance of the tissue against stretching or passive movement.<sup>47,48</sup>
2. Normal pelvic floor muscles: Pelvic floor muscles which can voluntarily and involuntarily contract and relax.
3. Overactive pelvic floor muscles: Pelvic floor muscles which do not relax, or may even contract when relaxation is functionally needed, for example, during micturition or defecation.
4. Underactive pelvic floor muscles: Pelvic floor muscles which cannot voluntarily contract when this is appropriate.
5. Non-functioning pelvic floor muscles: Pelvic floor muscles where there is no voluntary action palpable.
6. Pelvic floor muscle spasm or pelvic floor myalgia: defined as the presence of contracted, painful muscles on palpation and elevated resting pressures by vaginal manometry.<sup>49</sup> This persistent contraction of striated muscle cannot be released voluntarily. If the contraction is painful, this is usually described as a cramp. Pelvic floor myalgia (a symptom) may be present with or without a change in PFM tone (a sign).
7. Pelvic floor muscle tenderness: occurrence of the sensation of pain or painful discomfort of the pelvic floor muscles elicited through palpation.
8. Hypertonicity: A general increase in muscle tone that can be associated with either elevated contractile activity and/or passive stiffness in the muscle.<sup>47,48,50</sup> As the cause is often unknown the terms neurogenic hypertonicity and non-neurogenic hypertonicity are recommended.
9. Hypotonicity: A general decrease in muscle tone that can be associated with either reduced contractile activity and/

or passive stiffness in the muscle. As the cause is often unknown the terms neurogenic hypotonicity and non-neurogenic hypotonicity are recommended.<sup>48</sup>

10. **Muscle strength:** Force-generating capacity of a muscle.<sup>48,51</sup> It is generally expressed as maximal voluntary contraction measurements and as the one-repetition maximum (1RM) for dynamic measurements.<sup>52,53</sup>
11. **Muscle endurance:** The ability to sustain near maximal or maximal force, assessed by the time one is able to maintain a maximal static or isometric contraction, or ability to repeatedly develop near maximal or maximal force determined by assessing the maximum number of repetitions one can perform at a given percentage of 1 RM.<sup>48,54</sup>

#### 4.5 | Urogenital aging (NEW): genitourinary syndrome of menopause—(GSM)<sup>q,r</sup>

1. Pallor/erythema: Pale or erythematous genital mucosa
2. Loss of vaginal rugae: Vaginal rugae flush with the skin
3. Tissue fragility/fissures: Genital mucosa that is easily broken or damaged
4. Vaginal petechiae: A petechia, plural petechiae, is a small (1-2 mm) red or purple spot on the skin, caused by a minor bleed (from broken capillary blood vessels)
5. Urethral mucosal prolapse: Urethral epithelium turned outside the lumen
6. Loss of hymenal remnants: Absence of hymenal remnants
7. Prominence of urethral meatus vaginal canal shortening and narrowing: Introital retraction
8. Vaginal dryness: Complaint of reduced vaginal lubrication or lack of adequate moisture in the vagina.

#### 4.6 | General examination

Identify chronic systemic diseases and their treatments (eg, Diabetes, Multiple Sclerosis, Depression, Hypertension, lichen sclerosis) which can be associated with sexual dysfunction.

#### 4.7 | Neurological examination

For women with neurological disease affecting the pelvic nerves clarify light touch, pressure, pain, temperature sensation, and vaginal tone, voluntary tightening of the anus and vagina, anal and bulbocavernosal reflexes.<sup>55</sup>

### 5 | INVESTIGATIONS QOL; MEASUREMENT OF SEXUAL FUNCTION/HEALTH

While some physiologic measures of sexual activity and function exist, most are not readily available in the clinical or

research setting, and many do not accurately reflect patient rating of improvement. Therefore, measurement of sexual activity and function is largely limited to self-report and the use of sexual diaries or event logs, clinician-administered interviews, or questionnaires. The US Food and Drug Administration drafted guidelines in 2016 which support the use of event logs and diaries as the primary measures for the evaluation of the efficacy of interventions. Further, they specified that diaries and event log should record “Sexually Satisfying Events (SSE)” and that the number of SSE’s may be used as a primary endpoint in efficacy trials. Unfortunately, these measures do not correlate well with patient report of improvement using other validated sexual function and quality of life measures.<sup>56</sup> Personal interviews are time consuming and have wide variation in application making the reliability of findings suspect.

The FDA also recommended the use of patient reported outcomes for evaluation of sexual function. Most clinicians and researchers feel that questionnaires are the most accurate in measuring sexual function. Sexual function questionnaires include measures which were developed to include concepts important to women with pelvic floor dysfunction and those that were developed to address sexual health in women without pelvic floor dysfunction. In general, pelvic floor condition specific measures are more likely to be responsive to change than measures that are not condition specific, although both have been used in the evaluation of women with pelvic floor dysfunction. In addition, some questionnaires contain individual items or domains relevant to sexual function, such as the King’s Health Questionnaire, which has a domain specific to sexual function.

Increasingly, other measures, including those that evaluate body image, also impact sexual function and are associated with pelvic floor dysfunction. Measurement of these confounders may be important in order to assess the impact of pelvic floor dysfunction on sexual health.

#### 5.1 | Sexual diaries

A daily log of sexual thoughts, activities; supported by the US FDA as a primary outcome measure for the efficacy of interventions to evaluate sexual function.

#### 5.2 | Event logs

Record individual sexual events or activities. Each event is classified as a “sexually satisfying event (SSE)” or not. Event logs record individual events rather than activities on a daily basis.

#### 5.3 | Sexually satisfying event

This term is coined by the US FDA, and is defined by the individual completing the questionnaire. The FDA stated that

**TABLE 1** Sexual function questionnaires

Instrument	Description	Number of items	ICI* Grade	Condition-specific
ICIQ-FLUTSsex (BFLUTS) (International Consultation on Incontinence Questionnaire-Female Lower Urinary Tract Symptoms Sex) <sup>57</sup>	Female sexual matters associated with urinary symptoms and related bother	4	A	Yes
GRISS (The Golombok-Rust Inventory of Sexual Satisfaction) <sup>58</sup>	Anorgasmia, vaginismus, impotence, and premature ejaculation, avoidance, dissatisfaction and non-sensuality, infrequency and no communication about sex	28	A	No
ICIQ-VS (International Consultation of Incontinence Questionnaire -Vaginal Symptoms) <sup>59</sup>	Assess effects of vaginal symptoms of sexual quality of life	14	B	Yes
PISQ (Pelvic Organ Prolapse Urinary Incontinence Sexual Questionnaire) <sup>60</sup>	Evaluates sexual function in women with incontinence and prolapse	31	B	Yes
PISQ-12 (short form version of the PISQ-31) <sup>61</sup>	Evaluates sexual function in women with incontinence and prolapse	12	Not rated	Yes
PISQ IR (IUGA- revised version of the PISQ) <sup>8</sup>	Evaluates sexual function in women with incontinence and prolapse includes evaluation of women with anal incontinence as well as women who do not report sexual activity	33	Not rated	Yes
FSFI (Female Sexual Function Index) <sup>62</sup>	Assesses multiple dimensions of sexual function	19	A	No
SFQ (Sexual Function Questionnaire) <sup>63</sup>	Assess the impact of OAB on sexual health function in the male and female population	31	C	Yes
SQOL-F (Sexual Quality Of Life-Female) <sup>64</sup>	Assess the impact of female sexual dysfunction of quality of life	18	B	Yes

\*International Consultation on Incontinence.

the term “satisfying” and what activities will be classified as a sexual encounter should be defined but did not supply a definition.

## 5.4 | Questionnaires

Psychometric properties of some tools are reported in Table 1.<sup>64</sup>

1. Pelvic Floor Condition specific sexual function measures: A validated sexual function measure which is developed to include concepts relevant women with pelvic floor dysfunction.
2. Generic sexual function measures: A validated measure that was developed to evaluate sexual function but does not contain items relevant to pelvic floor dysfunction such as coital incontinence or vaginal looseness.

## 6 | INVESTIGATIONS; MEASUREMENT OF PHYSIOLOGIC CHANGES

Physical investigations aim to evaluate different causes of sexual dysfunction and include investigations that focus on

the vascular, neurologic, musculoskeletal, and hormonal systems. The clinical utility of these investigations in the routine assessment of female sexual health needs further validation. In many instances, these investigations are utilized in the research setting. Supplemental Table S1 reviews the validity and reliability testing of physiologic investigations.

### 6.1 | Vascular assessment

Sexual arousal results in increased blood flow allowing genital engorgement, protrusion of the clitoris and augmented vaginal lubrication through secretion from the uterus and Bartholin's glands and transudation of plasma from engorged vessels in the vaginal walls. Several instruments are available to measure blood flow during sexual stimulation.<sup>65,66</sup> Inadequate vasculogenic response may be related to psychological factors as well as vascular compromise due to atherosclerosis, hormonal influence, trauma, or surgery.

1. Vaginal photoplethysmography: A tampon shape intra-vaginal probe equipped with an incandescent light that projects toward the vaginal walls is inserted; the amount of light that reflects back to the photosensitive cell provides a measure of vaginal engorgement which can be expressed as

vaginal blood volume or vaginal pulse amplitude depending on the mode of recording.<sup>67,68</sup> Likewise, labial and clitoral photoplethysmography can also be evaluated.<sup>69,70</sup>

2. Vaginal and clitoral duplex Doppler ultrasound: The anatomical integrity of clitoral structures and the changes in clitoral and labial diameter associated with sexual stimulation can be evaluated in B mode.<sup>71</sup> Movement of the blood relative to the transducer can be expressed as measurement of velocity, resistance, and pulsatility.<sup>72</sup> Blood flow in arteries irrigating the clitoris and the vagina are more commonly assessed during sexual stimulation.<sup>71,73,74</sup>
3. Laser Doppler imaging of genital blood flow: An imager positioned close to the vulva allows the assessment of skin/mucosae microcirculation at a depth of up to 2-3 mm.<sup>75</sup> This method has been used to assess response to sexual stimulation and correlated with subjective arousal.<sup>75</sup> It has also led to a better understanding of microvascular differences in women with provoked vestibulodynia compared to asymptomatic controls.<sup>76</sup>
4. Magnetic resonance of imaging of the genito-pelvic area: Evaluation of the increase in clitoral structure volume related to tissue engorgement occurring during arousal.<sup>76</sup>
5. Measurements of labial and vaginal oxygenation: A heated electrode and oxygen monitor are used to evaluate the arterial partial pressure of oxygen (PO<sub>2</sub>) transcutaneously.<sup>78,79</sup> The temperature of the electrode is kept at a constant elevated temperature by an electric current. Increase in blood flow under the electrode results in more effective temperature dissipation (heat loss) with the result that more current is needed to maintain the electrode at its prefixed temperature. The changes in current provide an indirect measurement of blood flow during sexual stimuli.<sup>79,80</sup> The electrode also monitors oxygen diffusion across the skin.<sup>78,79</sup>
6. Labial thermistor: Temperature measurement evaluated with a small metal clip attached to the labia minora and equipped with a sensitive thermistor.<sup>80,81</sup>
7. Thermography or thermal imaging of the genital area: Evaluation of genital temperature using a camera detecting infrared radiation from the skin during sexual stimulation.<sup>82</sup> This method has been correlated with subjective arousal.<sup>83</sup>

## 6.2 | Neurologic assessment

Related to intact sensation, neurological innervation is important for arousal and orgasm. Peripheral neuropathy or central nervous system disorders (eg, diabetic neuropathy, spinal cord injury) may lead to anorgasmia and decreased

arousal.<sup>84-86</sup> Different approaches can be used to evaluate motor and sensory neurological function.

1. Functional magnetic resonance imaging: Investigation of neural activation in anatomically localized cerebral regions evaluated through monitoring subtle changes in regional cerebral blood flow that occur with activation of the neurons. These patterns of activation and deactivation are used to examine the cerebral and cognitive response to sexual stimulation.<sup>77</sup>
2. Quantitative sensory testing: Assessment of the sensitivity by applying different stimuli (light touch, pressure, temperature, or vibration) using an ascending or descending method in order to evaluate the detection threshold. These methods can be used to evaluate different vulvo-vaginal sites including the clitoris, labia minora, and majora as well as vaginal and anal margins.<sup>84,87,88</sup>
3. Reflex examination: Evaluating sacral arc integrity, the bulbocavernosus reflex can be elicited by squeezing the clitoris and assessing the contraction of the anal sphincter.<sup>89</sup> The external anal reflex is tested by repetitive pricking delivered to perianal skin and observing anal sphincter contraction.<sup>89</sup> Latencies can also be evaluated by stimulating the nerve and evaluating muscle response through a needle electrode.<sup>90</sup>

## 6.3 | Pelvic floor muscle assessment

Assessment of pelvic floor muscle (PFM) function involves evaluating the tone, strength, endurance, coordination, reflex activation during rises in intra-abdominal pressure as well as the capacity to properly relax this musculature. These muscles are involved in sexual function as PFM contraction occurs during arousal and intensifies with orgasm and PFM tone is related to vaginal sensation.<sup>91-93</sup> Superficial PFMs such as the bulbospongiosus and ischiocavernosus are also involved in erection of the clitoris by blocking the venous escape of blood from the dorsal vein.<sup>94</sup> Thus, reduction in PFM strength and endurance has been related to lower sexual function.<sup>95,96</sup> Likewise, PFM hypotonicity may be related to vaginal hypoesthesia, anorgasmia, and urinary incontinence during intercourse<sup>9</sup> while hypertonicity may lead to dyspareunia.<sup>97,98</sup>

1. Pelvic floor manometry: measurement of resting pressure or pressure rise generated during contraction of the PFMs using a manometer connected to a sensor which is inserted into the urethra, vagina, or rectum. Pelvic floor manometric tools measuring pressure in either mmHg, hPa, or cmH<sub>2</sub>O can be used to assess resting pressure, maximal squeeze pressure (strength), and endurance.<sup>99</sup> Details about recommendations to ensure validity of pressure measurements are provided elsewhere.<sup>99</sup>

2. Pelvic floor dynamometry: measurement of PFM resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina.<sup>100–102</sup> Dynamometry measures force in Newton (N). Several parameters such as tone, strength, endurance, speed of contraction, and coordination can be evaluated.<sup>100–102</sup>
3. Pelvic floor electromyography (EMG): the recording of electrical potentials generated by the depolarization of PFM fibers. Intra-muscular EMG consists in the insertion of a wire or needle electrode into the muscle to record motor unit action potentials while surface EMG requires electrodes placed on the skin of the perineum or inside the urethra, vaginal, or rectum. EMG amplitude at rest and contraction can be recorded.
4. Pelvic floor ultrasound imaging: evaluation of PFM morphology at rest, during maximal contraction and Valsalva. Several parameters pertaining to assess the bladder neck and anorectal positioning and hiatus dimensions can be measured.<sup>103–105</sup>

**6.4 | Hormonal assessment**

Hormones such as estrogen, progestin, and androgen influence sexual function and imbalance may lead to various symptoms including decreased libido, lack of arousal, vaginal dryness, and dyspareunia.<sup>106, 107, 107</sup> Depending on the underlying suspected conditions associated with sexual dysfunction, hormonal investigations such as estradiol (or FSH if symptoms of deficiency), serum testosterone, dehydroepiandrosterone acetate sulphate (DHEAS), free testosterone, dihydrotestosterone, prolactin, and thyroid function testing may be considered.<sup>108</sup> Moreover, the evaluation of vaginal pH and vaginal maturation index (ie, percentage of parabasal cells, intermediate cells, and superficial cells) can be helpful in women with vulvovaginal atrophy as it has been shown to be correlated with patient's symptomatology.<sup>109</sup>

**7 | COMMON DIAGNOSES**

The Diagnostic and Statistical Manual of Mental Disorders fifth edition (DSM-5), the International Classification of

**TABLE 2** Sexual dysfunction diagnoses

Diagnosis	Description
DSM—5 Diagnoses (American Psychiatric Association)	
Female Sexual Interest/Arousal disorder	Lack of, or significantly reduced, sexual interest/arousal as manifested by 3 of the following: 1. Absent/reduced interest in sexual activity 2. Absent/reduced sexual/erotic thoughts or fantasies 3. No/reduced initiation of sexual activity and unresponsive to partner's attempts to initiate 4. Absent/reduced sexual excitement/pleasure during sexual activity in almost all or all (75-100%) sexual encounters 5. Absent/reduced sexual interest/arousal in response to any internal or external sexual/erotic cues (written, verbal, visual) 6. Absent/reduced genital or non-genital sensations during sexual activity in almost all or all (75-100%) sexual encounters
Genito-Pelvic Pain/Penetration disorder	Persistent or recurrent difficulties with 1 or more of the following: 1. Vaginal penetration during intercourse 2. Marked vulvovaginal or pelvic pain during intercourse or penetration attempts 3. Marked fear or anxiety about vulvovaginal or pelvic pain in anticipation of, during, or as a result of vaginal penetration 4. Marked tensing or tightening of the pelvic floor muscles during attempted vaginal penetration.
Female orgasmic disorder	Presence of either of the following on all or almost all (75-100%) occasions of sexual activity: 1. Marked delay in, marked infrequency of, or absence of orgasm. 2. Markedly reduced intensity of orgasmic sensations
Joint terminology from the International Society for the Study of Women's Sexual Health and the North American Menopause Society	
Genitourinary Syndrome of Menopause	The genitourinary signs and symptoms of menopause that arise from decreasing level of estrogens and other steroids. This includes burning and irritation of reproductive organs and structures, dryness, pain with intercourse and urinary urgency, dysuria and recurrent infections.

Diseases 10th edition (ICD-10), and the Joint Terminology from the fourth International Consultation of Sexual Medicine (ICSM) all have proposed diagnoses for sexual disorders in women. Many of the diagnoses from the various societies overlap; we have chosen the diagnoses from the DSM 5, as well as the diagnosis of genitourinary syndrome of menopause as these diagnoses seem most relevant to the population of women with pelvic floor dysfunction, as shown in Table 2.

The DSM 5 has combined disorders that overlap in presentation and reduced the number of disorders from six to three. Hypoactive sexual desire disorder (HSDD) and female sexual arousal disorders (FSAD) have been combined into one disorder, now called Female Sexual Interest/Arousal Disorder (FSIAD), based on data suggesting that sexual response is not always a linear, uniform process, and that the distinction between certain phases, particularly desire and arousal, may be artificial. Although this revised classification has not been validated clinically and is controversial, it is the new adopted standardization. One reason offered for the new diagnostic name and criteria were clinical and experimental observations that sexual arousal and desire disorders typically co-occur in women and that women may therefore experience difficulties in both.<sup>110,111</sup>

The DSM-IV categories of vaginismus and dyspareunia have been combined to create “genito-pelvic pain/penetration disorder” (GPPPD). Female Orgasmic Disorder remains its own diagnosis. The DSM 5 has also changed the relevant specifiers of these disorders with the goal of increasing objectivity and precision and to avoid over-diagnosis of transient sexual difficulties. In particular, all diagnoses now require a minimum duration of approximately 6 months and are further specified by severity.

Genitourinary syndrome of menopause (GSM) is a new term introduced by the International Society of Sexual Medicine to describe a variety of symptoms which may be associated with sexual health. Although not validated, this diagnosis was introduced in an effort to improve communication between providers and patients regarding symptoms which may be difficult to discuss. While not a sexual dysfunction diagnosis, given the age of women who typically develop pelvic floor dysfunction, symptoms associated with GSM may be relevant to the assessment of the sexual health of women with pelvic floor dysfunction.

For each of the DSM-5 diagnoses, providers should indicate whether or not the condition is lifelong or acquired, generalized or situational, and rate the severity as mild, moderate or severe in terms of the distress it causes. All of the diagnoses, except for the pain diagnoses, need to meet the criterion that it has been present for 6 months, causes significant distress, and are not a consequence of non-sexual mental disorder, severe relationship distress and are not solely or primarily attributable to a medication or underlying illness.<sup>112</sup> For genitourinary syndrome of menopause, not all

signs and symptoms need be present, but the symptoms must be bothersome and not better accounted for by another diagnosis.<sup>113</sup>

## 8 | TERMS FOR CONSERVATIVE TREATMENTS

### 8.1 | Lifestyle modification

Alterations of certain behaviors may improve sexual function. These include weight loss, appropriate sleep, adequate physical fitness, and management of mood disorders.<sup>114–118</sup> Vulvovaginal pain may be treated by dietary changes and perineal hygiene (avoiding irritant soaps, detergents, and douches), although data are conflicting.<sup>119</sup> Dietary modifications may be disorder specific including low oxalate diet as reduction in dietary levels of oxalate may improve symptoms of vulvodynia,<sup>120</sup> or a bladder friendly diet with reductions in acidic foods and bladder irritants may treat bladder pain and associated sexual pain.<sup>121,122</sup>

### 8.2 | Bibliotherapy

Use of selected books and videos to aid in treatment and reduce stress. Shown to improve sexual desire.<sup>123,124</sup>

### 8.3 | Topical therapies

Lubricants and moisturizers-Application of vaginal lubricant during sexual activity or vaginal moisturizers as maintenance may assist with atrophic symptoms and dyspareunia.<sup>125–127</sup> Examples of some lubricants are described below, although no one lubricant or moisturizer has been adequately studied to recommend it over others. Additionally, not all products are available in all countries.

- Essential arousal oil: Feminine massage oil applied to vulva prior to activity. Some evidence to support efficacy in treatment of sexual dysfunction, including arousal and orgasm, compared with placebo.<sup>128,129</sup>
- Vulvar soothing cream: Non-hormonal cream containing cutaneous lysate, to be applied twice daily. Study shows improvement in vulvar pain with use compared to placebo.<sup>130,131</sup>
- Prostaglandin E1 analogue, may help increase genital vasodilation. Ongoing trials to determine efficacy in arousal or orgasmic dysfunction.<sup>131–133</sup>

### 8.4 | Psychological intervention

Counseling and therapy are widely practiced treatments for female sexual dysfunction.<sup>114,134</sup> Even when a sexual

problem's etiology and treatment is primarily urogenital, once a problem has developed there are typically psychological, sexual, relationship, and body image consequences and it may be tremendously validating and helpful for these women to be referred to counselors or therapists with expertise in sexual problems. Psychological interventions include cognitive behavioral therapy (CBT), sex therapy, and mindfulness training. While there is insufficient evidence with regard to controlled trials studying the efficacy of psychological treatment in women with sexual dysfunction, the available evidence suggests significant improvements in sexual function after intervention with traditional sex therapy and/or cognitive behavioral therapy.

Specific techniques include:

- Sex therapy: Traditional treatment approach with aim to improve individual or couple's sexual experiences and reduce anxiety related to sexual activity.<sup>114</sup>
- Cognitive-behavioral therapy: Incorporates sex therapy components but with larger emphasis on modification of thought patterns that may interfere with sexual pleasure.<sup>114</sup>
- Mindfulness: An ancient eastern practice with Buddhist roots. The practice of "relaxed wakefulness," and "being in the moment," has been found to be an effective component of psychological treatments for sexual dysfunction.<sup>135–137</sup>

## 8.5 | Non-pharmacologic treatments

- Clitoral suction device: Non-pharmacological treatment, this is a battery-operated hand held device, designed to be placed over the clitoris. It provides a gentle adjustable vacuum suction with low-level vibratory sensation. Intended to be used three or more times a week for approximately 5 min at a time, this therapy has been shown to increase blood flow to the clitoral area as well as to the vagina and pelvis.<sup>117</sup> Small non-blinded studies have shown it may significantly improve arousal, orgasm, and overall satisfaction in patients with sexual arousal disorder.<sup>137,138</sup>
- Vaginal dilators: Vaginal forms or inserts, dilators are medical devices of progressively increasing lengths or girths designed to reduce vaginal adhesions after pelvic malignancy treatments or in treatment of vulvar/vaginal pain.<sup>139,140</sup> Can be useful for perineal pain or introital narrowing following pelvic reconstructive repairs, however, routine use after surgery not supported.<sup>141</sup> Dilators can also be used for pelvic floor muscle stretching (ie, Thiele massage) and was found helpful in women with interstitial cystitis and high-tone pelvic floor dysfunctions.<sup>142</sup>

- Vaginal vibrators, external and internal: May be associated with improved sexual function, data controversial.<sup>143,144</sup> Possibility that use of vibrators for self-stimulation may negatively impact sexual function with partner related activity.<sup>145</sup>
- Vaginal exercising devices: Pelvic muscle strengthening tools in form of balls, inserts or biofeedback monitors. May improve pelvic floor muscle tone and coordination by improving ability to contract and relax. Studies are lacking assessing their use without concurrent physical therapy.
- Fractional CO2 laser treatment: Use of thermoablative laser to vaginal mucosa may improve microscopic structure of epithelium.<sup>146–148</sup> This results in increased thickness, vascularity, and connective tissue remodeling, which can improve climacteric symptoms. Although long term data are lacking, some studies have shown significant improvements in subject symptoms of vaginal dryness, burning, itching, and dyspareunia as well as quality of life.<sup>147,149,150</sup>

### 8.5.1 | Alternative treatments

- Acupuncture: Ancient Chinese practice that involves insertion of small needles into various points in the body in an effort to heal pain or treat disease. It may help with stress reduction, pelvic pain, and sexual dysfunction.<sup>122,151,152</sup>

### 8.5.2 | Physical therapy

Manual therapy: Techniques that include stretching, myofascial release, pressure, proprioceptive neuromuscular facilitation, and massage applied externally on the perineum and internally to increase flexibility, release muscle tensions and trigger points in the pelvic floor muscles. It was found to be effective to improve sexual function in women with pelvic floor disorders in recent meta-analysis and systematic review.<sup>17,153,154</sup> These therapies have also been found helpful in women with genito-pelvic pain.<sup>155</sup>

- Pelvic muscle exercises with or without biofeedback: May improve sexual function in women with pelvic floor disorders<sup>154</sup> or pain.<sup>122</sup>
- Dry needling: Placement of needles without injection in myofascial trigger points.<sup>156</sup>
- Trigger point injections
  - i. Anesthetic: Injection of local anesthetics, often Lidocaine, directed by trigger point palpation, can be external or transvaginal.<sup>156–158</sup>
  - ii. Botox: Injection of Botulinum toxin type A, a potent muscle relaxant, into refractory myofascial trigger points to reduce pelvic pain.<sup>122,156,157</sup>

## 8.6 | Prescription treatments

### 8.6.1 | Hormonal

- Estrogen: Available via prescription for both systemic use (oral or transdermal preparations); or locally use (creams, rings, or tablets). May assist with overall well-being, sexual desire, arousal, and dyspareunia.<sup>117,127,159</sup> Role for topical use in treatment of post-surgical atrophy or mesh extrusion.<sup>160</sup>
- Ospemifene: Selective estrogen receptor modulator for treatment of moderate to severe dyspareunia related to vulvar and vaginal atrophy, in postmenopausal women.<sup>161–163</sup> Acts as an estrogen agonist/antagonist with tissue selective effects in the endometrium
- Testosterone: Not approved for use in women in the USA or UK, may be available in other countries. Variety of preparations including transdermal, oral, or pellet administration. Long term safety unknown, studies suggest improvements in satisfying sexual events, sexual desire, pleasure, arousal, orgasm, and decreased distress.<sup>114,127,133</sup>
- Tibolone: Synthetic steroid with estrogenic, progestogenic, and androgenic properties. It is not currently available in the USA. Studies have suggested a positive effect on sexual function with use.<sup>159</sup>
- Prasterone: dehydroepiandrosterone suppository available as a vaginal insert. It has been shown to be efficacious when compared to placebo in decreasing vulvovaginal atrophy.<sup>164</sup>

### 8.6.2 | Non hormonal

- Bremelanotide; formerly PT-141- Melanocortin agonist, initially developed as a sunless tanning agent, utilizes a subcutaneous drug delivery system. Treatment significantly increased sexual arousal, sexual desire, and number of sexually satisfying events with associated decreased distress in premenopausal women with FSD.<sup>165</sup>
- Serotonin receptor agonist/antagonist; Flibanserin-5-hydroxytryptamine (HT)1A receptor agonist and 5-HT2A receptor antagonist, initially developed as antidepressant. Challenges in FDA applications, due to possible long term risks. Studies show improved sexual desire, satisfying sexual events, and reduced distress.<sup>166,167</sup>
- Dual control model in differential drug treatments for hypoactive sexual desire disorder and female sexual arousal disorder:
  - i. Testosterone in conjunction with phosphodiesterase type 5 inhibitor (PDE-5)
  - ii. Testosterone in conjunction with a 5-HT1A agonist

May be able to target physiologic and subjective measures of sexual functioning in a more specific manner. Premise of

two types of HASDD subjects: low sensitivity to sexual cues, or prone to sexual inhibition. Tailoring on demand therapeutics to different underlying etiologies may be useful to treat common symptoms in women with lack of sexual interest and provide the appropriate therapy. Testosterone is supplied as a short acting agent 4 h prior to sexual event to lessen the side effect/risk profile.<sup>168–171</sup>

- Apomorphine: Nonselective dopamine agonist that may enhance response to stimuli.<sup>133,172</sup>
- Antidepressants and Neuropathics: Include tricyclic antidepressants, and anticonvulsants, may be useful in treating sexual pain, and vulvar pain.<sup>120,122</sup>
- Bupropion: Mild dopamine and norepinephrine reuptake inhibitor and acetylcholine receptor antagonist, it may improve desire and decrease distress or modulate Selective Serotonin Reuptake Inhibitor (SSRI) induced FSD.<sup>173</sup>

Supplemental Table S2 presents studies evaluating the effect of various treatments on sexual dysfunction.

## 9 | SURGERY

### 9.1 | The effect of pelvic reconstructive surgery for prolapse and incontinence on sexual health

Women with pelvic floor dysfunction commonly report impaired sexual function, which may be associated with the underlying pelvic floor disorder. Treatment of the underlying disorders may or may not impact sexual function.<sup>13</sup> While both urinary incontinence and pelvic organ prolapse affect sexual function, prolapse is more likely than urinary incontinence to result in sexual inactivity. Prolapse is also more likely to be perceived by women as affecting sexual relations and overall sexual satisfaction. This perception is independent of diagnosis or therapy for urinary incontinence or prolapse.<sup>29,174,175</sup> Very little is known about the impact of fecal incontinence on sexual function.<sup>14</sup> The effect of pelvic reconstructive surgery on sexual function has increased but there is need for more focused research.<sup>30,176</sup> Overall, randomized trials are lacking, varied outcome measures are used among studies.<sup>18</sup> There is a lack of reporting per DSM-IV/DSM 5 categories and a lack of long-term follow-up. Level of Evidence (LOE) is poor in many studies, and sexual dysfunction is usually reported as a secondary outcome measure. While any surgery can impact sexual function postoperatively, most commonly performed pelvic floor surgeries were not designed with the intent to improve sexual function. In general, successful surgical treatment of incontinence or prolapse may improve sexual symptoms associated with the underlying disorder. For example,

coital incontinence improves after sling surgery, but whether it impacts other aspects of sexual function such as orgasm, desire, or arousal is unclear.<sup>18</sup> Surgery for prolapse may improve underlying symptoms of laxity or embarrassment from bulge, which in turn may improve sexual function, but does not seem to have a direct impact on other aspects of sexual function. A small but significant number of patients will develop pain or other sexual disorders following surgery. These pain disorders spring from a variety of causes including those caused by the use of grafts. Prediction of who will develop these pain disorders is challenging. A recent paper which evaluated the effect of vaginal surgery on sexual function reported that women overall reported improved function, decrease in dyspareunia rates, and that de novo dyspareunia rates were low at 5% at 12 months and 10% at 24 months.<sup>177</sup> Nonetheless, assessment of sexual activity and partner status and function prior to and following surgical treatment is essential in the evaluation of surgical outcomes. Because of the negative impact of pain on sexual function, assessment of sexual pain prior to and following procedures should also be undertaken.

## 9.2 | Female genital cosmetic surgery

A number of surgeries have been developed that aim to improve sexual function by altering the appearance and/or the function of female genital tract. Evidence supporting the efficacy and safety of these procedures is lacking. In addition, standardized definitions of these procedures may help foster high quality research, standardization of technique, and outcome measurement in this field, but is currently lacking, and beyond the scope of this document. These procedures include, but are not limited to, labioplasty, vaginoplasty, laser vaginoplasty, perineoplasty, laser rejuvenation, clitoral de-hooding, labia majora augmentation, G spot amplification, laser treatment of vulvovaginal atrophy, and platelet rich plasma treatments.

## 10 | CONSIDERATIONS FOR REPORTING IN RESEARCH

Sexual health should be included as an outcome for reporting research related to pelvic floor dysfunction; this is particularly important in the case of surgical interventions as adverse or advantageous sexual function outcomes would likely impact patient's choice and satisfaction with interventions. The IUGA/ICS Joint Report on terminology<sup>39</sup> for reporting outcomes of surgical procedures for POP described in detail items to be considered when reporting outcomes for prolapse surgical intervention.<sup>18</sup> De novo painful intercourse following prolapse surgery should be classified as described in these documents. While pain and its impact on sexual function is

important, assessments limited to descriptions of sexual pain are not an adequate assessment of sexual health, and absence of pain should not be inferred to indicate that sexual function is intact or changed.

At a minimum, sexual activity status should be assessed. Assessment of sexual activity status should be self-defined and not limited to women who engage in sexual intercourse. In addition, it is important to not assume the gender of the woman's partner. When reporting level of sexual activity, authors should report numbers of all patients who are sexually active (or inactive), with and without pain, pre- and post intervention.

In addition to sexual activity status, its associated level of bother should be documented. Use of validated patient reported outcome questionnaires to further assess the quality of sexual function should also be considered. These and other self-reported outcomes including sexually satisfying events and sexual diaries are described in Section 4, in this document. Assessment of the impact of pelvic floor disorder treatment on women's sexual partners should also be considered. Conditions, among others, that commonly impact sexual function include hormonal status, body image, underlying medical conditions, and history of sexual abuse. Researchers may want to consider inclusion of these outcomes.

## 11 | LIMITATIONS

This document includes a broad overview of terms important in the diagnosis and treatment of women with pelvic floor disorders. We have not included an in-depth description of all sexual disorders as this is beyond the scope of this document. Some disorders such as the persistent vulvar pain and vulvodynia are described elsewhere and we have tried to reference these documents as appropriate.<sup>37</sup> Not all management strategies presented are supported by robust evidence as to their efficacy; we have tried to include the data that supports interventions as it is available. In addition, there are ongoing debates regarding terms and diagnoses. For example, subsequent to the publication of the DSM-5, the International Consultation on Sexual Medicine (ICSM) in 2015,<sup>180</sup> and the International Society for Study of Women's Sexual Health (ISSWSH)<sup>181</sup> published consensus papers on the nomenclature for female sexual dysfunctions. Based on the available evidence regarding clinical presentation, risk factors, and treatment response, both organizations recommended maintaining desire and arousal as distinct and separate clinical entities.

## ACKNOWLEDGMENTS

This document has involved 14 rounds of full review, by co-authors, of an initial draft, with the collation of comments.

The co-authors acknowledged the input to an earlier version of this document by Dr. E Lukacz, Dr. V Handa, Dr S Jha, and Professor Bernard Haylen. The authors further acknowledge the contributions of members of ICS SSC (2017). The authors would also like to acknowledge the helpful comments provided by Elisabetta Constantini, Beth Shelley, Helena Frawley, together with the substantial review by ISSWSH.

## ENDNOTES

<sup>a</sup> Coital incontinence is defined as a complaint of involuntary leakage of urine during or after coitus. Coital incontinence seems to be an aggravating factor that women generally describe as humiliating.<sup>1</sup> The prevalence of urinary incontinence during intercourse has been evaluated to range from 2% to 56%, depending on the study population (for eg, the general population or a cohort of women with incontinence), the definition used (any leakage, weekly, on penetration, during orgasm, only severe leakage) and the evaluation method used (questionnaire, interviews). In a literature review reported in 2002 that covered English-language papers from 1980 to 2001, Shaw<sup>21</sup> reported a 2-10% prevalence of coital incontinence in randomly selected community samples. The physio pathological mechanisms involved have been widely debated,<sup>22</sup> with bladder overactivity conventionally being implicated in orgasmic incontinence and SUI in penetration incontinence. In the past 5 years, studies however, have underlined the role of the urethral sphincter in coital incontinence, which is thought to be crucial even in women with detrusor overactivity and orgasmic incontinence.<sup>23</sup> The penetration form of coital incontinence is largely associated with urodynamics findings of

SUI, whereas orgasmic incontinence might be associated with both detrusor overactivity and SUI.<sup>23,24</sup> Nevertheless, among women with OAB, orgasmic incontinence is more common than penetration incontinence. Coital incontinence on penetration can be cured by surgery in 80% of women with urodynamically proven SUI. Similarly, orgasmic incontinence can respond to treatment with anticholinergics in 59% of women with detrusor overactivity.<sup>25,26</sup>

<sup>b</sup> Rare condition mostly described in women who have genital abnormalities such as micro perforate hymen.<sup>27</sup>

<sup>c</sup> A third of sexually active women with POP complain that their prolapse interferes with sexual function.<sup>29,30</sup> However, it has been shown that women with POP have comparable rate of sexual activity to similarly aged individuals without POP.<sup>31,32</sup>

<sup>d</sup> A recent survey of IUGA members noted that 57% of responders considered vaginal laxity a bothersome condition that impacts relationship happiness and patient's sexual functioning. The most frequently cited (52.6%) location responsible from laxity was the introitus and the majority of respondents (87%) thought both muscle and tissue changes were responsible.<sup>33</sup>

<sup>e</sup> Dyspareunia rates reported in the literature range from 14 % to 18%.<sup>34</sup>

<sup>f</sup> There is often (phobic) avoidance and anticipation/fear/experience of pain, along with variable involuntary pelvic muscle contraction. Patients with vaginismus could present with severe fear avoidance without vulvar pain or fear avoidance with vulvar pain. Structural or other physical abnormalities must be ruled out/addressed.<sup>35</sup> There is controversy of whether or not this term should be retained; the Diagnostic and statistical manual of mental disorders 2013 proposed to replace dyspareunia and vaginismus with the term "Genito-Pelvic Pain/ Penetration Disorder (GPPPD)."<sup>36</sup>

<sup>g</sup> Decreased vaginal lubrication is often involved in pain with sexual activity among postmenopausal women, women with hypo-estrogenic states for other reasons or after pelvic surgery and may result in persistent or recurrent vaginal burning sensation with intercourse (penile or any device).<sup>4</sup>

<sup>h</sup> A non-relaxing pelvic floor that is mainly associated with dyspareunia. See 4.4.<sup>8</sup>

<sup>i</sup> In certain disorders such as genital herpes, vestibulitis, endometriosis, or bladder pain syndrome, pain may also occur after non coital stimulation.<sup>4</sup>

<sup>j</sup> The term "Hispareunia" has been first suggested by Brubaker in one editorial to describe partner dyspareunia after sling insertion.<sup>38</sup>

<sup>k</sup> It has been suggested that a distinction could be made between women with sexual arousal concerns that are psychological or subjective in nature (ie, absence of or markedly diminished feelings of sexual arousal while vaginal lubrication or other signs of physical response still occur), those that are genital (impaired genital sexual arousal—reduction of the physical response), and those that include complaints of both decreased subjective and genital arousal.<sup>1,4</sup>

<sup>l</sup> A normal examination is highly informative to the women and can be of reassurance value.<sup>4</sup>

<sup>m</sup> Other conditions that may influence sexual function are fissures, vulval excoriation, skin rashes, cysts, and other tumors, atrophic changes or lichen sclerosis, scars, sinuses, deformities, condylomata, papillomata, hematoma.

<sup>n</sup> Increased blood flow in the vaginal walls associated with arousal increases the force in the vaginal walls, which drives transudation of

NaCl+-rich plasma through the vaginal epithelium, coalescing into the slippery film of vaginal lubrication and neutralizing the vagina's usually acidic state.<sup>33</sup> Reduced vulvo-vaginal sensitivity has been associated with sexual dysfunction and neurologic impairment.<sup>34</sup>

<sup>o</sup> Sitting often exacerbates the pain, which may be relieved in the supine position. Presentation may be unilateral or bilateral in presentation.

<sup>p</sup> Intra-vaginal or intra-rectal assessment palpation is useful to provide a subjective appreciation of the PFM. PFM tone can be evaluated and defined as hypotonic, normal, and hypertonic,<sup>41</sup> or assessed using Reissing's 7 point scale from -3 to +3.<sup>42</sup> Squeeze pressure or strength during voluntary and reflex contraction can also be graded as strong, normal, weak, absent, or alternatively by using a validated grading system such as Brink's scale or the PERFECT scheme.<sup>42-44</sup> These scales also include quotations of muscular endurance (ability to sustain maximal or near maximal force), repeatability (the number of times a contraction to maximal or near maximal force can be performed), duration, co-ordination, and displacement. Each side of the pelvic floor can also be assessed separately to allow for any unilateral defects and asymmetry.<sup>42</sup> Voluntary muscle relaxation can be graded as absent, partial, complete, delayed.<sup>42</sup> The presence of major morphological abnormalities of the puborectalis muscle may be assessed for by palpating its insertion on the inferior aspect of the os pubis. If the muscle is absent 2-3 cm lateral to the urethra, that is, if the bony surface of the os pubis can be palpated as devoid of muscle, an "avulsion injury" of the puborectalis muscle is likely.<sup>45</sup> Tenderness can be scored during a digital rectal (or vaginal) examination of levator ani, piriformis and internal obturator muscles bilaterally, according to each subject's reactions: 0, no pain; 1, painful discomfort; 2, intense pain; with a maximum total score of 12.<sup>46</sup>

<sup>q</sup> GSM is a syndrome associated with aging that results in alkalization of vaginal pH, changes in the vaginal flora, increased parabasal cell on maturation index and decreased superficial cells on wet mount or maturation index. In addition, there is a loss of collagen, adipose, and water-retention of the vulva which results in loss of elasticity, generalized reduction in blood perfusion of the genitalia. The vaginal epithelium may become friable with petechiae, ulcerations, and bleeding after minimal trauma.<sup>48</sup>

<sup>r</sup> Two classification systems for complications following prolapse surgery, includes the more generic Modified Clavien Dindo<sup>178</sup> and the more specific IUGA ICS classification of complications related to insertion of grafts/prosthesis<sup>40</sup> or use of native tissue.<sup>179</sup> These classification systems did include pain related to prolapse surgery complications which was sub-classified depending on whether pain was at rest, provoked during examination, during sexual activities, physical activities, or spontaneous.

**Introduction and hypothesis** There has been an increasing need for the terminology on the conservative management of female pelvic floor dysfunction to be collated in a clinically based consensus report.

**Methods** This Report combines the input of members and elected nominees of the Standardization and Terminology Committees of two International Organizations, the International Urogynecological Association (IUGA) and the International Continence Society (ICS), assisted at intervals by many external referees. An extensive process of nine rounds of internal and external review was developed to exhaustively examine each definition, with decision-making by collective opinion (consensus). Before opening up for comments on the webpages of ICS and IUGA, five experts from physiotherapy, neurology, urology, urogynecology, and nursing were invited to comment on the paper.

**Results** A Terminology Report on the conservative management of female pelvic floor dysfunction, encompassing over 200 separate definitions, has been developed. It is clinically based, with the most common symptoms, signs, assessments, diagnoses, and treatments defined. Clarity and ease of use have been key aims to make it interpretable by practitioners and trainees in all the different specialty groups involved in female pelvic floor dysfunction. Ongoing review is not only anticipated, but will be required to keep the document updated and as widely acceptable as possible.

**Conclusion** A consensus-based terminology report for the conservative management of female pelvic floor dysfunction has been produced, aimed at being a significant aid to clinical practice and a stimulus for research.

## KEYWORDS

consensus, conservative management, female, pelvic floor dysfunction, terminology

This document is being published simultaneously in *Neurourology and Urodynamics* (NAU) and the *International Urogynecology Journal* (IUJ), the respective journals of the sponsoring organizations, the International Continence Society (ICS) and the International Urogynecological Association (IUGA). IUJ DOI: 10.1007/s00192-016-3123-4

Standardization and Terminology Committees of the IUGA\* and ICS<sup>†</sup>: Bernard T. Haylen\*, Jane Meijlink\*, Elizabeth Shelly\*

Joint IUGA/ICS Working Group on the Conservative Management of Pelvic Floor Dysfunction: Kari Bo, Helena Frawley, Bernard Haylen, Yoram Abramov, Fernando Almeida, Bary Berghmans, Maria Bortolini, Chantale Dumoulin, Mario Gomes, Doreen McClurg, Jane Meijlink, Elizabeth Shelly, Emanuel Trabuco, Carolina Walker, and Amanda Wells

## INTRODUCTION

There is currently no single document addressing the conservative management of female pelvic floor dysfunction in a comprehensive way. The report is based on, and follows on from, the terminology proposed by the International Continence Society (ICS) Standardization of Terminology of Lower Urinary Tract Function,<sup>1</sup> the Standardization of Terminology of Pelvic Floor Muscle Function and Dysfunction: Report from the Pelvic Floor Clinical Assessment group of the International Continence Society,<sup>2</sup> and the International Urogynecological Association (IUGA)/International Continence Society (ICS) Joint Report on the Terminology for Female Pelvic Floor Dysfunction.<sup>3</sup>

The terminology in current use related to conservative management generally lacks uniformity, often because different disciplines use their own terminology. The range of terms in use can lead to uncertainty, confusion, and unintended ambiguity. It hampers the ability to build a body of literature concerning conservative interventions, e.g., the terms “behavioral therapy,” “lifestyle intervention,” “conservative treatment,” “nonsurgical treatment,” “physiotherapy,” “biofeedback,” and “pelvic floor muscle exercise” are often used interchangeably and, at times, incorrectly, to describe both the same and different interventions. A more standardized terminology would aid interdisciplinary communication and understanding.

Existing published reports address some of the aspects of this topic, but there are some areas of terminology currently lacking standardization, e.g., Messelink et al.<sup>2</sup> and Haylen et al.<sup>3</sup> refer to evaluation and diagnostic terminology, but not to treatment terminology.

There is a need for a more extensive description of the management of the pelvic floor and pelvic floor muscle (PFM) dysfunction than is currently provided in existing terminology reports. With the development of the evidence base for conservative therapies in the management of pelvic floor dysfunction (PFD), especially treatment of conditions such as incontinence and pelvic organ prolapse (POP), terminology linked with these managements has evolved, but with regional and discipline variations. A consensus on currently accepted terminology is required. Elements in the title of the document need to be defined:

Conservative: restricted to nonsurgical and nonpharmacological approaches.

Management: includes the following aspects:

- a) Assessment: including history and physical examination and investigations
- b) Diagnosis
- c) Prevention
- d) Treatment of pelvic floor dysfunction

Pelvic floor: structures located within the bony pelvis, i.e., urogenital and anorectal viscera, PFM and their connective tissues, and nerves and blood vessels.

Pelvic floor dysfunction: following on from Messelink et al.'s report from the Pelvic Floor Clinical Assessment Group of the ICS,<sup>2</sup> this report will focus on the terminology of the management of pelvic floor function and dysfunction, including bladder and bowel dysfunction, pelvic organ prolapse (POP), sexual dysfunction, and pelvic pain.<sup>4</sup> Terminology regarding pelvic pain and anorectal dysfunction related to PFM dysfunction aligns with the current working groups on chronic pelvic pain and anorectal dysfunction. Terminology includes symptoms, signs, and investigations (expanding on Messelink et al.'s paper<sup>2</sup>; diagnoses of PFM-related conditions (avoiding duplication with Haylen et al.<sup>3</sup>); prevention and treatment (including new therapies, e.g., exercise and adjunctive therapies, including equipment, and lifestyle modifications not covered by Messelink et al.<sup>2</sup> or Haylen et al.<sup>3</sup>

Additional descriptions related to the terms used in this manuscript are:

Clinicians/practitioners: conservative management of PFD may be provided by clinicians or practitioners of different disciplines, commonly physiotherapists/physical therapists, nurses, midwives, and medical doctors. However, other professions, e.g., fitness instructors and personal trainers, may also play a role in education, health promotion, and prevention of PFD. Terminology related to the accepted names of professions and the different types of therapies must be specified and distinguished (e.g., “physiotherapy” as a management provided by a registered physiotherapist, as distinct from “conservative therapy” and “exercises”/“biofeedback,” which may be provided by any clinician). The emphasis in this document will be on management commonly undertaken by clinicians practicing conservative management.

Multidisciplinary approach: relating to, or involving, two or more disciplines that are usually considered distinct,<sup>5</sup> e.g., physical therapy, urology, gynecology

Gender: with the increasing specificity and complexity of female diagnosis and management it can be argued that a gender-specific report is needed. However, many of the terms defined in this report are not gender-specific and are the same for males, e.g., PFM training and electrical stimulation. This report does not preclude an additional future report on male pelvic floor dysfunction

## METHODOLOGY

All working group members were asked to provide terms that they knew existed in the area. After the first “brainstorming activity,” all terms were listed and grouped according to introduction, symptoms, signs, examination methods, investigations, diagnosis, prevention, and treatment. All members were given the text to which to add

more terms. Additional searching for omitted terms in existing terminology papers of the ICS and IUGA, Cochrane reviews, and the 2013 ICI document<sup>6</sup> was undertaken. Existing definitions of established terms from general medicine,<sup>7,8</sup> physiotherapy,<sup>5</sup> and exercise science were used where available. Only in situations where there was no existing terminology were new definitions introduced. We have not referred to or described the responsiveness, reliability, and validity of the measurement methods of symptoms, signs, and evaluations, nor have we acknowledged the evidence for the treatment efficacy of any of the therapies defined.

Agreement on the definitions was reached by consensus. Wherever possible, evidence-based principles were followed. However, this was a challenge in conservative management, as there are many suggested therapies that do not have proven effectiveness.<sup>9,10</sup> Discussion meetings with representatives of the IUGA and ICS were held at the following annual meetings: IUGA Brisbane 2012, ICS Beijing 2012, IUGA Dublin 2013, ICS Barcelona 2013, IUGA-AUGS Washington DC 2014, and IUGA Nice 2015.

It is recommended that acknowledgment of these standards in written publications related to the conservative management of female pelvic floor dysfunction is stated as follows: "Methods, definitions, and units conform to the standards jointly recommended by the IUGA/ICS Joint Report on the Terminology for the Conservative and Nonpharmacological Management of Female Pelvic Floor Dysfunction, except where specifically noted."

## ASSESSMENT

### Symptoms

Symptom: any morbid phenomenon or departure from the normal in structure, function or sensation, experienced by the woman and indicative of disease or a health problem. Symptoms are either volunteered by, or elicited from the individual, or may be described by the individual's caregiver.<sup>3</sup>

#### *Existing (defined) symptoms*

1. Urinary incontinence (UI) symptoms<sup>3</sup>
2. Bladder storage symptoms<sup>3</sup>
3. Sensory symptoms<sup>3</sup>
4. Voiding and postmicturition symptoms<sup>3</sup>
5. POP symptoms<sup>3</sup>
6. Symptoms of sexual dysfunction<sup>3</sup>
7. Symptoms of anorectal dysfunction<sup>3, endnote 1</sup>
8. Lower urinary tract infection UTI<sup>3</sup>

#### *Lower urinary tract pain and/or other pelvic pain*<sup>endnote 2</sup>

1. Pain (in general): "an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage".<sup>11</sup>
2. Tenderness: sensation of discomfort with or without pain; discomfort elicited through palpation, indicates unusual sensitivity to pressure or touch.<sup>12</sup>
3. Acute pain: pain related to acute trauma, infection or other well-defined disease processes or conditions.
4. Chronic pain: persistent or continuous/recurrent pain for at least 6 months. If non-acute and central sensitization pain mechanisms are well documented, then the pain may be regarded as chronic, irrespective of the time period.<sup>13,14</sup>
5. Myalgia: muscle pain. Pelvic floor myalgia (a symptom) may be present with or without a change in PFM tone (a sign).<sup>endnote 3</sup>
6. Myofascial pain: pain caused by the presence of trigger points within muscles or their fascia.<sup>15, endnote 4</sup>

### Signs

Sign: any abnormality indicative of disease or a health problem, discoverable on examination of the patient; an objective indication of disease or a health problem.<sup>1</sup>

#### *Existing (defined) signs*

1. Urinary incontinence signs:<sup>3</sup>
  - a) UI<sup>3</sup>
  - b) Stress (urinary) incontinence<sup>3</sup>
  - c) Urgency (urinary) incontinence<sup>3</sup>
  - d) Extraurethral incontinence<sup>3</sup>
  - e) Stress incontinence on prolapse reduction (occult or latent stress incontinence)<sup>3</sup>
2. Pelvic organ prolapse signs:<sup>3</sup>
  - a) Uterine/cervical prolapse<sup>3</sup>
  - b) Vaginal vault (cuff scar) prolapse<sup>3</sup>
  - c) Anterior vaginal wall prolapse<sup>3</sup>
  - d) Posterior vaginal wall prolapse<sup>3</sup>
3. Other pelvic examinations/signs:<sup>3</sup>
  - a) Vulval abnormalities<sup>3</sup>
  - b) Urethral mucosal prolapse<sup>3</sup>
  - c) Urethral caruncle<sup>3</sup>
  - d) Urethral diverticulum<sup>3</sup>
  - e) Total vaginal length (TVL): the distance from the posterior fornix to the hymen.<sup>16</sup>
  - f) Valsalva maneuver: the action of attempting to exhale with the nostrils and mouth, or glottis closed.<sup>7</sup> Valsalva

is usually performed with digital closure of the nose, as when trying to equalize pressure in an airplane. Straining/bearing down may have a similar meaning to Valsalva; however, in practice, straining/bearing down may be interpreted as meaning pushing downward and trying to relax the pelvic floor, as when defecating.

- g) Bimanual pelvic examination<sup>3</sup>
  - h) Perineal elevation: inward (ventrocephalad) movement of the vulva, perineum, and anus during, for example, PFM contraction.
  - i) Perineal descent: excessive dorsocaudal movement of the vulva, perineum, and anus, for example, during coughing, Valsalva or straining.<sup>3,17</sup>
  - j) Trophic: promoting cellular growth, differentiation, and survival.<sup>8</sup> This is the normal status of an organ, tissue or cell with regard to nutrition, size, number, form, and function. A trophic urogenital tract is usually well-estrogenized.
  - k) Atrophic: decrease from previous normal size of the body or a part, cell, organ, or tissue. An organ or body part's cells may be reduced in number, size or both. Atrophy of some cells and organs is normal at certain points in the life cycle. Other causes include malnutrition, disease, disuse, injury, and hormone over- or underproduction.<sup>8, endnote 5</sup>
4. Anal signs<sup>18</sup>
5. Abdominal signs
- a) Bladder fullness/retention: abdominal palpation or suprapubic percussion may indicate a full bladder; however, in overweight patients this may not be easily detected.
  - b) Pelvic bone irregularities: indication of a previous fracture or sacral agenesis.
6. Neurological signs: abnormalities of the nervous system detected by physical examination that reflect an underlying neurological disease or injury. Examples of abnormal signs may include altered sensation, muscle tone or reflexes. If present, the patient should be referred for a full neurological examination.

#### *Pelvic floor muscle function signs*

1. Normal PFM: have a level of constant resting tone (except just before and during voiding and defecation), symmetry, and the ability to voluntarily and involuntarily contract and relax.
2. Normal PFM contractile function: a constriction and inward (ventrocephalad) movement of the pelvic openings. Normal, well-functioning pelvic floor muscles may demonstrate some (controlled or limited) downward dorsal perineal movement in response to increased intra-abdominal pressure in the absence of incontinence or POP.
3. Muscle tone: state of the muscle, usually defined by its resting tension, clinically determined by resistance to passive movement.<sup>19–21</sup> Muscle tone has two components: the contractile component, created by the low-frequency activation of a small number of motor units, and the viscoelastic component, which is independent of neural activity and reflects the passive physical properties of the elastic tension of the muscle fiber elements and the osmotic pressure of the cells.<sup>19, endnote 6</sup>
  - a) Hypertonicity: an increase in muscle tone related to the contractile or viscoelastic components that can be associated with either elevated contractile activity and/or passive stiffness in the muscle.<sup>20,22</sup> The terms neurogenic hypertonicity and non-neurogenic hypertonicity are recommended to describe the diagnosis and inform management.
  - b) Hypotonicity: a decrease in muscle tone related to the contractile or viscoelastic components that can be associated with either reduced contractile activity and/or passive stiffness in the muscle. The terms neurogenic hypotonicity and non-neurogenic hypotonicity are recommended to describe the diagnosis and inform management.<sup>endnote 7</sup>
4. Stiffness: resistance to deformation.<sup>23</sup> Passive elastic stiffness is defined as the ratio of the change in the passive resistance or passive force ( $\Delta F$ ) to the change in the length displacement ( $\Delta L$ ) or  $\Delta F/\Delta L$ .<sup>24</sup> The term should only be used if stiffness is measured quantitatively, such as with the use of instruments such as dynamometry or myotonometry.
5. Tension: may have a similar meaning to tone and stiffness. Muscle tension can be increased or decreased because of exogenous factors such as the amount of pressure applied and endogenous factors such as thickness/cross-sectional area of the muscle itself, fluid present within the muscle (swelling, inflammation), position (e.g., standing versus sitting) or increased neural activity.
6. Spasm: persistent contraction of striated muscle that cannot be released voluntarily. If the contraction is painful, this is usually described as a cramp. Spasms occur at irregular intervals with variable frequency and extent,<sup>25</sup> and over days or weeks may lead to a contracture.
7. Contracture: an involuntary shortening of a muscle. Clinically, a muscle cramp and contracture may appear similar; however, contractures are electrically silent.<sup>26</sup>
8. Cramp: a painful involuntary muscle contraction that occurs suddenly and can be temporarily debilitating. Pain is intense and localized. It tends to occur when the muscle

- is in the shortened position and contracting, is generated by motor units, and displays a high firing rate (20–150 Hz).<sup>26, endnote 8</sup>
9. Fasciculation: a single, spontaneous, involuntary discharge of an individual motor unit. The source generator is the motor unit or its axon, before its terminal branches. Fasciculations display an irregular firing pattern of low frequency (0.1–10 Hz).<sup>5,26</sup> Clinically, fasciculations are recognized as individual brief twitches. They may occur at rest or after muscle contraction and may last several minutes.
  10. Tender point: tenderness to palpation at soft-tissue body sites.<sup>19</sup>
  11. Trigger point (TrP): a tender, taut band of muscle that can be painful spontaneously or when stimulated.<sup>27</sup> The taut band is electrically silent.<sup>endnote 9</sup>
  12. Pelvic floor muscle dyssynergia<sup>2</sup>: incoordination of the PFM and another muscle group during a functional activity, for example, the pelvic floor muscles may not relax appropriately during micturition or defecation.
  13. Nonfunctioning PFM (modified from Messelink et al.)<sup>2</sup>: a situation in which there is no PFM action measurable either on instruction to contract (inability) or as the absence of an automatic response to an increase in intra-abdominal pressure. This condition can be based on any pelvic floor symptom and on the sign of a noncontracting or nonrelaxing pelvic floor.
  14. Pelvic floor muscle injury (PFMI): on clinical palpation, PFMI is diagnosed when one or more of the following is present:
    - a) A discontinuity of the puborectalis muscle at its attachment to the inferior pubic ramus.<sup>28</sup>
    - b) A distance of >3.5 finger widths between the two sides of puborectalis muscle insertion.<sup>29,30</sup>
    - c) A gap in the continuity of the pubovisceral muscle between the pubic rami and the anorectum.<sup>31</sup>
  15. Muscle action characteristics:
    - a) Maximal voluntary contraction (MVC): the attempt to recruit as many fibers in a muscle as possible for the purpose of developing force.<sup>32</sup> MVC of the pelvic floor can be assessed by vaginal palpation, manometers, and dynamometers.<sup>endnote 10</sup>
    - b) Muscle strength: force-generating capacity of a muscle.<sup>5</sup> It is generally expressed as maximal voluntary contraction measurements and as the one-repetition maximum (IRM) for dynamic measurements.<sup>32–34</sup>
    - c) Local muscle endurance: the ability to sustain near maximal or maximal force, assessed by the time a patient is able to maintain a maximal static or isometric contraction, or the ability to repeatedly develop near maximal or maximal force determined by assessing the maximum number of repetitions the patient can perform at a given percentage of IRM.<sup>35</sup>
    - d) Muscle power: the explosive aspect of strength; the product of strength and speed of movement (force × distance/time).<sup>35</sup>
    - e) Co-ordination: property of movement characterized by the smooth and harmonious action of groups of muscles working together to produce a desired motion.<sup>5</sup>
    - f) Motor control: the ability of the nervous system to control or direct the muscles in purposeful movements and postural adjustment by selective allocation of muscle tension across appropriate joint segments.<sup>5,36</sup>
    - g) Submaximal contraction: all contractions without maximal effort, expressed as a percentage of IRM.
    - h) Synergistic contraction: the combination of several muscle actions that serve to optimally achieve a motor task.<sup>37</sup>
    - i) Co-contraction: contraction of two or more muscles at the same time. Co-contraction of muscles can be synergistic (e.g., resulting in an augmentation of motor activity) or it could be counterproductive to normal function (e.g., contraction of antagonistic muscles resulting in abnormal movement or training other muscles instead of the targeted ones, e.g., training of gluteal muscles instead of the PFM).
    - j) Antagonistic contraction: contraction of muscle/muscle groups with the opposite action to the desired action (activity that hinders the targeted muscle/muscle group from contracting).
  16. Other:
    - a) Hypertrophy: the increase in size (volume) of the muscle fibers.<sup>37</sup>
    - b) Atrophy: the decrease in size of muscle fibers as a result of inactivity, illness or aging.<sup>38</sup>
    - c) Bulk: the absolute volume of a muscle measured using imaging techniques such as anatomical magnetic resonance imaging and ultrasound.<sup>39</sup>
    - d) Anatomic cross-sectional area: for an individual muscle, the largest cross-sectional area along the length of that muscle and 90° on the muscle length.<sup>7</sup>
    - e) Physiological cross-sectional area: the total area of cross-section perpendicular to the muscle fibers.<sup>7</sup>
    - f) Flexibility: the ability of a muscle to lengthen and allow one joint (or more than one joint in a series) to move through a range of motion. Loss of flexibility is defined as a decrease in the ability of a muscle to deform.<sup>40</sup>
    - g) Proprioception: sensory information from receptors of muscles, joints, capsules, and ligaments that provides information related to posture and movement.<sup>41</sup>

- h) Exteroception: sensory information from receptors in the skin registering touch, vibration, heat, and cold.<sup>41</sup>

## INVESTIGATIONS AND IMAGING

All methods and devices used for assessments (e.g., palpation, manometers, dynamometers, EMG, urodynamics, ultrasound, and magnetic resonance imaging [MRI]) must be described in detail, and their responsiveness (ability to detect small changes), reliability and validity should be reported.<sup>42</sup>

### Existing (defined) investigations

#### Urodynamics

Urodynamics is the functional study of the lower urinary tract<sup>3</sup>:

1. Uroflowmetry<sup>3</sup>
2. Post-void residual (PVR) urine volume<sup>3</sup>
3. Cystometry<sup>3</sup>
4. Pressure flow study<sup>3</sup>
5. Assessment of urethral function<sup>3</sup>
  - a) Urethral pressure measurement<sup>3</sup>
  - b) Abdominal leak point pressure (ALPP)<sup>3</sup>

#### Frequency–volume chart

The frequency–volume chart (FVC) records the time of each micturition and the volume voided for at least 24 h, although 2 or 3 days of recording (not necessarily consecutive) generally provide more useful clinical data.<sup>3</sup>

1. Bladder diary: in addition to the FVC, a bladder diary includes fluid intake, pad usage, number incontinence episodes, and the degree of incontinence.<sup>3</sup>

#### Pad testing

Quantification of the amount of urine lost over the duration of testing, by measuring the increase in weight of the perineal pads used (weighed pre- and post-testing).<sup>3</sup>

#### Ultrasound imaging

1. PFMI: PFMI is diagnosed on ultrasound when at least one of the following is present:
  - a) Undetected puborectalis-to-ipsilateral sidewall attachment on any of the three central slices (full avulsion)

- b) Undetected puborectalis-to-ipsilateral sidewall attachment on at least one slice (partial avulsion)<sup>43</sup>
  - c) A levator–urethra gap (LUG) of greater than 2.5 cm<sup>44</sup>
2. PFM position in the pelvis: can be measured in the sagittal plane in relation to defined landmarks, and may be related to PFM dysfunction (elevated or descended pelvic floor).
  3. Hiatal dimension: is the cross-sectional area of the pelvic floor/levator hiatus, including anteroposterior and transverse distances (Fig. 1).

#### Radiological imaging

Videocystourethrography (VCU); intravenous urography (IVCU); micturating cystography (MCU); defecography; colpocystodefecography.

#### Magnetic resonance imaging

1. PFM injury: can represent a full spectrum, from disruption of a single fascicle, to complete disruption of the muscle origin. At present, there is no universally accepted system for the diagnosis and evaluation of the extent of the injury. Essentially, abnormalities are judged to have occurred

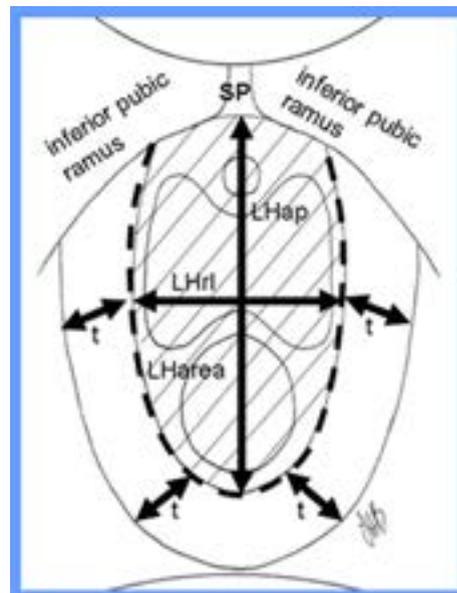

FIG. 1 Levator hiatal dimensions measured using transperineal ultrasound (reproduced with permission from Ingeborg Hoff Braekken). LHap levator hiatus antero-posterior, LHrl levator hiatus right-left, LHarea levator hiatus area, SP symphysis pubis, *t* pubovisceral muscle thickness

when the morphology of the pubococcygeal portion of the levator ani muscle deviates from what is seen in normal nulliparous women.<sup>45</sup> Several groups have studied and defined levator damage on MRI when one or more of the following is present: absence of pubococcygeal muscle fibers in at least one 4-mm section, or two or more adjacent 2-mm sections in both the axial and the coronal planes.<sup>46</sup> The degree of injury can be assessed based on the amount of muscle involved in the injury, with reasonable repeatability among different examiners in a single group.<sup>47</sup> More than half the expected muscle bulk is associated with the presence of POP.<sup>48</sup>

2. PFM position in the pelvis: location of the PFM in the sagittal plane in relation to defined landmarks. They may be elevated or descended.

### Palpation

The process of using fingers/hands as part of assessment, to gather information about the tissues. Digital palpation of the PFM is described by Messelink et al. (Fig. 2)<sup>2</sup>.

**FIG. 2** Digital palpation of the pelvic floor muscles (reproduced with permission from subjects in the photo and photographer Andreas Birger Johansen)

### Manometer

A manometer is a device for measuring pressure.

#### *Pelvic floor manometry*

Measurement of resting pressure or pressure rise generated during contraction of the PFM using a manometer connected to a sensor, which is inserted into the urethra, vagina or rectum. Pelvic floor manometric tools measure pressure in mmHg, hPa or cmH<sub>2</sub>O.<sup>42, endnote 11</sup> Conversion of data to the international standard unit of measurement (hPa) is recommended (Figs. 3, 4).

1. Perineometer: the first PFM vaginal pressure device connected to a manometer developed by Kegel.<sup>49, endnote 12</sup>

### Dynamometer

A dynamometer is an instrument that measures power or force.<sup>8</sup>

#### *Pelvic floor dynamometry*

Measurement of PFM resting and contractile forces using strain gauges mounted on a speculum (a dynamometer), which is inserted into the vagina.<sup>50</sup> Dynamometry measures force in Newton units ( $N = 1 \text{ kg} \times \text{m/s}^2$ ) (Figs. 5, 6).<sup>endnote 13</sup>

### Electromyography

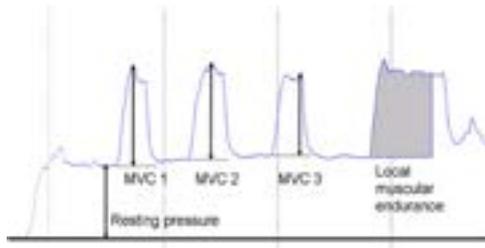

Electromyography (EMG) is the recording of electrical potentials generated by the depolarization of muscle fibers.

#### *Electromyographic diagnosis*

Electromyographic diagnosis is made by evaluating the state of the muscle (muscle pathology) by recording and analyzing the electrical activity generated by the muscle.<sup>36, endnote 14</sup>

**FIG. 3** Peritron manometer (reproduced with permission from Laborie)

**FIG. 4** Graphical illustration of pelvic floor muscle manometry readings (reproduced with permission from illustrator Ingeborg Hoff Braekken). MVC maximum voluntary contraction, 1/2/3 repetition 1/2/3

1. Intramuscular EMG: insertion of a wire or needle electrode into the muscle to record motor unit action potentials.<sup>endnote 15</sup>
2. Surface electromyography: electrodes placed on the skin of the perineum or inside the urethra, vaginal or rectum (Fig. 7).<sup>endnote 16</sup>

**Pain assessment**

*Pain evaluation*

Pain evaluation consists of baseline and ongoing regular evaluation of severity, quality of life, thoughts, emotions, and behavior associated with the pain (via direct consultation or questionnaires) and investigations to identify well-defined/confusable/non-pain syndromes.

1. Pain measurement: pain can only be measured subjectively. Patient-reported outcome measures include:
  - a) Numerical rating scale (NRS), from 0 (no pain) to 10 (extreme pain), with half-points marked.<sup>51,52</sup>

**FIG. 5** Ann Arbor, USA, dynamometer speculum. Note that the bills of the speculum are covered by a condom when in use (reproduced with permission from J.A. Ashton-Miller, R. Zielinski, J.O. DeLancey, J.M. Miller)

**FIG. 6** Montreal, Canada, pelvic floor dynamometer (reproduced with permission from Chantale Dumoulin)

- b) Visual analog scale (VAS), a 10-cm line with the same labels at the ends
- c) A simple verbal rating scale can be used, e.g., “none,” “mild,” “moderate,” “severe.”<sup>endnote 17</sup>
2. Pain mapping: identifying pain generators through diagnostic procedures such as questionnaires, digital palpation, EMG, quantitative sensory threshold measurement, trigger point injections, nerve blocks, and imaging.
  - a) Questionnaires: several pain questionnaires can be used in the evaluation of musculoskeletal pain in the pelvis; the choice will be determined by which is most appropriate to the presenting pelvic floor dysfunction: McGill Pain Questionnaire,<sup>53</sup> Pelvic Floor Distress Inventory (PFDI),<sup>54</sup> Female Sexual Function Index,<sup>55</sup> Female Sexual Distress Scale,<sup>56</sup> Pelvic Pain and Urgency/Frequency Questionnaire.<sup>57</sup>
  - b) Pain chart/body map: a simple line drawing of an outline of the front and back (or relevant body part) of the human body, onto which the patient sketches or ticks or marks areas of bodily pain to demonstrate the site and extent of perceived pain.<sup>58</sup>
  - c) Pain checklist: a list of anatomical locations from which the patient selects sites that are relevant to his/her complaint.

**FIG. 7** Verity Medical NeuroTrac Myoplus Pro surface electromyography biofeedback apparatus (also incorporating electrical stimulation (reproduced with permission from Quintet, Norway)

- d) Measurement of muscle tone: there is no single tool that is able to measure all components of muscle tone. Some tools may be able to measure aspects of tone such as contractility, stiffness or elasticity. Instrumented methods may play a role in the valid and reliable evaluation of muscle tone, e.g., surface electromyography (sEMG), wire and concentric electromyography, dynamometry, real-time ultrasound, elastometry, myotonometry.
- e) TrP injection or needling: a diagnostic test to confirm if the identified TrP is a pain generator. The technique is the same as that used in TrP treatment.
- f) Imaging: tissue-specific evaluation to identify if morphological trauma or deficit is present, which may relate to the presenting pain. Types of imaging may include X-ray, ultrasound, and MRI.

## DIAGNOSES

Diagnosis: the act or process of identifying or determining the nature and cause of a disease or injury through evaluation of patient history, examination, review of laboratory data, and the opinion derived from such an evaluation.<sup>59</sup>

A diagnosis of female PFD is based on the information obtained from the patient's symptoms, signs, and any relevant diagnostic investigations. For the terminology of the six most common PFD diagnoses—urodynamic stress urinary incontinence, detrusor overactivity (DO), POP, voiding dysfunction, bladder oversensitivity, and recurrent UTI—the reader is directed to Haylen et al.<sup>3</sup>

### Additional anorectal diagnosis

1. Local (fissures, hemorrhoids)<sup>18</sup>
2. Fecal incontinence<sup>18</sup>
3. Obstructed defecation syndrome<sup>18</sup>
4. Rectocele<sup>18</sup>
5. Enterocele/sigmoidocele<sup>18</sup>
6. Intussusception<sup>18</sup>
7. Internal mucosal prolapse<sup>18</sup>
8. Abscess/fistula<sup>18</sup>

### Pain syndromes

1. Chronic pelvic pain syndrome (CPPS): persistent pain perceived in structures related to the pelvis, in the absence of proven infection or other obvious local pathology that may account for the pain. It is often associated with negative cognitive, behavioral, sexual or emotional consequences,

and with symptoms suggestive of lower urinary tract, sexual, bowel or gynecological dysfunction.<sup>14</sup>

2. Chronic PFM pain syndrome: the occurrence of persistent or recurrent, episodic, pain in the PFM, in the absence of a proven or well-defined local pathological condition. It is often associated with negative cognitive, behavioral, sexual or emotional consequences, and with symptoms suggestive of lower urinary tract, sexual, bowel or gynecological dysfunction.<sup>14, endnote 18</sup>

### Female sexual dysfunction

Any departure from normal sensation and/or function expressed by a woman during sexual activity.<sup>3</sup>

1. Dyspareunia<sup>3</sup>
2. Obstructed intercourse<sup>3</sup>
3. Vaginal laxity<sup>3</sup>

## TREATMENTS

### General terms

#### *Behavioral*

The way someone behaves, especially toward other people, and behavioral science is the study of human behavior.<sup>60</sup>

1. Behavior therapy: a type of psychotherapy that attempts to modify observable maladjusted patterns of behavior by substituting a new response or set of responses to a given stimulus. The treatment techniques involve the methods, concepts, and procedures derived from experimental psychology; they include assertiveness training, aversion therapy, contingency management, flooding, modeling, operant conditioning, and systematic desensitization. It is also called behavior modification.<sup>12, endnote 19</sup>
2. Cognitive therapy: any of the various methods of treating mental and emotional disorders that help a person to change their attitudes, perceptions, and patterns of thinking, from rational to realistic thoughts about the self and situations. The technique is often used in association with behavior therapy principles.<sup>12</sup>
3. Cognitive behavior therapy (CBT): Cognitive techniques are often used in association with behavior therapy principles; this is called cognitive behavior therapy (CBT).

#### *Physiotherapy*

Physiotherapy involves “using knowledge and skills unique to physiotherapists” and “is the service only provided

by, or under the direction and supervision of, a physiotherapist".<sup>61, endnote 20</sup>

### *Adherence*

Adherence is the extent to which a client/patient's behavior corresponds to the agreed treatment protocol and/or regime as recommended by their healthcare provider.<sup>62</sup> It does not refer to the intervention itself; rather, the patient's commitment to undertaking the behavioral change to adhere to the intervention.<sup>endnote 21</sup>

### *Compliance*

Compliance is the extent to which a client/patient's behavior matches, or complies with, their healthcare provider's recommended treatment protocol and/or regime.<sup>63, endnote 22</sup>

### **Combination therapy (also known as polytherapy, multimodal therapy or combined modality therapy)**

Combination therapy is the use of more than one intervention concurrently to treat a single condition with one or multiple symptoms, for example, a combination of medication with PFM training (PFMT).

1. **Adjunctive therapies:** any treatment or modality used to augment or assist the main treatment. In conservative treatments, adjunctive therapies often refer to equipment or a secondary therapy used to supplement the effect of the primary therapy, e.g., biofeedback-assisted PFMT or neuromuscular electrical stimulation to augment PFMT.

### *Prevention*

Prevention is the act of preventing or decreasing the risk of disease or disability. Activities that are directed toward slowing or stopping the occurrence of both mental and physical illness and disease, minimizing the effects of a disease or impairment on disability, or reducing the severity or duration of an illness.<sup>5</sup>

1. **Primary prevention:** prevention of the development of disease in a susceptible or potentially susceptible population through such specific measures as general health promotion efforts.<sup>5</sup>
2. **Secondary prevention:** efforts to decrease the duration of illness, reduce the severity of diseases, and limit the sequelae through early diagnosis and prompt intervention.<sup>5</sup>
3. **Tertiary prevention:** efforts to limit the degree of disability and promote rehabilitation and restoration of

function in patients/clients with chronic and irreversible diseases).<sup>5</sup>

## **Lifestyle**

### *Lifestyle modification*

Lifestyle modification is the application of interventions in the management of lifestyle-related health problems, e.g., change to a healthy diet and regular participation in physical activity and smoking cessation. The following lifestyle modifications may be applied to treat pelvic floor dysfunctions, either in combination with other therapies or as "stand-alone" treatments.

1. **Fluid consumption/restriction:** fluid consumption is the intake of fluid over 24 h. Fluid restriction is the limitation of fluid to a prescribed amount over a period of 24 h. These measures are often undertaken as part of a bladder training process.
2. **Dietary modification:** an alteration or adjustment of food to treat bowel disorders (e.g., constipation and fecal incontinence) or urinary disorders (e.g., incontinence or urgency), for example, increasing fiber to treat constipation. The specifics of the dietary changes should be described.
3. **Elimination diet:** a form of dietary modification. A diet designed to detect what ingredient in the food causes symptoms in the patient, food items to which the patient may be sensitive are withdrawn separately and successfully from the diet until the item that causes the symptoms is discovered. This is used frequently in patients with fecal incontinence, urinary urgency and urinary urgency incontinence (bladder diet).<sup>64,65</sup>
4. **Physical activity:** any body movement produced by the skeletal muscles that results in a substantial increase above resting energy expenditure. Physical activity can be done at work, as transportation, as household and other chores, and as leisure time/sport and fitness activities.<sup>66, endnote 23</sup>

### *Counseling*

Counseling is the provision of professional assistance and guidance in resolving personal or psychological problems,<sup>7</sup> and may be part of any clinician's management.

1. **Patient education:** providing patients with knowledge and understanding of their condition, thereby empowering them to play an active role in its management (Fig. 8).<sup>67</sup>
2. **Motivational interviewing:** a directive, client-centered counseling style for eliciting behavior change by helping clients to explore and resolve ambivalence. Compared with nondirective counseling, it is more focused and

**FIG. 8** Patient education of pelvic floor muscle function (reproduced with permission from *Women's and Men's Health Physiotherapy*)

goal-directed. The examination and resolution of ambivalence is its central purpose, and the counselor/clinician is intentionally directive in pursuing this goal.<sup>68</sup>

3. Coping strategies: intervention aimed at helping patients to live with the condition in the best way possible under the circumstances, to regain a feeling of being in control, to adjust their lifestyle where necessary, and to take a positive rather than a negative approach.<sup>67</sup>
4. Self-care: the set of activities that comprise daily living, such as bed mobility, transfers, ambulation, dressing, grooming, bathing, eating, and toileting.<sup>5</sup>
5. Self-help: various methods by which individuals attempt to remedy their difficulties without making use of formal care providers.<sup>5</sup>
6. Self-efficacy: an individual's belief that he or she is capable of successfully performing a certain set of behaviors.<sup>69</sup>

### Scheduled voiding regimes

Toileting on a fixed schedule around the patient's normal voiding pattern, which includes a progressive voiding schedule using relaxation and distraction techniques for urgency suppression.<sup>70</sup> Scheduled voiding regimes have been categorized as: bladder training, timed voiding, habit training, and prompted voiding.<sup>71</sup>

#### Bladder training

In the past, bladder training has also been referred to as bladder drill, bladder discipline, bladder re-education, and bladder retraining. It consists of a program of patient education, along with a scheduled voiding regimen with gradually adjusted voiding intervals. Specific goals are to correct faulty habit patterns of frequent urination, improve control over bladder urgency, prolong voiding intervals, increase bladder capacity, reduce incontinent episodes, and

restore patient confidence in controlling bladder function (modified from Moore et al.<sup>71</sup>),<sup>endnote 24</sup>

#### Timed voiding

Timed voiding is a passive toileting assistance program, initiated and maintained by caregivers for patients who cannot participate in independent toileting. It is a fixed voiding schedule.<sup>71</sup>

#### Habit training

Habit training consists of a toileting schedule matched to the individual's voiding patterns based on their voiding diary. The toileting schedule is assigned to fit a time interval that is shorter than the person's normal voiding pattern and precedes the time period when incontinent episodes are expected.<sup>71</sup>

#### Prompted voiding

Prompted voiding is used to teach people to initiate their own toileting through requests for help and positive reinforcement from caregivers, often done in combination with a scheduled voiding regimen, typically every 2 h.<sup>71</sup>

#### Other techniques for bladder and bowel control

Other techniques consist of doing something that takes the patient's mind off the condition. Distraction techniques utilized in urgency may include (but are not limited to) counting backward from 100 in 7 s, reciting a poem, doing breathing exercises, reading or working.

#### Urgency suppression techniques

Urgency suppression techniques are methods/maneuvers that are used to decrease the feeling of urgency, which may include, but are not limited to: distraction, PFM contraction, perineal pressure such as sitting on a hard chair, relaxation and breathing, toe curling or plantar flexion of the ankle.

#### Double voiding

In double voiding, the patient is taught to urinate, relax, and attempt to urinate again.<sup>59</sup>

#### Defecatory dynamics

Defecatory dynamics is a postural and respiratory technique to aid defecation. The mechanics involves co-ordination of the diaphragm, abdominal and PFM, with the intent to maintain rectal support whilst releasing the anal outlet with sufficient expulsion to be effective.<sup>72,73</sup>

### *Bowel habit training*

Bowel habit training is aimed at establishing a regular, predictable pattern of bowel evacuation by patient teaching and adherence to a routine to achieve a controlled response to bowel urgency (modified from NICE guideline).<sup>74, endnote 25</sup>

### **Exercise/exercise training**

Exercise is a form of leisure time activity that is usually performed on a repeated basis over an extended period of time (exercise training) with specific external objectives, such as improvement of fitness, physical performance, or health.<sup>66</sup> Exercise training includes: endurance training, strength training, flexibility training, and motor control (including balance), all of which may apply to the PFM.

### *Therapeutic exercise/exercise therapy*

Therapeutic exercise consists of interventions directed toward maximizing functional capabilities. It includes a broad range of activities intended to improve strength, range of motion (including muscle length), cardiovascular fitness, flexibility, or to otherwise increase a person's functional capacity.<sup>5</sup>

1. Rehabilitation/re-education: help individuals to regain skills and abilities that have been lost as a result of illness, injury or disease, or incarceration, restoring a disabled individual to maximum independence commensurate with his or her limitations.

### *Mode of exercise training*

The mode of exercise training is not only the type of activity to be performed (for instance, fast walking, jogging, or swimming, strength training), but also the temporal pattern of activity that is recommended (that is, continuous or intermittent activity), with a detailed specification of the duration of exercise and rest periods in the case of intermittent activity bouts.<sup>66</sup> Authors are encouraged to specifically describe all components of the mode of exercise and the dose provided.

1. Muscle training: exercise to increase muscle strength, endurance, power, flexibility or relaxation.
  - a) Strength training: training with high resistance (close to maximal contractions) and few repetitions with the aim of increasing muscle volume and neural adaptations.
  - b) Resistance: the amount of force opposing a movement.<sup>39</sup>
  - c) Resistance devices: any object used to increase resistance to contraction, e.g., hand weights.
  - d) Vaginal resistance device: objects inserted into the vagina or rectum that are inflated or spring-loaded devices to increase resistance to contraction.

- e) Local muscle endurance training: training with a low load and a high number of repetitions or holding the contraction over time.
- f) Muscle power training: all training with the aim of generating power; can be close to maximal contraction training and/or rapid contractions.<sup>endnote 26</sup>
- g) Overload: a situation in which the body is required to perform exercise beyond that to which the neuromuscular system is accustomed during routine activities. Training adaptation occurs in response to a progressive "overload".<sup>75</sup>
- h) Progressive overload: the gradual increase in stress placed upon the body during exercise training.<sup>76</sup>
- i) Detraining: cessation of training, but also planned or unplanned reduced volume or intensity of training.<sup>77</sup>
- j) Maintenance training: a program designed to prevent loss of the previous level of functioning.
- k) Isometric/static contraction: a muscular action during which no change in the length of the total muscle or joint angle takes place.<sup>77</sup>
- l) Isotonic contraction: a muscular action during which the tension developed by the muscle remains almost constant while the muscle shortens.<sup>78</sup>
- m) Eccentric contraction: a muscular action in which the muscle lengthens in a controlled manner.<sup>77, endnote 27</sup>
- n) Repetition: the completion of a whole cycle from the starting position, through the end of the movement, and back to the start,<sup>75</sup> e.g., one PFM contraction with relaxation.
  - o) Set: the number of times the desired number of repetitions is performed,<sup>33</sup> e.g., three sets of 12 PFM contractions.
  - p) PFMT: exercise to improve PFM strength, endurance, power, relaxation or a combination of these parameters.
  - q) Kegels: a PFM contraction or PFM exercise. This term is named after Arnold Kegel, an American gynecologist who first described the clinical effect of PFMT in the late 1940s.<sup>49</sup> We recommend the use of the term PFMT (not the word Kegels) to refer to exercises that specifically target the PFM.
  - r) Individualized PFMT: an individual PFM program aimed at improving the specific deficiencies in PFM structure or function based on assessment of the woman's ability to contract the PFM.
  - s) Supervised PFMT: a PFMT program taught and monitored by a health professional/clinician/instructor.
  - t) Group PFMT: PFMT conducted in an exercise class.<sup>79</sup> Class participation may occur with or without previous individualized PFM instruction.<sup>endnote 28</sup>

- u) Home training/home PFM exercise program: an unsupervised PFMT program, which the individual performs at home.
  - v) Weighted vaginal cones: objects of different shapes, sizes, and weights, which are inserted into the vagina above the level of the PFM with the aim of providing sensory biofeedback and load on the PFM to increase muscle recruitment and strength.<sup>80, endnote 29</sup>
3. Facilitation technique: any method of increasing recruitment/response of a nonresponding muscle. In the case of noncontractile or very weak PFMs, this may include a quick stretch of the PFM, with tapping or stretching the PFM digitally. An overflow effect from a strong contraction of a nearby synergistic muscle (e.g., external rotators) may also assist facilitation or recruitment of PFMs.

#### *Dose–response issues related to exercise training*

1. Dose–response: amount/volume of training and its effect on the speed and degree of the effect of the training program.
2. Frequency of exercise: the number of activity sessions per day, week, or month.<sup>33</sup>
3. Duration of exercise: the unit of time (number of seconds/minutes) of activity in each repetition or session, e.g., a 10-s PFM contraction.<sup>33</sup> It also refers to the length of the whole training period (intervention), e.g., 3/6 months.
4. Intensity: the amount of resistance used or the effort associated with the physical activity.<sup>33</sup> For strength training, it is often expressed as a percentage of one repetition maximum: 1RM (the maximum load a person can lift once), e.g., 70 % of maximum.<sup>75</sup>
5. Session/bout: the block of time devoted to the training, e.g., a 1-h session.<sup>75</sup>

#### *Relaxation training*

1. Relaxation: the ability to control muscle activity such that muscles not specifically required for a task are quiet, and those that are required are fired at the minimal level needed to achieve the desired results.<sup>81</sup> Relaxation “can be considered a motor skill in itself because the ability to reduce muscle firing is as important to control as the generation of firing”.<sup>40</sup>
  - a) General relaxation technique: a technique that involves the whole body, with the aim of effecting a global relaxation, including a decrease in the skeletal and smooth muscles, a decrease in the heart rate and respiration rate, and an increase in parasympathetic activity. General relaxation techniques can also be used aimed at relaxing local muscles.

- b) Progressive muscular relaxation (also known as Jacobsen's technique): monitoring tension in each specific muscle group, by contracting, then relaxing the tension, with attention paid to the contrast between tension and relaxation.<sup>82</sup> This type of relaxation is also termed “contract–relax.”
- c) Meditation: a practice of concentrated focus upon a sound, object, visualization, the breath, movement, or attention itself to increase awareness of the present moment, reduce stress, promote relaxation, and enhance personal and spiritual growth.<sup>83</sup>
- d) Mindfulness: intentionally bringing one's attention to the internal and external experiences occurring in the present moment. Mindfulness is often taught through a variety of meditation exercises.<sup>84</sup>
- e) EMG relaxation techniques: techniques to decrease EMG muscle activity or activation through a variety of methods, including a conscious effort to relax.

#### *Stretching*

1. Stretching (also referred to as flexibility training when the method is used on skeletal muscles where increased range of motion over the joints is the aim): the application of an external force to muscle and connective tissue to elongate it in the direction opposite to its shortened position. This can be done parallel or perpendicular to the muscle fiber direction. For the PFM this can be applied as a widening of the levator hiatus in the axial plane (laterolaterally) via a digit or use of a dilator, or a caudal movement (via a straining/bearing down maneuver) in the sagittal plane.
  - a) Dilator therapy: a conical or cylindrically shaped device (made of an inert material) inserted intravaginally or intra-anally, with the aim of increasing the flexibility or elasticity of the soft tissues via application of a prolonged elongation or stretch. Dilators may also be used as a desensitizer device, to reduce fear, anxiety or pain associated with vaginal touch and in conjunction with vaginismus or sexual pain. When combined with EMG, dilators can be used to train PFM relaxation during penetration. Dilators may also be used to increase the tolerance of skin to sliding when the dilator is moved in and out.

#### *Functional training*

Functional training consists of training for tasks of daily living and self-care activities, e.g., squatting to train quadriceps and gluteal muscles.

1. Functional PFM training: training and exercises that incorporate a correct PFM contraction into activities of

daily living such as lifting, transferring out of bed, or sneezing. A PFM contraction before a rise in intra-abdominal pressure, e.g., a cough (“the Knack”) is part of functional PFM training.

2. Coordination training: the ability to use different parts of the body together smoothly and efficiently.<sup>7</sup> Related to PFM training, coordination training means PFM contraction with other muscles or other muscle groups, e.g., respiratory muscles.
3. Functional mobility training: an intervention directed at improving the physical ability to perform a daily task. For voiding/defecation, this may include: gait training, transfer training, stair training, and other mobility training to improve speed and safety in reaching the toilet.

## Biofeedback training

### *Feedback*

Feedback is sensory information that is available as the result of an activity that a person has performed. It can be provided by an intrinsic source (from within the individual), or an extrinsic source (from the clinician), and can occur concurrently with the activity or post-activity, e.g., verbal information from the clinician to the patient during or following PFM assessment.<sup>85, endnote 30</sup>

### *Biofeedback*

Biofeedback is the use of an external sensor to give an indication with regard to bodily processes, usually with the purpose of changing the measured quality.<sup>86</sup> It is an adjunctive therapy.<sup>endnote 31</sup>

## EMG biofeedback unit instrumentation

1. EMG signal amplitude: number of microvolts ( $\mu\text{V}$ ) a muscle is generating.<sup>87</sup> EMG biofeedback units can deliver either the actual amount of EMG activity in  $\mu\text{V}$  or an average  $\mu\text{V}$  value.<sup>endnote 32</sup>
2. Artifact: extraneous information nonrecognizable in the EMG signal from sources other than the target muscle such as the environment or other body functions.<sup>87, endnote 33</sup>
3. Cross talk: muscle activity from nearby muscles that can artificially increase EMG amplitude; a type of artifact.<sup>87, endnote 34</sup>
4. Dual-channel EMG: use of two channels to monitor two separate muscles or muscle groups at the same time, such as the PFM and abdominal muscles, with the goal of either promoting synergist activity or reducing EMG activity of one muscle while increasing the other.
5. Band pass: limits muscle fiber frequencies that are monitored and displayed in the EMG tracing.<sup>87, endnote 35</sup>

## EMG assessment of PFM

Electromyography assessment of PFM consists of the use and interpretation of the surface EMG recording of a muscle for rehabilitation purposes should be done cautiously, recognizing that the main goal is the qualitative description of the muscle activation pattern, and not a qualitative diagnosis.

1. Baseline muscle activity: amount of microvolts generated by the target muscle during rest.<sup>endnote 36</sup>
2. Peak microvolts: the highest EMG amplitude achieved.
3. Slow recruitment: slow initiation of muscle activation contraction.<sup>endnote 37</sup>
4. Slow de-recruitment or slow latency to return to baseline: slow relaxation of the muscle contraction.<sup>88, endnote 38</sup>
5. Inconsistent resting baseline: variation of baseline between contractions, between sets, or between days may be related to a change in patient symptoms, e.g., hypertonic PFM.
6. Excessive accessory muscle contraction: increased amplitude in accessory muscles often resulting in cross talk and is indicative of poor isolation of target muscle contraction.

## EMG training of PFM

1. Up-training: EMG biofeedback training to increase the EMG activity of a hypotonic muscle with low EMG activity.<sup>87, endnote 39</sup>
2. Down-training: EMG biofeedback training to decrease EMG activity and relax muscles.<sup>87, endnote 40</sup>

## Manual therapy

Manual therapy is a clinical approach utilizing skilled, specific hands-on techniques, including but not limited to, massage, manipulation or mobilization.<sup>endnote 41</sup>

### *Joint therapies*

1. Mobilization: skilled passive movement of a skeletal joint including graded passive oscillations at the joint to improve joint mobility, e.g., movement of the coccyx.
2. Manipulation: a passive (for the patient) therapeutic movement, usually of small amplitude and high velocity, at the end of the available joint range.<sup>5</sup> Manipulation is a sudden small thrust that is controlled by the clinician.<sup>endnote 42</sup>

### *Soft-tissue therapies*

1. Touch desensitization: use of finger/hand, vibration or device to reduce hypersensitivity of soft tissues to touch/contact.

2. **Massage:** the manipulation of the soft tissues of the body for the purpose of affecting the nervous, muscular, respiratory, and circulatory systems.<sup>5</sup>
3. **Abdominal massage:** therapist or self-directed massage of the abdominal wall with the aim of stimulating peristalsis and relieving the symptoms of constipation. Generally, the technique follows the ascending, transverse, and descending colon to aid emptying. The effect may be mechanical or sensory.<sup>89</sup>
4. **Myofascial release techniques:** the use of deep friction and stroking of the fascia of the body to improve the ability of the fascia to deform and move within the body.<sup>5</sup>
5. **Skin rolling:** a manual technique in which skin is pulled away from the underlying structures and elongated in various directions.
6. **Scar massage:** a specific application of soft-tissue mobilization to an adherent scar.
7. **Perineal massage:** intravaginal massage by the woman, her partner or the clinician. Technique includes alternating downward and sideward pressure, using thumb and forefinger and a natural oil, with the aim of stretching and elongating the tissue in preparation for vaginal childbirth, or for treatment of adherent scarring in the perineum.<sup>90</sup>
8. **Transverse friction:** the operator's fingertip is placed on the exact site of the lesion and rubbed firmly across the direction of the fibers of the affected tissue.<sup>91</sup>
9. **Thiele's massage:** per rectal digital massage of the levator ani, sweeping lengthwise along the muscle fibers. Massage is begun lightly, and pressure is increased as tenderness decreases.<sup>92</sup>
10. **TrP treatment:** (sometimes called myofascial trigger point treatment): soft-tissue mobilization specifically targeting trigger points and may include ischemic pressure, massage, myofascial release, electrotherapy, ultrasound, laser, spray-and-stretch, injection (a variety of chemicals including local anesthetic, botox or steroids), dry needling (insertion of a solid needle into the TrP), and stretching.<sup>endnote 43</sup>

## Thermal modalities

### *Cold treatment/cryotherapy*

Cold treatment is the application of ice for therapeutic purposes. It is used in the initial management of acute musculoskeletal injuries, to decrease edema through vasoconstriction and to reduce secondary hypoxic injury by lowering the metabolic demand of injured tissues.<sup>93</sup>

### *Heat treatment (moist or dry)*

Heat treatment consists of the application of heat to a body part, with the aim of relieving pain and/or stiffness. It is usually applied when an injury is older than 48 h.

## Electrical therapy

Electrical therapy is the use of electric potential or currents to elicit therapeutic responses. Current may be directed at motor or sensory functions. It is not within the scope of this document to define all electrical stimulation terms. Readers are referred to more complete text books.<sup>94</sup>

*Electrical muscle stimulation (also known as neuromuscular electrical stimulation or electromyostimulation)*

Electrical muscle stimulation (EMS) is the application of electric impulses directly to striated PFM (end-plate) to facilitate contraction. EMS is often referred to as “pelvic floor muscle electrical stimulation” (PFES) or “functional electrical stimulation.” PFES is the application of electrical current to the PFM.<sup>95</sup> All of these stimulations may (indirectly) cause inhibition of the detrusor contraction (Fig. 9).

### *Mode of application*

1. **Surface electrodes:** non-invasive placement of electrodes, including intravaginal and intra-anal electrodes, in contrast to electrodes that pierce the skin, i.e., needle stimulation.
  - a) **Non-invasive electrical nerve stimulation<sup>96,97</sup> or transcutaneous electrical nerve stimulation (TENS):** the application of electrical energy to stimulate cutaneous nerve and peripheral motor nerves, via suprapubic, perineal or sacral placement of electrodes, or other external sites, or intravaginal or intra-anal plug electrodes. Tibial nerve stimulation (TNS) is a form of peripheral neuromodulation targeting symptom relief of overactive bladder (OAB) and urinary urge incontinence. Indirect access to the sacral plexus is achieved by

**FIG. 9** Enraf-Nonius Myomed pelvic floor machine, including electrical stimulation (reproduced with permission from Enraf-Nonius)

intermittent, electrical stimulation of the tibial nerve, which lies behind the medial malleolus, using skin surface electrodes applied to the medial malleolar area (transcutaneous TNS).<sup>98</sup> There are two main types of electrical stimulation with surface electrodes:

- i) Long-term or chronic electrical stimulation: is delivered below the sensory threshold. It is aimed at inhibiting detrusor activity by afferent pudendal nerve stimulation. The device is used 6–12 h per day for several months.<sup>99</sup>
  - ii) Maximal neuromuscular electrical stimulation: applies a high-intensity stimulus, set just below the pain threshold. It is aimed at improving urethral closure, via striated muscle recruitment. Detrusor inhibition by afferent pudendal nerve stimulation has also been suggested as a mechanism of effect.<sup>96</sup> Maximal electrical stimulation (35–70 Hz) is applied over short period (15 to 30 min), is used several times per week (and up to 1–2 times daily), and may be provided via in-clinic application or via portable devices at home).<sup>100–102</sup>
2. Percutaneous electrical nerve stimulation: a therapeutic modality that stimulates peripheral sensory nerves performed with a (few) needle electrode(s) that are placed in close proximity to the area to stimulate. Percutaneous neuromuscular electrical stimulation (e.g., posterior TNS) is a peripheral neuromodulation technique, in which the posterior tibial nerve is electrically stimulated three fingerbreadths above the medial malleolus, via insertion of a percutaneous needle electrode. This is coupled with an adhesive reference surface electrode placed near to the needle. This intervention is offered to patients with OAB.<sup>103–105</sup>

#### *Electrophysiological parameters*

1. Electrical current: the flow (current) of electrons (electricity) from an electron source (stimulator) the wires and electrodes used to deliver such an electrical current to soft tissues.<sup>106</sup>

There are three types of current: direct, alternating, and pulsed. –

  - a) Direct: the continuous, unidirectional flow of charged particles for 1 s or longer, the direction of which is determined by the polarity selected. Polarity refers to two oppositely charged poles, one positive and one negative. Polarity determines the direction in which current flows.<sup>106</sup>
  - b) Alternating: the continuous, bidirectional flow of charged particles, for 1 s or longer, relative to the isoelectric baseline.<sup>106</sup>
  - c) Pulsed: the noncontinuous, interrupted, and periodic flow of direct (DC) or alternating (AC) currents.<sup>106</sup>

Currents used in therapy:

- a) Faradic current: an alternating and interrupted low-frequency current capable of stimulating (depolarizing) nerve fibers through the skin using surface-stimulating electrodes. It is used to stimulate innervated muscles, causing them to contract.<sup>107</sup>
- b) TENS: an alternating and interrupted low-frequency current capable of stimulating (depolarizing) nerve fibers through the skin using surface-stimulating electrodes for pain modulation or pain relief.<sup>106</sup>
- c) Interferential current: a medium frequency, amplitude-modulated electrical current that results from the interference (hence the word interferential) caused by crossing two or more medium-frequency alternating sine wave currents with different carrier frequencies. The carrier frequency of these medium, alternating sine wave currents ranges between 2,000 and 5,000 cycles per second.<sup>106</sup>

#### *Neuromuscular electrical stimulation parameters*<sup>endnote 44</sup>

1. Pulse frequency (or rate): the number of pulse cycles that are generated per unit of time (seconds). This is reported in hertz (Hz).<sup>106</sup>
2. Pulse width: the determined period of time elapsing from the beginning to the end of one pulse cycle, usually expressed in microseconds or milliseconds.<sup>106</sup>
3. Current amplitude: the magnitude of current relative to the isoelectric baseline, expressed in amperes (A). The current amplitude of therapeutic electrical stimulators ranges from micro- to milliamps.<sup>106</sup>
4. Train: the continuous series of pulse cycles over time, usually lasting seconds. For example, a train of impulses may be the results of successive pulse cycles delivered at 50 Hz for a duration of 5 s.<sup>106</sup>
5. Train ramp-up time and ramp-down time: ramp-up time is the time elapsed from the onset (or baseline) to the plateau current amplitude (or maximum) of the train, whereas ramp-down time is the time elapsed from the plateau current amplitude to zero baseline.<sup>106, endnote 45</sup>
6. Duty cycle (D): the ratio of ON time to the summation of ON time + OFF time, expressed as a percentage (duty cycle = (ON)/(ON + OFF time) x 100, e.g., a duty cycle of 20 % is calculated when the ON and OFF times equal 10 and 40 s respectively.<sup>106</sup>
7. Impedance (electric resistance): the opposition of our biological tissues to the flow of an electrical current. Measured in ohms and designated as Z.<sup>106</sup>
8. Evoked potentials: electrical potentials recorded from the nervous system following a delivered stimulus.

## Magnetic stimulation

Magnetic stimulation (or extracorporeal magnetic innervation): a pulsed magnetic technology developed for the transmission of nerve impulses that is aimed at causing PFM contraction. Patients receive therapy by sitting in a chair, which contains the device that produces the pulsing magnetic fields.

## Mechanical devices

### *Intravaginal devices*

Intravaginal devices are intended to provide some support to the bladder neck and possibly some compression to the urethra, to correct urinary stress incontinence. These can be traditional tampons, pessaries, and contraceptive diaphragms and devices designed specifically to support the bladder neck (removable, reusable intravaginal ring or single-use disposable devices).<sup>108</sup>

### *Anal plugs*

Anal plugs are containment devices aimed at blocking the loss of stool to control fecal incontinence. Plugs come in different designs, sizes, and compositions, such as polyurethane and polyvinyl-alcohol.<sup>109, endnote 46</sup>

### *Rectal irrigation*

Rectal irrigation is the use of liquid solutions given by enema to remove material from the rectum.<sup>110</sup>

### *Urethral plugs*

Urethral plugs are containment products aimed at blocking urine leakage.<sup>111</sup>

### *Pessaries*

Pessaries are intravaginal devices used to try to restore the prolapsed organs to their normal position and hence to relieve symptoms. Vaginal pessaries can be broadly divided into two types: support pessaries (ring, ring with support, Gehrung, Hodge, shelf) and space-filling pessaries (donut, Gellhorn, cube, inflatable).<sup>111–113</sup>

## Hygiene

### *Bladder hygiene*

Bladder hygiene prevents UTI by using techniques such as wiping the urethral meatus with clean wipes in an anterior-to-posterior direction after voiding, wearing clean

underwear, keeping the genital area clean, and emptying the bladder before and after sexual intercourse.<sup>114,115</sup>

### *Vulval hygiene*

Vulval hygiene involves maintaining a clean perineum by means of washing the area on a regular basis, and wearing cotton underwear. To avoid vulval irritation, shampoo, perfumed creams or soap should be avoided.<sup>116</sup>

### *Anal hygiene*

Anal hygiene involves keeping the perianal region clean, which is especially important when fecal seepage is present. Advice includes using soft toilet paper or moist wipes (avoiding any with an alcohol base), always wiping from front to back, washing after a bowel movement, then gently patting dry.<sup>89</sup> To avoid irritation from products, the vulval hygiene advice above should be followed.

### *Vaginal lubricants*

Vaginal lubricants are pharmacological preparations aimed at reducing friction during coital or any other sexual activity and thereby alleviating dyspareunia,<sup>117</sup> or at reducing discomfort associated with a clinical (per vaginum or per rectum) examination. Pharmacological preparations and natural plant-based oils may be used.

## Aids and appliances

### *Absorbent products*

Absorbent products are those that have been specifically developed to help manage leakage or soiling, such as absorbent pads and pants, absorbent bed sheets and chair covers.<sup>108,118</sup>

### *Catheters*

Urinary catheters are small tubes inserted via the urethra or into the bladder suprapubically, to allow the drainage of urine. Catheters are made of plastic, latex, teflon or silicone, and may be impregnated with antiseptic or antibiotic solution.<sup>119</sup>

1. Self-catheterization: a procedure performed intermittently to empty the bladder by inserting a catheter into the urethra when normal voiding is not possible or if the bladder cannot be emptied completely. If a caregiver undertakes this procedure it is usually a sterile procedure; if a patient undertakes it, it is termed

“self-catheterization” and is generally a clean rather than a sterile procedure.<sup>120–122</sup>

## CONCLUSION

We trust that this consensus-based terminology report for the conservative management of female pelvic floor dysfunction will be a significant aid to clinical practice and a stimulus for research. Future updates will be required to reflect evolving knowledge and applications in this field.

## ACKNOWLEDGEMENTS

We thank Professors Jacques Corcos (Urologist McGill University, Montreal Canada, Mandy Fader (Nurse, University of Southampton, UK), Ingrid Nygaard (Urogynecologist, University of Utah, Salt Lake City, USA), Marijke van Kampen (Physiotherapist, University Hospital Gasthuisberg, K.U. Leuven, Belgium) and David Vodusek (Neurophysiologist, University of Ljubljana, Slovenia) for expert advice on the draft manuscript.

## COMPLIANCE WITH ETHICAL STANDARDS

**Disclaimer** Any products/companies referred to in this document are not necessarily recommended or endorsed by the ICS.

## CONFLICTS OF INTEREST

Elizabeth Shelly is a consultant to Analytica and Amanda Wells is a consultant to ARC Health Services. None of the other authors have any conflicts of interest.

## ENDNOTES

endnote 1 Terminology for Female Anorectal Dysfunction.<sup>18</sup>

endnote 2 A comprehensive definition of these terms is covered by Doggweiler et al.<sup>123</sup>

endnote 3 Symptoms of pelvic floor myalgia should be described in terms of location, quality, intensity, pattern, duration, frequency, moderating factors, and associated symptoms. Pain details may include: (a) Whether pain is present at rest or mechanical in nature (related to muscle contraction or relaxation or body posture) and/or altered with a change of posture (lying to sitting, sitting to standing) or movement (bending, walking, sexual activity) (b) Whether uni- or bilateral in nature (c) Whether accompanied by bladder or bowel dysfunction, vulvodinia or dyspareunia (superficial/deep)

endnote 4 The evidence for the existence of trigger points is debated.<sup>124</sup>

endnote 5 Atrophy of the urogenital tract is normal at certain points in the life cycle, mainly caused by aging and hypoestrogenism.<sup>8,125</sup>

endnote 6 Muscle tone is evaluated clinically as the resistance provided by a muscle when a pressure/deformation or a stretch is applied to it.<sup>19–21</sup> Muscle tone may be altered in the presence or absence of pain. There is no single accepted or standardized way of measuring muscle tone, and there are no normative values.

endnote 7 The terms hyper- and hypotonicity are commonly used in neurology and muscle physiology. Messelink et al.<sup>2</sup> introduced the terms overactivity and underactivity related to PFM. These terms are not defined with cut-off points, nor are they based on comparison with normal populations. As activity can only relate to the active (i.e., contractile) portion of muscle tone, activity cannot be used interchangeably with muscle tone, unless it can be shown that the active component of the muscle is altered. If increased (over-) or decreased (under-) activity in the PFM can be demonstrated using electromyography (EMG) or another measure, then these terms may be used appropriately.

endnote 8 Muscle cramp either during or immediately after exercise is commonly referred to as “exercise-associated muscle cramping”<sup>93</sup>; however, cramps are not specific to exercise.

endnote 9 Local or referred pain may be reproduced. An active TrP is said to have a characteristic “twitch” response when stimulated; however, the twitch response to palpation has been shown to be unreliable.<sup>126</sup> The most reliable sign of a TrP is sensitivity to applied pressure. Trigger points are implicated in myofascial pain; however, the validity of this theory is controversial and has recently been refuted.<sup>124</sup>

endnote 10 Palpation is less reliable and responsive than manometers and dynamometers.<sup>42</sup>

endnote 11 The pressure measured does not confirm its origin, and pressure measurement is only valid when used in combination with other methods, e.g., simultaneous observation of the inward movement of the perineum or device during PFM contraction.

endnote 12 The term perineometer is somewhat misleading as the pressure-sensitive region of the manometer probe is not placed at the perineum, but inside the vagina at the level of the levator ani. Vaginal pressure devices should be referred to as PFM manometers.<sup>42,49</sup>

endnote 13 Today’s dynamometers for the pelvic floor also detect resting and contractile contributions from muscles other than the PFM, contributing to the force recordings. As dynamometers can be opened at different muscle lengths to measure PFM force, the process of measurement should respect the maximum achievable vaginal aperture without inducing discomfort, so as not to influence the validity of the measurement.

endnote 14 EMG in this case usually means “concentric needle EMG,” but other EMG methods exist. EMG is typically distinguished as either intramuscular or surface. EMG diagnosis is often used as a synonym for “neurophysiological diagnosis of the peripheral neuromuscular system,” and that would also include the measurement of motor and sensory conduction, the recording of reflex responses, etc.<sup>36</sup> EMG does not directly measure muscle strength. The type of electrode being used should be specified.

endnote 15 This is not typically used in clinical assessment, but may be included in research or advanced examinations, for example, to diagnose striated muscle denervation/re-innervation.<sup>36</sup>

endnote 16 Surface EMG is considered to be less specific than intramuscular EMG. The large surface area of the electrodes

- may result in cross-talk from adjacent muscles and other artifacts; therefore, technical expertise is required. EMG can reveal the pattern of activity of a particular muscle, as in the diagnosis of detrusor sphincter dyssynergia during urodynamics.<sup>2,36</sup>
- endnote 17 Because pain is multidimensional, a single rating scale combines these dimensions in unknown quantities. One may separately assess pain intensity, pain distress, and interference of pain with activities of daily life.
- endnote 18 Other urological, gynecological, gastrointestinal and colorectal pain conditions without related PFM dysfunction, are well described in standard texts. Many pelvic floor pain-related conditions or syndromes (e.g., vulvodynia, interstitial cystitis/bladder pain syndrome, irritable bowel syndrome) are described in the Standard for Terminology in Chronic Pelvic Pain Syndromes (CPPS): A Report from the Ad Hoc Working Group of the International Continence Society Standardization Steering Committee (ICS-SSC) on Chronic Pelvic Pain, ICS Standardization of Terminology document on Chronic Pelvic Pain.<sup>123</sup> Several other systemic disorders (e.g., chronic fatigue syndrome, diabetes) may have an impact on the pelvic floor; however, PFD is not part of their recognized etiology.
- endnote 19 We recommend that “behavioral” be limited to studies that evaluate how people do or do not behave as desired, e.g., commencement or cessation of PFM training or change of a diet.
- endnote 20 We recommend that the specific treatment is described, e.g., PFM training, electrical stimulation, rather than the unspecific term physiotherapy, the latter also referring to a specific profession. Publications should report the actual professional who provided the intervention (e.g., physiotherapist, general practitioner, urogynecologist, urologist, midwife, nurse, fitness instructor), rather than using the vague term, “therapist”/“clinician”/“researcher.”
- endnote 21 Adherence is usually reported as the number or percentage of clinical visits attended and home exercises or regimen components followed or completed by the client/patient.
- endnote 22 The term “adherence” is generally preferred within health-care, as it acknowledges client/patient autonomy and implies a willingness on their part to participate and cooperate rather than the traditional view, inherent in “compliance,” of an expert clinician dictating to a naive patient.<sup>62,63</sup> Simply, adherence is agreeing what to do; compliance is being told what to do.
- endnote 23 An increase in the physical activity level may affect UI positively via weight reduction in obese persons. Conversely, several studies have shown that there is a high prevalence of UI in physically active women during exercise (especially during high impact activity, defined as running and jumping). Strenuous exercise/work has been suggested to be a risk factor for the development of PFD.<sup>71</sup> A well-functioning pelvic floor responds before and during an increase in intra-abdominal pressure.
- endnote 24 Ideally, the voiding intervals should be increased by 15–30 min each week, according to the patient's tolerance to the schedule, until a voiding interval of 3–4 h is achieved. Use of a bladder diary is recommended for self-monitoring of progress.<sup>70</sup>
- endnote 25 A bowel habit intervention may: encourage bowel emptying at a specific time of day, mainly after a meal (to utilize the gastrocolic response), encourage patients to adopt a sitting or squatting position where possible while emptying the bowel, teach patients techniques to facilitate bowel evacuation and stress the importance of avoiding straining.<sup>74,127,128</sup>
- endnote 26 Speed changes little with training. Thus, power is increased almost exclusively by gaining strength.<sup>35</sup>
- endnote 27 PFM training can be isometric, concentric or eccentric or a combination of any of these.
- endnote 28 Whether PFMT is performed with or without previous assessment of the ability to contract should be reported.
- endnote 29 The original shape was conical; however, different shapes are currently available. Maintenance of the weight in position can be challenged via different body positions and activities.
- endnote 30 PFM feedback can be provided by the therapist or patient during manual palpation internally or externally, or with a mirror. The purpose of feedback is to increase accuracy of contraction for maximum benefit.
- endnote 31 Biofeedback can be visual, auditory or both. Biofeedback is not a treatment on its own. It is an adjunct to training and can be used to help the patient be more aware of muscle function, and to enhance and motivate patient effort during training.<sup>129</sup> The correct terminology should be PFM strength training with biofeedback or relaxation training with biofeedback. Types of PFM biofeedback include: perianal, vaginal, and anal surface EMG, urethral, vaginal or anal manometry, vaginal dynamometry, real-time ultrasound.<sup>129</sup>
- endnote 32 Clinicians are to be cautious with regard to the interpretation of the information, as many factors influence amplitude, including muscle activity, skin conductance, and artifact. “EMG amplitude does not equal force”.<sup>87</sup> More microvolt activity means more muscle activity, but does not always mean more strength.
- endnote 33 Artifact examples include movement or contact quality artifact, cross talk, heart rate, skin electrode shear, and electrode bridging.
- endnote 34 Minimizing cross talk is essential in research into quality EMG tracings.
- endnote 35 Recording with surface electrodes is prone to artifact and cross talk. The user should be trained appropriately and understand the limits of the EMG instrument and of the methodology. It is not within the scope of this document to define all EMG terms. Readers are referred to other texts for further terminology.<sup>87,88</sup>
- endnote 36 Baseline EMG reading can be influenced by many factors and therapists must take into account the patient's symptoms, digital palpation results, overall tension of the patient, the possibility of artifacts, and other factors in determining the meaning of the baseline muscle activity.
- endnote 37 Slow recruitment can be symptomatic of leakage during coughing and sneezing when a quick muscle contraction is needed to counteract increased intra-abdominal pressure.
- endnote 38 Slow de-recruitment can be indicative of a hypertonic PFM.
- endnote 39 The general principles of strength training are the same with and without biofeedback. (See the sections “Mode of exercise training” and “Dose–response issues related to exercise training”)

- endnote 40 The general principles of relaxation training are the same with and without biofeedback.
- endnote 41 Manual therapy is used to treat soft tissues and joint structures for the purpose of modulating pain; increasing the range of motion; reducing soft tissue edema; inducing relaxation; improving contractile and noncontractile tissue extensibility, and/or stability; facilitating movement; and improving function. This broad group of skilled hands-on treatments can be divided into two groups: joint therapies and soft-tissue therapies.
- endnote 42 Neither mobilization nor manipulation should be used when referring to muscle.
- endnote 43 The notion of trigger points causing myofascial pain is controversial.<sup>124</sup>
- endnote 44 Depending on the particular device being used, the type of electrical current, the specific health problem and condition being treated, and the individual's needs and circumstances, many electrical stimulation parameters may be adjusted by the therapist administering the treatment.
- endnote 45 The slower the current intensity rises to the preset amplitude or threshold level, the more comfortable the stimulation may feel. Conversely, the faster the ramp, or the more vertical the ramping up signal, the more discomfort may be felt.
- endnote 46 Terminology for female anorectal dysfunction.<sup>18</sup>

**Introduction and Hypothesis:** Standardized terminology has yet to be developed for reporting the outcomes for surgery for pelvic organ prolapse (POP). **Methods:** This report combines the input of the Terminology and Standardization Committees of the International Urogynecological Association (IUGA) and the International Continence Society (ICS) and a joint Working Group on this topic, as well as expert external referees. The aim was to present a standardized terminology for the definitions of surgery and propose a structure for reporting the outcomes of surgical procedures for POP. An extensive drafting and review process was undertaken, as well as open review on both IUGA and ICS websites. **Results:** A terminology report was developed outlining the recommended structure for reporting outcomes of surgical trials involving POP. This document does not define success and failure. The report includes patient-reported subjective and objective outcomes to enable researchers to report on their results and compare them with other studies. **Conclusions:** A consensus-based method for standardizing terminology for reporting outcome measures of POP surgery was developed to aid clinicians working in this area of research. *NeuroUrol. Urodynam.* 31:415–421, 2012. © 2012 Wiley Periodicals, Inc.

**Key words:** terminology; outcomes; surgical procedures; pelvic organ prolapse; female pelvic floor dysfunction

### INTRODUCTION

Whereas recommendations for reporting outcomes of surgery for stress urinary incontinence have been reported<sup>1,2</sup> few exist for surgery of pelvic organ prolapse (POP). In addition, there has been ambiguity in reporting of “prolapse surgery outcomes,” particularly with regards to success/failure and further surgery/re-operation. Within the literature, there is limitation in the methodology as evidenced by the recent Food and Drug Administration (FDA) report<sup>3,4</sup> and other reviews.<sup>5</sup> For example, information is often incomplete or limited relative to the inclusion and exclusion criteria and study design. In addition, the power calculation is often poorly described. Issues such as detection bias (lack of blinding), conflict of interest and reporting of adverse events are problematic

Christopher Chapple led the peer-review process as the Associate Editor responsible for the paper.

and make it difficult to interpret the information. In addition, many studies include both primary and repeat prolapse repairs, as well as additional procedures including other prolapse and/or stress incontinence surgery. Long-term follow-up past 2 years is infrequent. As a result, it is difficult to draw conclusions from these studies relative to other studies or populations in order to provide guidance for patient care. Standardized information is required to help answer the important questions regarding efficacy and safety of traditional and new POP procedures. The aim of this report, therefore, is to present a standardized terminology for the definitions of POP surgery and propose a structure for reporting the outcomes of surgical procedures. Consistency in reporting has the potential to help produce meta-analyses and reliable clinical guidelines.

The document does not define success and failure, but outlines the recommended structure for reporting outcomes of surgical trials involving POP. It complements published IUGA-ICS Joint Standardization Reports on (i) Terminology for Female Pelvic Floor Dysfunction<sup>6</sup> and (ii) Terminology and Classification of Complications related directly to the insertion of prostheses and grafts in female pelvic floor surgery<sup>7</sup> and (iii) concomitantly published terminology and classification of complications related to native tissue female pelvic floor surgery.<sup>8</sup>

#### BACKGROUND

The perceived ambiguity in the reporting of POP surgery outcomes might have arisen from two studies assessing success/failure and further surgery/re-operation.<sup>9,10</sup> The former study by Olsen et al.<sup>9</sup> suggested that the lifetime risk of requiring incontinence and/or prolapse surgery was 11% (for prolapse surgery alone, the figure was 6.7%) and 29.2% of patients required repeat surgery/re-operation. The definition of repeat surgery was any operation for prolapse or urinary incontinence following an index (first) procedure, often some years previously. While the 29.2% re-operation rate is still commonly quoted and often interpreted similarly to that stated by the authors (i.e., that this implies a high rate of surgical failure), the failure to adjust for both time and variation in operative site reduces the usefulness of the conclusions and might be misleading with regards to the true failure rate of POP surgery. This observation is borne out when the same cohort was reviewed 10 years later with the authors quoting a 17% re-operation rate.<sup>11</sup> On further analysis of the same compartment recurrence (i.e., repeat anterior repair), the re-operation rate was significantly lower at 4.6%.<sup>12</sup> More recently, several investigators have looked specifically at the issue of site-specific recurrence, with re-operation rates ranging from 2.8% to 9.7%.<sup>13–15</sup> A recent Cochrane review<sup>16</sup> looking at vault suspension suggested that re-operation rates after POP surgery, which includes suspension of the vaginal vault/apex, are 1.3–3.9% at 17–32 months respectively, depending upon the type of vault suspension. These data become more useful in terms of site and timescales.

The second study<sup>10</sup> reported a 58–70% anatomical failure rate for anterior colporrhaphy. This study has recently been subject to further analysis, as the definitions of objective success and failure were based on POP quantification (POPO) changes of small magnitude. When more clinically relevant criteria for success are used (anatomic recurrence beyond the hymen, symptomatic recurrence and re-operation), the outcome is considerably better with only 10% of subjects developing anatomic recurrence beyond the hymen, and 5% developing symptomatic recurrence and re-operations in <1% (at 23 months follow-up).<sup>17</sup>

*Neurourology and Urodynamics* DOI 10.1002/nau

The lack of subjective/patient-reported outcomes was highlighted in a systematic review on mesh repairs commissioned by the National Institute for Clinical Excellence (NICE) in the UK.<sup>18,19</sup> As a consequence of this and the uncertainty following further consideration of the studies mentioned above, there is a need for clear definitions and standardization for reporting of outcomes for POP surgery.

#### NEW DEFINITIONS

It is understood that there is close interaction among three commonly defined compartments: apical/vaginal vault, anterior, and posterior, when discussing pelvic organ support or prolapse. However, for ease of use, the definitions are limited to “primary” or “recurrence at specific sites” defined as apical/vaginal vault, anterior and posterior. As our understanding of how these compartments interact improves, the definitions of “primary prolapse surgery/different site” and “repeat surgery/same site” will evolve.

The following standardized terminology is proposed for surgical trials and clinical audit:

- A. **Primary Surgery:** This indicates the first procedure required for the treatment of POP in any compartment.
- B. **Further Surgery:** Provides a global term for the number of subsequent procedures the patient undergoes, directly or indirectly, relating to the primary surgery. Further surgery per se should not be interpreted as a measure of failure as the definitions of success and failure will be defined within the context of the individual study. Further surgery is subdivided into:
  - I. *Primary prolapse surgery/different site:* a prolapse procedure in a new site/compartment following previous surgery (e.g., anterior repair following previous posterior repair).
  - II. *Repeat surgery:* a repeat operation for prolapse arising from the same site. Where combinations of procedures arise, such as new anterior repair plus further posterior repair, these should be reported separately as primary anterior repair and repeat posterior repair.
  - III. *Surgery for complications:* mesh exposure or extrusion, pain, or patient compromise such as hemorrhage (see Complications section).
  - IV. *Surgery for non-POP related conditions:* subsequent surgery for stress urinary incontinence or fecal incontinence.

#### STANDARDIZATION OF REPORTING OUTCOMES—OVERVIEW

One of the major difficulties in reporting the results of prolapse surgery is that, unlike most surgeries, there is a range of outcomes which are not reported in a consistent manner; this makes uniform assessment of procedures difficult.

The International Consultation on Incontinence (ICI) has already suggested that POP and urinary incontinence surgery should report subjective, objective, and quality of life outcomes.<sup>1</sup> This is significant in that there are a number of measures that can be used to generate useful information to benchmark practice for and against a particular procedure, as well as inform patients about potential outcomes. Therefore, it is recommended that in clinical research studies, entry criteria, design, methodology, power, and absence of bias are addressed to allow the reader to assess the reliability of findings which have the potential to influence clinical practice.

Conflict of interest should be reported due to the potential for positive reporting bias and this declaration should be at the start of the paper.

- I. Chronic cough,
- J. Chronic constipation,
- K. Smoking.

#### REPORTING OF METHODOLOGICAL DATA

##### General Criteria

The following should be defined:

- A. Inclusion criteria.
- B. Exclusion criteria.
- C. Recruitment time span.
- D. Flow diagram including<sup>20</sup>
  - (i) Number of patients evaluated.
  - (ii) Number suitable for inclusion.
  - (iii) Number agreed to participate.
  - (iv) Clear documentation accounting for all patients' progress throughout the study period.

##### Comparative Studies

- A. Clear explanation of patient allocation to treatment groups.
- B. Allocation concealment from surgeon and/or patient.
- C. Randomized trials: explanation of randomization process.
- D. Stratification of associated issues utilized such as concomitant continence surgery or hysterectomy.

##### Interventions

- A. Clear documentation of interventions performed, experience level of surgeons and number of interventions performed prior to study commencement.
- B. Criteria for performing concomitant surgery.

##### Evaluation Process

- A. Who performed the evaluation and the training received.
- B. Were reviewers and/or participants blinded.
- C. Evaluation tools: were validated, patient-completed assessments standardized.
- D. Evaluation timeline:
  - i. Very early (up to 3 months).
  - ii. Early (up to 1 year).
  - iii. Intermediate (12–36 months).
  - iv. Late (3–5 years).
  - v. Very late (>5 years).

##### Power Analysis

Details of the assumptions made in the Power calculation, estimate of the type 1 error and sample size should be reported.

#### REPORTING DEMOGRAPHICS IN POP SURGICAL RESULTS

The reporting of minimum demographics in POP surgery should include:

- A. Age,
- B. Parity,
- C. Body mass index (BMI),
- D. Menopause status,
- E. Hormone replacement therapy (HRT) usage,
- F. Prior hysterectomy,
- G. Prior POP surgery,
- H. Prior continence surgery,

Neurology and Urodynamics DOI 10.1002/nau

#### REPORTING OF RANDOMIZED CONTROLLED TRIALS (RCTs)

There are already accepted standards for reporting RCTs such as the CONSORT (Consolidated Standards of Reporting Trials)<sup>20</sup> which requires detailed information provided by authors to reviewers with a checklist added as an appendix. However, many studies fail to provide complete descriptions of critical information.

#### REPORTING OF SYSTEMATIC REVIEWS AND META-ANALYSES

Due to the lack of consistent descriptions of critical information reported from RCTs, a new instrument, Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA),<sup>21</sup> has been introduced to evaluate systematic reviews and meta-analyses. The aim of the PRISMA statement is to give authors an evidence-based minimum set of items to improve the reporting of systematic reviews and meta-analyses in POP issues. Other standards include the Standards for the Reporting of Diagnostic (STARD) accuracy studies,<sup>22</sup> and STROBE (STrengthening the Reporting of OBServational studies in Epidemiology).<sup>23</sup> Researchers should quote which standard they adopt and reference accordingly.

#### REPORTING OF PATIENTS' PRE-OPERATIVE GOALS AND EXPECTATIONS

To date, few studies have provided data on patients' preoperative goals and expectations.<sup>24–27</sup> These might have advantages over objective measures of outcome. With this in mind, goals should be reported using SMART criteria.<sup>28</sup> The aim of the SMART criteria is to help clinicians review and confirm the utility of the chosen endpoint and how it will relate to other studies and reports. Criteria comprise:

Specific	Defining goal (for POP: absence of bulge)
Measurable	Validated symptom scale or objective measure such as the POPQ
Appropriate	Relevant to improving patient lifestyle
Realistic	Achievable by treatment
Timely	For example at 6 months/2 years

The following is an example of good and poor reporting of patient expectations and outcomes, using the SMART Schema:

*Good example:* "The absence of bother from a vaginal bulge as measured using a defined tool at 2 years." This statement has Specific, Measurable, Appropriate, Realistic, and Timely attributes.

*Poor example:* "Feeling perfect" when followed-up. "Perfect" is not specific (OB compared with absence of bulge), is less measurable (because it is difficult to define), has no defined timepoint and is not appropriate or relevant to the surgery as many factors define "perfect."

Definitions relating to the SMART criteria should be derived from the symptoms the researchers feel are important. When designing a study, the symptoms should be listed and then SMART should be applied. Authors should use this as a *checklist* to ensure that the methodology is sound and relevant.

**REPORTING OF OUTCOMES FOLLOWING SURGICAL TREATMENT OF POP**

**Perioperative Data**

Perioperative data includes blood loss (ml) and/or hemoglobin change, operating time, length of hospital stay, return to normal daily activities and complications.

**Patient Reported Outcomes**

The primary patient reported outcome should be subjective and would usually be the absence of a bulge.<sup>29</sup> This can be regarded as a “subjective cure”<sup>29</sup> and can be recorded as part of a symptom scale. Details of validated questionnaires for patient reported outcomes can be found on ICI’s website.<sup>30</sup> To adhere with the SMART criteria, patient/subjective outcomes should be defined at a specific time interval and classified on a 7-point Likert scale (i.e., very much better, moderately better, a little better, no change, slightly worse, moderately worse, very much worse) such as the Patient Global Impression of Improvement (PGI-I) scale.<sup>31</sup>

**Patient Satisfaction**

Patient satisfaction can be measured using qualitative measures, such as a patient-defined measure or a validated instrument (PGI-I scale).<sup>31</sup> Qualitative assessment can include Expectations, Goal setting, Goal achievement and Satisfaction (EGGS).<sup>32</sup> Again these should be in accordance with the SMART acronym. The number of pre-specified goals and the number achieved post-operatively should be recorded and reported for responsiveness and reliability of goal achievement.<sup>24</sup>

**Quality of Life**

Appropriate and fully validated quality of life instruments should be used to cover prolapse, urinary, bowel and sexual function.<sup>30</sup>

New questionnaires can be included when they have demonstrated good psychometric properties (i.e., validity, reliability and responsiveness) in women with POP. It is important to verify that the questionnaire has been validated in the language of the trial investigator(s).

**Objective Outcomes**

Objective outcomes (e.g., POPQ<sup>33</sup>) should be tabulated with percentages achieving each level to allow studies to compare results, as definitions of success will vary among studies (see below). This report does not attempt to provide a definition for success and failure, as these are unknown. However, authors should report data on the leading edge of the prolapse for each site (e.g., patients who achieve points -1 and 0 post-operatively having had prolapse greater than -1 or 0 before surgery). These data, which may help identify the level of anatomical restoration that leads to improvement in symptoms, should be reported separately.

When possible, raw data should be provided for POPQ, quality of life measures and all primary symptoms. These should be reported in separate tables, which can be published as supplementary material in the electronic (online) version rather than the printed version.

**Reoperation or Further Surgery**

See Further Surgery in “New Definitions” above.

*Neurourology and Urodynamics* DOI 10.1002/nau

**Timelines**

Timelines should be described chronologically, as outlined below, using the classification above. Of note, these timescales are different to those described in the classifications of complications reports related to female pelvic floor surgery using either prostheses and meshes<sup>7</sup> or native tissue.<sup>8</sup>

- I. Very early (up to 3 months).
- II. Early (up to 1 year).
- III. Intermediate (12–36 months).
- IV. Late (3–5 years).
- V. Very late (>5 years).

**Economic Evaluation/Cost Analysis**

Despite considerable cost, sparse cost-effectiveness data exists related to POP surgery. Investigators are encouraged to include economic analyses in their studies whenever possible. Further details are below in the section Reporting on Economic Evaluation/Cost Analysis.

**COMPLICATIONS**

Complications specifically related to prostheses and grafts<sup>7</sup> and native tissues<sup>8</sup> should be reported as per the IUGA-ICS classifications of complications directly related to the insertion of prostheses and grafts or the use of native tissue in female pelvic floor surgery.<sup>5,6</sup> These classifications both use the CTS Classification System:

- (C) Category of complication.
- (T) Time the complication was diagnosed in relation to primary surgery.
- (S) Site of the complication.

There are seven Categories with subdivisions of (A–D). For the majority of complications, this would mean:

- (A) Asymptomatic,
- (B) Symptomatic,
- (C) Infection,
- (D) Abscess.

For complications involving bowel or bladder injury or patient compromise, variations in the pattern of the increasing index of severity exist: e.g., Category 5: rectal or bowel injury (both classifications—<sup>7,8</sup>) (A) Small intraoperative defect; (B) rectal injury or compromise; (C) small or large bowel injury or compromise; (D) abscess.

Studies, in particular of a specific surgical procedure, should have a procedure-specific list of complications using the CTS Classification Systems<sup>7,8</sup> as part of the reporting. Only in this way can the nature and chronology of possible complications be determined (in relation to time of surgery) and at which sites they might most commonly occur.

Note is also made of the generic Clavien-Dindo complication classification<sup>34</sup> which consists of four severity grades of complications. This has been modified to include a fifth category:<sup>35</sup>

- Grade I Requires no treatment
- Grade II Requires drug therapy
- Grade III Requires a procedure or intervention (a: in local; b: general anesthesia)

Grade IV	IC/ICU organ or system dysfunction (a: single organ; b: multi-organ dysfunction)
Grade V	Death

**POSTOPERATIVE PAIN**

Pain associated with surgical complications is addressed separately in the IUGA-ICS classifications of complications of female pelvic floor surgery (7,8). The addition of a letter (a to e), as part of a subclassification to the CTS Classification System, specifies the presence of pain as part or all of the abnormal finding or complication and the grade in terms of the presence and severity of symptoms.

- (a) Asymptomatic or no pain.
- (b) Provoked pain only (during vaginal examination).
- (c) Pain during sexual intercourse.
- (d) Pain during physical activities.
- (e) Spontaneous pain.

Additional information on pain may include “permanent or temporary” and “severity” as measured by impact on quality of life and treatment required (e.g., simple oral analgesia, compound analgesia, opiates, referral and management by pain team or further surgery).

**REPORTING OF SECONDARY OUTCOMES**

Secondary outcomes to be reported include an assessment of other symptoms known to be associated with prolapse:

*Lower urinary tract symptoms (LUTS):* Overactive bladder, stress urinary incontinence (either pre-existing or de-novo) and voiding dysfunction.

*Bowel dysfunction:* Obstructed defecation, feeling of incomplete emptying, constipation and digitation.

*Sexual dysfunction:* Dyspareunia, loss of libido, abstinence due to prolapse symptoms and change in sexual satisfaction. Authors should report numbers of all patients who are sexually active with and without pain, pre and post-intervention.

Figure 1 has been developed to illustrate the reporting of these data. All participants in trials should be accounted for pre- and post-intervention.

*De novo/new onset symptoms (if not previously reported):* LUTS, sexual dysfunction, pain and bowel dysfunction.

*Backache:* Backache is a common presenting symptom, the resolution of this may be an important outcome.

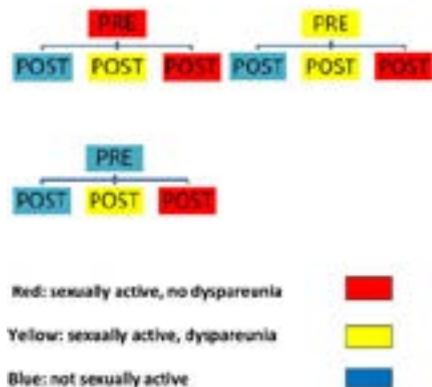

Fig. 1. Reporting of sexual function.

Neurology and Urodynamics DOI 10.1002/nau

**REPORTING ON ECONOMIC EVALUATION AND COST ANALYSIS**

Economic evaluation techniques provide systematic methods of comparing the costs and consequences of clinical and other health sector interventions. Cost-utility analysis (CUA), a form of cost-effectiveness analysis (CEA), is by far the most commonly used and requires quantifying the effects of interventions on both morbidity and mortality.

In a CUA, benefits are measured in units of health gain (or loss), most commonly using quality-adjusted life-years (QALYs) and combined with estimates of cost to create a ratio of incremental costs to incremental consequences (e.g., “incremental cost per QALY”). QALYs are usually calculated using a generic health status measure, such as Short Form (SF)36 or EuroQOL-5D, which can be used with a standard set of health state values or by other measures of utility, such as the standard gamble or time-trade off technique. These incremental cost effectiveness ratios (ICERs) enable comparison of competing interventions on the basis of the cost at which they create improvements in health-related quality-of-life.

In economic evaluations, it is important to consider the perspective (e.g., patients, hospital, third-party payer, government and society) of the evaluation, as this will have significant influence on which costs should be included in the analysis. For example, the perspective of the analysis will influence whether it should include both direct and indirect costs. Direct medical costs typically relate to the intervention and the immediate impact of the intervention on the health system: e.g., personnel costs/time (physician, nurse, technician), diagnostic and laboratory tests, hospital costs, treatment costs (drugs, operating room time, etc.), treatment of side effects and outpatient visits. Indirect costs will be of more relevance to a patient and/or societal perspective (e.g., loss of productivity, time lost from work, loss of service to family and community and premature mortality) and are often more difficult to quantify and to put a monetary value on.

**DISCUSSION**

This document was born from the recognition that contemporary practice lacks sufficient reproducible evidence to help clinicians translate published literature into clinical practice and enable patients to be aware of likely outcomes.

For example, the assessment of prolapse surgery has been subject to a number of limitations. First, and perhaps most important, is the quality of the studies. The majority are case series, with very few well-constructed and sufficiently powered RCT. As a result, the quality of the available evidence is questionable.<sup>3,4</sup> The emphasis then lies within systematic reviews and meta-analyses, which may be less robust due to the lack of good quality data.

New surgical procedures for POP reconstructive surgery have evolved dramatically in recent years, suggesting that the perceived dissatisfaction with conventional/traditional surgery as expressed by White<sup>36</sup> at the turn of the twentieth century persists. This perception is based on clinical experience and reports of anatomical failure and re-operation.<sup>9,10</sup> As the findings of these studies<sup>9,10</sup> have been questioned by more recent studies,<sup>12,13,17</sup> this highlights the need for a standardized method of reporting surgical outcomes so that appropriate recommendations for patient care can be provided from meta-analyses and systematic reviews. This report sets out to provide a framework through which researchers and clinicians can standardize reporting and allow results to become more transferable.

**TABLE I. Recommendations for Reporting in Audit of Clinical Practice and Surgical Trials**

	Audit	Research trial
Type of surgery	R	R
Primary outcome including patient satisfaction	R	R
Secondary outcomes	O	R
Timelines	O	R
Cost analysis	N	O <sup>a</sup>
Complications	R	R
Commitment to longer term follow-up	O	R
Audit database	R	O

R, routine; O, optional; N, not required.  
<sup>a</sup>It is recognized that this is ideal and not all researchers will be able to do this, but it is recommended.

History has taught that surgical complications (particularly in the case of implants) may be long-term and researchers should be encouraged to revisit early results (e.g., 1 year) and include long-term data of 5–10 years.

The Austrian and Finnish experiences with mid-urethral slings have demonstrated that, in addition to properly constructed prospective trials, there is a moral and ethical responsibility for users of advanced techniques, such as those employing implants, to contribute to clinical governance and audit through local, regional or national databases.

**SUMMARY OF RECOMMENDATIONS FOR POP SURGICAL OUTCOMES**

In all surgical trials of POP surgery, authors should clearly report their Methodology. These should follow CONSORT/STROBE and type of surgery (primary or further using the agreed definitions, see above) should be stated. Table I outlines what should be reported in both clinical audit and surgical trials. In addition, researchers should give a commitment in the original trial design and at publication of early results, to publish longer term data at a minimum of 5 years.

**ACKNOWLEDGMENTS**

This final document has undergone 23 versions and 7 collations prior to being available for review on both the IUGA and ICS websites to allow members to submit comments and recommendations which have enabled appropriate revisions. We acknowledge the comments of Dr. Annette Holden, Dr. Giuseppe Di Paola, Dr. Rufus Cartwright, Prof. Hans Peter Dietz, Dr. Joseph Gauta, Dr. Jian Wein, and Dr. Alexandros Derpapas. In particular, we thank Elektra McDermott, managing editor of the International Urogynecology Journal for her support and help in the preparation of the final draft and proof reading, and the Peninsula College of Medicine and Dentistry (UK) for the section on Economic Evaluation and Cost Analysis. We acknowledge the support of the IUGA and ICS leadership in this Joint Report from the two societies, following on from the Joint Reports on Terminology for Female Pelvic Floor Dysfunction, and Prostheses and Mesh Complications and, concurrently, Complications Related to Native Tissue Female Pelvic Floor Surgery.

**Introduction and hypothesis:** A terminology and standardized classification has yet to be developed for those complications arising directly from the insertion of synthetic (prostheses) and biological (grafts) materials in female pelvic floor surgery. **Methods:** This report on the above terminology and classification combines the input of members of the Standardization and Terminology Committees of two International Organizations, the International Urogynecological Association (IUGA) and the International Continence Society (ICS) and a Joint IUGA/ICS Working Group on Complications Terminology, assisted at intervals by many expert external referees. An extensive process of 11 rounds of internal and external review took place with exhaustive examination of each aspect of the terminology and classification. Decision-making was by collective opinion (consensus). **Results:** A terminology and classification of complications related directly to the insertion of prostheses and grafts in female pelvic floor surgery has been developed, with the classification based on category (C), time (T) and site (S) classes and divisions, that should encompass all conceivable scenarios for describing insertion complications and healing abnormalities. The CTS code for each complication, involving three (or four) letters and three numerals, is likely to be very suitable for any surgical audit or registry, particularly one that is procedure-specific. Users of the classification have been assisted by case examples, colour charts and online aids ([www.icsoffice.org/complication](http://www.icsoffice.org/complication)). **Conclusion:** A consensus-based terminology and classification report for prosthesis and grafts complications in female pelvic floor surgery has been produced, aimed at being a significant aid to clinical practice and research. *NeuroUrol. ### PREFACE

The Standardization and Terminology Committees of the International Urogynecological Association (IUGA) and the International Continence Society (ICS) and the Joint IUGA/ICS Working Group on Complications Terminology seek to provide a terminology and a standardized classification for those complications arising directly from the insertion of prostheses and grafts in female pelvic floor surgery. This document would then be, amongst its various other possible applications such as medical records and surgical audits (often procedure-specific), the basis for a registry of such complications. As the first aim is to standardize the terminology used in this classification, the terms used in the title need to be initially defined.

- **Classification:** A systematic arrangement into classes or groups based on perceived common characteristics.<sup>2</sup> N.B. *Division:* A separation into two or more parts.
- **Complication:** A morbid process or event that occurs during the course of a surgery that is not an essential part of that surgery (“surgery” replacing “disease” in the definition; “course” includes postoperative of whatever duration).<sup>1</sup>
- **Directly:** Without an intermediary or intervening factor.<sup>2</sup>
- **Related:** Connected.<sup>2</sup>
- **Insertion:** Putting in.<sup>1</sup>
- **Prosthesis:** A fabricated substitute to assist a damaged body part or to augment or stabilize a hypoplastic structure.<sup>1</sup>
- **Mesh:** A (prosthetic) network fabric or structure; open spaces or interstices between the strands of the net.<sup>2</sup> The use of this term would be for *prolapse surgery with synthetic materials*.
- **Implant:** A surgically inserted or embedded prosthesis.<sup>1</sup> (*Explant:* a surgically excised prosthesis).
- **Tape (Sling):** A flat strip of synthetic material.<sup>1</sup> The use of this term would be for *incontinence surgery with synthetic materials*.
- **Graft:** Any tissue or organ for transplantation.<sup>1,2</sup> This term will be used to refer to *biological materials inserted*<sup>3</sup>:
  - (a) *Autologous grafts:* From patient’s own tissues, for example, dura mater, rectus sheath, or fascia lata.
  - (b) *Allografts:* From post-mortem tissue banks.
  - (c) *Xenografts:* From other species, for example, modified porcine dermis, porcine small intestine, and bovine pericardium.
 Terminology for grafts has not been separated into the different applications for prolapse and continence surgery.
- **Trocar:** A surgical instrument with either a pyramidal, conical, or needle-type cutting or dissecting point.

### INTRODUCTION

A significant increase in the use of an ever-widening array of prostheses and grafts has occurred in female pelvic floor surgery over the last 30 years. In the 1980s, silastic slings and artificial urinary sphincters<sup>4</sup> were used for urodynamic stress incontinence (USI). McGuire repopularized the rectus sheath fascial sling (an autologous graft) described originally by Aldridge.<sup>5</sup> In the early 1990s, variations on the Stamey-type<sup>6</sup> needle suspension procedures were used involving permanent sutures and modified needles or bone anchors.

*Neurourology and Urodynamics* DOI 10.1002/Inau

In the mid to late 1990s, suburethral synthetic slings for USI using mesh were introduced, the tension-free vaginal tape (polypropylene mesh) being the most notable.<sup>7</sup> Trocars were used both retropubically and, over the last 8–10 years, laterally passing the obturator membrane and the insertion of the obturator internus muscle.<sup>8</sup> These trocars have the potential for causing trocar insertion-related complications in addition to complications due to the use of the prostheses or grafts themselves.

The prosthetic materials used to date have, in retrospect, been of different surgical propriety, not appreciated at the time of their introduction. Amid<sup>9</sup> has presented a classification for different types of meshes for repair of abdominal wall herniae (the behavior of meshes around the vagina may differ) based on pore size and fiber type used and the likelihood of complications according to these factors. This has been extremely useful in directing clinicians and the mesh and/or device manufacturers to more appropriate mesh types and designs. The consensus today is that the least morbidity will be achieved by using a low weight, inert, large pore, monofilament prosthesis, with an elasticity between 20% and 35%.<sup>10,11</sup>

Deprest et al.<sup>11</sup> have presented an excellent analysis of the biology behind the use of prostheses (synthetic) and grafts (biological) in pelvic organ prolapse repair. The classification to be outlined will cover insertion issues as well as infection, healing abnormalities, and other signs of poor integration of these materials, though not the materials themselves.

In terms of prolapse surgery, there has been at times a quest to achieve a prolapse repair with as close to 100% efficacy (anatomical success) and reduce the 29% long-term risk for a woman to undergo a subsequent prolapse surgery after prior prolapse or continence surgery.<sup>12</sup> Anatomical benefits have not been necessarily matched by subjective benefits, that is, functional acceptability for the patient. “Kits” (defined as a set of articles or equipment needed for a specific purpose<sup>2</sup>) have been introduced for all types of prolapse repairs, again involving the use of different materials with different fixation devices or trocars. Papers on such procedures meeting the scientific criteria for randomized prospective trials have been relatively slow to emerge. In addition to “kits,” the same materials have also been independently laid in place or fixed with surgical sutures. The use of prostheses or grafts has progressed questionably in some areas from an indication for recurrent prolapse to that of using them in primary procedures.<sup>13</sup>

Historically, discontinuation of a surgical procedure occurs generally due to either (i) a lack of efficacy or (ii) the nature or frequency of complications. Native [patient’s own, not an autologous (transplanted) graft] tissue repairs are also not without complications. Prostheses or grafts potentially add to the complication profile the aspects of (i) trauma of insertion; (ii) reaction of the body to the prosthesis in terms of inflammation or infection; (iii) the stability of the prosthesis over time; (iv) morbidity at the donor site from harvesting an autologous graft.

One key precept in the Hippocratic oath, often quoted in Latin, is *primum non-nocere* (first, to do no harm). Surgeons need to know the possible complications that their surgeries might cause and when and where they might occur. In respect of the use of prostheses and grafts, such information might be

## 4 Haylen et al.

generated from a table of complications (personal, institutional, or multi-center), classified according to three aspects: category, time, and site (defined below). In addition, there have been examples of personal, multi-center, national, and industry-coordinated registries. It is a simultaneous aim, with the production of this document, to initiate the development of a user-friendly, online accessible joint ICS-IUGA web-based registry of the complications referred in this document. With the information from a codified table of procedure-specific complications, possibly involving a registry (at whatever level): (i) a surgeon might better know the value and risk of a certain procedure; (ii) informed counseling might be provided before a woman embarks on that procedure; (iii) if the procedure involves a prosthesis supported by industry, then that group would have detailed feedback on the complications of that procedure. Should the overview in terms of complications be sufficiently adverse, the procedure and/or the prosthesis or graft should be abandoned.

In drawing up such a classification of complications based on category, time, and site, the bias would be towards optimizing sensitivity, clarity, and interpretability. Increasing sensitivity comes with the natural risk of the classification appearing overly complex. It is hoped that the following outline and explanatory notes, user-friendly tables, case examples, and some online aids (to be introduced in conjunction with the publication of this document – see abstract and discussion for web reference) might alleviate any such concern. It would be of greater concern if the classification did not cover all the different complication scenarios, such that previously undefined additional terminology might be needed.

#### PROPOSED NEW DEFINITIONS

Complications involving the use of meshes, tapes, and grafts in female pelvic floor surgery need to involve the following viewpoints of (i) local complications; (ii) complications to surrounding organs; and (iii) systemic complications. The generic term of “erosion” (medically defined as the “state of being worn away, as by friction or pressure”<sup>1</sup>), does not necessarily suit the clinical scenarios encountered. Its use is best avoided, to be replaced by terms with greater physical specificity and clarity.

The additional terms to be used are (see also Table 1):

- **Contraction:** Shrinkage or reduction in size.<sup>1</sup>
- **Prominence:** Parts that protrude beyond the surface<sup>1</sup> (e.g., due to wrinkling or folding with no epithelial separation).
- **Separation:** Physically disconnected,<sup>2</sup> for example, vaginal epithelium.
- **Exposure:** A condition of displaying, revealing, exhibiting, or making accessible<sup>1</sup> (e.g., vaginal mesh visualized through separated vaginal epithelium; Fig. 4).
- **Extrusion:** Passage gradually out of a body structure or tissue<sup>1</sup> (e.g., a loop of tape protruding into the vaginal cavity; Fig. 5).
- **Compromise:** Bring into danger.<sup>2</sup>
- **Perforation:** Abnormal opening into a hollow organ or viscus.<sup>1</sup>
- **Dehiscence:** A bursting open, splitting, or gapping along natural or sutured lines.<sup>1</sup>
- **Sinus tract formation:** (Localized) formation of a fistulous tract towards vagina or skin, where there is no visible implant material in the vaginal lumen or overlying skin.

*Neurourology and Urodynamics* DOI 10.1002/nau

#### CATEGORY, TIME, AND SITE (CTS) CLASSIFICATION

The overall aim of the classification is to summarize any of a large range of possible clinical scenarios into a code (“a numeric system for ordering and classifying information”<sup>1</sup>) using as few as three numerals and three (or four) letters. No additional verbal description, possibly involving undefined terminology, should be necessary (see Table 2).

#### SELECTION OF CATEGORIES

The selection of category (C) has used the principal that the least severe complication would involve the prosthesis remaining within the anatomical site into which it was inserted. More severe complications would involve (i) increasing exposure in surrounding anatomical structures; (ii) opening into surrounding organs; and (iii) systemic compromise. The following seven categories (by number) have been formed:

1. *Vaginal complication—no epithelial separation:* This incorporates the terms prominence (e.g., due to wrinkling or folding) or contraction (shrinkage). Also incorporated here is the palpation of mesh fibers.
2. *Vaginal complication—(smaller) exposure:* A smaller (1 cm or less) degree of vaginal epithelial separation is involved.
3. *Vaginal complication—(larger) exposure or extrusion:* A larger degree (>1 cm) of vaginal epithelial separation or prosthesis or graft extrusion is involved.

Categories 1–3 have been separated into the following divisions:

**1A–3A: Asymptomatic—abnormal mesh finding:** These are generally physician-diagnosed at any episode of clinical care. It can be argued that the “abnormal prosthesis or graft finding” aspects of category **1A**, in particular, aren’t really complications as the patient isn’t bothered by the potential problem. It may be, however, that the woman may not have engaged in an activity that is likely to provoke symptoms for herself, for example, pain or bleeding during sexual intercourse (or for her partner), which would convert these complications to category **1B**.

**1Aa–3Aa: Asymptomatic—abnormal mesh finding—no pain:** The addition of an “a” specifies that the patient experiences no pain in association with the abnormal finding.

**1B–3B: Symptomatic—unusual discomfort or pain; dyspareunia (for either partner):** Bleeding or discharge may be possible symptoms.

**1Bb–3Bb: Symptomatic—provoked pain only (during vaginal examination):** The addition of a “b” to the category code specifies that pain, provoked only during vaginal examination, is associated with the abnormal finding.

**1Bc–3Bc: Symptomatic—pain during sexual intercourse:** The addition of a c to the category code specifies that pain, provoked during sexual intercourse (patient only), is associated with the abnormal finding.

**1Bd–3Bd: Symptomatic—pain during physical activities:** The addition of a d to the category code specifies that pain, provoked during physical activities, is associated with the abnormal finding.

**1Be–3Be: Symptomatic—spontaneous pain:** The addition of an e to the category code specifies that pain, spontaneously

TABLE 1. Terminology Involved in the Classification

TERMS USED	DEFINITION
<b>PROSTHESIS</b>	A fabricated substitute to assist a damaged body part or to augment or stabilize a hypoplastic structure
<b>A: Mesh</b>	A (prosthetic) network fabric or structure
<b>B: Implant</b>	A surgically inserted or embedded prosthesis
<b>C: Tape (Sling)</b>	A flat strip of synthetic material
<b>GRAFT</b>	Any tissue or organ for transplantation. This term will refer to biological materials inserted
<b>A: Autologous Grafts</b>	From the woman's own tissues e.g. dura mater, rectus sheath or fascia lata
<b>B: Allografts</b>	From post-mortem tissue banks
<b>C: Xenografts</b>	From other species e.g. modified porcine dermis, porcine small intestine, bovine pericardium
<b>COMPLICATION</b>	A morbid process or event that occurs during the course of a surgery that is not an essential part of that surgery
<b>CONTRACTION</b>	Shrinkage or reduction in size
<b>PROMINENCE</b>	Parts that protrude beyond the surface (e.g. due to wrinkling or folding with no epithelial separation)
<b>SEPARATION</b>	Physically disconnected (e.g. vaginal epithelium)
<b>EXPOSURE</b>	A condition of displaying, revealing, exhibiting or making accessible e.g. vaginal mesh visualized through separated vaginal epithelium
<b>EXTRUSION</b>	Passage gradually out of a body structure or tissue
<b>COMPROMISE</b>	Bring into danger
<b>PERFORATION</b>	Abnormal opening into a hollow organ or viscus
<b>DEHISCENCE</b>	A bursting open or gaping along natural or sutured line

present (i.e., without physical activity), is associated with the abnormal finding.

**1C-3C: Clinical infection:** This is always a possibility with a synthetic prosthesis or graft. Signs of local tenderness are suggestive with the combination of redness and a purulent discharge being more conclusive.

**1C-3C (b-e): Infection-pain:** The addition of the letters *b* through to *e* specifies that pain (as defined in Table 4) is part or all of the infected abnormal finding.

**1D-3D: Abscess formation:** This is a more serious possibility with a synthetic prosthesis or graft.

**1D-3D (b-e): Infection-pain:** The addition of the letters *b* through to *e* specifies that pain (as defined in Table 3) is

part of the abnormal finding associated with abscess formation.

Category 4: Urinary tract compromise or perforation. This category class has been subdivided into:

**4A: Small intraoperative defect:** For example, bladder perforation. Such a complication does not generally create longer-term compromise for the bladder if recognized, prosthesis (graft) removed as indicated, defect oversewn (if necessary), and some minor precautions are taken, for example, short-term bladder drainage, with suitable antibiotics commenced.

**TABLE 3. Subclassification of Complication Categories to Specify the Presence of Pain (by the Patient only, not the Partner) Associated with the Abnormal Finding and the Grade in Terms of the Presence and Severity of Symptoms**

GRADE OF PAIN	SYMPTOMS
a	Asymptomatic or no pain
b	Provoked pain only (during vaginal examination)
c	Pain during intercourse
d	Pain during physical activities
e	Spontaneous pain

*4B: Other lower urinary tract (bladder or urethral) complication or compromise:* This division would incorporate injuries causing longer-term bladder issues, for example, ongoing prosthesis or graft perforation, fistula, calculus around the prosthesis, or graft. This category also incorporates urinary retention directly related to the procedure requiring subsequent surgical intervention (apart from any form of bladder drainage). The time and site divisions relates to those for the surgical intervention.  
*4C: Ureteric or upper tract complication or compromise:* This division is self-explanatory.

Category 5: Rectal or Bowel compromise or perforation. This category class has been subdivided into:

*5A: Small intraoperative defect:* Such a complication may not generally be expected to cause compromise if the defect is recognized, prosthesis (graft) removed as indicated, defect oversewn (as necessary) with appropriate precautions taken, for example, short-term bowel rest is instituted with suitable antibiotics commenced.  
*5B: Rectal injury or compromise:* This division would incorporate injuries causing longer-term rectal issues, for example, ongoing prosthesis (graft) perforation, fistula.  
*5C: Small or large bowel injury or compromise:* This division would incorporate injuries causing longer-term bowel issues, for example, ongoing prosthesis (graft) perforation, fistula, obstruction.  
*5D: Abscess formation from bowel injury/compromise.*

Category 6: Skin and/or musculoskeletal complications:

*6A: Asymptomatic:* Physician-diagnosed complication at any episode of care.  
*6B: Symptomatic:* For example, discharge, pain, lump.  
*6C: Infection from skin or musculoskeletal complication:* Including sinus tract formation.

*6D: Abscess formation from skin or musculoskeletal complication.*  
 Category 7: Patient compromise. This category recognizes that the patient might be brought into systemic danger with some of the complications in addition to any localized issue.

*7A: Bleeding complication including hematoma:* This division refers to any clinically diagnosed hematoma as well as those where blood transfusion or surgical intervention is a consideration.  
*7B: Major degree of resuscitation or intensive care:* This division refers to significant hemodynamic or cardiopulmonary resuscitation directly related to the procedure, and/or patient transfer for management in intensive care facilities.  
*7C: Mortality:* The insertion of the prosthesis, whilst not necessarily fatal at the time, has set in train further morbid events leading to mortality.

N.B. Because of their systemic nature, *7B* and *7C* will not have a specific site division. They will be denoted *50*.

**SELECTION OF TIME (T) DIVISIONS**

The time (T) for the complication is when it is *clinically diagnosed*. This section incorporates four time periods, all of the possible episodes where clinical care might be given by the physician or sought by the patient. It might not always be possible to predict with any prosthesis or graft when complications might be more frequently seen. This would depend on the results of a procedure-specific surgical audit using the classification. The earliest time division (*T1*) might involve more insertion issues, whilst later divisions (*T2–T4*) might be biased towards healing abnormality issues.

*T1: Intraoperative—48 hr:* Insertion complications more likely.

**Fig. 1.** 52-year-old female underwent a transobturator tape. At 6 weeks, she was cured of her USI and reported no vaginal discharge. Vaginal examination revealed a smaller mesh exposure away from vaginal suture line. **Classification:** 2A T2 S2.

**Fig. 3.** 65-year old with urinary incontinence, underwent a multifilament transobturator sling. At 14 months follow up, she experienced severe pelvic pain and vaginal discharge. Clinical examination revealed hyperthermia to 40°C, (i) sling exposure at right vaginal sulcus and (ii) severe cellulitis in the genito-crural fold. **Classification:** (i) 3C T4 S2; (ii) 6C T4 S3.

**T2: 48 hr–2 months:** Healing or infection complications more likely.

**T3: 2–12 months:** Later healing abnormalities more likely.

**T4: Over 12 months:** Late healing abnormalities and other mesh complications more likely.

**Fig. 2.** 55-year-old female had a retropubic tape. At 2 years follow up, she reported vaginal discharge. Examination revealed a palpable but unseen lateral mesh exposure, together with a cutaneous fistula with local purulent discharge. **Classification:** (i) 2B T4 S2; (ii) 6C T4 S4.

*Neurourology and Urodynamics* DOI 10.1002/nau

#### SELECTION OF SITE (S) DIVISIONS

The selection of these divisions incorporates the current sites where prosthesis or graft complications have been noted:

**S0: Systemic complications (no specific site):** As mentioned earlier, category divisions 7B and 7C which are systemic complications will be denoted S0.

**S1: Vaginal: area of suture line:** Perhaps the commonest site for prosthesis and graft complications from vaginal surgery is close to the vaginal suture line.

**S2: Vaginal: away from the vaginal suture line:** As most suture lines would be midline, this would generally be lateral in the vagina.

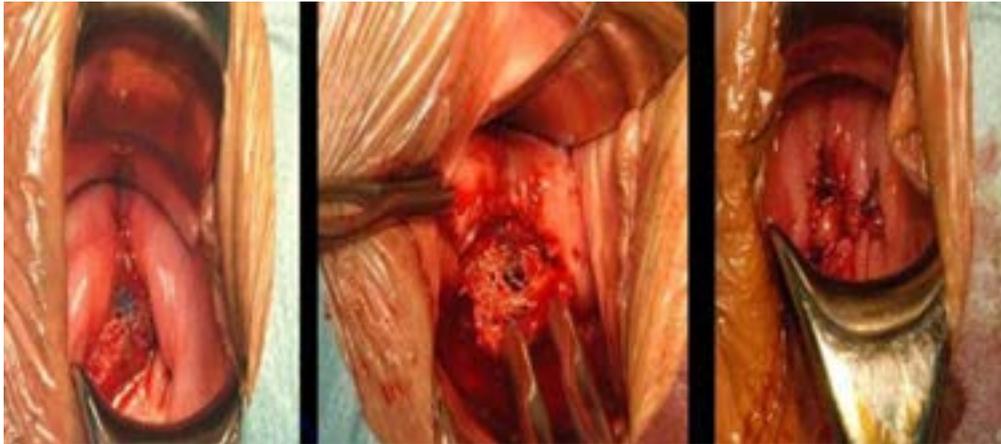

**S3: Trocar passage:** The passage of any sharp surgical instrument can cause damage along the path of insertion. This division incorporates any extraperitoneal, bladder, or rectal complication, but not intra-abdominal complications which are S5.

**S4: Other skin or musculoskeletal site:** This division is relevant to any skin or musculoskeletal complications away from the sites of trocar entry or exit. Included might be cutaneous sinus or fistula formation.

**S5: Intra-abdominal:** Included in this section would be bowel perforation or obstruction.

**CTS Classification:** (Complete code):

- Example of complete CTS code: 3B/T2/S3 (for simplicity, there is no “C” in front of the category class and division). The letters *a–e* may be added to the category code, for example, 3Bc/T2/S3 to indicate that pain is part of the abnormality (*c*—pain with intercourse).

**Fig. 4.** A 67 year old woman had undergone a vaginal prolapse repair with hysterectomy. She subsequently had a transvaginal mesh repair for a large recurrent cystocele. At 5 months follow up, she complained of dyspareunia. Vaginal examination revealed a mesh exposure of 20 mm by 15 mm at anterior vaginal wall and vaginal cuff. **Classification: 3Bc T3 S1.**

**CLASSIFICATION GUIDELINES**

The following should be noted:

- *Multiple complications may occur in the same patient:* These should be reported separately as noted in Table 3.
- *There may be early and late complications in the same patient:* again, these should be reported separately.
- *All complications should be listed.*
- *If there is progression of a particular complication over time, the highest final category is to be used:* progression of a

**Fig. 5.** A 47-year-old woman underwent a transoburator tape for USI. At 5 months follow-up, she reported vaginal discharge. Clinically she was febrile at 38°C with a large sling extrusion as depicted. **Classification: 3C T3 S1.**

Neurourology and Urodynamics DOI 10.1002/nau

vaginal tape exposure from asymptomatic to symptomatic; an exposure progresses from smaller to larger.

**CLASSIFICATION LIMITATIONS**

- *The classification does not note the specific type of mesh:* Use of prostheses other than those with the least morbidity (as described in the Introduction Section) might be further reflected in an increased rate of the healing abnormalities.

**Fig. 6.** A 65-year-old woman underwent a transvaginal mesh repair for a grade 3 prolapse. At 32 months, she had recurrent urinary tract infections, urgency and urge incontinence, pelvic pain and deep dyspareunia, bladder pain, and lumbar pain. Radiology: right hydronephrosis and ureteral obstruction. (i) Cystoscopy: mesh extrusion (<0.5 cm) with stone. No right ureteric patency. (ii) Vaginal examination: severe anterior mesh shrinkage and pain during anterior vaginal wall palpation. **Classification: (i) 4C T4 S3; (ii) 1Bc T4 S1.**

**Fig. 7.** A 56-year-old woman underwent a posterior vaginal mesh procedure using a trocar. At 3 months, clinical examination confirmed an (i) infected midline 15 mm vaginal mesh exposure together with (ii) a recto-vaginal fistula. There had been mesh penetration of the rectum. **Classification:** (i) 3C T3 S1; (ii) 5B T3 S3.

- **Functional issues** (e.g., voiding dysfunction) are not included: Voiding dysfunction can be defined as abnormally slow (assessed by urine flow rate data) and/or incomplete (assessed by postvoid residual) micturition.<sup>14</sup> Surgical intervention for severe voiding dysfunction, namely urinary retention is included in Section 4B.

**Fig. 8.** A 62-year old woman underwent a transobturator anterior vaginal mesh procedure. At 24 months follow up, she reported no vaginal discharge. Clinical examination revealed skin erosion with local inflammation and some discomfort at (trocar) exit point. **Classification:** 6B T4 S3.

*Neurourology and Urodynamics* DOI 10.1002/nau

- **Urinary tract infections** have not been included.
- The small risk (about 1 in 2 million) of prion or viral infection associated with a xenograft<sup>15</sup> is not included.
- **Recurrences:** It is claimed that meshes are used to prevent recurrence of pelvic organ prolapse. However, a mesh procedure might fail resulting in a recurrence. This can be either by degradation or local release of sutures, the clinical result being the same. Sometimes local complications can lead to the removal of the mesh, which could further increase the risk for recurrence. However, it should be emphasized that recurrence is not a complication.
- **Intraperitoneal adhesions:** Some procedures involve the use of implant material into the abdomen. As a consequence, intraperitoneal adhesions can arise either on the implant or remotely.
- **Bulking agents:** Complications related to bulking agents including migration are not included.

#### DISCUSSION

The present classification has been developed to be sensitive to all possible physical complications involving the use of a prosthesis or graft in a female pelvic floor surgical procedure. Both insertion complications (e.g., trocar related) and healing abnormalities are covered. Whilst this creates a large number of possible complication scenarios, appropriate organization has still been possible by category, time and site. The end-point is a code of three letters (4 if *a–e* are used) and three numerals. The addition of the pain subclassification reflects the recognition of the authors that chronic pain, especially if in the higher subclasses (*c–e*), can be amongst the most disabling surgical outcomes from the use of prostheses or grafts in female pelvic floor surgery.

A key advantage of a standardized classification is that all parties involved in female pelvic floor surgery including surgeons, physicians, nurses, allied health professionals, and industry will be referring to the same clinical issue. It is anticipated that a (CTS) codified table of complications will be a necessary part of reports of surgical procedures relevant to this document. Many countries already have national databases for new surgical devices. It is inevitable that there will be more regulation over time for their introduction. With a standardized classification in place, quicker assessment of adverse events will be achieved together with uniform reporting of prosthetic-related complications. Any procedure showing a consistently high rate of complications in a surgical audit would need closer scrutiny and/or possible abandonment. As result of the use of such a classification, in terms of patient care, the principle from the Hippocratic oath, “first, to do no harm” is more likely to be observed.

It is acknowledged that to optimize the coverage of complications, the classification might still appear complex and not immediately mastered. However, as noted in the Introduction Section, we anticipate that the case examples provided below, the color charts and the online ICS-IUGA Complication Classification Calculator ([www.icsoffice.org/complication](http://www.icsoffice.org/complication)) will ameliorate any initial concerns.

It has been a consensus view of the authors that a formal academic terminology and classification should be completed prior to attempts at further simplification. This otherwise might run the risk of compromising coverage of complications.

TABLE 4. An Example of a *Non-Procedure Specific* Table of Complications Related Directly to the Insertion of Prosthese (Meshes, Implants, Tapes) or Grafts in Female Pelvic Floor Surgery using the Category (C), Time (T) and Site (S) system. The CTS Classification Code is Placed Adjacent to the Description of the Complication. One Might Expect these Tables to be Often Procedure-Specific.

Patient Number	Description of complications	Code	Code
000	Retropubic haematoma following a tape procedure (first 24 hours)	7A/T1/ S3	
111	Persistent thigh pain six weeks after an obturator tape	6B/T2/ S4	
222	Bowel obstruction and 2cm vaginal vault exposure with bleeding 6 months after a mesh sacrocolpopexy	5C/T3/ S5	3B /T3/ S1
333	Mesh fibre exposure (lateral vaginal) in a woman at a 6 week postop review whose partner is describing discomfort with intercourse	1B/T2/ S2	
444	A midline vaginal exposure of mesh (< 1cm) with redness, dyspareunia, discharge 15 months after an anterior colporrhaphy using mesh.	2Cc/T4/S1	
555	Lateral vaginal extrusion with malodorous discharge and a midline rectovaginal fistula 8 months after a posterior vaginal tape	3C/T3/ S2	5B /T3/ S1
666	Intraoperative obturator vessel injury during a transobturator tape procedure requiring major resuscitation	7B/T1/ S3	
777	Persistent intravesical tape / calculus formation / haematuria 2 years after a retropubic tape procedure	4B/T4/ S3	
888	Pelvic abscess presenting 8 days after a mesh sacrocolpopexy complicated by an intraoperative bowel defect (final category). Initial code was 5A/T1/S5	5D/T2/S5	
999	Tender prominent mesh contraction noted 9 months after an anterior mesh repair (no symptoms, husband unwell)	1Bb/T3/S1	
XXX	Persistent postvoid residual of 150mls with recurrent UTI requiring posterior division of suburethral tape 4 months after insertion	4B/T3/S1	

#### ACKNOWLEDGMENTS

The co-authors acknowledge the support and goodwill of the IUGA and ICS leadership in this second Joint Report from the two societies, following on from the Joint Report on Terminology for Female Pelvic Floor Dysfunction.<sup>14</sup> We thank Mr. Dominic Turner and Mr. Ashley Brookes from the ICS Office for their assistance and expertise in developing the online aids and the progress towards an ICS-IUGA Registry. This document has involved 11 rounds of full review by co-authors. Following website publication (Version 8), there have been four rounds of further review. Versions 3 and 10 were subject to live meetings in Cancun (June 2007) and Toronto (August 2010). The valuable input of Professor Bernard Jacquetin is gratefully acknowledged. The comments of the following reviewers in response to website publication (April–June, 2010) are also much appreciated: Dr. Angamuthu

## Developing Evidence-Based Standards for Diagnosis and Management of Lower Urinary Tract or Pelvic Floor Dysfunction

Peter F.W.M. Rosier,<sup>1</sup> Dirk de Ridder,<sup>2</sup> Jane Meijlink,<sup>3</sup> Ralph Webb,<sup>4</sup>  
Kristene Whitmore,<sup>5</sup> and Marcus J. Drake<sup>6\*</sup>

<sup>1</sup>University Medical Centre Utrecht, The Netherlands

<sup>2</sup>Department of Urology, University Hospitals KU Leuven, Leuven, Belgium

<sup>3</sup>Chairman, International Painful Bladder Foundation, The Netherlands

<sup>4</sup>Department of Urology, Norfolk & Norwich University Hospital, Norwich, United Kingdom

<sup>5</sup>Pelvic & Sexual Health Institute, Philadelphia, Pennsylvania

<sup>6</sup>Bristol Urological Institute, University of Bristol, Bristol, United Kingdom

The International Continence Society (ICS) has a key role in standardizing terminology related to lower urinary tract and pelvic organ dysfunction. The ICS Standardization Steering Committee (SSC) presents the new structure and process by which future ICS Standards will be developed. The new processes aim to meet present-day evidence-based practice requirements, and to foster unbiased, inclusive, and transparent development. For each new ICS Standard, the SSC will oversee a dedicated ad hoc Working Group (WG). Applications to chair or contribute to a WG will be invited from the ICS membership. The SSC will select the Chairperson, and work with him or her to select the WG composition, balanced to represent key disciplines, stakeholders, and regions. Consultants can be invited to contribute to the WG where specific need arises. Every WG will review current knowledge, adhering to evidence-based medicine requirements. Progress reports will be reviewed by the SSC, and amendments recommended, culminating in a first draft. The draft will be offered to the ICS membership and additional relevant experts for comment. Further revision, if needed, will result in a document, which the SSC will submit to the ICS Trustees, as arbiters of whether the document should be adopted as an ICS Standard. The SCC will then coordinate with the WG to ensure that the new ICS Standard is published and disseminated. Implementation strategies, such as education, audit, accreditation, and research initiatives will be linked to the Standards where appropriate. Revisions of ICS Standards will be undertaken to maintain contemporaneous relevance. *NeuroUrol. Urodynam.* 31:621–624, 2012. © 2012 Wiley Periodicals, Inc.

**Key words:** standards; evidence-based medicine

### INTRODUCTION

One of the most recognized activities of the International Continence Society (ICS) has been the publication of standardizations of terminology for diagnosis and testing in functional urology. This work started in 1976, with subsequent updates. The 1988<sup>1</sup> and the 2002<sup>2</sup> reports, with  $\pm 1,000$  and  $\pm 2,500$  citations, respectively, are amongst the most widely quoted publications in urology.

There have been two particularly important categories of publication. The first is the standardization of terminology, such as the “Standardization of Terminology of Lower Urinary Tract Function.”<sup>2</sup> Standardized definitions of key medical terms with international consensus are increasingly needed as analysis and registration in healthcare become ever more automated and communication increasingly global. The establishment of the International Health Terminology Standards Development Organization (IHTSDO; <http://www.ihstdo.org/index.php?id=502>) signifies the increasing weight attached to the agreed definitions of terminology to describe conditions at a fundamental level in medicine. The second category deals with the provision of guidelines for quality control and improvement of standards, which serve as a benchmark for professional activity, exemplified by the “Good Urodynamic Practice” document.<sup>3</sup>

ICS standards and standardization have led the way and have been widely accepted. The process by which they have been produced has been based on intensive expert discussion

and consensus with input from the ICS membership, but without inclusion of the published evidence in a systematically weighed and transparent manner. The most recent report, a joint report with the International Urogynecological Association,<sup>4,5</sup> was developed in a similar manner. Ease of modern electronic communication has allowed more experts to monitor the content of draft editions of newer documents. This has meant that expert opinions were included in a “numerically” more balanced manner. However, no “methods” paragraph was given to explain explicitly how decisions on topics to include were made, nor how evidence and expert opinion were prioritized, included or excluded beyond acknowledgement of the commenting experts in a final paragraph.

Ideally, only “genuine evidence” is included in standards and guidelines. Where genuine evidence is lacking or conflicting, it is preferable that expert opinion is separately added to

Peter F.W.M. Rosier and Dirk de Ridder contributed equally to this work.

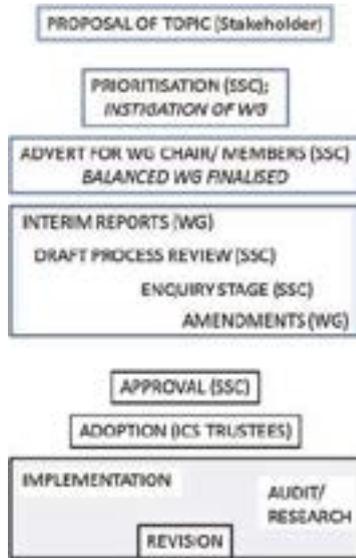

Fig. 1. Summary diagram of the key stages in development of an ICS Standard. (SSC, Standardization Steering Committee; WG, Working Group).

recommendations in a transparent and explicit manner. In the mid-eighties a group around David Sackett, a key figure in evidence-based medicine (EBM),<sup>6</sup> developed a systematic approach to evaluate published evidence, after he analyzed the problem of “observer error” in the interpretation of medical literature.<sup>7</sup> “EBM is the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. The practice of EBM means integrating individual clinical expertise with the best available external clinical evidence from systematic research.”<sup>8</sup> Standards to produce evidence-based clinical practice guidelines have been developed,<sup>9</sup> with guidance manuals.<sup>10</sup>

EBM as a strategy to improve healthcare is not disputed, but the implications in a rapidly expanding field of knowledge are

substantial.<sup>11</sup> In the modern era of information technology, transparency, accountability, and complex multidisciplinary responsibilities cannot be ignored; expert opinion is only acceptable where evidence is lacking and must be clearly marked and explained as being expert opinion.

The ICS Standardization Committee recognized the importance of adhering to EBM principles. In 2010, a reorganization took place from which the renamed Standardization Steering Committee (SSC) emerged. A key difference between the new SSC and the old Standardization Committee is that the SSC does not itself deliver standardization documents; instead it oversees ad hoc Working Groups (WGs) (see below) which deliver the documents, aiming to ensure transparency, balance, and adherence to the methods and principles of EBM. The SSC Chairman is elected from the ICS membership according to the ICS articles and bylaws. The Chairman and the SSC members serve for a term of 3 years, once renewable.

The ICS SSC aims to ensure ongoing development of high quality terminology and/or practice standards, for guidance of professionals dealing with the basic scientific investigation, diagnosis, and management of lower urinary tract, pelvic floor, genital, and anal function and dysfunction. Developing these standards requires transparency and integrity; the SSC’s process and expectations for modern-day development of some of the most important ICS documents are described below and illustrated in Figure 1.

**PROCESS OF DEVELOPING AN ICS STANDARD**

Topics selected by the SSC for development or revision of standardization reports will be based on areas of priority need, whether identified by the SSC itself, or in response to stakeholder suggestions. The delivery of a standardization document on a selected topic will be the remit of a specifically created ad hoc WG, which will focus on that specific subject (see Table I). The SSC’s role is to agree the scope of the WG’s activity, instigating and steering activity, checking compliance with suitable working practices, monitoring progress, ensuring adequate stakeholder input and evaluating the end result.

Once the need for a new or revised standard has been identified, the SSC will invite applications from ICS members wishing to chair the relevant WG. The person selected will have submitted the proposal with the best strategy for developing the document in the opinion of the majority of SSC members.

**TABLE I. Structure and Function of Standardization Document WG**

---

The composition needs to be multidisciplinary and multinational, representing the most important stakeholders (including, e.g., patient representatives, health economists, and others as appropriate)

Non-ICS members can be part of the WG as experts or representatives of specific stakeholders

The WG should generally not include more than 15 people

Selection of WG members should follow a transparent process, which is recorded and publicly available

Additional contributions to a WG’s deliberations can be received from outside individuals

The WG should not receive any sponsorship from industry and the members should disclose all relationships

All members of the WG will be responsible for the entire content of the document as a group.

The WG has a chairman who:

- will propose the key question or topics of discussion to the SSC, together with a strategic plan.
- will keep a digital working log of the WG activities
- will make sure that the composition of the WG is well balanced and that the process of standardization is transparent
- will use web-based and e-mail exchange of information and monitor the execution of assignments within the assigned timeline
- will adhere to EBM principles, where appropriate
- will report to the SSC
- will be responsible for production of a first draft of the report within a stipulated time frame (generally 18 months)
- will be responsible for submission for publication and dissemination.

After publication of the standard, the WG will be dissolved.

A typical lifespan for an ad hoc WG will maximally be 36 months. If the WG fails to be productive, the SSC dissolves the WG.

The ICS or ICS SSC will not provide financial budget for face-to-face meetings of any ad hoc WG.

---

**TABLE II. SSC Criteria for Assessing WG Proposals**

Title of the project
Name of applicant
Description of the topic: The arguments for creating the WG are: (Explain why one or more of the following arguments is relevant)
area of clinical uncertainty or "debate" exists
evidence of better treatment is available
evidence for renewal of the existing standard is available
evidence of practice variation is available
other clinical or scientific relevance
there is significant controversy in practice or literature
there is conflicting or incomplete evidence
there are cultural differences in practices or viewpoints
there is socio-economic relevance
List of proposed names (with CVs):
confirmation that individuals have agreed to contribute
evidence of multinational and interdisciplinary balance
opportunity for ICS members to apply to join the WG and transparent, documented process for selection
process to register contributions from individuals or groups not in the WG
Description of the methodology and how it will be used:
web-based approach
e-mail
conference calls or webcasts
face-to-face meeting (mainly during ICS international meetings)
proposed timeline
Description of topic, proposed WG composition, likelihood of implementation, likelihood of publication, innovation of approach, realistic timeline, use of electronic tools.

The SSC will evaluate proposals according to key criteria (Table II).

**WG Composition**

The selected Chairperson will establish a WG of interested and knowledgeable individuals from a multinational and interdisciplinary background, representing all key stakeholder groups. Technical expertise relevant to the WG's remit will be taken into consideration in the selection of members. The WG will also be permitted or asked by the SSC to invite input from outside consultants where this is needed. This will typically be applicable in specialist contexts that are not widely represented within the ICS, such as engineering, computer sciences, or data handling. It may also be relevant in other fields, such as consumer perspectives, or economic issues, for example.

**TABLE III. Development of an ICS Standard**

	Timescale (months)	WG	SSC
Proposal stage	-6 to 0	Applications for Chairmanship or membership.	Call for applications. Review subject, Chair, Group, criteria, timeline and starting date.
Preparatory stage	0 to 18	WG constituted. Development of draft.	Evaluate progress. Appoint mentor. Evaluation (at least every 6 months).
Committee stage	18 to 21	Draft submitted to SSC.	Review of the process and document against criteria. Approval by consensus.
Enquiry stage	21 to 24	Draft on ICS website.	Internal and external review. Comments by ICS members and stakeholders.
Approval stage	24 to 27	Submit final document to SSC.	Process review. Submission to ICS Board of Trustees.
Publication	27 to 36	Final text to ICS office for web publication. Journal submissions.	Official ICS document. WG dissolved.
Implementation stage	>36		Support implementation. Education (with ICS Education Committee). Register of comments. Identify research needs. Support health technology and economic assessment.
Revision stage		Submit proposal to SSC.	Start new process.

*Neurology and Urodynamics* DOI 10.1002/nau

The SSC will ensure a transparent process for selection of WG members, and will evaluate and adapt the composition to ensure a balance between different viewpoints (professional, patient, and other stakeholders' perspectives). Once agreed, the proposal and the names of the WG's members will be published on the ICS website. If a member of the SSC is also a member of a WG, he/she will not be included in SSC decisions related to that particular WG. All (potential) conflicts of interest will be published on the ICS website.

**Stages of a Standard**

Stages through which a standardization document will progress are summarized in Table III. These will be listed in the project management-working log of the WG and the Chairperson of the WG should report progress to the SSC. The SSC will provide a mentor for the WG, who will evaluate the progress at least every 6 months and be available if any problems arise. The mentor will keep a log of these contacts.

**Preparation of a Draft Report**

The WG will prepare successive working drafts, circulating the drafts, and amending according to comments, until the group is satisfied that it has developed the best solution for the subject being addressed. Standards should adhere to EBM principles, where appropriate and possible. At an early stage, therefore, the WG has to devise a strategy for a comprehensive review of published literature and use an inclusive and transparent approach to derivation of expert opinion. It might sometimes be necessary to use the Delphi method.<sup>12</sup> Each WG will ensure a strategy for capturing and assimilating the views of all groups of stakeholders and criteria for inclusion or exclusion of these views in the finished document.

Throughout, the WG's Chairperson is responsible for:

- keeping a digital log of the WG's activities
- documenting the methods that were used to produce the draft document
- promoting web-based and e-mail exchange of information and monitoring the execution of assignments within the agreed timeline
- reporting to the SSC
- producing a first draft of the report within 18 months.

#### Committee Stage (Assessing the Process of Standardization)

As soon as a draft is available, the Chairperson of the SSC will forward it to all the members of the SCC for internal process review. The process by which the draft standard was created will be evaluated according to preset criteria. The document requires SSC approval prior to progressing to the next stage of development. The SSC may require revisions or amendments which will need to be undertaken by the WG in a defined time frame. A document that fails to meet the objectives or was not developed in accordance with the appropriate approach will be rejected, and the WG will be dissolved.

#### Enquiry Stage (Wider Assessment of the Content of the Document)

The actual assessment of the content of the document will be undertaken by internal and external experts (invited by the SSC) and the ICS membership. The draft standard will be circulated to all members by website publication for commenting over a period of 3 months.

#### Approval Stage

The WG should resubmit the final version based on the comments received. Explicit criteria for the inclusion or exclusion of comments should be developed and each comment should be accompanied by a narrative explaining the reason why it was either included in or excluded from the final version. All comments and accompanying narrative will be published on the relevant document web forum. The revised version should be resubmitted to the SSC for process review and assessment of the amendments. If approved, the document and the log of the development process will be sent to the ICS Board of Trustees for confirmation and adoption.

#### Publication

Once the Board has confirmed and adopted the document and the process, the final text will be published on the ICS website and will then be referred to as the new ICS Standard, superseding previous Standards. Thus, the new report must outline where it differs from previous reports. The WG will be encouraged to submit the document as an ICS Standard to *Neurourology and Urodynamics*, and the SSC will advise in this process. Co-publication with other journals can be considered if relevant, within copyright regulations. Publication of the respective ICS Standard will conclude the WG's activities.

#### Implementation Stage

The ICS SSC will promote implementation of the standards by publication, dissemination and education, and the proposing of new standards to its affiliate and collaborating societies and organizations. Additionally, the SSC will monitor the undertaking of clinical audit based on the ICS Standards' recommendations as a key aspect of successful introduction of the documents into mainstream practice,<sup>13</sup> and the undertaking of the research and development necessary for ongoing development of the evidence base.

Standards will be written in UK English. Translation into other languages will be supported; for terminology standards, this will require that appropriate linguistic validation procedures are followed (for an example of the application of linguistic validation in the context of translation of symptom assessment tools, see Acquadro et al., 2006).

*Neurourology and Urodynamics* DOI 10.1002/nau

#### Revision of Standards

The ICS SSC will also keep track of comments that are received for consideration during a future revision of the standard text, as well as identifying future research needs. A revision or update can be proposed by the SSC or any ICS member or group of ICS members when there is a perceived need, and the timescale for anticipated revision of a standard will be specified at the time of adoption—subject to future developments in the field. The SSC can discuss not to revise outdated documents and declare them obsolete.

#### CONCLUSIONS

In developing evidence-based standardization documents, the ICS SSC aims to ensure inclusiveness, responsiveness, transparency, accessibility, flexibility, and evolution. The ICS SSC presents a structured process for ad hoc WGs to develop ICS standards, and a strategy to guide that process. Consequently, each WG will be responsible for several stages of development, each clearly documented, until a high quality document has been approved as an ICS standard.

The presented structure and strategy place emphasis on the principles of EBM and transparency in the development of ICS standards. They also provide the flexibility necessary for the varied nature of the initiatives established by the ICS, where multiple stakeholders are generally present, and also circumstances in which the evidence base may be limited. ICS standards will continue to be adopted and promoted as the basis for good professional practice, suitable for the demands of the modern era of EBM.

## 2. FUNDAMENTALS

The Fundamentals of Assessment articles are commissioned by the ICS Board of Trustees, setting out the core knowledge for any practitioner needing to assess lower urinary tract dysfunction (LUTD) in their clinical work. The documents aim to give a solid knowledge basis for several different aspects of LUTD, suitable for trainees, allied health professionals, and people working in related disciplines like neurology, primary care, and care of the elderly. They describe what any practitioner really must know for everyday practice, and provide examples, covering;

- Urinary symptoms in general.
- Specific patient groups: nocturia; neurological disease; chronic pelvic pain
- Pelvic organ prolapse quantification
- Urodynamic tests: flow rate testing; urodynamics; videourodynamics
- The relevance of Standardisation

As well as a knowledge base, the Fundamentals are a starting point for the ICS Standardisations, which are the basis of specialist practice in LUTD in substantial detail.

**S67** Why ICS Standardization of Lower Urinary Tract Symptoms Matters

Dirk De Ridder and Marcus Drake

**SOUNDING BOARD**

**S69** Critical Steps in Developing Professional Standards for the International Continence Society

Peter F. W. M. Rosier

The International Continence Society (ICS) Board of Trustees is glad to present a special supplement of *Neurology and Urodynamics* which sets out the core knowledge for any practitioner needing to assess lower urinary tract dysfunction (LUTD) in their clinical work. The material will be useful to trainees, allied health professionals, and people working in related disciplines like neurology, primary care, and care of the elderly. The documents are written in a simplified way to offer a helpful source of education and knowledge of several different aspects of LUTD.

A significant motivation for this effort is the need to be concise, explicit, and definitionally correct when using a common lexicon, as with the ICS Standardization documents, that govern the manner in which professionals in our field define their research and report results thereof. A sequence of documents is included which covers;

- Urinary symptoms in general, and in specific patient groups (nocturia; neurological disease; chronic pelvic pain)
- Pelvic organ prolapse quantification
- Urodynamic tests (flow rate testing; filling cystometry with pressure flow studies; videourodynamics)
- The importance of standardization and how the ICS Standards are developed

The knowledge base is drawn from the ICS Standards, which constitute the basis of specialist practice in LUTD, supplemented by practical application. The authors were

asked to write succinct and approachable documents, describing what they feel any practitioner really must know for everyday practice, and providing examples. Thus, these documents are derivatives of the many reports and publications that represent the ICS Standards but are not in themselves ICS Standardization documents. Inevitably, the choice of content is subjective, but each document seeks to offer simplicity and clarity. For those working to become specialists in the area, this supplement is a starting point for getting to grips with the comprehensive repository of detailed professional consensus documents established by the ICS over the course of several decades and available on the ICS website (<https://www.ics.org/folder/189>).

A significant aspect of the knowledge transfer is the education of those who are students or early career clinicians and investigators. Thus, the supplement aims to facilitate clarity, accuracy, and specificity of reports in the fields of urodynamics, neurourology, pelvic floor disorders, and urogenital reconstruction. Health care practitioners and clinicians will benefit from these documents, which give a brief review of those subjects related to LUT dysfunction, and as their knowledge grows, we hope they will feel enthused to engage with the full ICS Standards.

The Continence Society (ICS) has sustained a drive to improve the clinical assessment of lower urinary tract function for many years. Increasingly, healthcare professionals (HCPs) engage with the guidance, and patients benefit from the precision that results when their carers apply a sensible and logical approach to assessment. The current supplementary issue of *Neurourology and Urodynamics* (NAU) summarizes the fundamentals derived from major ICS initiatives, emphasizing what HCPs must know when dealing with these patients, regardless of the medical discipline in which they work. It also introduces the basics of urodynamics testing to trainees and HCPs who may refer patients for testing. In this editorial review we draw out some additional points of consideration. We emphasize the need to avoid using terms in a clinical context that could imply causative mechanism, until the mechanism has actually been identified. We caution against the use of severity thresholds, until there is proper data to justify their application for any given patient group. Finally, we provide a description of the philosophical basis of urodynamics testing, including videourodynamics. This commentary should be read in the context of the other articles provided in the NAU supplement.

### KEYWORDS

LUTS, overactive bladder, standardization, urodynamics

## 1 | INTRODUCTION

LUTD is encountered in some form by a wide range of healthcare practitioners (HCPs), notably medical, nursing, and allied professionals working in Primary Care, Gerontology and Neurology. For these, awareness of a fundamental knowledge base should include the correct use of the terminology for lower urinary tract symptoms (LUTS), and the relevant signs and urodynamic observations. Likewise, residents in urology and gynaecology need to appreciate the fundamentals of LUTS and lower urinary tract dysfunction (LUTD), as a stepping stone for the more

detailed knowledge used in specialist practice. The International Continence Society (ICS) has developed standards which set the specialist terminology and diagnostic methodology in great precision for the full scope of practice in LUTD with considerable detail as needed by specialists in the area. These documents produced by the Standardization Steering Committee and other ICS Committees meet the needs of specialists, and professionals who have mastered the fundamentals and who are strongly encouraged to engage with the full standards.

The ICS approach is founded on the importance of logical and clear-thinking clinical diagnosis and therapy selection,

Dr. Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

making sure that treatment options are specifically matched to the individual patient. Well-worded terminology has steadily evolved over the years to make sure that it is suited to the potential presentations. Standards for testing in Urodynamics have been refined to give practitioners the best chance to identify abnormalities in their patients and interpret the features appropriately. This supplement of Neurourology and Urodynamics was commissioned by the Trustees of the ICS to introduce a new generation of residents and recently appointed consultants to the important work of standardization in functional urology. It aims to set out and exemplify the fundamentals as a starting point to engaging with the ICS Standards. Experts have been asked to extract pertinent aspects from some of the most widely used Standards, to facilitate awareness of key points in LUTS, nocturia, neuro-urology, chronic pelvic pain, pelvic organ prolapse quantification, flow rate testing, urodynamics, and videourodynamics.

## 2 | LOWER URINARY TRACT FUNCTION

The description of lower urinary tract function breaks it down into symptoms, signs, and urodynamic observations. The terminology is phrased to ensure that patients and doctors can align their discussions appropriately. A key requirement is to ensure that the words HCPs use do not imply a mechanism without good justification. In male patients, words or phrases like “obstructive,” “prostatism,” or “prostate symptom score” insinuate that the mechanism of symptoms is already known, and caused by the prostate. Yet it is wrong to imply this at the start of the patient’s assessment; it innately biases the doctor (and sometimes the patient) to expect therapy aimed at relieving obstruction and dealing with the prostate. That may come later, but only once other causes which can lead to very similar symptoms have been excluded. Weak or slow stream may be due to the prostate and the possibility of an underactive detrusor being the cause must also be considered. Likewise, “irritative” is not appropriate, given that there is generally no evidence for irritation in the context of storage LUTS. Fundamentally, the potential to misrepresent mechanism by careless use of terminology needs to be avoided.

Two areas where clinicians can get a little bit muddled by terminology are frequency and overactivity. “Frequency” indicates how often a person passes urine in a given time period, so it is a sign. “Increased daytime frequency” indicates that the patient feels he or she voids too often by day, so it is the correct phrase to describe a symptom reported by a patient. The word “Overactivity” is used in two terms: firstly, it is used in the context of overactive bladder (OAB), which is a symptom syndrome, and by its definition, everyone with OAB experiences urinary urgency. Secondly, detrusor overactivity (DO), is a urodynamic observation of a bladder contraction during filling, which is usually, but not always,

associated with urgency. Therefore, DO and OAB are not interchangeable terms.

The categorization of LUTS relates the timing of the symptom to the micturition cycle, hence storage LUTS, voiding LUTS, and LUTS happening straight after voiding has finished (post-micturition symptoms). Many individuals present with several LUTS, and these can be grouped into symptom syndromes. OAB is one, in which storage LUTS are principal features. Underactive bladder (UAB) is another, in which voiding LUTS are prominent. Because OAB and UAB occur mainly in the storage and voiding phases, respectively, it is perfectly possible for one person to have both overactive and underactive symptoms, that may or may not be shown by urodynamics to be due to DO and detrusor underactivity (DU).

## 3 | SEVERITY THRESHOLDS

The HCPs need to be careful in setting thresholds to “qualify” someone as having symptoms (eg, not counting someone as having nocturia because they only get up once per night to pass urine). Unfortunately, there is only limited robust evidence to warrant thresholds. Furthermore, quantifying the significance of symptoms can be difficult as symptoms are subjective, and may vary a lot from day to day, so even a 3 day observation period of a bladder diary may not capture the full story. Furthermore there is considerable variation from person to person, so values are difficult to compare. Thus the ICS emphasises the need to distinguish a symptom’s frequency from the impact on quality of life and bother it brings, as they are not necessarily correlated. For example, many men report a relatively severe level of slow stream, but do not describe themselves as particularly bothered by it. In contrast, symptoms like urgency and post micturition dribble can be highly bothersome even if severity appears relatively mild to the impartial observer. For nocturia, people who generally experience a single episode on average each night should be cataloged as having nocturia; it will be non-bothersome for many patients, but that does not mean nocturia is absent.

In practice, it seems reasonable to suggest;

- A symptom is important if the patient says it is bothersome. For example, the symptom of increased daytime frequency (the complaint by the patient who considers that he/she voids too often by day<sup>1</sup>) is very much dependent on the patient’s attitude, and there is a large variation in what patients consider intrusive.
- A symptom or sign is important if it can explain mechanism or identify disease. For example, nocturia (**symptom**: the complaint that the individual has to wake at night one or more times to void; **sign**: the number of times an individual passes urine during their main sleep period<sup>1</sup>) may be non-bothersome to the patient if they only void once per night,

but it might identify the early stages of a systemic medical condition, such as chronic kidney disease, needing diagnosis and therapy.<sup>2</sup>

- All urodynamic observations should be noted, as they may explain symptoms or signs, and guide treatment selection. The urodynamic observation of detrusor overactivity (involuntary detrusor contractions during the filling phase) should be noted, even if the contraction is only very low amplitude.

#### 4 | FUNDAMENTALS OF URODYNAMIC PRACTICE

Practitioners must show due consideration to their patients. It is important that staff recognize that somebody attending to do a flow rate test may be a patient experiencing urgency in their day to day life, so it is not appropriate to demand of them that they must pass a minimum voided volume of 150 mL, if they say that they are desperate to go! Furthermore, it is not appropriate to load somebody with very large volumes of liquid in an attempt to try to make them pass urine a bit more quickly for the convenience of the flow rate clinic. This is an unrealistic expectation, and is often detrimental to reliable voiding behavior. For filling cystometry and pressure flow studies, patients are apprehensive about undertaking a test in which their urethra and anus are going to be cannulated. People may feel the whole process is very undignified and compassionate handling by staff is essential. Patients are much more satisfied after urodynamics if they received an information leaflet before they come for their tests.

In flow rate testing, some key points are;

- Calibrate the equipment for reliable results.

- Ask the patient to complete a 3 day bladder diary in advance.
- Provide a suitable environment for testing (a place to wait, rapid access to the meter when needing to pass urine, privacy, a hygienic setting).
- Validate that the voided volume is representative, by comparing with the bladder diary.
- Check that bladder volume at the start of voiding (derived by adding voided volume and post void residual) is in a suitable range (150-500 mL).
- Identify key artefacts; knock, squeeze, and release, to ensure the values reported are indicative of the patient rather than an artefact.

Some basic principles are important for urodynamic units;

1. A urodynamic unit must follow the appropriate instructions given by the equipment manufacturers, and practitioners should calibrate and check their equipment regularly. All staff must be trained and properly supported by experienced clinicians.
2. Before a test, each patient's symptoms should be fully understood, with a symptom score and bladder diary completed. Ideally, potential treatment options should be considered before the test by the referring clinician, who has already discussed them with the patient. Thereby, the test can be done so as to help select the treatment, based on chance of success and identification of potential adverse outcome.
3. When running a test, the pressure traces should be scrutinized throughout the study to be confident recordings are genuinely picking up the pressures. This requires looking to see that the bladder and abdominal pressure lines detect breathing and movement similarly, and that

**TABLE 1** Contents of a urodynamics report proposed in the UK continence society (UKCS) minimum standards for urodynamics<sup>3</sup>

UKCS recommendation	Possible urodynamic observations
Record of the urodynamic findings during filling, whether normal or abnormal	
Detrusor function during filling	Normal/detrusor overactivity
Urethral function during filling	Competent/incompetent
Bladder and urethral sensation	<ul style="list-style-type: none"> <li>• At what volume did the patient report FSF, NDV and SDV?</li> <li>• Did they experience urgency?</li> </ul>
Bladder capacity	Report volume
Record of the urodynamic findings during voiding, whether normal or abnormal	
Detrusor function during voiding	Normal/underactive or acontractile
Urethral function during voiding	Normal/obstructed
Post void residual	Report volume
Statement on whether the patient's everyday symptoms were reproduced <sup>a</sup>	

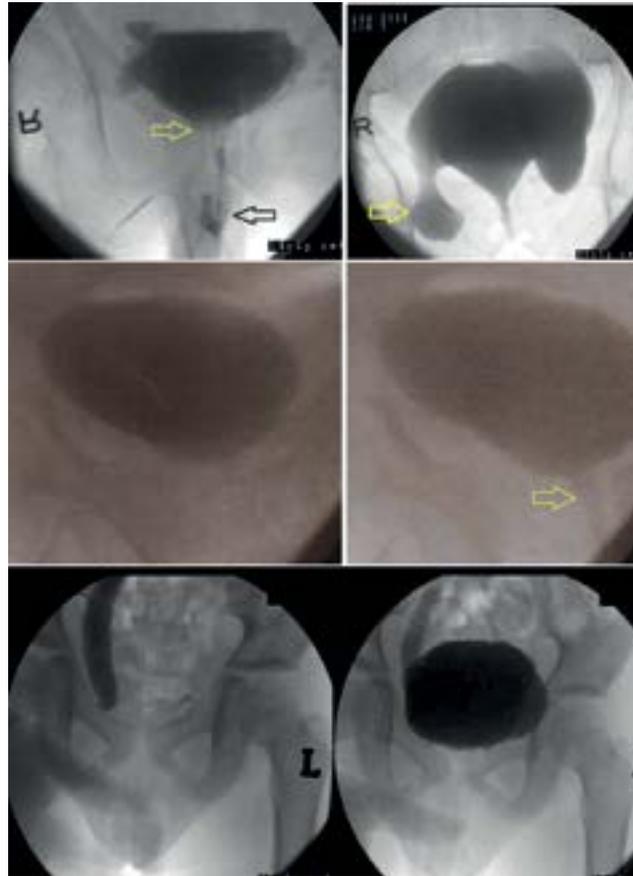

FSF: first sensation of filling; NDV: normal desire to void; SDV: strong desire to void?

<sup>a</sup>The report should document whether the patient's everyday symptoms were fully reproduced/ partly reproduced/ not reproduced.

coughs are done throughout filling, plus before and after voiding to monitor trace quality.

- a) Regular labels must be applied during the study; these annotations will help anyone not present at the study to interpret the findings later on.
- b) The “zero” button is a software button which drops the vesical and abdominal pressure lines onto zero. This must only be clicked when recording from atmosphere, not when the transducers are connected to the patient- this is a common mistake.

4. After the test, the trace must be scrutinized to make sure that crucial pressure and flow values are genuinely indicative of the patient's urinary tract function. High pressures caused by knocking the equipment, or low pressures because a tube got blocked, must be identified, corrected if possible, and interpreted accordingly. Urodynamic machines and software are not reliably able to identify artefacts with current technology. Key parameters such as maximum flow rate, bladder outlet obstruction (BOO) index or bladder contractility index

**FIGURE 1** Additional information with radiological imaging during urodynamics. Top left; identifying the site of BOO in a man with Parkinson's disease. In this case, the obstruction is at the bladder neck (yellow upper arrow). This man also had significant pooling in the bulbar urethra (black lower arrow), which caused post micturition dribble. Top right; a man with large bladder diverticula, the one on the right entering an inguinal hernia (arrow). These diverticula made it very difficult to measure bladder pressure. Middle pictures; a man with prior transurethral resection of the prostate (TURP) whose presenting complaint was urgency. He did not have detrusor overactivity. During filling cystometry, contrast was not present in the proximal urethra to begin with (middle left image), but it was seen to enter the urethra (arrow, middle right) synchronous with the patient's report of urgency, which was the typical sensation of his presentation. Lower pictures; images taken at the end of voiding in a boy with vesico-ureteric reflux. The left hand image confirmed bladder emptying was complete. The right hand image was taken 30 s later, and a lot of contrast had re-entered the bladder- a “pseudo-residual.” If this patient had been studied with a bladder scanner instead of videourodynamics, a post void residual might wrongly have been presumed

may be reported by a urodynamic machine, but practitioners must check the source traces for plausibility, noting any spikes which the machine may inappropriately have used for deriving those parameters, and moving the cursors to instruct the machine where the values can be taken.

The final report must be carefully phrased, describing whether symptoms reported by the patient were actually encountered during the test, and what was the urodynamic observation at that time (Table 1). Of course, certain symptoms simply cannot be reproduced during a urodynamic test—obvious examples being nocturia, nocturnal enuresis, and coital incontinence. For these symptoms, observations made during urodynamics must not be claimed as the cause of the symptom. The “only report what you see” approach is crucial for safer consideration to making treatment recommendations.

## 5 | VIDEOURODYNAMICS

Conventional urodynamic tests principally can be used if there is a relatively evident underlying mechanism. The main situations are;

- Post-obstetric stress incontinence in a healthy woman, where urethral hypermobility has been identified on physical examination.
- Voiding LUTS in a man in the right age range, where benign prostate enlargement is identified on rectal examination.

For these individuals, the underlying mechanism can be assumed with reasonable confidence. Thus, if stress urinary incontinence is seen in the first situation, the hypermobility is probably the cause. In the second, if BOO is seen, the prostate enlargement is probably the cause. However, many other presentations throw up more complex possibilities and a range of causes should be considered. Using X-ray contrast as the urodynamic filling medium, and taking images at key moments during the tests (“videourodynamics”) allows greater confidence when deciding what mechanism(s) are present, and potentially linking them to symptoms. The additional information that X-ray screening can achieve includes;

1. Instantaneous detection of leakage.
  - a) If there is delay for the leakage reaching the flow meter, for example, in men with post prostatectomy incontinence due to sphincter damage.
  - b) When evaluating leak point pressures in a patient with neurological disease.

This precision on identifying timing of leakage allows the urodynamicist to know the detrusor pressure at the precise moment when it matters.

2. Identifying the exact location of bladder outlet obstruction; bladder neck (Figure 1a), prostate, urethral sphincter/pelvic floor, stricture. This can be very valuable for establishing the cause of BOO, and hence deciding on treatment.
3. Detecting muscle function deficits in patients with neurological disease.
  - a) An open bladder neck may indicate a deficit in sympathetic innervation.
  - b) A poorly supported bladder base and proximal urethra, which can be seen to descend on straining, may be due to pelvic floor weakness and may reflect muscle denervation in men, or women with no obstetric history.
4. Explaining difficulty in detecting expected increased pressure change, due to dispersal into a low pressure region.
  - a) A large bladder diverticulum (Figure 1b).
  - b) Significant vesico-ureteric reflux (VUR).
5. Identifying VUR in its early stages; potentially it may be possible to treat early VUR with a bulking injection of the ureteric orifice.
6. Correlating a patient's reported urgency sensation with urine entering the proximal urethra (Figure 1c); this might help explain why some people with urgency do not gain benefit from medical therapy of OAB.
7. Demonstrating whether the bladder empties fully; a well-timed X-ray taken at the exact end of voiding confirms whether the bladder has emptied fully. This is more accurate than bladder scanning, since the scanner takes a while to get in position, during which time people with VUR may have had enough liquid come back in to the bladder to show up on a scanner— a “pseudo-residual” (Figure 1d).
8. Identifying pooling in patients with post micturition dribbling.
  - a) Pooling in the male urethral bulb (Figure 1a).
  - b) Vaginal pooling.

## 6 | CONCLUSIONS

The ICS has pushed a logical and systematic approach to terminology and assessment in lower urinary tract function. In the current review we emphasize the importance of being specific with the language used, the need to justify severity thresholds, the philosophy underlying urodynamic testing and the potential benefits of videourodynamics in patients whose underlying pathophysiology is potentially complex.

**Aims:** To summarize basic definitions in the International Continence Society (ICS) Standardization of Terminology in lower urinary tract (LUT) function and their application.

**Methods:** Fundamental terminology in the ICS Standardization of Terminology LUT Function was identified and summarized.

**Results:** Evaluation of LUT requires appreciation of symptoms, signs and urodynamic observations. Symptoms are categorized according to their occurrence during the micturition cycle into storage symptoms (eg, increased daytime frequency [IDF], urgency, nocturia, or incontinence) or voiding and post-voiding symptoms (eg, slow stream or post micturition dribbling). Several problems may be present, giving rise to symptom syndromes, notably overactive bladder (during the storage phase) or underactive bladder (during the voiding phase). Signs may be derived from a bladder diary or may be elicited on physical examination. Urodynamic observations may be made by assessing flow rate, and this is combined with pressure measurement when undertaking filling cystometry and pressure flow studies. Key elements of flow and pressure measurement are described.

**Conclusions:** The review provides a succinct summary of symptoms, signs, and urodynamic observations as set out in the ICS Standard on LUT Function.

**KEYWORDS**

LUTS, overactive bladder, standardization, urodynamics

## 1 | INTRODUCTION

The International Continence Society (ICS) has for many years led the development of standardized definitions of the symptoms, signs, urodynamic observations, and conditions associated with lower urinary tract dysfunction (LUTD). The current document is a summary of core terminology related to LUTD for use in a general medical context. For example, LUTD is commonly encountered by healthcare professionals working in gerontology, neurology, and nephrology. The terminology is also useful for residents in urology or gynaecology preparing for examinations. This document is not intended for subspecialists working in functional urology,

urogynaecology, and neuro-urology, for whom the ICS has developed a range of standardizations (see [www.ics.org](http://www.ics.org)). These cover the full scope terms in different contexts and patient groups for use in subspecialty research and clinical practice, which are beyond the scope of the current review.

## 2 | METHODS

Recommendations in the ICS Standard on LUTD<sup>1</sup> were reviewed and summarized, this document being selected as the terminology is applicable to all patients regardless of gender. Definitions of nocturia,<sup>2</sup> underactive bladder,<sup>3</sup> and pelvic organ

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

prolapse (POP)<sup>4</sup> are those given in subsequent context-specific ICS consultations or documents. Definitions and key terms are generally transcribed verbatim. In the original document, many of the definitions are accompanied by explanatory or exemplary footnotes. The footnotes have been adapted (non-verbatim) in certain cases for the current review, or have been excluded for the sake of brevity, and additional explanatory text is included. Readers should note that in urogynaecology practice, some terms have been updated in the International Urogynecology Association/ICS joint report on the terminology for female pelvic floor dysfunction,<sup>4</sup> where there is some divergence from the reported definitions in the current review. Accordingly, users are advised to specify the source of the definitions they employ when publishing in the area.

### 3 | LOWER URINARY TRACT SYMPTOMS

Normal lower urinary tract (LUT) function relies on the facility for storage of urine in the bladder, and the ability to pass urine (voiding) at a time to suit the individual. The alternation between these two modes of storage and voiding is known as the micturition cycle (Figure 1). Lower urinary tract symptoms (LUTS) are categorized according to the time at which they are experienced in relation to the micturition cycle;

#### 1. Storage symptoms

- a) Increased daytime frequency (IDF) is the complaint by the patient who considers that he/she voids too often by day.<sup>1</sup> There is no minimum voiding frequency serving as a threshold for the symptom, since it is highly subjective, and there is a wide overlap between normal and symptomatic.

**FIGURE 1** The micturition cycle as anchor for categorizing LUTS. Each individual person stores urine until they make an active decision to switch to voiding in response to a sensation or a social reason (eg, anticipation that toilets will be difficult to access in the foreseeable future as a result of a meeting or journey, or when going to bed for sleep). Once voiding is complete, storage mode is re-established. Voiding occupies only a very small part of the cycle (eg, if frequency is six times daily, and duration of each void is 20 s, then only 2 min of 24 h may be in voiding mode). NDV, normal desire to void; SDV, strong desire to void

- b) Nocturia is waking at night to pass urine.<sup>2</sup> If a person typically passes urine once per night, they should be documented as having nocturia even if it does not cause them impairment of quality of life.

“Day” and “night” for IDF and nocturia refer to the patient’s sleeping pattern, not environmental daylight and night-time.

These symptoms are strongly influenced by fluid intake, and healthcare practitioners need to factor in whether the symptom reflects LUTD, or rather a physiological mechanism dealing with excessive intake of free water or salt, or a pathological consequence of a systemic medical condition (eg, chronic kidney disease).<sup>5</sup>

- c) Urgency is the complaint of a sudden compelling desire to pass urine which is difficult to defer.<sup>1</sup>
- d) Urinary incontinence is the complaint of any involuntary leakage of urine.<sup>1</sup>

Incontinence is subclassified according to the circumstances most typically eliciting the problem

- (i) Urgency urinary incontinence is the complaint of involuntary leakage accompanied by or immediately preceded by urgency.
- (ii) Stress urinary incontinence is the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing.
- (iii) Mixed urinary incontinence is the complaint of involuntary leakage associated with urgency and also with exertion, effort, sneezing, or coughing.

#### 2. Voiding and post-voiding symptoms

##### *Voiding symptoms*

- a) Hesitancy is the term used when an individual describes difficulty in initiating micturition resulting in a delay in the onset of voiding after the individual is ready to pass urine.<sup>1</sup>
- b) Slow stream is reported by the individual as his or her perception of reduced urine flow, usually compared to previous performance or in comparison to others.<sup>1</sup>
- c) Intermittency is the term used when the individual describes urine flow which stops and starts, on one or more occasions, during micturition.<sup>1</sup>

In addition, a person may report splitting of the stream, or spraying. They may also describe straining to void, which is muscular effort used to either initiate, maintain, or improve the urinary stream.

Post-voiding symptoms are experienced immediately after voiding.

- d) Feeling of incomplete emptying is experienced by the individual after passing urine.<sup>1</sup>

- e) Post-micturition dribble describes the involuntary loss of urine immediately after an individual has finished passing urine.<sup>1</sup>

All these symptoms may vary considerably over time, even fluctuating on successive days. The healthcare professional needs to take into account this variability, and clarify with the patient how often each symptom may be experienced to try to build a representative picture. Likewise, the presence of a symptom (severity) does not always lead to impact on quality of life (bother), and healthcare professionals should consider both severity and bother for a complete evaluation of LUTS.

### 3.1 | Symptom syndromes

Initial management may rely on empirical diagnoses applied after clinical assessment of a patient's LUTS, combined with basic investigations, such as urinalysis. These may be used for the purposes of applying initial conservative management, and do not rely on invasive urodynamic observations.

1. Overactive bladder syndrome (OAB) is characterized by urinary urgency, with or without urgency urinary incontinence, usually with IDF and nocturia, if there is no proven infection or other obvious pathology.<sup>6</sup>
2. Underactive bladder syndrome (UAB) is characterized by a slow urinary stream, hesitancy, and straining to void, with or without a feeling of incomplete bladder emptying sometimes with storage symptoms.<sup>3</sup>

OAB is applicable during the storage phase of the micturition cycle, and UAB during the voiding phase, so it is possible for one individual to manifest both symptom syndromes.

## 4 | SIGNS SUGGESTIVE OF LOWER URINARY TRACT DYSFUNCTION

### 4.1 | Voiding frequency

Frequency refers to the number of voids observed in a defined time period<sup>1</sup>; it is not a symptom (ie, it should not be confused with IDF). The frequency of voiding is generally identified by asking the patient to complete a record;

1. A micturition time chart, which records only the times of micturitions for at least 24 h.
2. A frequency volume chart (FVC), which also records the volumes voided, as well as the time of each micturition, day and night, for at least 24 h.
3. A bladder diary: this records the times of micturitions and voided volumes (VV), and additional information

appropriate for the individual being evaluated. It could include incontinence episodes, pad usage, fluid intake, the degree of urgency, and the degree of incontinence.

Three-day recordings are generally used in clinical practice. Any of these charts make it possible to identify 24-h frequency of voiding; provided the waking and sleeping times are marked, this can be broken down into the daytime frequency and nocturia (Figure 2). The sign of nocturia is the number of times an individual passes urine during their main sleep period.<sup>2</sup> Polyuria is the measured production of more than 2.8 L of urine in 24 h in adults.<sup>1</sup> Nocturnal polyuria is present when an increased proportion of the 24-h output occurs at night. If polyuria or nocturnal polyuria is present, the observation of a high voiding frequency may reflect a cause other than LUTD (eg, systemic illness or behavioral factors such as a high fluid intake).

A diary that includes fluid intake and urine output measurement generally shows the former exceeds the latter each day, but on some days there can be a discrepancy (as seen on the totals for the second day in Figure 2). Such discrepancies generally even out if the diary is completed over a longer time. Alternatively, they may suggest inaccurate completion of the diary, or inability to measure the liquid content of the person's food intake.

### 4.2 | Physical examination

In LUTD, examination should cover abdominal, pelvic, and perineal examination. In general, a focused neurological examination is needed, and this will be more extensive for patients with possible neurogenic LUTD.<sup>7</sup>

1. Urinary incontinence (the sign) is urine leakage seen during examination.<sup>1</sup>
  - a) Stress urinary incontinence is the observation of involuntary leakage from the urethra, synchronous with exertion/effort, or sneezing or coughing
  - b) Extra-urethral incontinence is the observation of urine leakage through channels other than the urethra.
2. POP is the descent of one or more of the anterior vaginal wall, posterior vaginal wall, the uterus (cervix), or the apex of the vagina (vaginal vault or cuff scar after hysterectomy).<sup>4</sup> The presence of any such sign should be correlated with relevant POP symptoms. More commonly, this correlation would occur at the level of the hymen or beyond.<sup>4</sup>
3. Pelvic floor muscle function can be qualitatively evaluated according to the tone at rest, and the strength of a voluntary or reflex contraction.<sup>1</sup> Strength, duration, displacement, and repeatability should be considered. It may be reported qualitatively as strong, weak, or absent, and there are validated grading systems.

**FIGURE 2** Information abstracted from a bladder diary,<sup>10</sup> showing some commonplace features. “Woke” indicates the start of each day, “sleep” for the start of each night. Daytime frequency is the number of voids recorded during waking hours and includes the last void before sleep and the first void after waking and rising in the morning. Frequency was 4-5 over the three complete days of the study period. Twenty-four hour production is measured by collecting all urine for 24 h. This is usually commenced after the first void produced after rising in the morning and is completed by including the first void on rising the following morning. The range in the current example was 1450-1800 mL for the two complete 24 h using this definition. Nocturia (nocturnal frequency) is the number of voids recorded during a night's sleep: each void is preceded and followed by sleep. It was 0-1 over the two complete nights of the study period. Nocturnal urine volume (NUV) is the total volume of urine passed between the time the individual goes to bed with the intention of sleeping and the time of waking with the intention of rising; it excludes the last void before going to bed but includes the first void after waking. NUV was high on the second night, perhaps due to alcohol consumption in the preceding evening. This also is associated with a high nocturnal polyuria index (NPi, calculated from  $NPi = NUV/24\text{ h volume}$ ) at 0.47. The maximum VV was normal (450 mL). Bladder sensation was generally 1 or 0; the only 2 was on day 3, and followed a couple of caffeine drinks

4. Pad testing may be used to quantify the amount of urine lost during incontinence episodes and methods range from a short provocative test to a 24-h pad test.<sup>2</sup>

## 5 | URODYNAMIC OBSERVATIONS

Bladder and bladder outlet function both need to be considered for a full understanding of a person's LUT. Urodynamics is a general term for tests that assess bladder and urethra function during the micturition cycle, and includes tests such as uroflowmetry, ambulatory urodynamics and videourodynamics. Urodynamics is also commonly used more specifically to indicate filling cystometry and pressure flow studies (PFS).

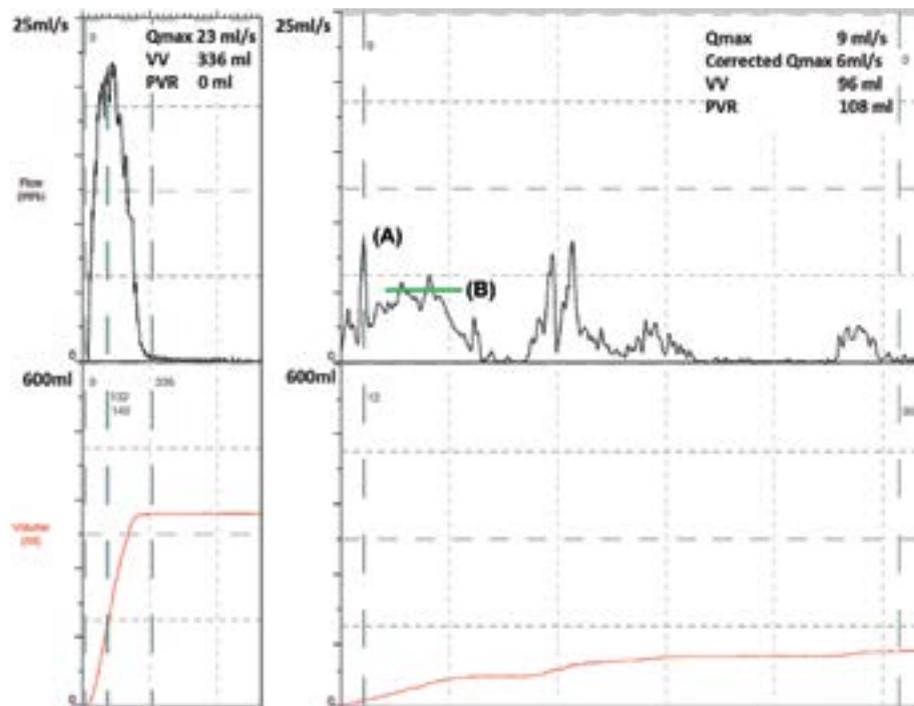

### 5.1 | Measurement of urine flow

Flow rate is defined as the volume of fluid expelled via the urethra per unit time (in mL/s) (Figure 3). “Free flow rate”

means that no tube is present for recording bladder pressure. Urine flow is either continuous or intermittent, depending on whether any interruptions happen during flow. A continuous flow curve may be a smooth arc-shaped curve, or it may be fluctuating, when there are multiple peaks during a period of continuous urine flow. Maximum flow rate ( $Q_{max}$ ) is the maximum measured value of the flow rate after correction for artefacts. VV is the total volume expelled via the urethra. Post void residual (PVR) is the volume of urine left in the bladder at the end of micturition.<sup>1</sup> If, after repeated voiding, no residual urine is demonstrated, then the finding of a PVR should be considered an artifact, due to the circumstances of the test.

### 5.2 | Measurement of bladder pressure

Both vesical pressure in the bladder ( $p_{ves}$ ) and abdominal pressure ( $P_{abd}$ ) are measured together, since the bladder is an abdominal organ.  $P_{abd}$  is generally estimated from rectal or vaginal recordings. Detrusor pressure ( $P_{det}$ ) is that component of intravesical pressure that is created by forces

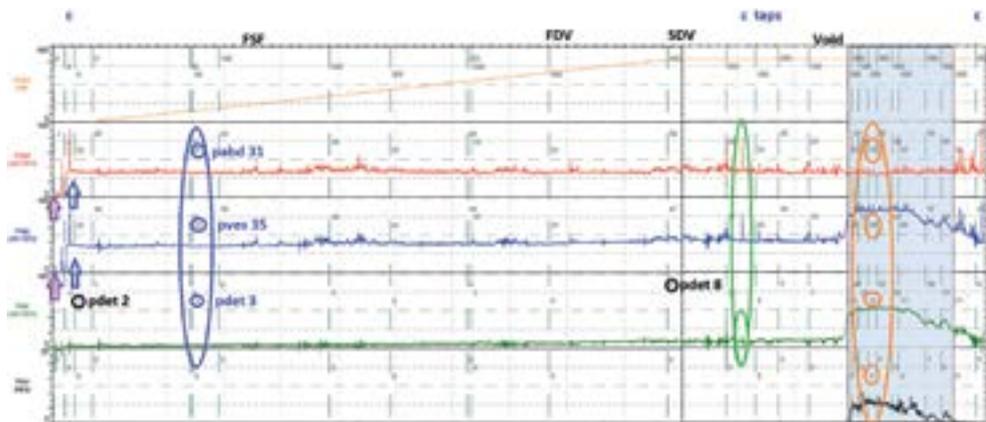

**FIGURE 3** Uroflowmetry (free flow rate testing). On the left is a normal flow rate test for a women. It shows a continuous flow, with a good maximum flow rate (Qmax) and complete emptying, with a suitable VV. On the right is an abnormal test suggesting voiding dysfunction. The pattern of flow is interrupted. The Qmax reported by the machine was 9 mL/s, but inspection of the trace shows the machine interpreted a spike (A) as the maximum flow, which will not be indicative of the patient's own urinary tract function, but rather is likely to be an artefact (eg, an aberration of flow delivery to the meter, a strain by the patient, or the patient moving on the commode). By definition, Qmax must be corrected to exclude artefacts.<sup>1</sup> Correcting the Qmax to a part of the curve (B) that is likely to be properly representative of urinary tract function gives a lower Qmax of 6 mL/s. The VV was low, but when the PVR of 108 mL is factored in, the bladder volume can be considered adequate when the flow test was done (96 + 108 = 204 mL)

in the bladder wall (passive and active), and it is calculated by subtracting  $P_{abd}$  from  $P_{ves}$ .<sup>1</sup>  $P_{det}$  is computed throughout filling cystometry and PFS, and is plotted alongside the two measured pressures ( $P_{ves}$  and  $P_{abd}$ ) and flow ( $Q$ ) (Figure 4).

Filling cystometry assesses the storage phase of the patient's micturition cycle. Filling cystometry should be described according to bladder sensation, detrusor activity, bladder compliance, and bladder capacity. Bladder compliance describes the relationship between change in bladder volume and change in detrusor pressure, and is calculated by dividing the volume change by the change in  $p_{det}$  during that change in bladder volume<sup>1</sup> (Figure 4). The standards points are (i)  $p_{det}$  at the start of bladder filling and the corresponding bladder volume (usually zero) and (ii) the  $p_{det}$  and bladder volume at cystometric capacity or immediately before the start of any detrusor contraction that causes significant leakage.

Both points are measured excluding any detrusor contraction. Detrusor overactivity (DO) is a urodynamic observation characterized by involuntary detrusor contractions during the filling phase which may be spontaneous or provoked. Provocative maneuvers are techniques used during urodynamics in an effort to provoke DO, for example, rapid filling, use of cooled medium, postural changes, and hand washing.<sup>1</sup>

Cystometric capacity is the bladder volume at the end of the filling cystometrogram. It is the volume voided, plus any PVR. The PFS starts when "permission to void" is given (Figure 4), or when uncontrollable voiding begins, and ends when the patient considers voiding has finished. PFS is a model of the patient's voiding phase and combines synchronous flowmetry with measurement of  $p_{ves}$ . Thus, flow rate testing in PFS differs from free flowmetry by the presence of a fine tube to enable pressure measurement. Normal voiding is achieved by a voluntarily initiated

**FIGURE 4** Pressure measurement. The record shows continuous tracings of two measured pressures; the abdominal pressure  $p_{abd}$  in red, and the vesical bladder pressure  $p_{ves}$  in blue. These are continuously subtracted ( $p_{ves}-p_{abd}$ ) to give the detrusor  $p_{det}$ , in green. Also shown are the volume instilled in orange, and flow rate in black. Filling cystometry precedes permission to void (indicated with “void”), and the pressure flow study (PFS) follows it. The zero reference point is atmospheric pressure (purple arrows), so when the transducers are connected to the patient (blue arrows), there is an obvious rise in  $p_{abd}$  and  $p_{ves}$ , referred to as “resting pressures”—the blue oval indicates the resting pressures for this patient at one timepoint. Coughs (indicated with “c”) are used to check that  $p_{abd}$  and  $p_{ves}$  detect a short spike of pressure (larger green oval), and that the  $p_{det}$  has a deflection which is equal above and below the line, the biphasic artefact (smaller green oval). It is important to check pressure recording with a cough at the start of filling, and on each side of the PFS. Normal detrusor function allows bladder filling with little or no change in pressure, and there should be no involuntary phasic contractions despite provocation.<sup>1</sup> In this study, the  $p_{det}$  was 2 cmH<sub>2</sub>O at the beginning of the filling cystometry, and eight at the end; since filled volume was 500 mL, the compliance (change in volume/change in pressure = 100/[8-2]) was 17 mL/cmH<sub>2</sub>O. Sensations are reported by the patient and annotated on the trace. First sensation of bladder filling (FSF) is the feeling the patient has, during filling cystometry, when he/ she first becomes aware of the bladder filling. First desire to void (FDV) is the feeling that would lead the patient to pass urine at the next convenient moment, but voiding can be delayed if necessary. Strong desire to void (SDV) is a persistent desire to void without the fear of leakage.<sup>1</sup> A provocation was applied to try to elicit DO by making the sound of running water “taps”; no change in  $p_{ves}$  or  $p_{det}$  was seen, so this patient had a stable detrusor. In the PFS, the key parameters derive from the time of maximum flow rate ( $Q_{max}$ ). The current patient had a  $Q_{max}$  of 8 mL/s and detrusor pressure at  $Q_{max}$  of 51 cmH<sub>2</sub>O, so his BOO Index was 35 and Bladder Contractility Index was 91.  $p_{abd}$  did not change at that time, so no allowance has to be made for the effect on  $p_{det}$ .

continuous detrusor contraction that leads to complete bladder emptying within a normal time span, and in the absence of obstruction. Detrusor underactivity (DUA) is a contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete emptying within a normal time span. Bladder outlet obstruction (BOO) is the generic term for obstruction during voiding and is characterized by increased detrusor pressure and reduced urine flow rate.<sup>1</sup> For male patients, BOO and DUA can be quantified using the BOO Index and the Bladder Contractility Index.<sup>8</sup> They rely on measuring  $Q_{max}$  and detrusor pressure at maximum flow, which is the lowest pressure recorded at maximum measured flow rate (see <sup>9</sup>).

## 6 | CONCLUSIONS

The ICS Standardization provides a logical framework and definitions to describe symptoms, signs, and urodynamic observations in relationship to the micturition cycle.

**Aims:** To review the recommendations on nocturia in the International Continence Society (ICS) Standardization documents, setting out key definitions and parameters for use in clinical practice.

**Methods:** Definitions and evaluations described in the ICS Standards on Nocturia and Terminology for Lower Urinary Tract Function were identified and summarized.

**Results:** The terms have been divided into signs and symptoms. Nocturia as a symptom is waking at night to pass urine and as a sign is the number of times an individual passes urine during their main sleep period. Nocturnal polyuria as a symptom is passing large volumes of urine at night and as a sign is the excessive production of urine during the individual's main sleep period. These should be quantified using a 3-day bladder diary, thereby facilitating identification of 24-h polyuria, nocturnal polyuria, lower urinary tract dysfunction, or sleep disorder.

**Conclusions:** The summary reflects the multifactorial influences in nocturia and provides a pragmatic insight into bladder diary analysis for deriving key parameters relevant to clinical therapy.

enuresis, International Continence Society, nocturia, nocturnal polyuria, terminology

## 1 | INTRODUCTION

Nocturia is a significant problem affecting a large proportion of the population, especially in older age groups.<sup>1,2</sup> Increasing recognition of its prevalence and potential health impact for individual patients and for population health has led to recognition of the need to establish the specific underlying mechanisms relevant for anyone presenting with the symptom. Crucially, a range of observations need to be properly understood by any clinician responsible for caring for these patients.

In 2002, the International Continence Society (ICS) defined nocturia as the complaint that the individual has to

wake at night one or more times to void.<sup>3</sup> In 2014, a new ICS Nocturia working group was set up to review the terminology related to that document and will be reporting in 2018. The current review sets out the principles underlying the fundamental nocturia terminology, and describes how they are applied in an example bladder diary to help direct healthcare professionals toward the most logical approach to investigation and therapy. The aim is for this to be a practical and pragmatic guide for use in both clinical and research settings.

## 2 | METHODS

Recommendations in the ICS standards on Nocturia<sup>4</sup> and Lower Urinary Tract Function,<sup>5</sup> and the 2018 ICS consultation on nocturia terminology, were reviewed and

Roger Dmochowski led the peer-review process as the Associate Editor responsible for the paper.

summarized. From these, definitions and key terms are generally transcribed verbatim. Additional explanatory text is included for context. Explanatory or exemplary footnotes from the original documents have been adapted or excluded for the sake of brevity. Users are advised to refer to the source documents and specify the source of the definitions they employ when citing definitions.

The terminology is broken into symptoms, that is, as reported by the patient, and signs. Lower urinary tract symptoms (LUTS) are broken down into storage, voiding and post-voiding symptoms, depending on their timing in relation to the micturition cycle. Nocturia is categorized as a storage symptom, based on the fact that a person is in the storage phase of the micturition cycle when asleep. For nocturia, the key signs are the voiding frequency and the voided volumes during the main sleep period; these are usually captured from a frequency/volume chart (FVC) or bladder diary.

“Night-time” for the purposes of the nocturia terminology refers to the individual's sleep cycle, rather than the solar cycle (from sunset to sunrise). For this reason, a shift worker sleeping between shifts may experience nocturia during daylight hours.

### 3 | URINE OUTPUT

The production of urine by the kidneys is a continuous process of filtration in the glomeruli, and reabsorption (water and soluble nutrients) in the tubules. Urine production serves to balance water, salt, and acid levels according to the homeostatic needs of the person, and this is principally a result of adjustments to the tubular reabsorption. Surplus water increases urine production (diuresis), and surplus salt also increases urine production (natriuresis). Making urine also serves to dispose of toxins and by-products.

The rate of urine production increases if there is;

- Diuresis
- Natriuresis
- Products in the glomerular filtrate in such large quantities that the tubules cannot reabsorb it all (poorly controlled diabetes mellitus can cause this, due to glucosuria)
- Dysfunction of the renal tubules

Tubular dysfunction can occur in chronic kidney disease. If associated with disease affecting the glomeruli, estimated glomerular filtration rate (eGFR), and creatinine levels will be abnormal. If it is a selective tubular dysfunction, eGFR and creatinine levels may be normal.

The continuous production of urine is the task of the upper urinary tract (UUT). Expelling the urine at appropriate times, and storing at other times, is the task of the lower urinary tract (LUT). The “micturition cycle” is a concept describing how

the LUT serves these two contrasting tasks of urine storage and voiding. Voiding generally can be initiated by someone at any time that suits them, but the main driver prompting people to take active steps to pass urine is when they feel their bladder is “full.”

The number of times someone has to pass urine over a specified time period reflects;

1. How fast the UUT is producing urine
2. The bladder volume at which the LUT signals “fullness”

Renal regulation tends to see the rate of urine production reduced when the person is asleep. In young people living a healthy lifestyle, rate of UUT urine production is low and LUT storage volume is high, so nocturia is uncommon.

#### 3.1 | Voiding frequency

The symptom of nocturia is present if the patient reports waking at night to pass urine. Nocturia is also a sign indicated by the number of times an individual passes urine during their main sleep period.

#### 3.2 | Volume of voiding

In order to decide whether the presence of nocturia reflects production of large quantities of urine from the UUT, an estimate of urine output is needed. 24-h voided volume is the total volume of urine passed during a 24-h period excluding the first morning void of the period. A 24-h polyuria indicates that 24-h urine output is more than 40 mL/kg, in men and women. The general increase in urine output will elevate the voiding frequency in the daytime and night-time, outstripping even normal bladder capacity. The symptom of nocturnal polyuria is present if the patient reports passing large volumes of urine at night. Nocturnal polyuria is also a sign indicated by excessive production of urine during the individual's main sleep period. It is often expressed as a proportion of the 24-h voided volume. The nocturnal polyuria index is the nocturnal urine volume/24-h voided volume, expressed as a percentage. NP is said to be present if the NPi is more than 33% in the elderly (eg, aged more than 65), and more than 20% in younger individuals.

### 4 | CAPTURING THE SYMPTOMS

The ICS emphasises the need to distinguish a symptom's severity from the bother it brings, as they are not necessarily correlated. In nocturia, there are various symptom scores which can assess both the severity and associated bother of nocturia and other LUTS, such as the International Consultation on Incontinence Questionnaires (ICIQ).<sup>6</sup> There

is a specific score for quality of life in nocturia (ICIQ-NQoL<sup>7</sup>). Practitioners need to be clear that waking once per night to pass urine, on average, means nocturia is present. Research shows that a single episode of nocturia is generally of relatively low bother to the patient (assuming they return to sleep satisfactorily). However, even if causing low bother, it still constitutes nocturia. Future research is needed to identify whether nocturia once per night might actually be medically significant (eg, the start of a medical problem for which early identification and treatment might avoid future progression).

Direct questioning is needed to establish the symptom of NP. Some discussion is also needed to review “reason for waking”; the symptom of nocturia implies that the need to pass urine was the reason for waking. This is distinct from the situation that sleep disturbance may actually have been for some other reason, but the person went to pass urine because they happened to be awake.

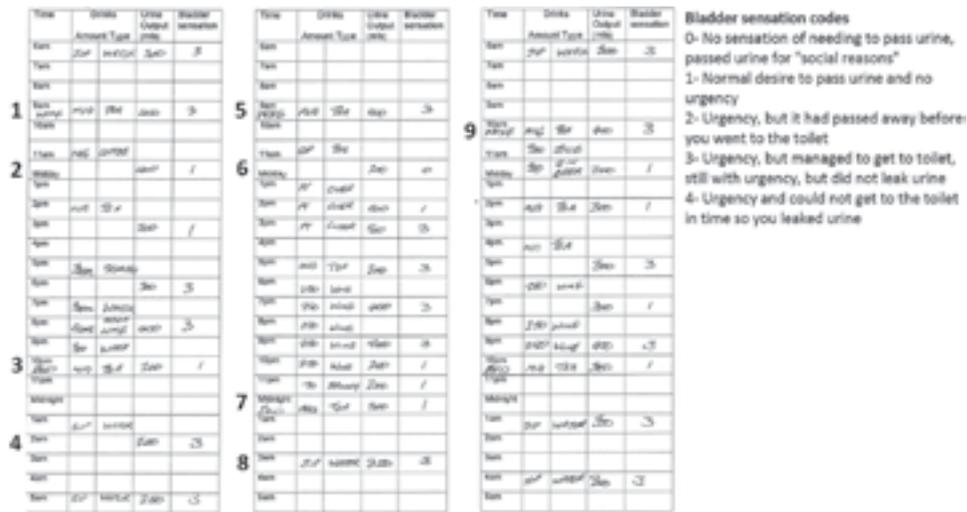

**5 | ASSESSING THE SIGNS**

The fundamental tools for assessing signs in LUTS are the physical examination and the bladder diary. Examination can

identify whether the person has risk factors for NP (eg, a physical body habitus suggesting risk of obstructive sleep apnoea or the presence of peripheral oedema), or whether they have chronic urinary retention.

A well-completed FVC or bladder diary<sup>8</sup> recorded for three days<sup>9</sup> is invaluable. The time of going to bed and the time of waking up from sleep must be clearly marked by the patient (it is rather common for patients to overlook noting these, rendering the diary uninterpretable for analyzing nocturia). From the chart or diary the following can be calculated (Figure 1):

- The daytime and night-time voiding frequency
- 24-h voided volume: the total volume of urine passed during a 24-h period excluding the first morning void of the period.
- Nocturnal urine volume: the total volume of urine produced during the individual's main sleep period.
- Nocturnal polyuria index: the nocturnal urine volume/24-h voided volume.
- Maximum voided volume, average voided volume, and bladder sensation scores
