In the past the specific use of this EMG technology in faecal incontinence was for the differentiation of patients with potential voluntary sphincter defects from those without sphincter defects thought to be reparable but who had an attendant presumptive neurological cause for their incontinence. CN-EMG is performed with single-use needles employed at multiple sites. Inherent differences exist at rest in sphincter musculature when compared with peripheral (non-sphincteric) musculature showing basal resting activity whereas non-sphincter musculature is electrically silent [183,184]. The technique can help identify neurogenic from myopathic causes of anal sphincter dysfunction [185]. There is no correlation between severity of EMG findings and degree of incontinence [186]. Denervation is diagnosed as a reduction in the number of continuously firing low-threshold MUPS. CN-EMG has disappeared with improved accurate sphincter imaging; however, it may have a specific place in those patients where ultrasonography and/or MR imaging is equivocal.

Single Fibre EMG (SF-EMG) has a smaller recording surface with a pickup of activity from a smaller muscle volume than that recorded with CN-EMG, recording generally 1-3 single muscle fibres from the same MU. Surface EMG has no value in assessing neurogenic aspects of sphincter function (but may be used as part of biofeedback therapy)[18].

5.2.2 Pudendal Nerve Conduction Testing
Pudendal nerve conduction testing measures the nerve conduction velocity in the pudendal nerve as latency time between direct stimulation of the pudendal nerve and EAS contraction. There is a customised (Dantec Electronic Tonsbaaken 16-18 DK-2740 Skovlund, Denmark) St. Mark’s electrode that has been designed. Prolongation of the pudendal nerve terminal motor latency (PNTML) is common after vaginal delivery and with aging [187-189]. The technique tends to underestimate the degree of pudendal neuropathy since the latency measured reflects the function of the most rapidly conducting nerve fibres[73]. Unlike needle EMG, it does not show direct neurological damage.
It has been suggested that the delay in PNTML is associated with a worse overall prognosis of external anal sphincter repair for patients presenting with faecal incontinence [162-164], although there is little available evidence to suggest that PNTML measurement alters specific surgical decision-making or outcomes after surgery [190]. In addition, the measurement is influenced by body habitus and clinician factors [191,192]. There is little available evidence that the presence or extent of a pudendal neuropathy correlates with objective incontinence [179] or with the specific response to biofeedback therapy with or without the presence of an external anal sphincter defect [193].

5.2.3 Sensory System Testing
Anorectal sensitivity plays a significant role in the defaecation process and in maintaining faecal continence. Variation in anorectal sensitivity is also important in pain disorders and in irritable bowel syndrome. Basic sensory testing of light touch and pin-prick and sensation of bladder filling is standard. The ano-cutaneous sensation of the perianal area and in the anal canal below the dentate line is conveyed by the efferent fibres of the pudendal nerve (S2-S4) [194].

5.2.4 Anal Mucosal Electrosensitivity
Anal mucosal electrosensitivity (MES) testing was originally described independently by Roe et al. [195] and Sigel [196] using two electrodes with a constant square wave of current with variable intensity. It is unknown precisely which receptors are involved in this standardised and reproducible response [197]. Incontinent patients invariably have a high MES whereas patients with anal sphincter defects, (with or without faecal incontinence), show an increased MES with the highest values found in patients with a combined internal anal sphincter and external anal sphincter defect.

Current Recommendations for Practice for Neurophysiological Testing
- Assess reproducibility of testing of anorectal sensation on predicting outcome of surgical and conservative/medical treatment for faecal incontinence in large patient samples.

V. FAECAL INCONTINENCE SYMPTOM SEVERITY SCALES

1. DESCRIPTION OF SCALES
There are over 20 scales for rating the severity of faecal or anal incontinence. Many scales were developed prior to 1992, are rarely used and have been reviewed elsewhere [198]; these are not included in this review. Subsequently, six other scales; the instrument developed by Pescatori and Wexner [16,198], which is also known as the Cleveland Clinic incontinence score, the Vaizey or St. Marks incontinence score [19], the Fecal Incontinence Severity Index by Rockwood et al. [20], Modified Manchester Health Questionnaire [21,199], and the Fecal Incontinence and Constipation Assessment (FICA) symptom severity instrument [4,18,200] now referred to as the Fecal Incontinence Symptom Severity Scale (FISS) have been developed and used in clinical studies to rate the severity of faecal or anal incontinence. More recent instruments, the Bowel version of the International Consultation on Incontinence modular questionnaire (ICIQ-B) [5,23] and the Revised Fecal Incontinence Scale [201], have been developed and validated but not been widely used in clinical studies. These eight scales are summarised in Table 16-1.

None of the scales provide a measure of the severity of faecal incontinence only. Three scales score the severity of anal incontinence and, in five scales, the severity of anal incontinence is combined with a score of the impact of anal incontinence on lifestyle. Use of these instruments typically relies on patient recall as they are not part of a daily diary.

All of these instruments contain an assessment of frequency of different types of rectal leakage suggesting that frequency is considered one of the most important dimensions of incontinence severity. Some scales assess additional issues related to incontinence, such as rectal urgency, amount or volume of leakage, or use of perineal protective products (e.g., pads). Three scales, Vaizey, FICA [FISS], and ICIQ-B include a measure of rectal/defaecation urgency [4,18,19,23]. The Vaizey scale [19] evaluates urgency with a question that asks about the “lack of ability to defer defaecation for 15 minutes” for which 2 response options are provided; weekly or daily. However, clinical observations suggest that this question may not accurately discriminate between people who have and do not have urgency because most people with severe urgency have a few, perhaps 5 minutes, at most to reach the toilet.

Current Recommendations for Practice for Neurophysiological Testing
- Neurophysiological testing is of limited value in the assessment of patients with faecal incontinence (Recommendation Grade C).
- PNTML is not useful in the preoperative assessment of patients before sphincteroplasty or sacral nerve stimulation. (Recommendation Grade C).
- CN-EMG may have a specific role when ultrasonography and/or MR imaging is equivocal (Recommendation Grade D).

Current Recommendations for Research for Neurophysiological Testing
Population-based studies from the Rochester Epidemiology Project defined urgency as the need to "rush to the toilet" often (>25% of time) or usually (>75% of time) because of an "urgent need to empty the bowels" [18]. Through an initial survey followed by a case-control study that included a two-week daily bowel diary, this study observed that bowel disturbances are the most important factors associated with faecal incontinence and for incontinent bowel movements in women with faecal incontinence [4,18,44,202,203]. Rectal/defaecation urgency was an independent and the strongest factor associated with faecal incontinence even after adjusting for other bowel disturbances.

Urgency is a distressing symptom [204]. Patients with more severe urge faecal incontinence report greater use of pads [205]. Urgency is associated with loose stools, increased rectal sensitivity [18,205], and reduced rectal capacity (i.e., a smaller reservoir) [18]. Nonetheless, the time required for measuring the inability to reach a toilet before leakage occurs is not standardised and patients' estimates and sense of being rushed may vary greatly.

A recent state of the science summary emanating from a workshop organized by the U.S. National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), National Institutes of Health [15], emphasised the importance of considering the amount/volume of leakage when characterizing the severity of faecal incontinence. When the amount of leakage was greater, the impact on quality of life was worse [202]. Only one scale, the FISS, incorporates the amount of leakage into the assessment of anal incontinence severity, with a question that categorises the "usual leakage" as staining, a moderate amount (i.e., requiring change of underwear), and a large bowel movement (i.e., requiring change of all clothes) [4,18,44,202,203]. Conceivably, a matrix defined by amount*frequency, which assesses the amount of leakage for each consistency of faeces leaked (e.g., solid, liquid or mixed), may more comprehensively characterise the severity of faecal incontinence. This type of matrix scoring of faecal incontinence severity was used by Bliss et al. [28] in summarizing data from a stool diary in a clinical trial of fibre supplementation for the treatment of faecal incontinence. Using this assessment for anal incontinence would comprise four options for type of leakage (i.e., solid and liquid faeces, flatus, and mucus) and three for amount/volume (e.g., small, moderate, and large) requiring 12 items. The challenge is to develop measures that are comprehensive and useful for clinical practice and research but are not overly burdensome.

The current anal incontinence severity scoring systems assume that leakage of solid and liquid stools is equivalent. However, the FISI study observed that patients and physicians have different perspectives of severity; loss of liquid and solid stool was the worst for patients and physicians respectively [17]. Patients with faecal incontinence are able to reliably distinguish solid from loose/liquid stools [27,28]. Some measures (e.g., Wexner [16] and Vaizey [19] scales) consider the use of pads when characterising severity. However, use of these measures may conceivably reflect not only the severity of anal incontinence but also fastidiosity regarding one's sense of hygiene. Finally, the relationship between symptom severity and anorectal functions (e.g., anal resting and squeeze pressures) has not been established.

**2. ASSESSING CLINICALLY IMPORTANT DIFFERENCES IN SYMPTOM SEVERITY**

Recent clinical trials have considered a 50% or greater reduction in the number of days or episodes of faecal incontinence recorded with bowel diaries as the primary endpoint [206,207]. On the other hand, it has been suggested that a 50% reduction does "not constitute a clinically meaningful improvement from the patient's perspective, mainly because the degree of improvement does little to allay the anxiety of the patient that an accident may occur at any time" [208]. In accepting this assumption, it is necessary to ascertain whether a statistically significant change in the frequency of faecal incontinence is also clinically significant [209]. One way to accomplish this is to assess the minimum clinically important difference (MCID), which is the smallest change detected by an instrument that is associated with a clinically meaningful change[210]. The MCID can be identified with distribution-based (½ of standard deviation of the population mean at baseline,[211] and the effect size (mean change/standard deviation at baseline or an anchor based approach [209]. These anchor-and distribution-based approaches [210] have been used to estimate the MCID for the FISI, FISS, and Modified Manchester Health Questionnaire [212,213]. Based on the 0.5 SD threshold, the improvement in FISS exceeded the MCID in 75% and 83% of patients in whom the faecal incontinence frequency declined by 50–74% and ≥75% respectively [213].

A few practical issues pertaining to assessment of the MCID deserve emphasis. First, the distribution-based MCID (e.g., 0.5*SD, effect size) can be readily calculated. The SD is not a universal value but is unique for each study. The anchor-based methods require additional data to be collected at all follow-up assessments. This may be as simple as adding one additional item to the "post" measurement (for e.g., a global rating of better/worse for the time period between baseline and post measurement.) While MCID represents a step in the right direction and current methods have demonstrated a utility relative to identify meaningful ‘day-to-day’ life changes for a person with faecal incontinence, we have to be more cautious if considering them “Clinically Important.” None of the methods rely on a clinical gold standard to determine the amount of change that is clinically significant as defined by a gold standard. These methods rely on either distributional properties (1/2 standard

**FAECAL INCONTINENCE SYMPTOM SEVERITY SCALES | 2013**
deviation, MCID) or other self-reported assessments (anchor based) to identify meaningful change, not clinical indicators. These two questions may be considered as the anchor for assessing the MCID:

1. Over the past <period of time> please rate whether or not the frequency of bowel accidents has become: Much Less Frequent, Moderately Less Frequent, Somewhat Less Frequent, Somewhat More Frequent, Moderately More Frequent, Much More Frequent.

2. Thinking about the bowel accidents you have had over the past <period of time> do you think that you are getting: Much Better, Moderately Better, Somewhat Better, Somewhat Worse, Moderately Worse, Much Worse.

### 3. BLENDING SYMPTOM SEVERITY AND QUALITY OF LIFE SCALES

Faecal and anal incontinence can have a devastating impact on quality of life (QOL), which can be evaluated by generic or disease-specific instruments [214]. Some symptom severity scales also include typically one [16,19,201], sometimes more [23] questions related to impact of faecal incontinence on lifestyle and QOL. The alternative approach is to use dedicated instruments with more questions that provide a more refined assessment of the impact of faecal or anal incontinence on QOL (e.g., Fecal Incontinence Quality of Life Scale and modified Manchester Health Questionnaire, and FICA QOL scale) [4,20,21]. There is a significant correlation between symptom severity and QOL in faecal and anal incontinence [4,17] (See Qualitative Research section below). The Pelvic Organ Prolapse/Incontinence Sexual Questionnaire - IUGA Revised is validated in women with faecal incontinence, allowing for measurement of sexual function with a condition-specific measure [215].

Bowel diaries are widely used to record bowel habits and track the severity of faecal or anal incontinence. Bowel diaries are less prone to recall bias than questionnaires. They not only quantify faecal or anal incontinence but also the relationship of episodes of incontinence to bowel habits, e.g., whether episodes of faecal or anal incontinence are related to liquid or formed stools or preceded by urgency [203]. These features are useful for guiding therapy. However, maintaining daily bowel diaries entails more work for patients and more analysis. With advancements in digital technology, mobile “apps”, internet, and telephone-based daily reporting of symptoms will likely be increasingly used in future.

In summary, the severity of faecal or anal incontinence is based on the symptoms evaluated by a standardised and validated questionnaires. A scale that scores the severity of faecal incontinence only is lacking and development is needed. The assessment of anal incontinence severity is currently comprised of four domains (i.e., frequency and type of leakage, amount, and rectal/defaecation urgency). Not all anal incontinence questionnaires incorporate all four domains. At present, a 50% or greater reduction in the number of days or episodes of faecal incontinence is a primary outcome measure in therapeutic trials. In one study, this outcome measure reflects a clinically important difference as measured by the minimal clinically important difference in 75% of patients[213].

### Recommendations for Research for Symptom Severity Scales

- Develop an instrument offering a severity score for faecal incontinence only (separate from that of anal incontinence and from quality of life measures).
- Evaluate the addition of weighting the scoring of the consistency of leaked faeces (e.g., liquid vs. solid) in faecal or anal incontinence severity scales.
- Further studies are necessary to ascertain whether use, size, or number of pads is an indication of faecal or anal incontinence severity, hygiene preference, affordability, or a coping mechanism that mediates the relationship between severity and QoL.
- Evaluate the role of behavioural/coping factors (e.g., staying near a toilet, ability to respond to urgency) in faecal or anal incontinence severity. Develop measures for including the effects of these factors in faecal incontinence severity scales.
- If rectal/defaecation urgency is to be used as an item in faecal or anal incontinence severity scales, a way to standardize and measure urgency is necessary.

VI. EDUCATION AND LIFESTYLE CHANGE

**Faecal incontinence Education, Weight Loss, Smoking, Medication Side Effects, Toilet Facilities, and Complementary Therapies**

In community-living adults, conservative management of faecal incontinence relies on patient participation and self-management or caregiver-assistance [220]. A number of self-management strategies for faecal incontinence have been identified including lifestyle changes such as modification of diet and eating patterns, learning the location of public toilets, planning the timing of social events, public outings, and taking anti-diarrhoeal medications, preparing kits of cleansing supplies and clothing changes [221-224]. These strategies often rely on trial and error or borrowing recommendations for other gastro-intestinal problems [221,222]. Many patients with faecal incontinence or their caregivers lack understanding about how the bowel functions, how it may be altered in some disease processes such as dementia, or how lifestyle practices might influence defaecation [12]; therefore, expert opinion supports educating patients and caregivers about these topics [220]. Furthermore, self-management of health practices and caregiving for faecal incontinence are influenced by knowledge and attitudes as well as stigma and cultural taboos. Associations of lifestyle changes such as weight loss and smoking cessation with improvements in urinary incontinence and an association between obesity and faecal incontinence in middle to older aged women have led to suggestions for similar changes to reduce faecal incontinence [226-228].

**Recommendations for Practice for Faecal Incontinence Education and Lifestyle Change from the 5th ICI**

- Educate the patient (Recommendation Grade B/C) and their carer about faecal incontinence and normal bowel function (Recommendation Grade C).
- Assess medication side effects and consider alternatives if they include diarrhoea and faecal incontinence (Recommendation Grade C).
- Make available appropriate toilet facilities and convenient toilet access especially for people with disabilities (Recommendation Grade C).
- No recommendation about use of complementary therapies can be made due to lack of evidence (Recommendation Grade D).

There is insufficient evidence to recommend or discourage most lifestyle modifications either for the prevention or treatment of faecal incontinence. Interventions such as education and environmental modification such as easier toilet access pose few risks of harm to patients, and therefore are encouraged.

**Summary of Studies about Faecal Incontinence Education and Lifestyle Change from the 5th ICI**

Nurse-led education and advice about conservative faecal incontinence management alone or as part of a combined intervention that added exercises and/or biofeedback reduced frequency of faecal incontinence [229]. Nurse-led education and advice addressed diet modification, medication titration, and bowel retraining and was as effective as the combination therapies in reducing faecal incontinence (Level of Evidence 1).

Caregivers of people with dementia, over half of whom had some degree of faecal incontinence, increased their knowledge scores after receiving a videotape and information booklet about maintaining bowel control in those with dementia [230]. It is not known if the improved knowledge resulted in less faecal incontinence.

Faecal incontinence did not resolve in obese women with dual (faecal and urinary incontinence) on a nonsurgical weight loss programme [231] (Level of Evidence 3). Results of two studies of decreases in faecal incontinence after weight loss following bariatric surgery for morbid obesity are conflicting [232,233] (Level of Evidence 3). Faecal incontinence after bariatric surgery decreased in the study of women [232].

Nicotine is thought to slow upper gut motility and increase total transit time [234], but it can reduce rectosigmoid transit time [235]. This colonic effect is associated with a sense of defaecation urgency and anecdotal reports that cigarette smoking promotes the initiation of defaecation. However, epidemiological studies have shown no association of smoking and faecal incontinence [236-238] (Level of Evidence 3). No studies of the effects of smoking cessation on faecal incontinence were found.

Liquid stool consistency and diarrhoea, which are common side effects of many medications, exacerbate faecal incontinence [28,36,239]. A thorough review of prescribed medications as well as of over-the-counter and herbal preparations taken by persons with faecal incontinence can identify the unintended side-effect of faecal incontinence. Change or discontinuation of the medications/preparations is recommended when possible (Level of Evidence 4).

Continence is promoted by sitting well-supported, leaning forward somewhat with feet slightly raised to enable appropriate use of abdominal effort if needed [240]. An environment with lack of privacy such as with commode use in the home [241,242] or physical or social obstacles, especially for individuals with physical or mental disabilities, may impair the ability to maintain continence. Environmental obstacles include toilet facilities that are too few or distant, inac-
cessible due to stairs, needing to obtain a key, requiring money to access, or having no public access [243]. Other obstacles are clothing that is difficult to manipulate, a commode that is too high, low, or unstable, or a wheelchair with arms that are difficult to remove. No studies were found examining the effect of modifying the physical or social environment to reduce faecal incontinence.

A review of complementary mind-body therapies for functional gastrointestinal disorders, i.e., diarrhoea (but not faecal incontinence) and constipation suggested there were some positive outcomes but recommendations for their effectiveness and could not be made [244]. Therapies included yoga, hypnotherapy, cognitive therapy, and biofeedback, and about one-third of studies used patients with inflammatory bowel syndrome. The use of cognitive therapy for managing incontinence has been proposed but not studied [245]. No studies of the use of acupuncture, reflexology, homeopathy or other complimentary therapeutic approach for faecal incontinence were found.

Summary of Evidence on Education and Lifestyle Interventions for Faecal Incontinence from the 5th ICI

- Educating patients and caregivers about their bowel function and faecal incontinence may improve faecal incontinence (Level of Evidence 5).
- Weight loss without surgery did not reduce faecal incontinence (Level of Evidence 3) and findings about the benefit of weight loss after bariatric surgery for morbid obesity were inconsistent (Level of Evidence 3).
- Smoking was not associated with faecal incontinence (Level of Evidence 3) and there were no studies of the effects of smoking cessation on faecal incontinence.
- Medication side effect of diarrhoea may cause faecal incontinence (Level of Evidence 4).
- Environmental barriers in public facilities or private homes increase the risk of faecal incontinence; environmental modifications may promote continence (Level of Evidence 5).

1. WHAT IS NEW ABOUT EDUCATION AND LIFESTYLE CHANGES IN THE CURRENT REVIEW?

1.1. Education About Faecal Incontinence

There was one observational study supporting the need for educating patients and caregivers about faecal incontinence. One new experimental study investigated the effectiveness of a mnemonic to assist women receiving counselling for faecal incontinence to recall the lifestyle-related therapies that they were to perform. Bliss et al. [12] described the health literacy needs of caregivers related to managing incontinence and preventing skin problems in their care recipients with Alzheimer’s disease or dementia (Level of Evidence 3). From focus groups and interviews of 48 family and friend caregivers with culturally diverse backgrounds, three main areas of incontinence literacy needs were identified: knowledge, skills, and attitudes. For example, caregivers sought information about the risk of and reasons for incontinence in dementia, therapies other than using absorbent products, understanding many over-the-counter products available for skin care and types of absorbent products, and trustworthy resources. Caregivers were interested in improving skills for managing incontinence, preventing incontinence associated skin problems, and lessening resistance of care recipients to those strategies. Almost all caregivers expressed a desire for incontinence to be framed as a health versus behavioural problem and saw a need for greater public awareness and empathy so the stigma associated with incontinence would be less. Results can guide the selection of educational topics for patients with faecal incontinence and their caregivers [12] (Level of Evidence 3).

A series of educational and supportive materials for clinicians to provide their patients were developed from this study and are available free via the webpage of the Nursing Committee of the International Continence Society (ICS) [246] or the first author of the study [12]. A continence product advisor website [247] to assist in selecting absorbent products has also been developed from a collaboration of ICS, International Consultation on Incontinence, University College of London and University of Southampton.

In teaching counselling-naïve women about faecal incontinence management [248], randomized women with faecal incontinence to a standard counselling group or counselling and use of a mnemonic to assist them to recall the types of lifestyle therapies that they were to perform. The mnemonic was RELIEF: routine lifestyle and routine bowel habits, exercise, live, Imodium, effort, and fibre and food diary. At two months following counselling, there was no difference in recall of faecal incontinence treatments between groups. The group using the mnemonic had higher (better) scores on the Manchester Health Questionnaire however. Results show that although education about faecal incontinence increases knowledge, the effectiveness of different teaching strategies needs to be evaluated (Level of Evidence 2).

1.2. Weight Loss

Several recent studies investigating weight loss and faecal incontinence were found. Two studies were observations [249,250], one was a secondary analysis [231], and one study had a one-group, pre-post
design [228]. Findings by Bussen et al. [249] add to observations of the association between faecal incontinence and weight in women. In a retrospective review of women evaluated at a coloproctological clinic, being overweight or obese was identified in 26% of 98 women presenting with faecal incontinence compared to 9% of 98 control women with outlet obstruction (Level of Evidence 3).

Ellington et al. [250] described anorectal manometry findings in women with faecal incontinence grouped by weight (normal, overweight, or obese) in a retrospective review of medical records. Women with faecal incontinence who were obese had higher baseline anal resting tone and squeeze pressures compared to those with normal weight (Level of Evidence 3). The authors concluded that obese women have a lower threshold to leakage with pressure increases (Level of Evidence 3).

In a secondary analysis of 338 overweight and obese females completing an experimental programme of weight loss and maintenance for urinary incontinence using dietary fibre [231], examined whether there would be a decrease in anal incontinence at 6, 12, or 18 months. Although there was an overall combined decrease in anal incontinence in 13% of women, the change was not significantly different from that of the control group receiving education. In comparing women with and without improvement of anal incontinence, those who showed a decrease in anal incontinence had a lower weight and BMI at baseline, but total caloric intake after 18 months did not differ between the groups. A decrease in lower urinary tract symptoms (LUTS) was associated with lesser anal incontinence severity in all women. In 33 women with incontinence of liquid faeces, an increase of 10 g of dietary fibre and a decrease in LUTS were associated with less anal incontinence. Limitations of this study included using an untested modification of the FISI score to measure anal incontinence and the lack of adjusting for baseline anal incontinence severity in the analysis (Level of Evidence 2).

Scozzari et al. [228] compared the presence and severity of anal incontinence before and after bariatric surgery in 32 obese women. At 15.6 months after surgery, the women lost about 40 kg on average. However, the presence of anal incontinence increased 12.5% postoperatively but this was not a statistically significant change from baseline. The increased anal incontinence was attributed mainly to incontinence of flatus. The mean Wexner score of anal incontinence severity differed by only 0.1 before and after surgery and was not statistically significantly different. Limitations of this study were lack of a power analysis for its sample size, no comparison treatment and therefore no random assignment was possible, and inability to describe/quantify faecal incontinence separately from flatus incontinence (Level of Evidence 2).

1.3. Complementary Therapies

A survey of patients utilizing a biofeedback service revealed that a variety of complementary therapies were used for bowel problems [251]. The most common therapies for bowel problems were the use of herbal medicines (n=27) or acidophilus/probiotics (n=26). Other therapies included acupuncture, massage, homeopathy, kinesiology, relaxation therapy, reflexology, and traditional Chinese medicine. Of the 93 survey respondents, 31% were being treated for faecal incontinence, but use of complementary therapies for faecal incontinence was not specified. Users considered complementary therapies safe, natural, and providing them with some control over their health feeling that conventional treatment had failed them or was not available (Level of Evidence 3).

A case report describes naturopathic treatment of faecal incontinence, urgency and soft stools in a 44 year-old woman with multiple sclerosis [252]. Her first treatment consisted of an herbal preparation (Parex, Health World LTD) considered antimicrobial and a probiotic (Probiotic Ultra flora LGG (Lactobacillus rhamnosus), (Health World LTD)). The second treatment consisted of a different herbal mixture and Intestamine, a biocutential containing Aloe vera, Ulmus rubra, Citrus bioflavonoids, apple pectin, Piscaria lemtiscus, glutamine and Curcuma longa. After six weeks, the patient reported no faecal incontinence, fewer liquid stools and less urgency, albeit outcomes were not quantified before or after treatment (Level of Evidence 4).

There is one case report of the occurrence of faecal incontinence in a middle-aged woman with multiple sclerosis after receiving bilateral needling of trigger-point acupuncture ("dry needling") for a painful musculoskeletal condition [253]. Acupuncture was administered in spinal, gluteal and occipital areas (Level of Evidence 4).

Current Recommendations for Practice for Faecal Incontinence Education and Lifestyle Change

- Educate patients their caregiver about bowel function and alterations in disease states, faecal incontinence, and available therapies (Recommendation Grade B/C).
- Weight loss may be recommended for better health in general but no recommendation can be made regarding faecal incontinence due to inconsistent evidence of improvement (Recommendation Grade B).
- Inform patients using complementary therapies to do so with caution as there is minimal evidence of their effects and some may result in worsening of faecal incontinence(Recommendation Grade C).
- Recommendations for practice regarding medication side effects, smoking and toilet access are similar to the 5th ICI:
  - Consider alternatives to medications if possible when faecal incontinence is a side effect (Recommendation Grade C).
- Improve access to toilet facilities especially for those with disabilities (Recommendation Grade C).
- Smoking cessation is recommended for better health in general but no recommendation can be made regarding benefit for reducing faecal incontinence due to a lack of studies showing association (Recommendation Grade D).

Current Recommendations for Research for Faecal Incontinence Education and Lifestyle Change

- Develop and evaluate innovative gender and culturally appropriate educational strategies for increasing patient and caregiver health literacy about bowel function and preventing or managing faecal incontinence.
- Randomized controlled trials on the effectiveness of weight loss in reducing faecal incontinence especially in moderately obese patients using non-surgical interventions are needed.
- Randomized controlled trials on the effectiveness of smoking cessation in reducing faecal incontinence are recommended.
- Evaluate the impact of environmental modifications including better toilet access in reducing faecal incontinence.
- Evaluate the individual or additive effect of various lifestyle changes and contribution of complementary therapies in reducing faecal incontinence.

VII. DIET AND FLUID INTAKE

Background

Some individuals with faecal incontinence believe the severity of their faecal incontinence is related to dietary intake and can be altered by modifying the type and amount of their food and drink and when they eat.

Community-living individuals with faecal incontinence, more so in women than men, report that they manipulate their diet and eating patterns as part of their self-management strategies to reduce faecal incontinence [222,254,255] (Level of Evidence 3). Dietary modifications most often restrict intake of certain foods (for example, fried or spicy foods, caffeine-containing beverages and chocolate, or foods that increased flatus such as cabbage); however, some foods are purposively eaten as a therapy to decrease faecal incontinence (for example, yogurt) [222]. Skipping meals is also a common strategy to manage faecal incontinence [221,222].

Some community-living individuals report increasing fluid intake especially when faecal incontinence is loose or liquid to prevent dehydration or subsequent constipation. Nutritional deficiencies and subsequent poor health are concerns of dietary modification in persons at high risk for malnutrition. In comparing diet intake of 39 community-living individuals with faecal incontinence with 39 age and sex matched controls with normal bowel function [34], reported there were no significant differences in the intake of total kilocalories, protein, fat, dietary fibre, caffeine, or lactose. The group with faecal incontinence had a significantly greater intake of carbohydrates, manganese, and vitamin B1 compared with the control group. The percentages of the RDA for calcium and vitamin D were less for the group with faecal incontinence (84%± 6% and 56% ±8%, respectively) than controls (90% ± 8% and 69% ± 11%) but differences were not statistically significant (Level of Evidence 3).

Recommendations for Practice for Diet and Fluids from the 5th ICI

- Patients should be asked about dietary restrictions and meal skipping to assess nutritional impact especially in groups who may be at higher risk for malnutrition (Recommendation Grade C).
- Soluble dietary fibre is recommended for the management of faecal incontinence especially when stool consistency is loose or liquid (Recommendation Grade B).
• Soluble dietary fibre is recommended as part of a combination therapy involving rectal/ transanal irrigation (Recommendation Grade B).

• No recommendations about the use of dietary fibre as an adjuvant to antimotility medications can be made because evidence is conflicting and study methods vary in quality (Recommendation Grade B).

1. LACTOSE, YOGURT, SORBITOL, FRUCTOSE, CAFFEINE, AND ALCOHOL

Background
Several diet components may induce alterations of normal gastrointestinal function resulting in faecal incontinence. In individuals with a deficiency of the intestinal enzyme, lactase, hydrolysis and absorption of the disaccharide lactose is reduced. Consumption of lactose creates an osmotic shift of water into the small intestinal lumen which can increase transit. In the large intestine, lactose is fermented by colonic bacteria resulting in flatulence, distension, diarrhoea, and possibly faecal incontinence. Malabsorption of fructose and sorbitol results in osmotic diarrhoea and faecal incontinence similar to lactose. Caffeine, of which coffee is a popular source, induces a desire to defecate in some individuals [256-260]. Chronic alcohol consumption accelerates gastric emptying and small bowel transit in animal studies.[261-263] Excessive alcohol consumption leads to injury of cells in the small intestine, reduced sodium and water absorption, and bacterial overgrowth, which may contribute to loose stools, diarrhoea, and faecal incontinence [264].

Summary of Studies about Intake of Diet, Fluid, Lactose, Yogurt, Sorbitol, Fructose, Caffeine, and Alcohol from the 5th ICI
• Studies about diet and faecal incontinence are observational and have not measured the effectiveness of diet modification on faecal incontinence in a controlled manner.
• There were no studies assessing the effect of reducing lactose, sorbitol, or fructose intake on faecal incontinence.
• Regular consumption of coffee is not associated with faecal incontinence in elderly men and women [238] (Level of Evidence 3). No studies examining caffeine restriction to improve faecal incontinence were found.
• There were no studies in which alcohol was restricted to reduce faecal incontinence.

2. WHAT’S NEW ABOUT DIET AND FLUID INTAKE IN THE CURRENT REVIEW?

Two observational studies examining the effects of fluid or serum levels of Vitamin D were found. In one study, women with urinary incontinence were surveyed about their fluid intake or restriction and bothersome bowel symptoms [265]. There were no associations between faecal incontinence of solid or liquid faeces and the volume of daily fluid intake or the behaviour of restricting fluid (Level of Evidence 3). Fluid intake by women with bothersome flatus incontinence was less than those with no bother from flatus incontinence.

As Vitamin D is important for normal muscle function, serum Vitamin D levels were compared in 31 women with faecal incontinence or 81 female controls with normal bowel function referred to a tertiary care centre for faecal incontinence or gynaecological care, respectively [266]. Women with faecal incontinence had significantly lower serum total Vitamin D levels (29.2±12.3 ng/ml) (mean±sd) than controls (35±14.1). The authors concluded that Vitamin D deficiency may contribute to faecal incontinence in women (Level of Evidence 3).

3. PREBIOTICS, PROBIOTICS, SYNBIOtICS

Background
A prebiotic is diet ingredient that is not digested by human enzymes in the small intestine and stimulates the growth or activity of bacteria in the colon. Dietary fibre, fructo-oligosaccharides and galacto-oligosaccharides are prebiotics. A probiotic is a food supplement containing live non-pathogenic and non-toxic microbial organisms, such as Bifidobacteria and lactobacilli, which have the potential to modify the profile microbes in the colon. Yogurt which has active microbial cultures is a probiotic. A synbiotic refers to a product containing a prebiotic and probiotic. In the previous reviews, there were no studies examining the use of probiotics or synbiotics to treat faecal incontinence.

4. DIETARY FIBRE

Background
Dietary fibre is the non-starch, polysaccharide component of plant cell walls and lignin that resists digestion by human intestinal enzymes[267]. Faecal incontinence is associated with low dietary fibre intake (Level of Evidence 1). Overweight women with faecal incontinence were 2.5 times as likely to have a low fibre intake (≤ 10 g/d) than those without faecal incon-
In two non-experimental studies, a staged intervention in which dietary fibre was the initial treatment, reduced faecal incontinence [269,270]. In one of these studies, 46% of women taking a supplement of methylcellulose followed by the antimotility medication loperamide as needed were cured of faecal incontinence while none in the control group receiving no intervention was cured [269]. In the second study [270], faecal soiling resolved in 24% of patients after psyllium supplementation alone, in 48% who added rectal/transanal irrigation to psyllium supplementation, and in 2% in those who added cholestyramine to psyllium supplementation transanal irrigation.

In one randomized clinical trial [27], supplementation with one of two soluble dietary fibres of moderate fermentability (psyllium) or high fermentability (gum arabic) was compared to placebo (See Table 16-2). The percentage of incontinent stools was significantly lower in those taking the fibre supplements than the placebo (Level of Evidence 1). The percentage of stools that had a loose/liquid consistency was also significantly lower in the fibre groups [27].

Another randomised clinical trial investigated two combination treatments: one treatment consisted of loperamide, a diet advice sheet describing a high vs. low fibre diet, and a fibre supplement, and the other treatment used loperamide and a placebo supplement [271]. There was no additional benefit of a dietary fibre supplement and diet advice sheet over use of the antimotility medication in reducing incontinence of flatus, mucus or solid or liquid stool (Level of Evidence 1).

5. WHAT IS NEW ABOUT PROBIOTICS AND DIETARY FIBRE IN THE CURRENT REVIEW?

A case report [252] in which a probiotic (Lactobacillus rhamnosus) was included as part of a naturopathic therapy for faecal incontinence is described in the section on complementary therapies (Level of Evidence 4).

Two new randomised clinical trials investigating the effects of dietary fibre on faecal incontinence were conducted. Both studies showed a reduction in faecal incontinence from consumption of psyllium fibre, one using a higher dose of psyllium [28] and the other a lower dose [28,272]. Bliss et al. [28] compared three soluble dietary fibre supplements of 16 g total fibre/day and a placebo supplement on the frequency of faecal incontinence in community-living adults. The supplements were carboxy-methylcellulose, psyllium, and gum arabic and had low, medium, and high fermentability. There was a 14-day baseline period and a 32-day treatment period during which the fibre amount was increased over six days. The primary outcome of faecal incontinence frequency was reported daily on a diary for 14 days at the end of each period. Secondary measures of all subjects were wet and dry stool weights, the water content and total fibre content, adverse symptom severity, and quality of life (FIQL score). In 52 randomly selected subjects, gel formation and water-holding capacity of stools was also measured.

In the intent-to-treat analysis, data from 206 adults with faecal incontinence of loose/liquid faeces who were randomly assigned to a group were analysed; 189 subjects completed the protocol. Both the intent-to-treat and per protocol analyses showed that faecal incontinence frequency significantly decreased after supplementation with psyllium fibre compared to placebo (Level of Evidence 1). The percent change of faecal incontinence in the psyllium group was 51%. Faecal incontinence severity, measured by a severity index of frequency, consistency, and amount, significantly decreased in the psyllium group (Level of Evidence 1). The fermentability of psyllium was moderate [273] and a gel formed in stool during psyllium supplementation only suggesting a mechanism of psyllium’s effect in faecal incontinence. Secondary measures did not differ among groups.

The severity of adverse symptoms, including flatus, was small and did not differ among groups ingesting dietary fibre or placebo [268] (Level of Evidence 1). Those withdrawing from the study were more likely to experience bloating or a feeling of fullness and emotional upset from symptoms. Strengths of the study included binding of subjects, pre-prepared supplements with a known amount of fibre, monitoring dietary intake with a food diary and faecal incontinence severity and reliability, not double-blinded, some lab measures only on a subsample.

Markland et al. [272] examined the effectiveness and tolerance of loperamide (2 mg) versus a supplement of psyllium fibre in a cross-over design with a two-week washout period. Subjects (68% male) were patients at clinics at veterans’ hospitals who were randomly assigned to take loperamide first then psyllium for 4 weeks each or psyllium then loperamide after a two-week baseline period. The dose of loperamide...
was 2 mg/day and that of psyllium was 3.4 mg/day, but these could be titrated depending on effects. The primary outcome of faecal incontinence frequency was reported daily on a diary for 7 days during each period. Secondary measures were anal incontinence severity (FISI score), quality of life (MMHQ), adverse symptoms, and impression of improvement for all subjects, and anorectal manometry for a subset of 26 subjects. There was no significant difference in faecal incontinence between treatment groups (Level of Evidence 1).

Within each treatment group, faecal incontinence frequency significantly decreased from baseline during the first treatment period for both treatments, but did not significantly change after the crossover to the other treatment (Level of Evidence 1). No differences were found between groups for secondary measures. Anal incontinence severity (FISI) scores improved in both groups as did quality of life after the second treatment and subjects’ impressions of improvement. Loperamide users complained of constipation and headache and one serious adverse occurred in this group.

Most anorectal manometry measures did not differ between treatment groups except transit time increased with loperamide after the second intervention. A supplement of low dose psyllium was as effective as loperamide in reducing faecal incontinence frequency and was associated with fewer side effects (Level of Evidence 1). Strengths of the study were its double-blinding and use of a longitudinal analysis. Limitations were self-report measures, use of a stool diary untested for validity and reliability, potential error due to subjects needing to prepare part of their supplement, possible unmeasured cross-over effects, a non-equivalent baseline period, and attrition during the washout period.

6. SUMMARY OF CURRENT EVIDENCE ON DIETARY FIBRE AND PROBIOTICS

- Two new randomized clinical trials showed that a supplement of moderately fermentable, soluble dietary fibre (i.e., psyllium) reduced the frequency of faecal incontinence (Level of Evidence 1).
- A supplement of a low amount of psyllium fibre (3.4 mg/day) was as effective as a low dose of loperamide (2 mg/day) in reducing faecal incontinence (Level of Evidence 1).
- Gel formation in faeces may be a mechanism by which psyllium dietary fibre exerts its effect in faecal incontinence (Level of Evidence 1).
- The severity of adverse symptoms of dietary fibre supplementation up to 16 g total fibre/day are small on average but tolerance may be more individual (Level of Evidence 1).

Current Recommendations for Practice on Diet and Fluids

- Patients should be asked about dietary restrictions and meal skipping to assess nutritional impact, especially in groups who may be at higher risk for malnutrition (Recommendation Grade C).
- Soluble dietary fibre fibre with moderate fermentability such as psyllium is recommended for the management of faecal incontinence; starting with a lower fibre amount and assessing its effect then increasing to a higher amount if needed is suggested (Recommendation Grade A).
- Supplementation with psyllium fibre, especially when a low dose is used, is recommended as an alternative rather than an adjuvant to antimotility medication as a therapy for faecal incontinence as their effects may be similar (Recommendation Grade B).
- Soluble dietary fibre with moderate fermentability is recommended as part of a combination therapy involving transanal irrigation (Recommendation Grade B).

Current Recommendations for Research on Diet and Fluids

- Because dietary fibres differ in their chemical composition and properties, future studies are recommended to determine the optimal type and amount of fibre to use for faecal incontinence.
- The extent to which modifying usual diet including specific foods, caffeine, and alcohol and eating patterns can reduce faecal incontinence or augment other behavioural interventions, such as pelvic floor muscle exercises or bowel training, needs further study.
- More research is needed about the role of Vitamin D in the management of faecal incontinence.

</table>
Irrigation (also called rectal irrigation) to empty the rectum, or incomplete evacuation of the rectum, are advised to patients, mainly those with passive faecal incontinence. Some biofeedback protocols aim to modify altered rectal sensory thresholds as discussed below. Some patients with passive faecal incontinence mainly in adults with neurogenic faecal incontinence or in those in long-term care institutions. The possibility of managing faecal incontinence through bowel habit training by community-living adults with normal cognitive function is relatively unexplored.

As the sensation of a strong urge to defecate is associated with some forms of faecal incontinence, some biofeedback protocols aim to modify altered rectal sensory thresholds as discussed below. Some patients, mainly those with passive faecal incontinence or incomplete evacuation of the rectum, are advised to use laxatives, suppositories, enemas, or transanal irrigation (also called rectal irrigation) to empty the rectum and reduce the risk of faecal incontinence in those in long-term care institutions. The possibility of managing faecal incontinence through bowel habit training by community-living adults with normal cognitive function is relatively unexplored.

Irrigation of the lower bowel via the rectum has been used for many years to manage both faecal incontinence and constipation by patients with neurogenic bowel problems such as spinal cord damage, spina bifida, multiple sclerosis, stroke etc. Antegrade irrigation is possible after surgical construction of a portal into the intestine. Observational studies have shown that transanal irrigation reduced faecal incontinence in 47% to 61% of patients (Level of Evidence 3). Patients discontinuing transanal irrigation complained of the time required, difficulties with the irrigating procedure, incontinence of irrigation fluid later in the day, lack of benefit, and bothersome symptoms. Transanal irrigation was included as part of a staged intervention for faecal incontinence by patients who still had faecal incontinence after consuming 3.25 g psyllium fibre per day and high fibre diet. Patients whose faecal incontinence continued added cholestyramine. Faecal soil resolved in 24% of patients consuming psyllium alone, 48% of patients who added transanal irrigation to psyllium supplementation, and 2% who added cholestyramine to the other treatments (Level of Evidence 2).

Recommendations for Practice for Bowel Training Rectal Evacuation, and Transanal Irrigation from the 5th ICI

- Attempt to establish a bowel habit routine (Recommendation Grade C).
- No recommendation can be made about establishing a toileting schedule for non-institutionalized adults due to a lack of studies (Recommendation Grade D).
- Urgency resistance training is possibly useful for defaecation urgency (Recommendation Grade D).
- Transanal irrigation is recommended for patients who do not respond to other conservative therapies and as part of a combined approach of therapies (Recommendation Grade C).

1. WHAT IS NEW IN THE CURRENT REVIEW?

In the current review, one study described the use and evaluation of a mini-irrigation system (Qufora®, MBH International A/S, Allerod, Denmark) by 50 adults with passive faecal incontinence (n=11), incomplete rectal evacuation during defaecation (n=35) or both (n=4) undergoing biofeedback therapy. The mini irrigation system consists of a handheld bulb used to draw up and deliver tap water through a cone at the other end that is inserted into the rectum while sitting on the toilet. Thirty-six patients (72%) reported on a questionnaire completed at their clinic that they irrigated less than once a day, 11 patients (22%) irrigated once per day, and three (6%) irrigated more than once a day. More than half of the patients (n=29 58%) thought their symptoms improved while using the system, two patients thought their symptoms completely resolved, whereas 14 (34%) did not think the irrigation system helped, and one patient said their symptoms worsened. The rate of faecal incontinence was not measured daily before or during use of the irrigation system. Only 14 patients 28% thought that using irrigation system was uncomfortable. Eighteen patients (36%) said they would continue using the irrigation system as designed (Level of Evidence 2).

In a long-term prospective observational study, the effectiveness of transanal irrigation was assessed in patients who received sphincter-saving anterior resection for rectal cancer and developed a combination of faecal incontinence and defaecation difficulty. Ten patients had received pre-operative radiotherapy, All patients had tried other conservative measures (dietary counselling, loperamide, or an
The Peristeen® irrigation system (Coloplast A/S, Humblebak, Denmark) which consists of a rectal catheter with a balloon, bag with a screw top for water, pump for activating the balloon and flushing water, and a control unit for regulating water, was used. Five patients irrigated less than once per day, and nine patients (64%) irrigated daily. After an average of 29 months using transanal irrigation, the Cleveland Clinic Score for anal incontinence decreased from 17 (15-20 (median (range))) to 5 (4-9) (p< .01). The total number of defaecations per day significantly decreased from 8 (1-4) to 1 (1-2) after using transanal irrigation. Transanal irrigation also resulted in a significant decrease in defaecations during the night from 3 (2-5) to 0 (0).

Median scores on all domains (Lifestyle, Coping/Behaviour, Depression/Self-perception, and Embarrassment) of the Fecal Incontinence Quality of Life Scale significantly improved after using transanal irrigation (Level of Evidence 3). Adverse symptoms included minor rectal bleeding in four patients and transient abdominal pain after irrigation in three patients.

Patton and Lubowski [282] reported a retrospective case series of use of an indwelling antegrade continence enema for 2 to 5.5 years by 54 patients with constipation, faecal incontinence, or other elimination difficulties from a variety of aetiologies. Six patients had incontinence and two had constipation and incontinence but results for those with faecal incontinence were not reported separately.

Lyons [283] instituted group sessions for teaching and supporting patients using transanal irrigation. She observed that the groups helped patients feel that they were not alone in needing to use transanal irrigation and were a cost-effective means to providing psychosocial support and improve patients’ skills in the procedure (Level of Evidence 2).

**Current Recommendations for Practice for Bowel Training and Rectal Evacuation or Irrigation**

- Attempt to establish a bowel habit routine (Recommendation Grade C).
- No recommendation can be made about establishing a toileting schedule for non-institutionalized adults due to a lack of studies (Recommendation Grade D).
- Urgency resistance training is possibly useful for defaecation urgency; urgency resistance training is part of some biofeedback regimens (See Section XI Pelvic Floor Muscle Exercises, Biofeedback, and Electrical Stimulation). (Recommendation Grade C).
- Evacuation of the rectum using a suppository or enema in patients with passive faecal incontinence or incomplete rectal evacuation is possibly useful (Recommendation Grade D).
- Transanal irrigation is recommended for patients with passive faecal incontinence, incomplete rectal evacuation, or faecal incontinence with defaecation difficulty who do not respond to other conservative therapies (Recommendation Grade C).
- Consider group sessions as a way of teaching and supporting patients performing transanal irrigation (Recommendation Grade D).

**Current Recommendations for Research for Bowel Training and Rectal Evacuation or Irrigation**

- Randomised clinical trials of transanal irrigation are needed.
- Research is needed in all areas of bowel habit training and rectal evacuation.

**IX. COMBINATION THERAPIES**

*Summary from The 5th ICI*

Faecal incontinence may be the result of a complex combination of alterations in normal anatomy and physiology, stool consistency, gut motility, colonic microorganism environment, emotional and psychological status, and access to toilet facilities. Many patients use a combined approach, for example, adjusting diet, medications, lifestyle, and pelvic floor muscle function. Studies of combinations of interventions are addressed by the main topic of the intervention in the respective section above when possible. A limitation of these studies is that the contribution of the individual components to the overall effect or the effect of the order of components has not been determined and remains unknown.

**1. WHAT IS NEW ABOUT COMBINATION THERAPIES IN THE CURRENT REVIEW?**

A study by Sjodhal et al. [284] which compared biofeedback to treatment with loperamide and stool bulking agents, isphagula and stericilia, then to both therapies combined in a randomised crossover design is addressed in the section on biofeedback therapy.

Collins et al.[ 285] performed a retrospective study in which patients treated for anal incontinence or constipation were classified into three groups: those receiving (1) defaecatory techniques and biofeedback, (2) dietary advice and education about medications and suppositories, and (3) rectal irrigation and anal plugs. Anal incontinence was graded in 231 patients with...
anal incontinence before and after treatment using St. Mark’s score. There was a decrease in the median St. Mark’s score from 10 of a possible 24 (5-14) to 4 (1-6) (median (interquartile range)). However, the results were not reported by the type of treatment (Level of Evidence 3).

X. MEDICATION TREATMENT OF FAECAL INCONTINENCE

1. GOALS

With the recognition that severity is subjective, treatment should be allocated according to symptom profile and patient lifestyle. The goals of this section are to identify the drugs and other conservative/medical interventions that have been used to treat faecal incontinence and to evaluate the evidence regarding their efficacy (See Table 16-3). Drugs can be combined for synergistic effect, helping reduce individual doses; loperamide plus codeine phosphate and loperamide plus amitriptyline are examples. The conservative/medical management of faecal incontinence has focused exclusively on three mechanisms:

1. Reduction of diarrhoea. Diarrhoea is consistently found to be a strong risk factor for faecal incontinence.
2. Increasing resting anal canal pressure. Low resting anal canal pressure is a risk factor for passive faecal incontinence, and is commonly seen following some types of anorectal surgery (e.g., ileal pouch procedures, sphincterotomy, abdomino-perineal pull-through for imperforate anus).
3. Treatment or prevention of constipation. Constipation is frequently found to be a risk factor for faecal incontinence, especially in children and the elderly [286].

Recommendations for Clinical Practice for Drug Treatment of Faecal Incontinence from the 5th ICI

• Treat faecal incontinence with diarrhoea with anti-diarrhoeal medication. (Recommendation Grade C); titrate the dose to individual response (Recommendation Grade C).
• We are unable to recommend sphincter modifying drugs (Recommendation Grade D).

Summary of Evidence on Medication Treatment for Faecal Incontinence from the 5th ICI

Treatment of Diarrhoea-Associated Faecal Incontinence with Antidiarrhoeal Drugs, Loperamide and Diphenoxylate

Loperamide (synthetic opioid with μ-agonist activity) is the most studied drug specifically for diarrhoea-associated faecal incontinence. The mechanism of action is slowing of gut transit, increasing fluid reabsorption and reducing secretion, as well as directly increasing resting anal pressure. There were 9 studies in adult subjects [133,149,287] and 3 studies in children [126,288,289].

• Due to design, sample size and case selection, a methodologically sound meta-analysis is not feasible.
• Loperamide improves continence by reducing diarrhoea, being superior to codeine and diphenoxylate in this respect.
• Syrup formulation offers the opportunity of finer dose-titration to avoid constipation.
• Tolerance does not seem to develop with chronic use.
• Diphenoxylate, a natural opioid, is usually combined with atropine to reduce abuse potential and can cause anticholinergic effects.
• Codeine phosphate is another opiate derivative. Clinical effects are like those of loperamide, but it is harder to titrate and adverse effects (nausea and tolerance) become prominent with time.

Palmer [290] compared loperamide (average of 4.6mg/day) to codeine (average of 103mg/day) and diphenoxylate (average of 12.5mg/day) in 30 patients with diarrhoea, of whom 19 had faecal incontinence. Loperamide significantly decreased stool frequency, improved stool consistency, and showed a trend for less faecal incontinence. Effect was like codeine and superior to diphenoxylate.

Fox et al. [291] undertook a double-blind placebo-controlled cross-over trial of loperamide in 10 obese subjects taking orlistat with resulting faecal incontinence. Loperamide significantly decreased soiling and faecal incontinence and increased resting anal canal pressure.

Lahti et al. [271] conducted a double-blind cross-over trial comparing loperamide plus fibre supplementation to loperamide with a low fibre placebo supplement in 63 patients. Both groups showed a significant improvement in faecal incontinence, but the addition of fibre to loperamide did not increase benefit.

Sze and Hobbs [151,269] investigated the additional benefit of loperamide over methylcellulose in an open controlled, study of 69 patients. Combination therapy “cured” 46% with a tendency towards constipation (which was modified by dose reduction).

Other Antidiarrhoeal Drugs

Santoro et al. [292] carried out an uncontrolled study of amitriptyline 20 mg at bedtime, in 18 patients with faecal incontinence of whom 3 reported improvement and 13 became constipated.
Sucralfate is a formulation of aluminium hydroxide used primarily for the treatment of peptic ulcers. A large randomised controlled trial showed no significant benefit for diarrhoea [135] and a worsening of faecal incontinence [138] in patients with radiotherapy-induced symptoms.

Bharucha and Fletcher [219] undertook a 4-week trial of clonidine showing a modest reduction of stool frequency and improvement of faecal incontinence.

**Adrenoceptor Agonists**

Phenylephrine gel, an alpha-1 adrenergic agonist, has been investigated for the treatment of passive faecal incontinence [178,179,181,293,294]. Two studies failed to show any benefit [178,179,181] and two others [178,179,293,294] suggested a modest benefit. The clinical utility of phenylephrine gel seems limited, and the topical preparation was associated with local discomfort. L-erythro methoxamine gel, an alpha-1 adrenoreceptor agonist like phenylephrine, was shown to increase internal anal sphincter resting pressure [180,183].

**Valproate Sodium**

This gamma-amino butyric acid transaminase inhibitor increases anal canal resting pressure. It was compared to placebo in two randomised placebo-controlled studies of post-operative patients and found to improve rectal physiology and faecal incontinence [184,187].

**Drug Treatment of Constipation-Associated Faecal Incontinence**

Constipation-associated faecal incontinence, sometimes referred to as “overflow incontinence” [295]. It is more common in children, nursing home residents, and in patients with spinal cord injury. Chapter 11 deals specifically with faecal incontinence in the frail elderly where more detail can be found. No studies of treating constipation-associated faecal incontinence in community, independent-living adults with medications were found in 2012 or the current review.

### 2. WHAT IS NEW ABOUT MEDICATION TREATMENT IN THE CURRENT REVIEW?

Two studies on loperamide for faecal incontinence showed benefit of the drug alone or in combination with standard medical therapy or biofeedback. Judah et al. [284] undertook an open controlled study of biofeedback with loperamide and fibre supplementation in 57 patients. They showed that such combination therapy improved stool consistency and faecal incontinence. Markland et al. [272] conducted a randomised, double-blind, placebo-controlled cross-over trial comparing loperamide (followed by psyllium) and psyllium (followed by loperamide). Whilst both drugs reduced faecal incontinence, loperamide was associated with greater frequency of constipation.

A recently developed opioid agonist, eluxadoline, has been shown to have antidiarrhoeal properties, and has been licensed for use in the irritable bowel syndrome in North America [296]. The drug acts on alpha-receptors (and to an extent also the beta-receptors) in the gut to improve stool consistency, reduce bowel frequency and faecal urgency [297]. Its potential use in faecal incontinence remains to be studied.

In a placebo-controlled clinical trial, a topical adrenoceptor agonist agent had no benefit over placebo in increasing sphincter pressure, and the study showed a strong placebo response by the subjects [298]. This underlines the vital importance of having placebo-controlled studies in this disease area where uncontrolled studies and case series can predominate.

#### Current Recommendations for Clinical Practice for Medication Treatment of Faecal Incontinence

- Loperamide is useful for diarrhoea-associated faecal incontinence. There is some evidence that the loperamide may be superior to diphenoxylate (Level of Evidence 2).
- Use of loperamide can be similarly effective to supplementation with psyllium fibre in reducing faecal incontinence (Level of Evidence 1).
- Sodium valproate may have a modest role in post-surgical faecal incontinence (Level of Evidence 3).

#### Current Recommendations for Research for Drug Treatment of Faecal Incontinence

- Well-designed studies are needed to validate the common clinical practice of using laxatives to treat constipation-associated faecal incontinence.
- There is a need for further research on preparations, doses and combination therapies for all types of faecal incontinence and all patient subgroups.
- There is need to develop new targets for potential topical treatment, informed by the negative data from recent studies.
- The vital importance of placebo-controlled studies is emphasized by the negative data on L-erythro methoxamine gel.
- Eluxadoline, a novel opioid agonist with low bioavailability, needs to be studied in patients with faecal incontinence.

XI. PELVIC FLOOR MUSCLE EXERCISES, BIOFEEDBACK, AND ELECTRICAL STIMULATION

1. BACKGROUND

Pelvic floor muscle training (PFMT), biofeedback (BF), electrical stimulation of the anal mucosa (ES), and tibial nerve electrical stimulation (TNS) are distinctly different therapeutic techniques for treating faecal incontinence; see descriptions below. However, they are discussed together in this section because many studies compare these techniques to each other while other studies test combinations of these techniques (e.g., BF combined with ES) (See Table 16-4).

1.1. Pelvic Floor Muscle Training

The patient is instructed to contract the pelvic floor muscles (usually maximally) including the external anal sphincter and puborectalis while keeping abdominal wall muscles relaxed and to do this multiple times each day with the goal of strengthening pelvic floor muscles. In a typical protocol the patient may be instructed to squeeze for 10 seconds while continuing to breathe deeply so that the abdominal wall muscles do not also contract. Ten to 20 such 10-sec squeezes are separated by 20 second periods of pelvic floor relaxation. Often patients are instructed to squeeze 10-20 times in a block and to repeat this block of exercises 3-5 times a day. The patient may be taught how to perform this exercise using only verbal or written instructions [305], or they may be given verbal feedback on their performance by the therapist during a digital rectal examination [306,307]. However, electronic or mechanical devices are not used to amplify the sensory information available to the patient to make them more aware of how well they are performing the exercises; this distinguishes PFMT alone from PFMT with BF.

1.2. Biofeedback

BF is distinguished from PFMT alone using electronic or mechanical devices to augment the intrinsic sensory information available to the patient on how well they are contracting and relaxing their pelvic floor muscles. The purpose of this type of training is to ensure that patients learn the appropriate way to selectively contract and relax the pelvic floor muscles while keeping abdominal wall muscles relaxed.

Another feature of many biofeedback training protocols is sensory training (rectal balloon training) or coordination training [308]. Because of neurological injuries, many patients lose the ability to recognize sensations associated with the movement of stool into the rectum and may fail to contract the pelvic floor muscles to avoid stool leakage. In sensory training, a balloon-tipped catheter is introduced into the rectum and distended with varying volumes of air to help the patient learn to recognize weaker distensions. Coordination training is a variant of sensory training and refers to having the patient practice contracting pelvic floor muscles in response to any sensation of rectal distention until this becomes a well-practiced habit [240].

A third type of BF training for faecal incontinence (in addition to strength training and sensory training) has recently been described and is referred to as urge resistance training [308]. This is intended for patients who experience intense sensations of urgency to defecate prior to stool leakage. These sensations may be associated with prolonged smooth muscle contractions of the rectum leading to reflex inhibition of the external anal sphincter and puborectalis muscles and rectal evacuation [309]. These smooth muscle contractions may be triggered by stress or anxiety [310] or by food ingestion [311]. Urge resistance training has the goal of desensitizing the patient to the sensation of rectal fullness or rectal contraction. This is accomplished by (1) teaching the patient to use deep breathing or another relaxation technique to counteract anxiety and (2) progressively inflating a balloon in the rectum to desensitise the patient to the sensation of rectal filling [312].

1.3. Electrical Stimulation

Electrical stimulation from probes placed in the anal canal as far up as the puborectalis muscle or from electrodes on the perineum adjacent to the anus has also been used to treat faecal incontinence. In typical applications, stimulation is performed daily at home using a battery operated electrical pulse generator connected to the anal electrodes [307]. Different theories have been advanced to account for how this might facilitate continence [307]. In the earliest applications, ES was used at intensities that triggered a contraction of the pelvic floor muscles, and patients were encouraged to try to augment the contractions produced by ES or to try to reproduce these contractions without electrical stimulation. Others have suggested that the stimulation of afferent nerves by lower intensities of ES may help by increasing the sprouting of synapses peripherally or the size of the receptive
fields for these nerves in the brain [313]. ES is sometimes combined with BF [314].

1.4. Tibial Nerve Stimulation

This is a form of ES in which surface electrode is placed on the skin over the tibial nerve on one ankle and referenced to another electrode on the ipsilateral foot (transcutaneous, TTNS) or a needle inserted beneath the skin close to the tibial nerve on one side and is referenced to an electrode on the ipsilateral foot (percutaneous, PTNS) [315]. Typical TTNS stimulation parameters are 200 microsecond pulses at a frequency of 10 Hz and current of up to 30 mA. Typical PTNS stimulation parameters are 200 microsecond pulses at a frequency of 10-20 Hz and up to 9 mA. In the 5th ICI, Chapter 17, the faecal incontinence Surgery Committee reviewed the evidence for tibial nerve stimulation available at that time and concluded: “Posterior tibial nerve stimulation is an investigational technique with few available data regarding efficacy and outcome.”

Summary of Assessment of Biofeedback Therapy from the 5th ICI

In the last International Consultation on Incontinence the working committee concluded with a cautious endorsement of biofeedback: “Manometric biofeedback training is possibly effective” [but] “the variability between studies suggests that results may be dependent on the training and experience of the therapist.” The evidence supporting this conclusion was based largely on a randomised clinical trial (RCT) by Heymen et al.[305] and an updated Cochrane review [316]. Other studies included in this review were judged to have significant limitations.

In the study by Heymen et al.[305] patients with at least weekly solid or liquid faecal incontinence were randomized to either BF PFMT or PFMT alone for 6 sessions. However, before they began their investigational treatment, all patients were first provided with 4 weeks of conservative management consisting of patient education about the physiology of faecal incontinence and instructions in how to normalise stool consistency with fibre or non-prescription medication. Only patients who failed to report adequate relief from conservative management (79%) could continue and be randomised to receive BF PFMT or PFMT alone.

The primary assessment was at 6 months, corresponding to 3 months after the end of the 3-month treatment period. Patients who reported adequate relief at 3 months were followed up again at 12 months, whereas patients not reporting adequate relief at 3 months were assumed to be non-responders at 12 months. Patients treated with BF PFMT were significantly more likely than patients treated with PFMT alone to report adequate relief (76% vs. 41%). Continence (zero faecal incontinence episodes in the previous month) was achieved by 44% of biofeedback-treated patients compared to 21% of PFMT-only patients. Scores on the validated Fecal Incontinence Severity Index [17] also showed significantly greater improvement in the biofeedback patients compared to the PFMT-only patients at 3 months and again at 12 months’ follow-up. Biofeedback-treated patients increased their anal canal squeeze pressures and decreased their abdominal wall tension significantly more than PFMT-only patients when squeezing to prevent stool leakage. This study showed that BF PFMT was superior to PFMT alone in patients with moderate to severe faecal incontinence. It also showed that treatment benefits for both biofeedback and PFMT were not explained by nonspecific effects of conservative treatment.

The updated Cochrane review [316] surveyed the literature until January 2012 and identified 21 studies for analysis. Unlike the previous Cochrane review [317], this one resulted in a qualified endorsement of biofeedback for the treatment of faecal incontinence: “We found some evidence that biofeedback and electrical stimulation may enhance the outcome of treatment compared to electrical stimulation alone or exercises alone...While there is a suggestion that some elements of biofeedback therapy and sphincter exercises may have a beneficial effect, this is not certain.”

Summary of Assessment of Pelvic Floor Exercises from the 5th ICI

The 5th ICI concluded: “PFMT is possibly effective for the treatment of faecal incontinence.” This conclusion was based on a study showing that PFMT was more effective than conservative management, although it was less effective that BF combined with PFMT [305].

Summary of Assessment of Electrical Stimulation of the Anal Mucosa or Perineum from the 5th ICI

In the previous ICI report [318] reviewers concluded: “There is no support for the addition of electrical stimulation from non-implanted devices” This conclusion was based on the lack of good quality RCTs during the period from 2008 to January 2012, and the absence of any Cochrane systematic review of the effects of ES from peripheral devices since 2007 [313]. By January 2012 it seemed evident to the reviewers that interest had shifted from peripheral ES of the rectum and anal canal to two new types of ES: stimula-
tion from wire electrodes surgically implanted alongside sacral nerves [319,320] or tibial nerve stimulation [321,322] In the 5th ICI these topics were reviewed by the surgery committee.

2. WHAT IS NEW IN THE CURRENT REVIEW?

Biofeedback Compared to Standard Conservative/ Medical Care

Two new RCTs followed a traditional design by comparing BF to standard conservative/medical care, defined as dietary counselling and use of antidiarrhoeal drugs or laxatives to normalise stool consistency. Damon et al. [323] randomised patients to receive either standard medical care alone or standard medical care plus 20 sessions of BF, and found that significantly more of the BF-treated patients met the responder definition compared to the standard medical care only group. Sjodahl [284] used a crossover design in which patients were initially randomised to receive either standard medical care or 3 sessions of EMG BF in phase 1 and the combination of standard medical care and BF in phase 2. There was no evidence of differential effects in phase 1, but the combined treatment was associated with significant improvement compared to baseline. Since most patients had tried standard conservative/medical care prior to the study and the BF training was less than is usually employed in phase 1, this study may also be supporting the efficacy of BF.

The Pelvic Floor Disorders Network, which is a consortium of 8 academic surgical divisions supported by the National Institute for Child Health and Human Development, is conducting a multicentre trial of biofeedback and/or loperamide for the treatment of faecal incontinence. Results are not yet available, but the study design and methods have been published [324]. This study uses a factorial design which compares 4 groups: biofeedback plus loperamide, loperamide plus education (control for biofeedback), biofeedback plus placebo tablets, and patient education plus placebo tablets. A detailed protocol for conducting biofeedback training using new software which provides the therapist with prompts to help standardise the biofeedback intervention across sites as well as individualising biofeedback to the patient’s specific deficits, has been published [312].

Electrical Stimulation

Two RCTs evaluated the efficacy of a triple therapy (3T) protocol in which medium frequency electrical stimulation (3000 Hz, 500 mV) plus EMG BF was compared to either EMG BF alone [300] or to low frequency ES (100 Hz, 50 mV) alone [325]. These two studies were published prior to 2012 but were inadvertently missed in the previous review. Triple therapy is a complex protocol in which patients are directed to practice during two 20-minute sessions each day at home. In the morning session, they received EMG BF and alternately contracted their pelvic floor muscles voluntarily or stimulated contractions with medium frequency ES. In the afternoon session, they received EMG BF and were also provided with medium frequency ES contingent on a voluntary contraction that exceeded an individually determined threshold. The threshold required to trigger ES was progressively raised as performance improved to encourage stronger contractions. Triple therapy was provided by battery-operated devices at home. A minimum of 6 months of twice daily sessions was required to improve faecal incontinence.

A study by Schwandner et al. in 2010 [300] compared 3T to EMG BF alone and found that the 3T group improved significantly more than the group treated with EMG BF at 9 months but not at 3 months. However, this study had limitations: Some patients had only mild faecal incontinence and 15% were only incontinent for flatus. In addition, the drop-out rate was high: only 24% of the EMG BF-only group completed the 9-month trial and only 54% of the combined ES plus BF group completed the trial. However, these limitations do not explain the findings because the data were analysed by intention to treat.

A second study from this group of investigators [325] compared 3T to low frequency (100 Hz, 50 mV) ES, with both treatments provided twice a day for 20 minutes each for a total of 6 months. There were few drop-outs: 92% of the 3T group and 84% of the EMG BF group completed the 6-month trial. The 3T group showed significant improvement by 3 months whereas the low frequency ES group showed no change from baseline at 3 or 6 months. A limitation of this study was the lack of blinding.

Two other studies tested low frequency ES alone [326] or combined ES with BF [327]. The aim of the first study was to compare daily home ES to standard BF training in six weekly sessions provided in the clinic. There was no difference between these two treatments in overall improvements in faecal incontinence, although there was a significant decrease in faecal incontinence frequency from baseline to the end of treatment for the ES group. Home ES was less costly than BF provided in the clinic.

In the second study, ES was combined with BF but only in half of patients (28/62), and then only if, in the opinion of the investigators, ES was needed to “help the patient identify and contract their sphincter;” There was no difference in faecal incontinence severity or faecal incontinence quality of life between the BF/ES group and the dextranomer–injected group at the six month assessment.

Home Biofeedback Training

The efficacy of home-based BF, which allows for more frequent BF training and reduces the amount of
professional time required, was the focus of six studies. Two studies in which 3T was provided twice daily for 6-9 months were described above [300,325]; both supported the efficacy of 3T. Dehli et al. [327] compared intra-anal injections of a bulking agent to 6 months of twice-daily BF and found that both treatments improved faecal incontinence severity and quality of life with no significant difference between treatments. Damon et al. [323] compared 4 months of home-BF to standard medical care and reported that significantly more patients in the BF group were responders. Bartlett et al. [328] tested whether the addition of home BF to clinic BF improved outcomes compared to clinic BF alone: for the whole group, supplementation with home BF did not significantly improve outcomes, but a post hoc analysis showed that the youngest half of the patients (below the median age of 61) did benefit significantly more when clinic-based BF was augmented by home BF [240]. A study by Peirce et al. [329] compared daily home BF to daily PFMT for 3 months to determine whether either treatment could prevent faecal incontinence in women with a third-degree sphincter laceration sustained during childbirth. There was no evidence that home based biofeedback training prevented the development of faecal incontinence, but the study was underpowered to show a difference in incident faecal incontinence.

The six studies of home biofeedback described above suggest that home practice 1-2 times daily with a battery-operated BF device is more beneficial than either ES or BF in the clinic, or standard conservative/medical care. Home BF may also be less costly to provide. However, these studies also suggest that home BF has possible limitations: (1) longer periods of BF training may be required (at least 6 months according to one investigator); (2) on average, younger patients benefit more than older patients; and (3) daily practice is a burden which may increase the drop-out rate.

**PFMT Studies**

Daily pelvic floor muscle exercises are often combined with clinic-based BF [284]. Three studies published since 2012 evaluated PFMT as the primary treatment [329-331]. Glazener et al. [330] reported the long-term follow up of a study comparing PFMT to standard medical care. All 747 women included in this study had urinary incontinence 3 months after vaginal delivery, and 15.7% of them also reported faecal incontinence. PFMT had a significantly greater impact on faecal incontinence than standard medical care at 1 year follow up but not at 12 years. Limitations to this study are that comparisons at 12 years are confounded by some patients undergoing additional treatments, especially if they had an inadequate response to the initial treatment, and progression of underlying disease.

Pierce and colleagues [329] compared PFMT alone to PFMT supplemented by clinic based BF in 120 women with a third-degree sphincter laceration during vaginal delivery, to determine whether supplemental BF is more effective at preventing faecal incontinence. No differences were seen, but the study was underpowered to detect a difference in incident cases of faecal incontinence.

Lin et al. [331] tested whether PFMT and a pamphlet (recommendations for post-surgical care) were more effective than the pamphlet alone in reducing faecal incontinence following low anterior resection for cancer. PFMT was taught by a research assistant the day before discharge from the hospital, and appropriate performance of the exercises was confirmed by physical examination before discharge and at the first follow up visit. PFMT patients were provided with a DVD to remind them how to perform PFMT, and they were instructed to practice 20 squeezes 4 times each day. Cleveland Clinic Incontinence scores were significantly lower in the PFMT group compared to the no-exercise group at follow-up visits for months 1-6, but by 9 months’ continence had improved in the no-exercise group to the same level as in the PFMT group. An unanswered question remains whether PFMT taught by digital palpation of pelvic floor muscles rather than by verbal or printed instructions, is as effective as BF augmented by PFMT, as some earlier studies suggested [229,306].

<td>126 adults with faecal incontinence, minimum severity of 4 on St Mark's scale. Patients with any prior treatment for faecal incontinence were excluded.</td>
<td>BF was performed 5 days/wk for 6 mo at home using a portable device. BF patients met with PT 5-6 times and 28/62 received supplemental ES. Anal injection of 4 ml bulk- ing agent was repeated in 21/64 at 3 mo.</td>
<td>Primary assessment at 6 mo showed significant improvement in both groups but no between-group difference. Also, no difference at 24 mo. QOL also showed no between-group difference. More adverse events seen in anal injection group, but most could be prevented by antibiotic prophylaxis.</td>
<td>Well designed, adequately powered study showed no difference between BF and dextranomer injection in moderately severe, treatment naive patients. Study limitation: no minimum severity requirement for eligibility except St. Mark's score &gt;3.</td>
</tr>
<tr>
<td>Bartlett, 2015[328]</td>
<td>(1) Assess acceptability of home biofeedback (BF); (2) compare clinic home BF to clinic-only BF</td>
<td>75 faecal incontinence patients aged 18-80, average of 61 years</td>
<td>Unblinded, parallel group study of 6 wks duration. All patients had 4 BF sessions in the clinic, but the home BF group practiced daily with a BF device while standard group practiced using PFMT instructions.</td>
<td>Supplementing BF with home practice had no overall effect but post hoc analysis found that patients younger than 61 yrs improved more when treated with home BF than with clinic-only BF; home BF was acceptable to most patients.</td>
<td>Daily home practice with a BF device improves faecal incontinence and QOL more than standard BF with PFMT practice at home. Study limitation: Only 4 sessions of BF in clinic, which may be insufficient.</td>
</tr>
<tr>
<td>Peirce, 2013[329]</td>
<td>Compare home BF to PFMT for prevention of faecal incontinence in women with 3rd degree obstetric tears.</td>
<td>120 women with 3rd degree tears were randomized to begin EMG BF (n=30) or PFMT (n=90) prior to discharge.</td>
<td>All were assessed 3 months later. BF and PMTF were taught in hospital before discharge. Both groups were told to practice twice daily.</td>
<td>There were no between-group differences in Cleveland Clinic Continence Scores, QOL, anal canal resting or squeeze pressures.</td>
<td>This study shows no added value for home BF compared to PFMT. It is unclear whether either helps to prevent postpartum faecal incontinence in women with obstetrical tears.</td>

<td>Cohen-Zubary, 2015[326]</td>
<td>Compare daily electrical stimulation (ES) at home to weekly BF in the clinic on continence scores and cost.</td>
<td>Analysis limited to 18 in each group who completed the protocol. Eligibility required normal colonoscopy, normal ultrasound, no diabetes or other severe comorbidity.</td>
<td>BF was 6 weekly 30-45 min sessions for strength and sensory factors, supplemented by home PFE. ES was 25 min twice daily for 6 weeks with no clinic training.</td>
<td>No significant differences between groups. ES improved faecal incontinence from baseline to end of treatment but BF did not. Costs were lower for ES than BF.</td>
<td>Authors argue that ES is at least as effective as BF, and it is less costly and more widely available.</td>
</tr>
<tr>
<td>Schandner, 2011[325]</td>
<td>Triple Therapy (3T) compared to low frequency ES</td>
<td>80 patients with faecal incontinence of any severity including gas only</td>
<td>Two 20-min sessions per day for 6 mos. For 3T group, morning BF session included alternating between ES and voluntary contraction. Afternoon session involved medium frequency ES triggered by voluntary contractions above a threshold determined by ability. Control group received low frequency ES in both sessions each day.</td>
<td>Cleveland Clinic scores improved more in 3T than in low frequency ES at 3 and 6 mos. QOL was also significantly better in 3T group. 54% of 3T group were continent at 6 mos vs. none in the low frequency ES group. The attrition rate was low in this trial (8% in the 3T group vs. 15% in the low frequency ES group).</td>
<td>3T was superior to low frequency ES and was better tolerated. Limitation: Trial could not be blinded, and 6 mos of twice daily practice may be more than most patients will tolerate.</td>
</tr>
<tr>
<td>Schandner, 2010[300]</td>
<td>9 mos of twice daily ES combined with EMG BF (3T) compared to EMG BF only</td>
<td>158 patients from 8 sites were enrolled. Severity varied from loss of flatus only to solid or liquid stool loss.</td>
<td>For 3T protocol, see above. Control group received only EMG BF in morning and afternoon.</td>
<td>3T group improved significantly more than BF only group (8 points vs. 3 points) improvement on Cleveland Clinic scale from baseline to 9 months. More subjects dropped out in the BF only group. Significant differences between groups did not emerge until 6 mos of twice daily therapy. Dropout rate was higher in BF only group.</td>
<td>Data show 3T is superior to EMG BF only, but the high burden of undergoing training twice daily for at least 6 mos may be a limitation.</td>

<td>Leroi, 2012[332]</td>
<td>Compare TTNS to sham ES</td>
<td>144 patients with faecal incontinence &gt;1/week and no response to conservative treatment were recruited from 9 centres in France.</td>
<td>Multisite RCTPatients used battery operated stimulator twice daily at home for 3 mo. Electrodes were on calf and ankle in both active and sham groups. No current was used for sham group. Primary outcomes were frequency of faecal incontinence and urgency/week. QOL and time to defer defaecation was also measured.</td>
<td>No significant differences between groups on any outcome. Active TTNS tended to show greater decreases in frequency of faecal incontinence and urgency, but differences were not significant.</td>
<td>TTNS showed no evidence of efficacy in this large RCT.</td>
</tr>
<tr>
<td>George, 2013[333]</td>
<td>Comparison of PTNS, TTNS, and sham TTMS in parallel groups</td>
<td>30 patients with &gt;2/week episodes of faecal incontinence were randomly assigned to 3 groups.</td>
<td>RCT conducted at one centre. 12 treatment sessions scheduled 2/week for 6 weeks. Primary outcome was &gt;50% reduction in faecal incontinence frequency.</td>
<td>PTNS but not TTNS patients improved significantly more than sham group on number with &gt;50% decrease in faecal incontinence, number of faecal incontinence episodes per week, and ability to defer defaecation. No differences in QOL or St Mark's scale.</td>
<td>Underpowered study which nevertheless suggests PTNS is superior to TTNS and sham.</td>
</tr>
<tr>
<td>Knowles, 2015[334]</td>
<td>Comparison of PTNS to sham ES</td>
<td>Inclusion based on &quot;faecal incontinence sufficiently severe to warrant intervention as recommended by PI&quot; at each of 17 sites and failure to respond to conservative treatment.227 women were randomized.</td>
<td>RCT comparing 12 sessions of PTNS to 12 sessions of sham (ES between 2 electrodes on one foot). Responder was defined by &gt;50% decrease in faecal incontinence frequency on diary.</td>
<td>Responder rates were no different (38% for PTNS, 31% for sham, N.S.). However, faecal incontinence frequency decreased significantly more in PTNS group, especially in patients with urge-related faecal incontinence.</td>
<td>This RCT fails to support the efficacy of PTNS, but the differences seen in secondary outcomes make it unclear whether PTNS may have a specific benefit for urge faecal incontinence. Further research is needed.</td>

2.1. Systematic Reviews and Meta-Analyses

Table 16-5 lists the systematic reviews and guidelines documents published since January 2012 that addressed the use of BF, ES, TNS, and PFMT for the treatment of faecal incontinence [314-316, 337-339]. The Cochrane review [316] published in 2012 provided qualified evidence for the efficacy of biofeedback as summarised in its conclusion: “While there is a suggestion that some elements of biofeedback therapy and sphincter exercises may have a therapeutic effect, this is not certain. Larger well-designed trials are needed to enable safe conclusions.” The other reviews and guidelines documents that addressed BF (Table 16-5) were consistent in recommending it, alone or in combination with PFMT or ES, for the treatment of faecal incontinence.

2.2. Tibial Nerve Stimulation

A variant of ES is to stimulate through electrodes attached to the skin overlying the tibial nerve of one ankle (transcutaneous stimulation, abbreviated TTNS) or to stimulate through a needle inserted through the skin and into the region of the tibial nerve (percutaneous stimulation, abbreviated PTNS). A systematic review of tibial nerve stimulation published in 2014 [315] reviewed two RCTs of TNS and PTNS [332,333] published up to 2013 and multiple uncontrolled studies of both percutaneous and transcutaneous TNS. This review concluded that transcutaneous TNS was not superior to sham electrical stimulation and that no adequate RCT of percutaneous TNS was available by 2013.

A pilot study published by Thin et al. in 2015 [335] compared sacral nerve stimulation to PTNS and found support for the efficacy of PTNS. Subsequently a rigorous RCT of PTNS was reported by the same group [334]. They randomised 227 patients with faecal incontinence from 17 clinical sites to receive 12 weekly sessions of percutaneous PTNS or sham PTNS. There were no significant differences in the primary outcome measure, which was the proportion achieving at least a 50% reduction in faecal incontinence episodes (38% in PTNS, 31% in sham). However, some of the secondary outcomes showed differences: The average number of faecal incontinence episodes decreased significantly more in the PTNS group than in the sham group, and this was found to be due to a greater reduction in urgency-related faecal incontinence episodes but not in the number of passive faecal incontinence episodes. Thus, this well conducted study failed to show a significant benefit of PTNS on the a priori selected primary outcome measure, but it leaves doubt about whether PTNS may be an effective treatment for urgency-related faecal incontinence. Further research is needed in groups stratified at the outset between urgency and passive faecal incontinence.

3. SUMMARY OF CURRENT EVIDENCE FOR PELVIC FLOOR MUSCLE EXERCISES, BIOFEEDBACK, AND ELECTRICAL STIMULATION

New studies [284,323] (Table 16-4) and new systematic reviews (Table 16-5) support the hypothesis that biofeedback augmented by PFMT, when provided by an experienced therapist, is more effective than PFMT alone, but the variability between studies suggests that results may be dependent on the training and experience of the therapist (Level of Evidence 1).

- PFMT is possibly effective for the treatment of faecal incontinence. Studies comparing PFMT alone to BF augmented by PFMT and ES have shown mixed results, and the optimal protocol for teaching PFMT has not been standardised, limiting the generalisability of findings (Level of Evidence 2).

- Home practice of BF and/or ES using battery-operated portable devices, appears to improve treatment outcomes when compared to clinic-based treatment. Younger patients may benefit more from home practice than older patients, and it may take up to 6 months to see benefits from home practice (Level of Evidence 2).

Mixed results from two studies continue to suggest that low frequency ES is weakly effective or not effective when used alone [326] or in combination with BF [327]. However, two studies from a single group suggest that the Triple Therapy protocol involving electrical stimulation at a frequency of 3000 Hz combined with BF, when practiced twice daily for at least 6 months, may be more effective than biofeedback alone [300] or low frequency (100 Hz) electrical stimulation alone [325]. This represents a significant change from the recommendation in our previous review (the 5th ICI) that ES is not effective (Level of Evidence 2).

Percutaneous electrical stimulation of the tibial nerve is a possibly effective approach to the treatment of faecal incontinence. An underpowered RCT suggests that PTNS is more effective than sham stimulation [333], and a second adequately powered RCT [334] shows mixed results (not significant for the primary endpoint but significant for frequency of faecal incontinence episodes preceded by urge) (Level of Evidence 2).

Current Recommendations for Research for Biofeedback, Pelvic Floor Muscle Therapy, Electrical Stimulation, and Tibial Nerve Stimulation

- There is a need to conduct further RCTs to determine which specific biofeedback protocols alter physiological parameters of anorectal function with concomitant changes in bowel control. These studies should address:
  - Clear description of modalities and evaluation of different components of BF
  - Long term follow up
  - Adherence monitoring
  - Standardisation of outcome measures
  - Exploration of possible synergies between urinary and faecal incontinence interventions and diagnostic evaluations
- Standardisation of protocols for teaching PFMT are needed.
Pelvic floor rehabilitation, as practiced by physical therapists for the treatment of faecal incontinence, is not adequately described in the medical literature. Can this be standardized and manualized so that it can be compared to biofeedback and to the PFMT protocols described in the literature?

Compare the effectiveness of PFMT taught by verbal or printed instructions (as is commonly done) to PFMT taught during digital rectal examination. Standardise techniques for teaching PFMT via digital rectal examination.

RCTs are needed of the Triple Therapy protocol or other ways of combining electrical stimulation with biofeedback.

Investigate different modalities of ES, specifically distinguishing high frequency stimulation (e.g., 3000 Hz) from low frequency (e.g., 100 Hz) stimulation.

Investigate ways to shorten the amount of training required to see benefits for faecal incontinence.

Percutaneous tibial nerve stimulation requires additional randomised controlled trials, specifically addressing:

- Whether urgency associated faecal incontinence is more responsive to treatment than passive faecal incontinence and why this might be the case
- Patient characteristics and physiological mechanisms associated with successful PTNS
- Biofeedback

Qualitative methods such as ethnography, grounded theory and phenomenology provide “understanding”, that is the aim of qualitative research. These methods are primarily applicable to similar contexts. Included below is a qualitative evidence pyramid and accompanying criteria that parallel the evidence pyramid for ranking quantitative evidence only. The qualitative evidence pyramid provides a novel strategy for ranking qualitative evidence for practice recommendations.

Criteria for Evaluation

Given that qualitative research employs different methodologies than quantitative research, a relevant evaluation framework for decisions on levels of evidence was developed for the 5th ICI review. This framework was informed by the most significant literature on quality and rigor in qualitative research, and is described below again in this update [342-351]. These criteria were used to critique studies, note strengths and limitations, and assign an evidence level.

The Type of Study: The Qualitative Evidence Pyramid

1. Qualitative meta-synthesis, meta-ethnography, meta-analysis
2. Interpretive designs including phenomenology, grounded theory, ethnography
3. Descriptive qualitative designs using content analysis (including inductive and deductive content analysis approaches, analysis of focus group data, photovoice, participatory action research, single or multiple case studies)
4. Surveys with semi-structured open-ended questions

1. CRITERIA FOR EVALUATION OF QUALITATIVE STUDIES

1. There is a clear research purpose or questions that are appropriate for qualitative inquiry.
2. The purpose or questions are directly related to the review of the literature and the literature identifies a gap or new understanding of the phenomenon.
3. There is a guiding framework for the study that fits the phenomenon being studied.
4. The method and the research purpose are related.
5. The sampling plan is purposeful and exemplifies the purpose and method that is being studied.
6. The sample size is appropriate for the sampling strategy.
7. Inclusion and exclusion criteria are described and appropriate.
8. Data collection strategies are appropriate for the purpose, method and sample.
9. The analysis plan fits the method.
10. Data are adequately analysed and interpreted, and reported so that meaning is recognised. The interpretation or description is distinguishable from the raw data.
11. The participants’ voices are perceptible and demonstrate the meaning of the categorical, thematic or conceptual findings.
12. The findings (categories, themes and concepts) are well developed and organised to support each other.
13. The results offer a new understanding of the phenomenon and are transferrable to similar contexts.
14. Reflexivity is addressed.
15. Evidence of an audit trail of how key decisions were made is clear. Strategies to achieve rigour are described.
16. Study specific limitations are summarised.
17. Ethical considerations are described.

2. WHAT IS NEW IN THE CURRENT REVIEW?

In this review, numerical levels of evidence related to the quality of studies have been created in addition to the articulation of the grades of recommendations for the practice recommendations.

Because of the length of recommendations for practice from qualitative studies in ICI5, new practice recommendations in this section are made in addition to those from ICI5. Previous recommendations for practice are still supported.

3. LEVELS OF EVIDENCE FOR QUALITATIVE STUDIES

- **Level 1**: Study includes all criteria marked in bold above. Level 1 studies are typically ones listed as types 1-2 above (qualitative evidence pyramid).
- **Level 2**: Study includes all the criteria marked in bold and italic above. Level 2 studies are ones listed as types 3-4 above.
- **Level 3**: Study does not include most the criteria above for evaluation.

4. GRADES OF RECOMMENDATION FOR QUALITATIVE STUDIES

- **Grade A** recommendation: Excellent evidence leads to a practice recommendation. A Grade A recommendation is based on Level 1 studies.
- **Grade B** recommendation: Moderate evidence leads to a possible practice recommendation (more evidence is needed). Grade B recommendation is based on a combination of level 1 and 2 studies or only level 2 studies.
- **Grade C** recommendation: Poor evidence from level 3 studies that does not lead to a practice recommendation.

5. THE EXPERIENCE OF FAECAL INCONTINENCE AND QUALITY OF LIFE

5.1. Review of Studies from the 5th ICI

Thirteen studies were included in the 5th ICI and an additional five papers detailing three studies were located for this update (See Table 16-6). As higher quality evidence had been recently published, Level 3 studies from the 5th ICI were also excluded. The included studies explored topics on the experience of faecal incontinence from multiple perspectives of men and women in relation to: colorectal cancer; sexuality; quality of life; pelvic floor dysfunctions; aging and frailty; diet strategies; goals of faecal incontinence management; post-natal onset; spina bifida; and inflammatory bowel disease (IBD). Refer to Table 16-6 for summary and quality appraisal of the studies from the 5th ICI review and the new additions.

The included studies used varied qualitative methods to explore the experiences of quality of life. A thematic analysis was completed on the content of the studies. The philosophical framework of life worlds or overlapping realms of experience was employed to organise the findings in the following themes: relationships; time and planning; bodily symptoms, self-esteem and body image; sexuality; and dietary issues [352]. These themes remained consistent with the additional support of the newly included studies, which are referenced below in the descriptions of the themes.
6. LIVING WITH FAECAL INCONTINENCE RELATED TO RELATIONSHIPS

6.1. Summary of Evidence from the 5th ICI

Men and women found that faecal incontinence was a perceived threat to their social acceptability, privacy and relationships [221,222,353-355] (Level of Evidence 2).

Who to tell about the faecal incontinence problem and when was a matter of great concern. Family, close trusted friends or co-workers were told because the secret could not be completely concealed [221,223,354] (Level of Evidence 2).

Discussing problems with others who experienced faecal incontinence was comforting and allowed conversation about how to manage the problem [221,223] (Level of Evidence 1).

Humour was used as a resource to avoid humiliation and embarrassment in dealing with daily symptoms of faecal incontinence and relationships, even though feelings of shame and humiliation persisted [23,222,223,344,355] (Level of Evidence 2).

Men and women felt discomfort in being with ‘mixed company’ and having a possible accident. Gender was an issue in relation to perceived social risk [221,223] (Level of Evidence 1).

Men and women described trying to protect themselves from the unpredictability of their symptoms and kept up a façade to keep the secret of faecal incontinence from others [23,348] (Level of Evidence 2).

Support from spouses was noted to be very important for men and women [221,223,354,356] (Level of Evidence 2).

Relationships with healthcare providers were not helpful in providing advice concerning symptom management and control. Misinformation or no information was commonly given [23,221,223,345,354,357] (Level of Evidence 2).

Women felt embarrassed, humiliated and marginalized when their faecal incontinence problem was minimized or trivialized by rude or blaming health care providers [23,221,355,356] (Level of Evidence 2).

Women had concerns about entering new relationships due to their fear and shame of having to disclose faecal incontinence [23] (Level of Evidence 2).

Anxiety was present in both men and women who suffered from social isolation because of faecal incontinence [23,222,223,344,345,354,356,358] (Level of Evidence 2).

6.2. Recommendations for Practice from the 5th ICI

- Acknowledge the problem of faecal incontinence compassionately and initiate the assessment and discussion of faecal incontinence symptoms as stigma, embarrassment and sensitivity associated with faecal incontinence may impede communication and provision of therapeutic advice [221,222,355,357] (Recommendation Grade B).

- Recognize and eliminate dismissive or blaming responses as they retard future care-seeking and contribute to patient distress and under-reporting of faecal incontinence [221,222,355,357] (Recommendation Grade B).

- Facilitate gender sensitive support groups to share practical knowledge of faecal incontinence symptom management [221,223] (Recommendation Grade B).

6.3. What Is New in the Current Review?

Women reported that faecal incontinence is a sensitive topic to discuss with others and is strongly associated with the emotions of guilt and shame [355] (Level of Evidence 2).

Women did not attend social events and made excuses not related to faecal incontinence [355] (Level of Evidence 2).

Men and women attributed their adaptation to faecal incontinence to loving, empathic, unconditional support from significant others [359] (Level of Evidence 2).

After years of dealing with faecal incontinence men and women’s interactions with health care providers had become confident, assertive control-seeking in decision-making [360] (Level of Evidence 2).

After years of living with faecal incontinence men and women felt they could provide support to others with faecal incontinence [359,360] (Level of Evidence 2).

Additional Recommendations

- Health care providers can assist adaptation to faecal incontinence by being aware of clinical interventions to improve symptoms [360] (Recommendation Grade B).

- Also See Section XII-Qualitative Research on the Experience of Faecal Incontinence and Quality of Life-Recommendations for Practice for Living with Faecal Incontinence Related to Relationships from the 5th ICI.
Current Recommendations for Research

- Investigation of the use of humor as a therapeutic coping strategy for dealing with the symptoms of faecal incontinence [221].
- Exploration of attitudes and treatment goals of health professionals treating faecal incontinence to identify barriers to effective treatment [223].
- Implementation and evaluation of gender sensitive support groups to facilitate sharing of practical management strategies for faecal incontinence symptom management [223].
- Investigation of role-modelling effectiveness in adapting to faecal incontinence [360]
- Investigation into living with faecal incontinence long-term [360]

7. LIVING WITH FAECAL INCONTINENCE RELATED TO TIME AND PLANNING

7.1. Summary of Evidence from the 5th ICI

Participants described spending a significant amount of time planning for and worrying about accidents [221,223,355] (Level of Evidence 2).

Men and women perceived their symptoms of faecal incontinence grew worse with aging in relationship to severity, onset and duration [221,223] (Level of Evidence 1).

Men and women had symptoms for months or years before seeking help for the condition [221,223] (Level of Evidence 1).

Women reported the frequency of stool leakage was unpredictable and because of this they needed to be vigilant and prepared for the unexpected [23,221] (Level of Evidence 2).

“Being prepared” was a common theme. Planning and management strategies to avoid an accident included: morning bathroom rituals, changing the location of their workstation (relative to the bathroom), altering eating habits (foods and timing), taking a fibre supplement, or using anti-diarrhoeal products [23,221,223,345,354,355,357] (Level of Evidence 2).

Many women discussed packing ‘kits’ of absorbent products, cleansing supplies and extra clothing as a routine part of planning to leave their home [221,354] (Level of Evidence 2).

Women postponed business meetings because of faecal incontinence [221] (Level of Evidence 1).

Space was experienced as a measure of risk exposure of faecal incontinence and personal space shrank inward or expanded related to perceived comfort or lack of perceived social safety [221,223,344,345,350,353,354,357,358] (Level of Evidence 2).

Seeking out the location and availability of a bathroom was major consideration in all dimensions of space outside the home [23,221,223,344,350,354,355,357,361] (Level of Evidence 2).

Travel was limited to familiar spaces and significant planning was required to prevent an accident. Faecal incontinence limited travel for the family [221,223,344,355-357] (Level of Evidence 2).

Women and men experienced heightened anxiety about faecal incontinence symptoms and the risk of accidents in public spaces [221,345,350,354,357] (Level of Evidence 2).

Work life presented complicated situations for both men and women and limited some people’s ability to engage in productive work outside the home [221,223,357,358,361] (Level of Evidence 2).

7.2. Recommendations for Practice from the 5th ICI

- Share practical management strategies, such as preparing cleansing kits and locating public restrooms, etc., with clients with faecal incontinence to help them understand and manage their experiences [221,223] (Recommendation Grade A).
- Promote self-efficacy by coaching clients on how to plan for and prevent unpredictable accidents and teaching strategies to go out confidently (such as, education on product, packing a change of clothes, disposable wipes, etc.) [221,223] (Recommendation Grade A).

7.3. What Is New in the Current Review?

Clients with IBS and faecal incontinence had significant worry that their symptoms would worsen with aging [357] (Level of Evidence 2).

Additional Recommendations for Practice from Current Review

- Clients with IBS and faecal incontinence noted the services they would want to manage faecal incontinence included access to bathrooms in both public and employment spaces [361] (Recommendation Grade A).
- Also see Section XII-Qualitative Research on the Experience of Faecal Incontinence and Quality of Life-Additional Recommendations for Practice from Current Review.
8. LIVING WITH FAECAL INCONTINENCE RELATED TO BODILY SYMPTOMS, SELF ESTEEM, AND BODY IMAGE

8.1. Summary of Evidence from the 5th ICI

Feelings of shame and embarrassment related to faecal incontinence were noted across all studies (Level of Evidence 2).

Men and women with faecal incontinence felt stigmatized and stigmatized themselves [221,223,354-357] (Level of Evidence 2).

Men and women reported their emotional life and self-confidence was undermined because of the faecal incontinence and embarrassment [221,223,344,354-356] (Level of Evidence 2).

Men and women reported altered body image, low self-esteem, guilt, and distress as a result of their inability to control faecal incontinence and associated odour [23,221,223,344,355] (Level of Evidence 2).

Not talking about the problem and denying the faecal incontinence was coping mechanisms used to protect from threat to self-esteem and prevent public embarrassment [356] (Level of Evidence 2).

Faecal incontinence as well as the fear of faecal leakage and odour caused women view themselves as shameful, guilty, unworthy [345,356,355,361] (Level of Evidence 2).

Some women reported the need for psychological consultations because of the feeling insufficient, incompetent, or vulnerable [23,336] (Level of Evidence 2).

Unpredictability of the type, timing and magnitude of faecal incontinence events were key concerns of men and women [350,357] (Level of Evidence 2).

Faecal incontinence was considered a consequence of exercise, heavy chores and lifting [223,350,354] (Level of Evidence 2).

Bodily sensations that bothersome, embarrassing, or distressing associated with the faecal incontinence included: sensations in the intestines, itching, burning, cramping, feelings of incomplete bowel movements, and odour associated with flatus and leaked faeces. Other distressing symptoms discussed included: leaking stool without defaecation sensations, and false abrupt and urgent sensations usually indicative of defaecation [221,223,345,350,355,357] (Level of Evidence 2).

Skin excoriation at the rectum was reported due to frequent bowel movements, soiling and associated cleansing [344,350] (Level of Evidence 2).

Women were attentive to their body image and dressed carefully to conceal pads and wore dark clothing to hide stains if an accident should happen [23,221,353,357] (Level of Evidence 2).

Men and women wore only small disposable pads that were not obvious through their clothing. Large diaper-like pads were avoided because of their perceived visibility beneath clothing [23,221,223] (Level of Evidence 2).

The essential theme in the phenomenological study of men managing faecal incontinence was ‘secret resignation’: men came to expect the consequences of faecal incontinence as normal [223] (Level of Evidence 1).

Major goals of people experiencing faecal incontinence was to have: fewer dietary restrictions, less faecal leakage, especially during exercise, improved public toilet accessibility, more confidence in controlling faecal incontinence symptoms and associated odour, and a normal daily routine [346] (Level of Evidence 2).

8.2. Recommendations for Practice from the 5th ICI

• Acknowledge and support the common feelings of shame and embarrassment by facilitating self-management of faecal incontinence [221,223,344,354,356,361] (Recommendation Grade B).

• Raise awareness with clients and the general public that faecal incontinence is not something to be tolerated and that it responds to conservative treatment [223,344,361] (Recommendation Grade B).

• Educate patients regarding conservative symptom management: causes of faecal incontinence, dietary modifications including fibre supplements, behavioural strategies such as pelvic floor exercises and biofeedback, anti-motility medications, use of absorbent products and ways to reduce odour and flatus [223,361] (Recommendation Grade A).

• Share positive coping strategies identified by participants with other people managing the symptoms of faecal incontinence that include: managing privacy issues in the bathroom, counselling, restricting activity, carrying a change of clothes, humour, knowing the location of toilets when out, diet, clothing selection, cleansing, odour control and use of absorbent products [23] (Recommendation Grade B).
Consider patient’s goals when developing a plan for faecal incontinence [346] (Recommendation Grade B).

Request completion of a daily stool diary when accurate information of faecal incontinence severity is important [223] (Recommendation Grade A).

Refer to psychologists to manage the emotional impact of faecal incontinence on self-efficacy, self-esteem and mood, as indicated and appropriate [345,361] (Recommendation Grade B).

8.3. What is New in the Current Review?

A sense of mastery and new self-confidence were achieved by some after years of successfully dealing with the symptoms of faecal incontinence [359,360] (Level of Evidence 2).

Poor public knowledge of faecal incontinence created feelings of stigma in persons with IBD and faecal incontinence [357] (Level of Evidence 1).

Urgency to have a BM and associated fear and unpredictable nature of faecal incontinence were the most troubling bodily symptoms for persons with IBD and faecal incontinence [357] (Level of Evidence 1).

The essential theme in the phenomenological study of women managing faecal incontinence was ‘controlling the body out of control’ and a similar subtheme in the Dibley and Norton study [357] of ‘loss of control’: women tried to control all aspects of their life in relationship to the faecal incontinence and avoiding accidents [223,344,355,357,360] (Level of Evidence 2).

Women reported a sense of self-affirmation that they would stop worrying of what others thought of them [355] (Level of Evidence 2).

To deal with faecal incontinence women used a personal approach to adapt as “life has to go on”. Women were hopeful and optimistic they would get better. They believed their incontinence would be easier to accept if they had an explanation for their symptoms [355] (Level of Evidence 2).

There are negative feelings associated with living with faecal incontinence such as anger, frustration, injustice, guilt, shame, disappointment, hopelessness, despair and sadness [355] (Level of Evidence 2).

Men and women perceived that additional chronic illnesses with worsening bowel control affected one’s whole self-concept [360] (Level of Evidence 2).

Men and women adapted in the presence of obstacles, downgrading aspirations and “making the best of it” (re-evaluating control) [360] (Level of Evidence 2).

After 10 or more years of living with faecal incontinence, men and women found comorbidity and aging posed further challenges to adaptation. By using trial and error, adaptation was ongoing [359] (Level of Evidence 2).

Additional Recommendations from the Current Review

- People with faecal incontinence wanted to be referred to, or at minimum, informed of, other services for continence by the specialist health care professionals in their circle of care [357] (Recommendation Grade A).
- Ensure that clients are aware of other specialists in the care continuum and support agencies, making referrals as appropriate[361] (Recommendation Grade A).
- Also see Section XII-Qualitative Research on the Experience of Faecal Incontinence and Quality of Life-Living with Faecal Incontinence Related to Time and Planning- Recommendations for Practice from the 5th ICI.

Current Recommendations for Research

- Determination of how goal setting and tailoring interventions for faecal incontinence is effective in promoting adherence to a management plan [346].
- Further exploration of the phenomenon of secret resignation as a method of coping by men and effective attitudes in treating these attitudes to assist them with improved communication with health care professionals and health-care seeking [223].
- Investigation of appropriate and effective interventions to educate and support men and women in adopting practices for managing faecal incontinence and associated odour and urgency symptoms [223].
- Investigation of the experience of having and managing faecal incontinence in presence of other multiple chronic conditions [359].

9. LIVING WITH FAECAL INCONTINENCE RELATED TO SEXUALITY

9.1. Summary of Evidence from the 5th ICI

Although asked about sexuality and intimacy women were reticent to discuss their sexuality or the effect of their symptoms on their sexual functioning [23,221] (Level of Evidence 2).

Some women felt there were no changes in their sexual drive [355,356] (Level of Evidence 2).

Women arranged timing of sex to meet their needs and the needs of their husbands in relation to the
symptoms of faecal incontinence [356] (Level of Evidence 2).

Women reported a range of psychosocial issues including lack of sexual arousal or desire to abstinence [23,345,353,355] (Level of Evidence 2)

Choice of clothing was an outward expression of sexuality and faecal incontinence and UI restricted clothing to wearing patterned materials to avoid people detecting an accident [353] (Level of Evidence 2).

Men and women reported continually washing themselves to avoid smelling [353] (Level of Evidence 2).

Health care professionals did not discuss sexuality even after surgeries that affected sexual functioning [353,358] (Level of Evidence 2).

9.2. Recommendations for Practice from the 5th ICI

- Ask directly about the impact of faecal incontinence on patients sexuality [23,221] (Recommendation Grade B).
- Establish a comfortable, stigma-free climate in order to elucidate the impact of faecal incontinence on sexuality and teach practical strategies [23,345,353] (Recommendation Grade B).

Additional Recommendations for Practice

- Current recommendations for practice for living with faecal incontinence related to sexuality are the same as those for the 5th ICI.

Additional Recommendations for Research

- Develop and test interventions that minimize stool leakage during intercourse.

10. LIVING WITH FAECAL INCONTINENCE RELATED TO DIETARY ISSUES

10.1. Summary of Evidence from the 5th ICI

Men and women discussed fasting or not eating for a number of hours or days as a strategy to deal with faecal incontinence symptoms outside the home [23,221,223,356,357,362] (Level of Evidence 2).

Alteration in the timing of meals to avoid an accident was a common management strategy for faecal incontinence [221,223,344,354,357] (Level of Evidence 2).

Restricting foods noted as affecting faecal incontinence included: sweets, alcohol, onions, rich and spicy foods, caffeine, fruits, greasy, fat, fried foods, and dairy products [356,362,363] (Level of Evidence 2).

Limiting portion or meal size was a strategy to limit faecal incontinence [221,344] (Level of Evidence 2).

Avoiding gas-producing foods such as, pea soup, onions, cabbage, cauliflower, and dairy products used as a treatment for flatus [221,223,344] (Level of Evidence 2).

Increasing fluids was another practice used as a management technique for constipation [221] (Level of Evidence 2).

Some women reported using protracted voluntary constipation for up to one month as a management technique for leakage [345] (Level of Evidence 2).

Increasing dietary fibre and taking fibre supplements along with digestive enzymes and yogurt were noted as treatments for faecal incontinence [221,223] (Level of Evidence 2).

Women reported eating foods they enjoyed at home and then dealt with the consequences of faecal incontinence symptoms [221,344] (Level of Evidence 2).

Women lacked therapeutic guidance regarding diet modifications and adapted recommendations from other gastrointestinal disorders such as IBS and lactose intolerance or approached diet modification by trial and error [221] (Level of Evidence 2).

10.2. Recommendations for Practice from the 5th ICI

- Teach successful diet strategies including: timing of food intake, restricting food amounts to minimise leakage, avoiding aggravating foods, increasing water intake, and increasing the consumption of yogurt, high fibre foods or a fibre supplement [362] (Recommendation Grade B).
- Enquire directly about dietary restrictions because not all strategies employed by people with faecal incontinence are helpful or evidence-based [23,221,223,356] (Recommendation Grade B).

Additional Recommendations for Practice for Living with Faecal Incontinence Related to Dietary Issues

- The same recommendations for practice as those from the 5th ICI are made are supported.
- Also see Section XII-Qualitative Research on the Experience of Faecal Incontinence and Quality of Life-Living with faecal incontinence related to dietary issues—Recommendations for Practice from the 5th ICI.
• Investigate strategies to relay best-evidence related to dietary advice and faecal incontinence in manner that is experienced as therapeutic by persons with faecal incontinence, such as patient directed goal-setting.

SUMMARY OF KEY RESEARCH RECOMMENDATIONS

• Develop techniques for diagnosing faecal incontinence and its aetiologies using new and available diagnostic technologies.

• Develop user-friendly measures and instruments for quantifying the severity of faecal incontinence and other components of anal incontinence separately from each other and in total.

• Investigate the epidemiology of the different types and subtypes of bowel and anal incontinence.

• Collect data on faecal incontinence whenever practical as part of research on urinary incontinence.

• Well designed and adequately powered studies are needed to evaluate faecal incontinence treatment modalities and management strategies currently available including:
  o Effectiveness of lifestyle modifications including weight loss, exercise, diet and eating pattern modifications, and supplementing dietary fibre as an adjuvant or combined strategy
  o Comparative effectiveness trials of instrumented biofeedback training versus neurostimulation
  o Effectiveness of tibial nerve stimulation (transcutaneous and percutaneous)

• Develop and test interventions for promoting care seeking and self-management of faecal incontinence (and associated odour and urgency).

• Develop and test interventions for increasing coping skills and health literacy related to faecal incontinence for patients and family caregivers.

• Evaluate tailoring the management of faecal incontinence based on patients’ goals, peer support, and the use of current technologies such as mobile devices for delivering management and support interventions to patients and family caregivers.

ALGORITHM

The algorithm for assessment and conservative management of faecal incontinence was updated based on a review of new evidence in the literature within the context of previous evidence and consensus of an international group of experts on faecal incontinence (See chapter Recommendations of the International Scientific Committee).

**APPENDIX 1**

**Literature Search Strategies**

**Clinical Assessment**

The following search terms were used in searching PubMed, Web of Science and Cochrane Review databases: faecal incontinence, fecal incontinence, anal incontinence, symptoms, signs, clinical assessment, history, examination, digital examination, vaginal examination. The search was conducted for the literature from January 1, 2011 until December 31, 2015, because the literature before January 1, 2011 was covered by the previous edition of this chapter.

**Endoanal Ultrasound Imaging**

The following search terms were used for PubMed, Web of Science and Cochrane reviews: faecal incontinence, fecal incontinence, anal incontinence, endoanal ultrasound, endovaginal ultrasound, transperineal ultrasound, translabial ultrasound, pelvic floor ultrasound, obstetric anal sphincter injuries (OASIS), three-dimensional ultrasound. The search was conducted for the literature from January 1, 2011 until March 31, 2016, because the literature before January 1, 2011 was covered by the previous edition of this chapter.

**Defaecography**

The following search terms were used for PubMed, Web of Science and Cochrane reviews: faecal incontinence, fecal incontinence, anal incontinence, defaecography, evacuation proctography, MRI defaecography, ventral rectopexy. The search was conducted for the literature from January 1, 2011 until December 31, 2015, because the literature before January 1, 2011 was covered by the previous edition of this chapter.

**Magnetic Resonance Imaging (MRI)**

The following search terms were used in searches in PubMed and Cochrane Reviews: MRI faecal incontinence, MRI fecal incontinence, MRI anal incontinence. The search was conducted for the literature from January 1, 2011 until December 31, 2015, because the literature before January 1, 2011 was covered by the previous edition of this chapter.

**Clinical Neurophysiologic Testing**

A search of PubMed, Web of Science, CINAHL and Cochrane reviews was undertaken using the following terms: faecal incontinence, anal incontinence, neurophysiology, neurophysiologic evaluation, anorectal manometry, anorectal physiology, anorectal sensation, mucosal electrosensation, anorectal testing, anorectal reflexes, anal sphincter EMG. The search was conducted from January 1, 2011 until December 31, 2015, since earlier literature had been considered in the previous version of the chapter.

**Symptom Severity Scales**

Ovid/MEDLINE and EMBASE were searched for relevant literature on the assessment and severity of symptoms in fecal incontinence. This combination allows for expanded coverage (articles from both databases, as well as meeting abstracts) use of unique controlled vocabulary (fecal incontinence (MeSH), feces incontinence (EMTREE)), as well as searching titles with adjacency (feces or faec* or fecal or anal or anus) within 3 words of incontinence. PubMed does not permit adjacency searching. Once the concept of fecal incontinence was established, the results were combined with subject headings as well as text words, specific tools, as well as specific symptoms: severity of illness index, disability severity, disease severity assessment, disease severity, exp symptom, exp symptom assessment, exp Symptom Distress Scale, gastrointestinal symptom, sever*, modified Manchester, wexner, st Mark*, fis, fica, icic; or specific symptoms: symptom, diarrhea, diarrhoea, urge*, frequent*, soil*, leak*, stool*, constipat* associated with methods of assessment: (survey, questionnaire, scale, score, validat, instrument, assess, tool, evaluat, index, indi-ces, grade, grading, classif*). The study by Pescatori, which is the earliest of the contemporary studies evaluating the severity of symptoms in faecal incontinence, was published in 1992(198). Hence, results were limited to literature published since 1992, and to formal study design in English.

**Medications**

Ovid/Medline and Cochrane Review databases were searched for studies in any language and any year through October 2011 which matched the following search terms:

“Faecal incontinence” OR “anal incontinence” AND “drug” OR “medical management” OR “medical treatment.”

“Faecal incontinence” OR “anal incontinence” AND “loperamide” OR “diphenoxylate.”

“Faecal incontinence” OR “anal incontinence” AND “laxative” OR “polyethylene.”

“Faecal incontinence” OR “anal incontinence” AND “phenylephrine gel.”

**Education and Lifestyle Changes**
PubMed, Ovid/Medline and EMBASE, CINAHL, and Cochrane Review databases were searched for articles from January 1, 2011 to December 31, 2015 for each topic separately in this section using syntax and combinations of terms that were appropriate for each database. Articles were limited to the English language and duplicates removed before review. An example of the search terms used is as follows: anal or anorectal* or bowel* or faecal* or fecal* or rectal* or stool*).mp, and (continen* or incontinen*).mp, and:

Pelvic Floor Muscle Exercises, Biofeedback, and Electrical Stimulation

PubMed and Cochrane Review databases were searched for articles published between January 2012 and March 2016. These searches were limited to studies in which the subjects were adult humans. No restrictions were placed on language of publication. The search terms were: (fecal incontinence OR anal incontinence or accidental bowel leakage) AND (biofeedback OR neuromuscular conditioning OR...
pelvic floor exercise OR Kegel exercise OR electrical stimulation OR percutaneous tibial nerve stimulation).

Qualitative Research on the Experience of Faecal Incontinence and Quality of Life

PubMed, Ovid/Emeline, and CINAHL databases were searched from January 2012 - December 2015. The following subject headings and key words were searched: stool incontinence; self-report; narratives; qualitative research; anal, bowel, faecal and incontinence; quality of life and faecal incontinence. Additional articles were identified by examining reference lists from articles and citation search of early work. Articles were included if they met the following criteria: (a) focus on adults; (b) were published in English; (c) featured qualitative research; and (d) explored the experience of faecal incontinence. Articles were excluded if they were: (a) focused on caregivers; or (b) exploring another condition as the primary experience (i.e., sphincter saving surgery).

INTRODUCTION

Normally, therapy for faecal incontinence is readily divided into non-surgical and surgical therapy. Selection of specific therapy is based upon a number of considerations, including the severity of incontinence and structural integrity of the anal sphincter.

Non surgical therapy is most applicable to relatively mild cases of incontinence. Biofeedback retraining can be attempted for incontinence of any cause or severity, as the therapy is painless and risk-free. These treatments are discussed in detail elsewhere in this monograph.

Traditionally, the most widely accepted surgical therapy for faecal incontinence was overlapping sphincteroplasty. Typical of other well-established therapies, the evidence base supporting this approach is paradoxically less robust than that supporting more recent treatment options. Sphincteroplasty is useful only in cases in which there is an anatomical anal sphincter defect. Sphincteroplasty provides satisfactory results in the majority of patients, however the results of sphincteroplasty deteriorate with time (2-4).

A number of operations were developed to treat patients whose native sphincter was either intact but weak or not amenable to repair. Parks' conceived the postanal repair to accentuate the anorectal angle in patients with incontinence due to pelvic neuropathy (5). Muscle transposition procedures using either gluteus maximus or gracilis were devised to create a functional biological neosphincter. The results were modest but electrical stimulation of the neosphincter, known as dynamic graciloplasty, led to improved continence outcomes. An artificial anal sphincter was devised as a salvage procedure for patients who had failed or were not candidates for standard therapy. A simplified magnetic bead artificial sphincter has been developed and is currently the subject of clinical trials.

Sacral nerve stimulation (SNS), which was being studied for treatment of urinary incontinence, was found to improve faecal incontinence in a sub-set of patients with dual incontinence. This observation led to application of SNS as a primary treatment of faecal incontinence in patients with intact or minimally disrupted anal sphincters. Approximately 55% of patients assessed achieve a substantial benefit from SNS (50% reduction in incontinence episodes) such that SNS is increasingly offered to patients with major incontinence difficulties including those with larger anal sphincter defects.

There has been considerable interest in the development of minimally invasive approaches to faecal incontinence for patients with less severe symptoms. These include the use of injectable biomaterials, radiofrequency energy treatment, a vaginal pessary device and pelvic sling procedures. The potential for use of autologous stem cells to augment residual anal sphincter function is also being explored.

Several important caveats apply to interpretation of the results of surgery for faecal incontinence reported in the literature. Firstly, the vast majority of reports are uncontrolled case series. Randomised controlled studies are rare, and those reported include only small numbers of patients (6). Secondly, numerous quantitative measures have been used to report outcomes, but only recently have any of these been validated, such as the Faecal Incontinence Quality of Life (FIQL) instrument (7). Thirdly, the criteria for establishing “successful” outcomes have been variable and often appear arbitrary. Fourthly, the quality of data reported is variable, though this has generally improved in more recent studies. Chart review has been supplanted by patient questionnaires and interviews by independent data auditors. Daily continence diaries, the most stringent form of data collection, have become increasingly commonplace (although not routine). A recent systematic review has highlighted many of the limitations (8). Notwithstanding this, clinical guidelines published by the American College of Gastroenterology (9) and the American Society of Colon and rectal Surgeons (10) do provide a framework under which to consider the evidence available to support clinical decision making regarding surgical treatments for faecal incontinence.
A PubMed search was conducted to identify studies published on the use of surgery for faecal (fecal) incontinence. Keywords used were faecal (fecal) incontinence and surgery. Full text copies of studies deemed to be potentially relevant were obtained. Priority was given to systematic reviews, randomised controlled trials, and controlled clinical trials; if those were unavailable or inadequate, comparative observational studies, case series, case reports and narrative reviews were also included. Reviewers were not blinded to the names of studies’ authors, institutions or publications. In view of the nature of the guideline, priority was given to the reports with large number of patients and long follow-ups assessing efficacy of surgical interventions. Particular emphasis was placed on those reporting techniques and functional outcome including quality of life after an operation.

Non-English language papers were noted but excluded from the review unless they contained an English language abstract providing sufficient information.

II. SURGERY FOR ADULT FAECAL INCONTINENCE

1.1. Sphincter Repair

Anal sphincter repair is the term used to describe primary repair of the anal sphincter mechanism following direct trauma. The most common indication is following childbirth and repair in this situation is usually performed by the attending obstetrician. Colorectal surgeons are more commonly involved in primary repair of injury that is the result of blunt or penetrating trauma. Occasionally, the anal sphincter mechanism is damaged during anorectal surgery for other anal pathology, particularly surgery for anal fistula.

In Western obstetric practice, the incidence of overt anal sphincter injury (grade 3 or 4 tear) is low, 3-5% following primiparous delivery and 0.5-1% following second and subsequent deliveries (11). When prospectively looked for with endoanal ultrasound, the actual incidence of anal sphincter injury is higher (12, 13). A meta-analysis of 717 vaginal deliveries found an incidence of new anal sphincter defects of 27% in primiparous and 9% in multiparous women using 2D endoanal ultrasound (14). 3D and transperineal ultrasoundography suggest that the incidence is somewhat less, perhaps 11%, following primiparous delivery (15, 16). The risk factors for sphincter injury include instrumental vaginal delivery, prolonged second stage of labour, fetal macrosomia, and a persistent occipital position of the fetal head (13, 17, 18). Midline episiotomy is associated with higher incidence of anal sphincter injury and the angle of mediolateral episiotomy may also influence perineal outcome (19). LEVEL OF EVIDENCE 2.

A policy of restrictive use of episiotomy may reduce the incidence of anal sphincter injury (20-22). LEVEL OF EVIDENCE 2.

Obstetric injury of the perineum is classified as a first degree tear if confined to vaginal epithelium and skin, second degree if the perineal muscles are torn, third degree if the anal sphincter muscles (external: EAS; internal: IAS) are torn, (3a: less than 50% EAS torn; 3b: more than 50% EAS torn; 3c: IAS torn) or fourth degree if both EAS and IAS and rectal or anal mucosa are torn (23). Primary repair of an obstetric tear is correctly termed anal sphincter repair and is frequently performed by the obstetrician immediately after delivery, most commonly in the delivery room under local or epidural anaesthetic. However recent guidelines issued by the Royal College of Obstetricians and Gynaecologists in the UK recommend that all such repairs should be performed in an operating theatre with adequate exposure, lighting and adequate anaesthesia (24). By tradition, the technique of repair has been a direct oppositional repair of the severed EAS, however an overlapping technique, as commonly used in secondary repair (vide infra), has been recommended as it obliges identification and adequate mobilization of the severed ends of the EAS (25). The IAS, if damaged, is difficult to identify separately and is usually repaired en-block with the anal canal mucosa in a complete or 4th degree tear. However, Mahoney et al (26) have shown that persistence of an IAS defect is adversely associated with continence outcome following repair of a 3rd or 4th degree tear, while Roos et al (27) have found that women with major tears (grade 3c or 4) were significantly more likely to have ultrasound evidence of a persisting IAS or combined IAS and EAS defect following obstetric repair. These women were more likely to have poor functional outcomes. Separate repair of the IAS is now recommended when the sphincter can be separately identified using a direct appositional technique (21, 24, 28, 29). LEVEL OF EVIDENCE 3.

There have been six randomised clinical trials (588 women) (25, 30-34), a meta-analysis (35), and a systematic review (36) that have investigated different techniques of immediate primary anal sphincter repair following obstetric injury. Compared with primary end-to-end repair, immediate primary overlap repair of the EAS appears to be associated with lower risks of developing faecal urgency and anal incontinence, however at 36 months following repair there appears to be no difference in outcome between the two techniques. Norderval et al have shown that the continence outcome in women with an obstetric anal sphincter tear was improved if the entire length of the EAS was repaired in addition to separate repair of the IAS if a co-existing injury was found (37). Guidelines from the American College of Obstetrician and Gynecologists state that end-to-end or overlap repair are both acceptable for full-thickness external anal sphincter injury (29). A recent Cochrane review concluded that more evidence is needed to establish the optimum technique of repair (35). LEVEL OF EVIDENCE 2.

2090 | COMMITTEE 17. SURGERY FOR FAECAL INCONTINENCE
As colorectal surgeons are, in general, quite familiar with the anatomy of the anal canal, it has been suggested that primary anal sphincter repair might be best performed by a colorectal surgeon rather than an obstetrician. Nordenstam et al (38) concluded, in a single institution study of 165 women, that technique and expertise affect the outcome of primary repair and that if needed, the repair could be safely delayed until such expertise was available. In a similar study, Soerensen et al (39) also found no adverse outcome with delayed primary repair. Co-operation between obstetric and colorectal surgical colleagues can result in much improved outcomes (40), while a structured training programme for obstetric trainees also improves clinical outcomes (41). LEVEL OF EVIDENCE: 2

There have been two randomised trials of post-operative management of the bowel after primary anal sphincter repair. These have shown benefit in use of a laxative rather than a constipating regimen but no advantage to the addition of a stool bulking agent (42, 43). LEVEL OF EVIDENCE: 1

Some alteration in faecal continence occurs in approximately 13 - 17% of women following primiparous vaginal delivery, even in the absence of a recognised sphincter tear (12, 44, 45). The prevalence is greater if urgency of defaecation is included as a symptom (13). MacArthur et al (46) found flatual incontinence in 27% of 7,879 women surveyed 12 weeks after delivery. Fenner et al (47) found that women who had sustained third and fourth degree tears were more likely to have bowel incontinence than women without anal sphincter injury 6 months following delivery. This was more pronounced in women with a history of 4th degree tear. Samarasekera et al (48) found long-term effects on anal continence and quality of life following postpartum anal sphincter injury. Oom et al (49) suggested that concomitant injury to the pelvic floor may be an associated determinant of outcome, in addition to adequacy of sphincter repair. Following repair of obstetric anal sphincter injury patients should be referred for pelvic floor physiotherapy (50, 51) LEVEL OF EVIDENCE: 2

Management of subsequent labour following a previous anal sphincter tear must take account of obstetric risk factors, symptoms of incontinence and patient preferences. Harkin et al (18) found an approximately 5 fold increase in the incidence of recurrent sphincter tear compared to the incidence of first sphincter injury during second labour. Fynes et al (52) found that women with altered continence after first vaginal delivery were at risk of deterioration if delivered vaginally on their second pregnancy. Caesarean delivery before the onset of the second stage of labour was found to be protective (53); however, Nelson et al (54) in a systematic review found that pregnancy rather than delivery was more important in predicting post-partum continence. Scheer et al (55) have confirmed that subsequent vaginal delivery is reasonable in asymptomatic women after a previously repaired third degree tear. LEVEL OF EVIDENCE: 3

A number of studies have looked at long-term outcomes after repair of a 3rd or 4th degree tears and all have shown an increasing prevalence of continence disorders in association with greater age. These findings parallel those in the general population of parous women who have not had a recognized tear (44, 56, 57). Eogan et al (58) found in a study of women 10, 20 and 30 years following delivery that onset of menopause was the most significant determinant of symptoms, whereas Mous et al (59) found the incidence of incontinence increased with age irrespective of menopausal status. Fornell et al (60) found that subjective and objective anal function after anal sphincter injury deteriorates with time and subsequent deliveries. A persistent defect in the IAS was also found to be an important determinant, an observation supported by Mahony et al (26). LEVEL OF EVIDENCE: 3

There is some evidence that hormone replacement therapy may be of value in women who develop symptoms post menopause (61). LEVEL OF EVIDENCE: 3

Summary: Primary anal sphincter repair should be undertaken by an experienced operator under optimal conditions. End to end and overlap EAS repair appear equivalent. Separate IAS repair should be considered when divided. Following obstetric injury, management of subsequent deliveries should take account of patient symptoms and preferences as well as obstetric factors. Grade of Recommendation: C

1.2. Sphincteroplasty

The term “anal sphincteroplasty” is used to describe secondary or delayed reconstruction of the anal sphincter musculature, injury to which has either not been recognised at the time of injury or when the outcome of primary repair has been unsatisfactory. Delayed sphincteroplasty is usually performed a minimum duration of three months after the initial injury. Anterior sphincteroplasty is the most common type of reconstruction performed because of the association with obstetric injury. In this situation, the anal sphincter muscles and perineal body have separated leaving a horseshoe type configuration to the anal sphincter mechanism, with a large defect in the anterior quadrant. Occasionally, the defect is such that the anal and vaginal mucosae have healed to form a cloacal defect. Anal sphincter defects related to previous anal fistula surgery or direct trauma are usually less complex and are not associated with a deficient perineum unless there has been an avulsion injury with significant tissue loss.

The decision to perform anal sphincteroplasty is based on an assessment of symptoms and the anatomical extent of the sphincter defect (62). In assessing symptoms one of several faecal continence scores should be used. The two most commonly applied are the Cleveland Clinic Continence Score (63) and the St Mark’s Continence Score (64). In addition a quality of life instrument should be applied (65). LEVEL OF EVIDENCE: 4
Anorectal function can be evaluated objectively using different modalities, including colorectal transit time (CTT), anorectal manometry, rectal sensation, rectal compliance, defaecography or scintigraphy, pelvic floor electrophysiology including, but not limited to, pudendal nerve terminal motor latency (PTNML), endoanal ultrasound and MRI. The results from objective measurement techniques should be applied with caution in the assessment of faecal incontinence as they are often inadequate in determining the presence and/or severity of the condition. The American Society of Colon and Rectal Surgeons considers as having a surgical indication those symptomatic patients with localised anal sphincter defects, without defining exactly the minimum size of the injury detected as indication for this surgery (66). LEVEL OF EVIDENCE: 4

Other causes of disordered continence should be excluded e.g. inflammatory bowel disease, colorectal cancer and neurological disorders. Patients with background IBS are more likely to be symptomatic than those with more predictable bowel habit and equivalent anal sphincter defects (67). Pelvic floor electrophysiological assessment, while not essential, if performed, should be comprehensive and not confined to measurement of pudendal nerve terminal motor latency (68).

For symptomatic patients with a less than one quadrantal anal sphincter defect, a trial of dietary modification, stool regulating drugs and physiotherapy is appropriate. Anal sphincter exercises (pelvic floor muscle training) and biofeedback therapy have been used to treat the symptoms of people with faecal incontinence. However, standards of treatment are still lacking and the magnitude of alleged benefits has yet to be established. A recent Cochrane review concluded that while some elements of biofeedback therapy and sphincter exercises may have a therapeutic effect, this is not certain. Larger well-designed trials are needed to enable safe conclusions (69). LEVEL OF EVIDENCE: 3

For patients with a more than one quadrantal anal sphincter defect, anal sphincteroplasty is appropriate (6, 23, 62). Preoperative counselling should identify post-operative wound healing as the most common difficulty. The majority of patients can expect significant improvement in continence after the procedure with a mean of 66% reporting excellent or good results in the short term (62), however, the long-term outcome is not satisfactory, decreasing to between 30-80% at 80 months and to 6% at 120 months. Concomitant repair of a cloacal defect or vaginal fistula should be undertaken (70, 71). There is no evidence that a defunctioning colostomy improves outcome. The results of anal sphincteroplasty in recent series reporting more than 50 patients are given in Table 1.

Anal sphincteroplasty can be performed in the lithotomy position or the prone jack-knife position. Full bowel preparation is not needed, although most would give a cleansing enema pre-operatively. The conventional incision is an inverted ‘V’ that may be closed as an inverted ‘Y’ as described by Parks and McPartlin (90). If anterior levatorplasty or rectocele repair is contemplated, a posterior fourchette incision with the patient in the lithotomy position may have advantages (81). The external anal sphincter is usually repaired using an overlapping technique without separate identification and repair of the IAS (23), however, Maslekar et al (87) attribute their good long-term results to a selective policy of separate repair of the IAS. There has been one small randomised trial of direct versus overlapping sphincteroplasty which showed similar outcomes (91). To prevent dehiscence and subsequent failure, the two divided ends of the external sphincters must have an adequate blood supply and the reconstructive suture cannot be under excessive tension. Occasionally the EAS defect is not full thickness and overlapping repair in such circumstances would require division of the residual intact fibres to facilitate overlap. Oberwalder et al (92) have, in a small series of patients, found that imbrication of the EAS in such cases is associated with outcomes similar to formal overlapping sphincteroplasty. LEVEL OF EVIDENCE: 3

More recently, Zutshi et al developed a modified sphincteroplasty with the application of a biological porcine collagen mesh for reinforcement of the reconstruction, but only 10 patients were included (93). Larger studies are needed.

Anterior levatorplasty may be performed in conjunction with external anal sphincter repair (94, 95) or as an isolated procedure (79, 96). No technique has shown superiority and it is possible that the operative technique should be individualised to the particular patient (97). LEVEL OF EVIDENCE: 3

Initial success of sphincteroplasty is related to whether the anal sphincter defect is corrected (98, 99). Early failure is usually associated with a persisting defect identified using endoanal ultrasound (100). This may be amenable to a further attempt at repair (99, 101, 102). There is however increasing evidence that continence outcomes deteriorate with long-term follow-up (23, 62, 103). The effect of age at time of operation on long-term function is controversial (95, 104), however long-term effects of aging and menopause coupled with atrophy of the sphincters may be relevant (3, 23, 69). LEVEL OF EVIDENCE: 3

Pre-operative physiological testing is helpful in the overall management of patients with faecal incontinence, however the value of anal manometry and pelvic floor electrophysiological assessment as diagnostic indicators for outcome following sphincteroplasty is controversial (105). There are no established parameters that reliably predict outcome following sphincteroplasty (87, 106). Patients with an unsatisfactory clinical outcome following sphincteroplasty may be considered, if sufficiently symptomatic, for adjunctive sacral neurostimulation (vide infra) (107).

$ defined as “successful”

** Overall improved symptoms in regard to solid, liquid and flatus

Summary: Anal sphincteroplasty should be considered in symptomatic patients with a defined defect in the external anal sphincter. Overlapping EAS repair is usually performed. Results appear to deteriorate with time. Redo sphincter repair may be feasible in patients with a poor continence outcome. Grade of Recommendation: C

1.3. Post Anal Repair

Postanal repair was first reported by Sir Alan Parks in 1975 (108). This procedure was designed to increase the length of the anal canal, restore the anorectal angle and re-create the flap valve mechanism, which at the time was thought essential for maintaining faecal continence. Success rates ranged from 15% to 83%, depending on the definition of the success, the length of follow-up, and possibly the cause of incontinence.

The published studies regarding postanal repair include four systematic reviews of randomised controlled trials (6, 109-111), two randomised controlled trials (94, 112), two non-randomised cohort studies (113, 114), 8 case series of good quality (5, 98, 115-120) and 11 case series of poor quality (120-130). Since the 5th International Consultation on Incontinence in 2012, no new studies regarding the role of...
postanal repair for the treatment of faecal incontinence, other than one systematic review have been reported (111).

Subsequent observational studies with a median follow-up of more than 5 years revealed that continence deteriorated with time. Despite 60-80% of patients reporting persisting symptomatic improvement, only one-third were actually continent to liquid or solid stool (116, 118-120, 130). Even in the most recent study reporting the long-term outcome of postanal repair (131), only 26% reported none to minimal incontinence with the Cleveland Clinic Florida Fecal Incontinence score being between 0 and 5, while 79% improved symptomatically with a mean follow-up of 9.1 years. Possible explanations for deterioration of continence following initial improvement included unrecognized denervation and/or muscular injury of the sphincter and pelvic floor musculature, and the presence of occult anal sphincter disruption, particularly in the studies reported before endoanal ultrasonography or magnetic resonance imaging were available. Moreover, physiological and radiological evaluations before and after postanal repair have not demonstrated consistent changes in anal canal length, resting pressure, voluntary contraction pressure, anorectal sensitivity and movement of the anorectal angle (5, 112-114, 132, 133). These reports of increasingly poor outcomes have significantly diminished the popularity of this procedure.

Deen et al (94) in a randomised controlled trial, comparing three procedures in 36 women with neuropathic faecal incontinence, found that complete continence was achieved in 42% of patients after postanal repair, 33% after anterior levatorplasty and 67% after total pelvic floor repair. In contrast, van Tets et al (112) conducted a randomised controlled trial comparing postanal repair and total pelvic floor repair in 20 women with neurogenic faecal incontinence. Complete continence to solid or liquid stool was achieved in 27% of patients after postanal repair and in 22% after total pelvic floor repair.

Summary: Postanal repair can be performed with modest success in carefully selected patients. However, this procedure is now rarely performed due to the advent of newer treatments Grade of Recommendation: D.

1.4. Non-Stimulated Muscle Transposition

A variety of muscle transposition procedures have been devised for the treatment of faecal incontinence. Early efforts focused upon the use of transposed skeletal muscle to supplement the function of a weak or disrupted anal sphincter. Early in the 20th century, a variety of configurations to create a neosphincter. In 1952, Pickrell et al (134) described the use of transposed gracilis muscle to create a neosphincter for incontinent children.

Published series of gracilis transposition are uncontrolled and demonstrate variable success rates (134-143). LEVEL OF EVIDENCE: 3.

One study reviewed the functional results of graciloplasty longitudinally in 22 patients followed for a median 63 months (144). Eighteen patients (81%) were improved at 6 months, though only one regained normal continence. Results deteriorated in 5 patients during subsequent follow up. Bilateral gracilis transposition has been used successfully in several small series (135, 145).

Success rates following gluteus transposition have likewise been variable (146-149). A prospective randomised trial in women with post-obstetric neuropathic incontinence showed similar significant degrees of improvement following both gluteus maximus transposition and total pelvic floor repair (150). A recent retrospective review of 25 gluteoplasty patients reported restoration of continence in 18 patients (72%) and partial restoration in an additional 4 patients (16%). Donor-site and peri-rectal complications occurred in 16 patients (64%) (151). LEVEL OF EVIDENCE: 3.

Summary: Unstimulated graciloplasty should not be routinely offered. It is now rarely performed due to the advent of newer treatments Grade of Recommendation: D

1.5. Stimulated Muscle Transposition

Successful electrical stimulation of a previously transposed gracilis muscle was first reported in 1988 (151), and subsequently in 1990 in a case series of 6 patients of whom 5 had closure of a defunctioning stoma with improvement in continence (152). This series was later increased to 20 patients (including 12 in whom the anus had been surgically removed or was congenitally absent) in whom continence improved in 12 (153). Baeten et al (154) showed improved continence in 8 of 10 patients.

Even after successful muscle transposition, functional outcomes are limited by two physiological factors. First, patients are unable to consciously maintain tonic contraction of their neosphincters over long periods of time. Furthermore, even if patient volition were not a problem, the gracilis muscle is poorly suited to tonic contraction. While the external anal sphincter comprises predominantly slow-twitch, fatigue-resistant type I fibres, the gracilis muscle comprises predominantly type II, fast-twitch fibres that are rapidly fatiguable (155). Graded electrical stimulation transforms type II into type I muscle fibres, and the use of an implantable electrical pulse generator has been shown to convert transposed gracilis to a muscle with predominantly type I fibres (150). The gracilis muscle is well suited to electrical stimulation due to the relatively constant proximal location of its neurovascular bundle, which is easily identified at surgery (153). The results of stimulated graciloplasty are shown in Table 2.
In 1995, Baeten reported results in 52 patients, with 38 (72%) becoming continent after surgery (156). In a subsequent paper published by this group in 2003, 200 patients followed for a median of 261 weeks were reported (163). The overall success rate was 72%. Patients with incontinence due to trauma had the best results (82% success), while patients with incontinence due to congenital anorectal malformation had the worst results (52% success). A total of 138 complications were reported, including disturbed evacuation in 32 patients (16%), infection in 24 (12%), pain in 16 (8%) and pulse generator displacement in 12 (6%). Ten patients (5%) had anorectal perforations, 7 of whom eventually obtained a successful outcome. Rosen et al (167) reported restoration of continence in 9 of 10 patients treated by dynamic graciloplasty using a “split-sling” wrap configuration. Sielezneff et al (168) treated 16 patients and 13 had improved continence. However, 8 patients suffered morbidity, resulting in 33 subsequent admissions and 23 reoperations.

Three multicentre prospective trials of dynamic muscleplasty have been performed to date. In each of these studies, patients served as their own controls. No randomised prospective trials have been performed. Madoff et al (159) studied 139 patients from 12 centres, 128 of whom had gracilis wraps and 11 gluteus wraps. Of those patients, 104 were treated for faecal incontinence, and 35 underwent total anorectal reconstruction following abdominoperineal resection for cancer. Success rates for graciloplasty were 71% for patients with acquired incontinence and 50% for those with incontinence due to a congenital abnormality. There was a total of 138 complications for the entire group. Wound complications (41 major and 35 minor) were both the most prevalent and the most consequential. Other complications included pain in 28 patients (22%), hardware problems in 14 (11%) and tendon detachment in 4 patients (3%). Centres with significant prior experience of the procedure had substantially fewer major wound complications (17.4 vs. 33.1%) and significantly higher success rates (80% vs. 47%).

Mander et al (160) reported the results of dynamic graciloplasty in 64 patients with refractory faecal incontinence treated at 7 centres. There were 24 infectious complications, 5 of which involved perineal wound breakdown and 3 of which required re-operation. Forty-four (69%) patients became continent to solid stool 1 month following stoma closure. Evacuation problems developed in 16 patients (25%), and this lead to failure in 14. At a median of 10 months follow-up, 29 patients had a good functional result.

Baeten et al (161) reported the results of dynamic graciloplasty in 123 patients treated at 20 centres as part of the Dynamic Graciloplasty Therapy Study Group (DGTSG). The aims of this study were to assess both the safety and efficacy of this treatment; 189 adverse events occurred in 91 patients, including one death due to pulmonary embolism. There were 18 major and 31 minor infectious complications. There were 42 instances of therapy-associated pain, occurring variably in the donor leg, at the anal canal, or at the device site. There were 11 lead dislodgements but no problems with lead breakage or pulse generator malfunction. A follow-up study showed full or partial recovery from these complications in 87% of patients (165). This study, in contrast to others, was based upon data from daily continence diaries. A

*variable definitions; does not necessarily denote perfect continence. Issues of divergence in technique arose from these studies, each of which has seen increasing consensus in the literature despite a lack of randomised trial data. Thus, intramuscular (vs. epineural) electrodes are now universally employed, and diverting stomas and ‘vascular delay’ prior to muscle transposition are no longer utilized.
successful result (defined as a 50% or greater decrease in incontinent events in patients without pre-existing stomas) was achieved in 63% of patients after one year. Another follow-up of this patient cohort demonstrated stable success rates at 18 months (55%) and 24 months (56%) (168). Statistically significant improvements in the physical and social function scales of the SF-36 were also recorded at 12 months.

A multicentre retrospective trial from Belgium using dynamic graciloplasty treated 60 patients with 27 failures (164). Continence was achieved in 78% of the group. However, more than half (26 patients) required the use of antegrade continence enemas or other measures to maintain continence. Seven patients had a permanent stoma constructed. Seventy-five complications occurred with 61 total reoperations. Loss of muscle stimulation occurred in 22 patients; 10 were due to issues specific to the stimulator and leads, 4 were due to technical failure of the muscle wrap. Functional outcome was directly associated with a maintenance of stimulation and initiation of stimulation within 50 days of surgery.

Very few studies have examined the long term results with dynamic muscle wraps. Thornton et al (169) reported on the 5-year follow up of 38 patients who had undergone dynamic graciloplasty. Of the 33 patients available for follow-up by telephone interview, obstructive defaecation was a problem for 11% of the cohort and 16% had been converted to a permanent colostomy. Of those with a functioning graciloplasty (22 patients) who reported a faecal incontinence score of less than 12 (range 0-24), 50% reported problems with obstructive defaecation and 64% felt their bowel habits had negatively affected their quality of life. Long-term complications were primarily related to stimulator problems; ten patients required 15 operations to replace stimulator components. However, 72% of patients reported pain, swelling or paresthesia of the donor leg and 27% reported sexual dysfunction. Hassan et al (166) reported follow-up of 31 patients who underwent gracilis muscle transposition with periodic electrical stimulation and postoperative supplemental biofeedback. Twenty-two patients (71%) reported improvement at five-years. Nine patients (29%) were deemed failures, requiring further surgical intervention (colostomy formation, contralateral dynamic gracilis muscle transposition, implantation of artificial bowel sphincter). Six patients developed perineal wound infections (5 resolved with antibiotics, 1 required surgical drainage), and 2 patients had evacuation difficulties requiring regular enemata. Those who underwent operation due to traumatic injury to sphincters had better outcome (82% improvement) compared to patients with congenital faecal incontinence (55%).

Tillin et al (165) performed a prospective case-comparison study of 49 patients who had a dynamic graciloplasty and 87 patients who either refused the surgery or who were not offered the surgery. The primary outcomes evaluated were symptoms, quality of life, anxiety, and depression. Of the treated group, the procedure failed completely in 15 patients. At two year follow-up, bowel-related QoL and continence had improved by more than 20 per cent compared with the preoperative status for two-thirds of patients who had dynamic graciloplasty. Up to 50% of patients with a satisfactory outcome reported disordered evacuation and 8 other patients were deemed failures due to this problem.

Chapman et al (170) performed a systematic review of dynamic graciloplasty for faecal incontinence on behalf of the Australian Safety and Efficacy Register of New Interventionsal Procedures-Surgical (ASERNIP-S). The authors reviewed 37 original articles published between 1991 and October 2000. All of the papers were judged to be of low-evidence quality, as all but one paper were case series, and the sole comparative study utilized historical controls. Mortality excluding cancer deaths was 1% (95% confidence interval 0-3%) and morbidity 1.12 (95% CI 0.14 - 2.08) events per patient. Success was variably defined between studies, but was reported as ranging from 42-58%. The ASERNIP-S Review Group determined that “the safety of the procedure cannot be determined at the present time due to an incomplete and/or poor-quality evidence base” and that “efficacy is established.” Tan et al(171) examined three treatments for faecal incontinence including dynamic graciloplasty, artificial bowel sphincter and end stoma. They concluded that the most cost effective intervention was an end stoma, the artificial bowel sphincter was most cost-effective after 10 years and that dynamic graciloplasty should only be considered as an alternative in highly specialized centres. These findings are subject to the criticism that a colostomy does not attempt to restore continence whereas the other two procedures do.

Summary: Stimulated graciloplasty should be offered to selected patients who have failed other modalities of treatment particularly where there has been loss of native sphincter tissue. Otherwise, it has largely been superseded by sacral neuromodulation. Grade of Recommendation: B

1.6. **Artificial Anal Sphincter**

In parallel to the now recognised and, for some, approved nerve stimulation procedures various types of artificial sphincter devices have been designed and proposed to treat severely incontinent patients. These options have some common characteristics: they frequently derive from innovations and experiments from sister specialties, urology for instance, but also upper GI surgery; their development is associated with significant efforts from companies that invest heavily to establish them in the market; they are not yet universally approved and have to be regarded as investigational/experimental in many ways as strong evidence is still missing in terms of feasibility, cost-effectiveness, durability and reproducibility.
Artificial bowel sphincter (ABS) - Acticon™ Neosphincter

This innovative procedure for anal sphincter replacement was developed in the 1990s. This technique is in effect a sophisticated modification of a Thiersch wire implantation. During the surgical procedure, a silicone-made pressure-regulated inflatable cuff is placed around the upper anal canal and tubing from the cuff is directed along the perineum and connected to a pump placed in the scrotum or labia. Tubing is used to connect the pump to a pressure regulating balloon implanted in the pre-vesical space. The balloon contains 40 ml of isotonic radio-opaque solution which gives approximately 100 cm H2O pressure into the perianal cuff. The control pump allows a fluid transfer from the cuff to the balloon. To do so, the patient squeezes the pump to empty the cuff allowing for the anal canal to open and defaecation to occur. The fluid then slowly returns to the cuff which results in the closing of the anal canal and restoration of continence.

Two papers have reported the outcome of ABS implantation in the long term. The first from Cleveland Clinic Florida, USA (172) investigated the risk factors related to ABS implantation in a single centre series. Fifty-one implantations were performed in 47 patients with faecal incontinence (84.3% female - mean age of 48.8 years - range, 19-79) from 1998 to 2007. Twenty-three (41.2%) of the ABS implantations became infected, 18 (35.3%) of which developed early-stage infection, all explanted, whereas 5 (9.5%) had late-stage infection. Time to the first bowel movement was an independent risk factor for early-stage ABS infections, which are significantly higher in those whose first bowel movement occurred before day 2. Patients with a stoma also had a tendency toward a higher infection rate. Common late-stage complications were device malfunction, device erosion, persistent perianal pain, device migration and constipation. Ultimately a third of the 33 participants required ABS explantation with device malfunction being the most common reason for explantation. The authors found that the rate of explantation increased with the time after implantation; the longer the ABS was in use, the more the ABS was explanted. The 1, 2, 3 and 4-year cumulative risk of ABS explantation was respectively 9.7, 13, 43 and 48%. At 5 years after ABS implantation, the risk of explantation was 57%.

The second report from Nantes, France (173) focused more on ABS functional outcome in a report of a 52 patients consecutive series treated for severe faecal incontinence from 1996 to 2010. All of the participants failed to respond to medical treatment / pelvic floor retraining for at least 1 year. Indications for implantation were sphincter destruction, pudendal neuropathy, perineal colostomy and congenital malformation. The mean follow-up period was 64.3 ± 46.5 months (range 2-169). Of the 52 patients, 26 (50%) required revisions primarily due to device malfunctions from a leaking cuff, with 7 of the participants (13.5%) requiring 2 revisions. Thirty-five (67.3%) still had an activated device in situ at the last review. Two patients had their device deactivated and 14 (26.9%) required definitive explantation with the majority (42.9%) due to infection. With regards to the 35 patients with an activated device in situ, the authors report a significant improvement in the continence (CCIS) and quality of life scores (FIQL) scores at last follow-up.

More recently Wang et al focused on the outcome of ABS reimplantation and the overall results of ABS at Cleveland Clinic Florida (174). They concluded ABS implantation has a high failure rate with explantation in 72% of patients but reimplantation is often possible with a success rate of 47% with reimplantation for non-infectious complications (perforation of the cuff mainly) has better outcomes than reimplantation following device infection. Short- and long-term outcomes of reimplantation were comparable in this series to initial implantation.

A systematic review of the ABS found that the need for surgical revision increases and continence decreases with time (175). Although functioning devices stabilize to a pooled rate of 59% after 5 years of follow-up, continence as measured by the CC-FIS in patients with a functional device decreases with time, although interestingly the QOL of implanted patients remained high. Although evacuation difficulty was common, it was severe in only 8% of patients. Thus preoperative assessment for outlet obstruction and surveillance in the follow-up with instructions to use laxatives or enemas as needed is important to achieve a good functional outcome. They concluded that both device refinements by the manufacturer and meticulous aseptic procedures at implantation are keys to help improve these outcomes.

LEVEL OF EVIDENCE: 3

Recently another systematic review studied, among others, the results of ABS (8) The authors highlighted the existing discrepancy in recommendations for this invasive approach of severe FI. They observed that the American Society of Colon and Rectal Surgeons in their latest recommendations gave the ABS a strongly favourable support to its use in selected patients yet noting that the evidence was of low or very low quality (10) In contrast, the American College of Gastroenterology identified the ABS evidence as insufficient and gave it a weak recommendation (9). From their review, Forte et al found the evidence about ABS to be insufficient to enable conclusions about its effectiveness (8). That being stated, in patients who retain the device, several studies report good restoration of continence and a positive impact on quality of life. The primary concern with ABS implantation is infection, with rates ranging from 20 to 45%. Mechanical failure is as well a recognized complication of the ABS the most common cause being a micro-perforation at the folds of the cuff membrane, which leads to a loss of fluid and pressurization of the system. Cuff perforation that reflects intrinsic "wear.
and tear" of the device components over time contributes to a number of revision procedures, especially detrimental when patients experience a satisfactory functional ABS results. Revision rate with the ABS is directly proportional to the length of follow-up. With this background, even in specialist centres with dedicated interest and experience in ABS the number of implantations has significantly decreased and the ABS Acticon Neosphincter™ is no longer commercially available. This is unfortunate for those few patients that retained the device with good restoration of continence as they will encounter difficulties if and when a replacement device is needed. There are no similar options presently available.

Summary: The artificial bowel sphincter is a treatment for patients who have failed other modalities of treatment. Obstructed defaecation and device erosion have been problematic. Currently the device is not commercially available. Grade of Recommendation: C

1.7. Magnetic Anal Reinforcement – Fenix™

The magnetic anal reinforcement device (or magnetic anal sphincter – MAS (FENIX™; Torax Medical, Inc, Shoreview, MN – USA)) is a new device designed to augment the native anal sphincter. It consists of a series of titanium beads with magnetic cores hermetically sealed inside. The beads are interlinked with independent titanium wires to form a flexible ring that rests around the external anal sphincter in a circular fashion. The device is manufactured in different lengths based on the number of beads (14 to 20) necessary to accommodate the variation in anal canal circumference (176). The procedure used for MAS device implantation is substantially simpler than the ABS implantation. A single anterior incision is made on the perineal body and the rectovaginal septum is dissected down to a depth of 3-5 cm. Next, a perianal tunnel is created around the posterior side of the anus to place a sizing tool allowing for measurement of the proper size of the MAS device. The sized MAS device is then placed into the tunnel and the sutures attached to each end of the device are tied to secure the device around the upper anal canal and the incision is closed without drainage. Early data concerning safety and short/middle term effects on continence are available, however this device is still investigational and only conditionally available on the market in Europe and USA.

Unlike the ABS, the MAS works immediately once implanted, without the need for further manipulation by either the patient or surgeon. The device is initially placed under fluoroscopic guidance to make sure that it adapts adequately to the anal canal and benefits from a new sizing tool that efficiently measures the anal canal circumference. Plain X-rays can assess the device postoperatively. It is not MRI-compatible.

A multicentre feasibility study demonstrated a good restoration of continence with limited complications in short term (177). Based on these results, MAS was granted a CE mark on November 2011 and its commercial use has started in selected centres in Europe. Barussaud et al reported the medium term results of a series of 23 patients (178) (Table 5). A German centre reported results from 18 patients implanted with a MAS for severe FI. No devices became infected or were explanted. CCIF scores decreased from 17.5 to 7.3 and FIQoL improved in all 4 domains. Bowel diary results showed 76% of the implanted patients experienced a > 50% reduction in the number of FI episodes per week (179). More recently Sugrue et al analysed the 5-year results of the original feasibility study group of 35 patients (34 females) implanted at 4 centres in the world. Assessment at 5 years was completed for 23 patients. Eight patients underwent a subsequent operation including 7 MAS explantations due to device failure or complications, mainly occurring in the first year. Thirty adverse events were reported in 20 patients, most commonly defaecatory dysfunction (20%), pain (14%), erosion (11%) and infection (11%). Success rates were 63%, 66% and 53% respectively at year one, three and five. In patients who retained their device, the number of incontinent episodes per week and CCIF scores significantly decreased from baseline, with also a significant improvement in quality of life. The authors concluded that MAS provided excellent outcomes in patients who retained a functioning device at long-term follow-up and therefore protocols to reduce early complications will be important to improve overall results (180).

Presently the place of the MAS in the treatment algorithm of FI remains to be determined. It appears to be a promising innovation but undoubtedly there is a learning curve with this technology, particularly in patient selection. With a limited number of patients treated and only middle-term follow-up available, it remains to be seen if the MAS can withstand the test of time. Two on-going trials in France (MOS STIC – registered in Clinicaltrials.gov NCT01920607) and in UK (SAFARI - ISRCTN 16077538 http://ukctg.nihr.ac.uk) will help to answer this question. These randomised controlled trials are of similar design, aiming to compare MAS to SNS in terms of FI successful treatment and cost-effectiveness. Results are expected in 2017 and 2018 on more than 150 and 350 randomized patients respectively.

Summary: The magnetic anal sphincter is a novel treatment for patients who have failed other modalities of treatment. Early results are promising, however long term and comparative studies are required. Grade of Recommendation: C

1.8. Sacral Nerve Stimulation

Sacral nerve stimulation (SNS), also termed sacral neuromodulation (SNM) was first applied for the treatment of faecal incontinence in 1994 by Matzel et al (181) in patients with functional deficits of the anal sphincter but no morphologic defect. The concept of recruiting residual function of an inadequate anorectal continence organ by electrostimulation of its peripheral nerve supply, i.e. the sacral spinal nerves, was adapted from the field of urology in the early 1990s (182), where it has been used since 1981 (183). The rationale for applying SNS to faecal incontinence was based on both clinical observations and anatomical considerations (from the former, the beneficial effect on bowel habits and anorectal continence function and increased anorectal angulation and anal canal closure pressure seen in urological patients; from the latter, the demonstration by dissection of a dual peripheral nerve supply of the striated pelvic floor muscles that govern these functions (182), with the sacral spinal nerves being the most distal common location of this dual nerve supply). It was hypothesised that stimulating the sacral spinal nerves could both enhance physiological function and improve the symptoms of faecal incontinence.

1.8.1 Technique

SNS has become a minimally invasive technique with low morbidity. The surgical technique can be divided into two stages. As no other predictors of SNS outcome exist at present, patients are uniformly selected for operative implantation of a permanent neurostimulation device on the basis of clinical improvement during test stimulation. This first stage, termed percutaneous nerve evaluation (PNE), is used to confirm a satisfactory neural response and then to evaluate the clinical effect of stimulation before implantation of a permanent device. Trial stimulation is performed for 1 – 3 weeks, a period sufficient to demonstrate its therapeutic effect–commonly considered as a decrease in the frequency of incontinence episodes (documented by bowel-habit diary) by at least 50% and reversibility after discontinuation of stimulation. Two technical options are used for PNE: a temporary, percutaneously placed, unipolar test stimulation lead (or multiple leads) that will be removed at the end of this phase; or operative placement of a quadripolar lead, the so-called “foramen electrode,” close to a target nerve, usually the S3 root, less frequently that of S4. This electrode can stay in place and be used for permanent stimulation if the trial is effective. Today most commonly a minimally invasive technique places this foramen electrode with a modified anchoring device, the so-called “tined lead,” through a trochar. This technique has lately been redefined by introducing the regular use of a softer, curved stylet to guide the electrode placement (184). For screening, both types of leads are connected to an external pulse generator, the tined lead with a percutaneous extension cable.

The second stage is implantation of a permanent electrode and neurostimulator if the screening test is successful. The therapeutic outcome for permanent SNS appears to be best when both sensory/anal motor and toe flexion responses are achieved during test stimulation (185).

Patients with a temporary lead require simultaneous implantation of the pulse generator and the quadripolar lead, most commonly as a tined lead procedure. Those with a foramen electrode already in place for screening will undergo removal of the percutaneous extension before placement of the pulse generator (so-called “two-stage implant”(186)).
Bilateral placement of foramen electrodes remains the exception, based either on improved outcome of bilateral stimulation during the screening phase (187) or on conceptual considerations (188). A recent study exploring the benefit of bilateral over unilateral sacral neuromodulation had to be discontinued prematurely after an interim analysis of 20 patients demonstrated no additional benefit in symptom score, quality-of-life score, or findings on anorectal manometry (189).

The pulse generator is placed subcutaneously, usually in the gluteal area or under certain circumstances in the abdominal wall. It is activated and stimulation parameters are set early after surgery by telemetry; it can be deactivated by the patient with a small, handheld device commonly referred to as a “patient programmer.” The patient programmer also offers the ability to vary among four preset stimulation protocols.

1.8.2 Patient Selection and Indications

Today, a variety of causes leading to faecal incontinence can be treated with SNS. During the initial SNS experience, only patients presenting with deficient function but no morphologic defect of the striated anal sphincter and levator ani were eligible (182, 190, 191), however, because of the high predictive value of the test stimulation, a more pragmatic, trial-and-error approach to patient selection evolved. Patients are now selected for SNS based upon PNE results rather than conceptual considerations of the potential mechanism of action. Test stimulation is indicated, not by an underlying pathophysiological condition, but by the existence of an anal sphincter with reduced or absent voluntary squeeze function and existing reflex activity, indicating an intact nerve-muscle connection (that may be confirmed by intact anocutaneous reflex activity or by muscular response to pudendal stimulation with the St. Mark’s electrode) (190). LEVEL OF EVIDENCE: 2

At present, the test stimulation is the only reliable method for selecting patients who will likely benefit from permanent therapeutic stimulation. Various studies have attempted to identify potential predictors of success of SNS. In a study by Gourcerol et al. (192), age was the only variable related to success of temporary stimulation. In patients with a permanent implant, neurological disorders, delay of the left bulbocavernous reflex and a prolonged or absent bulbocavernous reflex was more frequent in patients with a successful outcome. In another cohort analysis, the need for repeated temporary procedures was associated with failure during the screening in univariate and multivariate analysis (193). A low threshold to obtain motor response during temporary lead placement was revealed to be associated with improved outcome only in univariate, but not in multivariate, analysis. Evidence of anal sphincter injury was related to a greater risk of failure during temporary testing, but not with permanent implant. In a large single-centre study comprising 245 patients with test stimulation and 169 patients with permanent implant, Govaert et al. (194) determined in univariate analysis that older age (>70 years), presence (but not size) of an external sphincter defect, and the need for repeated procedures after initial failure were significantly related to failure of test stimulation. In multivariate regression analysis presence of an external sphincter defect and need for repeated procedures remained significant. The permanent implant was successful in 76.9% of the patients, but no predictor was found to be significantly related. Brouwer and Duthie (107), in a cohort of 55 patients with permanent SNS, demonstrated that continence scores did not differ significantly in those with a defect, pudendal neuropathy, or previous sphincter repair. Melenhorst et al. (195) found no difference in outcome with chronic SNS in patients after sphincter repair and those with an external sphincter lesion of up to 33% of the circumference; they concluded that a morphologically intact sphincter is not a prerequisite for successful SNS. In 244 patients undergoing test stimulation with a success rate of 78.3%, Maeda et al. (196) determined that low amplitude of the sensory threshold during PNE and lead placement anterior to the sacral cortex are positive predictors of PNE outcome. No other demographic, physiological or morphological variable (motor response threshold) was a negative predictive factor. In a cohort of 200 patients with permanent SNS from 6 centres (197) only loose stool consistency, a history of diarrhoea management by medical treatment, and low stimulation intensity were associated with improved medium-term outcome. Multivariate regression analysis confirmed that stool consistency and stimulation intensity were independent predictive factors of success or failure of SNS. In a cohort of 45 consecutive patients, temporary stimulation was successful in 32 (71%). At a median follow-up of 33 months, the neurostimulator remained in place in 25 (55%) and active in 23 (51%). No statistically significant differences were found in the characteristics (including anorectal physiological workup) of the 32 patients who underwent implantation and the 13 who did not in those 23 with a functioning stimulator (198).

In a single centre study, at 3-year follow-up with 33 (of 66) patients with a ≥ 30% improvement in Cleveland Clinic Incontinence score (CCIS), Roy et al. were not able to demonstrate any predictive factor of success based on preoperative and postoperative assessment (199).

Altomare et al. in a recent study from four European centres of 228 patients with chronic SNS, could find no determinant of success at last follow-up of ≥ 60 months (200). Factors investigated included: demographics, technique, symptom severity and cause (age, sex, PNE vs. timed lead test, implant side, implant site, sphincter lesion, extension of sphincter lesion, incontinence type and baseline episodes of incontinence, CCIS, and St. Mark’s incontinence score). Factors associated with a significantly lower failure rate over the long term included a reduction of
six incontinence episodes per week and eight Cleveland Clinic and St. Mark's score points during test stimulation (200). **LEVEL OF EVIDENCE: 3**

In a retrospective analysis of prospectively obtained data from 65 patients, Prapasrivorakul et al. (201) found less success at one-year follow-up in patients with a coexisting high-grade internal rectal prolapse (HIRP Oxford Grade III and IV) when compared with those without HIRP (FISI 37 to 23; p < 0.01 vs. 38 to 34 p= 0.16) (200). In a univariate analysis, concomitant rectocele, enterocoele and HIRP were found to be associated predictors of outcome of permanent SNS; in multivariate analysis only HIRP was predictive (201). Other than this recent report of HIRP, none of the variables usually considered in preoperative evaluation are of any help in selecting the appropriate patient for chronic SNS.

Contraindications to SNS include pathological conditions of the sacrum preventing adequate electrode placement (such as spina bifida), skin disease at the area of implantation, anal sphincter damage requiring a sphincter substitute (e.g. artificial bowel sphincter, dynamic graciloplasty), trauma sequelae with micturition disorders or low bladder capacity, pregnancy, bleeding complications, psychological instability, low mental capacity, limited cognitive function that interferes with the operation of the neurostimulation device, anticipated future need for magnetic resonance imaging and the presence of an implantable defibrillator or a cardiac pacemaker. With reference to the latter, a case series has shown the relative safety of the use of SNS in the presence of a cardiac pacemaker when monitored intraoperatively. If the distance between the devices is greater than eight inches, interference is unlikely (202).

**1.8.3 Mechanism of Action**

The mechanism of action of SNS remains in part uncertain. Clinical outcome has been seen to correlate with results of anorectal physiology studies, but the effect of chronic stimulation varies greatly among published reports (190, 191). Data monitoring colorectal and anal function are in part contradictory and inconclusive and sometimes not reproducible. The effect appears to be somatomotor (203-209), somatosensory (203), autonomic nervous system-based (203, 205, 210), and mediated by somatovisceral reflexes (211, 212). The effects appear not to be limited to the continence organ per se, but also to the central nervous system: corticoanal excitability in patients with faecal incontinence was found to be reduced with SNS (213); in successfully treated patients cerebral somatosensory evoked potential (SEP) latencies were higher at baseline than in the normal population, whereas they were normal in patients with SNS failure. Success was also associated with a fall of the SEP latency to the normal range after one month of SNS at 40 Hz (214). SNS induces changes in anal representation on the primary somatosensory cortex (215). The effect on the CNS induced by SNS changes during its course: at its initiation, changes are seen in the contralateral frontal cortex, reflecting focus attention; subsequent changes are found in the ipsilateral caudate nucleus, an area related to learning (216).

Qualitative changes in anal, rectal and colonic motility - i.e., reduction of spontaneous rectal motility complexes (217, 218), spontaneous anal sphincter relaxation (217), reduction in antegrade transport from the ascending colon (219) or no change (220), and increased retrograde transport from the descending colon at defecation (219, 220), increase rectal perception thresholds (221, 222) and improve pelvic floor contraction during SNS (223). The findings on rectal capacity with SNS have been inconsistent: unaltered (223-225) or increased (217, 226). No changes in gastric retention, gastric emptying, small bowel transit or colonic passage have been seen with scintigraphic measurements during SNS (227). A recent review indicates that physiological functions outside the anorectum are influenced by stimulation of afferent nerve fibres via the sacral spinal nerves (228). Corticoanal pathways, brainstem and specific parts of the CNS and the spinal cord appear to be involved.

An effect on mucosal neurochemistry during SNS has also been shown, with elevation of Substance P and TRPV1 levels (229), although the relevance of each of these has not been proven in specific pathophysiological conditions. The mechanism of action is most likely multifactorial and dependent on the underlying condition. **LEVEL OF EVIDENCE: 4**

**1.8.4 Outcome**

The results of permanent SNS after pragmatic, trial-and-error, patient selection are shown in Tables 4-6 (107, 193, 196, 199, 205, 229-244). Most studies have encompassed patients with heterogeneous pathophysiology, and they vary with regard to design and patient number, but there is general agreement regarding the test stimulation for selection for permanent implant. Most commonly, clinical outcome is reported as an improvement in the number of incontinence episodes or days with incontinence during the period of observation, percentage of this improvement, and changes in the CCIS and quality of life.

In a first multicentre prospective trial of SNS adherent to the initial, confined spectrum of indications, Matzel et al. (245) reported 37 patients, 34 of whom underwent a permanent implant. Not only was the frequency of incontinence episodes and the CCIS score improved significantly, so too was the ability to postpone defaecation. These effects were attained immediately. Multiple case series have been published, but the number of randomised controlled trials is small. **LEVEL OF EVIDENCE: 3**

Mellenhorst et al. (206) published a large mid-term-follow-up, single-centre study, with 100 patients undergoing permanent SNS. Late failure defined as a relapse of symptoms to less than 50% improvement over baseline, implementation of another therapy for faecal incontinence, or patient dissatisfaction, occurred in 21 patients. The mean time for definitive failure was 13.6 months (range 3–42). There was no evidence of technical failure such as lead migration or lead breakage.

A report by Rosen et al. (203) highlighted the effect of SNS in a cohort of patients of whom 75% suffered from faecal incontinence of neurological origin. Frequency of incontinence episodes/week was reduced from 6 to 2 at 15 months’ follow-up.

In a larger multicentre study Wexner et al. (233) confirmed the efficacy of SNS in reducing symptoms of faecal incontinence: of 112 patients with permanent SNS followed for a mean of 28 months (2-69), 83% experienced a ≥50% improvement, including 41% who gained complete continence (at 12 months). Mellgren et al. (235) reported on the same cohort after a mean follow-up of 3.1 years (0.2 – 6.1 years). With a complete or partial data set available in 64% of the patients, a ≥ 50% reduction of incontinence episodes was seen in 86% of these, with 40% achieving perfect continence. Symptom improvement resulted in improved quality of life, which was stable over follow-up. If a “last observation carried forward analysis” is performed, the 50% reduction of symptoms at 3 years is a 78% success rate; in a “modified worst-case analysis”—with all missing data classified as failure—the success rate at 3 years is 59%. Again, this same cohort was reported upon at follow-up ranging from five years (63% of patients) to more than eight years: faecal incontinence episodes per week decreased from 9.1 (mean at baseline) to 1.7 at 5 years; 89% reported a ≥ 50% improvement of incontinence (36% complete continence). After 5 years, therapy was active in 81% of the patients (235).

In a systematic review including 61 publications from 2001 to 2012, Thin et al. (239) found higher median rates of ≥50% improvement in incontinence episodes/week when patients’ data were analysed “per protocol” (PP) (i.e., implantation after a successful test period) than when the denominator for analysis was PNE (i.e., comparable to “intention-to-treat” [ITT] principles): short-term (median 12 months) 79% (69-83%) vs. 63% (33-66%); medium-term (25 months) 80% (65-88%) vs. 58% (51-81%); long-term (56 months) 84% (75-100%) vs. 54% (50-58%). In the ITT analysis only two studies comprising 86 patients were long-term (250, 251). Perfect continence was likewise greater in the “per protocol” analysis than in the ITT: short-term 42% (21-68%) vs. 36% (8-68%); medium-term 44% (5-74%) vs. 32% (4-72%); long-term 35% (4-52%) vs. 20% (2-48%). The CCISs were also significantly improved and remained stable over follow-up.

A summary of the published long-term outcome of SNS up to 2015 included 12 studies with a median follow-up of 85 months (44-118) in 745 patients (200). As in the report of Thin et al. (239), improvement (≥ 50% reduction in incontinence episodes) was greater on PP than on ITT analysis: median 78% (21-96%) vs. 50% (42–89%). Full continence was also greater: median 36% (4–52%) vs. 20% (2–48%).

*values at specific time

§ mean value, standard deviation

n.a. data not available, n.c. not calculable
In most studies, quantitative measures are used to describe the clinical benefit, such as days with incontinence episodes or absolute numbers of incontinence episodes per period of observation, ability to postpone defaecation (in minutes), and percentage improvement. Even though published reports differ with regard to patient population, a general pattern of outcome can be observed: when compared with baseline status, the clinical outcome is significantly improved. Outcome reporting increasingly includes both PP and ITT analyses.

In a meta-analysis of publications from 2000-2008 comprising 790 patients, 28 studies compared incontinence episodes per week before and with SNS, and 14 studies compared incontinence scores. Both outcome criteria were significantly decreased. Another nine studies documented the ability to postpone defaecation, and this criterion also was significantly improved (252). **LEVEL OF EVIDENCE: 2**

Whereas cohort studies and observation studies are numerous, only a limited number of randomised controlled trials could be included in a recent Cochrane review of SNS for faecal incontinence: four crossover trials and two parallel group trials (253). In a randomised controlled trial of patients with severe faecal incontinence, Tjandra et al (230) compared the effect at 12 months of SNS with that of supervised optimal medical therapy comprising pelvic floor exercises, bulking agents, and dietary manipulation. Permanent SNS in 53 patients was significantly better than conservative treatment in 60 patients: CCIS 1.2 vs. 14.1; incontinence episodes/week 3.1 vs 9.4; days with incontinence/week 1 vs. 9.4 (mean difference (213) \(-5.20, 95\% CI \(-10.34 to \(-2.26 at 12 months; MD \(-6.30, 95\% CI \(-10.34 to \(-2.26 at 12 months). Mean (±SD) faecal incontinence episodes per week at baseline and 3 and 6 months of follow-up with chronic stimulation were: 11.4 (12.0), 4.0 (4.0) and 4.9 (6.9), respectively, for SNS compared with 10.6 (11.2), 5.8 (6.9) and 6.3 (6.9) for PTNS. Mean (±SD) CCIS values at baseline and 3 and 6 months were: 16.2 (3.0), 11.1 (5.2) and 10.4 (5.6) for SNS versus 15.1 (2.7), 11.7 (4.4) and 12.1 (5.2) for PTNS.

In the blinded crossover trial in two patients by Vaizey et al., participants were allocated to two weeks of “off” and “on” periods of subsensory stimulation(255). They reported a clear difference in number of episodes of incontinence per week during the off and on periods (Patient 1, 20 vs. 2 episodes; Patient 2, 4 vs. 0 episodes).

Leroi et al (256) reported a double-blind, crossover multicentre study in 34 patients. The indication to progress from temporary to permanent SNS (N = 27) was based on at least a 50% reduction in the number of episodes of incontinence or faecal urgency per week, or both. After implantation each participant underwent a 1 – 3 month phase with the stimulator turned on to determine the most effective stimulation parameters. At the end of this post-implantation period, patients were randomised in a double-blind manner to on- or off-stimulation for a 2-month period, with reversal of the activation mode after 1 month. Of these, 24 of the 27 (89%) patients completed the 2-month trial. A significant decrease in median frequency of faecal incontinence episodes was noted during the on-stimulation period. No significant difference was observed between on- and off-stimulation for frequency of urgency episodes, delay in postponing defaecation, or median number of bowel movements per week (10.2 and 11.1 for on and off, respectively). There was a trend towards greater improvement in the CCIS during on-stimulation (8.5 vs 10.5 [ns]). All 24 patients considered that they had improved during the on period, although 17 (63%) also felt they had improved during the off period. In 19 participants who preferred the on period and five who preferred the off-period outcomes were reported separately: For the group of 19, the median (range) episodes of faecal incontinence per week fell from 1.7 (9) during the off period to 0.7 (0-5) during the on period; for the group of five, however, the median (range) rose from 1.7 (0-11) during the off period to 3.7 (0-11) during the on period.

In the crossover trial by Kahlke et al. (257), 16 of 31 patients who had had SNS for a median of 26.8 months agreed to be randomised in a crossover design to two three-week periods each of stimulation on and off. After six weeks, the patients—still blinded to the stimulator status—chose which stimulation period they preferred. The mode of stimulation corresponding to the selected period was then continued for 3 months (final period). All patients (N=14 of 16) selected the on mode. They experienced significantly fewer episodes of faecal incontinence per week (1 [SD 1.7]) compared with the off period (8.4 [8.7]). The CCIS was significantly higher (P < 0.05) during the off period (14.6 [SD 4.6]) compared with the on period (8.7 [SD 3.6]). The overall number of bowel movements per week declined significantly (P < 0.05) in the crossover on period (10.9 [SD 4.1]) compared with the off period (18.2 [SD 8.7]). During the final 3-month period incontinence episodes per week remained low 0.3 (SD 0.5), CCIS was 6.4 (SD 3.3), and the number of bowel movements per week was 9.4 (SD 2.6). **LEVEL OF EVIDENCE: 3**
1.8.5 SNS for Patients with Anal Sphincter Lesions

An increasing body of evidence indicates that SNS may also be a treatment option for patients with sphincter defects, either unrepaird or after attempted anatomical reconstruction. The presence of an internal anal sphincter defect on endoanal sonography is reportedly unrelated to the success of permanent SNS (193). Since the first report that three of five patients with ultrasound evidence of sphincter disruption measuring 25–33% of the circumference benefited from chronic SNS (258), several studies have been published (195, 240, 258-263). The origins and morphologic findings regarding the extent of the sphincter gap differ in these studies, but lesions up to 180° have been treated. It appears that outcome is not dependent on the radial extent (259, 261). A significant improvement in clinical function, measured either as frequency of incontinence episodes or CCIS, has been seen in a substantial number of patients in all studies (195, 258, 260, 263). Follow-up is still limited. LEVEL OF EVIDENCE: 3

Melenhorst et al. (195) showed that the primary use of SNS in patients with a sphincter gap 17-33% of the circumference appeared to result in an outcome similar to its use after failed sphincter repair. In another study, SNS in 6 of 8 patients with faecal incontinence related to obstetric full-thickness anal sphincter lesions of >30-150° resulted in improved frequency of incontinence episodes (from 5.5 to 1.5 per week) (262), improved ability to postpone bowel emptying, and improved ASCRS quality-of-life scores at a median follow-up of 26.5 months (259). No correlation between improvement and the radial extent of the sphincter defect was seen. In patients with internal and external sphincter disruption owing to Crohn’s disease SNS was demonstrated to be beneficial in one study (258).

A recent review of SNS for faecal incontinence associated with anal sphincter lesions identified ten publications (nine retrospective, one prospective) from 1995-2011 comprising 119 patients, of whom 106 (89%) had a definitive implant after PNE testing (264). A lesion of the external and/or internal anal sphincter was confirmed on endoanal ultrasound. Outcome reporting was not uniform. Follow-up ranged from 4.5 to 48 months. The weighted average number of incontinence episodes per week decreased from 12.1 to 2.3, the weighted average CCIS decreased from 16.5 to 3.8, and the ability to defer defaecation, when evaluated, increased significantly. Quality of life improved significantly in almost all studies.

In the one prospective investigation, a comparative cohort study (261), the effect of permanent SNS was reported in 53 patients with either an intact external anal sphincter (N=32, 37.5% after sphincter repair) or an external anal sphincter lesion (N=21, 81% after prior sphincter repair) of <90° (N=11) or 90-120° (N=10). Improvement in symptoms and quality of life was achieved, and outcome after 12 months was not significantly different between groups. LEVEL OF EVIDENCE: 3

The therapeutic potential of SNS has also been demonstrated in some, mostly small, case series and individual case reports of patients with distinct pathological conditions or well defined anorectal pathophysiology: e.g. muscular dystrophy (265); proctocolectomy with ileoanal J-Pouch reconstruction for colitis (266); neurological dysfunction including spinal disc prolapse (267); rectal prolapse repair (268, 269); rectal resection for cancer (270) with or without neo-adjuvant chemoradiation (188, 271-273); after neoadjuvant and adjuvant chemoradiation / radiotherapy for endometrial and ano-rectal cancer (274, 275); after unilateral traumatic pudendal neuropathy (276); in spina bifida (277); and incontinence related to external anal sphincter atrophy (278). LEVEL OF EVIDENCE: 4

1.8.6 Quality of Life

Outcome assessment has also evolved, and aspects of quality of life have been added to the evaluation (CCIS, SF-36 and Fecal Incontinence Quality of Life [FIQL] Score). The therapeutic impact of SNS is most evident when a disease-specific quality-of-life instrument, the ASCRS FIQL scale, is applied.

In the first study to apply this instrument, the multicentre clinical trial by Matzel el al. (245), ASCRS FIQL was significantly increased in all 4 scales; SF-36 scores improved in 7 of 8 scales, the greatest being social functioning and mental health, but only the former reached statistical significance. A similar result was published by Leroy et al (256) with the French version of the ASCRS QOL (FIQL): at the final follow-up visit, improvements in lifestyle, coping behaviour, depression, and self-perception and embarrassment were significant. Hetzer et al (279) demonstrated a significant improvement of the median Gastrointestinal Quality of Life Index score with permanent SNS from a baseline of 96 (range 47–128) to 107 (range: 36–128) at 6 months’ post-implantation.

In most studies on outcome, quality-of-life evaluation is a secondary endpoint (107, 187, 191, 203, 230, 245, 256, 267, 268, 270, 272, 280). When used, the finding of improved quality of life is consistently related to symptom relief and remains stable with longer follow-up (107, 235, 238, 246, 279). Indeed, recent long-term data with a follow-up of at least 5 years indicate a significant improvement of all four scales of the FIQL score (235, 251).

In a meta-analysis (252) of 34 studies with 790 patients, SF-36 score data were analysed from 7 studies with 98 to 102 patients and ASCRS FIQL data from 9 studies comprising 199 patients: SF-36 outcome was significantly increased in all categories (physical functioning, social functioning, role physical, role emotional, mental health, vitality, general health) with one exception (bodily pain). FIQL outcome was
significantly increased in all categories (lifestyle, coping/behaviour, depression/self-perception, embarrassment).

In a two-centre study of patients with permanent SNS for a median of 46 months (11-122), 108 of 127 patients responded to questionnaires regarding bowel habits and quality of life. Using a non-validated score, 75.8% reported satisfaction, which in most was related to clinical improvement. However, at last follow-up 11 of 23 patients who had failed to achieve a 50% reduction in incontinence episodes reported satisfaction, and 6 of these had more incontinence episodes than at baseline (237).

Four of the randomised controlled trials discussed above, when relating quality of life to clinical efficacy of SNS, have used varying instruments: SF-12, ASCRS FIQL (230); SF-36 (255); the French version of the ASCRS FIQL (256); and ASCRS FIQL, SF-36 and EQ-5D (254). Improvement was found in all, except for EQ-5D with chronic SNS. **LEVEL OF EVIDENCE: 2**

### 1.8.7 Cost Benefit

Permanent SNS is expensive; however, its cost-effectiveness has been demonstrated in several European nations. Hetzer et al (281) compared the costs of SNS with those of conservative treatment, anterior sphincteroplasty, dynamic graciloplasty, and stoma creation in 34 consecutive patients. The 5-year cumulative cost for SNS was €19,333, compared with €35,965 for a stoma (with annual costs of €5,339) and €34,953 for dynamic graciloplasty (annual costs €1,659). The equivalent cost for conservative treatment was €3,895, and the overall median real cost for an anterior sphincteroplasty was €5,327. Muñoz-Duyos et al (282) analysed the direct medical costs of SNS in a series of 47 patients undergoing 57 PNEs and the consequent 29 patients with a permanent unilateral implant for a median follow-up of 34.7 (2.3-81.2) months. The cost totalled €371,434, including €317,791 for the devices. In patients without anal sphincter damage SNS provided €317,791 for the devices. In patients without anal sphincter damage SNS provided 0.34 incontinence-free life-years and entailed additional costs of €1,054, which generates a cost-effectiveness ratio of €16,181 per quality-adjusted life-year (QALY). The nationally accepted threshold is around €30,000/QALY. The economic impact of the introduction of SNS would be to add 0.07-0.1% to the care of these patients (2008 data).

In a decision-analysis model based on prospectively collected data in 70 patients undergoing test stimulation and implantation of the permanent SNS device, incontinence episodes/week were reduced from 6 at baseline to 0.5. Dudding et al. (234), based on direct medical and non-medical costs, found an incremental cost-effectiveness ratio (ICER) for SNS of £25,070 per QALY gained. It cost £1,038 per year to achieve a median reduction of 238 incontinence episodes, equal to £3.61 per reduced episode. The ICER of £25,070 per QALY was within the UK nationally accepted £30,000 per QALY threshold.

In a similarly designed study based on published reports and expert opinion, Indinnimeo et al (283) found that the ICER was €28,285 per QALY gained in patients with a structurally deficient anal sphincter and €30,662 per QALY in patients with an intact anal sphincter. Both are below the relevant national threshold of €40,000 per QALY gained. Budget-impact analysis demonstrated that the implementation of SNS would have an estimated impact of 0.56% over a 5-year period on the budget allocated for faecal incontinence treatment.

In a French study clinical outcome and cost-effectiveness analyses were performed in parallel with a prospective, multicentre cohort study that included 369 consecutive patients with urge urinary and/or faecal incontinence with a follow-up of 24 months (284). Cost-effectiveness outcomes were expressed as incremental costs per 50% of improved severity scores (incremental cost-effectiveness ratio). Based on a national health perspective the average cost of SNS for faecal incontinence was €6,581 more for the first 2 years when compared with alternative treatments (95% confidence interval, €2,077–€11,804; P = 0.006) when an improvement of more than 50% in the incontinence severity score was used as the criterion of effectiveness. The incremental cost-effectiveness ratio for SNS was €94,204 and €185,160 at 24 months of follow-up for urinary and faecal incontinence respectively. These findings were above the generally accepted range of cost effectiveness, but SNS was considered to offer marked health benefits for patients with faecal incontinence (measured by the severity score). **LEVEL OF EVIDENCE: 3**

### 1.8.8 Safety

SNS is a relatively safe procedure (233, 285). A meta-analysis (252) is in accordance with earlier reports, which describe a relatively low rate of complications (190, 191) and a need for device removal in only approximately 5% because of loss of effect, symptom deterioration, pain from lead dislocation, or infection. The results of the meta-analysis, which covered the period 2000 – 2008 and included patients undergoing the more invasive, open-approach electrode placement technique, found a complication rate of less than 15% in 665 patients with a permanently implanted device. In only 3% did the device need to be removed. In patients in whom infection necessitated removal, re-implantation later was reportedly successful (280).

In an FDA study with strict monitoring of adverse events (235), 334 were reported in 99 patients at three-year follow-up; 67% occurred in the first year, and most required no or minimal intervention at the time. The adverse events included pain at the implant site (28%), paresthesiae (15%), change in the sensation of stimulation (12%), implant site infection (10%) (233), urinary incontinence (6%), diarrhoea (6%), and extremity pain (6%). Half of the infections required surgical intervention with removal of the device in 5 of 6 patients (235). More recent data of the
same patient cohort report a 39% need for device revision, replacement or removal. With 5 years’ follow-up 26.3% of patients had a revision, replacement or removal of the device for reasons other than battery depletion (235). Significant differences between those who exited because of a lack of efficacy before five years and those who remained in the study were found in two areas: average percentage of improvement at test stimulation (90% vs. 80%, p=0.007) and the percentage of patients completely continent during the test stimulation (47% vs 7%; p=0.004).

A single report of a consecutive series of 87 patients over a mean follow-up of 48.5 months describes the need for revision surgery in 41%--one-third for device-related failure—including 24% for removal (242). In a French multicentre study comprising 200 consecutive patients with a mean follow-up of 12 months, the rate of device-related adverse events was 24.5% (197).

Major complications are rare: one case report of a life-threatening haemorrhage after elective tined lead electrode removal has been published (286).

A review of 48 cohort studies (45 for faecal incontinence and 3 for constipation) documented the post-operative issues in the 1661 patients with test stimulation and 1600 patients with a permanent SNS implant (287): it found that the incidence of suboptimal outcome was 12.1%, pain 13%, and infection 3.9%. The most common problem during test stimulation was lead dislodgement (5.3%). Systematic literature review suggests a possible underreporting of suboptimal outcome and adverse events. In one single study, the rate of adverse events reached up to 85.2% in patients with a median follow-up of 11 months: loss or lack of efficacy and pain or discomfort accounted for 88.5% of these (288). In a recent review with 45 studies including 1953 patients the pooled rate of infection was 5.1% (4.1-6.4) without significant heterogeneity between trials (289).

In their summary of studies with long-term follow-up (70-118 months), Altomare et al. reported minor complications in 79 patients (PP, 29%; ITT, 19.4%), of which 64 (PP, 23.5%; ITT, 15.7%) were device-related. The most common was pain at a subcutaneous site (23 patients) prompting device removal in 12 patients and replacement in seven. Removal and repolishing for dislocation or battery depletion was necessary in another 17 patients (200). LEVEL OF EVIDENCE: 2/3

1.9. Puborectal Sling

The puborectal sling operation was first reported by O’Rourke in 1974 (290). In this procedure, an artificial sling is routed behind the anorectal junction and its two ends are fixed to the pubic bone, pulling the anorectal junction up forward with some tension. Similar to the postanal repair, the rationale of this operation is the restoration of the anorectal angle normally maintained by puborectal muscle.

No systematic reviews, randomised controlled trials, non-randomised cohort studies or case control studies have been reported regarding puborectal sling operation for faecal incontinence, while one prospective comparative study (level 2) (291), three prospective case series of good quality (level 3) (292-294) and three retrospective case series of low quality (level 4)(290, 291, 295) were identified.

O’Rourke (290) reported using Dacron® mesh for the treatment of 3 patients with full rectal prolapse as well as 4 patients with mucosal partial rectal prolapse and faecal incontinence. Of the 4 patients with faecal incontinence and partial prolapse, 3 were reported to have “benefited considerably” from the procedure although a formal evaluation of the faecal incontinence was not performed and the follow-up period was not documented. O’Rourke and Egerton (295) also reviewed 24 patients in whom the sling operation was performed using a strip of rolled Mersilene® mesh. This procedure, however, was performed mainly for the treatment of rectal prolapse, while it was conducted because of faecal incontinence alone only in two out of the 24 patients, and the outcomes regarding the continent were not formally evaluated.

Shafik (291) reported another sling operation called puborectoplasty utilising a Teflon™ sling for faecal incontinence. Of 31 patients who had been incontinent to solid stool and underwent this procedure, “good results” were achieved in 26 patients (84%) after a follow-up period of between 2 - 4 years: 20 became continent to solid and liquid stool as well as flatus; 6 to solid and liquid stool but not to flatus; 4 to solid stool only; and only one remained incontinent to solid stool.

Shafik and Shafik (291) conducted a prospective comparative study comparing two fascia lata slings (double loop) in 22 patients and one fascia lata sling (single loop) in 22 for the treatment of faecal incontinence. After 12 months follow-up, “good results” were achieved in 14 (64%) and 8 (36%) by the double loop and the single loop, respectively.

Yamana et al. (292) performed the perineal puborectalis sling operation in 8 patients with passive faecal incontinence using polyester mesh sling. A rectal ulcer developed in one patient requiring the sling removal. In the 6-month evaluation of the remaining 7 patients, all reported some extent of improvement of their faecal incontinence. Both the Faecal Incontinence Severity Index and the Cleveland Clinic Florida Fecal Incontinence Score (CCIS) signif-
The puborectal sling operation, particularly with the TOPAS™ system, seems promising because it is a simple procedure and yielded reasonably good results with low rate of serious complications so far. More prospective studies of longer follow-up period are warranted. These should closely evaluate complications such as sling infection, erosion and rectal ulcer requiring the sling removal.

**Summary:** The use of a puborectal sling remains unproven but may be of value in selected patients. Grade of Recommendation: D

### 1.10. Injectable Biomaterials

Injectable agents for urinary incontinence (UI) have had variable success rates but they offer the benefit of performing an outpatient procedure without anaesthesia and with minimal morbidity (296). This has resulted in their continued use for urinary incontinence, as well as continuing research on different injectable agents for use in faecal incontinence. The ideal agent for injection should be biocompatible, non-allergenic, non-immunogenic, non-carcinogenic, easy to inject, and should not migrate within the tissues. Liquid agents that have particles with a diameter of 80 μm are felt to be less prone to migration, but agents with a larger particle size require a larger bore needle to inject, which put them at a higher risk for leakage from the injection site. More recently there has been increasing interest in solid “injectables” in the form of Hi-Hexpan™ [GateKeeper™ (297) - SphinKeeper™ (298)] which expand after their insertion through a custom-made introducer. The results of injectable biomaterials used for faecal incontinence to date are shown in Table 7. However, Injection of liquid bulk-enhancing agents into the anal canal to treat faecal incontinence has reduced in popularity since the date of the 5th ICI.

**LEVEL OF EVIDENCE:** 3

Injectable agents for faecal incontinence were first used in 1993 when Shafik (299) treated 11 patients with injections of polytetrafluoroethylene paste into the anal submucosa. After 18-24 months of follow up, 64% reported complete cure and 36% had partial improvement. Shafik (300) subsequently treated 14 patients with autologous fat injections with a reported 100% success rate at 2-3 months and all patients who lost continence to gas or stool became continent after repeat injections. There were no complications using either agent. However, other reports of autologous fat injection have resulted in death from pulmonary fat embolism, and a randomised clinical trial using fat for UI demonstrated no efficacy over placebo; thus, it is currently not used for faecal incontinence (301). Other agents used for injection in the past, that have not achieved widespread use include micro balloons, bovine dermal collagen, and polycyramide hydrogel (Bulkamid®).

The first reported injections of glutaraldehyde cross-linked synthetic bovine dermal collagen (Contigen™) for faecal incontinence included 17 patients (302), 11 (65%) of whom showed marked symptomatic improvement at 8 months. A much larger series of 73 patients was then reported (303) in which subjects received injections of 1.7 ml of collagen transanally into the rectal submucosa in three separate areas just proximal to the anal canal. Overall, 63% reported an improvement in their incontinence and the 49 patients with idiopathic incontinence (no sphincter defect and no pudendal neuropathy) had a significant decrease.
in their incontinence score. The disadvantages of using synthetic collagen are its potential to be allergenic and degrade over time.

A series of six patients injected with self-detaching cross-linked silicone micro balloons with a biocompatible filler material demonstrated fairly good results, with Browning-Parks incontinence scores for the group decreasing from 16 to 5 (range 0-20) (304). However, sterilization issues have prevented the ongoing use of this product.

Two pilot studies using polydimethylsiloxane particles (PDMS) suspended in a bioexcretable carrier hydrogel of polyvinylpyrrolidone (Bioplastique™) for faecal incontinence in 2001 and 2002 (305, 306) led to increased use of this product in Europe and it was renamed PTQ™ implants (PTP™ implants in Australia). The initial pilot study (305) looked at 10 patients with passive incontinence who received circumferential or single site injections of PDMS. At six weeks, six patients showed either marked improvement or complete cessation of leakage and an additional patient improved after a second injection. However, after six months, only two of seven patients had maintained marked improvement. Complications included anal pain and ulceration at the injection site. In the largest study of PDMS injection to date (307) 82 patients with severe faecal incontinence were randomised to receive PDMS implants either with or without endoanal ultrasound guidance for injection. All patients had a significant improvement in their CCF-FIS. At 12 months, this score decreased from 14.5 to 3 in the ultrasound guidance group and from 14.5 to 11 in the non-ultrasound group. Six patients, two from the ultrasound guidance group, complained of pain at the injection sites. There were no other complications. The ultrasound guidance group had more significant improvement in resting pressures and quality of life scores. The same investigators injected PDMS into seven patients with passive incontinence after haemorrhoidectomy and found significant improvement in CCF-FIS and quality of life scores in all patients (308).

Several other series have been reported PDMS use for faecal incontinence (309-312). In all, 2.5 ml of product was injected into 3-4 sites in the intersphincteric space and CCF-FIS decreased significantly. In one study of 20 patients, the CCF-FIS decreased significantly from 13.5 to 4.5 at one month and slowly increased to 9.4 at two years, which was a still a significant improvement from the baseline score. Quality of life scores also improved, but there was no effect on resting or squeeze anal canal pressures pressures measured at baseline and 3 months after injection. Seventy percent of patients experienced pruritus ani and one patient developed an infection at an injection site (309). In a study of 33 patients, CCF-FIS decreased from 12.7 to 10.4 at one year, yet quality of life was not improved (310). Both of these studies examined implant migration and 67% (310) and 84% (313) had detectable implants at the site of injection by ultrasound, though this did not seem to affect clinical response. The largest of these studies is notable for its sample size of 74 patients and that half of these subjects were men. It found that 70% of patients reported complete satisfaction with their continence (post-treatment CCF-FIS = 0). In the remaining 30%, CCF-FIS decreased from 12 to 3.5 at 33 months with associated improvements in quality of life measures. All patients, but especially those who became continent, had significant improvements in mean resting pressures, squeeze pressure and mean anal canal length.

Worse results were seen in women with pudendal neuropathy or those for whom biofeedback had already failed (311). Another study specifically compared the anorectal manometry of patients injected with PDMS with that of normal controls and found that after injection in the symptomatic patients there was a similar decrease in CCF-FIS with associated improvements in FIQL scores. The symptomatic patients had lower resting and squeeze pressures than controls at baseline and these pressures did not improve with injection. However, these patients did have elongation of their high-pressure zone, as well as improvements in the asymmetry index, indicating that morphologic but not physiological changes had occurred with injection (312).

The only report of long-term results for injectable agents was for Bioplastique™ (314). The 5-year outcome for 6 patients injected with this compound in 1999 included a median St. Mark’s incontinence score that was essentially unchanged from 11 to 13 (range 9-20). One patient had undergone a colostomy, but four of the five remaining patients reported subjective improvement in their incontinence and better quality of life scores. In 2012 van Wunnik et al (315) reported on 2 patients who were said to have developed local giant cell foreign body reactions after PTQ injections; both required surgical intervention and further treatment for their incontinence. LEVEL OF EVIDENCE: 3

A pilot study conducted in 2008 examined two other products, cross-linked porcine dermal collagen (PDC) (Permacol™), and polyacrylamide hydrogel (PAH) (Bulkmid®)(316). Ten patients with passive faecal incontinence to liquid or solid stool who had failed conventional treatments were prospectively randomised to receive either of the two products. The needle was first inserted into the skin 2 cm from the anal margin and the product was then injected trans-sphincterically. The median volume to achieve closure of the anal canal under direct vision was 9 ml for PAH and 15 ml for PDC. The St Mark’s incontinence score decreased at 6 weeks for both groups, but this decrease was sustained at 6 months only for the PAH group. This pilot study lacked power to determine if these two treatments for faecal incontinence was significantly different.

There has been a further nonrandomised retrospective study in which PDC was injected into the internal
anal sphincter in 110 patients 100 of whom were available for follow up for a minimum of 36 months (317). Three injections of 2.5 ml with a further 2.5 ml injected into any defect identified on endoanal ultrasound. The CCF-FIS scores improved from a median of 14 (range 5-14) to a median of 8 (range 5-14) but this difference was not statistically significant. A total of 68% of patients reported a subjective improvement at 3 years but there was deterioration with time. Thirty eight percent of patients were given a second injection and 15% required a third injection.

Several other injectables have been used for faecal incontinence with variable results. In one of the few adequately powered, randomised controlled trials using injectables, 44 patients were randomised to receive transdermal injections of polydimethylsilozane elastomer silicone biomaterial (PDMS) or saline into the intersphincteric space (318). Three 2.5ml injections were performed using local anaesthesia. Only the patients were blinded to the treatment. There was no difference in the percentage of patients in the two groups who had a successful treatment, defined as having a CCF-FIS score <8 or the decrease in CCF-FIS scores post treatment. The saline group tolerated treatment better and had fewer adverse effects overall. Thus, the study concluded that the use of PDMS should not be recommended.

Two small studies using calcium hydroxylapatite ceramic microspheres (HCM) (Coaptite™) and ethylene vinyl alcohol (EVOH) showed some promise but the testing was much less rigorous. In one of these studies, HCM were injected transphincterically to four submucosal sites using 1ml at each site with the patient under local anaesthesia. The average Faecal Incontinence Scoring System (FISS) score for 10 patients decreased from 85.6 to 28 at 12 months (p=0.008) and the lifestyle, coping and behaviour/embarrassment subscales of the Fecal Incontinence Quality of Life Scale (FIQL) showed improvements (p<0.05). Anorectal manometry also showed better resting pressures (40 to 47 mmHg, p=0.018). There were no complications, but one patient experienced leakage of product from the injection site that required another injection (319).

In the second of these smaller studies, 21 patients received ethylene vinyl alcohol (EVOH) injections with 1-2 ml in up to 8 sites in the intersphincteric space under general or local anaesthesia. At 12 months, Faecal Incontinence Severity Index (FISI) scores dropped from 32.8 to 22 and CCF-FIS scores decreased from 11 to 6.9. Two subscales of the FIQL improved significantly and repeated anorectal manometry demonstrated some increase in anal canal length and resting pressures (320).

Another commonly used injectable, pyrolytic carbon-coated zirconium oxide beads (PCZO) (Durasphere®), is non-reactive and not biodegradable. However, the beads are known to migrate within the tissues and require a large bore needle to inject the substance. The injected substance is placed in the submucosal plane using either a transanal or intersphincteric approach. The initial trial (321) assessed the short and long-term efficacy in 18 patients with an internal anal sphincter defect refractory to conservative management. About 1.3ml was injected in the submucosal plane at the site of the sphincter defect in 1-4 sites until adequate anal sphincter symmetry was restored. At 12 months, CCF-FIS and patient satisfaction scores were significantly improved. Fifteen of 18 patients reported improvement in their incontinence. Weiss et al. also demonstrated improvement in ten patients who were followed for only 3 months (322).

In a larger study, 33 patients with minor or medium severity faecal incontinence (CCF-FIS < 14 and/or American Medical Systems (AMS) score < 89) received injections (mean of 8.8 ml (range 2-19 ml) of PCZO into the submucosa at the level of the dentate line using an 18-gauge needle at four different sites (323). After a mean follow-up period of 21 months, the CCF-FIS for the group decreased significantly from 12 to 8 and the AMS score from 89 to 73 but the faecal incontinence specific quality of life measures did not change. Resting and squeeze pressures also increased 12 months after injection. Adverse events included anal pain in two patients, asymptomatic leakage of material in one patient, and distal migration of product in two patients. A study of 11 patients in which about 2.8ml of PCZO was injected into 3-4 sites in the submucosal space reported a decrease in CCF-FIS from 12.7 to 4.9 at 2 years with improvements in the coping and embarrassment subscales of the FIQL at 6 months. Although manometry pressures did not change initially, the resting and cough pressures were higher at 2 years than at 1 year (324).

The most recent study using PCZO injected the product using a slightly different approach. In all 23 subjects, the product was injected into the intersphincteric space in four sites. Again, about 2.8ml of product was injected at each site. At 12 months, patients had a decrease in the CCF-FIS from 18.7 to 10.9 and an increase in FIQL score from 46 to 55.8. Mean squeeze pressures on anorectal manometry increased significantly at 12 months. Adverse complications included prolonged pain in one patient and a sterile perianal fluid collection in another (325).

**LEVEL OF EVIDENCE: 4**

Two trials have compared the safety and efficacy of PDMS and PCZO (326, 327). In the first sample size was calculated to detect a 50% reduction in the CCF-FIS post injection. Thus, 40 patients with faecal incontinence (mean CCF-FIS 11.45) were randomised to receive either PDMS or PCZO. Both groups were similar in terms of age, medical history, faecal incontinence severity and quality of life scores, as well as anorectal manometry results. Although the PCZO group had a more significant reduction in CCF-FIS at 2 weeks (11.45 to 8.25 vs. 11.45 to 10.9), the PTQ group had a greater reduction in CCF-FIS at 6 weeks, 6 months and 12 months (4.6, 2.95 and 3.8 vs. 7.65, 6.2 and 7), and had no complications. The PCZO

**SURGERY FOR ADULT FAECAL INCONTINENCE**
group had several complications including anal pain (5%), mucosal erosion (10%), arthritis and skin rashes (5%). Furthermore, the PDMS group demonstrated significant improvements in general and faecal-incontinence-specific quality of life scores that were not seen in the PCZO group. Thus, the conclusion was that PDMS was safer and more effective than PCZO for the treatment of faecal incontinence (326). **LEVEL OF EVIDENCE: 3**

In the second trial, Morris et al. (327) performed a smaller study of 35 patients with 17 randomised to receive PDMS and 18 to PCZO; numbers were limited as the trial was closed early due to the removal of PDMS from the Australian Pharmaceutical Benefits scheme. Circumferential injection was performed under local anaesthesia and sedation. The primary outcome measure was the CCF-FIS incontinence score with the SF-36 and maximum resting and squeeze pressures being secondary outcomes. Follow-up was up to 1 year and despite early improvements in incontinence scores were not significantly improved at 12 months. SF36 scores did not significantly improve at any stage of the follow-up. One of the patients receiving PDMS developed a perianal abscess.

The newest liquid injectable agents to be used for faecal incontinence are acid/dextranomer (NASHA Dx) copolymers (Zuidex™, Solesta®). Dextranomer microspheres are suspended in non-animal stabilized hyaluronic acid. As with other injectable agents, NASHA Dx has been used to treat urinary incontinence (328) and a pilot study of four patients reported no adverse events and a median decrease in St Mark’s incontinence score of 3.5 points (19.25 to 15.75) (329). In a subsequent study of 34 patients who received transanal injections into the submucosa just above the dentate line (about 1ml of product was injected into four sites), the median number of incontinence episodes in a four-week period dropped from 22 to 9 (325). When response was defined as a 50% or greater decrease in number of incontinent episodes, 56% of patients were defined as responders at 12 months. No adverse events were reported. These findings led to a randomised double-blinded sham-controlled trial of 206 patients randomised in a 2:1 fashion to receive NASHA Dx or placebo injection (330). The patients and the evaluating investigators were blinded to the treatment. More patients in the treatment group had 50% or greater reduction in the number of incontinence episodes (52% vs. 31% of controls; p=0.009), but the change in CCF-FIS did not differ after treatment between groups (14 to 2.5 in the treatment group vs. 13 to 1.7 in placebo group). The FIQL was only significantly improved compared to placebo for the coping and behaviour subscale. Both groups had a high retreatment rates: 82% of patients in the NASHA Dx group received reinjection of product and 87% of patients in the control group had repeat sham injection. The NASHA Dx group had significantly more adverse events, including proctalgia, rectal bleeding, pruritus, diarrhoea, constipation, fever, and two serious complications of rectal abscess and prostatic abscess. The control group had more injection site bleeding. Schwandner et al. (331) reporting on 21 patients who received injections of 1ml of NASHA Dx in four sites of submucosa there were no adverse events and 61% of patients had a significant decrease in incontinence episodes at 3 months and 56% had a sustained improvement at 22 months. The CCF-FIS decreased from 16.8 to 12.3 but was not significant. Improvements in FIQL scores were noted.

La Torre and de la Portilla reported on 83 of 115 patients who were followed up for 24 months after 4 injections of 1ml DHAC with 62.7% reporting a ≥ 50% reduction in the total number of episodes of faecal incontinence. This decrease and the increase in the number of incontinence free days were significant as was the reduction in the CCF-FIS and FIQL (332). Danielson et al reported on only 34 patients injected with 4 × 1 ml DHAC in the submucosal layer. At 2 year follow up 26 patients were said to have reported a “sustained improvement”. This assessment was done using median number of incontinence episodes [22 pre-treatment, 10 at 1 year and 7 at 2 years] and the Miller incontinence scores [14 pre-treatment, 11 at 1 year and 10.5 at 2 years]. It was also noted that only patients with more than a 75% improvement in the number of incontinence episodes had a significant improvement in quality of life at 24 months, resulting in the suggestion that this was a more accurate threshold to indicate a successful incontinence treatment than the more commonly used 50% (333).

A Cochrane review published in 2013 concluded that there had been no long term studies on the efficacy of injectable bulking agents for passive faecal incontinence (334). Whilst relatively safe, the studies done on these agents by the time of that review had been of poor quality and no firm conclusions could be reached. **LEVEL OF EVIDENCE: 3**

In 2014 the NASHA Dx Study Group reported on the 3-year follow up of NASHA Dx injection therapy for treatment of faecal incontinence (335). One hundred and thirty six patients were assessed post injection with success defined as a reduction in number of FI episodes by 50% or more compared with baseline. The CCF-FIS and Fecal Incontinence Quality of Life Scale were also used. A successful outcome was deemed to have occurred in 52% of patients at 6 months and this was sustained at 12 months (57%) and 36 months (52%). There were also significant decreases in the mean CCF-FIS and all four domains of the quality-of-life scores improved significantly between baseline and 36-months follow-up.

The newest injectables are polyacrylonitrile Hi-Hexpan™ cylinders, the Gatekeeper™ and SphincterKeeper™ prostheses. The first study on Gatekeeper™ reported on 14 patients who received transdermal injections of into the intersphincteric space. The CCF-FIS score decreased from 12.7 to 5.1(p<0.01) and there were no complications. Location of the prostheses was recorded by ultrasound.
and no dislodgement was seen at 1 year (336). A multicentre observational study of the efficacy of 6 Gatekeeper™ implants placed intersphincterically recorded the outcome in 54 patients. Incontinence to gas, liquid and solid stool improved significantly and all faecal incontinence severity scores were significantly reduced. At 12 months 56 per cent of the patients showed at least a 75 per cent improvement in all faecal incontinence parameters; 7 (13 per cent) were fully continent. Three patients extruded a single prosthesis during surgery; these were all replaced. Dislodgement occurred in three patients post-operatively but none required replacement.

The only study to date on the SphinKeeper™ has looked the feasibility of using this implant and prosthesis localization at 3 months (298). The SphinKeeper™ prostheses pre-implantation are 29mm in length and 3mm in diameter; they become 23 mm long and 7mm diameter within 48 h of contact with fluids. Ten prostheses were implanted in each patient under local anaesthesia and endoanal ultrasound guidance, into the upper-middle intersphincteric space of the anal canal. A partial dislocation of a single prosthesis causing anal discomfort was documented by EAUS post operatively in one patient. The discomfort resolved after 1 week.

Another newer agent is polyacrylate-polyalcohol which was used in non-consecutive series of 58 patients and reported to have achieved predefined successful treatment (50% of more improvement of CCF-FIS) in 60.4%, albeit only 34 patients and 22 patients were available at 6 months and 36 month follow-up respectively (337).

In conclusion, studies of injectable biomaterials comprise several small case series that in general show short-term efficacy and only three randomised trials, two of which compared PMDS and DHAC to placebo, and a third that compared PDMS to PCZO™. These trials indicated that PMDS should not be used, PDMS appears to be better than PCZO in terms of both safety and efficacy, and there are data indicating that NASHA Dx is more effective than placebo. Two systematic reviews (338, 339) and a Cochrane review (334) could not establish evidence to support the efficacy of any of these agents, however one review did find in multivariate analysis, use of the intersphincteric, instead of transanal or trans-sphincteric routes of injection, was associated with a higher complication rate. Furthermore, PDMS and HCM were more effective that other injectable agents with regard to short-term outcome and use of local anaesthesia was associated with a lower likelihood of success (338) [LEVEL OF EVIDENCE: 3]

Summary: The role of Injectable biomaterials in treatment of faecal incontinence remains to be established but may be of value in the treatment of passive incontinence. The optimum bulking agent and technique of application remains to be determined. Grade of Recommendation: D

1.11. Vaginal Bowel-Control System

The vaginal bowel-control system (Eclipse System) is a recently developed compression device designed to augment faecal continence. It consists of a silicone coated vaginal pessary with a stainless steel base and posteriorly directed balloon, both of which have a range of available sizes. It is inserted into the vaginal cavity and the air-filled balloon augments continence. The balloon is deflated to allow evacuation and is removed prior to intercourse (341).

There has been one open label prospective non randomised observational study reported to date (342). In 110 patients (required criteria of ≥4 FI episodes every two weeks) fitted with the device, only 56 patients entered treatment and completed the one-month follow up per protocol. The principal outcome was a reduction in the number of bowel movements per day which was associated with fewer loose stools and consequently less urgency and fewer incontinence episodes. There were no major adverse events. Collaborative studies and longer term follow-up are required, however the system is relatively simple to use and may have a role in moderately severe faecal incontinence unresponsive to conservative treatments.

Summary: The role of the vaginal bowel control system remains to be established but may be of value in the treatment of urge and / or passive faecal incontinence. Grade of Recommendation: D

1.12. Radiofrequency Energy Treatment

Temperature controlled radiofrequency energy was first used in treatment of gastro-esophageal reflux disease. Following initial animal studies, the technique (SECCA®) was adapted by Takahashi et al (343) as a minimally invasive technique to augment continence in a cohort of 10 women. CCF-FIS improved in 9 of the 10 (median 13.5 to 5.0, p=0.006 at 12 months). Follow-up to this cohort showed sustained improvement at 2 years (344) and at 5 years in a larger cohort of 19 patients (345). A larger multicenter study that enrolled 50 patients found significant but less dramatic improvement in CCF-FIS six
months following treatment (14.5 to 11.1, p<0.001)(346). Smaller European studies found moderate improvement in 11 (347) and 15 patients respectively (348), while Kim et al. found no continence improvement and considerable morbidity in 8 patients (349). Three-year follow-up in a prospective cohort study of 31 patients by Lam et al., found that only 6% maintained a 50% reduction in incontinence score and concluded that any benefits observed were of a temporary nature (350). Similarly, Abbas et al. noted that only 6 of 27 patients (22%) had a sustained long term response to treatment, and 14 (52%) were awaiting additional incontinence treatment at a median of 40 months follow up (351). A review of all published series with 220 patients in total concluded SECCA is associated with moderate clinical benefit (352). The mechanism of action is unclear but most probably relates to a degree of scarring or fibrosis of the anal canal that improves the barrier function that declines overtime (353), however recent studies in a porcine model have shown hyperplasia and hypertrophy of smooth muscle fibres in the IAS similar to myocardial remodelling that occurs following radiofrequency ablation (354). The results of randomised trials vs. placebo are awaited. LEVEL OF EVIDENCE 3

Summary: Temperature controlled radiofrequency energy may transiently improve continence in patients with mild to moderate symptoms, but long-term results are disappointing. The results of controlled trials are awaited. Grade of Recommendation: D

1.13. Stem Cell Therapy and Other Tissue Regeneration Techniques

Despite of the development of various different devices to augment or replace the lost function of the anal sphincter apparatus, there is an inherent feeling that the most ideal solution would be a biocompatible regeneration of tissue and restoration of its function.

A study by Frudinger et al. has reported successful treatment of faecal incontinence using autologous myoblasts cultured from a pectoralis muscle biopsy and injected into the external anal sphincter defect using ultrasound guidance (355). No adverse events were reported and the efficacy was sustained at 5 years (356). This has been followed by another group who have also reported a moderate success of autologous myoblast injection which was harvested from vastus lateralis (357). Raghavan et al. have produced a ring of smooth muscle from a combination of chitosan scaffold, mature smooth muscle and neuronal progenitor cells harvested during surgery to recreate an internal anal sphincter. The engineered internal anal sphincter had contractile properties and intrinsic innervation (358, 359).

While these approaches are undoubtedly promising, issues remain concerning the origin and preparation of the donor cells and whether the objective is to bulk existing tissues or recreate a substantial volume of lost sphincter. In that regard, if mature skeletal muscle cells are used as a source, fully differentiated cells are unlikely to further differentiate or integrate with native sphincter. Equally, as the internal anal sphincter is a smooth muscle, it is difficult to find an easy and accessible site for harvesting. Stem cell therapy may overcome these limitations as it has potential to regenerate not only muscles but also other types of cells such as nerves and connecting tissues that are needed to support the regenerated musculature. The source of cells could be accessible if adipose tissue or bone marrow is chosen. This option has been explored in animal models (360). Some groups are also exploring use of allogeneic stem cells which will improve the availability of the stem cells exponentially but immunological compatibility will be problematic.

The success of these techniques may hinge not on tissue bulking effects but creation of contractile muscle that aligns with the original tissue, together with the restoration of nerves and connecting tissues that control and structurally support the de novo muscles. The potential risk with this approach, such as abnormal growth patterns (including potential malignancy) and distant migration, remains a legitimate concern (361). Although the possibilities in this area are exciting, to date, there has been no clinical study that has demonstrated regeneration of a fully functional anal sphincter.

Summary: Stem cell therapy remains experimental and should only be offered as part of a well-designed research trial. Grade of Recommendation: D

1.14. Colostomy

A permanent colostomy for severe faecal incontinence is usually formed as a last resort when all other interventions have failed. Because colostomy is generally regarded as a failure of treatment and, therefore, not so frequently performed, its effectiveness, perioperative complications, and impact on the quality of life have never been properly evaluated except in patients with functional bowel disorders after spinal cord injury (362-364). For a specific role of colostomy for these patients, please refer to chapter XX. Not only for patients with spinal cord injury, but also for general patients with severe faecal incontinence, colostomy is a frequently successful management strategy that restores dignity and allows them to regain social function.

No randomised controlled trials or non-randomised cohort studies have been reported regarding colostomy for faecal incontinence, and only one systematic review (171), one case control study (365) and two case series (366, 367) were identified. No new study has been reported since the 5th ICI, The American Society of Colon and Rectal Surgeons’ Clinical Practice Guideline for the Treatment of Fecal Incontinence published in 2015 state “Creation of a colostomy is an excellent surgical option for patients who have failed or do not wish to pursue other therapies for fecal incontinence (strong recommendation, low- or very
Colquhoun et al. (365) conducted a cross-sectional postal survey, comparing quality of life between 71 patients with faecal incontinence and 39 with a colostomy created for rectal cancer, complicated colonic diverticular disease or faecal incontinence. Analysis of the Short Form 36 General Quality of Life Assessment revealed significantly higher social function scores in the colostomy group than in the faecal incontinence group (0 vs. -0.6, p=0.022). An age- and gender-adjusted regression analysis of the Fecal Incontinence Quality of Life score revealed significantly higher scores in the coping (2.7 vs. 2.0, p=0.005), embarrassment (2.7 vs. 2.2, p=0.014), and lifestyle scales (3.2 vs. 2.7, p=0.14) in the colostomy group compared to the faecal incontinence group. The authors concluded that a colostomy is a viable option for patients who suffer from severe faecal incontinence and offers a definitive cure with improved quality of life. Tan et al (171) performed a systematic review, specifically comparing the cost-effectiveness between end stoma (ES), artificial bowel sphincter (ABS) and dynamic graciloplasty (DG). The quality-adjusted life years (QALYs) and the incremental cost-effectiveness ratio (ICER) were compared between the three procedures, by obtaining the probability estimates for patients with faecal incontinence from published data, with being supplemented by expert opinion. The end stoma was the most cost-effective therapy at 5 years, with a QALY gain of 3.45 for GB£16,280 and an ICER of GB£4,719/QALY, compared to ABS (4.38 for GB£23,569; GB£5,387/QALY) and DG (4.00 for GB£25,035; GB£6,257/QALY). After 10 years, ABS became the most cost-effective surgical intervention, with a QALY gain of 8.384 for GB£32,397 and an ICER of GB£3,864/QALY, compared to ES (6.9 for GB£27,910; GB£4,046/QALY) and DG (7.678 for GB£35,165; GB£4,580/QALY). The results of this study, however, must be interpreted with great caution, because colostomy, unlike DG and ABS, does not attempt to restore normal continence. In addition, this report is not an interventional study but a systematic review with a rather complicated methodology and a variety of possible biases.

Norton et al (366) examined patients’ view of a colostomy by conducting a questionnaire survey of patients who had a colostomy created to manage their faecal incontinence. Sixty-nine people (58 women) responded. When patients were asked to rate their ability to live with their stoma now on a scale of 0-10, the median score was 8 (range 0 – 10). The majority (83%) felt that the stoma, within the past month, restricted their life “a little” or “not at all”. Eighty-four per cent answered that they would “probably” or “definitely” choose to have the stoma again. When they were asked the question “compared to when you were incontinent, how much change has having a stoma made to your overall quality of life?” on the scale of -5 (much worse) to +5 (much better), the median rating was +4.5 (range -5 to +5). The authors concluded that health care professionals should discuss the option of a stoma with incontinent patients because of the overwhelming positive outcomes.

An end sigmoid colostomy without proctectomy is usually recommended as a procedure of choice for patients who elect colostomy for the management of their refractory faecal incontinence. Creating such a colostomy, however, does not always solve all the problems of patients with faecal incontinence. Catena et al (367) reported a retrospective chart review of 44 patients (35 women) who underwent elective end sigmoid colostomy for faecal incontinence of various aetiologies. After colostomy formation 19 patients (43%) were asymptomatic, while the other 25 experienced such problems with their rectal stump as diversion colitis and leakage of mucus. Of the 25 patients, 12 (27% of the total) underwent a secondary proctectomy due to problems with the rectal stump sufficient to warrant the operation. Histological examination revealed diversion colitis in 6 patients. The factor associated with proctectomy was age, with younger patients being more likely to require rectal excision. The authors concluded that data are insufficient to recommend primary proctectomy in patients with severe faecal incontinence warranting permanent end sigmoid colostomy.

Colostomy provides restoration of a more normal lifestyle and improves quality of life. Colostomy should not be regarded as a treatment failure but rather a reasonable treatment option for patients whose lives are restricted by faecal incontinence that is not amenable to other therapies or not suitable for more complicated surgical procedures. An end sigmoid colostomy alone, without proctectomy, is recommended. The minority of patients who develop significant symptoms from their retained rectal stump may eventually require proctectomy as a secondary procedure.

Summary: Formation of an end colostomy should be considered as a reasonable treatment option for patients with refractory faecal incontinence who are unsuitable for or have failed other treatment modalities and who able to accept the associated alteration in body image. Grade of Recommendation: C
III. SURGERY FOR PAEDIATRIC FAECAL INCONTINENCE

1.1. Anorectal Malformations

Anorectal malformations (ARM) occur once in every 3000-5000 live births. ARMs range from the minor defects that are easily treated and have excellent functional outcome, to complex malformations that are difficult to manage and invariably associated with defaecatory problems including incontinence. The surgical approach to repairing these defects changed dramatically in 1980 particularly with the advent of posterior sagittal anorectoplasty (PSARP) [LEVEL OF EVIDENCE: 3].

This technique has enabled surgeons to visualize the anatomy under direct vision and perform corrective surgery more accurately (368, 369). It has become the predominant surgical method for anorectal anomalies. In brief, a mid-sagittal incision is performed and the sphincter mechanism is completely divided in the midline. The rectum is separated from the genitourinary tract and moved down to the perineum. The most challenging aspect of the operation is the separation of the rectum from the vaginal or urinary tract, which effectively requires creating two walls out of one septum without damaging each structure. This approach can also be used for reoperation in anorectal malformations (370) and can be applied for reconstruction of severe perineal trauma (371).

For both male and female babies, urethral-perineal fistula is the simplest to correct. This requires the so-called “minimal posterior sagittal approach” which enlarges the stenotic orifice and relocates the rectal orifice posteriorly within the limits of the sphincter complex. For males with recto-urethral-bulbar fistula or recto-urethral-prostatic fistula and females with recto-vestibular fistula or cloaca with a short (<3 cm) common channel, the posterior sagittal approach is the main operation performed. For males with higher fistulae such as a recto-bladder neck fistula and other complex and unusual defects and females with cloacae with a long (greater than 3 cm) common channel and complex defects, the posterior sagittal approach needs to be coupled with abdominal access.

The laparoscopically assisted anorectal pull-through procedure (LAARP) first described by Georgeson (372) in 2000, is becoming increasingly common in the management of patients with high/intermediate ARM, replacing many traditional open procedures (373). In brief, a sharp dissection and cautery is used laparoscopically to expose the rectal pouch down to the urethral or vaginal fistula, which is clipped distally and divided. The pelvic floor musculature and the puborectal sling are identified and electrostimulation is used externally to define the centre of the anal dimple. A skin incision is made, centred at the strongest cephalad contraction. Guided by laparoscopic visualization, a trocar, consisting of a radially expandable sheath over a Veress needle, is passed through the defined plane in the external sphincter muscle complex and advanced into the pelvis between the two limbs of the pubococcygeus muscle, forming a passage through the centre of the striated muscle complex and elevators. The rectal fistula, which has been dissected out laparoscopically, is grasped using the perineal trocar and exteriorized to the perineum. Anorectal anastomosis is then performed (372).

A recent study of long term functional outcome comparing PSARP (n=34) to LAARP (n=32) ARM children with recto-bladder neck and recto-prostatic fistula found that LAARP is a less invasive procedure (shorter operative time and post-operative hospital stay) and both short term- and long term outcomes after LAARP were equivalent if not better than those of PSARP in children with high ARM (374) LEVEL OF EVIDENCE: 3.

The most complex malformations are cloaca and cloacal exstrophy. In females with cloaca, the rectum, vagina and urethra fail to develop separately and instead drain via a common channel that opens into the perineum as a single orifice. The repair of cloacal malformations is most often performed using a posterior sagittal anorecto-vagino-urethroplasty (PSARVUP) or total urogenital mobilization (TUM) with or without laparotomy (375). The PSARVUP extends the anorectoplasty with a meticulous dissection of the combined vaginal-urethral walls, followed by the reconstruction of distal parts of both structures (376). In 1997, total urogenital mobilization (TUM) was presented by Peña as a new, faster, surgical approach for certain cases of cloacal repair with better cosmetic results (377).

This procedure separates the rectum from the vagina and both vagina and urethra are then mobilised together. The advantage of this technique is to avoid separating rectum, vagina and urethra completely which is not always feasible and risks damaging these structures. This technique avoids the risk of urethrovaginal fistula and vaginal stricture previously reported as complications in 10% of the cloacal repair and also gives enough mobilisation to allow more than 50% of all cloacal repairs without opening the abdomen (376, 377). Functional outcomes depend on the severity of the malformations. A review of more than 1000 anorectal malformation cases showed 100% of babies who had perineal fistula repair achieved continence. Approximately 55% of patients who had been operated for recto-vestibular fistula had bowel control. Any malformations more complicated resulted in only up to 30% achieving continence. All patients who had recto-bladder neck fistula repair were incontinent.

The defects are categorised by the length of the common channel that can be measured endoscopically. The length of the common channel can vary from 1 to 10 cm. The longer the common channel (>3 cm), the higher the chance for poor bowel control, neurogenic
bladder, and reproductive abnormalities (378). Overall it is estimated that nearly 40% will have voluntary bowel movement and no soiling but some of them may still lose bowel control in case of severe diarrhoea and 25% of all repairs will result in total incontinence (379).

For the group of patients with persistent incontinence following the corrective surgery, the next aim will be to keep the colon clean to avoid incontinence and improve quality of life. A good option is implementation of a bowel management program whereby the patient and family are instructed in the use of daily enema, manipulation of diet and medication to remain clean (380). This is also a good treatment for constipation, which is the most common difficulty after corrective surgery (381).

Although most young children accept their parents administering enemata, when they get older they want privacy and rectal enemas on daily basis become an unpleasant routine. In such cases, continent appendicostomy is a feasible option, whereby a conduit for the administration of an antegrade continence enema (ACE) is created. First described by Malone (382) it has become an important option in paediatric surgery for functional bowel disorder. According to the initial description by Malone, appendicostomy was created by dividing the appendix at its base and reimplanting by a reverse manner into the cecum, which was then exteriorized through the right lower quadrant. Malone later revised it and the reimplantation of appendix is no longer considered necessary (383). Levitt et al. (384) introduced utilising the appendix in situ and added caecal plication to prevent reflux of stool and exteriorizing through umbilicus fold rendering it less noticeable. This appears to yield good long-term results (385) though other studies have shown that caecal fixation and wrap may be unnecessary for appendicostomy (386). The construction of appendicostomy with burial of the appendiceal tip appears to help avoid problems of exposed mucosa such as bleeding and mucus discharge. From this perspective, a few techniques have been suggested such as V-Y flap (383) and Y-appendicoplasty (387).

For patients without an appendix, a neoappendix could be formed from ileum or cecum (388-390). Laparoscopically antegrade continence enema procedure has been reported to yield as good result as open procedure (391-394). This procedure is not a cure to the problem but a more acceptable method for many children to engage in a bowel management programme without the need for rectal enemas. Success rate is variable between 61-96% (383, 388, 395-398) with older children benefiting more (399). Hoekstra et al. reported that almost 85% of patients were satisfied with their ACE stoma (400) LEVEL OF EVIDENCE 3.

As with any operation, there are known complications associated with antegrade continence enema. Most recent literature reporting on 97 children with ACE due to faecal incontinence or constipation resistant to medical therapy found that overall 68% patients had at least one complication. Twenty-four per cent developed stomal stenosis, and 28% of patients had significant stomal leakage. Preteen patients (<12 years old) experienced more stomal leakage than teenage patients (401). These complications cause 10-33% of patients to undergo revision of the appendicostomy (379, 402). Stoma prolapse, pressure sore, wound infection, anastomotic leak, stomal granulation, caecal-flap necrosis and caecal volvulus are less common complications reported after ACE (403, 404). LEVEL OF EVIDENCE: 3.

Summary: Anorectal malformation is amenable to surgical reconstruction. Laparoscopically assisted anorectal pull-through procedure is the preferred technique. Outcomes primarily relate to the height and complexity of the abnormality. Evacuation disorders and incontinence often require daily enemas. The Malone antegrade continence enema may provide a more acceptable means of managing continence. Grade of Recommendation: C

IV. SURGERY FOR EVACUATION DISORDERS AND INCONTINENCE

1. RECTAL EVACUATION DISORDERS

Significant rectal retention of faeces results in faecal incontinence in children and older people, indeed, constipation with or without faecal impaction may be the commonest cause of incontinence in these age groups (405, 406). Similarly, if the rectum is completely empty then incontinence (at least of faeces) cannot occur. On this basis, health technologies that address rectal emptying are often recommended on a regular basis or for specific occasions e.g. enemata, trans-anal irrigation. There is however increasing recognition that a significant proportion of adults presenting for specialist management have occult symptoms and radio-physiological evidence of a rectal evacuation disorder. Such patients may describe classic symptoms of post-defaecatory leakage but as commonly have a mixed pattern of incontinence (e.g. urge / passive) that may not immediately indicate rectal evacuation disorder, not least because they may also have a functional or structurally defective sphincter concomitant on a shared pelvic pathophysiology (407).

This observation has important implications to specialist management. First, it supports the use of tailored biofeedback therapy given that this has potential to improve both sphincter function, sensation of rectal filling and coordinated anorectal relaxation (408, 409). Secondly, it promotes caution when using sphincter augmenting procedures. Worsened or new symptoms of obstructed defaecation have been reported in approximately one third of patients after
overlapping anterior anal sphincter repair (1) and up to 50% patients after gracilis neosphincter (165). There are also data suggesting that pre-existent evacuation disorder prejudices the outcomes of neurostimulation (201). This raises the question of whether proven structural causes of rectal evacuation disorder e.g. rectocele and internal prolapse should be surgically targeted before other procedures are offered. The latter is supported by some studies of rectocele repair that show significant improvement in faecal incontinence after surgery (410) but also an evolving body of literature on use of rectal suspension procedures, notably laparoscopic ventral rectoectomy (LVR) (411, 412). Significant improvements in incontinence symptoms and prospectively studied summative incontinence scores (413-417) have been documented for several studies of LVR in patients treated primarily for obstructed defaecation syndrome with internal prolapse. Further, LVR has been specifically targeted to patients with faecal incontinence in two studies (418, 419). The first of these studies evaluated the faecal incontinence severity index (FISI) in 72 patients with high-grade internal prolapse [Oxford grade III or IV] (420) with incontinence not responding to maximal medical treatment and demonstrated a reduction in median score from 31 to 15 points, [P <0.01]. These authors have gone on to suggest and a sequence of care where SNS is reserved for patients with persistent faecal incontinence after LVR (421). Despite concern that nearly all studies supporting this line of reasoning have arisen from one institution (Oxford), it seems reasonable that patients presenting with faecal incontinence should be directly questioned regarding symptoms of obstructed defaecation and undergo appropriate clinical examination and radio-physiological investigations e.g. proctography as part of the decision-making process.

**LEVEL OF EVIDENCE 4.** Those with high grade internal rectal prolapse should be considered for rectoectomy to address the internal prolapse before consideration of other advanced interventions. This is especially true for patients with transanal rectal intussusception [Oxford grade IV or V] where it is clear that the prolapse itself will compromise anal closure. A similar approach, i.e. repair, should be taken to clinically significant rectoceles in which trapping of contrast can be demonstrated post simulated defaecation.

**LEVEL OF EVIDENCE 4.**

Stapled transanal resection of rectum (STARR), a technique developed by Antonio Longo from the PPH (procedure for prolapse and haemorrhoids, also known as stapled haemorrhoidopexy) may also have a role in managing patients with rectal intussusception and rectocele resulting in obstructed defaecation and associated incontinence. A detailed review is beyond the remit of this monograph, however the European STARR registry reporting the outcomes in 2838 patients, found significant improvements in the CCFIS at both 6 and 12 months following surgery in addition to improvements in the symptoms of obstructive defaecation (422). This must however be viewed in the context of an increase in urgency of defaecation in 20% of patients and new onset incontinence in 1.8%. More recently a survey among colorectal specialists from European centres with experience of STARR reports up to 10% new onset incontinence following the procedure. The particular role for STARR in managing patients with incontinence associated with obstructed defaecation remains to be established (423).

**Summary:** Obstructed defaecation is common and may contribute to incontinence. Comprehensive assessment is required. Rectocele repair or ventral rectoectomy may improve continence in carefully selected patients. Randomized studies are lacking. Grade of Recommendation: C

### V. OUTCOME MEASURES IN FAECAL INCONTINENCE

While there is general agreement that patient-based outcome measures (PROMs) are most appropriate for studies of faecal incontinence, standardisation of the optimal instrument or combination of instruments remains a challenge in clinical incontinence research. While many incontinence-related quality of life measures have been proposed and claim to have been "validated," adequate psychometric validation is lacking for many (424). It is unknown if the main outcome measure following incontinence treatment ought to be incontinence severity, incontinence-related quality of life, or a combination of these factors.

Faecal incontinence is a complex symptom relating not only to the continence mechanism itself, but also to the general bowel function in terms of motility, neurohumoral balance, sensory and/or motor disturbances on spinal and supra-spinal levels. Thus, faecal incontinence as a symptom can present itself differently depending on the underlying disease and lifestyle.

Hallbook and Sjodahl developed a bowel questionnaire for assessment of functional outcome following restorative rectal resection that took account of how the function affected the individual’s daily life (425). Bakx et al (426) developed this concept with a colorectal functional outcome (COREFO) questionnaire which they validated in 179 patients. When compared with that of Hallbook, more patients found that the psychometric questions in the COREFO questionnaire reflected their concerns. ICI has extended the focus on psychometric outcomes in the recently developed (427, 428) and validated (429) ICI-B questionnaire suitable for use in patients with incontinence of varying cause, however the large number of items (forty-two) have thus far limited the application of ICI-B. A short version of this questionnaire (8 questions) has been used in two recent clinical trials (254, 430) where it proved highly acceptable to patients. Full validation of this shortened version is now underway.
As clinicians, we need to re-evaluate our perception of disease-specific symptoms and their impact on QoL and use this knowledge when choosing the right treatment for the patient. How patients and physicians rank the severity of faecal incontinence however differs. Clinicians put greatest importance on actual episodes and frequency of incontinence to solid stool, whereas patients are generally more concerned about leakage, hygiene, smell and social embarrassment (431). A study examining colorectal specialists’ perception of symptom severity using the LAR score revealed that specialists did not have a very thorough understanding of which bowel dysfunction symptoms truly mattered to the patient after sphincter-preserving treatment, nor how these symptoms affected the patient's QoL. Although the specialists performed better than random, there was considerable discrepancy between the specialist’s perspective and patient experience (432). The same was also true for specialists’ perception of symptoms bothering patients after restorative proctocolectomy (433).

Disease specific incontinence scores have been developed for neurogenic bowel dysfunction (434), Low Anterior Resection Syndrome (435) and pouch dysfunction after ileo-anal anastomosis (436). Included items were selected from a pool extracted from existing bowel function assessment instruments and the current literature. By applying binomial regression on the response to these items obtained from disease specific cohorts of Danish patients, those showing the highest prevalence and impact on QOL were identified and included in the score creating a patient-based outcome score. This has provided a platform for a common understanding and evaluation of functional outcomes for these patient categories. However, as these scores have been developed specifically in collaboration with these patient categories they are not necessarily applicable in others regardless of similar symptoms. Recently, the ICIQ-B questionnaire has been revised and validated for use in patients with inflammatory bowel disease as the ICIQ-IBD (437). For other non-specific diseases with a faecal incontinence component both the CCF-FIS (63) and St Mark’s scales (438) are available. Whereas the CCF-FIS does not score the urgency component, the St Mark’s scale scores it as ability to defer defaecation for more or less than 15 minutes. Though both scores include elements of severity, preventive measures and impact on quality of life, the individual elements are not weighted in the total score according to patient perception.

Bowel movement diaries are considered to be the gold standard measurement, but these are highly influenced by the patient’s willingness to stray from the toilet and the validity of the data has never been evaluated. A study on the effect of sacral nerve stimulation for faecal incontinence showed that 46% of the patients with more incontinence episodes at follow-up than at baseline were satisfied with the treatment result. These patients explained that they had obtained a more active social life after the SNS therapy, an aspect of social behaviour that is not addressed in the bowel habit diary, and traditional evaluation would consider these patients as failures (237). For both the bowel movement diaries and the FI scores additional validation work is needed to assess the potential effect of recall bias.

The FIQL is a well-validated quality outcome measure but it yields separate scores on 4 individual scales. It is desirable that a single score outcome be developed. Furthermore, quantitative changes in FIQL have not been anchored to the corresponding impact on patient quality of life and thus remain speculative.

In the future, when evaluating surgical interventions for faecal incontinence we should focus on patient satisfaction and QoL, in combination with bowel scores and diaries to obtain a more accurate measure of therapy efficacy. Striving to develop and implement a standardized tool our approach should be based on appropriateness, reliability, validity, responsiveness, precision, interpretability, acceptability and feasibility (439).

Summary: PROMs should be developed and validated according to the impact of symptoms from a patient perspective. It remains to be established if PROMs should be general / disease / treatment specific. Currently available technologies allow real time data capture that may be more relevant in assessing continence outcomes. Grade of Recommendation: C

VI. RESEARCH PRIORITIES IN FAECAL INCONTINENCE

1. BASIC SCIENCE AND PATHOPHYSIOLOGY

In comparison to the evolution of diagnosis and treatment of faecal incontinence, there has been little basic science work looking into the pathophysiology of faecal incontinence.

Faecal urgency is as debilitating as physical leakage of stool due to its unpredictability. Increased expression of transient receptor potential vanilloid receptor 1 (TRPV1), an ion channel in sensory fibres that are activated by noxious stimuli such as pain and heat, has been shown to be a possible mechanism of faecal urgency (440). Although the development of TRPV1 antagonist has been explored and there have been reports of preclinical studies, a clinical trial of such agent for faecal urgency has not been performed (441). There may be other ion channels or neurotransmitters that contribute also to faecal urgency but this has not been studied in depth.

Sacral nerve stimulation (SNS) was a ground-breaking innovation which not only shifted the paradigm of faecal incontinence treatment but has also provided
an interesting insight into the mechanism of incontinence. In the early phase of the treatment it was believed SNS exerted its efficacy by augmenting sphincter function via stimulation of efferent nerves. However, there have been a growing number of studies supporting a theory that its main efficacy may be due to afferent neuromodulation that results in improvement of urgency (216, 232, 442).

Substance P, which is a neuropeptide and plays a role in afferent signalling in visceral sensation, has been normalised by sacral nerve stimulation (229) and some animal studies have shown that SNS augments anal representation in the sensory cortex (215, 442). It remains to be seen whether this pathway could be explored to develop a non-invasive trial of SNS or better monitoring of efficacy.

Faecal incontinence is an important quality of life issue amongst patients who have survived pelvic cancer (443-445). The mechanism of faecal incontinence related to pelvic surgery/radiotherapy has not been fully understood. Volumetric changes of the neorectum compared to the original rectum or neuronal damage due to surgery/radiation are some of the hypotheses that have been postulated. There have been only a limited number of histological or manometric studies in this field and more work is needed to elucidate the mechanism of faecal incontinence relating to pelvic surgery and/or chemoradiotherapy. Any research into mechanism of faecal incontinence that may lead to new approach of diagnosis and treatment are strongly encouraged.

### 2. EVALUATION OF SURGICAL TECHNIQUES

Anterior sphincter repair or sphincteroplasty is an established operation to restore structural integrity of disrupted external anal sphincter. There have been numerous case series reporting the efficacy of both end-to-end and overlap repair techniques but there has been only one small randomised study comparing the two techniques. And when overlap repair is not technically possible, would it be better for the end-to-end repair to be reinforced with a piece of mesh? Furthermore, the definition of ‘defective’ external anal sphincter remains unclear. The circumferential size nor length of defect is defined in American Society of Colon and Rectum Surgeons Society clinical practice guideline (10). In contrast, NICE guideline clearly defines the defect size to be full-length that is 90 degrees or greater (446). More data from prospective comparative or randomised studies are needed to establish the indication for each technique together with consideration to size and time interval between sphincter injury and onset of symptoms, durability, and feasibility of reinforcement or any modification and its place in the treatment algorithm.

Injectable bulking agents have been proposed as a less invasive therapeutic option but the selection of patients and the appropriate techniques to be used remain unclear. The plane where biomaterial is injected varies: ‘into internal anal sphincter’, ‘submucosal’, and ‘around internal anal sphincter’. A liquid material may disperse in the injected plane and there have been reports of distant migration. There has been only one long-term study to date and critical appraisal of the durability of this treatment is required.

Colostomy has been regarded as the last resort for end-stage faecal incontinence when all other treatment options have been exhausted. Although this could offer a significant improvement of quality of life, some patients may remain reluctant to commit to this procedure with fear of permanent stoma and possible irreversibility. The idea of faecal diversion could be tested by formation of temporary loop ileostomy either laparoscopically or using a trephine incision. This has not been looked into in past and may warrant further investigation to assess whether this is a useful step in the treatment algorithm. In addition, more studies are required to investigate quality of life issues associated with faecal incontinence and its alteration with ileostomy/colostomy. Influence of diversion colitis and mucus leakage with a formation of end colostomy in comparison to pre-stoma status of faecal incontinence also warrants an investigation.

As the cost of novel therapies increases, it becomes more difficult to design a robust study without funding from industry. There remains a paucity of randomised, controlled trials in the field of surgical treatment for faecal incontinence. A study to randomise patients with sphincter injury for SNS versus sphincteroplasty, which was strongly recommended by the Committee during the last review, has collapsed due to a combination of reduced enthusiasm from industry, lack of funding and evolution of a pragmatic treatment algorithm in Europe. This emphasizes a requirement for coordinated efforts to collaborate between multiple centres with a large institutional or governmental funding for a swift delivery of large trials. An established treatment such as sacral nerve stimulation will also benefit from larger studies, as studies to date with regards to predictors and outcome have been mostly single-centred and may have been underpowered.

### 3. ASSOCIATED OBSTRUCTIVE DEFAECATION SYMPTOMS

Symptoms of obstructive symptoms, as complications of sphincter repair and concomitant pelvic floor disorder associated with faecal incontinence have received more attention recently. Laparoscopic ventral rectopexy may improve some elements of faecal incontinence symptoms such as those related to transanal rectal intussusception. At the same time, such mechanical phenomenon may be part of global weakness of pelvic floor and rectopexy may correct only a part of pelvic floor dynamics. As with other new surgical approaches in this field, larger prospective
studies by many other centres backed by radiophysical tests to correlate the change of symptoms with mechanical correction is strongly recommended. It is also worth revisit the concept of combining the surgical intervention with pelvic floor training or biofeedback afterwards.

4. OUTCOME MEASURES

Various outcome measures and scoring systems exist to evaluate faecal incontinence but most of them have been devised by clinicians. The only scoring system which was designed with rigorous qualitative interview of patients is International Consultation on Incontinence Modular Questionnaire-Bowel Symptoms (ICIQ-B)(427). However, it is lengthy and contains items that are not scored. There is an ongoing effort to create a short version with rigorous validation and the results of such process are eagerly awaited. Comparison of outcomes of different surgical interventions has been hampered by use of different scoring systems and various definitions of ‘successful treatment’ and active initiatives are needed to adopt the new short version once validated.

I. GENERAL INTRODUCTION

In the developing world fistulae are often a consequence of poor peri-natal care. The epidemiology, aetiology, diagnosis, treatment and prevention have been described in detail in the past three International Consultations on Incontinence.(1-3) A specific International Consultation report on obstetric fistula in the developing world has been published in 2012.(4) This chapter updates the literature and evidence on fistula till June 2016.

The published obstetrical series show impressive numbers and demonstrate the level of skill that many of the fistula surgeons have obtained while working in difficult and isolated situations.

In contrast to the field of obstetrical fistula where the numbers of patients are high, the prevalence of non-obstetrical fistula is much lower. The published series deal with small numbers, are usually retrospective and have a low level of evidence.

Iatrogenic urogenital fistulae are known complications of pelvic surgery and oncological treatments such as radiotherapy. For example a high quality population-based case-control study from Sweden found that the risk of urogenital fistula was 25 times higher amongst women undergoing hysterectomy (n=180,000) compared to an age matched control population (n=525,826) without hysterectomy. The risk appeared to be highest for laparoscopic hysterectomy and lowest for subtotal hysterectomy but absolute numbers were small with a number needed to harm of 5,700.(5)

This section is based on electronic searches of Medline, EMBASE (from 2012 to June 2016), the Cochrane Database of Systematic Reviews, Central Register of Controlled Trials (CENTRAL), Database of Abstracts of Reviews of Effects (DARE), Database of Health Technology Assessments, and Database of NHS Economic Evaluations, and the NICE website (all accessed June 2016); references included in identified systematic and non-systematic reviews were evaluated separately. Hand searching of recent (Jan-June 2016) issues of major American, European and British journals in urology, gynaecology and urogynaecology was undertaken, to capture recent publications not yet included in the online databases. Papers offering any relevant data were considered. This included systematic reviews, randomised and quasi-randomised trials, non-randomised cohort studies, case controlled studies, longitudinal studies and case series or reports. Those papers considered for inclusion were assessed for quality where relevant, in terms of sequence generation, allocation concealment, blinding, and handling of incomplete data, selective reporting and freedom from other biases. An evidence level was then assigned to all included studies according to the ICUD modified version of the Oxford Centre for Evidence-based Medicine system.(6) Where quality was considered to be poor – as in most of the studies included in these sections – the evidence level was reduced accordingly. Recommendations (graded A-D) were made on the basis of consistent or ‘majority evidence’ identified.(6)
II. EPIDEMIOLOGY

1. OBSTETRIC FISTULAE

Epidemiological studies on obstetric fistula (OF) are inadequate. Many of them are based on retrospective case series from a single fistula centre (hospital-based) or use questionnaire based approaches (community-based). A recent systematic review by Adler et al. found 19 studies that could be evaluated. (7) The studies included data from West Africa, Bangladesh, Turkey, Jordan, Ethiopia, Egypt and India. The number of new fistulae ranged from 0.09 per 1000 recently pregnant women in community-based studies to 0.66 per 1000 pregnancies in hospital-based studies. The WHO has suggested that over two million women, mostly from sub-Saharan African and Asian countries, have fistulae. Given an estimated population of 645 million women of reproductive age in sub-Saharan Africa and South Asia in 2010 (http://esa.un.org/wpp/unpp/p2k0data.asp), this would suggest that 3 per 1000 women of reproductive age have a fistula, which is considerably higher than other estimates. They estimated the pooled prevalence from population studies at 0.29/1000 pregnancies. For Sub-Saharan Africa this number rises to 1.6/1000 and for South Asia to 1.2/1000. The incidence was estimated at 0.009/1000 recent pregnancies. Rural areas probably under report the real prevalence. (8). Cowgill et al. performed another systematic review, also looking at the association of stillbirth and fistula. (9) They included 62 studies. Incidence estimates ranged from 0 to 4.09 OF cases per 1000 deliveries, while prevalence estimates were judged more prone to bias and ranged from 0 to 81.0 OF cases per 1000 women. Reported frequency of stillbirth (SB) associated with OF ranged from 32.3 % to 100 %, with estimates from the largest studies around 92 %. The major risk factors appear to be age at first marriage, short stature, pregnancy with a male child rather than a female child, failure to attend ante-natal care, low socio-economic status, low social class, lack of employment and illiteracy. Misconceptions on the cause of OF persist, mostly in rural areas and most in men. Misuse of family planning, intercourse during the menstruation, cursing by relatives, sexually transmitted diseases (STD) and rape or gender-based violence are still seen as potential causes. (10) Education programs should be directed against these misconceptions. Health system causes such as poor quality obstetrical care, staff unaccountability, late referral, poor nursing standards are very prevalent in sub-Saharan Africa and rural areas of Pakistan and other parts of Asia. (11-13)

The consequences of OF include divorce (16-92%), social isolation, worsening poverty, malnutrition, sexual dysfunction and mental illness (including anxiety/depression), insomnia, general ill health and thoughts of worthlessness and suicide. (14, 15)

There are few detailed reports documenting these women’s obstructed labours. The time of onset of labour is rarely recorded and reports from delivery locations may disregard the fact that the woman has laboured at home for days prior to attending the delivery location. The reason for the woman not receiving help rarely differentiates between the absence of health-seeking behaviour and the lack of services. A recent study looked at the pathway these patients followed. The mean duration of the fistula was 4 years and the entire care process took up to 2.7 years, of which 7 months were spent at the repair centre. (16, 17)

1.1. Recommendations

Community-based epidemiological studies using standardised and validated collection tools with acceptable sensitivity and specificity are highly recommended.

Observational and longitudinal studies are needed, utilising advanced epidemiological analyses for risk factors (multivariate analysis controlling potential biases), the impacts and consequences of vesicovaginal fistula (VVF) and for factors determining health-seeking behaviour.

2. IATROGENIC FISTULAE

While in the developing world poor obstetric care is usually at the origin of the VVF, gynaecological or pelvic surgery are the main causes of VVF in the industrialised world. In some developing countries, gynaecological procedures to treat benign and malignant conditions of the female reproductive tract are more commonly performed, the rate of iatrogenic fistulae is increasing (e.g. Pakistan). (18)

2.1. Post-gynaecological Surgery

The types of fistulae associated with gynaecological procedures may include communication between any reproductive organ (uterus, cervix, Fallopian tube, vagina), intestinal tract (colon, rectum), genitourinary organ (bladder, ureter, urethra), and cutaneous system (abdominal wall, perineum). In general, VVF are the most common type. The most common causes of VVF as a consequence of surgery, in developed countries is an injury to the urinary tract during hysterectomy for benign conditions (60-75%), followed by hysterectomy for malignant conditions (30%), caesarean section (6%), and obstetric injuries (1%). (19)

(20) Overall, the risk of pelvic organ fistula following hysterectomy has been reported to be between 0.1 and 4%. (21) It is important to recognise that most urinary tract injuries do not result in a fistula.

The prevalence of genitourinary injury and fistulae vary slightly from centre to centre. In one US retrospective study from the Mayo clinic, gynaecological surgery was responsible for 82% of the fistulae, obstetric procedures for 8%, and various forms of irradiation for 6%, and trauma or fulguration for 4%. The
majority of fistulae followed treatment for benign conditions. (22) The relative proportions of the types of urinary fistula have changed with urethral fistulae having increased from 6 to 13%, while ureteral, bladder and/or urethral fistulae having dropped from 20 to 16 and 11 to 7%. (2)

Given the various indications for, and types of hysterectomies, it is important to have an understanding of the type of hysterectomy since genitourinary or colonic fistula is reported with all of these procedures. The overall incidence of hysterectomy complications is estimated to be <2%, with bladder injury (1.3%) and ureteric injury (<1%) being most commonly reported. (23) Traditionally, the most common route used to remove the uterus for benign and malignant gynaecological conditions is abdominal (open incision, laparotomy); referred to commonly as total abdominal hysterectomy (TAH). The types of hysterectomies also include total vaginal (TVH), laparoscopically-assisted vaginal (LAVH), total laparoscopic (TLH), and subtotal or supracervical abdominal (SCH) or laparoscopic (LSH). Laparoscopic procedures may be done using traditional laparoscopic techniques, robotic assistance, and more recently, the single-site umbilical technique.

Benign and malignant conditions confined to the uterus are usually treated with a simple hysterectomy using any of the methods mentioned above. More advanced malignant conditions are usually treated with a radical hysterectomy in which parametrial and/or vaginal dissection and removal may be involved. In rarer cases, exenterative procedures to move the bladder or colon may be required if malignant extension to these organs is found. In some centres, robotic radical hysterectomies have been more commonly employed to treat gynaecological malignancies. The rate of urogenital fistula associated with simple abdominal hysterectomy for benign disease is often reported as being of the order of 1 in 1000. In a national study from Sweden the rate of women undergoing any fistula surgery was reported as 0.26% in women having had a hysterectomy compared to 0.0007% in those not exposed to hysterectomy, with the 'number needed to harm' being estimated at 5700. (24) From Finland the rate of VVF was reported to be 1 in 1250 after all hysterectomies, 1 in 455 after laparoscopic, 1 in 1000 after total abdominal, and 1 in 5000 after vaginal hysterectomy. (25) The publicly available tables from the national hospital database in England give similar figures of 1 in 600 after total abdominal hysterectomy, and 1 in 5000 after vaginal hysterectomy. (26, 27) More detailed longitudinal analysis of patient-level information from the same dataset suggests a rate of 1 in 788 for all types of hysterectomy, 1 in 540 for abdominal hysterectomy for benign disease, 1 in 896 following vaginal hysterectomy for benign disease (excluding prolapse), and 1 in 3861 following vaginal hysterectomy for prolapse. (28)

Naturally, caesarean hysterectomy is a recognised cause of fistula, (29) and, with the increase in the number of caesarean deliveries there have been more fistulae related to obstetric surgical trauma. (2)

The degree of bladder injury appears to be a major factor in iatrogenic fistula formation. In one study, 1,317 benign hysterectomies were reviewed (46% abdominal, 48% vaginal, and 6% laparoscopically-assisted vaginal) with reference to risk factors for VVF following intraoperative injury to the urinary tract. In all, 34 cystotomies occurred with 4 (11.7%) developing a VVF. Patients who developed a VVF were more likely to have a large cystotomy and these individuals tended toward greater tobacco use, larger uterine size, and more operative blood loss. (30) Another study involving 3,076 vaginal hysterectomies with or without additional gynaecological procedures, one ureteric injury and 54 bladder lacerations were noted yielding a total of 4 VVF. The bladder lacerations occurred during the hysterectomy portion of the surgery in 61% of cases and during the additional procedures in 39%. (31) Also in developing countries iatrogenic fistulae occur. Raassen et al. found 805 iatrogenic fistulae in a series of 5959 (13.5%) patients in 11 countries. Most fistulae occurred as a consequence of caesarean section, intervention or hysterectomy for ruptured uterus. (32)

VVF associated with hysterectomy may require ureteric reimplantation in as many as one-third of the cases. (33) Ureteric trauma should be considered in any hysterectomy or operative obstetric procedure regardless of the difficulty but certainly in more difficult cases. (34) Iatrogenic ureteric injury may occur after less common procedures such as ureteroscopy, lumbar sympathectomy, abdominal trauma, and iliac vessel ligation. (35)

2.2. Oncological Fistula

The literature relating to fistula of oncological aetiology is limited both in quantity and quality. Seventy-six papers of possible relevance were identified, of which only 52 contained any relevant material. Only one randomised trial was directly identified from the literature searches, (36) although one non-systematic review of relevance, (37) and two systematic reviews were found; (38, 39) each of the latter contained only one further randomised trial. One national cohort study, and one non-randomised cohort study, are included, (28, 40) but all other identified material comprised case series or case reports, and represent level 3 or lower evidence. Two cases of duplicate publication (i.e. the same paper in two journals) were found.

In the oncological context, fistulae may occur as a result of primary or recurrent malignancy, or as a consequence of cancer treatment by surgery, radiotherapy, chemotherapy, or a combination of therapies.

In one study, 536 women underwent a radical hysterectomy for invasive cervical cancer. More advanced stage of disease, obesity, diabetes, and postoperative surgical infection were predisposing factors to urinary tract complications. In this study, ureteric injury...
occurred in 1.32%, bladder injury in 1.49% with VVF forming in 2.61% and ureterovaginal fistula in 2.43% of cases, respectively. (41) In a similar report, 1,092 women with cervical cancer underwent a radical hysterectomy with obligatory pelvic lymphadenectomy. A VVF occurred in 0.3% and a ureterovaginal fistula occurred in 1.4%. (42) The rate of GU injury likely varies between centres. For example, in one report of 479 women undergoing different methods of radical hysterectomy for cervical cancer over a 15 year period, 52 (10.8 per cent) had urological complications (17 bladder and ureter injuries, 35 fistulae and strictures). (43) In contrast, one institution reported that, with modifications and careful dissection, ureteric and bladder injury have almost been eliminated. (44)

In two recently published case series, one of fistulae specifically associated with gynaecological cancers, (37) and one of urogenital fistula from all causes, (27) those relating directly to primary cancer were uncommon, (2/20=10%)(37) and (2/348=0.6% - 2/66=3% of the oncological cases in this series), (27) respectively. Fistulae associated with cancer surgery (3/20=15% and 30/348=8.6% - 30/66=45% of the oncological cases in this series) or radiotherapy (15/20=75% and 34/348=9.8% - 34/66=52% of the oncological cases in this series) made up a much larger proportion of both series.

Immune-deficiency may be a further contributory factor, and enterovesical fistula has previously been reported in association with non-Hodgkin’s lymphoma in HIV-AIDS. (45) and VVF has been seen in association with classical Hodgkin’s affecting the vagina in a long-term pessary user. (46)

2.3. Cancer Surgery

It is likely that all operations carried out in the pelvis can be complicated by genital tract fistula in some circumstances. (27) Operations carried out with the intention of curing malignant disease will inevitably carry a higher risk of subsequent fistula formation, as compared to those undertaken with less radical intent.

Following radical hysterectomy for cervical cancer (Wertheim-Meigs procedure) the rate of fistula formation reported from case series is between 0.6% and 4.4%. (41, 47-52) It should be noted that these data are very heterogeneous, some reporting all types of fistula together. Where they are reported separately, the rates of vesicovaginal and ureterovaginal fistula appear to be of the same magnitude with both being reported in between 0.9% and 2.5%, of cases (41, 53, 54). The data from UK cited above suggest a urogenital fistula rate of 1 in 95 following radical abdominal hysterectomy in women with malignant disease as compared to 1 in 540 for TAH for benign disease, and one in 2041 for TVH for all benign disease (including prolapse). (28) Overall, the rate of urogenital fistula appears to be approximately 9 times higher following radical hysterectomy in women with malignant disease as compared to that following simple hysterectomy (abdominal or vaginal) in women with benign conditions. (28)

The risk of visceral injury or subsequent fistula formation following radical hysterectomy undertaken in pregnancy, or immediately following Caesarean section is not obviously increased over those carried out electively in non-pregnant individuals; Monk & Montz described inadvertent cystotomy followed by vesicovaginal fistula in one of 21 women operated on during or immediately after pregnancy. (55)

Several modifications to the conventional Wertheim-Meigs’s procedure of radical hysterectomy have been described in an effort to reduce the associated morbidity. None of them seems to offer a benefit regarding fistula formation. (43, 47, 56)

Given the increased risk associated with radical surgery for malignancy, it is intuitive that the risks would increase with the stage of disease and with the extent of the surgery undertaken. There are few published reports of fistula following exenterative surgery. One study noted a 16% VVF rate in 19 women following exenteration for vulvar carcinoma; (57) while another describes a 15% bowel fistula rate and an 8% urinary fistula rate from a series of 75 exenterations for recurrent cervical cancer. (58) In contrast, Ungar et al. describe only one ureterovaginal fistula and one pouch-vaginal fistula in 212 women undergoing exenteration out of a total of 2540 women treated for cervix cancer in one centre over a 13 year period (0.9%). (59)

Bladder sparing techniques during pelvic exenteration can carry a risk for fistula formation. (60) Also when the bladder has been removed and a neo-bladder has been constructed, fistulae between the neo-bladder and the vagina may occur. (61, 62)

The introduction of laparoscopic surgery within oncology is seen to have considerable advantages in terms of patient recovery; the risk of operative injury to bowel and the urinar tract, and subsequent fistula formation may however remain a concern in such cases. Although some studies, both case series and non-randomised cohorts, describe similar rates of injury to those described following open radical surgery, (40, 53, 54, 63, 64) others have reported injury or fistula rates several times higher following laparoscopic radical hysterectomy. (48, 65)

The risk of urinary tract injury from minor surgical interventions is in general low, although the use of repeat procedures may confer a significant increase in risk. VVF has been reported following repeated use of CO2 laser for vaporisation of vaginal condylomata, (66) and following cone biopsy of the cervix. (67) In one personal series of 370 urogenital fistulae, 4 were associated with large loop excision of the transformation zone (LLETZ) of cervix, 3 of which followed a second LLETZ procedure (Hilton, personal communication).

Rarely, localised malignancies have been associated with VVF. One example is a primary mixed Mullerian vaginal tumour reported in a 48-year female. (68)
The mechanism for fistula formation is likely to be direct invasion into the bladder.

Genitourinary injuries during colorectal surgery are rare. Eswara et al. described 75 GU injuries in 42570 colorectal surgeries: cystotomy (35%), incomplete ureteral transection (29%), ureteral injuries (15%). Pre-operative external beam radiotherapy or chemotherapy and delayed repair were associated with worse outcome.(69)

2.4. Radiation Fistulae

Pelvic irradiation can be delivered by external beam as well as locally (intracavitary/brachytherapy). Fistula formation appears to be slightly higher for post-operative external radiation (1.9%) compared to intravaginal brachytherapy (0.8%). (70) It does not appear that pre-treatment factors accurately predict those who will develop fistula related to radiotherapy. (71)

The literature in this area is particularly heterogeneous in nature, with wide variation in (and some lack of clarity over) the tumour type and stage being treated, the form of radiation and the site and dose delivered. In a series of urogenital fistulae from the UK, 34/348 or 9.8% were associated with previous radiotherapy; of those related to gynaecological cancer, 34/66 or 52% had undergone radiotherapy.(27) In a further series of cases specifically related to gynaecological malignancy, 15/20 or 75% had undergone previous radiotherapy.(37) In both series most cases followed radiation used for the treatment of cervical cancer, although, 5/34 or 15% followed treatment of endometrial cancer, and 1/34 or 3% followed treatment of a multifocal gynaecological cancer in one series.(27) Amongst a series of 216 radiation-induced fistulae, the time to diagnosis of the fistula was made between 3 months and 10 years (mean 21 months) following radiation.(72) In other series fistulae have been reported to develop or present up to 30 years after the 'causative' influence.(27, 73) (Figure 1a and 1b)
The incidence of any deleterious clinical impact on the gastrointestinal and urinary tracts following radiation varies in the literature between 1% and 12%, (39, 74-80) with fistula rates of 1% to 5% (37, 75). In a retrospective review of 2096 patients treated for cervical cancer over a 10-year period using unspecified regimen/s of radiotherapy, 38 patients (1.8%) were found to have developed fistulae, all of whom had stage IIIa/b or IV disease at presentation. (77) Of these cases, approximately 3/4 involved the rectum, with 1/3 being combined rectovaginal and VVF; 1/4 were vesicovaginal only. (77)

Following a clearly defined regimen of external beam radiation plus brachytherapy for the treatment of primary squamous cell carcinoma of vagina in 91 women, de Crevoisier et al. reported 10.0% grade 2-3 urinary tract toxicity (using the Franco-Italian glossary) (82) and 12.1% grade 2-3 gastrointestinal toxicity. (75) Unsurprisingly, they found anterior tumour...
location to be correlated with increased risk of bladder toxicity and decreased rectal toxicity. Two women in this series developed rectovaginal fistulae (2%), and one ureterovaginal fistula (1%).(75)

In a series of 10,709 women treated by telebrachytherapy (67.5 Gy) for a range of gynaecological cancers in one centre over a 22 year period, 133 (1.2%) developed urological complications of which 35 (0.3%) developed fistulae.(79)

In a series of 28 women treated by brachytherapy for recurrent corpus or cervix cancer, four patients developed chronic morbidities related to treatment. Three fistulae were reported in two patients (7.1%): one combined rectovaginal and VVF and one ureterointestinal fistula; a further patient developed a ureteric stricture and small bowel obstruction requiring resection.(80)

These data tend to suggest a higher rate of fistula formation following the application of radiotherapy in locally recurrent disease than in primary disease. From a small series of urological complications following radiotherapy for gynaecological cancers, 14 had developed vesicovaginal fistula; of these 4 (29%) had evidence of tumour recurrence.(78) In the series reported by Jones et al. 326/1161 (28%) developed urological complications over a 20 year period; 46 developed fistulae (4%), of whom 33 (72%) had evidence of active malignant disease.(50)

In prostate cancer patients, recto-urethral fistula are described after cryotherapy (0.1-4%)(83), HIFU (0.7%)(84), brachytherapy (2%)(85).

When a fistula occurs after radiotherapy, it is considered good clinical practice to exclude tumour recurrence before attempting a fistula closure. Feddock et al. found 27 fistula in 325 patients after post-radiation biopsies for cervical cancer.(86) The fistula were toxicity related in 51.9%, a consequence of primary disease in 22.2% and of recurrent disease in 25.9%. The residual or recurrent cancer found in the biopsies was only 31.5%. Elevated radiotherapy doses to the rectum, advanced tumour stage and post-radiotherapy biopsy were considered risk factors for fistula formation.

2.5. Chemotherapy

There are few reports of fistula formation in association with the use of chemotherapy. One case report described a patient who developed a VVF having undergone TAH for atypical endometrial hyperplasia whilst taking tamoxifen following a previous modified radical mastectomy. Surgical repair of the fistula was initially unsuccessful, although after discontinuing the tamoxifen and continued bladder drainage, healing occurred.(87) It was hypothesised that the impaired healing was a result of the administration of the hormone therapy.

2.6. Combination Therapies

Adjuvant or neoadjuvant therapies are used to increase the efficacy of the primary treatment, compared to its use in isolation. It might be anticipated that this would also increase the range and magnitude of adverse effects.

In a case control study examining the urinary tract complications of radical hysterectomy only a single VVF was seen in 50 patients (2%) – in a patient receiving preoperative irradiation (45-50 Gy).(88) A small case series found 2/20 or a 10% rate of urinary fistulae following preoperative radiation and radical hysterectomy in a heterogeneous group of ‘high risk’ cervix cancers.(89) A further case series described the impact of combined external whole pelvic irradiation (50 Gy) and intravaginal cone boost (20-26 Gy) following radical hysterectomy in 108 women. The overall rate of fistula formation was 3.7%, 2.2% following ‘prophylactic’ radiation, and 10.5% in ‘salvage’ cases where recurrent disease was present.(90)

Modarress et al. reported a randomised comparison of preoperative combined chemoradiation (cisplatin plus external beam therapy) and neoadjuvant chemotherapy (cisplatin plus vincristine) followed by radical hysterectomy in stage IB-IIB bulky cervical cancer.(36) Four patients developed hydronephrosis (3 in the chemoradiation group – 13.3%) and two vesicovaginal fistula (both in the chemoradiation group – 6.7%).(36) Two further case series reported 2/36 or a 5.6% rate of fistulae following preoperative chemoradiation (cisplatin plus brachytherapy) followed by radical hysterectomy,(91) and 4/46 or 8.7% rate of fistulae following the use of neoadjuvant and postoperative chemotherapy using irinotecan, cisplatin and nedaplatin.(92)

2.7. Rare Causes of VVF

Foreign bodies such as pessaries, sex toys, herbs, cups etc… can be a cause of VVF. (93-96) Often the presentation is often delayed (up to 15 months). Also ketamine abuse can not only lead to severe changes in the bladder wall structure, but also to fistula formation, as was shown in 14.8% of 27 patients undergoing a CT-urography. (97)

3. UTEROVESICAL FISTULAE

Uterovesical fistulae are usually a consequence of caesarean sections. An increased number of caesarean sections leads to an increase in abnormally invasive placentae. Placenta previa and percreta can lead to dramatic obstetric situations, necessitating an emergency caesarean section. The uterovesical fistulae can form afterwards when the bladder and the uterus and the bladder are not well separated or sutured. (98)

This clinical entity was first described in the literature by Burkland in 1949 and by Nourse in 1953 but is referred to as Youssef’s syndrome since his publication
in 1957(99-101). Menouria and amenorrhea are the most common symptoms. In a study by Rao on 14 patient’s, an emergency caesarean section was at the origin of the fistula and in 58% the fistula was formed after the second caesarean section.(102) The mean duration between the caesarean and the diagnosis of the uterovesical fistula was 7 months. These findings have also been confirmed by Washington et al. looking at 34 patient’s with cervicovesical or ureterovesical fistulæ of whom 29% had caesarean section compared to 9% who delivered vaginally.(103)

Congenital forms of uterovesical fistulæ have been described as well, but are very rare.(104)

The treatment is surgical, although there is one case report of a successful conservative treatment as well.(105) Classically a trans-peritoneum approach will be used, where the plane between bladder and uterus will be developed, the fistula closed and eventually interposition material will be used. The outcome of the surgery is very good. A multidisciplinary approach is advocated to prevent infertility.(106)

4. URETERIC FISTULAE

A large prospective case series from Finland found an incidence of ureteric injury associated with hysterectomy for benign pathology of 0.2% (10/5279) with the lowest rate associated with vaginal hysterectomy previously abbreviated and no difference between open and TLH.(107) The incidence of immediate and delayed ureteric injury during radical hysterectomy was found to be 1.3% (7/536) and 2.4% (13/536) respectively in a series from Serbia; injuries appeared more common after prolonged surgery and in patients with diabetes, obesity or wound infection.(108) A registry study from the United States found an overall incidence of ureteric injury during radical hysterectomy of 0.8%.(109) Case series from referral centres in India, Pakistan, and Egypt showed that the proportion of urinary tract injuries resulting from obstetric or gynaecological surgical trauma that primarily affected the ureter varied from 1% to 23%.(110-113)

Ureteric fistulæ can occur as a consequence of open and laparoscopic colorectal surgery.(114)

Uretero-arterial fistula are uncommon, but can be life threatening due to massive bleeding in the ureter. They have a high mortality rate. (115) Predisposing factors are radiation therapy, vascular pathology, ureteral stenting. Das et al. reviewed the literature and found 61 cases. In terms of treatment, endovascular stenting has emerged as an appealing initial modality and should be considered in stable patients in whom open surgical intervention is less suitable to pre-existing comorbidities.(116)

5. FISTULA INVOLVING THE GI TRACT

The literature relating to non-obstetric fistula involving the gastro-intestinal tract is sparse and of poor quality. Although literature searching identified 78 papers of possible relevance, less than half of these contained any useful material; no randomised trials or truly systematic reviews were identified. One case controlled study is included, but all other identified material comprised case series or single case reports, and is considered to represent level 3 evidence.

It should be recognised that, whilst in most papers the term ‘enterovesical’ is used to describe fistulae between small bowel and bladder, and ‘colo/recto-vesical/vaginal’ to describe those between large bowel and bladder/vagina, in some reports ‘enterovesical’ appears to be employed generically to include all fistulæ involving the gastrointestinal tract. In this chapter, the term ‘intestino-vesical’ will be used in circumstances where the generic term is clearly more appropriate.

Whilst occasionally reported congenitally,(117) the most common non-obstetric causes of fistula involving the gastro-intestinal tract are diverticular disease, Crohn’s disease, and malignant disease or its treatment. There are few data on the incidence of fistula formation in these conditions, although published estimates are in the range 2-6% in Crohn’s disease,(118-120) and 20% in diverticular disease.(121)

Intestinal fistulæ in Crohn’s disease most typically involve the small bowel, although communication with urinary tract and large bowel are also found; involvement of the bladder was reported in 27% and of the colon in 14% in one series.(122) Two large series examining the urological complications in association with Crohn’s disease reported that whilst a majority of patients were female, the most serious complications were seen in males; most significantly, 13/14 or 93% of the iléo-vesical fistulæ described in these series were in men.(118, 123)

Whilst clearly diverticular disease involves the large bowel primarily in all cases, diverticular fistulæ have been reported to communicate with the bladder in 65% of cases, the vagina or uterus in 28% and small bowel in 7%.(121) Diverticular disease is the most common cause of colovesical fistula in most reports, accounting for up to 75% of cases,(124-131) with colorectal cancer, bladder cancer, radiotherapy and Crohn’s disease accounting for the remainder.

Although there are no direct comparisons between racial groups, the distribution of these causes may vary between populations. Malignancy and/or previous radiotherapy account for 53-93% of cases of
colovesical fistula reported from China, presumably reflecting the previously low prevalence of inflammatory bowel disease.

Previous hysterectomy appears to be a significant factor in the incidence of fistula associated with diverticulitis. In a national case controlled study from Sweden, involving a total of 783,245 women over a 30 year period, the risk of undergoing fistula surgery increased four-fold in hysterectomised women without diverticulitis (hazard ratio (HR) 4.0 (95% confidence interval (CI) 3.5 to 4.7)), seven-fold in women with diverticulitis without hysterectomy (HR 7.6 (95% CI 4.8 to 12.1)) and 25-fold in hysterectomised women with diverticulitis (HR 25.2 (95% CI 15.5 to 41.2)). Another study described previous hysterectomy in 50% of colovesical and 83% of colovaginal fistulae associated with diverticular disease.

5.1. Evidence Statements

| The risk of injury to the bowel or urinary tract and of subsequent fistula formation is higher in women with malignant disease undergoing radical surgery than in women with benign disease undergoing simple surgical procedures | 2 |
| Several modifications to conventional radical hysterectomy have been described, although they have not consistently been shown to mitigate the risk of urinary fistula postoperatively. | 3 |
| Data on exenterative surgery are inconsistent, although the risk of fistula formation may be higher following exenteration for recurrent disease as compared to that following radical hysterectomy for the primary treatment of malignancy | 3 |
| The rate of visceral injury and fistula formation is inconsistently reported following laparoscopically assisted radical hysterectomy, but may be somewhat higher than following open surgery | 3 |
| Local ablative treatments applied in gynaecological oncology, whilst apparently relatively low risk as single treatments, may carry considerable risk for fistula formation when repeated. | 3 |
| The rate of fistula formation following radiotherapy for gynaecological cancer appears to be of the same order as that following surgical treatment | 4 |
| The risk of fistula formation following radiotherapy for locally recurrent malignancy is higher than following its use in primary disease | 2 |
| The use of neoadjuvant or adjuvant therapies is likely to be associated with a greater risk of fistula development than the primary treatment alone | 2 |
| The most common non-obstetric causes of fistula involving the gastro-intestinal tract are diverticular disease, Crohn’s disease, malignancy and radiotherapy. | 2 |
| The causative factors may vary in different populations, with malignancy being more commonly reported in association with enterovesical fistula in China than in other countries | 3 |

5.2. Recommendations

| The development of fistula following radiotherapy for primary treatment should trigger a search for evidence of tumour recurrence | D |

### III. CLASSIFICATION OF VVF

The Consultation believes that fistula audit research is considerably hampered by the plethora of VVF classification systems, of which we believe there are 32. The Consultation feels that the fistula system that is able to relate its classification to outcome is the classification that should be used in the next few years. The Waaldijk and Goh classifications are the only ones that have been used to document sufficient numbers of patients from diagnosis to follow-up (Fig 2). Figure 2 shows the Waaldijk Classification assessing mainly the extent of the urethral involvement and whether the injury to the urethra is circumferential or not. Fistulas are classified into types I (distance between the distal edge of the fistula and the urethral meatus > 4cm with no involvement of the urethral closure mechanism), II (distance between the distal edge of the fistula and the urethral meatus 1-4cm (type IIA) or 0.5-1cm (type IIB) with involvement of the urethral closing mechanism at the bladder neck and mid-urethral level) and III. Type III fistulas are those fistulae other than vesico-vaginal fistulae and include recto-vaginal fistulae and uretero-vaginal fistulae.
Similarly, the Goh classification looks at three of the four proven variables known to affect the outcome for obstetric fistula repair. These are the location of the fistula (assessing the extent of urethral involvement), the size of the fistula and the amount of scarring (including whether or not it is circumferential). Also bladder capacity or size is known to affect outcome, but since this is difficult or even impossible to
measure pre-operatively, it has not been included in the Goh classification. (Fig 3) The predictive value of the several items of the Goh classification on persisting incontinence despite successful fistula closure is demonstrated in Table 1.

There has been one comparative study showing that the Goh system is superior to the Waaldijk in terms of predicting closure. (140) (141) Frajzyngier et al, in a prospective cohort study compared the classification systems of Lawson, Tafesse, Goh, Waaldijk and the WHO. (142) They included 1274 patients in 11 centres. The predictive accuracy for fistula closure was 0.63 for the WHO score, 0.62 for Goh and 0.60 for the Tafesse score. The Waaldijk and Lawson systems fared worse. They propose a new empirical and simplified scoring system. They also suggested including other items in a prognostic scoring systems such as HIV status, malnutrition, malaria and genital cutting.

Classification systems have been developed for an obstetric fistula population. For iatrogenic fistula the classification is highly variable. Most centres use their own classification. Probably the OF classifications could be used for iatrogenic fistula as well. At least the simple WHO classification should be recommended (Fig. 4).

Although the evidence on classification systems is level two evidence, the committee has upgraded these recommendations to grade A. The committee wants to encourage researchers to use and report the classification systems, given the major importance classification systems have in the scientific research in this field.

### IV. DIAGNOSIS OF FISTULAE

#### 1. CLINICAL DIAGNOSIS

Leakage of stool, urine, or possibly both is the hallmark sign of a fistula. The leakage is usually painless, may be intermittent if it is position dependent, or may be constant. Unfortunately, intraoperative diagnosis of a GU or GI injury is made in only about half of the cases that result in fistula. (143) In one study, 36% of VVF presented within one week of a laparoscopic hysterectomy and 50% in the second week. Most of the patients after TAH had leakage in the second week (90%). (144) As discussed above, more extensive dissection is a factor when lower urinary tract injury results in a fistula. However, other than a frank injury such as ureteric transection, not all injuries result in the formation of a fistula. With laparoscopic or abdominal dissection, ureteric injury may occur anywhere along the retroperitoneal ureter usually below the pelvic brim. Since the injury may not be recognised during surgery, post-operative pain is a key symptom.

The cause of VVF after hysterectomy varies with the extent of surgery and the amount of damage that has occurred. In an attempt to determine causative factors of post-operative fistulae, the records of 12 patients who had developed a vesicovaginal fistula after TAH were compared with 12 consecutive TAH patients without fistula formation. Most of the patients who developed VVF had extensive postoperative abdominal pain, distension or paralytic ileus, or both. Haematuria, symptoms of irritability of the bladder, prolonged postoperative fever, and increased white blood cell count were also noted more often in the fistula group. In contrast, the postoperative course was usually uncomplicated in the non-fistula group.

---

**Figure 4. Adapted WHO classification of fistula. Although this classification was developed for obstetric fistula initially, it could be relevant for iatrogenic fistula as well. (447)**

- **Simple fistula with good prognosis**
  - Single fistula <4cm
  - Vesicovaginal fistula
  - Closing mechanism not involved
  - No circumferential defect
  - Minimal tissue loss
  - Ureters not involved
  - First attempt to repair

- **Complex fistula with uncertain prognosis**
  - Fistula >4cm
  - Multiple fistula
  - Rectovaginal, mixed fistula, cervical fistula
  - Closing mechanism involved
  - Scarring
  - Circumferential defect
  - Extensive tissue loss
  - Intravaginal ureters
  - Failed previous repair
  - Radiation fistula
The clinical course observed in many of the patients with VVF suggests that the patient has an unrecognised or recognised injury to the bladder resulting in urinary extravasation. (145) It may be possible to abort the development of many VVF by early recognition and treatment of an unsuspected bladder injury. It is suggested that patients with severe abdominal pain, distension, paralytic ileus, haematuria or symptoms of severe irritability of the bladder after TAH should be investigated early for a possible genitourinary injury.

Another possible aetiology of VVF in the setting of laparoscopic procedures is trocar insertion injury. To prevent this the bladder should be emptied by intermittent or continuous bladder drainage prior to inserting the abdominal and pelvic trocars. During the laparoscopic procedure, gaseous distention of the urinary drainage bag may become evident indicating a hole in the bladder. This intraoperative sign however, has not been associated with fistula formation. (146)

The diagnosis of VVF usually requires clinical assessment often in combination with appropriate imaging or laboratory studies. Direct visual inspection (office evaluation or exam under anaesthesia) may confirm the presence of a fistula however it may not reveal the extent, location, or course of the fistula. Some fistulae are not readily visible. This is particularly true with iatrogenic fistula in which the fistula may be high in the vagina and may involve the ureter, bladder, or both. Therefore, most physicians rely on adjunctive tools for the diagnosis of VVF. This may include imaging studies in combination with other modalities such as cystoscopy. A simple approach in the office setting to confirm that a fistula is present is to fill the bladder retrograde with a coloured fluid. This could be a milky fluid such as baby formula or water or saline with methylene blue, or indigo carmine. Direct visualisation of dye extravasation or placement of a tampon into the vagina to identify staining may facilitate the diagnosis of a VVF. (Figure 5) A double-dye test to differentiate between an ureterovaginal and VVF may be useful in some cases. The patient is given phenazopyridine orally which will stain the urine orange while the bladder is filled with blue fluid. Blue tinting of the tampon leads to the presumptive diagnosis of a VVF while orange staining is suspicious for an ureterovaginal fistula. (147) A three swab test has also been described, lining up three swab in the vagina. The swab that is coloured most, indicates the presumed location of the fistula (proximal, mid or distal vagina). (148)

A number of studies have investigated the role of routine cystoscopy in avoiding/detecting urinary tract injury at pelvic surgery; Indraratna et al. have recently reviewed these. (149)

Gilmour et al. undertook a systematic review of urinary tract injuries at benign gynaecological surgery including all studies of >500 patients reported between 1966 and 1998. (150)

The overall rate of ureteric injury from 17 studies where cystoscopy was not undertaken (mostly hysterectomy) was 169/107,068=0.16%. In 10 studies where cystoscopy was undertaken routinely (mainly colposuspension or pelvic floor reconstruction), the rate of ureteric injury was 20/3235=0.62%. The corresponding rates of bladder injury were 0.26% (without cystoscopy) and 1.04% (with cystoscopy). Although the rates of detected urinary tract injury were approximately four-fold higher in those studies where cystoscopy was undertaken as a routine, it should be noted that none of these studies was randomised, and routine cystoscopy was undertaken predominantly during those procedures with intuitively the highest risk of injury.

Cystourethroscope may provide direct visualisation of the fistula. In several series using cystoscopy (mostly with IV indigo-carmine) the sensitivity and specificity in detecting ureteric injury intra-operatively were >95%.

Urine may extravasate externally or internally. Creatinine levels in the urine are higher than serum levels. Therefore, in the setting of a suspected fistula, testing the creatinine level in either the extravasated fluid or the accumulated ascites and comparing this value to the the serum creatinine levels will confirm urinary leakage but not the location of the fistula. Likewise, testing potassium levels will show higher levels compared to serum levels. (151)

A recent trend to use a flexible scope in the vagina, vaginoscopy, can provide magnification, direct visualisation with minimal discomfort to the patient, particularly in high fistulae.

2. IMAGING

Depending upon availability, radiologic studies (cystography, urography, intravenous urography, and CT urography) may be useful. Ultrasoundography and colour Doppler have been used by some, although their...
use in routine practice remains to be established. (152) (153) An unstructured review by Narayanan et al. suggested that magnetic resonance imaging, particular with T2 weighting, provided optimal diagnostic information regarding fistula associated with pelvic malignancy, with contrast-enhanced CT with late excretory phase an acceptable alternative. (154) These newer modalities were considered to be superior to other X-ray contrast techniques and ultrasound. Ureteroenteric fistula have been diagnosed using 99mTc-DTPA renal scans. (155)

### 3. DIAGNOSIS OF GI FISTULAE

Pneumaturia, dysuria and/or recurrent UTI’s are symptoms of a colovesical fistula but may be due to other causes as well. Accepting the limitations of small case series in this regard, a number of studies have investigated the value of a range of investigative techniques in the detection and evaluation of entero- or colovesical fistulae. (126, 128, 129, 133, 156-160) No test was shown to have consistent reliability; excluding those investigations for which only a single report was identified, CT (53%), cystoscopy (48%), and in the case of colovesical fistula, barium enema (38%) were perhaps the most useful; intravenous urography and sigmoidoscopy or colonoscopy appear to have limited utility in the diagnosis of GI fistula.

CT and cystoscopy appear more consistent in the confirmation and location of possible intestino-vesical fistulae, than other investigations. Level 3 evidence indicates that the routine use of cystoscopy with dye testing at gynaecological surgery has high sensitivity, specificity and negative predictive value in the detection of ureteric injury, although false positive tests do occur. The clinical and cost-effectiveness of routine cystoscopy remains to be established.

### V. MANAGEMENT OF VESICOVAGINAL FISTULAE

The literature relating to surgical fistula is extensive, but of limited quality. In the previous version of this chapter 356 papers of possible relevance were identified, of which only 173 contained any relevant material. In this edition 141 articles have been added.

#### 1. CONSERVATIVE MANAGEMENT

##### 1.1. Immediate Management by Catheterisation or Defunctioning

Before epithelialisation is complete an abnormal communication between viscera will tend to close spontaneously, provided that the natural outflow is unobstructed. Normal continence mechanisms, however, involve the physiological contraction and intermittent relaxation of urethral and anal sphincters. As a result, although completely spontaneous closure of genital tract fistulae does occur, it is the exception rather than the rule. Bypassing the sphincter mechanisms, or diverting flow around the fistula, for example by urinary catheterisation, percutaneous nephrostomy or defunctioning colostomy, may however encourage closure.

Bazi reported a non-systematic review of papers including information on the spontaneous fistula closure of VVF; whilst quality of the data was poor, he identified 30 studies from which 12 could be included; these included cases that were almost exclusively of surgical aetiology; it should be noted that in 9 of these 12 studies the sample size was less than 5 patients. (161) Few studies described catheter drainage in large fistulae, although it seemed that those of less than 1cm diameter were most likely to heal spontaneously. The time between the insult and institution of drainage in cases of non-surgical closure varied widely, although in most cases this was less than 3 weeks. Similarly, the duration of catheterisation prior to the initiation of conservative treatment was deemed to have been unsuccessful varied considerably, making true estimates of the effectiveness of this approach impossible; generally this varied between 10 days and 3 months. (161) Reported success rates varied between 0% and 100% (although 5 series had a sample size of 1!), although in several series it was difficult to determine how many women had attempted conservative management. (161)

In large series of obstetric fistulae where a consistent approach to conservative management has been applied, spontaneous healing has been reported in up to 28% of cases. (162-164) In one series of urogenital fistulae of varying aetiologies, spontaneous closure was seen in 19/238 or 8.0% of surgical cases, 4/38 or 10.5% of obstetric cases, 1/36 or 2.8% of miscellaneous (largely traumatic cases) and 0/34 or 0.0% of radiotherapy related cases. (27) Oakley et al. studied 226 patients, of whom 116 underwent immediate surgery and 60 were treated with catheterisation for 12 weeks. Of the conservative treatment group only 11.7 resolved spontaneously. The remainder had surgery. It is possible that in this, and many other reported series, data are an underestimate of the value of this approach.
approach to management,(27) nevertheless, combining available data (see table 2) gives an overall spontaneous closure rate from 348 surgical fistulae treated by initial catheterisation of 13% ± 23% (19, 27, 31, 165-174). Patients with ongoing, continuous vaginal leakage despite a functioning indwelling catheter are unlikely to have resolution of the VVF without additional measures such as surgery. Such patients should be spared prolonged catheter drainage and proceed with more definitive repair as soon as medically appropriate. Small epithelialized fistulae may benefit from minimally invasive cystoscopic electrocoagulation of the fistula tract, followed by prolonged catheter drainage. In patients with fistulae less than 3.5mm in diameter, 11/15 had successful fistula tract ablation with cautery and catheter drainage in a study by Stovisky et al. (175) In general, conservative measures are successful in small fistulae only, usually less than 2-3mm in diameter.

n.b. table includes studies considered by Bazi, (161) but only those of known surgical aetiology.

1.2. Pharmacotherapies to Assist Fistula Closure

Several case reports describe successful fistula closure following the induction of amenorrhoea by oestrogen, oestrogen/progesterone combinations, or luteinising hormone releasing hormone analogues, (176) in the management of vesicovaginal, (177) and more frequently, ureteric or vesico-uterine fistula following caesarean section. (179-182) The overall closure rate in these studies is 88% ± 16%. Spontaneous closure of vesico-uterine fistula has also been reported on a number of occasions, (179, 183) with a rate of 41/786 or 5% calculated in one review. (179) Whilst comparison across studies is obviously highly problematic (especially where many are single case reports, with success rates of 0% or 100%), it seems highly likely that the rate of closure following hormone treatment (14/16) is significantly higher than that of spontaneous closure (41/786) (p<0.0005 – Fisher’s exact test).

In quasi-randomised controlled study (alternate allocation) in patients with continuing urinary leakage following ureteric or pelvi-calyceal surgery, the use of intranasal desmopressin was shown to significantly reduce the duration of leakage compared to ‘watchful waiting’. (184) The use of such treatment should be avoided in patients with complicating factors such as infection.
It should be recognised that some fistulae may be associated with minimal symptoms, and even if persistent these may not require surgical treatment. Small distal urethro-vaginal fistulae, uro-vesical fistulae with menouria, colo-vesical fistulae associated with diverticular disease, and some low recto-vaginal fistulae may fall into this category.

1.3. Palliation and Skin Care

During the waiting period between diagnosis and repair, incontinence pads should be provided in generous quantities so that patients can continue to function socially to some extent as well as avoid skin complications related to chronic urinary leakage. Urinary fistula patients usually leak considerably larger quantities of urine than those with urethral incontinence from whatever cause, and this needs to be recognised in their provision of supplies.

The vulvar skin may be at considerable risk from urinary or faecal dermatitis,(185, 186) particularly if there is additional radiation change in the skin;(187, 188) liberal use of silicone barrier cream should be encouraged. Steroid therapy has been advocated in the past as a means of reducing tissue oedema and fibrosis, although these benefits are refuted and there may be a risk of compromise to subsequent healing. Some authors have recommended local oestrogen, and whilst empirically one might expect benefit in post-menopausal women,(189, 190) or those obstetric fistula patients with prolonged amenorrhoea,(191, 192) the evidence for this is limited.

1.4. Nutrition

To maximise the prospects for postoperative healing it is essential, that the general health of the patient should be optimised. This is most relevant to obstetric fistula patients, where social ostracism and the effects of prolonged sepsis, may commonly result in malnutrition and anaemia.(193-198) Where there is severe inflammatory bowel disease the question of an elemental diet or even total parenteral nutrition may need to be considered.(132, 135, 199-202) Nutritional support may also be important in patients with malignant or radiotherapy induced fistulae,(203) or in those with complications following diversion surgery.(202, 204, 205)

1.5. Physiotherapy

Obstetric fistulae are commonly associated with lower limb weakness, foot drop and limb contracture. In a group of 479 patients studied prospectively 27% had signs of peroneal nerve weakness at presentation and a further 38%, whilst having no current signs, gave a history of relevant symptoms.(206) Early involvement of the physiotherapist in preoperative management and rehabilitation of such patients is essential.(207) Although nerve injury is rarely seen in association with fistulae of other (non-obstetric) aetiologies, the value of physiotherapist support in the preoperative management and rehabilitation of patients with complex fistulae or with intercurrent pathologies should not be under-emphasised.(202)

1.6. Antimicrobial Therapy

Active infection in the genital or urinary tracts should be treated prior to attempted surgical repair. In tropical countries the treatment of systemic infections such as malaria, typhoid, tuberculosis and parasitic infections are not uncommon and should be rigorously pursued and treatment undertaken before elective surgery. One randomised trial reported no difference in outcome between single dose IV gentamycin and continued postoperative use of amoxicillin, chloramphenicol or cotrimoxazole in obstetric fistula patients (although re-analysis suggests that a difference favouring peri-operative gentamycin may be present).(208) A further placebo controlled trial of ampicillin found no evidence of benefit from prophylactic antibiotics in terms of fistula closure or residual incontinence following repair, although the use of postoperative antibiotics was reduced.(209)

A recent review of obstetric fistula practices has called for further trials in this aspect of fistula management.(210) Opinions differ on the desirability of prophylactic antibiotic coverage for surgery in the developed world, some avoiding their use other than in the treatment of specific infection, and some advocating broad-spectrum treatment in all cases. A systematic review found only weak evidence that antibiotic prophylaxis (compared to giving antibiotics when clinically indicated) reduced the rate of bacteriuria, pyuria and symptomatic urinary tract infection in female patients undergoing abdominal surgery who had a urethral catheter for at least 24 hours; this limited evidence related to women receiving antibiotics during the first three postoperative days or from postoperative day two until catheter removal.(211)

1.7. Bowel Preparation

Although many surgeons continue to employ mechanical or stimulant laxative bowel preparation prior to recto-vaginal fistula repair,(212) and may even suggest alternative approaches to surgery where this has not been possible,(130) a recent systematic review that included 18 trials (5805 participants), found no evidence that patients benefit from mechanical bowel preparation, nor the use of rectal enemas, and concluded that bowel cleansing can be safely omitted prior to colonic surgery, without increasing the risk of perioperative complications.(213)

1.8. Counselling

Surgical (non-obstetric) fistula patients are usually previously healthy individuals, who entered hospital for what was expected to be a routine procedure, and they end up with symptoms infinitely worse than their initial complaint. In contrast, obstetric fistula patients in the developing world are often social outcasts. In both situations therefore these women are invariably devastated by their situation; significant impact on
their mental health has been objectively confirmed.\(^{214, 215}\) It is vital that they understand the nature of the problem, why it has arisen, and the plan for management at all stages. In the setting of an iatrogenic fistula, there may be considerable medico-legal consequences. Confident but realistic counselling by the surgeon is essential and the involvement of nursing staff or counsellors with experience of fistula patients is also highly desirable. The support given by previously treated sufferers can also be of immense value in maintaining patient morale, especially where a delay prior to definitive treatment is required.\(^{216}\)

## 2. SURGICAL MANAGEMENT

Fistula surgery is not easy. One of the most important aspects of the unmet needs in fistula surgery training has been the lack of standardization. A global competency-based fistula surgical training manual has been created by the International Federation for Gynaecology and Obstetrics (FIGO) with International Society of Fistula Surgeons (ISOFS). The purpose of this manual is to enable health care providers to acquire the required knowledge, skill and professionalism to prevent fistula and provide holistic care to fistula patients that includes medical, psychosocial and surgical care. A multi-disciplinary team-based approach is encouraged in the training of each doctor and his/her team nurses, physiotherapists and other health professionals. The course is structured at three levels: standard, advanced and expert levels of fistula training.\(^{217}\)

In the developed world, fistula incidence is much lower. Most results of fistula repair in literature are extremely positive. Since there is no systematic reporting on fistulae and the complications or outcome of the repairs, underreporting, selection bias can be possible confounding factors leading to these positive reports.

If catheter drainage fails, then fistula repair will be necessary. There are certain surgical principles to observe during fistula repair:

- Necrotic tissue must be removed prior to fistula repair.
- Fistula repair must only be undertaken by a properly trained surgeon.
- Adequate post-operative care is essential.
- Proper follow-up should be arranged.

---

Total: 187 early cure 91%, late cure 27%

### 2.1. Timing of Surgery

The most appropriate timing for repair of vesico-vaginal fistulae remains one of the more contentious issues in this area. The debate continues between the advocates of early intervention, in order to minimise the distress to the patient from continuing urinary leakage, vs. those in favour of delaying intervention until local inflammatory change has resolved, necrotic tissues have sloughed, and the patient’s recovery from the causative event completed, so as to optimise results.
There is no consensus in the literature as to the definition of ‘early’ in this context, with different studies either failing to specify at all, or giving a broad range of definition. Although some studies have used the terms ‘immediate’, (218) ‘less than two weeks’, (219) or ‘less than 30 days’, (174) most reports have considered either less than 6 weeks, (220-222) or less than 3 months, (219, 223-225) as their definition of early intervention. Although relatively few studies have reported their outcomes for both early and late approaches to management, overall the results do not appear to be significantly different (see table 3). The overall results for early management are estimated at 91%±6% and for later management (where provided) 90%±27% (p=1.00; Fisher’s Exact test).

2.2. Outcomes from Treatment and Follow-up

Comparing the outcomes of treatment between different reports and different methods is made difficult by the inconsistent and relatively inefficient outcome measures used. These have ranged from the apparent achievement of a water-tight repair based on dye-testing in the operating theatre, to patient reported symptoms at the time of discharge from hospital. Follow-up in obstetric fistula patients is inevitably difficult in many developing world centres, but even amongst surgical or radiotherapy cases in the developed world, relatively few reports describe examination findings or symptoms at later postoperative review. Long-term outcomes and quality of life measures have only rarely been reported. (226, 227)

2.3. Surgical Approaches

Despite the fact that there is no universally agreed upon classification of iatrogenic fistula, it is probable that there is a relationship between the complexity of the fistula and the outcome of the fistula repair. The WHO published a classification of obstetric fistula in 2006 that divided fistula in simple or complex fistula. We adapted that classification by adding the radiation fistula to the complex fistula group. (Figure 4)

2.3.1 Vaginal Procedures

There are two main types of closure technique applied to the repair of urinary fistulae, the classical saucerisation technique described by Sims, (228) and subsequently modified as a partial colpocleisis by Latzko, (171) and the more commonly used dissection and repair in layers or ‘flap-splitting’ technique (variously attributed to Hayward, Collis & Lawson Tait). (229) Individual surgeons inevitably employ these techniques somewhat variably, and in different situations, and there are no data comparing their outcomes.

The conventional dissection and repair in layers is entirely appropriate for the majority of post-surgical fistulae, although modifications may be necessary in specific circumstances. In juxta-cervical fistulae in the anterior fornix, vaginal repair may be feasible if the cervix can be drawn down to provide access. Dissection should include mobilisation of the bladder from the cervix, and the repair should usually be undertaken in such a manner (usually transversely) to reconstruct the underlying trigone and prevent distortion of the ureteric orifices.

Vault fistulae, particularly those following hysterectomy, can again usually be managed vaginally. The vault is incised transversely and mobilisation of the fistula is often aided by deliberate opening of the Pouch of Douglas. (230) The peritoneal opening does not require to be closed separately, but is incorporated into the vaginal closure.

Where there is substantial urethral loss, reconstruction may be undertaken using the method described by Chassar Moir (231) or Hamlin & Nicholson. (232) A strip of anterior vaginal wall is constructed into a tube over a catheter. Plication behind the bladder neck is probably important if any prospect for continence is to be achieved. The interposition of a labial fat or muscle graft not only fills up the potential dead space, but may also provide additional bladder neck support and improve continence by reducing scarring between bladder neck and vagina. These are indeed technically demanding procedures and outcomes of such complex repairs using robust measures as regards continence or sexual function are lacking.

With very large fistulae extending from bladder neck to vault, the extensive dissection required may produce considerable bleeding. The main surgical difficulty is to avoid injuring the ureters. They are usually situated close to the supero-lateral angles of the fistula, and if they can be identified endoscopically, they should be catheterised. Straight ureteric catheters passed transurethrally, or double pigtail catheters may both be useful in directing the intramural portion of the ureters internally; nevertheless great care must be taken during dissection. In such cases where the ureters cannot be visualised cystoscopically, interventional radiological techniques may be utilised to place antegrade ureteral stents from a percutaneous nephrostomy access tract.

2.3.2 Abdominal Procedures

Repair by the abdominal route is indicated when high fistulae are fixed in the vault and are inaccessible through the vagina; most typically this might be following hysterectomy in nulliparous women, in endometriosis, or in those who have not delivered vaginally. Other indications for transabdominal repair are the need for simultaneous augmentation cystoplasty, or in the setting of a ureteric injury requiring reimplantation or simultaneous VVF and ureterovaginal fistula.

A transvesical repair has the advantage of being entirely extraperitoneal. It is often helpful to elevate the fistula site by a vaginal pack. The ureters should be catheterised under direct vision either endoscopically prior to skin incision, or following opening of the bladder. The technique of closure is similar to that of the
transvaginal flap-splitting repair except that for purposes of haemostasis the bladder mucosa is usually closed with a continuous suture.

A simple transperitoneal repair is relatively uncommonly employed (although this technique does seem to be favoured by some using the laparoscopic approach – see below), although a combined transperitoneal and transvesical procedure is favoured by many urologists and is particularly useful for fistula repair following Caesarean section. A midline incision is made in the vault of the bladder; this is extended downwards in a racquet shape around the fistula. The fistulous track is excised and the vaginal or cervical defect closed in a single layer. The bladder is then closed in two layers.

There are no randomised studies comparing abdominal and vaginal approaches; given that those surgeons undertaking both routes for repair would usually see specific indications for the two such a comparison is most unlikely ever to be seen as feasible, ethical or appropriate. Nine non-randomised cohort studies reporting results from both abdominal and vaginal procedures were identified in the current review. In all, these series included 388 vaginal repairs and 345 abdominal repairs with overall closure rates at first operation of 89% and 87% respectively (p=0.367; Fisher’s exact test). The same reports included 255 transvesical repairs with a 93% cure rate, and 399 transperitoneal repairs with an 89% success rate (p=0.130; Fisher’s exact test).

With respect to attempted repair of a previously failed VVF surgery, the law of diminishing returns appears to be as evident in these types of procedures as in many other forms of surgery. Although repeat operations are certainly justified, the success rate decreases progressively with increasing numbers of previously unsuccessful procedures. In a series of 2484 largely obstetric fistulae, the success rate fell from 81% for first procedures to 65% for those requiring two or more procedures. Series of surgical cases are rarely large enough for this effect to be evident, although the recent series published by Hilton found successful fistula closure was significantly more likely in the women who had not had attempts at closure before referral (98.2%) than in those who had one or more previous unsuccessful procedures (88.2%) (p=0.003; Fisher’s exact test).

There is only a single randomised trial comparing aspects of surgical technique; Shaker et al. report an RCT comparing trimming of the fistula edge with no trimming. Although there was no statistical difference in success rates between the two groups, in those cases where repair was unsuccessful and trimming had been undertaken, the fistula tended to become larger, whereas those where there was no trimming were more likely to be smaller upon recurrence (see figure 6).

Figure 6: Forest plots relating trimming of edges at fistula surgery

(i) Forest plot of comparison: 1 Trimming vs. no trimming of fistula edge, outcome: 1.1 Failure of fistula closure

(ii) Forest plot of comparison: 1 Trimming vs. no trimming of fistula edge, outcome: 1.2 Recurrence smaller than original

(iii) Forest plot of comparison: 1 Trimming vs. no trimming of fistula edge, outcome: 1.3 Recurrence larger than original
2.3.3 Laparoscopic

Laparoscopic repair of a VVF was first reported by Nezat et al., in 1994. (241) Fifteen series were identified in the current review. (218, 241-254) (plus an additional series in which 2 laparoscopic procedures were undertaken amongst a small series of vaginal and open abdominal operations). (238) All reported series are quite small (1-25 cases, median 6 cases), and in total only 119 patients were included, with an overall cure rate of 92% (confidence interval 4%) (See table 4). It is not clear from these series whether they include all fistula repairs undertaken in the reporting centres, or whether they were selected in some way; if the latter, it is not clear what selection criteria were used. It is possible that there may be both selection and reporting biases that make it difficult to fully evaluate laparoscopic procedures against alternative surgical approaches.

A combined vesicoscopic, laparoscopic and vaginal approach has been used successfully by some groups, but the experience remains limited. (255, 256)

2.3.4 Robotic

The first report of a robotically-assisted repair of vesico-vaginal fistula was from Melamud et al. in 2005. (257) Since that time four additional reports have been identified, (258-261) including a total of 17 cases (see table 4). The reported cure rate is 100% in all series, although the same comments as above, in relation to possible selection and reporting biases, apply equally here. At this stage, whilst one could state that fistula repair with robotic-assistance appears to be feasible, it is not possible to indicate what its place or potential advantages are over alternative approaches.

Some of advantages to the robotic technique include three-dimensional visualisation, increased dexterity with wristed instrumentation improving on the severe angulation required for laparoscopic or open VVF repair, and easier intracorporeal knot tying. The retrovesical approach through the vagina can reduce the time for bladder healing significantly and allow the procedure to be done as a single day procedure. Currently, there are no direct comparisons between the classical transabdominal VVF repair, transvaginal VVF repair, and the minimally invasive robotic/laparoscopic techniques.

Miklos JR et al. performed a systematic review on laparoscopic and robotic fistula repairs. They included 44 studies: 9 articles of robotic-assisted approach, 3 laparoscopic single-site surgeries, and 32 conventional laparoscopic approaches. A literature review revealed a balanced number of reports for both transvesical and extravesical approaches. The overall success rate of laparoscopic VVF repair was 80% to 100% with a follow-up period of 1 to 74 months. The success rate of transvesical and extravesical techniques were 95.89% and 98.04% (relative risk, .98; 95% confidence interval,.94-1.02). There was no statistical difference in success rates of VVF repair with different number of layers in the fistula closure or with use of interposition flaps, but there was a small increase in success in the cases that documented intraoperative bladder filling to test the integrity of the bladder closure. In conclusion, transperitoneal extravesical VVF repair has cure rates similar to the traditional transvesical approach. Laparoscopic extravesical VVF repair is a safe, effective, minimally invasive technique with excellent cure rates similar to those of the conventional transvesical approach in experienced surgeons' hands. (262)

Gellhaus PP et al. published a series of robotic repair either concomitantly with gynaecological surgery or as a salvage procedure after an previous attempted repair, showing good results for both approaches. (263)

2.3.5 Fibrin Glue

The use of fibrin glue in urological indications was reviewed by Shekarriz and Stoller; (264) they identified nine reports (eight in human subjects) of the use of fibrin glue in fistula repair, including a total of 16 patients. (265-272) A further six more recent reports were identified in the current review, where fibrin glue was used either by endoscopic injection or direct application, making a total of now 53 patients with fistulae of various aetiologies. (267, 273-278) Several of these publications were individual case reports, although there was also one randomised trial comparing fibrin glue (20 patients) with a Martius graft (20 patients) in obstetric fistula patients. (277) All of the case reports described successful repair (1/1=100% cure); the RCT reported 13/20=65% cure; the overall success rate therefore for the 53 reported patients was 77.4% (confidence interval 7.3%) (See table 5). In one case successful closure of a radiation induced fistula was reported from the combined use of bovine collagen and fibrin glue. (267) Overall, the indications for, and optimal patient selection for this approach are not defined.
### Table 4: Results from series reporting conventional and robotically-assisted laparoscopic fistula repairs.

### 2.3.6 Endoscopic Repair

Mackay described a technique for transurethral endoscopic suture repair of vesico-vaginal fistula in 1997. (279) There have been three further papers using a similar technique on between one and four patients (total 10 cases). (234, 279-281) Although in three of these series the reported cure rate was 100%, overall, fistula closure was found in 80% (confidence interval 24%).

### 2.3.7 Adjuvant Techniques in the Repair of VVF: Tissue Interposition

Tissue flaps are often added as an additional layer of repair during VVF surgery. (282-286) Most commonly, such flaps are utilised in the setting of recurrence after a prior attempt at repair, for VVF related to previous radiotherapy (described later), ischemic or obstetrical fistula, large fistula, and finally those associated with a difficult or tenuous closure due to poor tissue quality. However, there is no high level evidence for the use of such flaps in any of these situations. Furthermore, there is no high level evidence that the use of such flaps improves outcomes in the setting of an uncomplicated VVF.

For those VVF repaired transvaginally, a labial fat pad (Martius flap) or a peritoneal flap can easily be mobilised. From a transabdominal approach, greater omentum can be used as an interposition flap.

A variety of other flaps including gracilis muscle flaps, labial myocutaneous flaps, seromuscular intestinal flaps, and rectus abdominis flaps as well as free grafts of bladder mucosa have been utilized as adjuvant measures in the repair of complex VVF. (287-294)

There is no evidence that a Martius or any other interposition graft improves the outcome in primary fistula repair.

### 3. POST-OPERATIVE MANAGEMENT

#### 3.1. Catheter Type

No studies were identified comparing different catheter types or duration of drainage following fistula repair. Most reports do not describe their catheterisation practices in any detail; in those that do, the majority have employed urethral catheterisation, with a small number preferring suprapubic drainage or a combination of both. The reason for catheterisation is to ensure free urine drainage until such time as the repair is soundly healed; for this reason some have advocated both suprapubic and urethral drainage, arguing that whilst one catheter might easily become blocked, two are unlikely to do so simultaneously. (27)

#### 3.2. Duration

There appears to be no obvious consensus over the duration of catheterisation recommended following fistula repair of various types and aetiologies. In a retrospective study of obstetric fistula patients in Ethiopia, approximately equal numbers of patients were

catheterised for 10, 12 or 14 days. Patients were not randomised, and there were differences between the groups in terms of the extent of urethral involvement, fistula size, and degree of vaginal scarring, with the more extensively damaged patients being catheterised for longer. Despite this, there was no significant difference in outcome in terms of the rate of repair breakdown, and the authors therefore suggested that postoperative catheterisation for 10 days may be sufficient in the management of less complicated obstetric VVF. (295)

In a recent review of practices amongst obstetric fistula surgeons, Arrowsmith reported a considerable range of practice. For ‘simple’ fistulae, the average duration of bladder drainage used was 12 days (range 5-21 days); for ‘large’ fistula the average was 17 days (range 0-30 days); and for ‘difficult’ fistulae, the average was 21 days (range 14-42 days). (210)

Studies of non-obstetric fistula management are no more consistent in their description of duration of catheterisation. Most report periods of between seven and 21 days drainage; most typically 10-14 days for surgical fistulae and 14-21 days for radiotherapy-associated fistulae. There is no more than level 3/4 evidence to support any particular practice in these aspects of fistula management.

The summary of the surgical management of VVF can be found in Figure 7-9.

FIGURE 9. ALGORITHM FOR MANAGEMENT OF VESICOVAGINAL FISTULA

HISTORY

Leakage of urine from vagina / perineum

CLINICAL ASSESSMENT

• Clinical examination
• Urethro-cystoscopy
• Imaging (X-ray/CT/MRI, US)
• Evaluate upper urinary tract

PRESUMED DIAGNOSIS

Recent VVF

Consider Catheter, evaluate weekly

Established VVF

Healed

Persistant leakage

MANAGEMENT*

Primary simple

Vaginal repair
Consider timing

Primary complex

Surgical repair
Consider timing
Consider interposition material

Recurrence

If small, consider catheter, evaluate weekly

Post-irradiation

Surgical repair
6-12 months
Consider interposition material

Assess fistula closure & assess continence status

* Consider CONTINENCE PRODUCTS for temporary support during treatment
4. MANAGEMENT OF THE COMPLICATIONS OF VVF

The complications of VVF repair are many and can include:

- Persistence or recurrence of urinary incontinence
- Persistence of lower urinary tract symptoms or occurrence of new lower urinary tract symptoms, including overactive bladder and stress urinary incontinence
- Infections: wound, urinary tract infections (UTI) and pyelonephritis and urosepsis
- Ureteric obstruction (ligation – fibrosis – injury)
- Outlet obstruction (meatal stenosis, urethral stricture, bladder neck obstruction)
- Bladder contracture
- Vaginal stenosis (overcorrection – fibrosis)
- Sexual dysfunction (vaginismus – dyspareunia)
- Rare complications (granulomas – diverticulum formation)
- Neurological complications (foot drop – neurogenic bladder)
- Complex neuropathic bladder dysfunction and urethral sphincter incompetency often result, even if the fistula can be repaired successfully
- Psychological trauma (social isolation – divorce – mental illness)
- Infertility

The literature on the treatment and management of complications of fistula repairs is extremely scarce and is mostly experience-based. It is impossible to give any specific evidence-based guidance. There is need for centralisation of these cases.

**Recommendations:**

<table>
<thead>
<tr>
<th>A care programme for failed repairs with persisting incontinence after a successful repair, needs to be in place.</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>It is recommended that surgical treatment of post-operative stress incontinence should only be considered six months after fistula repair.</td>
<td>C</td>
</tr>
<tr>
<td>Autologous material should be used when a graft or sling is required and there is no place for synthetic sling material.</td>
<td>C</td>
</tr>
<tr>
<td>In order to prevent new fistulae/fistulae in women who become pregnant after a fistula repair, waiting homes should be provided to ensure that each woman is able to have an elective caesarean section when she goes into labour.</td>
<td>C</td>
</tr>
<tr>
<td>Patients complaining of persistent leakage due to urgency incontinence may try antimuscarinics, botulinum toxin injection or even augmentation cystoplasty in small contracted or poorly compliant bladders.</td>
<td>C</td>
</tr>
<tr>
<td>Those with a shortened or disrupted urethra, before or after repair, must be treated with urethral reconstruction, autologous slings or injection of bulking agents, delivered trans or peri –urethrally.</td>
<td>C</td>
</tr>
<tr>
<td>In cases with unilateral or bilateral ureteric ligation or injury, the early diagnosis is lifesaving. Patients must be promptly treated by endoscopic ureteric stenting, PCN or ureteric reimplantation.</td>
<td>B</td>
</tr>
<tr>
<td>Patients complaining of contracted vagina and dyspareunia with sexual dysfunction may use local oestrogen, vaginal dilatation or may require the surgical creation of vaginal flaps to augment the vagina.</td>
<td>C</td>
</tr>
<tr>
<td>Patients who develop dropped foot may respond to physiotherapy or require tibialis tendon transfer.</td>
<td>C</td>
</tr>
<tr>
<td>Psychological trauma, social isolation and depression is best treated by counselling and psychological rehabilitation.</td>
<td>C</td>
</tr>
</tbody>
</table>

**General recommendations:**

| The comprehensive use of an indwelling catheter with free urinary drainage should be instituted for all patients who have undergone either an emergency caesarean section or a traumatic vaginal delivery after prolonged (>24hours) obstructed labour. | B |
| When fistula surgery is necessary the woman must be assured of the surgeon’s competence to carry out her procedure. | A |
Spontaneous closure of surgical fistulae does occur, although it is not possible to establish the rate with any certainty; if a vesicovaginal fistula is diagnosed within six weeks of surgery, indwelling catheterisation can be considered for a period of up to 9 weeks (i.e. up to 12 weeks after the causative event).

Attention should be given as appropriate to skin care, nutrition, rehabilitation, counselling and support prior to and following fistula repair.

Perioperative antibiotic prophylaxis should follow local policies.

There is no benefit from mechanical or laxative bowel preparation prior to colonic surgery; it is reasonable that this recommendation be extrapolated to apply to fistula surgery.

There is no proven benefit to delayed repair of vesicovaginal fistula; the timing of repair should be tailored to the individual patient and surgeon requirements, but can be undertaken as soon as any oedema, inflammation, tissue necrosis, infection are resolved.

There are no high quality data to indicate greater cure rates for any one technique as compared to others; level 3 evidence indicates similar success rates for vaginal and abdominal, and for transvesical and transperitoneal approaches.

Surgeons involved in fistula surgery should have appropriate training, skills, and experience to select an appropriate procedure for each patient.

The majority of vesico-vaginal and all urethra-vaginal fistulae can be repaired vaginally, regardless of aetiology.

Where concurrent ureteric re-implantation or augmentation cystoplasty are required, the abdominal approach is necessary.

A variety of interpositional grafts can be used in either abdominal or vaginal procedures, although there is little evidence to support their use in any specific setting.

Conventional and robotically-assisted laparoscopic approaches have both been shown to be feasible in selected cases; the indications for, or optimal patient for these techniques is not yet clear.

A period of continuous bladder drainage is crucial to successful fistula repair; there are no high level data to support any particular type, route, or duration of catheterisation; current practice suggests: 10-14 days for simple and/or post-surgical fistulae; 14-21 days for complex and/or post-radiation fistulae.

VI. MANAGEMENT OF RADIATION FISTULA

The literature relating to the management of radiotherapy-associated fistula is again limited in quantity and quality. Forty-nine papers of possible relevance were identified, of which only 35 contained any relevant material. Seven systematic reviews were identified, although none contained information of direct relevance. No randomised trials and only four non-randomised cohort studies of relevance were identified. All other identified material comprised case series or individual case reports or procedure descriptions, and represent level 3 or 4 evidence.

Injury to the gastrointestinal or urinary tracts may arise following therapeutic radiation, with the incidence of complications increasing when the dose exceeds 50 Gy. The obliterate endarteritis associated with ionizing radiation in therapeutic dosages may proceed over many years and may result in fistula formation long after the primary malignancy has been treated.27, 73 The associated devascularisation in the adjacent tissues means that conventional surgical repair has a high likelihood of failure, and may also result in re-presentation with several fistulae over a period of many years. In those cases where abdominal repair surgery or urinary diversions are undertaken, a high risk of GI anastomotic leak and progressive sepsis has been reported perhaps related either to inadequate resection of irradiated bowel or to damage to other organs at operation.74 All these factors often make the management of post-radiation fistulae more challenging than that of post-surgical or even obstetric fistulae. Modified surgical techniques are often required, and indeed, where the same techniques have been applied to both surgical and post-radiation fistulae, the results from the latter have been consistently poorer.236, 296, 297 Spontaneous healing seems rarely if ever to occur.27, 51) and only one case report was identified, of a radiation fistula presenting 22 years after initial treatment, in which healing occurred following cauterisation (for biopsy) and prolonged catheter drainage.298

1. DIVERSION PROCEDURES

Because of the wide field abnormality surrounding many radiotherapy-associated fistulae, several authors have suggested that urinary and/or faecal diversion should be seen as the treatment of choice in such cases.50, 77, 78, 236) Others have employed...
a routine policy of preliminary urinary and faecal diversion, with later undiversion in selected cases. In a non-randomised cohort of recto-urethral fistula repairs, Vanni et al. reported 100% closure at first operation in 35 non-irradiated cases, compared to 84% in 39 irradiated cases. Additionally, 97% of the non-irradiated cases subsequently underwent 'undi
version', whereas 31% of the irradiated cases required permanent faecal diversion due to a non-compliant rectum or severe sphincter dysfunction.

Some authors have emphasised the place of repair in carefully selected cases of radiotherapy-associated fistulae. Of 36 radiation/malignant fistulae in the series reported by Hilton, although 11 declined surgery or died before treatment, and 6 underwent primary diversion, of the 19 (53%) who underwent repair, 18 (95%) were closed at first operation. Finally, some seem to take the view that diversion has little or no place in the management of radiation-induced vesicovaginal fistula in particular. Of 216 radiation-induced fistula managed over a 47 year period by Pushkar et al., 210 underwent a vaginal and 6 an abdominal repair procedure (although it should be noted that this is a retrospective case series, and whilst not stated in the paper, it is possible that other patients not included in this review actually underwent diversion). It should be noted, however, that with this almost exclusive use of the vaginal repair procedure, whilst a cumulative closure rate of 80% was eventually achieved after four or more operations, only 48% were closed after first repair, 40% were closed following a second operation, 52% following a third operation, and 35% following a fourth operation.

In view of the anastomotic problems associated with radiation-induced fistula, the transverse colon has often been favoured over ileum as a conduit in this context, to avoid the risk of employing irradiated bowel and distal ureter.(300-302) Whilst these benefits seem clear, it should be noted that high perioperative morbidity (37%) and re-operation rates (20%) have been reported from this procedure.

As an alternative to the latter operation, where both urinary and faecal diversion are proposed, Hampson et al. described the technique of left colic urinary diversion with distal transverse end colostomy. This technique allows a shorter operation time, and avoids the necessity for an intestinal anastomosis. In patients wishing to remain sexually active following such procedures, the residual bladder or rectal wall may be used to augment the vagina. Where vesicovaginal fistula co-exists with significant bladder contracture following surgery or radiation, an abdominal (transperitoneal) repair might be considered, along with simultaneous ileocystoplasty, or colocystoplasty. Fistula repair concurrently with vaginal reconstruction using sigmoidovaginoplasty has also been described by Verbaey et al. Whilst one might anticipate a very high operative and postoperative morbidity from such complex multiple procedures, the outcome in the very small numbers reported appears to have been good.

2. REPAIR TECHNIQUES

Several different techniques for the vaginal repair of fistulae have been reported, although the methods of 'flap-splitting' or dissection and repair in layers (variously attributed to Hayward, Collis & Lawson Tait),(229) and partial colpocleisis,(171) have been the most widely advocated in radiation-associated fistulae. Where patients do not wish to maintain sexual function, complete colpocleisis may be used to good effect.(309) In a non-randomised cohort study, Hilton reported anatomical closure by colpocleisis in 94.7% of radiation-associated cases, compared to 96.1% from a range of repair procedures in fistulae of surgical aetiology.(27)

The technique of sigmoid exclusion or isolation has been described for the management of radiation-associated colo- or entero-vesical and colo- or entero-vaginal fistulae.(310, 311) Although the results have generally been good, with the avoidance of a permanent urinary or faecal stoma, Levenback et al. reported poorer results than following resection of the affected bowel, largely related to bleeding from the isolated segment, and bacterial infection.

3. INTERPOSITION GRAFTS

Several techniques have been described to reinforce fistula repair in different sites depending on the type of repair undertaken. These include the Martius bulbocavernosus muscle and labial fat graft, a gracilis muscle or myocutaneous graft, omental pedicle grafts, and peritoneal flaps. Whilst there is no high level evidence to support the use of these techniques, the interposed tissue has been presumed to help by creating an additional layer in the repair, to fill in 'dead space' and reduce the risk of haematoma formation beneath the repair, to bring in a new blood supply into the area, and to reduce scarring. For each of these hypotheses, interposition grafts might be considered to have their greatest benefit in the repair of radiation-associated fistulae.

At abdominal repair of vesicovaginal or rectovaginal fistulae, the use of a pedicled omental graft has been widely advocated.(284, 312) The omentum is dissected from the greater curve of the stomach and rotated down into the pelvis on either the right or left gastro-epiploic arteries; this may be used at any transperitoneal procedure, but has its greatest potential advantage in radiation-associated fistulae.

The role of interposition flaps in trans-abdominal repair procedures was reviewed by Evans et al.(286) They reported 37 patients with fistulae of largely surgical aetiology, of whom 12 of 12 treated employing an omental or peritoneal interposition flap were cured, compared to 16 of 25 managed without interposition (64%); this finding was consistent for fistulae.
of both benign and malignant aetiology. Although their cases were not randomised, and the authors acknowledge that their overall cure rate (75%) was rather lower than many series, nevertheless, they concluded that an interposition flap should be recommended, when a trans-abdominal repair is undertaken, particularly when the repair is performed by a less experienced surgeon.

Although widely employed in the context of obstetric fistula repair in the past, there is no high level evidence to support the use of the Martius graft in this context and there seems to be a general move away from it amongst obstetric fistula surgeons. (Fig. 10) One small non-randomised cohort study reported benefit in patients with multiple or recurrent fistulae, based on a univariate analysis,(282) another reported no advantage to the experienced obstetric fistula surgeon.(313) In the series of fistulae of all aetiologies from UK reported by Hilton, the fistula closure rate was not significantly different between those procedures where an interposition graft (omental or labial) was (92.0%) or was not (96.1%) used in the repair (p=0.264; Fisher’s Exact test).(27)

Figure 10. Martius labial fat graft passed subcutaneously to overlie fistula repair (combined with complete colpocleisis)

In the situation of vaginal repair of radiation-associated fistula Pushkar et al. strongly advocate the use of the labial fat graft interposed at fistula repair;(72) Hilton advocates its use to fill ‘dead space’ in the lower vagina at complete colpocleisis.(27, 309) With the former technique closure at first operation was 48%, (72) with the latter 95% closure at first operation is described.(27)

Labial skin grafts have also been employed in the repair of radiation-associated fistulae, either as an interposition, or replacement for sloughed or indurated vaginal skin. Labia minora flaps, with the outer surface de-epithelialised,(314) and labia majora flaps,(315, 316) have both been described in this context.

Muscle and myocutaneous grafts have also been employed as interposition in fistula repair. These tend to be very bulky grafts, and are perhaps best used therefore in circumstances of extreme tissue loss. The technique of rectus abdominis flap interposition was described in one series of 10 patients, although none of their cases were radiotherapy related.(317) Viennas et al. reported one case of a radiation-induced vesicovaginal fistula repair by this technique.(291) Gracilis muscle along with selective use of a buccal mucosal overlay graft has been used in recto-urethral fistulae, with 84% cure in radiation-associated cases.(299)

4. OTHER MANAGEMENT APPROACHES

In patients with intractable urinary incontinence from radiation-associated fistula, percutaneous nephrostomy or ureterostomy might be considered.(78) This may in some cases extend life perhaps inappropriately, and where life expectancy is deemed to be very short, ureteric occlusion might be more appropriate. Several methods have been described, including the insertion of coils,(318) coils with gelatin sponge,(319, 320) clips,(321) nylon plugs with injection of polidocanol,(322) Isobuty1-2-cyanoacrylate,(323) and balloons.(323-326) These were reviewed by Avritscher et al. with success rates ranging from 50% to 100% for the different methods, and with an overall success of 77% in 150 cases from nine papers reviewed.(327)

MANAGEMENT OF RADIATION FISTULA | 2173
The literature relating to the management of urinary fistulae involving the gastro-intestinal tract is limited in quantity and quality. Forty-six papers of possible relevance were identified, of which 39 contained any relevant material. One systematic review was identified, albeit of only indirect relevance, and with no mention of fistulae. (213) A single non-systematic review of the management of internal fistulae in Crohn’s disease was identified; (328) this included only a single randomised trial, (329) although this did not include patients with urinary fistulae. No further randomised trials or cohort studies of relevance were identified, either from within the review, or independently. One decision analysis model, (330) 26 case series and 10 individual case reports or procedure descriptions were found, including a total of 852 patients.

2. NON-SURGICAL MANAGEMENT

In the context of colo-vesical fistulae associated with diverticular disease, a surgical approach is most commonly advocated. One non-randomised cohort of 30 patients included six who did not undergo surgery, four of whom remained well for periods of up to 14 years; of the 24 who underwent surgical treatment, five (21%) died in the postoperative period. (331)

Ileo-vesical fistula in Crohn’s disease may be managed with antibiotics, nutritional support, often including total parenteral nutrition, and various combinations of immunomodulatory agents; in a non-systematic review of the management of internal fistulae in Crohn’s disease, Levy & Tremaine describe the drugs that have been reported to close internal fistulae partially or completely including azathioprine, 6-mercaptopurine, mycophenolate mofetil, cyclosporine A, tacrolimus, and infliximab. (328)

One case series of 500 patients with Crohn’s disease included 17 with entero-vesical fistulae; all received sulfasalazine, and most were treated with corticosteroids and antibiotics intermittently, and eight in addition received 6-mercaptopurine. Although it is not clear that their fistulae closed completely, six continued on medical treatment alone for several years. (120)

Present et al. reported a placebo controlled randomised trial of the tumour necrosis factor α (TNFα) neutralising agent infliximab, a murine/human chimeric monoclonal antibody that binds both the soluble subunit and the membrane-bound precursor of TNFα, in patients with externally draining fistulae associated with Crohn’s disease. (329) Adverse events were very common, but complete resolution of all fistulae was achieved in 55%, and 50% reduction in fistulous drainage was achieved in 68% of patients on 5mg infliximab. This latter study did not include intestino-vesical fistulae, although a case of successful use of infliximab in an ileo-vesical fistula has been reported. (199)

3. SURGICAL MANAGEMENT

The most frequently advocated surgical approach to colo-vesical fistula in diverticular disease has been sigmoid resection with primary colorectal anastomosis, and closure of the bladder. Dissection of the fistula track followed by closure of the bladder and bowel, with interposition of omentum, but without resection was described in three patients by Lewis & Abercrombie. (332) This approach should perhaps be reserved for cases with minimal diverticular disease in otherwise healthy bowel, where, were it not for the presence of the fistula, there would be no indication for colonic surgery.

One series of 74 patients described a technique in which only visible or palpable full-thickness defects in the bladder were repaired; otherwise the bladder was not repaired, but simply drained by indwelling catheter for one week following sigmoid colectomy (in diverticular disease) or small bowel resection (in Crohn’s disease). (127) At median 6 month follow-up there was a single recurrence of a colo-cutaneous/vesico-cutaneous fistula, but no recurrence of the colovesical fistulae. Other authors have similarly advocated leaving the bladder unrepaired in patients with Crohn’s ileo-vesical fistulae, to heal by secondary intention with catheter drainage alone. (123, 333)

The main contention in the management of intestino-vesical fistulae has been over the feasibility and role of a one-stage management with resection of the affected bowel segment, primary anastomosis, and closure of the bladder, as compared to a two- or three-stage approach.

The authors of many case series have advocated a one-stage approach in the majority of cases, but have indicated that this should be limited to those patients whose nutritional state is good, and where there is no evidence of severe inflammation, radiation injury, advanced malignancy, intestinal obstruction, major medical problem, or advanced age. (126, 129, 130, 132, 334, 335) More recent series have tended to imply a greater advocacy of the one-stage approach; Garcea et al. in a series of 90 patients with colo-vesical fistula reported primary anastomosis in 61/65=94% of cases where left colon resection was undertaken. (128) Balaguera et al. argue against diverting colostomy or Hartmann’s procedure as being unnecessary, and possibly bringing additional morbidity. (336) Several reports have described a laparoscopic approach to one-stage treatment of colo-vesical fistulae, including a total of 30 patients. (131, 201, 337, 338) The overall conversion rate was seen to be higher for fistulae involving the duodenum, vagina.
and sigmoid colon, than those involving the bladder (10%), although a low threshold for conversion to open surgery was advocated in one series.(131)

In addition to the above criteria, it is intuitive that the more complex a fistula track, the more relevant a phased approach to treatment becomes. Shackley et al. described a series of 10 patients with highly complex fistulae involving between 3 and 6 separate organs/surfaces.(202) They advocate a three-stage multidisciplinary management package, involving: (1) an acute stage involving proximal defunctioning and distal drainage of both the gastrointestinal and urinary tracts to isolate the fistula, together with the eradication of sepsis; (2) a recovery stage consisting of total parenteral nutrition, organ support, radiological planning of surgical reconstruction and intensive nursing; (3) joint urological and gastrointestinal reconstructive surgery, when the patient was stable, nutritionally replenished, and sepsis was controlled. Whilst the mean time to reconstruction was 5 (1-20) months, the fistulae were treated successfully in all patients, with functional restoration in four, and/or diversion of the gastrointestinal and urological tracts in six.(202)

V. MANAGEMENT OF URETERIC FISTULA

1.1. General Principles

The relevant clinical principles are related to prevention, diagnosis, management, and after care. (339) Patients at higher risk of ureteric injury such as those undergoing complicated childbirth, radical or repeated pelvic surgery, or surgery following pelvic radiotherapy require experienced surgeons who can identify and protect the ureter and its blood supply to prevent injury and also recognise injury promptly when it occurs. Immediate repair of any intraoperative injury should be performed observing the principles of debridement, adequate blood supply and tension free anastomosis with internal drainage using stents.(340) Delayed presentation of upper tract injury should be suspected in patients whose recovery after relevant abdominal or pelvic surgery is slower than expected, if there is any fluid leak, and if there is any unexpected dilatation of the pelvi-calyceal system. Fluid should be sent for creatinine determination to differentiate serous from urinary leak. Repair of such cases should be undertaken by an experienced team and may consist of conservative management with internal or external drainage, endoluminal management using nephrostomy and stenting where available, and early (<3 months) or delayed (>6 months) surgical repair when required.(341) Surgery should again adhere to the standard principles of tissue repair and safe anastomosis. Functional and anatomical imaging should be used to follow up patients after repair to guard against late deterioration in function of the affected renal unit. These general aspects of care of patients with trauma to the upper tract and subsequent fistula formation are covered in standard textbooks of urology and guideline documents.(340, 341) This review will concentrate on developments in the past six years.

1.2. Evidence Quality

A total of 127 abstracts were screened which were categorised as being not relevant (26), cases reports
without useful information (63) and for possible inclusion (38). After review of full text, 27 were selected for the review and 11 rejected due to duplicate information (n=7) and no relevance (n=4). Four further possible papers were identified from the reference lists of included articles of which two were included in the review. The selected papers (29) included one poor quality randomised trial (342), one poor quality quasi-randomised trial (343), one high-quality population case control study(5), one registry study(109), one systematic review(344), one cost analysis(345), 14 cases series, 8 case reports, and one unstructured review.

1.2.1 Urinary Leak after Renal Preservation Surgery

A large case series identified urinary fistula, defined as urinary drainage from a drain site more than 14 days post-operatively, in 4% (45/1118) of patients undergoing partial nephrectomy.(346) This was associated with larger tumours, higher blood loss, and longer ischemia time, but not the mode of surgery (laparoscopic versus open). The majority resolved without intervention but 30% required ureteric stent insertion or percutaneous drainage. Another large series 752 patients showed that 21 (2.8%) experienced urinary leakage.(347) four of the 21 patients with urinary leakage had spontaneous resolution, one patient underwent nephrectomy, and 16 patients were treated by retrograde ureteral stents insertion. On univariate analysis, hilar renal masses (p < 0.04) and higher preoperative creatinine levels (p < 0.01) were found to be associated with higher rates of urinary leakage. None of these variables was significant on a multivariate analysis. Review of the urinary leakage rate over time revealed it has been constantly decreasing over time, from 4% in early cases to 1.3% among the most recent ones, suggesting that the decrease in incidence is related to the improved surgical skills, rather than to differences in tumours’ or patients’ characteristics. A poor quality quasi-randomised study involving 16 patients with persistent leakage after pelvi-calyceal surgery despite stenting found that use of intranasal desmopressin 40 µg daily resulted in a shorter time to resolution of leak compared to control.(343)

1.2.2 Urinary Leak After Renal Transplantation

A case series from Brazil observed a fistula rate of 2.9% (31/1046) presenting at a mean of 28 (1-131) days following transplantation predominantly due to distal ureteric necrosis and with most cases requiring open repair.(348) Fistula occurred more commonly in patients with diabetes and was associated with lower graft survival and two deaths from sepsis. A case series from China observed fistula development in 3.5% (43/1223) of patients presenting at a mean (range) of 6 (3-20) days following transplantation again primarily due to necrosis of the distal transplanted ureter.(349) Open intervention with re-implantation of the ureter into the bladder or native ureter was required in 34 patients, with one other patient requiring transplant nephrectomy. The occurrence of a fistula did not appear to prejudice graft or patient survival. Initial implantation of the transplant ureter into the native ureter appeared to result in a lower rate of fistula. A further case series form Serbia found a fistula rate following renal transplantation of 2.2% (5/224) and all required open repair.(350)

1.2.3 Urinary Fistula Following Percutaneous Renal Surgery

Case reports of ureterocolic fistulae occurring after renal cryotherapy, and gunshot trauma all resolved with insertion of ureteric stent.(351, 352) This is in line with previous accounts of this complication following percutaneous nephrolithotomy.(353)

1.2.4 Uretero-arterial Fistula

A systematic literature review found reports of 139 cases of uretero-arterial fistula published between 1999 and 2008.(344) All patients presented with haematuria with 25% also having other urinary symptoms or back pain. Virtually all cases had a relevant past surgical history particularly pelvic cancer surgery (54%) and arterial surgery with graft insertion (31%), and 61% had a ureteric stent in situ. The major avoidance affected the iliac segment and pre-operative imaging did not always diagnostic. A total of 18 (13%) patients died as a result of the fistula. Many vascular and urologic interventions were used either alone or in combination. Later cases suggested that endovascular repair of the arterial defect gave the best results with lower mortality. Another, more recent case series of 20 patients also showed a high mortality of 10 – 20% but did not find any difference in outcome between open and endovascular graft insertion techniques.(354)

1.2.5 Urerovaginal Fistula

Ureterovaginal fistula occurring in the early post-operative phase predominantly after hysterectomy is the most frequent presentation to urologists of upper urinary tract fistula. A recent retrospective cohort study by Kiran et al. studied 377 073 women who underwent hysterectomy between 2001-2010, of whom 1792 (0.5%) experienced a ureteric injury.(355) In both benign and malignant groups the rate of injury was higher in 2006-2010 than 2001-2005. The proportion of women having a ureteric injury was similar for ovarian and cervical cancer (1.9-4.0% depending on type of procedure). For benign conditions, the rate of injury tended to be lower, typically <1%. Women with endometriosis had the highest risk among this group (1.7% following total abdominal hysterectomy; 95% CI 1.4-2.0%). A randomised study involving 3,141 women undergoing open or laparoscopic gynaecological surgery lasting > 30 min found that the incidence of ureteric injury after prophylactic insertion of ureteric stents (1.2 % (19/1583)) was similar to control (1.1% (17/1558)).(342) A previous cost analysis from the United States perspective suggested
stenting was only worthwhile if the risk of injury was > 3.2%.(345) If injury does occur, many cases, even those with bilateral injury, can be managed by endoscopic techniques. (356) (Figure 11)

Figure 11. Conservative management of bilateral lower ureteric injury. Retrograde ureterogram showing successful cannulation of left ureter by guide wire and successful placement of right ureteric stent.

The use of ureteric stenting in patients with ureterovaginal fistulae was reported in 11 studies, including 126 patients in total;(357-367) this resulted in closure in 63 cases altogether. Success rates were between 6% and 100%, although the overall closure rate across all series is calculated at 50% ± 18% (see table 6).

Where retrograde stenting proves impossible, percutaneous nephrostomy and antegrade stenting might be considered if there is some degree of pelvicalyceal dilatation. Ureteroscopy may also be helpful,(362, 366) and a technique for combined antegrade and retrograde ureteroscopic cannulation has been reported.(359) In one report all cases of uretero-vaginal fistula were managed by temporary diversion using a percutaneous nephrostomy followed by delayed repair 4-6 weeks later,(186) and a similar approach was taken in the management of one uretero-uterine fistula.(368)

If endoluminal techniques fail or result in secondary stricture, the abdominal approach to repair is standard and may require end-to-end anastomosis, re-implantation into the bladder using psoas hitch or Boari flap, or replacement with bowel segments with or without reconfiguration. Recent case series suggest that this standard surgery can be performed safely and with reasonable operative times using laparoscopic or robotic techniques if the relevant skills and facilities are available.(369-371) A recent case report has suggested that open repair through the vagina is possible if abdominal access is problematic.(372)
1.2.6 Ureteric Fistula Associated the Terminal Phase of Pelvic Malignancy

Urinary leakage is very distressing for people dying of advanced pelvic malignancy but palliation by open diversion may be associated with a high rate of complications. Recent case series have described the technique of occlusion of the distal ureter with coils or other devices using an antegrade approach combined with chronic urinary diversion using nephrostomy tubes.\(^\text{373-375}\) Natarajan et al reported successful management of five patients with two requiring repeat embolization but all achieving good palliation until death without adverse effects.\(^\text{373}\) Shindel et al reported on 29 patients with bothersome urinary fistula despite chronic nephrostomy drainage, and poor performance status.\(^\text{374}\) In all cases palliation of the urinary leakage was achieved. The majority of patients (23/29) died of their underlying cancer at a mean of eight months after the procedure. Three patients with benign disease subsequently underwent definitive surgical diversion with the remaining two lost to follow up. Coil migration was seen in one patient without serious consequence and there were no other complications specific to the embolisation. Kim et al used the technique to temporally palliate five women with ureterovaginal fistula prior to delayed definitive repair.\(^\text{375}\)

The algorithm for uretero-vaginal fistula can be found in figure 12.

FIGURE 12. ALGORITHM FOR MANAGEMENT OF IATROGENIC URETERIC FISTULAE

HISTORY
Extra-urethral vaginal urinary leakage and/or signs of ureteric obstruction

CLINICAL ASSESSMENT
Clinical examination Urethro-cystoscopy Imaging (Xray/CT/MRI, US)
Evaluate upper urinary tract obstruction

PRESUMED DIAGNOSIS
Ureterovaginal fistula

MANAGEMENT*
Endoluminal technique (stenting, nephrostomy) for at least 6 weeks
Unable to stent (initially)...
Re-evaluate for fistula closure, ureteric obstruction
Persisting fistula or ureteric obstruction
Healed
Ureteric reimplantation (open, laparoscopic or robotic)

Long term follow-up for stricture and hydropehrosis

* Consider CONTINENCE PRODUCTS for temporary support during treatment
IX. MANAGEMENT OF URETHRO-VAGINAL FISTULA

1. INTRODUCTION

Urethrovaginal fistulae are a rather rare complication of some surgical and medical conditions or treatments. Most of the literature consists of small retrospective series or case reports. There are no randomised prospective trials.

Table 7: Etiology of Urethrovaginal Fistula

Excluding obstetric aetiologies, in the developing world, urethrovaginal fistula may occur as a result of obstructed labor with or without associated VVF. In industrialized countries urethrovaginal fistula in adults mostly have an iatrogenic aetiology. (See Table 7)

2. AETIOLOGY

In feminising genital reconstructions in children with ambiguous genitalia and surgical repairs of cloacal malformations, urethrovaginal fistula can occur as early or late complications. (376) (377, 378) (379, 380) Also in transsexual adults undergoing female to male reconstruction, urethrovaginal fistulae have been reported. (381)

In the surgical treatment of stress incontinence in women with bulking agents (382, 383) or synthetic slings several cases of urethrovaginal fistula have been reported. (384-387) (388-391) (see Figure 13)

Figure 13. Urethro-vaginal fistula following mid-urethral tape procedure for SUI

Even conservative treatment of prolapse with pessaries can lead to the formation of fistula, if these pessaries are neglected for an extended period of time, although fistula formation after only 2 weeks of pessary use has been described. (28, 392) (see Figure 14)

Figure 14. Fistula in anterior vaginal fornix following use of shelf pessary for utero-vaginal prolapse

Irradiation complications can also result in the formation of urethrovaginal fistula. (405)

3. DIAGNOSIS

Clinical vaginal examination is often sufficient to diagnose the presence of an urethrovaginal fistula. Urethroscopy and cystoscopy can be performed to assess the extent and location of the fistula. In cases of difficult diagnosis, voiding cystourethrogram (VCUG) or ultrasound can be useful. (406) Double balloon urethrography is the classic examination to show urethral diverticulum and urethrovaginal fistula, but 3D MRI or CT scan is becoming utilized more widely. (407-409)
4. SURGICAL REPAIR

Several techniques for urethrovaginal fistula closure have been described. A vaginal approach is mostly used. Surgical correction intends to create a continent urethra that permits volitional, painless, and unobstructed passage of urine. Depending on the size, localisation and aetiology of the fistula and the amount of tissue loss urethral reconstruction techniques may be necessary to restore the urethra and to achieve post-operative continence. (393)

4.1. Vaginal Approach

Goodwin described in his series that a vaginal approach yielded a success rate of 70% at first attempt and 92% at second attempt, but that an abdominal approach only leads to a successful closure in 58% of cases. A vaginal approach required less operating time, had less blood loss and a shorter hospitalisation time. (410)

Most authors describe surgical principles that are identical to those of vesicovaginal fistula repair: identifying the fistula, creation of a dissection plane between vaginal wall and urethra, watertight closure of urethral wall, eventual interposition of tissue, and closure of the vaginal wall. Primary closure rates of 53%-95.4% have been described (see table 8). Pushkar et al. described a series of 71 women, treated for urethrovaginal fistula. 90.1% of fistulae were closed at the first vaginal intervention. Additionally 7.4% were closed during a second vaginal intervention. Despite successful closure, stress incontinence developed in 52%. The stress incontinent patients were treated with synthetic or autologous slings and nearly 60% became dry and an additional 32% improved. Urethral obstruction occurred in 5.6% and was managed by urethral dilation or urethrotomy. (411)

Advancement flaps of vaginal wall can be used to cover the urethral suture line. In some cases more advanced methods are used to close or to protect the urethral closure.

In cases of difficult dissection and visualisation, urethral sectioning has been advocated. (412) This technique is also being used in the repair of complex urethral diverticula. (413) Fistulae that are located in the distal third of the urethra may also be marsupialized without compromising the continence mechanism. (414) Distal urethrovaginal fistula may be entirely asymptomatic in which case repair is unnecessary.

Blaivas advocates that vaginal flaps are usually the best option in dealing with urethral reconstruction, next to the possibility of offering anterior or posterior bladder flaps. Options for vaginal repair of fistula include primary closure, peninsula flaps, bilateral labial pedicle flaps, and labial island flaps. Outcomes are optimised by using exacting surgical principles during repair and careful postoperative management by an experienced reconstructive surgeon. (393) Patients with urethrovaginal fistulae due to synthetic slings, should be counselled that de novo or persisting stress incontinence can occur and that additional conservative or surgical treatment may be necessary. (389, 390, 415)

4.2. Labial and Vaginal Flaps and Neourethra

The simplest flap is a vaginal advancement flap. (416) Labial tissue can be harvested as a pedicled skin flap. This labial skin can be used as a patch to cover the urethral defect, but can also be used to create a tubular neo-urethra. (417, 418) The construction of a neo-urethra has mostly been described in traumatic aetiologies. In some cases a transpubic approach has been used. (419) The numbers of patients reported are small and there are no data on the long-term outcome of fistula closure and continence rates. The underlying bulbocavernosus tissue can be incorporated in the pedicled flap and probably offers a better vascularisation and more bulking to the repair. This could allow a safer placement of a sling afterwards, in those cases where bothersome stress incontinence would occur postoperatively. (420, 421)

4.3. Martius Flap

While in obstetrical fistula repair, it was not found to have any benefit in a large retrospective study in 440 women, the labial bulbocavernosus muscle / fat flap by Martius is still considered by some to be an important adjunctive measure in the treatment of genitourinary fistula where additional bulking with well vascularised tissue is needed. (422) Rangnekar et al. report on 12 patients with urethrovaginal fistula, of whom eight were treated with a Martius flap and four with a conventional repair. Only one out of the eight had a fistula recurrence, while three out of four of the conventional repairs broke down; it should be noted however that these cases were not randomised between surgical techniques. (423) Punekar et al. described 15 patients with complex and recurrent fistula, using the skin island flap modification with excellent results. (424) Radoopoulos published a small series of five recurrent and complex urethrovaginal fistulae that all healed using a Martius flap. (425) The series of non-obstetrical aetiology are small and all of them are retrospective. There are no prospective data, nor randomised studies. (426, 427) The indications for Martius flap in the repair of all types of fistula remain unclear.

4.4. Rectus Muscle Flap

Rectus abdominis muscle flaps have been described by some authors. (428, 429) Transvaginal urethrovaginal fistula closure was performed followed by a pedicled rectus abdominis muscle flap interposed between the fistula closure and vaginal suture line. The muscle flap was based on the inferior epigastric vessels, and provided additional support to the urethra, bladder neck and bladder base. Urethrovaginal fistulae...
repair with the rectus abdominis muscle flap was successful in all cases without recurrence. Of the patients five (83%) were continent and able to void to completion at a mean follow-up of 23 months (range two to 66).

4.5. Other Interposition Material

A range of non-traditional interposition flaps and grafts have been reported by several authors. All of the publications only report on small patient numbers without long term outcomes or continence data.

Golomb et al. reported the use of a fascial patch, while adding a rectus fascia sling to a urethrovaginal fistula repair. Omentum is extensively used in abdominoplasty approaches to VVF, but Janez et al. used it during a vaginal approach in three patients with good results.

The gracilis muscle can be used as well, although the experience is limited. The graciloplasty was described by Ingelman-Sundberg in 1947 and has been adapted by other surgeons in the treatment of fistula. The number of patients reported is low as is the quality of the evidence.

Non-autologous material has been used as well. Lowman et al. described the use of porcine dermis interposition and a synthetic sling in an irradiated patient. Other biodegradable materials have been used, although the quality of available data is low and insufficient to advocate their use.

A retropubic retrourethral technique has been described by Koriatim. This approach allows a urethrovesical flap tube to be fashioned to form a continent neourethra. Urodynamic studies showed that the proximal vesical and distal urethral components of the neourethra contribute to sphincteric function. For larger fistula an enwrapping technique has been described as well.

7. COMPLICATIONS

Little information can be found on complications after urethrovaginal fistula repair. A short report on four cases by Tehan et al. describes a disappointing experience in the transvaginal repair of these fistulae. These authors advocate a suprapubic bladder flap or bladder tube technique to achieve a functioning urethra. Complications following surgical repair have been fistula recurrence, urethral shortening and retraction, persistent reflux, bladder calculi, and bladder cancer.

8. FOLLOW UP

In most series of urogenital fistula repair, follow-up is of very short duration. Dolan et al. investigated urinary and sexual symptoms and quality of life in a group of 31 women 50 months (median) after successful repair of urogenital fistula using the Bristol Female Lower Urinary Tract Symptom questionnaire. All women had undergone urodynamic investigation prior to their repair surgery, and only 36% had normal findings. Almost all women reported one or more symptoms, and for 65%, these caused at least ‘a bit of a problem’, although 87% said that their urinary symptoms had little or no impact on their quality of life. Symptoms were similar in urethrovaginal and vesicovaginal fistulae and were not significantly associated with prior functional abnormality.

X. GENERAL CONCLUSION

Fistulae can have a devastating impact on the quality of life of women. In developing countries the number of obstetric fistula is still unacceptably high, due to poor peri-natal care in many countries. The experience and skill of several fistula surgeons should become available and transferable to many other surgeons, interested in this field. But more importantly, major efforts are necessary to prevent fistula in those circumstances.

In the developed world, fistulae are less common and the outcome of fistula repairs seems to be reasonable. More prospective research is needed in this field.

INTRODUCTION

1. EVIDENCE ACQUISITION

The unrestricted, fully exploded Medical Subject Heading (MeSH) “interstitial cystitis” (including all related terms as “painful bladder syndrome”, bladder pain syndrome”, or different terms such as “chronic interstitial cystitis”, etc.) were used to thoroughly search the PubMed database (http://www.ncbi.nlm.nih.gov/pubmed) of the United States National Library of Medicine of the National Institutes of Health fro the years 2013-2016. Six hundred seventeen publications in English or with English abstracts were reviewed.

Focus was on clinical trials, randomized controlled trials, meta-analyses, scientific guidelines, and core clinical journals. The literature update this achieved was added to the previously existing database reflected in the 2013 publication that was established according to a similar protocol. (1)

Rating of the level of evidence and grade of recommendation was performed according to the Oxford Scale. The committee believes that the Oxford system for categorizing levels of evidence is primarily relevant only for the sections on treatment which follow. While the committee’s opinions will be expressed, where applicable, regarding evidence and conclusions for other areas, including diagnoses, aetiology, and pathophysiology, use of the Oxford system in this context is more open to interpretation.

2. DEFINITION

Bladder Pain Syndrome (BPS) is a clinical diagnosis that relies on symptoms of pain in the bladder and or pelvis and other urinary symptoms like urgency and frequency. Based on the evolving consensus that BPS probably is strongly related to other pain syndromes like Irritable Bowel Syndrome, Fibromyalgia and Chronic Fatigue Syndrome, the European Society for the Study of Bladder Pain Syndrome (ESSIC) published a comprehensive paper on definition and diagnosis of BPS.(2)

BPS was defined as chronic (>6 months) pelvic pain, pressure, or discomfort perceived to be related to the urinary bladder accompanied by at least one other urinary symptom such as persistent urge to void or frequency. Confusable diseases as the cause of the symptoms must be excluded. Further documentation and classification of BPS might be performed according to findings at cystoscopy with hydrodistension and morphological findings in bladder biopsies. (table 2)

The presence of other organ symptoms as well as cognitive, behavioural, emotional, and sexual symptoms should be addressed.

This definition has been broadly accepted although actual wording differs somewhat (3). Because omitting the name “Interstitial Cystitis” might cause serious problems in different health systems by affecting reimbursement and disability determinations, the name Bladder Pain Syndrome/ Interstitial Cystitis (BPS/IC) could be used in parallel with BPS for the
time being. In this chapter, as in the 2008 Consultation, the term Bladder Pain Syndrome largely replaces the older Interstitial Cystitis term, but the two are essentially interchangeable as there is no accepted definition that clearly delineates the interstitial cystitis syndrome from bladder pain syndrome. The Consultation believes the latter term more appropriately describes the disorder. An argument to move Table 1 Historical definitions of interstitial cystitis

The International Continence Society (4) (ICS) used the term Painful Bladder Syndrome (PBS) defined as “the complaint of suprapubic pain related to bladder filling, accompanied by other symptoms such as increased daytime and night-time frequency, in the absence of proven urinary infection or other obvious pathology”. ICS reserved the diagnosis Interstitial Cystitis (IC) to patients with “typical cystoscopic and histological features”, without further specifying these. It has however been shown, that only a fraction of patients believed by experts to have BPS fulfill this definition (5).

The Hunner lesion phenotype out of the BPS framework and regard it as a separate disorder is made in section 2.

Historically, definitions of IC have moved from a severe inflammatory bladder disease to a condition described primarily by symptoms (table 1). (3)

</tr>
</tbody>
</table>

In the remainder of this chapter the condition will be referred to as bladder pain syndrome (BPS). Some of the older literature may be discussed using the original terminology in the interests of clarity. Logically “interstitial cystitis” should include some form of demonstrable inflammation in the bladder wall, while “bladder pain syndrome” should include pain in the region of the bladder (6). The diagnosis of BPS is based on exclusion of other diseases in the bladder, urethra, and other pelvic organs including the musculoskeletal system. As with other diseases without clear objective diagnostic criteria or pathophysiologi-
mental explanation, countless theories have been put forward without adding much to the delineation or understanding of the disease.

In practice, patients with symptoms of BPS are screened to exclude other relevant diagnoses or confusable diseases (2), and a focused evaluation is performed at the discretion of the physician or centre. This evaluation might include cystoscopy under local or general anaesthesia, bladder distension with registration of bladder capacity and/or the presence of glomerulations and Hunner’s lesion. Bladder wall biopsies might be obtained and evaluated for inflammation, ulcer, fibrosis, mast cells etc. The evaluation might also include urodynamics with registration of bladder capacity, compliance and bladder stability (7). One view of the relationship of BPS with OAB is graphically depicted in figure 1 (8). The 14% incidence of urodynamic detrusor overactivity in the BPS (9) patients is probably close to what one might expect in the general population if studied urodynamically (10).

In the end, these investigations might prove to be normal and the patients are identified as having BPS as a diagnosis of exclusion. The relevance of urodynamic, cystoscopic and histological findings is limited by a lack of consistency in technique, and it is therefore recommended to use the standardisations described by ESSIC (11).

II. HISTORY / NOMENCLATURE / TAXONOMY

1. HISTORICAL NOTES

Recent historical reviews confirm that interstitial cystitis was recognized as a pathologic entity during the 19th century. (12,13) In his textbook Practical Observations on Strangulated Hernia and Some Diseases of the Urinary Organs, Joseph Parrish, a Philadelphia surgeon, described 3 problematic cases of recurrent, severe lower urinary tract symptoms in which he made repeated attempts to locate a bladder stone, which was the most common source for these symptoms in early 19th century America. (14) As Teichman et al have convincingly argued, these patients displayed all of the clinical hallmarks of IC including chronic frequency, urgency, dysuria and pelvic pain in the absence of demonstrable pathology.
Although he used the term repeatedly in his manuscript, Parrish did not elaborate upon the clinical definition of “tic doloureux,” likely because contemporaneous physicians would have been familiar with the concept. However, Parrish attributed the term Tic doloureux to his mentor, Dr. Phillip Syng Physick, who had applied it to patients with severe lower urinary tract symptoms with no discernible etiology, with the most common etiology during the 19th century being bladder stones.

A review of archival material from the Philadelphia College of Physicians indicates that by 1808 Physick had developed a concept of bladder inflammation, a “bladder ulcer,” that produced lower urinary tract symptoms in the absence of bladder stone. (13) Tic doloureux at its time represented a neurological irritation, most often associated with the trigeminal nerve but applicable to other sensory distributions as well, which produced pain and discomfort in the absence of injury or other specific physical findings. In applying the concept of tic doloureux to bladder sensation Parrish was ascribing the paroxysmal lower urinary tract symptoms occurring in patients to an idiopathic process affecting the nerves of the bladder. This sophisticated concept continues to be a prominent component of modern theories of BPS pathogenesis. Furthermore, Tic doloureux allowed him to formulate a diagnosis for those patients who chronically manifested the symptoms caused by a stone (severe frequency, urgency, dysuria and pelvic pain) but had no stone that could be detected. That is, he considered a neuropathic etiology in the absence of any other tangible causes of bladder pain. Clearly, this experience strongly resonates with the contemporary diagnosis of BPS.

50 years after Parrish’s first publication on the condition, Skene used the term interstitial cystitis to describe an inflammation that has “destroyed the mucous membrane partly or wholly and extended to the muscular parietes”. (16) Early in the 20th century, at a New England Section meeting of the American Urological Association, Guy Hunner reported on 8 women with a history of suprapubic pain, frequency, nocturia, and urgency lasting an average of 17 years (17,18). He drew attention to the disease, and the red, bleeding areas he described on the bladder wall came to have the pseudonym “Hunner’s ulcer”. As Walsh observed, this has proven to be unfortunate (19). In the early part of the 20th century, the very best cystoscopes available gave a poorly defined and ill-lit view of the fundus of the bladder. It is not surprising that when Hunner saw red and bleeding areas high on the bladder wall, he thought they were ulcers. For the next 60 years, urologists would look for ulcers and fail to make the diagnosis in their absence. The disease was thought to be a focal, rather than a pancystitis.

Hand authored the first comprehensive review about the disease, reporting 223 cases (20). Many of his epidemiologic findings have held up to this day. His description of the clinical findings bears repeating. “I have frequently observed that what appeared to be a normal mucosa before and during the first bladder distention showed typical interstitial cystitis on subsequent distension”. He notes, “small, discrete, submucosal haemorrhages, showing variations in form…dot-like bleeding points…little or no restriction to bladder capacity.” He portrays three grades of disease, with grade 3 matching the small-capacity, scarred bladder described by Hunner. Sixty-nine percent of patients were grade 1 and only 13% were grade 3. Walsh later coined the term “glomerulations” to describe the petechial haemorrhages that Hand had described (19). But it was not until Messing and Stamey discussed the “early diagnosis” of IC that attention turned from looking for an ulcer to make the diagnosis to the concepts that 1) symptoms and glomerulations at the time of bladder distention under anesthesia were the disease hallmarks, and 2) the diagnosis was primarily one of exclusion (19,21). However, this description was not suitable for defining this disease in a manner that would help physicians make the diagnosis and set up research protocols.

The National Institute of Diabetes, Digestive, and Kidney Disorders (NIDDK) held a major meeting in 1987 with researchers and clinicians from around the world (22). This ultimately resulted in the 1990 Revised NIDDK Criteria: Pain associated with the bladder or urinary urgency, and, glomerulations or Hunner’s ulcer on cystoscopy under anesthesia in patients with 9 months or more of symptoms, at least 8 voids per day, 1 void per night, and cystometric bladder capacity less than 350cc. (23)

In order to validate the criteria, which were designed not for clinical diagnosis, but rather to ensure that patients enrolled in research trials could be agreed upon to have the disease, a database with broad entry criteria was created. The 1997 NIDDK Interstitial Cystitis Database Entry Criteria: Unexplained urgency or frequency (7 or more voids per day), OR pelvic pain of at least 6 months duration in the absence of other definable etiologies (24) Urgency was not defined in the protocol. Participants were given a 10 point scale, and those who scored 2 or higher on self report satisfied the urgency criteria. The protocol was written in 1992, a time when the definition of “urgency” was not a particularly controversial topic. When a comparison of the NIDDK revised criteria with the database entry criteria was performed, it was apparent that up to 60% of patients clinically believed to have interstitial cystitis by experienced clinicians were being missed when the NIDDK research criteria were used as a definition of the disease. (25) With the demise of the NIDDK criteria as an appropriate clinical definition of the disorder, the next decade became an active one from an international standpoint in terms of wrestling with the issues of nomenclature, taxonomy and diagnosis. (26)
A very complete and easily readable summary of the history of bladder pain syndrome was recently published and the interested reader is referred to Jane Meijlink’s superb review of the topic. (27)

2. NOMENCLATURE AND TAXONOMY

The literature over the last 170 years has seen numerous changes in description and nomenclature of the disease. The syndrome has variously been referred to as tic doloureux of the bladder, interstitial cystitis, cystitis parenchymatosa, Hunner’s ulcer, panmural ulcerative cystitis, urethral syndrome, and painful bladder syndrome. (12,15,16,18,28-30). The term “interstitial cystitis,” which Skene is credited with coining and Hunner for bringing in to common usage, is a misnomer; in many cases not only is there no interstitial inflammation, but also, histopathologically, there may be no inflammation at all. (31-34) By literally focusing exclusively on the urinary bladder, the term interstitial cystitis furthermore does not do justice to the condition from both the physician’s and the patient’s perspective. The textual exclusiveness ignores the high co-morbidity with various pelvic, extra-pelvic and non-urological symptoms (35) that frequently precede the onset of the bladder condition. (36)

With the formal definition of the term “painful bladder syndrome” by the ICS in 2002, the terminology discussion became an intense international focal point. (4)

- In Kyoto at the ICICJ in March 2003, it was agreed that the term “interstitial cystitis” should be expanded to “interstitial cystitis/chronic pelvic pain syndrome” when pelvic pain is at least of 3 months duration and associated with no obvious treatable condition/pathology. (37)
- The European Society for the Study of Interstitial Cystitis (ESSIC) held its first meeting in Copenhagen soon after Kyoto. Nomenclature was discussed, but no decision was reached, as the meeting concentrated on how to evaluate patients for diagnosis. (38)
- At the 2003 meeting of the NIDDK titled, “Research Insights into Interstitial Cystitis,” it was concluded that “interstitial cystitis” will inexorably be replaced as a sole name for this syndrome. It

ignores the high co-morbidity with various pelvic, extra-pelvic and non-urological symptoms (35) that frequently precede the onset of the bladder condition. (36)
At the 2004 inaugural meeting of the Multinational Interstitial Cystitis Association in Rome, it was concluded that the syndrome should be referred to as “painful bladder syndrome/interstitial cystitis” or “PBS/IC” to indicate an intellectual and taxonomical hierarchy within the acronym. (39)

The International Consultation on Incontinence in 2004, cosponsored by the ICS and Societe Internationale d’Urologie in association with the World Health Organization, included the syndrome as a part of its consultation. The chapter in the report was titled, “painful bladder syndrome (including interstitial cystitis),” suggesting that the IC formed an identifiable subset within the broader syndrome. Because such a distinction is difficult to define, within the body of the chapter, co-authored by nine committee members and five consultants from four continents, it was referred to as PBS/IC (one inclusive entity). (40)

In June 2006 Abrams and colleagues published an editorial focusing on the nomenclature problem. (41) They noted that: “It is an advantage if the medical term has clear diagnostic features that translate to a known pathophysiologic process so that effective treatment may be given. Unfortunately, the latter is not the case for many of the pain syndromes suffered by patients seen at most pain, gynecological, and urological clinics. For the most part these “diagnoses” describe syndromes that do not have recognized standard definitions, yet imply knowledge of a pathophysiologic cause for the symptoms. Unfortunately the terminology used to describe the condition may promote erroneous thinking about treatment on the part of physicians, surgeons and patients. These organ based diagnoses are mysterious, misleading and unhelpful, and can lead to therapies that are misguided or even dangerous.” The editorial went on to note that a single pathologic descriptive term (interstitial cystitis) for a spectrum of symptom combinations ill serves patients. The umbrella term “painful bladder syndrome” was proposed, with a goal to define and investigate subsets of patients who could be clearly identified within the spectrum of PBS. It would fall within the rubric of chronic pelvic pain syndrome. Sufferers would be identified according to the primary organ that appears to be affected on clinical grounds. Pain not associated with an individual organ would be described in terms of the symptoms.

One can see in this the beginnings of a new paradigm that might be expected to change the emphasis of both clinical and basic science research, and that removes the automatic presumption that the end-organ in the name of the disease should necessarily be the sole or primary target of such research.

At the major biannual IC research conference in the fall of 2006, held by the National Institute of Diabetes, Digestive, and Kidney Disorders (Frontiers in Painful Bladder Syndrome/Interstitial Cystitis), the ESSIC group was given a block of time in which to present their thoughts and conclusions. Because PBS did not fit into the taxonomy of other pelvic pain syndromes such as urethral or vulvar pain syndromes, and because IC is open to different interpretations, ESSIC suggested that Painful Bladder Syndrome be redesignated as Bladder Pain Syndrome (BPS), followed by a type designation. BPS is indicated by two symbols, the first of which corresponds to cystoscopy with hydrodistention findings (1, 2, or 3, indicating increasing grade of severity) and the second to biopsy (A, B, and C, indicating increasing grade of severity of biopsy findings) (Table 2). Although neither cystoscopy with hydrodistention nor bladder biopsy was prescribed as an essential part of the evaluation, by categorizing patients as to whether either procedure was done, and if so, the results, it is possible to follow patients with similar findings and study each identified cohort to compare natural history, prognosis, and response to therapy. (2As Baranowski et.al. conceived it in early 2008 (42), BPS is thus defined as a pain syndrome with a collection of symptoms, the most important of which is pain perceived to be in the bladder. IC is distinguished as an end-organ, visceral-neural pain syndrome, whereas BPS can be considered a pain syndrome that involves the end-organ (bladder) and neuro-visceral (myopathic) mechanisms. In IC, one expects end-organ primary pathology. This is not necessarily the case in the broader BPS.
A didactically very demonstrative way to conceptualize the dawning shift in conception of the condition is with the drawing of a target (Fig 2). There may be many causes of chronic pelvic pain. When an etiology cannot be determined, it is characterized as pelvic pain syndrome. To the extent that it can be distinguished as urologic, gynecologic, dermatologic, and the like, it is further categorized by organ system. A urologic pain syndrome can sometimes be further differentiated on the site of perceived pain. Bladder, prostate, testicular, and epididymal pain syndromes follow. Finally, types of BPS can be further defined as IC, or simply categorized by ESSIC criteria. Patient groups have expressed their concerns with regard to any nomenclature change that potentially drops the term “interstitial cystitis” because the U.S. Social Security Administration and private insurances recognize IC but not the term BPS, and benefits potentially could be adversely affected. Whether the term “interstitial cystitis”, as difficult as it is to define and as potentially misleading as it is with regard to aetiology and end-organ involvement, should be maintained in the context of bladder pain syndrome, is a subject of ongoing controversy.

Taxonomy and nomenclature in Japan, Korea, and Taiwan use the umbrella term of “frequency/urgency syndrome” characterized by frequency (frequent voiding) and urgency (strong desire to void). It is an inclusive term incorporating overactive bladder syndrome (OAB), hypersensitive bladder syndrome (HSB), and other conditions that are associated with frequency and urgency. Urgency in OAB is characterized by sudden onset and/or fear of leakage, while urgency in HSB is of a persistent nature and is associated with the fear of pain. OAB-wet is a subgroup of OAB. Painful bladder syndrome (PBS) is a subgroup of HSB with pain. Interstitial cystitis is one of the diseases manifest by frequency/urgency and overlaps with HSB and PBS.[11,44,45] (figure 3)

The American Urological Association refers to the syndrome under consideration as “interstitial cystitis/bladder pain syndrome” (IC/BPS) and considers the terms synonymous. (44)

![Figure 3: East Asian View of Taxonomy adapted from Homma](43) (see text for explanation) Homma Y. Lower urinary tract symptomatology: Its definition and confusion. Int J Urol 2008, Jan;15(1):35-43.

The International Association for the Study of Pain (IASP) has dropped the terms interstitial cystitis, painful bladder syndrome, and PBS/IC or BPS/IC and now recognizes the term “bladder pain syndrome” as the occurrence of persistent or recurrent pain perceived in the urinary bladder region accompanied by at least one other symptom, such as pain worsening with bladder filling and day-time and/or night-time urinary frequency. www.iasp-pain.org The reader is referred to the IASP website for an in depth discussion of pain taxonomy. This work was spearheaded by Dr. Andrew Baranowski and the Pain of Urogenital Origin (PUGO) group that is associated with IASP and contributed to advancement of nomenclature and taxonomy over the last 5 years. (41)

At the joint meeting of the 3’rd International Consultation on Interstitial Cystitis, Japan and the ESSIC held in 2013 in Kyoto, it was agreed to limit the use of the term “interstitial cystitis” to patients with bladder pain syndrome and a Hunner lesion. (45) This is supported by findings that suggest that Hunner lesions or what was classically referred to as “interstitial cystitis” denote a truly different disorder than “bladder pain syndrome” and can either be considered a distinct phenotype lying within the BPS framework or a separate disease entirely. (46) The finding of petechial bleeding in the bladder mucosa on distention (glomerulations) has not proven to be of any significance up to now and does not seem to guide either diagnostic or therapeutic decisions, and the absence of glomerulations likewise does not seem to impart any useful information in treating the symptomatic patient. (47)

The large number of therapies available and the relative lack of predictable success with any one treatment are largely a result of our inability at this time to properly phenotype patients who suffer from this
symptom complex. (48) Development of biomarkers and better clinical phenotyping will be the next frontier in improving therapies and secondarily improving the taxonomy and nomenclature. (49,50) Major placebo effects in clinical trials have hampered our ability to determine useful phenotypes that might improve treatment responses. (51,52)

The Consultation believes that based on the pathology and endoscopic findings characteristic of the Hunner lesion, the epidemiologic pattern that distinguishes it from bladder pain syndrome, the clinical response to local treatment of the lesion by resection, fulguration, or steroid injection, the response to cyclosporine, and the absence of reports in the literature that non-Hunner patients go on to develop Hunner lesions (ie, the finding of Hunner lesion does not represent a continuum in the natural history of bladder pain syndrome), the presence of a Hunner lesion should be considered a distinct disease. It therefore should drop out of the bladder pain syndrome construct, much like we do not consider other painful conditions like radiation cystitis, ketamine cystitis, or urinary tract infection a part of bladder pain syndrome. Figure 4

The Consultation concludes that it would be reasonable to designate the Hunner lesion in symptomatic patients with the term “interstitial cystitis”, thus indicating a true interstitial inflammation. It would be defined much as Hunner defined it 100 years ago, and harmonize to a great extent the Asian, European, and North American concepts of interstitial cystitis. At the present time, Consultation will continue to refer to the symptom complex as “bladder pain syndrome”. Hunner lesion will be considered a distinct phenotype, but in the future may be classified as a separate disorder entirely, albeit with local symptoms that are difficult to

differentiate from bladder pain syndrome in the absence of endoscopy. In other words, we may be coming full circle in the historical perspective.

III. EPIDEMIOLOGY

Since the clinical diagnosis of BPS remains controversial, epidemiology studies of BPS have been problematic (53). The lack of an accepted definition, the absence of a validated diagnostic marker, and questions regarding etiology and pathophysiology make much of the literature difficult to interpret. Overlapping patterns of bladder pain, lower urinary tract symptoms and pelvic pain are common and present challenges for clinical practice and research (54). The other major difficulty in evaluating various prevalence trials is that some are based on unverified self-report, others by physician diagnoses (with or without some type of verification) or by identification of BPS symptoms (with or without exclusion of other confusable conditions). This confusion becomes apparent when one looks at the variation in prevalence reports in the United States and around the world. These range from 3.5 per 100,000 population in Japan (55), to a questionnaire based study that suggests a figure in 20,000 per 100,000 in US women (56). Studies, however, have consistently shown that bladder pain symptoms are more common than suggested by coded physician diagnoses (57). Therefore, it is important to realize when examining epidemiological data in BPS, that the prevalence of this enigmatic condition can be estimated from patient self-reports, physician diagnoses and/or symptom based surveys, all of which will give a different figure. A Conceptual diagram of the various manifestations of pelvic pain illustrates the problems in determining prevalence data. (figure 5)

1. EARLY EPIDEMIOLOGICAL STUDIES

One of the first population-based studies (58) included “almost all the patients with interstitial cystitis in the city of Helsinki”. This superb, brief report from Finland surveyed all diagnosed cases in a population approaching 1 million. The prevalence of the disease in women was 18.1 per 100,000. The joint prevalence in both sexes was 10.6 cases per 100,000. Ten per cent of cases were in men.

Another early population study, this in the United States, first demonstrated the potential extent of what had been considered a very rare disease (59). The following population groups were surveyed: 1) random survey of 127 board-certified urologists 2) 64 IC patients selected by the surveyed urologists and divided among the last patient with IC seen, and the last patient with IC diagnosed 3) 904 female patients belonging to the Interstitial Cystitis Association and 4) random phone survey of 119 persons from the US population. This 1987 study reached the following conclusions (interestingly, most of these conclusions have stood the test of time and many further epidemiological studies described later in this section):

1. 43,500 to 90,000 diagnosed cases of IC in the USA (twice the Finnish prevalence)
2. Up to a five-fold increase in IC prevalence if all patients with painful bladder and sterile urine had been given the diagnosis, yielding up to half million possible cases in the USA
3. Median age of onset 40 years
4. Late deterioration in symptoms unusual
5. 50% temporary spontaneous remission rate, mean duration 8 months
6. 10 times higher incidence of childhood bladder problems in IC patients vs controls
7. 2 times the incidence of a history of urinary tract infection vs. controls
8. Lower quality of life than dialysis patients
9. Costs including lost economic production in 1987 of $427 million

2. PATIENT SELF REPORT SURVEYS

As mentioned earlier, the prevalence of BPS can be estimated from patient self-reports, physician diagnoses and/or symptom based surveys. Jones and Nyberg (60) obtained their data from unverified self-report of a previous diagnosis of IC in the 1989 National Household Interview Survey. The survey estimated an overall prevalence of 500 per 100,000 populations (0.5% of the population), or >1,000,000 people in the United States with a self-reported diagnosis of IC. For women this prevalence figure was 865 per 100,000. As part of the third National Health and Nutrition Examination Survey (NHANES III), patients who answered yes to two questions (pain in the bladder/frequent urination and a diagnosis of IC or PBS) resulted in a remarkably similar estimated prevalence of 470 per 100,000 (850 per 100,000 women) (61). These numbers must be viewed with caution because of inaccurate patient recall or confusion with other pain or bladder related conditions. However these patient-reported diagnoses figures certainly suggest that BPS is a common occurrence.

3. PHYSICIAN DIAGNOSES STUDIES

Estimations of prevalence based on physicians’ diagnoses may be thought to produce more accurate estimates, and while they do provide different figures, these are in part based on the local or geographic diagnostic criteria employed. Bade et al (62) used a physician questionnaire-based survey in the Netherlands yielding an overall prevalence of 8-16 per 100,000 females, with diagnosis heavily dependent on pathology and presence of mast cells. The Nurses
Health Study I and II (63) showed a prevalence of IC between 52 and 67 per 100,000 in the USA. This report was based on self-reports with validation using data from medical records. The prevalence of a physician based diagnosis of BPS in men and women in a managed care population in the US Northwest (61) was 197 per 100,00 women and 41 per 100,000 men. However, these rates decreased to 99 per 100,000 women and 19 per 100,000 men if the definition of the condition was limited to individuals who had undergone cystoscopy. Nickel, et al (64) performed a prospective practice audit in outpatient urology practice populations of 65 urologists and noted that the prevalence of IC and IC diagnosis in urology outpatient practice, confirmed by both investigation and symptom scoring, was determined to be 2.8%. This of course does not represent in any way the burden of this condition in the general population, but rather reflects the national referral and practice traditions. There are other limitations using physician diagnoses to determine prevalence. Studies that utilize physician diagnoses to define the presence of BPS will likely underestimate the true prevalence, primarily because they do not identify patients with undiagnosed disease or they may not assign a diagnosis when the symptoms are present (reluctance to label a patient with the condition or alternatively are not familiar with diagnosing it).

4. SYMPTOM BASED SURVEYS

Another and possibly more sensitive method to examine prevalence and incidence of BPS is to assess the presence of symptoms that suggest BPS. A follow-up study utilizing the Nurses’ Health Study (NHS) cohort (65) used a mailed questionnaire followed by a detailed supplementary questionnaire if the participant responded “yes” to a bladder or pelvic pain question. They observed that the prevalence of PBS symptoms was 1.7% in women younger than 65 years and increased progressively to 4.0% in women aged 80 years or older. This study suggested that the prevalence of PBS increases with age. Warren, et al (66) combined a mail-in survey with randomly selected telephone surveys to determine the prevalence of PBS amongst first degree relatives in comparison to that of the general population. They concluded that adult female first degree relatives of patients with BPS may have a prevalence of BPS 17 times that found in the general population. This suggests but does not prove a genetic susceptibility to BPS. The Boston Area Community Health (BACH) Survey (57), a population based cross-sectional survey of individuals in the Boston area which included an in person interview, determined the prevalence of painful bladder symptoms to be 0.83% to 2.71% in women and 0.25% to 1.22% in men depending of the definition used.

The O’Leary Sant (OLS) and the Pelvic Pain and Urgency/Frequency (PUF) questionnaires were compared by Rosenberg and Hazard (67) in the same general practice population of 1218 patients. The prevalence of BPS with the OLS was determined to be 0.57%, with the PUF the prevalence was determined to be 12.6%. Leppilahiti and colleagues (68,69) estimated the prevalence of BPS in the general Population of Finland using a rather robust definition based on the OLS to be 0.68%. However, when a sample of those women was examined by one of the urologists, the more accurate prevalence was 0.3%.

Clements et al employed (61) 3 different definitions of BPS related symptoms. The first included only self reported pelvic pain with voiding symptoms. The second included increasing pain with bladder filling and relief with urination. The third included a score of 12 or more on the OLS, including 2 episodes of nocturia and a pain score of 2 or greater. The prevalence estimates based on these definitions were 11,200 per 100,00 women and 6,200 per 100,000 men for definition 1; 3,300 per 100,00 women and 1,400 per 100,00 men for definition 2; and 6,200 per 100,000 women and 2,300 per 100,00 men for definition 3. Using a similar methodology, (70) it was concluded that the prevalence of BPS-like symptoms in South Korean women appear to be lower than in Europe (71) and the United States, similar to Japan and higher than in China (72). It is conceivable that the acknowledgement by individual patients of these specific IC/BPS symptoms may be influenced by cultural differences.

The most comprehensive and probably most accurate estimation of the prevalence of BPS symptoms involved population based symptom prevalence estimate using 2 validated case definitions to identify bladder pain syndrome/interstitial cystitis in 131,691 adult females (73). Based on a high sensitivity definition, 6.5% (6,500 per 100,000) of women met the symptoms criteria, while 2.7% (2,700 per 100,000) of women met the criteria for a high specificity definition. These percentages translated into 3.3 to 7.9 million US women over 18 years of age with symptoms of bladder pain and/or interstitial cystitis. But only 9.7% of these identified women reported being assigned a bladder pain syndrome or interstitial cystitis diagnosis. A further study compared 3,397 women identified in this RAND Interstitial Cystitis Epidemiology (RICE) survey (53) with urinary symptoms consistent with a diagnosis of IC/BPS to 277 women with an actual BPS diagnosis recruited from specialist practices in the USA (74). The two cohorts showed remarkably similar demographics, symptoms and quality of life measures, confirming that BPS is a very prevalent condition that is very likely under diagnosed and undertreated in the USA.

4.1. Conclusion

Based on these studies, it is impossible to determine an accurate estimation of the prevalence of BPS, but a review of studies done in the US shows that this is a very prevalent medical condition (Figure 4). It is clear that the most inaccurate prevalence figures are derived from patients self-reported recollection, while the prevalence of BPS symptom complexes are more
common than those based on physician diagnoses. It is apparent that there has been no standardized method of determining the prevalence of BPS, with wide variation of estimates in the same study employing different definitions or criteria for identifying the condition. Many factors including bias, cultural differences, methodology, geographic variations in diagnostic criteria and/or possibly real differences in different populations lead to further variations between countries.

4.2. Recommendation

A reasonable prevalence estimation for patients diagnosed with BPS would be about 100-200 per 100,000 women with a male prevalence of 10% to 20% of the female estimate. The prevalence of women and men with symptoms suggestive of BPS could be as much as 10 to even a 100 times more. (figure 4)

Level of Evidence: 1 Grade of Recommendation: A

5. INCIDENCE

Only a few estimates of Incidence have been reported. The annual incidence of new female cases in Oravisto et al, 1975 study (58) was 1.2 per 100,000. The overall age- and sex-adjusted incidence rate of physician assigned diagnoses of BPS in Olmstead county (75) was 1.1 per 100,000 per year (1.6 per 100,000 per year for women and 0.6 per 100,000 for men. Another review of physicians' diagnoses identified a much higher yearly incidence of 21 per 100,000 women and 4 per 100,000 men (61). A physician-coded diagnosis supplemented with chart review of the Kaiser Permanente database (76) suggested a BPS incidence rate of 15 per 100,000 women per year. The mean average age of patients was 51 years. With such a wide variation between two similar studies in the same country, it is evident that we really do not have an accurate estimation of BPS incidence.

5.1. Recommendation

The available data suggests that the incidence of BPS diagnoses is somewhere between 1 and 15 per 100,000 per year. This does not include the women who have developed symptoms but have not been diagnosed with the condition. Level of Evidence: 1 Grade of Recommendation: A

6. OTHER CONSIDERATIONS

6.1. Children

Geist and Antolak] (77) reviewed and added to reports of disease occurring in childhood. A childhood presentation of BPS is extremely rare and must be differentiated from the much more common and benign-behaving condition variously called the urinary frequency syndrome of childhood or dysfunctional elimination syndrome, a self-limited condition of unknown etiology. Nevertheless, there is a small cohort of children with chronic symptoms of bladder pain, urinary frequency, and sensory urgency in the absence of infection who have been evaluated with urodynamics, cystoscopy, and bladder distention and have findings consistent with the diagnosis of BPS. In Close and colleagues' review (78) of 20 such children, the median age of onset was younger than 5 years, and the vast majority of patients had long-term remissions with bladder distention. Rakow et al (79) assessed 28 women aged 13 to 25 with chronic pelvic pain syndrome and confirmed that 39% had a diagnosis of IC while a further 25% had both IC and endometriosis. The relationship between dysfunctional voiding and bowel symptoms in early life was suggested in a mail based questionnaire study in 215 BPS patients and 823 controls (80). Another study examining early childhood events (79) showed that early childhood trauma, in particular sexual trauma was more common in IC/BPS patients than asymptomatic control subjects. While not proven in these studies, it may be possible to link early childhood events to the eventual development of BPS symptoms.

6.1.1 Recommendation

IC/BPS should be evaluated in young women with complaining of chronic pelvic pain. Level of Evidence: 1 Grade of Recommendation: A

6.2. Men

Most studies show a female to male preponderance of 5:1 or greater (40,61,81). In the absence of a validated marker, it is often difficult to distinguish BPS from the chronic pelvic pain syndrome (nontuberculous prostatitis, prostatodynia) that affects males (82,83), and the percentage of men with BPS may actually be higher (84,85). Men tend to be diagnosed at an older age and have a higher percentage of Hunner's lesion in the case series reported. In the Rand NIH epidemiology prevalence study the male to female ratio approached one to one. (86)

6.2.1 Recommendation

The Male to Female ratio of BPS cases is 1:5. Level of Evidence: 1 Grade of Recommendation: A

6.3. Overlapping Non Bladder Syndromes

While the obvious clinical pain site associated with the diagnosis of IC/BPS is the bladder (pelvic pain only), it has become quite evident that most women with BPS have multiple pain sites outside the bladder and pelvis area, with over 75% of women with a clinical diagnosis of IC/BPS reporting pain outside the pelvis (pelvic pain and beyond). (87)

Multiple observations have shown that BPS patients are more likely than controls to have pain related syndromes manifesting symptoms beyond the bladder and even the pelvis. In 1997, Clauw, et al (35) reported on the symptom overlap between two cohorts of patients, one with fibromyalgia and one with BPS.
In the same year an analysis of a survey by Alagiri, et al (88) of over 6,700 persons who had a physician diagnosis of Interstitial Cystitis reported that individuals with IC were 100 times more likely to have inflammatory bowel disease, and that allergies, irritable bowel syndrome, sensitive skin, and fibromyalgia also have an increased association with IC. The presence of non-bladder syndromes (NBSs) and BPS has further complicated the interpretation of epidemiological studies. Investigators have subsequently compared BPS patients to controls on multiple NBSs. Wu et al. (36) compared 749 cases with BPS them to 1498 randomly selected and matched controls. Significantly more cases had FM, IBS, chronic pelvic pain (CPP), endometriosis, depression, anxiety and vulvodynia. Clemens et al. (89) compared 239 women with ICD-coded BPS to 717 matched controls and showed that cases significantly exceeded controls in myalgias, gastrointestinal symptoms, gynecologic pain, headache, back disorders, depression, and anxiety. Warren et al. (90) demonstrated that significantly more BPS cases than matched controls had 11 antecedent syndromes: FM, CFS, IBS, sicca syndrome, Chronic pelvic pain, migraine, allergies, asthma, depression, panic disorder, and vulvodynia. Nickel et al. (91) found significantly higher prevalence of self-reported FM, CFS, IBS, migraine and tension headaches, vulvodynia, temporomandibular disorder and low back pain in 207 female BPS cases than in 117 controls as well as significantly more with depression and anxiety (92) in a study in several urology practices in 3 continents. A review confirmed that fibromyalgia (FM), chronic fatigue syndrome (CFS), and irritable bowel syndrome (IBS) were associated with IC/BPS (93). The etiological and epidemiological questions that remain unanswered is how are these NBSs associated with BPS, do these NBSs precede or follow IC/BPS and do multiple NBSs increase the risk of BPS. Warren and colleagues (94) have introduced a number of hypotheses, however the studies to validate these have not yet been done. Relatives of BPS patients appear to have an increased risk of associated conditions including myalgia and fibromyalgia as well as constipation, suggesting shared underlying genetic factors. (95)

One other NBS that is sometime neglected or forgotten in these epidemiological associations is the association of BPS with sexual dysfunction. Multiple studies have shown that women with BPS diagnoses or symptoms experience very high levels of sexual dysfunction (96-99). This is likely related to deep dyspareunia associated with anterior vaginal wall pain from a hypersensitive bladder but can also be related to vulvodynia (100), a common NBS seen in female IC/BPS patients.

6.4. Progression
The disease onset is generally described as subacute rather than insidious, and full development of the classic symptom complex occurs over a relatively short time. It appears that BPS does progress continuously, but usually reaches its final stage rapidly (within 5 years) (101) and then continues without significant change in symptomatology. Subsequent major deterioration is unusual (58). The duration of symptoms before diagnosis was 3-5 years in the Finnish study (58) while a very early American study quoted 7-12 years (20). The Interstitial Cystitis Database Cohort (ICDB) of patients has been carefully studied, and the findings seem to bear out those of other epidemiologic surveys (102). Patterns of change in symptoms with time suggest regression to the mean and an intervention effect associated with the increased follow-up and care of cohort participants. Although all symptoms fluctuated, there was no evidence of significant long-term change in overall disease severity. The data suggest that BPS is a chronic disease and no current treatments have a significant impact on symptoms over time in the majority of patients. There is some data (91) to suggest that some patients undergo a phenotypic progression over time from a purely organ specific (eg. bladder) condition to a regional pain syndrome (eg. IBS, vulvodynia) to a more generalized pain syndrome (eg. FM, CFS). Long term longitudinal studies examining progression issues in BPS are lacking.

6.4.1 Recommendation
Epidemiological data required to describe progression patterns of BPS is lacking. Level of Evidence: 1 Grade of Recommendation: A

IV. ETIOLOGY
The etiology of BPS remains an enigma. Quite often hypotheses abound with sparse evidence to support them and some quickly are found to be untrue. For example, disturbed nitric oxide metabolism has been proposed to contribute to BPS, but later controlled studies using L-arginine therapy did not show therapeutic effect and failed to support the hypothesis. It is highly possible that BPS is induced by a variety of causes. Symptoms of urinary frequency and bladder pain are likely the final common presentation of bladder injury resulting from single or a combination of etiologies. And quite often it is hard to know whether the observed findings in clinical and animal research studies are results or causes of the bladder injury in BPS.

1. IMMUNE CELL ACTIVATION
Activation of immune cells, such as mast cells, is thought to have a role in the etiology and/or pathogenesis of BPS. Mast cells are multifunctional immune cells that contain highly potent inflammatory substances including histamine, leukotrienes, platelet activating factor, and tumor necrosis factor alpha. It is thought that mast cells are involved in the pathogenesis of BPS through a variety of mechanisms including the release of inflammatory mediators, the induction of adhesion molecules, and the recruitment of inflammatory cells to the bladder.
mediators such as histamine, leukotrienes, serotonin, and cytokines. (103) These cells are the repositories of many potent inflammatory factors. Many of the symptoms and findings in BPS with Hunner lesion, such as pain, frequency, edema, fibrosis, and the production of new vessels in the lamina propria, could possibly be ascribed to the release of mast cell-derived factors. Hence, the mast cell-IgE system and its interaction with other inflammatory cells and the nervous system (104) seems to be of importance when it comes to pathogenesis. There is a significant increase in mast cell count in subepithelial region from BPS patients with Hunner lesions as compared to non-Hunner lesion BPS patients or patients with overactive bladder syndrome. (103,105,106)

Activation of another type of immune cell, the plasma cell, could also be a factor in BPS. Akiyama et al found a characteristic infiltration of CXCR3-positive plasma cells in ulcer-type, but not in non-ulcer type, BPS. The CXCR3 pathway involves in chemotaxis of immune cells toward inflammatory sites and is important for inflammatory reaction. (107)

Level of Evidence: 1 Grade of Recommendation: A

2. INCREASED PERMEABILITY OF THE UROTHELIUM DUE TO UROTHELIAL DYSFUNCTION/GAG-LAYER DEFECTS

The bladder urothelium plays a key barrier to keep low and high molecular weight solutes in the urine from leaking into bladder interstitium. The barrier includes a dense layer of glycosaminoglycans on the luminal surface and intercellular junctions. Intracellular junctions consist of tight junction, adherence junction, desmosome and gap junction in the order of location from the luminal layer to the basal layer. Studies have shown impaired function of intercellular junctions of bladder urothelium of BPS patients. Zhang et al demonstrated significantly increased paracellular permeability, decreased expression of the tight junction proteins ZO-1 and occludin, and increased expression of the adhesion protein E-cadherin from patients with BPS. (108) Shie et al further showed that in the urothelium of the BPS bladder a reduced E-cadherin expression was associated with a higher level of apoptosis. (109)

Dysregulation of microRNA expression might contribute to impaired cellular junction in BPS. Monatyskaya et al identified a microRNA miR-199a-5p as an important regulator of intercellular junctions. In BPS patients, miR-199a-5p was overexpressed in urothelial cells, resulting in an incorrect tight junction formation with increased urothelial permeability. (110,111)

A defect in the glycosaminoglycan (GAG) layer has been proposed by Parsons and co-workers (112) and later by Hauser et al (113) With such a defect the sub-mucosal nerve filaments might become accessible to noxious substances in the urine and this might explain bladder pain and urinary frequency. In Hunner lesion BPS there is granulation tissue indicating a reparative process following repeated disruption of the mucosa. (114) Widened tight junctions and increased permeability have been demonstrated by scanning electron microscopy and other techniques. (115)

Level of Evidence: 2 Grade of Recommendation: B

3. INHIBITION OF BLADDER UROTHELIAL CELL PROLIFERATION

One explanation of the bladder epithelial dysfunction might be that the cells produce an inhibitor of heparin-binding epidermal growth factor-like growth factor in BPS. (116) It was shown that explanted urothelial cells from BPS patients differ from controls not only as to production of epithelial growth factors but also in the rate of proliferation and the production of an antiproliferative factor (APF). Keay and co-workers (117) studied gene expression patterns in normal bladder urothelial cells treated with APF and with mock APF as compared to patterns expressed by BPS urothelial cells. The results indicate that the mechanism of APF inhibition of urothelial cells may involve both down-regulation of genes that stimulate cell proliferation along with up-regulation of genes that inhibit cell growth. The same group of researchers has indicated that APF seems to be specifically elevated in the urine of patients with BPS but not in normals or patients with confusable diseases. These findings might open up avenues for identification of urine markers and treatment for BPS. (118,119)

There has not yet been confirmation of the importance of antiproliferative factor by other laboratories.

Level of Evidence: 2 Grade of Recommendation: B

4. AUTOIMMUNE MECHANISMS

There are numerous reports on autoantibodies in patients with BPS. (120-123) The precise identity of these of autoantibodies has yet to be determined. Some of the common clinical and histopathological characteristics present in BPS patients show certain similarities with other known autoimmune disturbances. Studies on autoantibodies in BPS have shown that these mainly consist of antinuclear antibodies (122) and these findings are in turn similar to the autoantibody profiles in some systemic diseases like Sjögren syndrome, which is known to be of autoimmune origin. (124-126) Only a portion of BPS patients have auto-antibodies. It has been proposed that the presence of auto-antibodies in these patients could be a reflection of disease severity. (127)
Vascular immunopathology with immune deposits in the bladder wall was found by Mattila. (128) Further studies also suggest activation of complement. (129) By means of immunophenotyping and flow cytometric analyses of the bladder mucosa and peripheral blood, differences between ulcerative and non-ulcer BPS patients have been demonstrated. In the former group intense T-cell infiltrates and B-cell nodules were seen, compared to far less T-cell infiltrates in non-ulcer BPS. (130) Involvement of the immune system is one feature found in some individuals with BPS, but findings are conflicting and have not been helpful in explaining the etiology. The lack of thorough descriptions of patients in many published studies has made classification and comparison between series impossible.

Level of Evidence: 2 Grade of Recommendation: C

5. INFECTION

No microorganism has ever been proven to cause BPS. Lynnes and coworkers did not find any evidence of recent or remote Gram negative or Gram positive infections in patients with BPS, nor did they find increased urinary IgA and IgG elevation. (131)(125) Warren et al (132) in a case control study of women with recent onset of BPS symptoms, reported that documented evidence of UTI at symptom onset was found in only a minority of patients. However, Zhang et al showed that a high prevalence (11 in 27 patients) of nanobacteria (NB) was observed in female BPS patients, and anti-NB treatment effectively improved the symptoms, suggesting that some BPS might be caused by nanobacteria. (133) Furthermore, using 16S ribosomal DNA(rDNA) sequence data Siddiqui et al demonstrated alterations of microbiota in urine from women with interstitial cystitis. (134) Using culture independent method to compare the microbiota of the lower urinary tract in standard culture negative (for bacteria) female patient with BPS, Nickel et al showed that among women with BPS the prevalence of fungi (Candida and Saccharomyces sp.) was significantly greater in those who reported a flare compared to those who did not. (135) Nevertheless, the possibility of a microbial contribution to the etiology of BPS remains an open question.

Level of Evidence: 1 Grade of Recommendation: A

6. NEUROBIOLOGY/PELVIC CROSS-TALK

Several authors have described autonomic nerve changes[130-132], but the findings are far from uniform. An increase of sympathetic innervation and activation of purinergic neurotransmission has been reported. The S-100 family of proteins appear in Schwann cells of the peripheral nervous system. (136,137) Decreased levels of S-100 protein in the non-ulcer group as compared to controls has been found (138), which is consistent with a decreased nerve content in patients with non-ulcer BPS, a finding conflicting with the results of Hohenfellner (139) and Regauer (140) who used PGP9.5 antibody and found the nerve content increased in BPS patients with or without Hunner lesions as compared to OAB patients and controls. A distinctive ultrastructural appearance of specimens from patients with non-Hunner BPS prompted Elbadawi and Light to propose neurogenic inflammation as a trigger to a cascade of events taking place in this disease. (141) In this context it should be noted that afferent nerves release transmitters like substance P which could activate immune cells, or vasoactive intestinal polypeptide. These events may constitute a link to the immune cell system and promote a decrease of lymphocyte proliferation.

A prominent increase of tyrosine hydroxylase immunoreactivity in bladder tissue of BPS patients, as compared to controls, has been described. (142) This can presumably be interpreted as a sign of generally increased sympathetic outflow. This lends support to the notion of a neurogenic aetiology and or pathogenesis.

Malykhina and others (143-147) have demonstrated in innovative animal studies that there is a bidirectional neural cross-sensitization of the colon and lower urinary tract. Acute colitis sensitized lumbosacral spinal neurons receiving input from the urinary bladder result in spinal neuronal hyperexcitability that may be involved in central cross-organ sensitization of visceral nociception between the colon and urinary bladder. This provides information which not only supports a neurogenic etiology but also may account for the substantial overlap of BPS with other pelvic pain disorders, especially the inflammatory bowel disorders. (84)

Using contrast enhanced magnetic resonance imaging, Towner et showed that in rats intravesical protamine sulfate not only increased permeability of bladder urothelium, the permeability of colon was also increased, further proving a cross-talk between bladder and colon. (148)

The brain might also play a role in the neurobiological component of BPS. Kairys et al found that females with BPS had a significant increase in gray matter volume in several regions of the brain, including the right primary somatosensory cortex, which was associated with greater pain, anxiety and urological symptoms. (149)

Level of Evidence: 2 Grade of Recommendation: B
7. URINARY TOXIC AGENTS

There are some publications suggesting that toxic substances in the urine may cause injury to the bladder resulting in symptoms consistent with BPS. One published hypothesis is that the increased cationic urine components in BPS patients may impair GAG layer function and exert a cytotoxic effect on urothelial cells. (150) Tamm-Horsfall protein, which is synthesized in the kidney and excreted into the urine, can neutralize cationic substance with its highly anionic property. A study has shown an abnormal glycosylation of Tamm-Horsfall protein occurs in patients with interstitial cystitis, resulting in a reduction in neutralizing capability, and may have a role in causing BPS. (151) Another group of investigators has suggested that defective constituent cytokine production may decrease mucosal defense to toxic agents. (152)

Level of Evidence: 3  Grade of Recommendation: D

8. HYPOXIA

Decreased microvascular density has been reported to be a feature of bladders from some individuals with BPS. (153) One group of investigators has reported that bladder perfusion decreased with bladder distension in some BPS patients compared to the opposite effect in control subjects. (154) The hypoxic hypothesis is further supported a report by Lee et al, who found an increased expression of hypoxia-inducible factor-1 (HIF-1) alpha in bladder tissue obtained from BPS patients. (155) However, it is still unknown why the BPS bladders would become hypoxic. Level of Evidence: 4  Grade of Recommendation: D

9. THE ROLE OF GENETICS IN BPS

Warren et al (156) report findings from a small cohort of twins which demonstrated a greater concordance of BPS among monozygotic that among dizygotic twins. A later study by the same research group (66) suggested that adult female first-degree relatives of patients with BPS may have a prevalence of IC 17 times that found in the general population. This coupled with the previously reported twin data suggests, but does not prove, a genetic component adds to the susceptibility for BPS. Another study on more than 25,000 twins, Altman et al found that in female twins genetic factors contributed less than one-third of the total variation in susceptibility to BPS, suggesting that there could be a genetic susceptibility to BPS, although environmental factors might also be substantial in the development of BPS. (157)

The report by Weissman et al (158) of the increased frequency of BPS in patients and their first degree relatives with panic disorder and other seemingly disparate disorders, has suggested that there is a familial syndrome consisting of BPS and other disorders of possible autonomic or neuromuscular dysfunction. More recent studies by the same group (159) from a case control study, suggested that this syndrome might include other anxiety disorders as well, and that families with and without this collection of symptoms were genetically distinguishable on chromosome 13.

Level of Evidence: 1  Grade of Recommendation: B

10. CONCLUSIONS

It is now believed that the etiology of BPS is more complex than has been previously envisioned. (35,84,88,160-162) The consideration of BPS as a part of a generalized somatic disorder should open new pathways to the study of BPS. Investigators should continue to explore central neurological mechanisms of pathogenesis, as well as genetic/familial, immunological and infectious etiologies of this puzzling, complex disorder.

An algorithm that attempts to illustrate an etiologic schema is presented (figure 6)
Figure 6: Theory of Etiology
V. PATHOLOGY

One can have pathology consistent with the diagnosis of BPS, but there is no histology pathognomonic of this syndrome.

The role of histopathology in the diagnosis of BPS is primarily one of excluding other possible diagnoses. One must rule out carcinoma and carcinoma-in-situ, eosinophilic cystitis, tuberculous cystitis, as well as any other entities with a specific tissue diagnosis (114, 163, 164). Level of Evidence: 1 Grade of Recommendation: A

The pathologic findings in BPS are not consistent. (165, 166) There has been a great variation in the reported histologic appearance of biopsies from BPS patients, and even variation among biopsies taken from the same patients over time. (22)

Lepinard and colleagues (167) reported a pancystitis affecting the 3 layers of bladder wall. In nonulcerative disease the vesical wall was never normal, epithelium being thinned and muscle being affected. Johansson and Fall (114) looked at 64 patients with ulcerative disease and 44 with nonulcerative IC. The former group had mucosal ulceration and hemorrhage, granulation tissue, intense inflammatory infiltrate, elevated mast cell counts and perineural infiltrates. The nonulcer group, despite the same severe symptoms, had a relatively unaltered mucosa with a sparse inflammatory response, the main feature being multiple, small, mucosal ruptures and suburothelial hemorrhages that were noted in a high proportion of patients. As these specimens were almost all taken immediately after hydrodistention, how much of the admittedly minimal findings in the nonulcer group were purely iatrogenic is a matter of speculation.

One can see completely normal biopsies in the nonulcerative BPS group (168). Transition from nonulcerative to ulcerative BPS is a rare event (169), and pathologically the two types of IC may be completely separate entities. While mast cells are more commonly seen in the detrusor in ulcerative BPS (170), they are also common in patients with idiopathic bladder instability (171). Mastocytosis in BPS is best documented by tryptase immunocytochemical staining (172). Larsen and colleagues recommend taking biopsies from the detrusor of patients with suspected BPS and examining them with tryptase-stained 3 micron thick sections, with every seventh section used for quantification. They consider 27 mast cells/mm² indicative of mastocytosis. (173) Despite attempts to develop a diagnostic algorithm based on the detrusor to mucosa mast cell ratio and nerve fiber proliferation (104), mast cell counts per se have no place in the differential diagnosis of this clinical syndrome.

Mast cells could be valuable in clinical phenotyping, but as yet that is unproven. Mast cells trigger inflammation that is associated with local pain, but the mechanisms mediating pain are unclear. In a murine model of neurogenic cystitis, Rudick and colleagues (174) demonstrated that mast cells promote cystitis pain and bladder pathophysiology through the separable actions of histamine and tumor necrosis factor respectively. Therefore, pain is independent of pathology and inflammation, and histamine receptors may represent direct therapeutic targets for the pain of BPS and other chronic pain conditions.

Lynes and coworkers (33) concluded that biopsy specimens are often not helpful in confirming the diagnosis. Although BPS patients in his study had a higher incidence and degree of denuded epithelium, ulceration, and submucosal inflammation, none of these findings was pathognomonic. In addition, these "typical" findings occurred only in BPS patients with pyuria or small bladder capacity. Epithelial and basement membrane thickness, submucosal edema, vascular ectasia, fibrosis, and detrusor muscle inflammation and fibrosis were not significantly different in the BPS and control patients.

Attempts to definitively diagnose BPS by electron microscopy have also been unsuccessful. Collan's group (175), in the first such study, wrote that the similarity of the ultrastructure of epithelial cells in controls and IC patients makes it improbable that the disease process originates in the epithelium. Other investigators found no differences in the morphologic appearances of the glococalyx and of urothelial cells in patients with IC when compared with controls (176). Andstrom and colleagues (115) saw no surface characteristics specific for IC, but believed that the mucin layer covering the urothelial cells seemed reduced in IC compared with controls, a fact disputed by Nickel in a very elegant paper (177). Elbadawi and Light (141) observed ultrastructural changes sufficiently distinctive to be diagnostic in specimens submitted for pathologic confirmation of nonulcerative interstitial cystitis. Marked edema of various tissue elements and cells appeared to be a common denominator of many observed changes. The wide-ranging discussion of the etiology of IC in his paper is fascinating, but the pathological findings are potentially marred by the methodology, in that specimens were obtained after diagnostic hydrodistention. (178)

So what is the place of pathologic examination of tissue in BPS? Attempts to classify the painful bladder by the pathoanatomical criteria described by Holm-Bentzen (179) are of questionable value. There is a group of patients with what she describes as "nonobstructive detrusor myopathy". (180) In her series, these patients with degenerative changes in the detrusor muscle often had residual urine, a history of urinary retention, and an absence of sensory urgency on cystometry with bladder capacities over 400cc. Most would not be clinically confused with BPS. A similar English series (181), however, included patients who met NIDDK research criteria and associated detrusor myopathy with diminished detrusor compliance and ultimate bladder contracture.

The Interstitial Cystitis Database (ICDB) study worked backwards from symptoms to pathology, and
concluded that certain symptoms are predictive of specific pathologic findings (31,182). Denson et. al. (34) analyzed forceps biopsies from 65 females and 4 males with BPS. Ten per cent of specimens showed vasodilatation or submucosal edema. Inflammation was absent in 30% of patients, and mild in another 41%. Cystoscopic changes did not correlate with degree of inflammation. Hanus and colleagues (183) studied 84 biopsies from 112 BPS patients and reported a linear relationship between the mean bladder capacity under anesthesia and severity of glomerulations. They did not find a correlation between severity of symptoms and histopathological changes observed by light or electron microscopy.

Richter and the Danish group showed studied 349 consecutive BPS patients and concluded that nocturia, detrusor mastocytosis, and detrusor intramuscular fibrosis are associated with multiple treatments and presumed failure of standard urological therapy while bladder capacity and glomerulations are not (184). In a Belgian study, cystoscopic parameters (glomerulations, bleeding, mucosal tears, bladder capacity) showed no correlations with the histological features of bladder biopsies. No correlations were found between inflammatory infiltrate and detrusor mastocytosis. In fact, detrusor mastocytosis was more elevated in biopsies with normal urinary epithelium than in those with damaged epithelium. The study concludes that the clinical significance of pathological findings awaits future research findings. (185)

Rosamilia reviewed the pathology literature pertaining to BPS in 2 publications and presented her own data (32,40). She compared forceps biopsies from 35 control and 34 PBS/IC patients, 6 with bladder capacities less than 400cc under anesthesia. Epithelial denudation, submucosal edema, congestion and ectasia and inflammatory infiltrate were increased in the BPS group. Submucosal hemorrhage did not differentiate the groups, but denuded epithelium was unique to the BPS group and more common in those with severe disease. The most remarkable finding in her study was that histological parameters were normal and indistinguishable from control subjects in 55% of BPS subjects. Method of biopsy can be important in interpreting findings, as transurethral resection biopsies tend to show mucosal ruptures, submucosal hemorrhage and mild inflammation (114), while histology is normal approximately half the time with cold-cup forceps biopsies (32,33,186).

Histopathology plays a supportive diagnostic role at best (187). Major reconstructive procedures appear to have better outcomes in patients with pathology consistent with Hunner’s lesions. (188) Inflammatory features can be seen in 24% to 76% of patients without a visible Hunner’s lesion. (189) While studies suggest that a severely abnormal pathology may be associated with poor prognosis (190, 191), this is not necessarily the case (192).

At this point in time, excluding other diseases that are pathologically identifiable is the primary utility of bladder biopsy in this group of patients. (193,194) Whether or not increased bladder permeability is present in an individual patient (195), cannot be determined by histopathologic techniques at the present time. Findings typical of Hunner lesion pathology can be ascertained on biopsy of these lesions and rule outs malignancy or other confusable disorders.

VI. DIAGNOSIS

Much work has been put into the attempt to define objective diagnostic criteria based on, among other factors, cystoscopy under local or general anesthesia, bladder distention with registration of bladder capacity and/or possible presence of glomerulations and Hunner lesion, bladder wall biopsies evaluated for inflammation, ulcer, fibrosis, mast cells, etc. and urodynamics with registration of bladder capacity, compliance and bladder stability. Results have, however, been frustrating. It is more fruitful to establish a broad clinical diagnosis, mainly on the basis of symptoms and exclusion of other diseases, and then stratify patients by urodynamics, cystoscopic, histological, and other tests on the basis of the significance of these findings for results of treatment and prognosis of disease. Current efforts to phenotype the disorder by the presence or absence of associated syndromes and diseases may also prove useful in the same way.

What follows is based solely on expert opinion.

Level of Evidence:4 Grade of Recommendation: C

It is hoped that future Consultations will have the data to base such suggestions on a firmer foundation.

1. HISTORY

A general thorough medical history should be taken. Special emphasis should be given to:

- Previous pelvic operations
- Previous UTI
- Bladder history/urological diseases
- Location of pelvic pain (referred pain) and relation to bladder filling/emptying.
- Characteristics of pain: onset, correlation with other events, description of pain
- Previous pelvic radiation treatment
- Autoimmune diseases
2. PHYSICAL EXAMINATION

A common physical examination should be performed including palpation of the lower abdomen for bladder fullness and tenderness:

- **Standing**: kyphosis, scars, hernia
- **Supine**: abduction/adduction of the hips, hyperaesthetic areas

In females physical examination should include a vaginal examination with pain mapping of the vulvar region and vaginal palpation for tenderness of the bladder, urethra, levator and adductor muscles of the pelvic floor. Tenderness might be graded as mild, moderate or severe.

**Pain mapping**

**Inspection:**

- **Vulva**
  - exclusion of vulvar/vestibular diseases (vulvitis, dermatosis etc.)
  - evaluation of introital area (endometriosis)
  - tenderness of vestibular glands or vulvar skin (Touch Test: use wet cotton stick or finger tip)
- **Vagina**
  - tenderness during insertion and opening of speculum
  - cervical pathology
  - vaginal fornices (endometriosis)
- **Bimanual physical examination**
  - tenderness of urethra, trigone and bladder
  - superficial/deep vaginal tenderness
  - tenderness of pelvic floor muscles (levator, adductor)
  - tenderness in adnexal areas

In males digital rectal examination (DRE) should be performed with pain mapping of the scrotal–anal region and palpation of tenderness of the bladder, prostate, levator and adductor muscles of the pelvic floor and the scrotal content.

3. LABORATORY TESTING

- Urine dipstick (ABS, pH, leucocytes, nitrate), urine culture in all. If sterile pyuria culture for tuberculosis.
- Urine cytology in risk groups.
- Investigations for vaginal Ureaplasma and Chlamydia in females and prostatitis in men are optional.

4. SYMPTOM EVALUATION

- Voiding diary with volume intake and output for 3 days at initial evaluation. Patient sensation at voiding might be recorded (see chapter outcome assessment, Hanno).  
- At follow-up only number of voidings during day and night time is necessary. Morning volume might be recorded as a help to monitor highest functional capacity.
- The O'Leary–Sant Symptom Score supplemented should be used as basic symptom score supplemented with the Quality of Life Score from the International Prostate Symptom Score (see chapter symptom scales, Hanno3).

Pain should be recorded using a Visual Analogue Scale (VAS) for pain during the last 24 hours (to fit with the voiding diary). Separate scores for the average, mildest and worst pain should be obtained (see symptom scales)

5. URODYNAMICS

The NIDDK criteria excluded patients with detrusor overactivity at filling cystometry in order not to confuse the picture in clinical trials (22). This does not however mean that detrusor overactivity cannot coexist with bladder pain syndrome. In the interstitial cystitis database approximately 14% of BPS patients had overactive bladders. (9) Whether these patients respond better to antimuscarinics than BPS patients with stable bladders has never been systematically investigated. If so, a rationale for routinely employing urodynamics as a part of the evaluation would follow. In males, infravesical obstruction might be a differential diagnosis (196), and it is recommended to do flowmetry in all males and pressure-flow studies in men with a peak flow rate below 20ml/seconds.

There are no data to support the following recommendations:

In females, flowmetry, post-void residual urine volume and pressure-flow study are optional. In males, a flowmetry should be done in all, and if maximum flow rate <20 ml/s a pressure-flow study and measure of residual urine volume should be done. It is recommended to perform filling cystometry with a filling rate of 50 ml/s (to comply with the revised Potassium Test - see below) to look for overactivity, volume at first desire to void and cystometric capacity.

**Level of Evidence:**4  **Grade of Recommendation:**C
6. POTASSIUM TESTING

Parsons has championed an intravesical potassium chloride challenge, comparing the sensory nerve provocative ability of sodium versus potassium using a 0.4 M potassium chloride solution. The test has proved controversial (39). Pain and provocation of symptoms constitutes a positive test. Whether the results indicate abnormal epithelial permeability in the subgroup of positive patients, or hypersensitivity of the sensory nerves is unclear. Normal bladder epithelium can never be absolutely tight, and there is always some leak, however small (197). The concentration of potassium used is 400meq per liter, far exceeding the physiologic urinary concentrations of 20-80meq/liter depending upon dietary intake (198). Healthy controls can distinguish KCl from sodium chloride, though they don’t experience severe pain (199). The hope is that this test may stratify patients into those who will respond to certain treatments (perhaps those designed to fortify the glycosaminoglycan layer) (200).

Used as a diagnostic test for bladder pain syndrome, the potassium chloride test is not valid (201). The gold standard in defining BPS for research purposes has been the NIDDK criteria. These criteria are recognized to constitute a set of patients that virtually all researchers can agree have BPS, though they are far too restrictive to be used in clinical practice (25). Thus, this group of patients should virtually all be positive if the KCl test is to have the sensitivity needed to aid in diagnosis. Up to 25% of patients meeting the NIDDK criteria will have a negative KCl test (202). In the group it should perform the best in, it is lacking in sensitivity. When we look at the specificity side of the equation, in the universe of asymptomatic persons, it performs relatively well and is rarely positive, although a recent study reported a 36% false positive rate in asymptomatic men (203). It is in the patient population with confounding conditions for which we would want help in sorting out BPS from other disorders. Sixty percent of patients with overactive bladder test positive (204) and virtually all patients with irritative symptoms from radiation cystitis and urinary tract infection test positive (202,205). The results with chronic prostatitis / chronic pelvic pain syndrome in men are variable, but 50-84% of men have been reported to test positive (203,206,207). In women with pelvic pain results are similar (208), and based on these findings, Parsons has expressed the view that BPS may affect over 20% of the female population of the United States[201]! Others have reported prevalence in unselected female textile workers in Turkey using similar methods at 32.8% (209). Another way to interpret the findings would be that the KCl test is very nonspecific, missing a significant number of BPS patients and over-diagnosing much of the population.

Prospective and retrospective studies looking at the KCl test for diagnosis in patients presenting with symptoms of BPS have found no benefit of the test in comparison with standard techniques of diagnosis (201,210,211). A later modification of the test using 0.3 molar potassium chloride for potential differentiation between patients with IC and detrusor overactivity (DO) showed that the 0.3 M KCl reduces maximum cystometric capacity in BPS and DO, the effect being more pronounced in DO. Urothelial hyperpermeability was not specific to IC. Comparative cystometry using NS and 0.3 M KCl does not help to differentiate BPS from DO (212,213).

The development of a painless modification of the potassium chloride test (214) using cystometric capacity and a 0.2M solution may improve acceptability among patients. The so-called revised or Comparative Potassium Test has shown prognostic value in bladder irrigation studies (215) but is considered optional by ESSIC. If performed it should be performed according to Daha et al. (214): A Foley balloon catheter (14F) is inserted and the bladder drained. Instill into the bladder 500 ml saline (0.9%) at a rate of 50 ml/min via an infusion set until the maximum capacity is reached. Drain the bladder and measure the saline filling volume. Repeat the instillation and measurement with 500 ml 0.2 M potassium chloride at a rate of 50 ml/min (taking care that filling lines are emptied of all saline before KCl instillation), and calculate the filling volume difference. A difference in bladder capacity > 30% is considered positive. Besides reduction of bladder capacity with 0.2 M KCl there is a stronger feeling of urgency in IC patients compared to the saline filling, which is also clinically relevant.

Level of Evidence:1 Grade of Recommendation: -A (not recommended)

7. CYSTOSCOPY

The classic cystoscopic picture of BPS as an “elusive” bladder ulcer with a corresponding cystoscopic appearance of patches of red mucosa exhibiting small vessels radiating to a central pale scar was described by Hunner in 1915 (17). (figures 7, 8 & 9 ) courtesy of Jorgen Nordling)

Level of Evidence:2 Grade of Recommendation:B
After 1978, glomerulations, described as punctuate petechial hemorrhages and observed after hydrodistention, became the primary cystoscopic feature of BPS (21). (Figures 10 and 11, courtesy of Tomohiro Ueda)

But not all patients with symptoms of BPS have glomerulations (25,34,184,216), and not all patients with glomerulations have symptoms of BPS (204,217-219). Neither presence nor severity of glomerulations correlate with any of the primary symptoms of BPS (31), although the presence of a Hunner’s lesion is significantly associated with bodily pain and urinary urgency (218). A recent review on glomerulations after bladder distension found no diagnostic or prognostic value of this finding (47). The finding of a Hunner’s lesion or glomerulations has been somewhat subjective. Some researchers find a Hunner’s lesion in 50% of their BPS patients (220), while others rarely see one (221).

No study comparing individual perceptions and variations in reporting or classifying glomerulations has ever been reported. Bladder capacity during hydrodistention has not drawn much attention, although it is strongly associated with increased urgency (222).

Because considerable variation in the duration of distension, repetition of distension, the pressure used for distension, and the measurement of bladder capacity have been described (223), the ESSIC has suggested a standardized procedure for cystoscopy and hydrodistension (38)
A rigid cystoscope is preferred to facilitate taking of adequate biopsies. Glycine or corresponding filling fluid should be used to allow for coagulation after biopsies. Infusion height should be approximately 80 cm above the Symphysis Pubis. A dripping chamber is used and the bladder is filled until fluid dribbling stops. If necessary, a digital block is applied around the urethra to prevent leakage. Pre-distention inspection includes observation for radiating vessels, coagulum or fibrine deposits, white spots, hyperaemia, oedema, cracks, scars or any other mucosal changes. Continuous inspection while filling the bladder is advised. When maximum capacity is reached, the distension is maintained for 3 minutes. The bladder is emptied and the colour of the fluid checked for the degree of bleeding. The total volume drained is the measured maximum bladder capacity. During a second filling, the bladder is filled to approximately 1/3rd to 2/3rd of the bladder capacity to achieve optimal vision for inspection and biopsies. The bladder should not be filled to maximum capacity or distended again to avoid further provocation of changes with doubtful reproducibility.

7.1. Inspection
Describe lesions in anterior wall, posterior wall, lateral quadrants and fundus. At the fundus one should be alert for possible artefacts if there is blind introduction of the scope. Bladder mapping by drawing is mandatory. Photographs are recommended but optional.

7.2. Classification
Grade 0 = normal mucosa
Grade I = petechiae in at least two quadrants
Grade II = large submucosal bleeding (ecchymosis)
Grade III = diffuse global mucosal bleeding Grade IV = mucosal disruption, with or without bleeding/oedema

The importance of the finding of the finding of glomerulations after hydrodistension is however as mentioned been questioned since 45% of asymptomatic females, 20% of males with LUTS suggestive of BOO and 85% of females with OAB and no bladder pain demonstrates typical glomerulations after hydrodistension (204,219,224) and 10-34% of patients with BPS do not (184,216)

How useful is hydrodistention?

Hydrodistension results fail to identify any statistically significant differences in post-distention objective findings (anesthetic capacity, glomerulations) or therapeutic benefits when patients are categorized according to presenting symptoms (225). Cystoscopy with hydrodistention may provide little useful information above and beyond the history and physical examination findings. In one study, 56% of 84 patients reported symptom improvement, but the duration was short lived with a mean of 2 months (226). It is necessary to distinguish between short term hydrodistension (2-10 min.) for classification of BPS and long term hydrodistension (20-30 min.) for treatment (227). Many reports on the therapeutic effect of hydrodistension are from Asia and from a patient material with IC based on the Asian definition (228), where up to 2/3 of the patients have frequency-urgency and no pain.

Lamale and colleagues examined the relationships between symptoms and cystoscopic findings in 12 women newly diagnosed with BPS who had not previously received treatment. Pain symptoms had consistent positive correlations with the cystoscopic findings. An increase in pain with bladder filling was associated with inflammation (P = 0.011), ulceration, and smaller bladder capacity. Pain relief after voiding correlated with smaller bladder capacity (P = 0.019), hematuria, and total cystoscopic score. Pain intensity in the urethra was related to ulceration and hematuria, and pain in the lower abdomen was related to a smaller bladder capacity (P = 0.047), glomerulations, and a larger total cystoscopic score. Daytime frequency correlated negatively with most cystoscopic findings, and nocturnal frequency had a positive relationship with most cystoscopic findings and was significantly associated with a smaller bladder capacity (P = 0.010). Urgency showed no strong associations with any cystoscopic findings. The results of this study contradict those of previous studies that found no relationship between symptom reports and cystoscopic findings suggesting possible effects of treatment on pain perception and therapeutic influence on cystoscopic findings (229).

It is important to keep in mind that the cystoscopic appearance of the bladder wall after hydrodistention may not be constant over time, and the absence of initial findings of glomerulations or terminal hematuria does not preclude further development of these findings of the disease on subsequent evaluation (230). Rare cases of hydrodistension induced bladder necrosis have been described (231).

8. MORPHOLOGY
Pathological changes in light microscopic and electron microscopic features in patients with BPS have been described including infiltration with inflammatory cells in all or specific parts of the bladder wall. Although these findings are important in our attempt to understand the disease and perhaps as an aid to stratification of patients, there are at this time no pathognomonic findings on biopsy in terms of diagnosis (31). Expert opinion as per the ESSIC suggests the following procedures when biopsy is planned for BPS evaluation (38):

8.1. Biopsies
During cystoscopy the bladder is distended to full capacity. After draining the bladder, bladder biopsies are taken at roughly half full bladder capacity. Biopsy procedures should be performed by using large for-
ceps and include detrusor muscle; alternatively double punch biopsies or resections of lesions can be used.

8.2. Number of Biopsies
At least 3 biopsies from the two lateral walls and bladder dome should be taken in addition to biopsies from visually abnormal areas. The biopsies are to be immediately fixed in neutral buffered 4% formalin.

8.3. Biopsy Handling
Biopsies are treated conventionally. Six adjacent 3 mm sections are cut and placed with 3 specimens on each of two specimen slides. The first slide is stained with H&E, the next with a connective tissue stain suitable for the individual institute. Twenty-four 10 mm sections are then cut and every third section is mounted on a specimen slide for mast cell counting. The specimens are stained by Lederstain (naptholesterase) according to routine procedures. Finally, a 3mm section is obtained to ensure the presence of detrusor muscle in the specimens.

8.4. Mast Cell Counting
The use of a measuring grid (e.g. Leitz periplan 6F10_N ocular containing a standardized grid) is necessary. Only mast cells containing nucleus are included. When counting the cells those covering or touching the bottom should be excluded whereas those covering the upper and left line are included. At least 3 biopsies must be the subject of mast cell counting and if possible one including a lesional area. Biopsies for mast cell counting should contain detrusor muscle.

8.5. The Pathology Report
- Epithelium
  - Not present
  - Present
  - Dysplasia with grading
  - Abnormal but no dysplasia: description is mandatory.
- Propria
  - Normal
  - Inflammation: description with a grading
  - Other findings are described
- Detrusor muscle. Abnormal muscle cells: describe
- Intrafascicular fibrosis
  - Not present
  - Present
- Mast cell count: At least three biopsies should be included in the counting. Only the biopsy with the highest number of mast cells per mm² should be reported

The enzymatic (naptholesterase) staining is, for the time being, recommended since standardized values are available:
- less than 20 mast cells/mm²: no detrusor mastocytosis;
- between 20 and 28 grey zone!
- more than 28 mast cells/mm²: detrusor mastocytosis.

Larsen recommends examining the detrusor biopsies with tryptase-stained 3 micron thick sections, with every seventh section used for quantification; 27 mast cells/mm² is considered indicative of mastocytosis (173).

These guidelines have been reported to be easy to follow. A statistically significant correlation was found between the cystoscopic aspect and inflammatory infiltration, mast cell count in the detrusor muscle and stromal edema. Maximum bladder capacity was negatively correlated with inflammation, detrusor mast cell count, hemorrhages and the overall cystoscopic aspect (232). Correlations have also been demonstrated between urothelial damage and inflammatory infiltrates and between normal epithelium and detrusor mastocytosis suggesting either 2 different types of BPS or different stadiums in the pathophysiological process of BPS (185). Also in a large retrospective study of 349 patients with BPS, it was found that treatment intensity ranging from hydrodistension only to major surgery correlated positively to detrusor mast cell count, detrusor fibrosis and nocturia, but not to maximum bladder capacity or glomerulations after hydrodistension (233).

9. BIOMARKERS
The lack of universally accepted clinical diagnostic criteria for BPS affects all aspects of making progress in understanding this disease. Insights into risk factors, pathogenesis, trials for effective therapy, prognosis, and outcome criteria for treatment are all affected by this lack of diagnostic criteria. A major factor affecting the controversy over accepted clinical diagnostic criteria is that the current criteria are predominantly symptom specific. An objective biomarker would advance the establishment of reproducible diagnostic criteria for BPS and also aid in monitoring effects of treatment.

A biomarker for any disease needs to demonstrate high sensitivity and high specificity. In addition, the marker assay needs to be reproducible in many laboratories and should be suitable for use in a clinical diagnostic laboratory.

Many of the published studies on biomarkers for BPS have been on biomarkers isolated from urine. Erickson et al has published excellent reviews of urine
Markers for BPS (234, 235). The most thoroughly investigated marker is antiproliferative factor (APF). This factor has been identified and characterized by Dr. Susan Keay and her colleagues at the University of Maryland (236, 237). Control subjects for this study included asymptomatic individuals, patients with bacterial cystitis, and patients with vulvovaginitis. APF is found in urine from the bladder and not from the renal pelvis (238-240). Treatment of symptomatic BPS by either hydrodistention or neurostimulation normalized the APF levels concurrent with symptom relief (241).

It is not known if other forms of treatment will affect APF levels. Preliminary studies in 58 women with documented BPS demonstrated a sensitivity value of 91.4% and a specificity of 90.6% (242). A later study with 219 symptomatic BPS patients and 325 controls with and without other urological disorders documented the sensitivity as 94% and the specificity at 95% (243). APF has been isolated from urine and found to be a frizzled 8 protein-related sialoglycopeptide which interacts with the epithelial cell receptor CKAP4/p63 (244, 245). Keay et al have suggested that APF might inhibit cell proliferation by the down-regulation of genes that stimulate cell proliferation along with the upregulation of genes that inhibit cell growth (117). Cell growth inhibition of human urothelial cells appears to be mediated by p53 (246). APF treatment caused significant increases in the paracellular permeability of normal bladder epithelial cell monolayers and the attenuation of tight junctions compared to mock APF, similar to changes seen in IC cells. APF treatment also decreased expression of the tight junction proteins zonula occludens-1 and occluding (245).

APF seems an ideal candidate for a biomarker for symptomatic BPS. There need to be additional studies to determine if it can serve as a BPS marker for patients in remission or for those who have not yet become symptomatic. As of 2016, the findings on symptomatic patients have yet to be replicated by laboratories around the world, and the biologic assay has not proven suitable for commercial development as it currently exists.

GP-51 is a glycoprotein present in both the transitional epithelium and urine of humans and other mammals. Moskowitz et. al have shown that bladder biopsies of BPS patients had decreased staining for GP-51 (247). The same laboratory also demonstrated that although GP-51 demonstrates a high specificity for BPS, it is not as sensitive as APF (248).

There have also been many published studies on heparin-binding epidermal growth factor-like growth factor (HB-EGF) (117, 239, 240, 249, 250). HB-EGF is a growth factor found in normal urine. It has been shown that APF inhibits the production of HB-EGF. There have been no large population studies focusing solely on HB-EGF as a biomarker for BPS.

Recent results from the MAPP studies indicate some urinary metabolites capable of discriminating female BPS patients from controls. Ethiocholan-3а-ol-17one sulfate (Etio-S) did so with a specificity and sensitivity >90%. Among BPS patients Etio-S levels are correlated with elevated symptom scores and could resolve high- from low-symptom BPS. (251). Clinically useful biomarkers may be a possibility in the future.

10. CONFUSABLE DISEASES

Criteria for a diagnosis are needed only if the target disease may be confused with other diseases (confusable diseases) because of overlapping features (252). For a diagnosis, the target disease has to be recognized in a pool of confusable diseases in one of two ways: by recognition of the specific combination of features of the target disease or by exclusion of confusable diseases. For the diagnosis of BPS both methods might be used because:

- Confusable diseases are more common than BPS, so recognition is mandatory because many can be treated.
- Failure to diagnose a confusable disease would automatically incorrectly yield a diagnosis of BPS.
- Patients may have a confusable disease plus BPS.

The diagnosis of BPS can thus made on the basis of exclusion of confusable diseases and confirmation by the recognition of the presence of the specific combination of symptoms and signs of BPS. If the main urinary symptoms are not explained by a single diagnosis (confusible disease or BPS), the presence of a second diagnosis is possible. Symptoms and signs for use in diagnostic criteria do not need to be specific for the target disease. On the contrary, if a specific symptom or sign existed for the target disease, a diagnosis would only require the presence of the specific feature and diagnostic criteria would not be necessary.

In evidence-based medicine, diagnoses are based on medical history, physical examination, and appropriate clinical investigations to eliminate diseases from a list of differential diagnoses (confusible diseases) and to confirm the final diagnosis. BPS may occur together with confusible diseases such as chronic or remitting urinary infections or endometriosis. Cystoscopy with hydrodistention and biopsies might in this situation document positive signs of BPS thereby making a double diagnosis more probable. For therapeutic studies it makes sense to exclude patients who also have a confusable disease because symptoms and signs may be caused by BPS, the confusible disease, or by both. For prevalence studies of BPS, on the other hand, all cases with BPS should be included, also those with a confusable disease. This approach eliminates the need for separate diagnostic criteria for clinical practice and scientific studies. Table 3 summarizes confusible diseases related to BPS and their mode of exclusion based upon the

VII. BPS & GYNECOLOGICAL ASSOCIATED / CONFUSABLE DISORDERS

1. INTRODUCTION

In female population affected by BPS/IC the gynecological diseases may be present in about 20% of pats. and there is also an overlapping of musculoskeletal pathologies in 12% of cases. (253)

Here below the following most frequent gynecological disorders in BPS/IC population:

2. PELVIC FLOOR DYSFUNCTION

Pelvic floor dysfunction affects the anterior, apical or posterior vaginal compartment. There are two types of dysfunction: hypotonic or LPFD and HPFD (see Table 1). Many patients with BPS/IC have concomitant HPFD, with muscle tenderness and spasms, and voiding dysfunction, both manifestations of pelvic floor hypertonicity. (254)

It has been estimated that the prevalence of HPFD in patients with BPS/IC ranges from 50% to 87%. (255)

Pelvic floor dysfunction exacerbates BPS/IC symptoms, and has been reported to appear in response to events such as bladder inflammation, gait disturbance, and trauma. (256)

Other pain disorders, such as irritable bowel syndrome, inflammatory bowel disease, fibromyalgia, and vulvodynia are all found to have a high prevalence in HPFD and myofascial pain. (88)

All these disorders are frequently associated with BPS/IC.

3. PATHOPHYSIOLOGY

In a normal bladder, the peripheral way of transmission is mediated by $A_\beta$-fibers that transfer tension, pain and cold. Instead, the $C$-fibers transfer burning, heat, pain and itching; they are normally silent, only becoming active in response to bladder inflammation or irritation. An inflammatory disorder of the pelvic viscera, a trauma or exceptional behavior might elicit noxious stimuli to the sacral cord that sets up a pelvic floor muscle dysfunction with sacral nerve hypersensitivity and a sacral cord wind-up. (257)

The guarding reflex is a visceromuscular reflex activated with the aim of increasing the tone of the pelvic floor during routine daytime activity. In BPS/IC patients, there is an afferent autonomic bombardment that can enhance and maintain a guarding reflex that manifests itself as a hypertonicity of the pelvic floor.

4. PHYSICAL EXAMINATION

Patients with HPFD are unable to produce more contractile strength and therefore cannot produce an effective squeeze. A single finger can be introduced in the vagina to assess pelvic floor awareness, and the ability to squeeze and relax the levator ani. Often patients with HPFD will have a “V” configuration of the introitus and, as a finger is advanced, it will drop off the shelf caused by the contracted levator muscles. Active “trigger points” are often identified by an exquisitely tender area palpable at the level of the pelvic side wall within a taut band that reproduces the patient’s pain, as well as the referral pattern of her pain.

5. DIAGNOSTIC STUDIES

Muscle activity can be measured using a perineometer or an electromyography probe. (258) Urodynamics include fluctuating or interrupted flow, abnormal voiding studies, elevated urethral pressure and urethral instability. Schmidt and Vapnek observed pain episodes in such patients coinciding with behavioral increase in the sphincter tone, more than in the bladder. (147)

When symptoms involve obstructed defecation and rectal pain, defecography should be used to identify the presence of a non-relaxing pelvic floor or even paradoxical activity of the pelvic floor during defecation.

6. TREATMENT

The pelvic floor therapy should be considered as a first-line treatment in the case of HPFD. The goal of these stretching exercises is to lengthen the contracted muscles by decreasing tension, releasing trigger points in the levator muscles, re-educating the muscles to a normal range of motion and improving patient awareness. The therapy also includes: behavior modification, muscle relaxants, Thiele’s massage, sacral and tibial neuromodulation, trigger point injections, and botulinum toxin.

7. ENDOMETRIOSIS

Endometriosis is the presence of endometrial glands or stroma outside of the endometrial cavity and affects 1–7% of the general population. (259)

Up to 70% of women with endometriosis have some type of pain symptoms, most commonly dysmenorrhea, cyclic pelvic pain or deep dyspareunia. (260)

In women who undergo a laparoscopy to evaluate CPP, the prevalence of endometriosis is 30–90%. (261)

Endometriosis pain is usually a visceral pain, and endometriotic lesions produce inflammatory mediators, particularly prostaglandins F2alpha and E2. (262)

There is a high prevalence and association of IC and endometriosis. A study by Chung et al. of 178 women with CPP found that 65% of CPP patients suffered from both active endometriosis and IC. (263)

In a prospective study carried out of 162 patients with CPP, Paulson and Delgado found that 66% of the sample was diagnosed with both endometriosis and IC. (264)
A recent systematic review estimated the prevalence of BPS/IC, and the coexistence of BPS/IC and endometriosis in women with CPP. Nine studies including 1016 patients with CPP showed the mean prevalence of BPS was 61%, of endometriosis 70%, and coexisting BPS and endometriosis 48% (range 84 16–78%, CI 44–51%).

These data suggest the importance of considering the bladder as the source of pain even where endometriosis is confirmed, and in the case of unresolved endometriosis and persistent pelvic pain, patients must be evaluated to rule out the presence of BPS/IC. (265)

### 8. VULVODYNIA AND VESTIBULODINIA

Vulvodynia, also known as vulvar vestibulitis or vulvar dysesthesia syndrome, literally means pain, or an unpleasant altered sensation, in the vulva. Pain can be unprovoked, varying from constant to intermittent, or occurring only on provocation, such as sexual intercourse.

The International Society for the Study of Vulvovaginal Disease defines vulvodynia as “vulvar discomfort, most often 98 described as burning pain, occurring in the absence of relevant visible findings or a specific, clinically identifiable, neurologic disorder”. This “burning pain” is suggestive of a neuropathic pain response.

Classification of the vulvar pain might include localized or generalized pain, or both, provoked or nonprovoked and primary or secondary. (266)

Sometimes an area of redness might be visible, but more often the vagina and the vulva show no abnormalities on gynecological or dermatological evaluation. This pain can affect women’s sexual life, which makes sex painful and, in some cases, impossible. Women with vestibulodynia are likely to have at least two additional pain conditions, such as fibromyalgia, irritable bowel syndrome, BPS/IC or chronic fatigue syndrome. (267)

Peters et al. reported that vestibulodynia affects 25% of women with BPS/IC. (268)

The etiology of vulvodynia is presumed to involve many factors: infections and altered vaginal acid-base balance, and the upregulation of pro-inflammatory immune responses. (269)

Furthermore, a large community-based study found that vulvodynia was strongly associated with childhood physical or sexual abuse. (270)

Because both the vestibule of the vulva and the bladder are derived from the urogenital sinus, it could be hypothesized that the coexistence of vulvodynia and BPS/IC in some patients represents a generalized disorder of urogenital sinus-derived epithelium. (271)

From a histological point of view, various noxious stimuli could cause changes in the vulvar epithelium: contraction in the pelvic floor, and mast cells activation with subsequent degranulation and release of histamine. This causes chronic pain and inflammation through the stimulation of peripheral neurons of the autonomic nervous system, an upregulation of the pain system, and a possible shift from nociceptive to neuropathic pain. (272)

The standard clinical test for vulvodynia is the cotton swab (Q-tip) test, measuring vulvar pain ratings on a visual analog scale. (273)

### 9. THERAPY

Several studies have shown that gabapentin as tricyclic yields significant results reducing pain perception, (274) with more than 80% of patients reporting improvement. (275) More recently, botulinum toxin has been proposed for the treatment of vulvodynia. It was found that the visual analog scale score was reduced from 8.1 to 2.5 (P < 0.001), and eight (72.7%) out of 11 patients were satisfied. (276)

### 10. PUDENDAL NEUROPATHY

Pudendal neuropathy is a common feature of syndromes such as dysfunctional voiding, non-obstructive urinary retention, chronic pelvic pain syndromes, and urinary and fecal incontinence. It could be ruled out as a confusable disease in BPS/IC patients.

Pudendal neuralgia is a functional entrapment of the pudendal nerve, and pain occurs during compression or stretch maneuvers, such as repetitive microtrauma, orthopedic fracture, straining with constipation and childbirth, falls onto the buttocks, and suture entrapment during pelvic surgery. The main symptom is pain aggravated by sitting/driving/exercise, reduced by recumbence or standing and relieved by sitting on a toilet.

The quality of neuropathic pain varies and can be described as burning, stabbing, ache, or pressure, and can be induced by voiding, defecating, vaginal penetration or orgasm. It can occur anywhere in the pudendal territory, but primarily includes the perineum and urethra, and extends to suprapubic, inguinal regions and to the upper medial thighs.

Urinary symptoms and rectal dysfunction might occur. Foreign body sensation in the rectum, vagina, urethra or perineum is frequent. Sexual dysfunction could be present. Females might suffer reduced clitoral sensation, pain at vaginal penetration, reduced lubrication and anorgasmia.

Pinprick sensation is tested bilaterally at the level of the clitoris posterior labia and posterior perianal skin. Hyperalgesia is more common than hypoalgesia. Pressure is placed at the level of the Alcock canal at-
tempting to reproduce pain, bladder or rectal symp-
toms (the Valleix phenomenon). The parasacral area
is also examined for a back mouse (episacroiliac li-
poma). Several tests can measure pudendal neurop-
athy including: biothesiometry, sacral latency test, sensory-evoked potentials, motor-evoked potentials and motor latency tests.

11. MANAGEMENT

11.1. Pharmacotherapy

Tricyclic antidepressants are the first medication cat-
egory effective in placebo-controlled trials. Other
drugs, such as gabapentin, pregabalin, oxcarbaze-
pine, tramadol and duloxetine, significantly reduce
pain and improve sleep, mood, and quality of life.

11.2. Minimvasive Approach

11.2.1 Transgluteal Pudendal Nerve Blocks

Two injections are given at the ischial spine at 1-
month intervals. A third is given into the Alcock canal
using computed tomography guidance.

11.3. Surgical Therapy

11.3.1 Transperineal and Transgluteal Ap-

The pudendal nerve decompression by the perineal
route is a blind procedure carried out under local or
regional anesthesia. To suppress the blind character
of the procedure, a transgluteal approach has been
proposed and the reported surgical success rates
range from 60% to 70%. Pain-free status might take
some years. Bladder, bowel and sexual dysfunctions
show variable improvement. (277) More recently, a
transvaginal approach has also been proposed. (278)

Until now, the results on pain are the same as those
obtained by the Shafik’s approach, (279) but with the
concurrent sections of one or two ligaments of the
pelvis (sacro-spinal and/or sacro-tuberous liga-
ments). However, the long-term effects of these sec-
tions on the stability of the pelvic region are as yet
unknown. Up to now, no data are available about a
potential effect of the transgluteal or transvaginal pro-
cedures on urinary or anal incontinence.

12. CONCLUSIONS

Women affected by BPS/IC can present in more than
20% times gynecological associated disorders. Fac-
ing with such group of patients is mandatory to ob-
serve not only the bladder, but also outside, consid-
ering the pelvis as a whole.

Therefore, it is of utmost importance to evaluate con-
comitant pathologies, such as vulvodynia, endometri-
osis and pelvic floor dysfunctions, ruling out confusa-
ble disease, such as pudendal neuropathy.

An optimal approach is a combined treatment ori-
ented not only to treat the bladder, but also the other
components responsible for the pain disorder. Pa-
tients with bladder tenderness alone responded bet-
ter than patients with multiple tender trigger points,
possibly because in these patients the bladder is the
only target organ and the patients are less severely
affected than patients with multiple trigger points.
Multimodal therapy remains the gold standard in the
management of female BPS/IC patients.

VIII. CLASSIFICATION

Interstitial cystitis was originally described as bladder
disease with severe inflammation of the bladder wall
described by Hunner as an ulcer (17). The lesion is
however not an ulcer but an inflammatory infiltrate
that can crack upon distention, and the name of the
bladder lesion has consequently been changed to
“Hunner lesion” (2). The finding of a Hunner lesion
could therefore originally be regarded as a diagnostic
criterion for IC. Messing and Stamey introduced glo-
merulations as another typical finding for IC and this
was included in the NIDDK criteria (280). Magnus Fall
proposed, that patients with Hunner lesion (classic IC)
and patients with glomerulations (non-ulcer type)
represented two different subtypes (169) with differ-
cental clinical pictures, different outcomes, and different
responses to treatment (220) meaning that patients
fulfilling the NIDDK criteria represents at least two dif-
f erent patient populations. Moreover up to 60% of pa-
tients clinically believed to have BPS by experienced
clinicians do not fulfill the NIDDK criteria (25) and
whether or not these patients are comparable to the
patients fulfilling the NIDDK criteria is unknown. Fi-
nally Japanese urologists consider that “interstitial
cystitis” should be preserved as a disease name for
patients with urinary symptoms and cystoscopic find-
ings of glomerulations or Hunner’s lesion as outlined
in the NIDDK criteria (228).

In an attempt to unite these different philosophies into
a coherent schema, ESSIC proposed a classification
of BPS based on findings during cystoscopy with hy-
drodistension and morphological findings in bladder
biopsies (2) (Table 2) . The classification includes
groups not having had cystoscopy with hydrodisten-
sion (groups 1,2,3) as well as groups not having had
morphological investigation of bladder biopsies
(groups A,B,C). By using this classification glomeru-
lations after hydrodistension are today regarded more
or less as a nonspecific finding, while BPS patients
with Hunner Lesion has been suggested to be a spe-
cific, confusable disease (classic IC). Further pheno-
typing of BPS patients by clinical, morphological or
other criteria, therefore seems to be fruitful way
ahead, if such classification can be demonstrated to
have significant importance for disease prognosis
and/or treatment outcome.
Complementary therapies for bladder pain syndrome have been shown to be beneficial, though larger, more rigorous placebo-controlled trials are sorely needed. A recent systematic review highlights dietary manipulation and physical therapy as useful modalities and suggests that acupuncture and relaxation therapies might also have a role, but the data for the latter two is somewhat lacking. (281) Many patients seem to respond to a variety of complementary and alternative medical options and they form a basic pillar of treatment and serve to empower patients. (282,283)

### 1. BEHAVIORAL MODIFICATION

Behavioral therapy for BPS includes education, timed voiding (scheduled voiding time and interval), controlled fluid intake, pelvic floor muscle training and bladder training (gradually extending voiding interval).

Chaiken et al (284) reported that when they conducted behavioral therapy consisting of frequency-volume chart, timed voiding, controlled fluid intake and pelvic floor muscle training for the treatment of 24 female patients, 50% of the patients showed improvement in the number of urinations and bladder capacity. At the same time, they considered that as the data was collected from 12 weeks' intensive therapy conducted by skilled therapists for selected patients whose main symptom was urinary frequency, it should not be generalized. Parsons and Koprowski (285) reported that when 21 patients with the main symptom of urinary frequency underwent bladder training using a frequency-volume chart, 15 patients showed improvement. In 15 patients, the mean voided volume after one month increased by 65cc, whereas a persistent sensation of bladder fullness remained unchanged.

Participants in both arms of a large NIH funded randomized placebo controlled trial evaluating amitriptyline in BPS (286) received a standardized education and behavioral modification program (EBMP). Adherence to the EBMP at 6 weeks was assessed in 4 categories of 1) symptom management, 2) fluid management, 3) diet modification and 4) bladder training. For each of these EBMP categories adherence was defined as the overall percentage of participants who reported adhering to each component of the EBMP at each telephone contact or clinic visit. For the 241 subjects evaluable for EBMP adherence, the rate at 6 weeks was 75% (181 of 241) for symptom management, 83% (201 of 241) for fluid management, 82% (196 of 240) for diet modification and 71% (172 of 241) for bladder training. The overall GRA response rate was approximately 57% for adherers in any of the 4 EBMP categories, whereas it was lower for non-adherers. This rate neared statistical significance for diet modification, which demonstrated only a 41% response rate among nonadherers (p = 0.051).

#### 1.1. Recommendation

Behavioral therapy should be a cornerstone of treatment for patients with BPS. **Level of evidence: 2** **Grade of recommendation: B**

### 2. PHYSICAL THERAPY

Women with BPS may have associated pelvic floor dysfunction (287). Physical therapy for the pelvic floor is said to be effective for genitourinary and anorectal disorders (288). Biofeedback and soft tissue massage may stimulate the relaxation of the pelvic floor muscles (289,290). Lukban et al (291) conducted a direct myofascial release treatment on 16 BPS patients with high-tone pelvic floor dysfunction and sacroiliac dysfunction. The treatment was effective for urinary frequency and suprapubic pain. Fifteen patients (94%) showed improvement in the O’Leary & Sant symptom score. Coital pain relief was observed in 15 of 16 patients, with 9 patients becoming able to resume sexual intercourse (292). Transvaginal Thiele massage was also reported to be effective for 9 of 10 patients of the same group (293). Mendelowitz et al (290) showed a 69% success rate when treating 16 patients using electromyographic biofeedback. However, it was suggested that a placebo effect may have occurred because the effect did not correlate with the improvement in patient’s awareness of the pelvic floor muscle movement and position before and after the therapy. Weiss (294) reported that 70% of 10 patients with IC showed symptomatic improvement, rating from “effective” to “remarkably effective”.

An NIH study (295) to determine the feasibility of conducting a randomized clinical trial was undertaken to compare 2 methods of manual therapy (myofascial physical therapy and global therapeutic massage) in patients with urological chronic pelvic pain syndromes. The global response assessment response rate was 57% in the myofascial physical therapy group compared to 21% in the global therapeutic massage treatment group. This statistically significant difference (P=0.03) was primarily driven by the response seen in women (24 women) compared to the men (24 men) enrolled in this small pilot study. A follow-up randomized trial comparing similar treatments (296) but only in women with BPS and demonstrable pelvic floor pathology showed a clear benefit of directed myofascial physical therapy. In the Myofascial physical therapy group, 59% of BPS women had a positive Global Response compared to 26% of BPS women who were randomized to the global therapeutic massage group (p=0.0012).

Pelvic floor physical therapy with myofascial trigger point release and Thiele massage can be successful in both men and women with chronic pelvic pain, and can be self-administered after a period of training. (297)
2.1. Recommendation
Physical therapy of selected and motivated patients with BPS, particularly those with demonstrable pelvic floor dysfunction, is indicated. Level of evidence: 1 Grade of recommendation: A

3. STRESS REDUCTION
It is long been observed that mental stress is one of the factors which aggravate the symptoms of BPS. Koziol et al (101) reported, in a survey of 374 patients, that more than half of the patients experienced intensified pain due to stress. Rothrock et al (298) reported that when comparing patients with BPS and healthy people, increased pain and urgency caused by stress were observed only in patients with BPS. Case-cohort studies have confirmed that patients diagnosed with IC/BPS experience considerably more stress than patients without the condition (91). Stress was shown to correlate with both the severity of symptoms and quality of life. In another study of patients with BPS identified in urology tertiary care clinic populations (299), mental health disorders were identified in 23% of IC/BPS female cases compared to 3% of female control subjects. Medications for anxiety, depression or stress were taken by 37% of patients with IC/BPS compared to 13% of female controls.

It is believed that exercise and bathing favorably influence the quality of life by reducing stress (300) however, the effect of such nonspecific therapies are difficult to assess and have not been proven in clinical trials. It would seem reasonable to suggest, when possible, to shorten working hours, choose a job with less stress or create a less stressful home environment. Involvement in patient education programs and patient support groups are considered by most practitioners to be beneficial (300,301). Mindfulness-based stress reduction has been shown to be effective in a small randomized controlled trial. (302) World-wide patient support groups, including the Interstitial Cystitis Association (ICA) (303), http://www.ichelp.org/, the International Painful Bladder Foundation, http://www.painful-bladder.org/, and the Interstitial Cystitis Network, www.ic-network.com/, are important sources of information for patients with BPS. Patients with BPS frequently suffer depression, which may negatively impact upon the quality of life (91) and perhaps symptoms. Effective self-care strategies taught by psychiatric nurses are considered to be useful (304,305).

3.1. Recommendation
Stress and depression are related to poorer quality of life and increase in severity of symptoms. Level of evidence: 1 Grade of recommendation: A

4. DIETARY MANIPULATION
Acidic beverages, coffee, spicy food, and alcohol may aggravate the symptoms of most patients with BPS (101,300,306,307). The symptoms of the majority of BPS patients are generally believed to be improved by dietary manipulation (300,306,308,309). However this has proven difficult to prove and Nguan et al (310) reported that there was no statistically significant difference in pain and other symptoms, when they evaluated the influence of the changes in urinary pH on the symptoms of 26 patients with BPS by instilling pH5.0 and pH7.5 saline solutions into the bladder. One of the best studies designed to determine the effect of particular foods, beverages and/or supplements (comestibles) on IC/BPS symptoms was undertaken by Shorter et al (311). One hundred and four patients with IC/BPS were asked to indicate on a validated questionnaire whether each of 175 individual items worsened, improved or had no effect on symptoms. Of the patients surveyed, 90% indicated that the consumption of certain foods or beverages caused symptom exacerbation. The comestible items that had the most effect were caffeinated, carbonated and alcoholic beverages, certain fruits, artificial sweeteners and spicy foods.

Dietary manipulation was ranked in the top five frequently used treatments in a cohort study of the Interstitial Cystitis Data Base (ICDB). (312). As the influence of diet is variable with regard to food, beverage, and patient, there is no reason for patients to be uniformly on a strict diet. It is advised that each patient experiment to find out the foods that tend to aggravate their symptoms and avoid them. The ICA home page, (http://www.ichelp.org/) introduces the foods that the consumption of certain foods or beverages often avoided by patients with BPS. The use of an elimination diet (eliminate all foods on the list) and then gradually reintroducing them one by one, will facilitate the development of an patient directed individualized diet strategy. In some cases when diet appears to play a major role in symptoms, a registered dietician nutritionist can become a critical part of the treatment team. Gordon et.al’s comprehensive review of dietary issues is worth reading and provides a helpful handout for patients. (313)

4.1. Recommendation
Personalized dietary manipulation should be part of the therapeutic strategy for patients with IC/BPS. Level of evidence: 2 Grade of recommendation: B

### X. ORAL THERAPY

Several categories of medication have been used in the management of patients with bladder pain syndrome including analgesics, antidepressants, antihistamines, Immunosuppressants, and glycosaminoglycans. Many of these drugs are used empirically. Only a few of them have been studied in randomized controlled trials and none have a grade A recommendation.

#### 1. Analgesics

The long-term, appropriate use of pain medications is indispensable in the treatment of bladder pain syndrome. Many nonopioid analgesics including acetaminophen and the nonsteroidal anti-inflammatory drugs (NSAIDs) and even antispasmodic agents (314) have a place in pain therapy. Patients with more severe symptoms can often be helped with medical pain management using medications commonly used for chronic neuropathic pain syndromes including antidepressants, anticonvulsants, and opioids.

Gabapentin, introduced as an anticonvulsant, has found efficacy in neuropathic pain disorders including diabetic neuropathy (315) and postherpetic neuralgia (316). It demonstrates synergism with morphine in neuropathic pain (317). Two patients with IC showed improved functional capacity and received adequate pain control when gabapentin was added to their regimen (318). Sasaki et al reported that 10 of 21 male and female patients with refractory genitourinary pain had subjective improvement of their pain following treatment with gabapentin (319). Recently gabapentin was one compound of a triple mix including amitriptyline and etodolac, a NSAID. The interpretation of the observed efficacy in 74 patients is hampered by an uncontrolled open label study protocol that additionally allowed up-titration of gabapentin and amitriptyline. The impact and contribution of amitriptyline, whose exclusive efficacy for BPS has been proven better than for any other oral drug, on the reported amelioration was not discussed (320).

Pregabalin has similar structure as gabapentin and also has been shown to reduce the pain of diabetic neuropathy (321). Preparations with reduced side effects were approved in Europe in 2003. Pregabalin mimics the GABAergic neurotransmitter, might be worthwhile to try for bladder pain syndrome, particularly for those with concurrent fibromyalgia, though studies are lacking.

Opioids are seldom the first choice of analgesics in chronic pain states, but they should not be withheld if less powerful analgesics have failed (323). Chronic opioid therapy can be considered as a last resort in selected patients, who have disabling pain and often receive inadequate doses of short-acting pain medications, which put them on cycles of short-term relief, anxiety, and pain.

The major impediment to the proper use of opioids when they are prescribed for long-term nonmalignant pain is the fear of addiction. Some studies suggest the risk is low (324), but not zero. Using opiates is a difficult decision that requires much thought and discussion between patient and urologist, and a pain specialist. They are best administered in a pain clinic setting, requiring frequent reassessment by both patient and physician (326).

In addition to narcotics, concurrent usage of nonsteroidal anti-inflammatory drugs, cyclooxygenase inhibitors, acetaminophen, and tricyclic antidepressants may provide better pain control (327). The common side effects of opioids include sedation, nausea, mild confusion, and pruritis. These are generally transient and easily managed. Respiratory depression is extremely rare if they are used as prescribed. Constipation is common and a mild laxative is generally necessary. The long-acting narcotic formulations that result in steady levels of drug over many hours are preferable.

**Level of Evidence: 4 Grade of Recommendation: C**

#### 2. Anti-depressants

##### 2.1. Amitriptyline

Amitriptyline is a tricyclic antidepressant with the property of blocking H1-histaminergic receptors (328). It stabilizes mast cells and inhibits mediator stimulated vascular leakage. It inhibits synaptic uptake of serotonin and norepinephrine, thus inhibiting painful nociception from the bladder at the level of the central nervous system. Its nighttime sedation
can be therapeutic in the BPS population and its purported beta-adrenergic receptor stimulation in the bladder may facilitate urine storage. (329).

Using a dose titration of up to 75mg taken before bed, Hanno and Wein reported success in about half of 20 patients who could tolerate the medication. Twenty percent of the initial 25 patients dropped out because of fatigue, weight-gain, or dry mouth. In a follow-up report (330), 18 of 28 patients who could tolerate the drug had major relief of symptoms within 3 to 6 weeks of onset of therapy with a mean follow-up of 14.4 months. However, about one-third of patients initially placed on the drug could not continue on it because of side effects. Kirkemo et al (331) treated 30 patients and 90% had subjective improvement in 8 weeks. Pranikoff and Constantino (332) reported improvement in 16 of 22 patients with urinary frequency and pain who did not have a diagnosis of interstitial cystitis, noting that 5 of the 22 could not tolerate the drug.

van Ophoven et al performed the first prospective, double-blind, placebo-controlled study of amitriptyline. Fifty patients were randomized to placebo or a titrated dose of amitriptyline up to 100mg daily. Forty-two percent of amitriptyline patients had greater than 30% decrease in O'Leary/Sant symptom and problem scores at 4 months compared to 13% in the placebo group (333). They subsequently reported a long-term follow-up of amitriptyline for patients who can tolerate the side effects and continued the medication. With a mean follow-up of 19 months, 64% of 94 patients had response (334).

Foster and Hanno reported a second multicenter, randomized, double-blind, placebo controlled clinical trial of amitriptyline in subjects with interstitial cystitis/painful bladder syndrome who were naive to therapy. Study participants in both treatment arms received a standardized education and behavioral modification program. Only of the subgroup of 207 subjects who achieved a drug dose of at least 50 mg, a significantly higher response rate was observed in the amitriptyline group (66%) compared to placebo (47%) (p = 0.01). When all randomized subjects were considered, amitriptyline plus an education and behavioral modification program did not significantly improve symptoms in treatment naive patients with interstitial cystitis/painful bladder syndrome versus education and behavioral modification alone. However, amitriptyline may be beneficial in persons who can achieve a daily dose of 50 mg or greater (286,335). Whether some of the benefits of amitriptyline were achieved by the beneficial effects of conservative therapy in the patients (all treatment naive) tested in this trial is an open question. Cystoscopic findings do not predict the treatment effect. (336)

**Level of Evidence: 2 Grade of Recommendation: B**

### 2.2. Doxepin, Desipramine, Duloxetine

Other tricyclic antidepressants that have been used for bladder pain syndrome are doxepin and desipramine. Wammack et al used the combination of doxepin and piroxicam, a cox-2 inhibitor. Twenty-six of 32 patients (81%) experienced remission of symptoms (337). One study reported satisfactory outcome with desipramine. (338) Duloxetine, a serotonin-norepinephrine reuptake inhibitor has also been tried but without therapeutic effects (339).

### 3. ANTIHISTAMINES

Simmons first proposed use of antihistamines in 1955 (340). His findings of mast cells in the wall of a normal bladder and the edema and increased vascularity seen in the IC bladder suggested that histamine may be responsible for the development of interstitial cystitis. He reported on 6 patients who had some improvement with pyribenazine for limited periods (341).

**Level of Evidence: 1 Grade of Recommendation: D**

### 4. HYDROXYZINE

Hydroxyzine is the most widely used antihistamine for bladder pain syndrome. Its ability as an H-1 receptor antagonist, to inhibit bladder mast cell activation, along with its anticholinergic and anxiolytic properties and good safety profile, have made it a reasonable candidate for use as a therapeutic agent for bladder pain syndrome. (342) In 1993, Theoharides first reported significant benefits of hydroxyzine in reducing pain and urinary symptoms. (343) His two subsequent reports of uncontrolled series further suggested the therapeutic effects of hydroxyzine. (344,345) However, in an NIDDK randomized controlled trial, the global response rate for hydroxyzine was only 31% compared to a 20% response to those not treated with hydroxyzine. When looked at by itself the response was 23% vs. 13% on placebo. None of the results in this under-powered trial reached statistical significance (346).

### 5. CIMETIDINE

Cimetidine, a H2 histamine receptor antagonist, has been explored for treatment of bladder pain syndrome. In a pilot study (347), 9 patients were treated with a dose of 300mg orally twice daily for one month. At follow-up 26 to 42 months later, 4 patients had complete relief of urinary symptoms and suprapubic pain. Lewi (348) reported 31 patients given 200mg three times daily with mean follow up of 6.6 months. Seventy-one per cent experienced varying degrees of symptomatic relief, 45% were pain free, and 26% went into remission of all symptoms. In a later report
(349) of 69 patients treated over a 4 year period, 67% of patients had complete relief of all symptoms.

A small, prospective, placebo-controlled RCT studied 36 patients who either received oral cimetidine or placebo (350). Median suprapubic pain and frequency scores improved significantly, but the publication does not state exactly how many patients in each group improved.

**Level of Evidence:** 3  **Grade of Recommendation:** C

### 6. IMMUNOSUPPRESSANT

#### 6.1. Cyclosporine

Cyclosporine, a widely used immunosuppressive drug in organ transplantation, was the subject of a novel bladder pain syndrome trial. (351) Eleven patients received cyclosporine for 3-6 months at an initial dose of 2.5-5 mg/kg daily and a maintenance dose of 1.5 to 3mg/kg daily. Micturition frequency decreased, and mean and maximum voided volumes increased significantly. Bladder pain decreased or disappeared in 10 patients. After cessation of treatment, symptoms recurred in the majority of patients.

In a longer-term follow-up study, 20 of 23 refractory IC patients on cyclosporine therapy followed for a mean of 60.8 months became free of bladder pain. Bladder capacity more than doubled. Eleven patients subsequently stopped therapy, and in 9, symptoms recurred within months, but responded to reinitiating cyclosporine (352). Sairanen et al further found that cyclosporine A was far superior to sodium pentosanpolysulfate in all clinical outcome parameters measured at 6 months. (353) Patients who responded to cyclosporine A had a significant reduction of urinary levels of epidermal growth factor (EGF) (354).

Forrest et al. retrospectively summarized results from Cyclosporine off-label use in 44 patients BPS patients. In 34 patients presenting with Hunners lesion upon cystoscopy the success rate was higher compared to those patients without lesions (68% vs 30%). However, side effects were common and demand a close monitoring of patients including blood pressure and renal failure. (355)

**Level of Evidence:** 3  **Grade of Recommendation:** C

#### 6.2. Suplatast Tosilate

Suplatast Tosilate (IPD-1151T) is an immune-regulator that selectively suppresses IgE production and eosinophilia via suppression of helper T cells that produce IL-4 and 5. It is used in Japan to treat allergic disorders including asthma, atopic dermatitis, and rhinitis. Ueda et al reported a small study in 14 women with interstitial cystitis. (356) Treatment for one year resulted in a significantly increased bladder capacity and decreased urinary urgency, frequency, and lower abdominal pain in 10 women. Concomitant changes occurred in blood and urine markers suggesting an immune system response. Larger, multicenter, randomized controlled trials in the United States and Japan have been completed and results did not justify further development for this indication. Further studies with this drug for bladder pain syndrome are not planned and approval for this indication is not expected.

**Level of Evidence:** 1  **Grade of Recommendation:** D

#### 6.3. Azathioprine and Chloroquine Derivatives

In a single report in 1976, Oravisto et al used azathioprine or chloroquine derivatives for BPS patients not responding to other treatments. (357) About 50% patients responded.

**Level of Evidence:** 4  **Grade of Recommendation:** D

#### 6.4. Corticosteroids

Reports on outcome with corticosteroid therapy have been both promising (358,359) and discouraging (360). Soucy et al. (361) have suggested a trial of prednisone (25 mg daily for 1–2 months, afterwards reduced to the minimum required for symptom relief) in patients with severe ulcerative IC, which is otherwise unresponsive to conventional treatment. The side effects of steroids can be very serious, making it difficult to justify their use (358,360,361)

**Level of Evidence:** 4  **Grade of Recommendation:** D

### 7. SODIUM PENTOSANPOLYSULFATE

Sodium pentosan-poly saccharide (PPS), a synthetic sulfated polysaccharide, is available in an oral formulation, 3-6% of which is excreted into the urine and theoretically may replenished the damaged glycosaminoglycan (GAG) layer overlying transitional epithelium of the urinary bladder of BPS patients. An intact urothelial GAG layer has been proposed to be essential to keep the urothelium impermeable to urinary components. A defective bladder GAG layer is hypothesized to be one important cause for BPS. (362)

PPS's mechanism of action has been attributed not only to correction of a putative defect in the GAG layer, but also its ability to inhibit histamine release from mast cells, (363) and a possible effect mediated by nonspecific binding of the molecule with the inflammatory stimulants of urothelial activation, an action that would occur in the urine rather than at the mucosal membrane. (364)

PPS is the most intensively studied treatment ever proposed for BPS. It is the only medication approved by the Food and Drug Administration for the pain of
interstitial cystitis. Parsons initially administered the drug at a dosage of 50mg 4 times daily or 150mg twice daily in an open trial involving 24 patients. (365) Twenty-two of 24 patients experienced a good or excellent response within 8 weeks. In a subsequent randomized, placebo-controlled trial using a dose of 100mg three times daily in 62 patients, pain and urgency improved in 44% vs. a placebo response of 15%. Urgency improved by 38% vs. 18% on placebo. The average number of daily voids was unchanged. (366)

Five randomized controlled trials for pentosan polysulfate have yielded conflicting results of efficacy. Holm-bentzen et. al (367) reported the first multicenter double-blind placebo controlled trial in 1987 looking at 115 patients with bladder pain syndrome. Patients were randomized to a dose of 200mg twice daily vs. placebo for 4 months. The results showed no difference between pre and post-trial values with regard to symptoms, urodynamic parameters, cystoscopic appearance, or mast cell counts in the two groups. The study concluded that the drug had no clinically significant effect.

The first of two pivotal studies for the FDA was performed in the United States in 1990. (368) A total of 110 patients in 5 medical centers were studied for 3 months on a dosage of 100mg three times daily. Twenty-eight percent of patients on PPS reported "more than slight improvement" versus 13% of those on placebo. Pain and pressure to urinate were the main parameters to show benefit with PPS.

The FDA asked for a second study which was reported 3 years later. (369) In a multicenter, placebo-controlled RCT 148 patients were randomized to 100mg three times daily of pentosan-polysulfate vs. placebo. In the primary endpoint of patient self-evaluation of global improvement, 32% of those on PPS reported 50% or more overall improvement vs. 16% on placebo at 3 months. Pain, urgency, and pressure showed significant improvement with drug. Frequency, nocturia, and volume voided showed no significant changes between study groups.

The NIDDK performed their own 2 x 2 factorial study to evaluate PPS and hydroxyzine. (346) Each drug was used alone and in combination and compared to a placebo group. Patients were treated for 6 months. There were 121 participants in 7 centers. No statistically significant response to these medications was documented. A non-significant trend was seen in the PPS treatment groups (34%) compared to non-PPS groups (18%). Of the 29 patients on PPS alone, 28% had global response (primary endpoint) of moderately or markedly improved vs. 13% on placebo, very similar in this 6-month study to improvement rates in the 3-month pivotal studies, though not reaching statistical significance in the longer study.

The latest report from a dose ranging study performed to satisfy a post-marketing commitment made to the FDA upon approval of PPS revealed no treatment effect of PPS compared with placebo at the currently established dose of 300mg/d or at 100mg/d. The primary end point, i.e. achieving a 30% or greater reduction from the baseline ICSI total score was reached by 40.7% (48 out of 118 patients) in the placebo group compared with 39.8% (51 out of 128 pts) in the 100mg once daily and 42.6% (52 out of 122 pts) 100mg 3 times daily group. (370) There appears to be no dose response with daily doses up to 3 times higher than recommended. (371)

In summary, of 6 RCTs 3 had unfavorable and 3 had favorable results for PPS. Most recent non randomized studies showed a complex heterogeneity in efficacy as well. (372-374) Such conflicting results might suggest that a small minority of patients may have some response to PPS, but currently there is no reliable method to identify such patients.

Long-term, open-label studies with PPS have been reported. Populations of patients receiving extended treatment for up to 90 months or more in the compassionate use program showed no further improvement in symptoms after 1-2 years, though there seemed to be little tachyphylaxis. (346,375) A total of 2809 patients had begun treatment with a 3 month supply of PPS and 21% continued with treatment beyond this point and reordered medication. This seems to correlate with the 28-32% improvement rate previously reported. The dropout rate in the first 6 months was extraordinarily high with only 178 active patients out of 1742 who initially ordered the drug. There was an overall improvement in symptoms in 62% of the patients who did remain in treatment for 6-35 months. On a long term basis, it appears only 6.2%-18.7% of patients with BPS derive a benefit from pentosanpolysulphate. (376).

PPS appears to be a very well-tolerated medication (375) with no common central nervous system side effects. At most, it appears to be beneficial with regard to improving the pain associated with interstitial cystitis in up to one-third of patients, a standard often expected with a placebo. A 3-6 month course may be required to see a treatment effect. Claims suggesting greater efficacy and claims urging its use in patients who do not meet the standard definition of bladder pain syndrome should be regarded with caution.

**Level of Evidence: 1 Grade of Recommendation: D**

### 8. Other Oral Medications That Have Been Used for BPS

#### 8.1. L-Arginine

Foster and Weiss were the original proponents of L-arginine in the therapy of interstitial cystitis. (377) Eight patients with BPS were given 500mg of L-arginine 3 times daily. After one month, urinary nitric oxide synthase activity increased 8-fold and 7 of the 8 patients noticed improvement in IC symptoms. An
open-label study of 11 patients showed improvement in all 10 of the patients who remained on L-arginine for 6 months. (378)

An open-label study of 9 women in Sweden failed to find any change in symptom scores or in nitric oxide production in the bladder. (379) A placebo-controlled randomized controlled trial of 53 IC patients could find no difference on an intention to treat analysis between drug and placebo-treated patients. (380) A smaller randomized placebo-controlled crossover trial of 16 BPS patients found no clinically significant improvement with L-arginine and concluded that it could not be recommended for BPS treatment. (381)

Data does not support the use of L-arginine for the relief of symptoms of interstitial cystitis.

Level of Evidence: 1 Grade of Recommendation: Not Recommended

8.2. Quercetin

Quercetin, a bioflavonoid available in many over-the-counter products, may have the anti-inflammatory effects of other members of this class of compounds found in fruits, vegetables, and some spices. Katske et al. (382) administered 500mg twice daily to 22 BPS patients for 4 weeks. All but one patient had some improvement in the O'Leary/Sant symptom and problem scores as well as in a global assessment score. Further studies are necessary to determine efficacy.

Level of Evidence: 4 Grade of Recommendation: D

8.3. Antibiotics

Warren et al. (383) randomized 50 patients to receive 18 weeks of placebo or antibiotics including rifampin plus a sequence of doxycycline, erythromycin, metronidazole, clindamycin, amoxicillin and ciprofloxacin for 3 weeks each. Intent to treat analysis demonstrated that 12 of 25 patients in the antibiotic and 6 of 25 patients in the placebo group reported overall improvement while 10 and 5 respectively noticed improvement in pain and urgency. The study was complicated by the fact that 16 of the patients in the antibiotic group underwent new BPS therapy during the study as did 13 of the placebo patients. There was no statistical significance reached. What was statistically significant were adverse events in 80% of participants who received antibiotic compared to 40% in the placebo group. Nausea and/or vomiting and diarrhea were the predominant side effects. Most patients on antibiotics correctly guessed what treatment arm they were in, and those that guessed correctly were significantly more likely to note improvement after the study. No duration in improvement after completion of the trial of antibiotics was reported.

Burkhard et al. (384) reported a 71% success in 103 women presenting with a history of urinary urgency and frequency and chronic urethral and/or pelvic pain often associated with dyspareunia and/or a history of recurrent urinary tract infection. This was a large, inclusive group and one that is probably broader than the bladder pain syndrome we are focusing on. Nevertheless, he recommended empiric doxycycline in this group. The overwhelming majority of BPS patients have been treated with empiric antibiotics prior to diagnosis. The role of tetracyclines to eradicate nanobacteria in urine of BPS patients has recently been addressed in a small Chinese open label study, leaving the significance of nanobacteria as a reasonable pathogen or trigger of the condition open. (133)

At this time there is no evidence to suggest that antibiotics have a place in the therapy of BPS in the absence of a culture-documented infection. (385)

Level of Evidence: 4 Grade of Recommendation: D

8.4. Methotrexate

Low dose oral methotrexate significantly improved bladder pain in 4 of 9 women with BPS, but did not change urinary frequency, maximum voided volume, or mean voided volume. (386) No placebo-controlled, RCT has been done with this agent.

Level of Evidence: 4 Grade of Recommendation: D

8.5. Montelukast

Mast cell triggering releases 2 types of proinflammatory mediators, including granule stored pre-formed types such as heparin and histamine, and newly synthesized prostaglandins, and leukotriene B4 and C4. Classic antagonists, such as montelukast, zafirlukast and pranlukast, block cysteinyl leukotriene 1 receptors. In a pilot study, 10 women with IC and detrusor mastocytosis received 10mg of montelukast daily for 3 months. Frequency, nocturia, and pain improved dramatically in 8 of the patients. Further study would seem to be warranted, especially in patients with detrusor mastocytosis, defined as >28 per mm2. (387)

Level of Evidence: 4 Grade of Recommendation: D

8.6. Nifedipine

The calcium channel antagonist nifedipine inhibits smooth muscle contraction and cell-mediated immunity. In a pilot study, (388) 30mg of an extended release preparation was administered to 10 female patients and titrated to 60mg daily in 4 of the patients who did not get symptom relief. Within 4 months five patients showed at least a 50% decrease in symptom scores, and 3 of the 5 were asymptomatic. No further studies have been reported.

Level of Evidence: 4 Grade of Recommendation: D

8.7. Misoprostol

The oral prostaglandin analogue misoprostol was studied in 25 patients at a dose of 600 micrograms daily. (389) At 3 months 14 patients were significantly improved, and at 6 months 12 patients still had a response. A cytoprotective action in the urinary tract and other beneficial effects were reported. (133)
8.8. Tanezumab

In Development

An initial randomized, double-blind, placebo-controlled phase two study investigated tanezumab, a humanized monoclonal antibody that specifically inhibits nerve growth factor as a treatment for BPS pain in 64 patients. (390) At week 6 tanezumab produced a significant reduction from baseline in average daily pain score vs placebo. A significantly higher proportion of patients on tanezumab responded as improved in the global response assessment and tanezumab also significantly reduced urgency episode frequency vs placebo.

Nickel et al. performed pooled analyses from three small, clinical trials of tanezumab in patients with urological chronic pelvic pain, including CP/CPPS and BPS/IC, to identify patient subpopulations more likely to benefit from tanezumab treatment. (87) They reported that least-squares mean change (standard error) from baseline in 24 h pain intensity versus placebo was −0.60 (0.24, 90% confidence interval −0.99 to −0.20) overall and −0.99 (0.32, p = 0.002) and −0.17 (0.36, p = 0.650) for females and males, respectively. It was suggested that tanezumab performed better in pain relief in women with BPS/IC and in patients whose symptoms suggested concomitant presence of somatic syndromes (nonurological) instead of patients only with pelvic pain symptoms. Clinical efficacy of tanezumab in BPS/IC indicates that the role of NGF in the pathophysiology of BPS/IC may not be uniform for all patients. If NGF is not the primary driver of pain, then tanezumab may have limited capacity to improve pain, irrespective of the clinical presentations.

Pain studies with this drug had been suspended by the developing company upon FDA request because of the occurrence of osteonecrosis and between 2012 until March 2015 due to CNS side effects. The FDA has now lifted the hold on studies of tanezumab for chronic pain due to non-clinical data characterizing the sympathetic nervous system response to the drug.

8.9. Adalimumab

Tumor necrosis factor-α (TNF-α), a pro-inflammatory cytokine released by immune cells, is suggested to play a key role in the inflammatory process in BPS/IC. (391) TNF-α is highly expressed in the urothelium of patients with ulcerative BPS/IC, which led to the suggestion that drugs inhibiting TNF-α (adalimumab) might decrease IC/BPS bladder inflammation and reduce symptoms. Bosch evaluated the efficacy of adalimumab (80 mg subcutaneous followed by 40 mg every two weeks or subcutaneous placebo for 12 weeks) for the treatment of BPS/IC. (392) 21 patients received adalimumab. There was a statistically significant improvement demonstrated in the O’Leary–Sant IC Symptom and Problem Indexes, Pelvic Pain, Urgency, Frequency Symptom Scale, and GRA at 12 weeks compared to baseline. However, there was no statistically significant improvement in any outcome measure in patients receiving adalimumab compared to placebo. There were no significant AEs. Adalimumab failed to demonstrate positive proof of efficacy compared to placebo due to a significant placebo effect.

Level of Evidence: 1 Previously in Development: failed clinical trial

8.10. PD-0299685, a Ca2+ Channel α2δ Ligand

The alpha2delta subunit of ligand gated calcium ion channels mediates afferent pain fibers and is promising in chronic pain. Nickel et al. investigated PD-0299685 30 mg daily (N = 54), 60 mg daily (N = 55), or placebo (N = 52) for patients with IC/BPS for 12 weeks. At week 12, the 60 mg dose produced a clinically significant reduction in daily worst pain severity score from baseline compared to placebo (treatment difference [90% CI] −0.82 [−1.72, 0.08]). A greater proportion of patients on 60 mg daily dose of PD-0299685 demonstrated an improvement in the GRA. PD-0299685 failed to show clinically significant effect on the IC Symptom Index score or urinary end points. More patients discontinued due to treatment-related AEs (dizziness, somnolence, and nausea) with 30 or 60 mg PD-0299685 daily than with the placebo. The authors concluded that PD-0299685 appeared to have an unfavorable benefit-tolerability profile in the IC/BPS population (393)

Level of Evidence: 1 Grade of Recommendation: Not Recommended

8.11. AQX-1125, a Novel SHIP1 Activating Compound

SH2-containing inositol-5’-phosphatase 1 (SHIP1) is an intracellular protein whose expression is primarily restricted to cells of the hematopoietic lineage. SHIP1 is an endogenous inhibitor of the phosphoinositide-3-kinase pathway that is involved in the activation and chemotaxis of inflammatory cells. SHIP1-deficient mice exhibited progressive inflammation. Drugs activating SHIP1 pathway (AQX-1125) can have a novel anti-inflammatory mode of action. The characteristic of AQX-1125 on the inhibition of mast cells activation and anti-inflammation provided the rationale for a clinical study on BPS/IC.

This 6-week, randomized, double-blind, placebo-controlled, multi-center trial randomized 37 women with BPS and mean pain of ≥5 (11-pt scale) despite previous treatment to 200mg AQX-1125 or placebo (32 patients), orally once daily for 6 weeks. (394) At 6 weeks average daily pain (e-diary) decreased by 2.4 points (AQX-1125) versus 1.4 (placebo) (p=0.061); average pain (clinic) by 2.6 vs 1.1 (p=0.008); maximum daily pain (e-diary) by 2.6 vs 1.4 (p=0.030) and
maximum pain (clinic) by 2.8 vs 1.1 (p=0.028). AQX-1125 reduced ICSI by 3.8 points vs 1.4 (placebo) (p=0.005), ICPI by 3.6 vs 1.6 (p=0.014) and BPIC-SS by 8.8 points vs 4.0 (p=0.011). Urinary frequency decreased on AQX-1125 by 3.6 voids/24 hours vs 0.8 (placebo) (p=0.040). Adverse event rates were similar between AQX-1125 (51.4%) and placebo (78.1%). No SAE were reported. Only a single dose was studied, thus it remains unclear if a higher dose of AQX-1125 would have been more effective. However, non-clinical data suggested maximum pharmacological effect at plasma levels equivalent to 100-150 ng/ml; therefore, higher doses would unlikely confer additional benefit.

**Level of Evidence:** 1 Grade of Recommendation: In Development phase 3 trials

### 8.12. SILDENAFIL

The contraction of smooth muscle caused by elevating potassium or adrenergic activity can be relaxed by phosphodiesterase type 5 inhibitors (PDE5i). PDE5i are a class of drugs approved to treat erectile dysfunction. Potential influence of the drug on detrusor activity and secondly on pain served as the rationale for a randomized clinic trial.

48 women with a clinical diagnosis of BPS were randomly assigned to treatment with daily low-dose sildenafil (25 mg, n= 24) or placebo (n = 24) for 3 months. (395) The O’Leary-Sant IC symptom and problem indices, visual analog scale scores, and a micturition diary with the interval of micturition, the frequency of nocturia, and urgency episodes were recorded before treatment, and every 2 weeks after the treatment until 3 months. Patient Overall Rating of Improvement in Symptoms was assessed and regarded as effective when the value was above 50%. The IC symptom and problem indices scores and urodynamic index were significantly improved in sildenafil treatment group as compared with placebo group and baselines at week 4, 6, 8, 10, and 12, as well as 3 months after treatment (p <0.05). Urodynamic index including first desire to void, strong desire to void, and maximum cystometric capacity was significantly improved in sildenafil treatment group at week 12 and at 3 months after treatment (P <.05). The efficiency of treatment reached 62.5%. However, no significant change of the visual analog scale values was observed between 2 groups except at week 12 in the sildenafil treatment group (P <.05). All adverse events were mild to moderate and transient.

Although a high PDE5 expression in human bladder detrusor muscle has been reported the mode of action of sildenafil in BPS remains unclear. Further large scale studies on dosage and duration of medication are necessary to confirm the results of this innovative study.

XI. INTRAVESICAL / INTRAMURAL THERAPY

Intravesical therapies form one of the staples of BPS therapy, though regulatory approvals and availability throughout the world differ from nation to nation. The data on use of intravesical therapy has been generally poor due to the limited number of controlled accessible studies on intravesical therapies for BPS/IC and non-standardised response criteria. (396,397) This situation is thankfully improving.

What follows are treatments that have been reported in the recent literature, some of which are commonly used. Older therapies that are rarely used now include silver nitrate (81,398-401) and chlorpactin WCS90. (21,402-406) These have not been included in this current edition of the Consultation, but have level 3 evidence to support a grade C recommendation based on original reports.

1. DMSO (DIMETHYL SULFOXIDE)

Grade of Recommendation: B Level of evidence 2

A small number of significant side effects.

DMSO is believed to reduce inflammation, relax muscles, eliminate pain, dissolve collagen, and degranulate mast cells. It has long been used as a therapeutic agent for BPS. Its mechanism of action, however, has not been clarified. Peeker et al reported that in a randomized study, frequency and pain were improved in ulcer-type IC patients, although no improvement was observed in maximum bladder capacity. (407) Perez-Marrero et al reported that in a non-randomized controlled study, 53% of the patients showed remarkable improvement in subjective evaluation (placebo 18%), and 93% in objective evaluation (placebo 35%). (408) Around an 80% improvement rate has been reported in case series and retrospective studies. (409-416)

With regard to side effects after instillation of DMSO, most patients recognize a garlic-like odor, which disappears within a day, and about 10% of patients report bladder irritative symptoms which resolve with or without symptomatic treatment. (417) It is hypothesized that these transient exacerbations occur as the result of mast cell degranulation. The number of significant side effects is considered to be small (416). Cataracts have been reported in animal studies, though not in humans. (418,419) Negative effects on bladder compliance have been noted in rat detrusor.

2. HEPARIN

Grade of Recommendation: C Level of Evidence: 3

Side effects primarily related to effects of intravesical catheterization and slight chance of bladder hemorrhage.

The glycosaminoglycan (GAG) layer on the bladder urothelium is a kind of muco-poly saccharide, working as a non-specific defense mechanism. It is believed that a deficiency or abnormality of GAG secondarily causes inflammation of the bladder by increasing the permeability of the bladder mucosa, leading to the pathologic cascade of BPS. Heparin has similarities to the GAG layer of the bladder. When instilled into the bladder, theoretically it might replace the damaged GAG layer as originally shown by Hanno. (424,425) Kuo reported that the International Prostate Symptom Score, as well as bladder capacity at initial desire to void and maximum bladder capacity, improved significantly. (426) According to the report by Parsons et al symptoms were reduced in 56% of patients treated 3 times weekly for 12 weeks. (427) These reports suggest the efficacy of DMSO may accelerate the absorption of other drugs instilled simultaneously, which could be a source of side effects.

The instillation method has not been standardized. Generally, 50cc of a solution of medical grade 50% DMSO is instilled into the bladder. If pain occurs immediately following instillation, local anesthesia (e.g. 20ml of 2% lidocaine solution) may be instilled. Average retention time is considered to be 10 to 20 minutes. (417) The instillation is performed weekly for 6-8 weeks. After an initial course, treatment is suspended until symptoms recur. If a good result was obtained, another 6 week course (often followed by monthly maintenance) can be initiated. The long-term effect is unknown, although there is no upper limit for the duration of the treatment. It is often administered as a cocktail combined with other medications sometimes including a steroid, heparin, sodium bicarbonate, and/or lidocaine. (421,422) The combination of triamcinolone and DMSO has been shown to increase bladder capacity and increase voiding intervals in a large, uncontrolled series of newly diagnosed patients. (423) DMSO is the only intravesical agent approved for the treatment of interstitial cystitis by the Food and Drug Administration.

heparin, however, there is no randomized comparative study to give conclusive evidence. One study indicated that intravesical heparin instillations may prolong the response to dimethyl sulfoxide treatment. (428) In another report, significant symptomatic benefits accrued from the addition of heparin to intravesical lidocaine solution treatments. (429)

No significant side effects have been reported, as it does not affect systemic coagulation parameters. In the case of patients with hematuria, however, it may exacerbate local hemorrhage.

The instillation method has not been standardized. Generally, 10,000-40,000 units of heparin are instilled. It is unusual to have pain or irritation as a result of instillation, and retention times can be 30 minutes or more. Instillation frequency can be up to every other day and it is often administered at home by the patient. Parsons et al recently reported that when 40,000 units of heparin combined with 1 to 2% lidocaine was instilled 3 times a week for 2 weeks, about 80% efficacy was obtained. (430) There is no upper limit for the duration of the treatment, but a long-term effect is unknown. A bleeding tendency may occur. Heparin for intravesical use is not approved by drug regulatory authorities.

### 3. HYALURONIC ACID

**Grade of Recommendation: C Level of Evidence: 1**

No significant side effects.

Hyaluronic acid, like heparin, is a muco-polysaccharide, that could theoretically repair a damaged GAG layer of the bladder mucosa. Several reports have indicated efficacy. (215,431-437) In the summer of 2003 Bioniche Life Science Inc http://www.medicalnewstoday.com/articles/112053.php and in the spring of 2004 Seikagaku Corporation reported double-blind, placebo-controlled, multicenter clinical studies of their hyaluronic acid preparations (40mg or 200mg per cc respectively) and neither showed significant efficacy of sodium hyaluronate compared to placebo in large phase 3 trials. These negative studies have not been published in peer reviewed literature. Neither preparation has been approved for use for BPS in the United States. At the same time, no significant side effects were observed.

A non-placebo-controlled study has demonstrated a favorable effect of hyaluronic acid on pain reduction. (200) Forty-eight patients with typical symptoms and a positive potassium (0.4 M) sensitivity test were treated with weekly instillations of 40 mg hyaluronic acid for 10 weeks. Visual analogue scale scores showed symptom relief due to hyaluronic acid therapy, irrespective of bladder capacity. The improvement was particularly evident in patients with a reduction in Cmax < 30% compared to patients with a reduction of < 30% with 0.2 M KCl solution (P = 0.003). Long-term effects were investigated in a study of 70 patients previously treated with hyaluronan. (438) Of the initial 70, 48 improved. Of these, 50% reported complete remission with no further therapy. Another 41.7% of patients with symptom recurrence improved after retreatment.

In a Korean study, intravesical instillation of 40mg of HA in 50ml of saline once a week, for 4 weeks, significantly improved VAS score, PUF, ICSI and ICPI in refractory IC/BPS. Previous treatment modalities did not affect the efficacy of the instillation and the presence of Hunner lesion was unrelated to outcomes. (439)

It has been suggested that HA and lidocaine be combined for instillation. In a non-randomized controlled open-label trial, 48women with refractory IC/BPS were enrolled and divided in three groups: the trial group received HA, alkalinized lidocaine (AL) and sodium bicarbonate once a week for 8 weeks and then monthly for 4 months with a subsequent follow-up of 24 weeks, while the two control groups received HA, and AL plus sodium bicarbonate respectively following the same procedure. The HA+LA and the LA groups showed a rapid improvement of symptoms at week 2, while the HA treatment was ineffective until week 4. In the later stage of the treatment, symptoms in AL group recurred, probably because AL relieves symptoms through its anesthetic activity, but it cannot repair the defect of the bladder mucosa. Once the instillation was stopped or the frequency was reduced, the effect disappears gradually. (440)

In a randomized prospective study, IC/BPS patients were randomized in two groups: group A received HA directly with a catheter and group B received HA with electromotive drug administration (EMDA). The VAS score and the micturition frequency were significantly lower in group B at 6 and 12 months. The difference between the two groups was not significant at 24 months, demonstrating that a lack of long-term efficacy is a major problem with this glycosaminoglycan substitution therapy. (441)

A study from China suggested a prolonged effect of bladder distension when combined with instillation of hyaluronic acid. (442)

### 4. CHONDROITIN SULFATE

**Grade of Recommendation: C Level of Evidence: 1**

No significant side effects.

Chondroitin sulfate is the only sulfatated glycosaminoglycan located on the urothelial luminal surface and contributes to the urothelial barrier function. (443) Its efficacy was suggested for the first time 2002 when used alone (444) and in another trial when used in combination with hyaluronic acid. (445) Intravesical chondroitin sulphate demonstrated beneficial effects in patients with a positive potassium stimulation test in two non-randomised, uncontrolled, open-label
pilot studies. Steinhoff (444) treated 18 patients with 40 mL instilled intravesically once weekly for 4 weeks and then once monthly for 12 months. Thirteen of 18 patients were followed for the entire 13-month study. Twelve of these patients responded to treatment within 3–12 weeks. A total of 6/13 (46.2%) showed a good response, 2/13 (15.4%) had a fair response, 4/13 (30.8%) had a partial response, and 1/13 (7.7%) showed no response. In a second trial 24 refractory patients with BPS/IC were treated with high-dose (2.0%) chondroitin sulphate instillations twice weekly for 2 weeks, then weekly with 0.2% solution for 4 weeks, and monthly thereafter for 1 year. (446) The average symptom improvement reported in 20 patients completing the trial was 73.1% (range: 50–95%). The time to optimum response was 4–6 months. A more concentrated 2.0% solution was needed in eight patients to maintain results. Chondroitin sulphate instillation was effective and well tolerated in the therapy of various chronic forms of cystitis associated with a possible GAG layer deficit including BPS in a large multicenter but open study. (447)

Two large randomized placebo controlled trials of chondroitin sulfate as monotherapy for BPS were carried out in North America by Watson. Sixty-five patients with IC/BPS were treated in a prospective, randomized, double-blind, inactive vehicle-controlled, 12-week study (6 weeks treatment, followed by 6 weeks follow-up) . At the primary endpoint analysis (week 7), 22.6% of the vehicle control group were responders compared with 39.4% of the active therapy group, however, the difference was not significant. (92) A follow up randomized placebo-controlled trial with 98 female patients showed only minor improvements in IC/BPS symptoms and pain and failed to demonstrate a statistically significant drug effect vs. placebo . (448) The authors concluded that the study did not support the use of intravesical chondroitin sulfate as a monotherapy for this condition.

In 2013 an individual participant data (IPD) meta-analysis was conducted to define the efficacy of intravesical 2% chondroitin sulfate in IC/BPS patients. (449) The main purpose of this IPS meta-analysis was to increase statistical power for primary outcomes from the data of 3 clinical trials to determine whether larger and long-term studies should be contemplated. (92,448,450) In total, 213 patients were included in this analysis. At the end of the treatment 2245

5. CHONDROITIN SULFATE AND HYALURONIC ACID COMBINATION THERAPY

Grade of Recommendation: C Level of evidence: 2

The combination of hyaluronic acid and chondroitin sulfate forms a more viscous agent, and was proposed several years ago for treatment of BPS by Cervigni and colleagues. (445,451,452) Studies are ongoing. The preparation has been approved in parts of Europe for use as an intravesical therapy. It has been shown in a pilot study to relieve some symptoms of radiation cystitis. (453)

In 2016 a randomized, open-label, multicenter study involving 110 women were randomized to receive 13 weekly instillations (3 months) of HA (1.6% - 800mg) and CS (2.0% - 1g) (Ialuril®; IBSA) or 50% DMSO solution (RIMSO®; Bioniche), with a 2:1 allocation ratio (HA/CS:DMSO). This study showed that treatment with HA/CS appears to be as effective as DMSO with a potentially more favorable safety profile. Both treatments increased health-related quality of life, while HA/CS showed a more acceptable cost-effectiveness profile. (454)

6. PENTOSAN POLYSUFATE

Grade of Recommendation: D Level of evidence: 4

No significant side effects are considered to be present.

Pentosan polysulfate (PPS) is a mucopolysaccharide similar to heparin, with a similar postulated mode of action when used locally. Like other muco-polysaccharides, it has not been well-studied clinically. Bade et al in a randomized controlled trial found benefit in 4 patients out of 10 on PPS versus 2 of 10 on placebo. (455) A placebo-controlled study of 41 patients found the addition of a 6 week course of intravesical PPS to a regimen of oral PPS significantly improved results. (456)

7. VANILLOIDS (CAPSAICIN, RESINIFERATOXIN)

Grade of Recommendation: -A (ineffective) Level of Evidence: 1

Significant side effects: local irritation possible

It would seem reasonable that capsaicin, a C-fiber affenter neurotoxin, could alleviate the pain of BPS by desensitizing bladder afferents. Resiniferatoxin (RTX) is considered to have a stronger action than capsaicin, by desensitizing C-fibers more quickly, and causing less initial irritation. Efficacy was indicated in
five relatively small clinical trials. (457-461) No severe side effects were reported. A randomized multi-center placebo-controlled clinical trial of RTX failed to demonstrate benefit over placebo. (462)

8. BACILLUS CALMETTE-GUERIN (BCG)

Grade of Recommendation: -A (ineffective) Level of Evidence: 1

Potential serious complications

Seven articles reported on a BCG instillation therapy. Zeidman et al first reported that 5 patients who did not respond to other therapies showed symptomatic improvement. (463) Peters et al conducted a randomized double blind study showing a 60% improvement compared to 27% placebo response with good long-term results at 27 months. (464,465) Sixty-five percent of the patients experienced burning sensation, 41% irritation of the bladder, and 35% pelvic pain. One patient was reported to have dropped out due to joint pain.

Peeker et al conducted a randomized double blind study comparing intravesical BCG and DMSO and failed to find any efficacy with BCG. (407) A very large, multicenter randomized placebo controlled trial conducted by the National Institute of Diabetes, Digestive, and Kidney Disorders failed to identify benefit from BCG, although the side-effect profile was surprisingly similar to that of placebo. (466)

9. OXYBUTYNNIN

Grade of Recommendation: D Level of Evidence: 4

Side effect profile is unknown

Barbalias et al observed significant improvement when combining intravesical instillation of oxybutynin with bladder training. (467) Randomized trials are lacking.

10. LIDOCAINE

Grade of Recommendation: C Level of Evidence: 3

No significant side effects.

Lidocaine is a local anesthetic that relieves pain by blocking sensory nerves in the bladder. It can be administered by electromotive drug administration (EDMA). (468-471) Using EMDA, ionized lidocaine is actively introduced into the bladder using an electrical current. Three articles reported that lidocaine and dexamethasone were instilled following hydrodistention. According to the report by Rosamilia et al, 85% of the patients had a good result, with the effect persisting for 6 months in 25%. (471) Other positive results are noted in case reports. (472,473) A report on a pharmacokinetic effect, demonstrated safe levels of lidocaine absorption into the bladder. (474) In a large, placebo controlled randomized trial, 102 adult patients (99 women) with a clinical diagnosis of BPS were randomised from 19 centres in the USA and Canada to receive a daily intravesical instillation of alkalinised lidocaine or placebo (double-blind), for 5 consecutive days. (475) Treated patients had significant sustained symptom relief for up to 1 month. The response rate in the active group was 30% vs 9.6% with placebo. However, further randomized, placebo-controlled trials are needed to ascertain efficacy, optimal treatment parameters, and length of response to intravesical lidocaine preparations. (476) Advantages seem to be immediate response, low-cost of generic medication, and ability of patients to self-administer at home.

In a comprehensive review of lidocaine and bladder pain syndrome, Henry et al conclude that only weak evidence exists for supporting its clinical use at this time. It appears to be a promising candidate drug to interrupt the self-perpetuating neuroinflammatory cycle found in BPS. In the absence of more definitive clinical trials with various lidocaine preparations, it is reasonable to try daily instillations of 10-20ml of a 2% lidocaine solution with or without alkalinization for 7 days to see if a clinical response justifies ongoing treatment. (477)

**XII. BOTULINUM TOXIN (INTRAMURAL) / NEUROMODULATION**

**1. BOTULINUM TOXIN**

Grade of Recommendation: B  
Level of Evidence: 2

Side effects include dysuria, incomplete emptying

Botulinum toxin type A (BTX-A) hinders neuromediator release, both centrally and peripherally and also impedes intracellular transient receptor potential vanilloid type 1 (TRPV1) receptor to the cellular membrane, in bladder afferent nerve fibers, thus enabling both symptomatic and urodynamic improvements. (478)

Thirteen BPS patients were injected with 100–200 IU of BTX-A (abobotulinumtoxin A or onabotulinumtoxin A) into 20–30 sites submucosally in the trigone and floor of the bladder. Overall, nine (69%) patients noted subjective improvement, and ICSI scores improved by 70% (P< 0.05). There were significant decreases in daytime frequency, nocturia and pain, and a significant increase in first desire to void and maximal cystometric capacity. However, dysuria occurred in a majority of patients and persisted in a minority for several months after initial injection. Three patients required clean intermittent catheterization for 2-3 months following therapy. (479)

To ascertain effect of repeat injections a total of 13 patients were followed up for 2 years, while 58 injections were administered with a mean of 4.8 ± 0.8 injections per patient. The mean interval between two consecutive injections was 5.25 ± 0.75 months. At 1 and 4 months follow-up, 10 patients reported a subjective improvement. Mean VAS scores, mean daytime and night-time urinary frequency decreased significantly. The three non-responders to the first intravesical treatment session underwent further treatment 3 months later with satisfactory results. At 1 and 2 years follow-up, the beneficial effects persisted in all patients (480)

These results are in contrast with those in another study from Kuo of BTX-A (onabotulinumtoxin A) in 10 patients with BPS. One hundred units were injected suburothelially into 20 sites in five patients, while 100 U were injected into the trigone in the remaining five. None of the patients became symptom-free; two showed only limited improvement in bladder capacity and pain score. (481)

However in an RCT, Kuo and Chancellor analysed the difference between hydrodistension and hydrodistension plus intravesical, submucosal BTX-A (onabotulinumtoxin A). (482) Of the 67 patients, 44 were divided in two groups: one received 200 U and the other 100 U, and cystoscopic hydrodistension was performed after 2 weeks. The remaining 23 patients received hydrodistension only. There was symptomatic improvement in all groups. However, in the hydrodistension group, 70% had returned to their previous symptoms after the first month, while in the BTX-A-treated groups, there was improvement of VAS, functional bladder capacity and cystometric bladder capacity at 3 months. At 12 and 24 months, the results in the active group were 55 and 30% versus 26 and 17% in the hydrodistension group

In a multicenter, randomized, doubleblind, placebo-controlled patients were randomized to hydrodistension plus suburothelial injections of BTX-A 100U or the equivalent amount of normal saline. Pain was assessed using a visual analog scale (VAS) at week 8 after treatment. Secondary endpoints included voiding diary and urodynamic variables. A total of 60 patients including 40 in the Botox and 20 in the N/S groups were enrolled. At week 8, a significantly
greater reduction of pain was observed in the BTX-A group compared to the N/S group (2.6 vs. 0.9, p=0.021). The other variables did not differ significantly between groups except for cystometric bladder capacity, which was increased significantly in the Botox group. The overall success rates were 63% (26/40) in the Botox group and 15% (3/20) in the N/S group (p=0.028). Adverse events did not differ between the groups. (483)

In order to ascertain effect of isolated BTX-A treatment only, Akiyama et al underwent a single-center, prospective, open labeled, randomized comparative study. Patients with refractory interstitial cystitis were randomly divided into two groups: immediate injection or 1 month delayed injection of botulinum toxin type A after allocation. The rate of treatment response and changes in symptom scores and frequency volume chart variables were compared between groups 1 month after allocation. Using subjects of both groups as a single cohort, predictive factors for treatment response at 1 month post-injection and the duration of response were explored. In a total of 34 patients the response rate was significantly higher in the immediate injection group (72.2% vs 25.0%, p = 0.01). All symptom measures showed significant improvement. When both groups were combined as a single cohort, the response rate was 73.5% at 1 month, 58.8% at 3 months, 38.2% at 6 months and 20.6% at 12 months. The mean duration of response was 5.4 months. The authors also found BTX-A to be more effective in patients with relapse after previous hидродистенсion, thus enhancing its value in refractory cases. (484)

Trigonal-only injection seems effective and long-lasting since 87% of patients (n = 23) reported improvement after a 3-month follow-up period in a study by Pinto et al. (485) Over 50% referred continuity of the beneficial effect 9 months after the first treatment. When retreatment was needed, similar results were obtained. No cases of urinary retention were reported. The authors concluded that this treatment is safe, effective and can be repeated.

Despite Kuo et al’s finding of BTX-A ineffectiveness in disease with Hunner’s lesions (482,484,486), both Akiyama and Pinto et al reported similar results for patients with or without Hunner’s lesions present at treatment, indicating pain is targeted by BTX-A, regardless of cystoscopic phenotype.

Lee and Kuo in a prospective study, treated patients with refractory IC/BPS, with 100 U of BTX-A injection plus hydrodistension followed by repeated injections every six months for up to two years or until the patient wished to discontinue. Of the 104 participants, 56.7% completed four BoNT-A injections and 34% voluntarily received the fifth injection due to exacerbated IC symptoms. With a follow-up period of up to 79 months, O’Leary-Sant symptom and problem indexes (ICSI, ICPI, OSS), pain visual analogue scale (VAS) functional bladder capacity, frequency episodes, and global response assessment (GRA) all showed significant improvement (p < 0.0001). Those who received repeated injections had a better success rate during the long-term follow-up period. The incidence of adverse events did not rise with the increasing number of BoNT-A injections. (487)

Although RCTs have been published establishing efficacy of single and repeated injections with few and mild side effects, studies are still scant and small. Further studies will be needed to obtain conclusive evidence for its efficacy, duration of effect, and side-effect profile.

### 2. NEUROMODULATION

#### Grade of Recommendation: B Level of Evidence: 1

Sacral nerve stimulation (SNS) involves implanting permanent electrode(s) to stimulate S3 or S4 roots. As early as 1989, Tanago et al showed that stimulation of S3 may modulate detrusor and urethral sphincter function (488). FDA approved the usage of sacral neuromodulation for treating refractory detrusor overactivity in 1997 and for urinary urgency and frequency in 1999. Although the effectiveness of SNS for detrusor overactivity is largely confirmed by a good number of studies, only a relatively few papers report the effect of SNS in treating BPS.

Zerman et al reported significant improvement in a 60-year-old woman treated for severe BPS pain using sacral nerve stimulation implant. Pain and accompanying bladder dysfunction were improved by temporary and permanent sacral nerve stimulation for up to six months (489). Maher et al (490) showed that temporary stimulation was effective in 73% of 15 women with refractory BPS. Mean voided volume during treatment increased and mean daytime frequency, nocturia and pain decreased significantly. As indicated by the Short Urinary Distress Inventory and SF-36 Health Survey, the quality of life parameters of social functioning, bodily pain and general health significantly improved during the stimulation period.

Chai et al (239) found that percutaneous S3 nerve root stimulation improves symptoms and normalizes urinary HB-EGF levels and antiproliferative activity in patients with BPS. Treatment response may coincide with a decrease in urine levels of chemokines, especially monocyte chemoattractant protein-1. (491) In their report in 2003, Comiter et al (492) prospectively investigated the effect of SNS on a series of 17 patients with refractory BPS. At an average of 14 months follow-up mean daytime frequency, nocturia and mean voided volume improved significantly. The average pain decreased from 5.8 to 1.6 points on a scale of 0 to 10 and Interstitial Cystitis Symptom and Problem Index scores (ICSI and ICPI) decreased from 16.5 to 6.8 and 14.5 to 5.4, respectively. Of the 17 patients 16 (94%) with a permanent stimulator demonstrated sustained improvement in all parameters at the last postoperative visit. Whitmore et al (493) applied percutaneous sacral nerve root stimulation on 33 patients with refractory interstitial cystitis.
Statistically significant improvements were seen in pain and urinary symptoms. Significant improvements were also seen in ICSI and ICPI scores.

Peters et al (494) reported a reduction of narcotic usage in 18 BPS patients following SNS for a mean of 15.4 months, although the dose reduction was modest (36%) and only 4 of 18 discontinued the narcotics. However, Elhilali and colleagues (495) found that both of two patients with interstitial cystitis reported no improvement following sacral neuromodulation. Zabihi et al (496) more extensively stimulate S2-S4 by implanting electrodes into epidural space through sacral hiatus. 23 of 30 (77%) patients had successful trial stimulation and were permanently implanted. Among these patients, the symptom score was improved by 35% (p=0.005). The pain score improved by 40% (p=0.04). Patients reported an average of 42% improvement in their symptoms.

In the first prospective, single-blind, crossover trial of sacral nerve stimulation (SNS) versus pudendal nerve stimulation (PNS) for patients with BPS (n = 22), PNS gave an overall 59% improvement in symptoms, whereas SNS gave an overall 44% improvement (P = 0.05). Most patients who tested both a sacral and pudendal electrode chose PNS as the better site. Follow-up showed marked improvements in voiding variables and validated BPS symptom questionnaires. Over 90% of patients treated with neuromodulation stated that they would undergo implantation again (497)

Long-term results were verified in a retrospective study of 78 patients treated from 1994 to 2008. Permanent sacral neuromodulation implantation was performed in patients who showed at least 50% improvement in their symptoms with a temporary peripheral nerve evaluation test. Median follow-up was 61.5 ± 27.7 months. Good long-term success of sacral neuromodulation was seen in 72% of the patients. The explantation rate was 28%. The most frequent reason for explantation was poor outcome (54% of the failed patients). The revision rate was 50% (498). In another observational, retrospective, case-controlled review (January 2002–March 2004), 34 female patients underwent permanent device implants. Mean pre-/postoperative pelvic pain and urgency/frequency scores were 21.61 ± 8.6/9.22 ± 6.6 (P < 0.01), and mean pre-/postoperative visual analogue pain scale (VAPS) scores were 6.5 ± 2.9/2.4 ± 1.1 (P < 0.01). Mean follow-up was 86 ± 9.8 months. Sacral neuromodulation showed adequate improvement for the symptoms of refractory BPS. Reoperation rate was 25% (499).

Sacral nerve modulation is still considered an investigational procedure for BPS by the Consultation. Pudendal nerve stimulation has shown better results. Therapeutic benefits of both appear to be significant in selected cases. Strict patient selection and detailed discussion with patients prior to surgery is mandatory. Long-term results should be collected and reported, and trial results discussed with patients before employing this treatment modality.

Percutaneous tibial nerve stimulation has been used to treat BPS, although there is little data on its efficacy at this time. (500,501)

XIII. PAIN EVALUATION AND TREATMENT

1. EVALUATION OF PAIN

The first premise that all physicians treating patients diagnosed with BPS is that they deserve to have their chronic pain assessed and treated. It is now recognized that successful management of BPS is only possible using a multidisciplinary and multimodal treatment approach which must include management of the associated chronic pain. This includes evaluation of the whole patient, not just the urology related symptoms. As described in previous sections, this will involve assessment of clinical symptoms, physical signs and history to best define the underlying diagnosis and overlapping conditions, while not ignoring the problems of mood, sleep and sexual problems. The patient’s self-report should be the primary source of assessment. Clinicians should assess pain with easily administered rating scales (see below for examples) and should document the efficacy of pain relief at regular intervals after starting or changing treatment. Systematic evaluation of the pain involves the following:

- Evaluation of severity
- Detailed history of the pain including assessment of pain intensity over time as well as character
- Evaluation of the psychological state of the patient, including assessment of mood and coping responses
- Physical examination emphasizing the neurologic examination
- Diagnostic workup to determine the cause of the pain
- Regular re-evaluation of therapeutic strategy and response.

The initial evaluation of pain should include a description of the pain; PQRST has been described for this purpose:

P: Palliative or Provocative factors, ‘what makes it less intense?’
Q: Quality, ‘what is it like?’
R: Radiation, ‘does it spread anywhere else?’
S: Severity, ‘how severe is it?’
1.1. Pain measurement

A number of different rating scales have been devised to attempt to methodically measure pain and to allow patient follow-up. These have been used in research, audit and in clinical practice. They all rely on a subjective assessment of the pain and therefore make inter-individual comparisons difficult. Additionally, pain is a multidimensional complex phenomenon and is not adequately described by one-dimensional scales, however there is value in making some sort of an assessment to aid clinical practice to follow individual patients.

- Categorical scales e.g., verbal rating scales: mild, moderate, severe pain
- Visual analogue, Likert or Numerical Rating scale (VAS)
- Complex pain assessment compendiums e.g., Brief Pain Inventory (BPI), McGill Pain Questionnaire (502-504)

The BPI consists of several visual analogue scales grouped together assessing pain at rest, on movement, and other aspects of the pain including interference with function and effect on work. The McGill Pain Questionnaire measures pain quality by asking patients to rate the intensity of 15 verbal descriptors of pain on a 0 to 3 rating scale. The pain rating index is composed of 2 scores, including a sensory pain score and an affective pain score. Some versions also use a standard pain intensity VAS.

1.2. Pharmacologic Management of Chronic Pelvic Pain

Physicians using pharmacologic measures to control BPS pain must be committed to the following principles (524):

1. Drugs are prescribed and monitored with knowledge of the patient’s history and risks,
2. Patients understand potential benefits and harms and participate in reducing harms
3. Clinicians assess outcomes for both effectiveness and harms.

1.3. Acetaminophen

Acetaminophen (paracetamol) is the main representative of this group. It has antipyretic activity and is a simple analgesic. There is very little evidence about its role in chronic pelvic pain (506,507). Acetaminophen should be considered for only mild pain. Acetaminophen is a common cause of hepatotoxicity (508-510) and risk increases with alcohol use.

1.4. Non-steroidal Anti-inflammatory Drugs

The classical non-steroidal anti-inflammatory drugs (NSAIDs) fall into this group and include salicylic acid. They are known to act on the cyclooxygenase (COX) enzyme. The early NSAIDs tended to have little selectivity for COX2 over COX1, and are therefore said to be associated with more side effects than the newer COX2 selective inhibitors (511). The COX1 enzyme is mainly involved in normal ‘housekeeping’ functions, such as mediating gastric mucosal integrity, and renal and platelet function. Blocking the COX1 enzyme is the cause of the platelet, gastric and renal complications that can occur with NSAIDs. It has been suggested that the COX2 enzyme is inducible as a result of tissue damage, and that it is the main enzyme involved in inflammation and peripheral sensitization of nociceptors (512). As a result, the analgesic efficacy of COX2 selective drugs should be as good as that of the nonselective drugs, however the benefit is primarily seen in acute inflammatory type pain. The selective COX2 agents should not be prescribed in patients with increased risk of cardiovascular disease including congestive cardiac failure (513). There is very little evidence for a role of NSAIDs in the management of chronic pelvic pain and even less evidence for a role for the COX2 selective drugs. Most of the analgesic studies have investigated dysmenorrhoea in which NSAIDs have been found to be superior to placebo and possibly paracetamol (512,514).

For practical purposes the NSAIDs may be divided into:

1. Non-selective, low potency (e.g. salicylic acid, ibuprofen).
2. Non-selective, high potency (e.g. ketoprofen, diclofenac, ketorolac).
3. COX2 selective drugs (e.g. celecoxib).

Non-selective, low potency NSAIDs can be used as first-line analgesics. (515) They are most likely to be of help if there is an inflammatory component to the pain. More potent NSAIDs should be reserved for those conditions in which the low potency drugs have been tried and failed to produce significant benefit. COX2 selective drugs should be used with caution as an alternative to the non-selective drugs where there is an increased risk of gastric complications. They should be avoided in patients with known cardiovascular disease. NSAIDs should be taken with food and consideration must be given to the use of gastric protective agents. The benefits of the NSAIDs must be demonstrated to outweigh the risks. All NSAIDs are contraindicated in active gastrointestinal ulceration/bleeding and renal disease. They may seriously exacerbate asthma and produce fluid retention. Even if stronger analgesics such as opioids are added, the NSAIDs can be continued as they are likely to have a synergistic action improving pain control above and beyond that obtained with opioids alone (516).
1.5. Neuromodulators (Neuropathic Analgesics)

Tricyclic antidepressants. Tricyclics have a definite analgesic effect on neuropathic pain compared with placebo (517): 30% of patients should obtain more than 50% pain relief; 30% will have minor adverse effects; and 4% will have to stop treatment because of side effects. Tricyclics are said to work in doses that are too low to affect mood. They may work by increasing levels of norepinephrine and/or serotonin. They also have actions at sodium channels. They have a long history when used for pelvic pain (518,519) and good evidence exists to justify their usage (333,334). A recent randomized placebo controlled study sponsored by the US National Institutes of Health (286) evaluated increasing doses of amitriptyline with or without standardized education and behavioural modification in treatment naïve patients with IC/PBS. While this study did not reach statistical significance when comparing amitriptyline plus education and behavior modification to education and behavioral changes alone, it did show that amitriptyline may be beneficial in persons who can achieve a daily dose of 50 mg or greater. (335)

Serotonin reuptake inhibitors. Selective serotonin reuptake inhibitors appear to be less effective for the management of pelvic pain (520). Fluoxetine can increase plasma levels of amitriptyline and induce toxicity, and therefore care must be exercised if the drugs are combined.

Anticonvulsants: There is evidence that gabapentin and pregabalin are effective in chronic neuropathic pain (521,522). Whereas there is little evidence to support the use of anticonvulsants in the management of genitourinary pain, they should be considered if there is a suggestion of neuropathic pain or central sensitization (320,523,319,505).

N-methyl-D-aspartate (NMDA) antagonists. Ketamine is thought to act primarily at the NMDA receptor, though it may also have actions at sodium channels, as well as opioid (kappa and mu) receptors (525). Ketamine has been shown in both human (526) and animal models (527) of neuropathic pain to reduce central sensitization and wind-up. Ketamine has been found to be useful in a number of chronic pain states including: peripheral neuropathies with allodynia, stump and phantom pain, central pain, as well as fibromyalgia (528-532). However, it has become evident that ketamine should only be used with caution (or not at all) by an experienced practitioner trained in its use. Ketamine is a street drug of addiction and has recently been associated with disastrous bladder consequences, the so-called ketamine bladder. (533)

1.6. Opioids

There is now a general acceptance that opioids have a role in the management of chronic non-malignant pain (534). Strategies that may improve safety and efficacy include appropriate patient selection through identification of risk factors, and access to prescription monitoring programs. Low initial dose, prescription of alternative non-opioid analgesics, and development of written care agreements to individualize and guide therapy improve patient outcomes. (535,536) While the use of opioids in urogenital pain is poorly defined, they should be considered for patients with BPS in whom all other treatments to reduce pain have failed. Opioid use does present very real risks and potential harms (327) and include overdose, addiction, and opioid diversion and prescribers have an obligation to assess risks and minimize harms. Unfortunately, not enough is known about the long-term benefits, risks, and side effects of opioid therapy, not only in IC/PS, but other chronic non-cancer pain conditions. More research is needed in this area. The following guidelines for the use of opioids in chronic/non-acute urogenital pain are suggested by the European Association of Urology (537).

1. All other reasonable treatments must have been tried and failed.
2. The decision to instigate long-term opioid therapy should be made by an appropriately trained specialist in consultation with another physician (preferably the patient’s family doctor).
3. Where there is a history or suspicion of drug abuse, a psychiatrist or psychologist with an interest in pain management and drug addiction should be involved.
4. The patient should undergo a trial of opioids.
5. The dose required needs to be calculated by careful titration.
6. The patient should be made aware (and possibly given written consent):
   I. that opioids are strong drugs and associated with addiction and dependency
   II. the opioids will normally only be prescribed from one source
   III. the drugs will be prescribed for fixed periods of time and a new prescription will not be available until the end of that period
   IV. the patient will be subjected to spot urine and possibly blood checks to ensure that the drug is being taken as prescribed and that non-prescribed drugs are not being taken
   V. inappropriate aggressive behaviour associated with demanding the drug will not be accepted
   VI. hospital specialist review will normally occur at least once a year
   VII. the patient may be requested to attend a psychiatric/psychology review
VIII. failure to comply with the above may result in the patient being referred to a drug dependency agency and the use of therapeutic, analgesic opioids being stopped.

Morphine. There is no compelling evidence that one opiate is better than another. Morphine has, however, become the traditional gold standard. Morphine is the first-line drug, unless there are contraindications to morphine or special indications for another drug. The drug should be prescribed in a slow release/modified release form. Short-acting preparations are undesirable and should be avoided where possible. Parenteral dosing is undesirable and should be avoided where possible. In an acute situation, the daily morphine requirement may be calculated by titration of the drug with progressively increasing doses of 4-hourly rapid-release morphine. However, in most cases, starting with a low dose of slow-release morphine and confining the increments to occur at intervals of no less than 3 days to 1 week is adequate. Chronic non-cancer pain can be managed effectively in most patients with dosages at or below 200 mg/day of morphine or equivalent.

A fentanyl patch can be used when oral absorption is restricted or when the patient suffers from nausea and vomiting. Patches are generally changed every 72 hours. The problem with the currently available patches is that the dosing increments between patches are large. Care needs to be exercised when increments in dose are undertaken. Fentanyl has contributed to numerous overdose deaths (538,539).

Methadone is a strong analgesic which has a long track record (540). While it may have a useful role in the management of urogenital pain, there is very little science to support this. Methadone has the tendency to accumulate with repeated dosing and cause delayed respiratory arrest. Therefore, whereas it may be a very useful drug, it should only be prescribed by a practitioner familiar with its use as an analgesic. Methadone as an analgesic is usually prescribed 6 hourly as its analgesic action is relatively short-lived compared with the longer benefits seen from using the drug in drug addiction.

Meperidine (Demerol) 300 mg intramuscular (i.m.) is about as effective as morphine 30 mg i.m. (conversion factor 0.1). Its oral bioavailability is, however, poor. Meperidine has a short duration of action, can accumulate with multiple dosing and is therefore not recommended for use in chronic, non-acute pain (541).

Oxycodone, hydromorphone and hydrocodone are available as slow/modified-release preparations. They may be useful for opiate rotation if side effects or tolerance is a problem. They are powerful opioids and should be used with the same caution as morphine. 20 mg of oxycodone and 6 mg hydro-morphine is equivalent to 30 mg of Morphine (1.5 and 5 X conversion factor). Oxycodone, hydromorphone and hydrocodone may have a higher abuse liability than morphine (542).

Codeine is a less potent opioid than morphine and the other opioids discussed and could be useful in mild to moderate pain. Tramadol produces analgesia by two mechanisms: an opioid effect; and an enhancement of serotoninergic and adrenergic pathways (543,544). It has fewer of the typical opioid side effects (notably, less respiratory depression, less constipation and less addiction potential) (545). Morphine dose equivalences with tramadol has not been reliably established. Codeine and tramadol may have a lower abuse risk than more potent opioids (542,546).

Opioid Recommendation: Opioids have been shown in randomized controlled trials to be highly effective in the treatment of chronic non-malignant pain. Long-term follow-up studies suggest that this effectiveness can be maintained. However, effectiveness has been limited in many clinical trials by failure to take into account high variability in dose requirements, failure to adequately treat depression, and frequency of side effects due to high inter-individual variability in side effect profiles aggravated by overly rapid dose titration. (547) The tremendous potential benefits balanced by the deadly risk of overdose would indicate the need for consultation with an expert in chronic pain management when the use of opiates is considered for more than the short-term management of a symptom flare. A stepped approach to opioid selection should be based on a patient’s clinical profile and individual characteristics and should proceed in a stepwise fashion. First line therapy for mild to moderate pain would include codeine or tramadol while second line therapy for mild to moderate pain could include morphine, oxycodone or hydromorphone. First line therapy for severe pain would include these same agents, morphine, oxycodone or hydromorphone while second and third line therapy for severe pain could include fentanyl and methadone respectively. It is important to determine the optimal dose, i.e., a dose that will improve function or reduce pain intensity by at least 30% without causing major adverse effects or complications. It is recommended to start the opioid trial with a low dose and increase the dose in small quantities over several days or weeks carefully monitoring for effectiveness (or plateauing of response) and adverse effects or complications. Opioids produce a graded analgesic response: the patient experiences the greatest benefits at lower doses and a plateauing of analgesic response and adverse effects at higher doses.

1.7. Recommendation:

BPS patients deserve to have their chronic pain treated. There are few well controlled long term pain therapy studies in this area, therefore most of our recommendations must come from studies in other non-cancer pain conditions. As discussed in the previous sections, management of symptoms of BPS, including the chronic pain must start with conservative therapies along with BPS condition-specific treatments. For those whose chronic pain is refractory to these therapies including standard analgesics, therapy for
the chronic pain should normally start with a tricyclic and/or gabapentinoid (gabapentin or pregabalin), followed by addition of an opioid such as codeine, tramadol, morphine or oxycodone as a last resort.

**Level of Evidence:** 4 **Recommendation:** C

---

**XIV. SURGICAL THERAPY**

Bladder Pain Syndrome (BPS) is a chronic and debilitating disease. Major surgical options should be considered only when all conservative treatment has failed.

The patient should be informed of all aspects of surgery and understand consequences and potential side effects of surgical intervention. An experienced surgeon familiar with the particular surgical technique should perform the procedure.

**1. HYDRODISTENTION**

Bladder distension has been used for many years (548) not only as a diagnostic/classification tool but also for treatment of BPS. In 1957 Franksson reported on a retrospective series of 33 patients, with symptom improvement in all, and lasting up to 1 year in 7 patients (549). Reports from the seventies were contradictory. Using the Helmstein method (550) Dunn reported complete absence of symptoms in 16 of 25 patients (551), while Badenoch found no improvement in 44 of 56 patients (358). More recent literature reports poor results with only a minority of patients reporting a small improvement in symptoms for a relatively short period of time (225,226,241,552). Reports from the seventies were contradictory. Using the Helmstein method (550) Dunn reported complete absence of symptoms in 16 of 25 patients (551), while Badenoch found no improvement in 44 of 56 patients (358). More recent literature reports poor results with only a minority of patients reporting a small improvement in symptoms for a relatively short period of time (225,226,241,552). Most studies are retrospective and uncontrolled. **Level of evidence 3; recommendation C**

**2. TRANSURETHRAL RESECTION**

In his first papers Hunner described open resection of the bladder ulcer in the treatment of patients with IC (17). He later abandoned this treatment due to operative morbidity and recurrence of symptoms. With better cystoscopes transurethral fulguration became more popular (553). Results of transurethral resection were originally reported by Greenberg et al. (554) and Fall (555). The retrospective results of this treatment in 116 patients with Hunner’s lesion from Fall’s Swedish clinic was later reported by Peeker et al. (556). Hunner’s lesion was first recognized by bladder distension under general anaesthesia. All lesions were then resected including at least half of the underlying muscular coat. Large areas of the bladder might be treated to resect all diseased tissue. Ninety-two of the 116 patients experienced amelioration of their symptoms. Average duration of symptom alleviation was 23 months ranging from 0-180 months. Up to 16 re-resections were performed if symptoms recurred. This is the only center having reported a large clinical series of patients with BPS treated in this manner. Shanberg and Malloy reported in 1987 on laser fulguration of 39 patients with BPS (557). Nineteen of 39 had Hunner’s lesion. Of the 19 patients with Hunner’s lesion 17 reported good pain relief lasting between 6 and 18 months. In the 20 patients without Hunner’s lesion, reddened areas in the bladder were photoagulated with the Neodymium:Yag laser. Thirteen felt marked improvement of symptoms but time to symptom recurrence was not reported. Small bowel perforation in 2 patients was the most important complication in this series. This series was extended to 76 patients (558) where 21 of 27 patients with Hunner’s lesion’s (BPS ESSIC type 3X) experienced symptom improvement; 12 had relapse within 18 months. Of patients with BPS ESSIC type 1 or 2, 20 of 49 improved but 10 required further therapy within 1 year. Rofeim et al. (559) reported on Nd:YAG laser ablation of Hunner’s lesion in 24 patients with BPS type 3X. All had symptom improvement within days without complications. Pain, urgency, nocturia, and frequency were improved after 23 months, but relapse in 11 patients required up to four additional treatments.

Payne et al. reported on 14 patients with Hunner’s lesion treated by cystoscopiv ablation. Eight became symptom free and 4 improved symptomatically more than 50%. Four had symptomatic recurrence with improvement after repeat ablation (560). Intravesical, submucosal injection of triamcinolone has in uncontrolled studies been reported to have as good symptomatic effect as resection/fulguration.

Transurethral resection, fulguration, or laser ablation of Hunner’s lesions is a recommended treatment for patients with BPS type 3X. **Level of Evidence:** 3 **Grade of Recommendation:** B

**3. CYSTOLYSIS – PERIPHERAL DENERVATION**

Hunner (17) simply dissected bladder from surrounding tissue. Initial results were encouraging, however after 3 years of follow-up, symptoms reoccurred. Worth and Turner-Warwick (561) attempted to do more formal cystolysis and were more successful with regard to symptoms. Worth (562) followed patients up to 7 years and found bladder areflexia to be a significant complication of this procedure. Patients had to use Credé technique or even be on intermittent self-catheterisation. Albers & Geyer (563) reported symptom recurrence after 4 years in most of the patients.

Cystolysis – peripheral denervation is not indicated for BPS;

**Level of Evidence:** 3 **Grade of Recommendation:** -A (not recommended)
4. SYMPATHETIC DENERVATION

Visceral pain is transmitted in most cases by the sympathetic nervous system. Gino Pieri (564) applied this principle to the bladder pathology and suggested resection of the superior hypogastric plexus (presacral nerves), paravertebral sympathetic chain, and gray rami from S1-3 ganglia (Level 4). This was repeated by Douglass (565) a few years later. Immediate results were very good; however Nesbit (566) showed that the long term results were short lived.

Sympathetic denervation is not indicated for BPS

Level of Evidence: 4 Grade of Recommendation: -A (not recommended)

5. PARASYMPATHETIC DENERVATION

Based on the contribution of S2-S4 segments to bladder innervation, Moulder and Meirowsky (567) used S3 neurectomy in 3 patients with good long term follow-up. Larger series were reported by Milner (568) and Mason (569) but results after five years were not encouraging. To improve results selective dorsal sacral root neurectomy, unilateral or bilateral, was introduced by Bohm and Franksson (570). The outcomes of this procedure were unclear.

Parasympathetic denervation is not indicated for BPS;

Level of Evidence: 4 Grade of Recommendation: -A (not recommended)

6. BOWEL SURGERY

6.1. Bladder Augmentation-Cystoplasty

Bladder augmentation-cystoplasty has been commonly used for refractory BPS for 50 years. First reports of ileocystoplasty from 1958 were very promising (571). Later publications were less sanguine with good results varying from up to 100% (572,573) to 25% (358,574). Cystoplasty is usually done with or without bladder resection.

Cystoplasty alone was reported as early as 1967 by Turner-Warwick and Ashken (575), advocating augmentation with removal of the diseased tissue. Several subsequent studies indicated that cystoplasty with subtrigonal cystectomy offers better results than without subtrigonal cystectomy (573,576-578). These were all retrospective studies and conclusions should be taken with reservation. Cystoplasty with partial or total removal of the bladder requires bowel tissue substitution. Different bowel segments are used to enlarge the bladder. It is the general consensus that the intestine segment used for bladder augmentation should be detubularized (579). Experiences with different bowel segments have been reported in numerous articles with level 4 evidence:

- ileum (358,572,573,578,580-584)
- ileocecum (398,573,574,576,585,586)
- cecum (572,587)
- right colon (358,573,588)
- sigmoid colon (576,578,582,585)
- gastric segments (589,590)

There is no significant different between different bowels segments with regard to outcome except for gastric tissue substitution which is associated dysuria and persistent pain due to production of acids

6.2. Cystoplasty with Supratrigonal Resection

Cystoplasty with Supratrigonal Resection (i.e. trigone-sparing) has been reported in various studies. Von Garrelts (572) described excellent results in eight of 13 patients with a follow-up of 12-72 months. Bruce et. al (578) reported satisfactory relief of BPS symptoms by ileocystoplasty and colocystoplasty in eight patients. Dounis and Gow (591) reported improvement in pain and frequency in seven BPS patients after supratrigonal cystectomy with ileocecal augmentation. Kontturi et. al (576) used segments of colon and sigmoid colon in 12 cases with 100% symptom-free outcome in five patients augmented with sigmoid colon over 4.7 years of follow-up. Two of seven cases augmented with colon required ileal conduit and cystectomy. Linn et. al (592) followed six BPS patients for 30 months, and reported that all were symptom-free and voided spontaneously. The report by Nielsen et. al (574) was less favorable. Six out of eight patients had good results. Van Ophoven et. al (593) reported the long-term (mean 5 years) results of orthotopic substitution enteroplasty in 18 women with BPS, using ileocecal (n = 10) or ileal (n = 8) segments with only two failures. In the group augmented with ileum, three patients required self-catheterization and one a suprapubic catheter. Peek et. al (594) found that patients with end-stage ulcerative BPS had excellent results following ileocystoplasty but not so the patients with non-ulcer disease. A follow up on this paper was published (188) with the same conclusion for the patients with end stage BPS ESSIC type 3C, while both continence diversion and illocystoplasty were unrewarding in patients with type 2X BPS. Patients with low cystoscopic capacity (<200 ml) under general anaesthetic have achieved better results (20,21,595,596).

There is some weak evidence that cystoplasty with supratrigonal resection may benefit some selected patients with end stage ESSIC type 3C BPS.

Level of Evidence: Level 3; Grade of Recommendation: C
6.3. Cystoplasty with Subtrigonal Cystectomy — Orthotopic Continent Bladder Augmentation

Cystoplasty with Subtrigonal Cystectomy — orthotopic continent bladder augmentation (i.e. with trigone removal but preservation of the bladder neck) in the management of BPS has been reported less often (597-600). Because of the need of ureteral reimplantation, it is associated with some risks of urine leakage, urethral stricture and reflux (599). Linn et. al (592) had three failures in 17 patients and half of the patients with good symptomatic response required self-catheterization. Nielsen et. al (574) had better results following orthotopic substitution with low bladder capacity (200 mL versus 525 mL, respectively). Orthotopic continent bladder augmentation, particularly when removing the trigone, may cause incomplete voiding requiring intermittent self-catheterization. Therefore, patients considering such procedures should be advised accordingly and must be considered capable of performing, accepting and tolerating self-catheterization. Nurse suggested that the decision on whether to do a subtrigonal or supratrigonal cystectomy be based on the results of trigonal biopsy, with the former procedure indicated in the patient with trigonal inflammation (601).

There is no compelling evidence that subtrigonal cystectomy with cystoplasty has any outcome advantage over supratrigonal cystectomy but it tends to be associated with more complications and poorer functional bladder rehabilitation.

Level of evidence: 3; Grade of Recommendation: C

6.4. Urinary Diversion With or Without Total Cystectomy and Urethrectomy

This is the ultimate, final and most invasive option. It should be used as a last therapeutic resort in selected patients. Techniques include simple or continent urinary diversion. Continent diversion may be preferable for cosmetic reasons in younger patients.

Simple urinary diversion with formation of an ileal conduit is the most common surgical treatment for BPS (602). Initially, diversion can be done without cystectomy and only when bladder pain is persistent, cystectomy may be considered. Bladder de-function-alization alone produced symptom-relief in several reports. (20,21,358,574,603-606). Whether or not cystectomy should be performed at the same time as urinary diversion is somewhat controversial (607). About 80% of patients seem to have clinically significant improvement after urinary diversion, but secondary cystectomy does not seem to improve refractory pain (605,606).

Often diversion is performed as a next step after unsuccessful bladder augmentation. To avoid further bowel resection, a bowel segment used for cystoplasty can often be converted to a conduit (608). In some patients chronic inflammatory changes have been seen in the cystoplasty pouch resembling interstitial cystitis (21,358,609,610), preventing one from using this technique. Similar bowel changes however have been described when cystoplasty is performed for pathology other than interstitial cystitis, suggesting that these pathologic findings are not a direct result of the exposure of bowel to BPS urine (611).

Urinary diversion with and without cystectomy may be the ultimate option for refractory patients. Continent diversion may have better cosmetic and life style outcome but recurrence of pain in the pouch is a real possibility.

Level of Evidence: 3; Grade of Recommendation: C

| Neuromodulation   | B                | 1                |
| Cystoplasty with Supratrigonal Resection | C | 3 |
Symptom scales have enabled patients to be categorized by symptom severity and have also served to follow results of treatment in patients with bladder pain syndrome. Their future development may enable a presumptive diagnosis of the syndrome but at this time that is not possible. A brief survey that reliably segregates BPS from other urologic disorders would make the ability to diagnose the syndrome reliable, inexpensive, and available to all healthcare providers. It would aid in epidemiologic studies as well. Currently such work sponsored by NIDDK is ongoing. www.mappnetwork.org

A process for development of a case definition for BPS has been developed by adapting the RAND/University of California, Los Angeles Appropriateness Method. (53) This involves a panel consisting of nine experts with experience in BPS and related diseases, literature review of case definitions of BPS, initial ratings of symptoms as indicators of the BPS diagnosis, and discussion and a second set of ratings to establish criteria for diagnosis through patient reports. Symptom questionnaire development, based on the results of the case definition exercise, and validation have been successful in establishing a population-based estimate for disease prevalence based on the results of the case definition exercise, and validation have been successful in establishing a population-based estimate for disease prevalence using both high specificity and high sensitivity models. (73) If this could be adapted for use in screening by primary care physicians, the potential benefits in early diagnosis of BPS are evident. Questionnaires and symptom scales are currently utilized to measure treatment outcome and are especially valuable in clinical research studies as well as for guiding therapy for individual patients.

There are 4 published BPS symptom questionnaires: the University of Wisconsin IC Scale (figure 12), the O'Leary-Sant IC Symptom Index (ICSI) and IC Problem Index (ICPI) (figure 13), the Pelvic Pain and Urgency/Frequency (PUF) Scale (figure 14) and the Bladder Pain/Interstitial Cystitis Symptom Score (BPIC-SS) (612) (figure 15).

The University of Wisconsin IC Scale includes 7 BPS symptom items and has not been validated for identification or diagnosis of BPS. It captures severity of symptom expression (613,614). Unlike the other two instruments, it addresses some quality-of-life issues, and this is an advantage when such issues are subject of investigation. Its most attractive aspects are its clinically apparent face validity and its ease of implementation.

The O'Leary-Sant indexes are validated questionnaires that were originally developed by focus groups, subjected to test-retest reliability analysis, and validated by administration to BPS patients and asymptomatic controls (615,616). The questionnaires center on 3 questions related to urgency/frequency and one on bladder-associated pain. It does not address generalized pelvic pain or symptomatology associated with sexual activity. This is not because these questions were not considered in the formulation of the questionnaire. Of 73 questions in the preliminary instrument covering domains of urinary symptoms, pain, sexual function, menstrual variability, and general health, only the four questions now in the instrument were needed to reliably and validly describe the illness experience of those with IC and distinguish these patients from those without the disorder (617).

The Pelvic Pain, Urgency, Frequency (PUF) questionnaire (618) was specifically designed to include questions that directly reflect a wide variety of the symptoms experienced by patients who are affected by this disorder. One-third of the questions address pelvic pain, including pain anywhere in the pelvis: the vagina, labia, lower abdomen, urethra, perineum, testes, penis, or scrotum.

The PUF is marred by the fact that patients were not included in its development. If used to monitor outcomes, question 4 regarding sexual activity may worsen the score as the outcome improves. These and other problems make its use highly dubious. (619)

A large study utilizing the PUF questionnaire has concluded that up to 23% of American females have BPS (618). This makes one wary as to the utility and face validity of the PUF[531]. A total score of 10-14 =74% likelihood of positive potassium test (PST); 15-19=76%; 20+=91%. To the extent that the PST is suspect, the reliability of PUF data comes into question.

Neither the PUF nor O’Leary Sant questionnaires have been shown to be of value in diagnosis of the individual patient (620). In an interesting epidemiologic study in Finland, Leppilahti and colleagues randomly selected 2000 participants from the Finnish population registry and administered the O’Leary Sant IC symptom and problem index (69). Women with symptom scores 7 or higher with no history of urinary tract infection in the preceding month were invited to undergo clinical examination. Of these 32 women, 21 underwent examination of whom 3 had probable interstitial cystitis and 4 had possible interstitial cystitis. Based on this specificity, a population

prevalence in Finnish women of 230/100,000 probable interstitial cystitis and 530/100,000 possible interstitial cystitis was calculated. Thus, one can get some idea as to O'Leary Sant specificity. For probable BPS it would be about 14% using a parameter of 7 or greater on the symptom index.

The O'Leary-Sant and University of Wisconsin instrument correlate strongly in a large population of patients with BPS. (621) Clemons and co-workers administered the ICSI to 45 patients scheduled to undergo laparoscopy for pelvic pain. Seventeen were diagnosed with BPS based on the finding of glomerulations on bladder distention associated with urgency, frequency, or nocturia. A score of 5 on the ICSI had a 94% sensitivity and a 93% negative predictive value in this enriched population of patients with pelvic pain (622). However, Clemons and colleagues have found a high degree of overlap in International Prostate Symptom Scores, the O'Leary Sant Symptom Index, and the Chronic Prostatitis Symptom Index in a random sample of over 1400 men and women with urologic symptoms, underscoring that we should be cautious in using these questionnaires as a basis for diagnosis in epidemiologic studies (75).

Rosenberg and Hazzard (67) surveyed 1218 consecutive patients presenting to their primary care office and found 7 (0.6%) who had a 7 ICSI score. Likely BPS was noted in 12.6% of patients on the PUF scale, a figure 21 times higher, suggesting that either the PUF drastically overestimates BPS or the ICSI lacks sensitivity. Based on the correlation of the potassium sensitivity test and the PUF questionnaire, Parsons (56) stated that 30.6% of 3rd year female medical students at his California institution had probable BPS. Sahinkanat and coworkers (209) in Turkey administered the PUF questionnaire to all 442 female textile workers in two local factories. Eighty-six per cent of those with a PUF score 7 or greater had an 86% positive rate of PST testing verses 9% positive in the group with PUF less than 7. They extrapolated that bladder epithelial permeability dysfunction was present in 32.8% of these unselected women. The ICSI estimate seems much more in line with current epidemiologic data.

While perhaps not ideally suited for epidemiologic studies, these questionnaires can reveal important epidemiologic data. Porru and colleagues (623) compared University of Wisconsin scores including both urinary and non-urinary symptoms, for 30 BPS female patients and 30 female controls. While the IC group had significantly higher scores for the urinary symptoms, they did not appear to indiscriminately report higher scores than controls for different somatic and general complaints, as might be expected if this disease is a manifestation of a more generalized disorder. Diggs and colleagues (624) used the ICSI to investigate how interstitial cystitis patients interpret urgency. The ICSI question regarding: “the strong need to urinate with little or no warning” consistently underestimated the response to the International Continence Society definition of urgency: “the compelling urge to urinate that is difficult to postpone.

With the results of a review of existing patient-completed measures indicating they did not meet current standards for the development of patient reported measures (625,626), and facing the need for a new patient friendly measure with good sensitivity and specificity, a new measure of BPS symptoms was developed (612). The Bladder Pain/ Interstitial Cystitis Symptom Score (BPIC-SS) is based on defined standards for patient-completed measures, including patient and clinical input, e.g. cognitive debriefing by patients during the development of the score and findings from cystoscopy and hydrodistension. The BPIC-SS appears to successfully discriminate BPS patients from OAB patients and healthy controls. It has not been validated to discriminate BPS patients from those with confusable diseases(e.g. endometriosis or UTI). The BPIC-SS appears more discriminative than the PUF or the ICSI. As a result, the BPIC-SS has been implemented into the standard sets within the FDA’s guidance for patient reported outcome development and has already been used in recent BPS trials (394). Finally, although developed for the purpose of screening into trials, the BPIC-SS could also be used for measuring outcome results during clinical trials. The questionnaire is available free of charge (http://www.prolutssh.com).

Treatment outcome studies have also used the Global Response Assessment (figure 15); a balanced patient self-report on overall response to therapy, developed for NIDDK sponsored multicenter therapeutic trial (346). The O'Leary Sant and University of Wisconsin questionnaires are responsive to change over time in patients with BPS and have been recommended as secondary endpoints in future clinical trials of the disorder. Propert and colleagues in the Interstitial Cystitis Clinical Trials Group determined that a 1.2 point change in the O'Leary Sant indexes and a 3.1 point change in Wisconsin IC inventory corresponded to a one-category change in the GRA. Individual symptoms were also responsive[538]. (627)

A research tool with an exclusive focus on pain mapping was reported in 2012 (628). It allows the identification and grading of additional pain sites outside the pelvic region in association to QoL aspects.
A simple visual analogue scale (VAS) where the patient reports level of pain by making a mark on an unmarked line continuum, or a numeric rating scale (NRS) in which the patient records a number corresponding to a degree of pain (ie mild 2-4, moderate 5-7, severe 8-10) can be used to evaluate the pain associated with bladder pain syndrome and is useful for following patients and for assessing response to interventions. In pharmaceutical testing, a single-symptom score such as these is commonly chosen as a primary endpoint with more generalized symptom scores comprising secondary endpoints. The genitourinary pain index was not developed specifically for bladder pain syndrome, but can be used to assess the degree of symptoms in both men and women with genitourinary pain complaints. (629) (figure 16)

Male Genitourinary Pain Index

1. In the last week, have you experienced any pain or discomfort in the following areas?
   a. Area between rectum and testicles (perineum) -1 Yes - No
   b. Testicles -1 Yes - No
   c. Tip of penis (not related to urination) -1 Yes - No
   d. Below your waist, in your pubic or bladder area -1 Yes - No

2. In the last week, have you experienced:
   a. Pain or burning during urination? -1 Yes - No
   b. Pain or discomfort during or after sexual climax (ejaculation)? -1 Yes - No
   c. Pain or discomfort as your bladder fills? -1 Yes - No
   d. Pain or discomfort relieved by voiding? -1 Yes - No

3. How often have you had pain or discomfort in any of these areas over the last week?
   Never -1 Rarely -2 Sometimes -3 Often -4 Usually -5 Always

4. Which number best describes your AVERAGE pain or discomfort on the days you had it, over the last week?
   0 No Pain
   1 Pain as bad as you can imagine
   2 3 4 5 6 7 8 9 10

5. How often have you had a sensation of not emptying your bladder completely after you finished urinating, over the last week?
   -6 Not at all -5 Less than 1 -4 Less than half the time in 5 -3 About half the time -2 More than half the time -1 Almost always

6. How often have you had to urinate again less than two hours after you finished urinating, over the last week?
   -6 Not at all -5 Less than 1 -4 Less than half the time in 5 -3 About half the time -2 More than half the time -1 Almost always

7. How much have your symptoms kept you from doing the kinds of things you would usually do, over the last week?
   None -1 Only a little -2 Some -3 A lot

8. How much did you think about your symptoms, over the last week?
   None -1 Only a little -2 Some -3 A lot

9. If you were to spend the rest of your life with your symptoms just the way they have been during the last week, how would you feel about that?
   6 Delighted
   5 Mostly satisfied
   4 Mixed (about equally satisfied and dissatisfied)
   3 Mostly dissatisfied
   2 Unhappy
   1 Terrible

   -6 Terrible
Conclusions

The three commonly employed clinical symptom scales include the O'Leary Sant, the University of Wisconsin, and the Pelvic Pain, Urgency, Frequency scales. None of the questionnaires have the sensitivity or the specificity to be used in the clinical diagnosis of the patients. The O'Leary Sant and University of Wisconsin indexes have been validated as reliable instruments for following the course of the disease and results of treatment interventions. All have shown some value in assessing the severity of the disease. The Global Response Assessment has become one of several primary endpoints used in the judging of the response to the specific therapies.

OUTCOME ASSESSMENT

1. THE PROBLEM

BPS/IC has been a difficult condition for which to assess therapeutic impact. There is a 50% incidence of temporary remission unrelated to therapy, with a mean duration of 8 months (59). A somewhat surprising finding from the Interstitial Cystitis Database was that although there was initial improvement in symptoms partially due to regression to the mean (630) and the intervention effect, there was no evidence of a long-term change in average symptom severity over the four year course of follow-up. (102) In a chronic, devastating condition with primarily subjective symptomatology, no known cause, and no cure, patients are desperate and often seem to respond to any new therapy. A skeptical view of outcomes is essential (figure 17), as patients can be victims of unorthodox health care providers using unproven forms of therapy, some medical, some homeopathic, and some even surgical.

2. THE PLACEBO ISSUE

Where possible, the results of randomized controlled studies should be used for decision making. Placebo, double-blind studies are optimal in this disorder for which there is no generally effective standard therapy.

Placebo effects influence patient outcomes after any treatment which the clinician and patients believe is effective, including surgery. Placebo effects plus disease natural history and regression to the mean can result in high rates of good outcomes, which may be misattributed to specific treatment effects. (102,631-633) Unfortunately, few BPS treatments have been subjected to a placebo-controlled trial. This is not to say that what seems effective is not, but rather that a high index of skepticism is healthy, even in treatments tested in controlled trials. (634)

While in many diseases an argument can be made against using a true placebo control as opposed to an orthodox treatment of approved or accepted value (635), a good case for true placebo comparison can readily be made for BPS. The vagaries of the natural history, the general lack of progression of symptom severity over time, and the fact that it is not life threatening, mean that there is little to lose and much to gain by subjecting new treatments to the vigorous scrutiny of placebo control. Many patients who volunteer for such trials have already run the gamut of accepted (though generally unproved) therapies. It has long been recognized in protocols that use subjective criteria for assessment that "improvement" may be expected in up to 35% of placebo-treated patients (636). As the spontaneous remission rate (though temporary) for BPS is 11% (357) to 50% (59), combined with the placebo improvement it can be difficult to prove efficacy.

Even in placebo controlled trials, it is reasonable to surmise that some degree of unblinding may occur as a result of somatic or psychological side effects of the active arm, impairing the validity of the trial results and giving the active arm a slight edge over placebo. (637,638) Failure to recognize unblinding can easily bias results of a study and has not been routinely measured in clinical trials. (639) When occurring late in a study after one would expect onset of a therapeutic effect, unblinding could be the result of side effect profile or drug efficacy. Early in the trial it reflects poor placebo or study design. The degree of blinding needs to be ascertained throughout the trial. This is of specific concern in BPS and any disorder where primary outcomes may be subject to patient-specific psychological and physiological factors.

The ethics and necessity of placebo-controlled trials have been questioned, especially in situations in
which an effective treatment exists and also where delay in treatment has been shown to result in disease progression (640-642). However, there are methodological concerns with equivalence and non-inferiority active agent comparison trials (643). These include an inability to determine if the treatments are equally good or equally bad, and the possibility that successive non-inferiority trials can lead to a gradual decrease in treatment efficacy. Although the use of placebo-controlled trials raises ethical concerns when proven effective treatment exists for the condition under investigation, they are ethically justified, provided that stringent criteria for protecting research subjects are satisfied (644).

The value of placebo-controlled trials is aptly illustrated by the decisions by pharmaceutical manufacturers not to pursue FDA approval in the United States for seemingly promising intravesical therapies for BPS (435,645) after placebo-controlled trials failed to establish efficacy. These include low concentration hyaluronic acid (Bioniche, Canada), high concentration hyaluronic acid (SKK, Tokyo), and resiniferatoxin (ICOS, Bothell, Washington, USA). Nalmefene, an initially promising oral therapy in the 1990’s, (646) also failed phase 3 trials (IVAX, Miami). Placebo trials are impractical in surgery and it can be difficult to evaluate surgical reports. The many older medications currently used off-label might not meet success if tested in the stringent manner in which new molecular entities are tested. The expense of testing therapies currently used off-label often requires dependence on the largesse of government agencies like the National Institute of Health. (346,466,647)

3. OUTCOME INTERPRETATION

As has been discussed with regard to rheumatologic disorders (648), the interpretation of measurements of physical functioning in clinical trials should consider the composition of the study sample, with attention to the stage of disease and the heterogeneity in disease duration. Patients with long-standing disease or compromised bladder capacity or central sensitization can be expected to be less responsive to treatments directed toward the bladder itself. Finally, when considering objective changes, the concept of statistical versus clinical significance is paramount. Investigators should, but rarely do, point out differences between statistical improvement and what they consider to be clinically significant improvement (649). As Gertrude Stein reportedly stated, “A difference, to be a difference, must make a difference”. An increase in bladder capacity of 30cc may be statistically significant but clinically irrelevant. Number needed to treat and number needed to harm data[560] may be particularly important in BPS and have not typically been included in efficacy analysis.

4. IMMPACT RECOMMENDATIONS

The core outcome domains for chronic pain clinical trials have been published. (502,650) The Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials (IMMPACT) recommendations indicate that core outcome domains should be considered in all clinical trials of the efficacy and effectiveness of treatments for chronic pain. These domains include:

1. Pain
2. Physical functioning
3. Emotional functioning
4. Participant ratings of improvement and satisfaction with treatment
5. Symptoms and adverse effects, participant disposition

CONCLUSIONS:

Currently for BPS/IC there are no accepted biologic disease markers that can be used for the assessment of response to therapy. The O’Leary Sant, University of Wisconsin, and Global Response Assessment are well-validated questionnaires to follow disease progression and response to therapy. The IMMPACT recommendations suggest that as well as symptoms scores, any future study on a pain syndrome must involve more general assessments of psycho-physical functioning. There is limited experience in BPS/IC for the use of well-validated measures available for the study of chronic pain. Future NIDDK research initiatives may help to rectify this. http://www.mappnetwork.org

International recognition of an agreed upon definition and inclusion and exclusion criteria of BPS/IC will help future studies to fulfill the highest standards available, and placebo-controlled, double blind, randomized controlled trials, where possible, will provide the highest level of evidence to move the field forward.

LEVEL 2 GRADE C RECOMMENDATIONS
Figure 17: Selected reported treatment outcomes in uncontrolled studies in IC literature: Percentage of patients initially improved.
PRINCIPLES OF MANAGEMENT

The information currently available in the literature does not lend itself to easily formulating a diagnostic or treatment guideline that will be acceptable to a wide range of practitioners. Different groups of “experts” would undoubtedly create different “best practices” (651). The compromise approach devised by an experienced cross-section of urologists and gynecologists from around the world at the International Consultation on Continence 2004 meeting in Monaco (40) and subsequently modified at the 2008 and 2012 meetings in Paris (1,652) have been reviewed and updated by the committee and allows for significant latitude to reflect varying individual practice patterns and to account for patient preference.

An underlying principle is that, where possible, decisions on the treatment of bladder pain syndrome should be evidence based (653). Unfortunately, high level evidence of efficacy is lacking for many common treatments, either because such studies have not been done, or were done and failed to demonstrate efficacy (48,654,655).

Another principle is that we should be guided by patient perceived and driven outcomes for bladder pain syndrome, which is, after all, diagnosed on the basis of symptoms after exclusion of confusable diseases. Newer symptom scores are based on this principle. (612,629) Many patients prefer noninvasive therapies (656), and it would seem reasonable to start with physical therapy and/or oral therapies if conservative non-medical interventions (i.e. education, diet, behavioral modification, stress reduction) fail to result in significant symptom amelioration. Use of surgical therapies should be approached with some caution. It has been reported that women with BPS have had significantly more pelvic surgeries than controls, and the majority were performed prior to diagnosis of BPS, possibly for pain related to undiagnosed BPS. (657,658)

1. HARMONIZATION

With representatives from Asia, Europe, and North America, the Consultation has attempted to create a document that is harmonious with guidelines developed around the world in the last several years. The Canadian Urological Association (659), the International Society for the Study of Bladder Pain Syndrome (ESSIC) (38,2), the European Association of Urology (515,660), the Spanish Urological Association (661), the Japanese Urological Association (228), East Asian countries (662,663), and the American Urological Association (44,664) all have published consensus guidelines, many of which have been reviewed (651).

In the Japanese and Asian view, urinary frequency/urgency is the primary symptom, with overactive bladder (OAB) and hypersensitive bladder (HSB) listed as subgroups with painful bladder syndrome (PBS) as its extreme form (43). (figure 3)

In the European view as reflected in European Association of Urology and ESSIC guidelines, pain is the key symptom, with frequency being secondary to pain, while urgency basically represents a different pathology. American and Canadian guidelines are concordant with the European view. They emphasize pain, pressure, and discomfort perceived by the patient to be related to the bladder and associated with urinary frequency or urgency.

Pathologic afferent activity is a feature in overactive bladder as well as BPS, making the philosophy of the Asian guidelines conceptually attractive. But the knowledge gaps on lower urinary tract sensory functions are tremendous and from a neurophysiologic point of view it may be premature to link the conditions.

As a disorder based on symptoms, it is remarkable that we do not know if sensations described by the patient as pain, urge, or pressure are physiologically different or identical; that is, if they represent various grades of the same pathology, or if this set of terms merely represents linguistically different ways of presenting the same problem. Do cultural differences play a part? Are Asian patients more reluctant to use the word pain to describe the same symptoms?

Cystoscopic and pathologic findings have a more important role in Asia and Europe than in North America, but nowhere do guidelines now recommend invasive procedures like endoscopy with or without biopsy (though critical to make a diagnosis of Hunner lesion) as essential to make a diagnosis of BPS.

The algorithms from the European Association of Urology, American Urological Association, and East Asian nations are presented below and illustrate different approaches to a difficult problem. (figures 18, 19, 20) Opportunities for future harmonization are apparent.
Figure 18: European Association of Urology guidelines for chronic pelvic pain and bladder pain syndrome 2012/2013 (515,660)
Figure 19: Management proposed by Japanese Urological Association and urologists in Taiwan and Korea, modified from Homma. Potassium diagnostic test was dropped in 2015 updated guideline. (662,663)

Figure 20: Management Guideline of American Urological Association (664)
Men or women with an unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than six weeks duration, in the absence of infection or other identifiable causes should be evaluated for bladder pain syndrome. The initial assessment consists of a bladder diary, residual urine determination, focused physical exam, urinalysis, and urine culture. Cytology and cystoscopy are recommended if clinically indicated. Baseline symptoms should be characterized with a validated symptom questionnaire that can be used for follow-up.

Patients with infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and/or hematuria are evaluated with indicated imaging and endoscopic procedures, and only if findings are unable to explain the symptoms are they diagnosed with BPS. Patients with symptoms compatible with a primary gynecologic or gastrointestinal etiology should be evaluated by an appropriate specialist before making a diagnosis of BPS.

Patient education and support, dietary manipulation, stress reduction, nonprescription analgesics, and pelvic floor relaxation techniques comprise the initial management of BPS. It is important at every stage to address the patient’s pain, and understand that at some point in the progression of treatment, referral to a pain specialty clinic may be desirable. When the conservative approach fails, or symptoms are severe and conservative management unlikely to succeed, oral medication, physical therapy, and/or intravesical treatment can be prescribed.

If oral or intravesical therapy fails, or before beginning such therapy at the discretion of the clinician, it is reasonable to consider further evaluation which can include urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anesthesia. Laparoscopy may be indicated if there is a suspicion of gynecologic disease. Findings of bladder overactivity suggest a trial of antimuscarinic therapy. Findings of a Hunner lesion suggest therapy with transurethral fulguration or resection of the ulcer. The finding of glomerulations should not alter therapeutic decision making. Distention itself can have therapeutic benefit in up to one-third of patients, though benefits rarely persist for longer than a few months.

Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive modalities. These might include neuromodulation, intradetrusor botulinum toxin, or cyclosporine. At any stage of the treatment algorithm, experimental pharmacologic protocols of promising new treatments are reasonable to consider if symptoms warrant and the risk-benefit ratio is acceptable.

The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urine stream. Augmentation (substitution) cystoplasty and urinary diversion with or without cystectomy have been used with good results in very well selected patients.

A treatment algorithm by the Consultation is presented in section 20.

It is the opinion of the committee that, because of the natural history of the disorder, it is best to cautiously progress through a variety of treatments. Whereas the shotgun approach, starting newly diagnosed patients on a variety of simultaneous medications, seems to have many adherents, employing one treatment at a time makes the natural history of the disease itself an ally in the treatment process. If a treatment has no efficacy, it should be stopped. If it a treatment results in modest improvement, it should be continued and another treatment option employed in an attempt to further improve symptoms. The goal is to maximize quality of life and dispense with ineffective treatments in a somewhat controlled fashion. The patient and clinician must remember that “perfect is the enemy of good” and expectations should be realistic. One should encourage patients to maximize their activity and live as normal a life as possible, not becoming a prisoner of the condition. Although some activities or foods may aggravate symptoms, nothing has been shown to negatively affect the disease process itself. Therefore, patients should feel free to experiment and judge for themselves how to modify their lifestyle without the guilt that comes from feeling they have harmed themselves if symptoms flare. Dogmatic restriction and diet are to be avoided unless they are shown to improve symptoms in a particular patient. If the patient has associated depression or cognitive distortions (catastrophizing), or if the patient has associated disorders (often other chronic pain disorders), these should be addressed as a part of the overall treatment plan.
The committee believes that further research is needed in many broad areas:

1. Pathology of BPS
2. Biomarker development
3. Immunology of BPS
4. Neurological aspects with particular attention to the relationship of BPS to overactive bladder
5. The relationship of bladder pain syndrome to chronic pelvic pain syndrome (nonbacterial prostatitis)

The majority of current treatments options are still targeting the bladder. However, bladder pain syndrome has now been recognized to occur in many individuals as a part of a spectrum chronic pain syndromes. There is a growing body of literature demonstrating that different visceral pain syndromes, as well as pain syndromes in other body regions, and other systemic diseases often occur together in the same patient. Thus, the efforts to understand the pathophysiology and to design therapeutic modalities have shifted from an organ-based approach to a more global approach. Phenotyping may be important to identify “bladder-related” and “non-bladder” components that contribute to the symptoms in order to improve treatment efficacy.

The following issues would benefit from major research initiatives:

1. To improve symptom-based classification to identify the degree of bladder and non-bladder symptoms.
2. To identify bladder-specific pathology (urothelial changes, ulcer, hypervascularity and the potential role of narrow band imaging (666)). Does the degree of true bladder inflammation correlate with results from specific treatments? Are there other markers that could be used to segregate therapeutic approaches? For the diagnosis of a Hunner lesion, using a cystoscope is indispensable. Checking for Hunner lesions using narrow band imaging (figure 21) has been reported to be useful and could improve diagnostic accuracy of Hunner lesions.
3. Further consensus to bridge the Asian concept of the hypersensitive bladder with the Western concept of bladder pain syndrome must continue.
4. To identify a bladder pain syndrome-specific biomarker (NGF or other neurotrophic factors, angiogenic growth factors, urothelial markers such as antiproliferative factor, cytokines/chemokines profile, uroplakin [antibody, splice variant]).
5. To identify bladder-specific or systemic immunological processes (cytokines/chemokines profile). Such research may also help to identify the difference in the disease process between bladder pain syndrome and over active bladder (lower urinary tract symptoms with and without pain, respectively).
6. If we can identify the “bladder-related” and “non-bladder” (=outside the bladder) components that contribute to the symptoms, we should be able to develop the agent(s) to control bladder pain based on its pathology.
7. Establish patient data bases in different regions and conduct longitudinal follow-up to understand the natural history of the disease and to examine the differences in disease natural history among regions.
8. Develop an easy-to-use tool for non-specialists to readily identify co-morbid conditions that may impact on the need for additional consultation and suggest specific treatment pathways.
9. Develop a simple, non-invasive diagnostic test for BPS.
10. Develop a practical multi-disciplinary care model and test it in various settings. This would include psychological interventions for those with psychological comorbidities, dieticians, physiotherapists, pain specialists, and patient support groups in addition to a specialist for any associated non-bladder related disorders.
XX. SUMMARY

1. DEFINITION

Bladder Pain Syndrome (in the absence of a universally agreed definition, the International Society for the Study of Interstitial Cystitis –ESSIC definition is given (2)

ESSIC: Chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent urge to void or urinary frequency. Confusible diseases as the cause of the symptoms must be excluded.

There is no published data as to what duration of symptomatology indicates that early spontaneous resolution of symptoms is unlikely. While ESSIC arbitrarily uses a 6 month duration, the American Urological Association Guideline suggests 6 weeks is long enough to initiate diagnosis and treatment of BPS. (664) Without further data, the Consultation cannot make a recommendation and believes that it is up to the discretion of the physician and patient as to the proper interval between symptom onset and evaluation and diagnosis of a chronic condition.

2. BLADDER PAIN SYNDROME (BPS)

2.1. Nomenclature

The scientific committee of the International Consultation voted to use the term “bladder pain syndrome” for the disorder that has been commonly referred to as interstitial cystitis (IC). The term painful bladder syndrome was dropped from the lexicon. The term IC implies an inflammation within the wall of the urinary bladder, involving gaps or spaces in the bladder tissue. This does not accurately describe the majority of patients with this syndrome. Painful Bladder Syndrome, as defined by the International Continence Society, is too restrictive for the clinical syndrome.
Propriely defined, the term Bladder Pain Syndrome appears to fit in well with the taxonomy of the International Association for the Study of Pain (IASP) (see below), and focuses on the actual symptom complex rather than what appears to be long-held misconception of the underlying pathology.

**Bladder Pain Syndrome (XXIII-2) (per IASP)**

Bladder pain syndrome is the occurrence of persistent or recurrent pain perceived in the urinary bladder region, accompanied by at least one other symptom, such as pain worsening with bladder filling and daytime and/or nighttime urinary frequency. There is no proven infection or other obvious local pathology. Bladder pain syndrome is often associated with negative cognitive, behavioral, sexual, or emotional consequences as well as with symptoms suggestive of lower urinary tract and sexual dysfunction.

The Consultation believes that based on the pathology and endoscopic findings characteristic of the Hunner lesion, the epidemiologic pattern that distinguishes it from bladder pain syndrome, the clinical response to local treatment of the lesion by resection, fulguration, or steroid injection, the response to cyclosporine, and the absence of reports in the literature that non-Hunner patients go on to develop Hunner lesions (ie, the finding of Hunner lesion does not represent a continuum in the natural history of bladder pain syndrome), the presence of a Hunner lesion should be considered a distinct disease. It therefore should drop out of the bladder pain syndrome construct, much like we do not consider other painful conditions like radiation cystitis, ketamine cystitis, or urinary tract infection a part of bladder pain syndrome.

The Consultation concludes that it would be reasonable to designate the Hunner lesion in symptomatic patients with the term “interstitial cystitis”, thus indicating a true interstitial inflammation. It would be defined much as Hunner defined it 100 years ago, and harmonize to a great extent the Asian, European, and North American concepts of interstitial cystitis. The Consultation will continue to refer to the symptom complex as “bladder pain syndrome”. Hunner lesion will be considered a distinct phenotype, but in the future may be classified as a separate disorder entirely, albeit with local symptoms that are difficult to differentiate from bladder pain syndrome in the absence of endoscopy. In other words, we may be coming full circle in the historical perspective. Figure 2, Figure 4

**2.2. History / Initial Assessment**

Males or females whose symptoms meet the requirements of the definition of bladder pain syndrome should be evaluated. The presence of commonly associated disorders including irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia in the presence of the cardinal symptoms of bladder pain syndrome also suggests the diagnosis. Abnormal gynecologic findings in women and well-characterized confusable diseases that may explain the symptoms must be ruled out.

The initial assessment consists of a frequency/volume chart, focused physical examination, urinalysis, and urine culture. In the absence of confusable disorders (uncomplicated disease), a diagnosis can be made and treatment instituted. Urine cytology, cystoscopy, and urodynamic evaluation are recommended if clinically indicated and/or the diagnosis is in doubt (complicated disease). Patients with urinary infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and microscopic or gross hematuria are evaluated with appropriate imaging and endoscopic procedures, and only if findings are unable to explain the symptoms, are they diagnosed with BPS. **Grade of recommendation: C**

**2.3. Initial Treatment**

- Patient education,
- dietary manipulation,
- nonprescription analgesics,
- stress reduction,
- pelvic floor relaxation techniques comprise the initial treatment of BPS. In the patient with findings suggesting pelvic floor dysfunction, pelvic floor physical therapy with myofascial trigger point release and intravaginal Thiele massage is often an effective therapeutic intervention. The treatment of pain needs to be addressed directly, and in some instances referral to an anesthesia/pain center can be an appropriate early step in conjunction with ongoing treatment of the syndrome.

  - When conservative therapy fails or symptoms are severe and conservative management is unlikely to succeed,
    - oral medication or
    - intravesical treatment can be prescribed. It is recommended to initiate a single form of therapy and observe results, adding other modalities or substituting other modalities as indicated by degree of response or lack of response to treatment.

**Grade of recommendation: C**

**2.4. Secondary Assessment**

If initial oral or intravesical therapy fails, or before beginning such therapy based on clinician judgment, it is reasonable to consider further evaluation which can include Urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anesthesia.

- Findings of bladder overactivity suggest a trial of antimuscarinic therapy.
• The presence of a Hunner lesion suggests therapy with transurethral resection, fulguration of the lesion, or direct steroid injection into the lesion.

• Distention itself can have therapeutic benefit in 30-50% of patients, though benefits rarely persist for longer than a few months.

**Grade of recommendation: C**

### 2.5. Refractory BPS

Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive modalities. Many of these are best administered within the context of a clinical trial if possible. These may include

- neuromodulation,
- intradetrusor botulinum toxin,
- oral cyclosporine A, or
- clinical trials of newly described pharmacologic management techniques. At this point, most patients will benefit from the expertise of an

- anesthesia pain clinic.

The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urinary stream.

- Urinary diversion with or without cystectomy has been used as a last resort with good results in selected patients. Cystectomy and urethrectomy do not appear to add any additional efficacy to diversion alone. (605, 606, 667)

- Augmentation or substitution cystoplasty seems less effective and more prone to recurrence of chronic pain in small reported series.

**Grade of recommendation: C**
Pain management is a primary consideration at every step of the algorithm; patient enrollment in appropriate research trials is a reasonable option at any point. Evidence supporting neurostimulation, cyclosporine A, and botulinum toxin for BPS indication remains limited. These interventions are appropriate only for practitioners with experience treating BPS and willing to provide long-term care post-intervention.
Note: The only FDA approved therapies are DMSO and pentosan polysulfate. Consider CONTINENCE PRODUCTS for temporary support during treatment.

- Pain management is a primary consideration at every step of the algorithm
- Patient enrollment in appropriate research trial is a reasonable option at any point
- Evidence supporting SNS, cyclosporine A, and botulinum toxin for BPS remains limited. These interventions are appropriate only for practitioners with experience in treating BPS and who are willing to provide long-term care post-intervention

2ND LINE TREATMENT
(no hierarchy implied)

Consider oral and or intravesical therapies; (B)
Consider physical therapy; (A)
Consider cystoscopy with hydrodistention under anaesthesia and treatment of any Hunner lesion (B)

3RD LINE TREATMENT

Consider, if not done previously:
Cystoscopy under anaesthesia with bladder hydrodistension fulguration, resection or steroid injection of Hunner lesion (B)

4TH LINE TREATMENT
(no hierarchy implied)

Sacral Nerve stimulation (B)
Intra-detrusor botulinum toxin (B)
Cyclosporine A (C)
Consider new treatment trials

5TH LINE TREATMENT

Consider:
Diversion with or without cystectomy (C)
Substitution cystoplasty

Improved with acceptable quality of life:
Follow and support

A. INTRODUCTION

Not all bladder or bowel incontinence problems can be cured completely and the challenge for those whose symptoms persist is to discover how to deal with their incontinence to minimise its impact on their quality of life. And this usually includes using continence products.

Even those whose incontinence is ultimately treated successfully may have to live with symptoms for a time - for example, while they wait for surgery, or for pelvic floor muscle training to yield its benefits – and they may use continence products temporarily during this waiting period. Others may use them as an adjunct to a treatment that reduces their leakage without eliminating it. Still others may use products intermittently, limiting their use to particular periods or activities associated with troublesome leakage. However, some use products permanently, either following treatment that has not been (completely) successful or because – depending on their frailty, severity of symptoms and personal priorities – they are not candidates for it.

Successful incontinence management with products is often referred to as contained incontinence, managed incontinence or social continence, in recognition of the substantial benefits it can bring to quality of life even though cure has not been achieved (1).

A wide variety of continence products exists and the choice can be confusing. In this chapter, the goal is to provide the current evidence to healthcare professionals so that they may make informed decisions as they choose – or help product users to choose - between continence product categories and, the most appropriate product(s) within a category. We have also aimed to make this information directly accessible to users.

Our main message is that continence is often best managed by a ‘mix’ of different products – often used at different times or for different activities (day/night/home/away/sport). One product is unlikely to be effective for everything.
The chapter provides (Section B) overall guidelines for selecting products to assist with toileting, to prevent or contain leakage, or to address urinary retention, as well as those for incontinence-related skin and odour problems. The key elements of patient assessment are described and a classification of people into broad groups is suggested based on gender, age (adult or child) and the nature and severity of their incontinence. Each of the major product categories is then addressed (Sections D-P) and – where possible – evidence-based recommendations for product selection and use are given. When little or no published data is available, expert opinion forms the basis of recommendations. Tables are provided summarising the user characteristics, priorities and contexts that commonly favour or discourage the use of each of the major product categories available. The chapter also includes (Section C) a review of the methodological challenges of conducting continence product evaluations and interpreting the results.

To accompany this chapter, the International Consultation on Incontinence and the International Continence Society (ICS) have collaborated to make the material more accessible via a web site hosted by the ICS at http://www.continenceproductadvisor.org. This interactive web site provides current evidence to healthcare professionals and users to facilitate informed choices in selecting appropriate products, and accessible, evidence-based advice on how to use them to best effect.

The literature search strategy adopted for the chapter is described in Appendix 1.

### B. OVERALL GUIDELINES FOR SELECTING CONTINENCE PRODUCTS

Suitable continence products are critical for the well-being and quality of life of product users and caregivers. Concealment enables people with incontinence to protect their public identity as a "continent person" and avoid the stigma associated with incontinence (2). Failure to do so can result in limited social and professional opportunities, jeopardise relationships and detrimentally affect emotional and mental well-being (3). Importantly, caregivers need to feel confident that the person(s) they care for will not be embarrassed publicly. Good product choice / use also reduces the level of care required in relation to maintaining hygiene, skin care and laundry (4).

The intimate and stigmatised nature of incontinence means that issues relating to self-image can affect users’ preferences when selecting products. This may be marked in younger people for whom body-image may be particularly important and for whom disruption to normal social and interpersonal development may result in isolation or lack of access to normal experiences (5) (6). A key measure of product success is the ability to conceal the problem (7) and concealment may involve compromises: for example, at some times the added reliability of products with a larger capacity than is strictly necessary may be preferred even though they may be less discreet when worn.

The range of products available can vary enormously between and within countries, depending on the funding available, healthcare policy and the logistics of supply. In publicly funded healthcare systems, some products may be provided free of charge, based on cost-sharing policy, or reimbursed by insurers whereas, in others, no cost support is available, and consumers must pay out-of-pocket. However, the provision of continence services is not considered a priority by health system administrators in most countries, and this is especially true in developing countries (8) (9) (10). In such contexts, this chapter and accompanying website may act as a resource that can foster greater awareness of product choice and may help clinicians and users to identify products that, although not readily available locally, may be sourced elsewhere.

#### 1. PRODUCT CATEGORIES

Apart from those for addressing incontinence-related skin and odour problems, all the products described in this chapter can be categorised as in Fig B-1, according to whether they are designed to: (i) assist with toileting; (ii) help manage urinary retention; or (iii) prevent / contain urinary or faecal incontinence.

All toileting products can be useful for dealing with urine and / or faeces except for handheld urinals which are just for urine. Containment / control products are subdivided into three overlapping classes: for urinary retention, urinary incontinence, and faecal incontinence. For example, someone with urinary retention is most likely to benefit from one of the products in the red ellipse (Fig B-1), while someone with urinary incontinence will most likely benefit from the blue ellipse. A patient experiencing both problems will need two products (one from each ellipse) or one product from the intersection of the two ellipses.
Fig B-1: Products for toileting (top) and for managing incontinence and/or urinary retention (bottom).

2. ASSESSMENT FACTORS

Assessment of a user’s physical characteristics - such as anthropometrics, level of independence, mobility and dexterity, mental acuity and the nature of the incontinence - will help determine the best product(s) for them. In addition, other practical and psychosocial considerations include user participation in selection (11) provision of adequate instructions for use (12) and the need for products to fulfil their function reliably and easily (5) (12) (13). The nature of the environments in which the products will be used, as well as the availability of caregivers are other important factors. Table B-1 summarises the key assessment elements, although currently no evidence-based assessment tool exists. Specific guidance on assessment issues is additionally provided within subsections of this chapter. Personal preference is known to play a substantial role in product selection (eg (14) and (15)) and information on the range of products that may suit an individual is therefore important in order that appropriate choices may be made. Education of users and/or caregivers is key to ensuring product use is optimal; this may range from straightforward instruction in the effective fitting and changing of absorbent products to more in-depth training in the ongoing care of, for example, a suprapubic catheter.

Table B-1: Key elements of assessing a patient and his/her environment

<table>
<thead>
<tr>
<th>Element</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nature of the incontinence problem</td>
<td>The frequency, volume and flow rate of the incontinence influences product suitability.</td>
</tr>
<tr>
<td>Gender</td>
<td>Males may consider and prefer sheaths as a more masculine option to pads. Females may be attracted to products that are more feminine in design and presentation. Some ‘unisex’ products such absorbent pads have different designs that work better for men (or women).</td>
</tr>
<tr>
<td>Physical characteristics</td>
<td>Anthropometrics (e.g. height and waist, thigh, penile circumference) will influence the comfort and effectiveness of a product.</td>
</tr>
<tr>
<td>Mental acuity</td>
<td>Mental impairment can affect the person’s ability to manage the product. Products that resemble usual underwear (e.g. some absorbents) may be easiest to manage. Products which have health implications if used incorrectly (e.g. mechanical devices or catheter valves) should be avoided if mental impairment is likely to preclude correct and safe use.</td>
</tr>
</tbody>
</table>
### Element | Rationale
--- | ---
Mobility | Impaired mobility may make some product choices impractical or require toilet or clothing modification to allow effective use of the product.
Dexterity | Problems with hand or finger movement can make it difficult to use some products (eg taps on leg bags, straps with buttons).
Eyesight | Impaired eyesight limits effective application and management of some products
Leg abduction problems | Difficulty with abduction can make the use of some products impractical or ineffective.
Lifestyle and environments | Daily activities and environments can influence the choice of product; mixture of products may provide optimum management. Different products may be most satisfactory for daytime and going out (when discreetness may be a priority) and nighttime or staying in (when comfort may be a priority), for holidays (when laundry and / or large quantities of disposables may be a problem) or for use at work. The proximity and accessibility of a toilet in the various environments may be a key factor.
Independence / assistance | If a caregiver is required to apply or change the product then it may be important to involve them in the selection of the product and to establish their willingness and ability to use it.
Laundry facilities | Washable pads and bed linen may be very heavy when wet and take a long time to dry. It is important to check that the person doing the laundry has the ability and facilities to cope.
Disposal facilities | Ability to appropriately, safely and discreetly dispose of the selected products needs to be considered.
Storage facilities | Some products – notably, pads for heavy incontinence – can be bulky. Adequate space to store supplies between deliveries / purchases needs to be available.
Personal preferences | Different people like different products and where possible patients should be given a choice of products with which to experiment to determine the most satisfactory product.
Personal priorities | Everyone wants to avoid leakage but other factors such as discreetness may be more or less important to individuals, or may vary according to different contexts and activities.

### 3. MAIN USER GROUPS

Seven primary user groups are identified in this chapter:
- People with urinary retention.
- People who need help with toileting / toilet access.
- Females with light urinary incontinence.
- Males with light urinary incontinence.
- Females with moderate / heavy urinary incontinence.
- Males with moderate / heavy urinary incontinence.
- People with faecal incontinence.

An individual may belong to more than one group. Each group includes children and young people: the products available for them are broadly similar to those for adults.

### 4. CHOOSING BETWEEN PRODUCT CATEGORIES

Tables B-2 to B-7 summarise the user characteristics, priorities and contexts which favour or discourage the use of each of the product categories for six of the seven user groups. Assistance with choosing appropriate products for the first group (people with urinary retention) is given in Section L (indwelling catheters) and Section M (intermittent catheters).

Although the content of these tables is based on the referenced evidence cited in the corresponding chapter sections, the unreferenced versions provided for the lay public on the accompanying website (www.continenceproductadvisor.org) are reproduced here.

The same product will not necessarily suit all people, even if the assessment is similar. Thus, providing access to a range of products to test will help determine the most satisfactory choice. Similarly, priorities vary between users; for example, some will opt for a bulky, less discreet pad to achieve an acceptably low risk of leakage while others will see the balance differently.
A mix of products drawn from more than one category may provide the best solution; for example, needs may vary between day / night, or home / away.

5. SUMMARY
In conclusion, continence products can play an important role in enhancing the quality of life and reducing the stigma of incontinence of those who are awaiting treatment; are waiting for treatment to take effect; elect not to pursue cure options; are unable to be fully cured and are living with an ongoing bladder / bowel problem.

6. RECOMMENDATIONS
- Users often require / prefer a mix of different products for use at different times and for different activities to achieve optimum management (Grade of recommendation C)
- Incontinence should be actively managed with products to minimise the impact of incontinence on quality of life (Grade of Recommendation C).
- Users should be carefully assessed (and reassessed periodically) to select the most appropriate products (Grade of Recommendation C).
- Users should be offered a range of products that are appropriate for their needs in order that they can make informed choices. (Grade of Recommendation C)

1. METHODOLOGICAL CHALLENGES
Part of the complexity of product evaluations stems from the sheer number of product categories and brands available, meaning that many different comparisons could be made. Table C-1 illustrates the problem using a hierarchy of questions relating to absorbent products. So, in this example, once the decision is made to choose an absorbent product in response to question 1, successive further questions can be used to narrow down the choice to a specific product brand. Questions at any of these levels may form the basis for research projects.

Table C-1: Levels of research questions

1. Which product category (eg catheter, sheath, absorbent pad)?
2. Which design of product design (eg pull-up or diaper design of pad)?
3. Which material type (eg reusable or disposable)?
4. Which features (eg with / without elastic gatherers)?
5. Which product brand?

In the field of absorbent products, the practitioner and / or patient wishes to know whether to use an under-pad or a bodyworn product, a reusable or a disposable, a diaper or an insert (if they select a bodyworn),
a diaper with internal elasticity (standing gathers) or without and, finally, which of the many diaper brands is likely to suit them best. This final question is the most pertinent for the practitioner (who may already have made decisions about questions 1-4, Table C-1), but it is particularly problematic because of the high rate of product change. By the time the results of a clinical trial of product brands are known many of the test products will have been modified and the results will have limited value for selection. However, these ‘single design’ studies do have value in demonstrating the range of performance between the brands within a product design category, and where objective measurements can be made (for example, of leakage performance), they can allow for comparisons to be made. Single design studies are also helpful in promoting product improvement by revealing common problems experienced by patients and exposing particularly poor products or poor product features which are amenable to change by manufacturers.

Overall product designs, generic features and classes of materials change much less frequently and attempting to answer questions 1-4 (Table C-1) is therefore likely to lead to more long-lasting results with value beyond the lifetime of the particular brands tested. Such studies have been attempted by many researchers, but these have frequently been confounded by problems with product representation.

The single greatest (and most frequently overlooked) threat to the validity of clinical trials of products is the selection of the brands entered into the study to represent the various designs. Evaluations of a number of product variants of a similar design (eg different brands) have shown that patient ‘overall opinion’ scores can vary by as much as 70 percentage points between apparently similar products (17). Accordingly, in an evaluation to compare different designs, the selection of one or more products to represent each design is crucial. Studies that have purported to compare different designs or materials have often included a small number (most often just one) of arbitrarily selected product(s). Generalising the results of such studies to whole product groups (e.g. reusable underpads, or disposable bodyworns) is meaningless and misleading. It is perfectly possible to select (either by accident or design) a particularly ‘good’ product from one group and a particularly ‘poor’ product from another. A well-designed study will therefore be seriously flawed if there is no clear process or pilot study to determine and justify the choice of particular brands. Even with a systematic process of product selection (or preferably a pilot study) it is unwise to select a single brand to represent a whole group of products and selection of a small group of brands (e.g. three) is preferable. This allows for any ‘within group’ differences to be detected and helps to demonstrate the ‘representativeness’ of the products selected.

The most controlled method of testing different designs, materials or features of products is to make up experimental batches which differ only in the aspect of interest (e.g. the material or the feature) and a small number of studies have attempted this (17) (18). However, experimentally made products are not usually identical to those available on the market which limits their value for product selection.

It is common for practitioners to be asked (by their employers or by companies) to do a small evaluation or trial – sometimes to ‘test out’ a new product and sometimes to help choose between competing brands for bulk-buying. Such trials should be approached with caution; they can be very demanding and their results may be of very limited value, even for local use. The methodological challenges identified above still apply but are compounded by small sample size and restricted product selection. These studies are likely to be helpful only for identifying gross product short-comings or benefits.

### 2. RESEARCH DESIGN

A randomised controlled trial is not possible for clinical trials of products in most categories simply because a ‘control’ product does not usually exist. Nor is there a ‘standard or reference’ product to act as a control, and comparisons with ‘standard practice’ (i.e. the product currently in use) are prone to bias.

Although it is methodologically simpler (and more robust) to compare only two different product groups, it is more clinically relevant to compare several competing groups, using a multiple cross-over design, where there are valid comparisons. For example, there are four main design groups of disposable bodyworn pads for moderate / heavy incontinence (inserts, diapers, pull-ups and T-shaped). Evaluation of all four groups together is much faster (and therefore gives more long-lasting results) and more cost-effective than several serial studies. Cross-over trials are vulnerable to order effects and randomisation of the order of testing should be carried out using Latin squares (19) to ensure balance.

It is important that clinical trials of single designs of products (which aim to enable selection of particular product brands) are comprehensive (i.e. cover all the available products) because otherwise manufacturers can justifiably claim that, although their product may be similar to one of those tested, even subtle distinctions may lead to clinically important differences.

A further problem with research design is the blinding of products. Different products have different appearances and it is impossible to blind subjects or staff to the product in use. Products can be repackaged to assist anonymising but this may have unwanted effects on the products and is expensive.

Previous product experience can also affect study results, particularly if a substantial proportion of subjects are currently using one of the brands included in the study. It is therefore important to record which
products are in current use in order to add this data to the model used in the analysis.

### 2.1. Sample size and study power

Studies that include more than two products (or two small groups of products) will need to be powered so that multiple comparisons can be made. As the number of products included in the study increases the number of possible comparisons of pairs of products rises. This requires a corresponding reduction in the significance level (e.g. by using the Bonferroni method for each pair-wise comparison to retain the overall level of significance (usually $p<0.05$). Thus as the total number of pair-wise comparisons increases the likelihood of a type 2 error (accepting the null hypothesis when it is false) also increases.

Sample sizes therefore need to be calculated to allow for each pair-wise comparison. Sample size requirements rise rapidly if each subject does not test each product and the number of products entered into a study must therefore be limited to avoid subject fatigue. As an example, a clinical trial of four product groups where the primary outcome variable will be binary (e.g. satisfactory / unsatisfactory) will require a sample size of approximately 80 subjects with an alpha of $<0.05$ and d (difference) of 20%.

#### 2.2. Outcome variables

Studies of product performance have most frequently used self-report questionnaires at the end of the product test period to assess participant ratings of product performance. Diaries of product-related events such as leakage, laundry generation and product consumption are also commonly included. Users in some absorbent pad studies have been asked to identify and prioritise aspects of product performance (20) (21) (22) to inform questionnaires and Table C-2 has measured the test re-test reliability of a questionnaire to assess sheath performance and found moderately good Kappa scores (around 0.7) when assessing the same sheath twice with four weeks between measurement periods.

Skin health, urinary tract infection, pain or discomfort are the main physical health consequences for containment products. Skin health (which can be rated by self-report or by skin inspection) has sometimes been used as the primary outcome variable (e.g. (24)). Urinary tract infection is an important outcome for invasive devices such as catheters and it has also been used for pads (25).

Although leakage performance is frequently rated as a high priority by product users, good leakage performance is not adequate as a sole measure of patient satisfaction with performance. A single (or multiple) fatal flaw such as poor comfort, bulkiness, or poor fit may cause a product that performs well for leakage to be unacceptable to the patient for other reasons. Accordingly, aggregate measures - which assume that the overall performance of a product can be calculated using a weighted sum of the scores for specific aspects of performance (like comfort and freedom from leakage) - are ill-adviced. Patient overall opinion or satisfaction with the product should therefore be used as the primary outcome variable (23).

There are no quality of life measurement tools specifically designed for clinical trials of continence products, although a tool has been developed for long-term catheter users (26). Existing incontinence-specific quality of life tools are designed to measure change after interventions to improve incontinence and include urinary symptoms. These tools are therefore likely to be insensitive to changes in quality of life brought about by products which are designed to contain incontinence rather than reduce or prevent it. The first stage in the development of a quality of life tool for absorbent product users has been reported by Getliffe et al. (21).

</table>

Questionnaire items vary depending on the products being tested and for product groups where few studies have been carried out it is particularly important to tailor questionnaires to user needs by asking study subjects to prioritise items and to assess final questionnaires for content and face validity. One study (23) has measured the test re-test reliability of a questionnaire to assess sheath performance and found moderately good Kappa scores (around 0.7) when assessing the same sheath twice with four weeks between measurement periods.

3. SUMMARY AND RECOMMENDATIONS

There is little published evidence on which to base summary and recommendations regarding methodology and so the following summary points are all Level of Evidence 3 / Grade of Recommendation C.

- Evaluation of continence products is methodologically complex and many attempts at providing robust evidence for product selection have been hampered by methodological weaknesses.

- Product representation is critical to providing robust and generalisable data. Selection of products for inclusion in a study should be transparent and systematic. Several products should be included to represent a product group. In particular, care should be taken not to select a particularly good or a particularly poor product to represent a whole class of products.

- Multiple crossover designs are likely to be more efficient than randomised controlled trials for many products (e.g. pads) and therefore sample size estimation needs to take into account the multiple comparisons that will be made.

- Outcome variables should include a patient (or caregiver) questionnaire including items that have been established as important to users.

- Diary data should be included to determine leakage performance, skin health, laundry and product consumption.

- Incidence of urinary tract infection should be included when testing invasive devices such as catheters, but “significant” UTI / bacteriuria needs to be carefully defined (Section L).

- The primary outcome variables should be patient overall opinion / satisfaction and patient preference.

- Health economics should be measured alongside product performance

4. PRIORITIES FOR RESEARCH

- The development of Quality of Life tools for users of continence products.

- Consistent use of a validated product assessment scale.

- Impartial product assessment that compares several products in the same category.

---

D. HANDHELD URINALS

Handheld urinals are portable devices designed to allow an individual to empty their bladder in circumstances where gaining access to a toilet is not possible or is inconvenient, often as a result of limited mobility or joint range of motion. To function effectively, handheld urinals must enable the user to empty his/her bladder comfortably, confidently and in the absence of spillage, during filling and emptying. Excessive physical effort should not be required. The main factors influencing the capacity of a user to successfully utilise a handheld urinal are listed in Table D-1.

**Table D-1: The main factors influencing the capacity of a user to successfully utilise a handheld urinal.**

- The position in which it will be used (e.g. lying in bed, sitting on the side of a bed, sitting back in a chair or on its front edge, standing, kneeling, crouching) together with the nature of the surface upon which the individual is being supported.

- The ability of the urinal user to move themselves (with or without aids or assistance) into the required positions.

- Postural control in those positions, together with hip range of motion, particularly abduction.

- The optimal direction of approach for positioning the urinal (e.g. anterior, posterior, lateral).

- Manual dexterity and strength to adjust clothing, initially position the urinal, maintain its position during voiding, remove the laden urinal post-void and empty or store it somewhere safely to avoid spillage.

- The ability to initiate a void, together with the volume typically voided.

- Cognitive functioning.

- Personal preferences and, where appropriate, the availability of assistance.

Handheld urinals are frequently made from moulded plastic, although single-use cardboard options are available. Some are equipped with handles to facilitate positioning and handling, and some are fitted with drainage bags to collect urine. Urinals designed for women are available in a variety of shapes and sizes (some are quite small and portable), incorporating an interfacing opening that is often anatomically shaped to fit snugly against the woman’s body.

Those intended for men tend to vary less in design, typically having a narrow neck opening to accommodate the penis, and some are fitted with integral non-spill valves or adaptors to prevent the back-flow of urine following use (27) (28) (29).

Some men may find that they can make their own urinal by recycling household bottles or containers (28).
Small, discrete, disposable and re-useable ‘travel’ handheld urinals are available for both men and women (27) (28).

As spillage is not always avoidable during use of handheld urinals, particularly if supine, the use of absorbent pads to protect furniture, bedding and clothing can be a useful addition (30).

An example selection of products is shown in Fig D-1, Fig D-2 and Fig D-3.

**Fig D-1:** Female handheld urinal (a) with drainage bag attached (b).

**Fig D-2:** Male handheld urinal with non-return (anti-spill) valve (a) and without (b).

**Fig D-3:** Collapsible, handheld travel urinals: female (a); male (b) and unisex (c). The male and unisex designs are shown collapsed for storage (top) and ready for use (bottom).
1. EVIDENCE

The 5th International Consultation (31) highlighted a paucity of clinical trials examining the effectiveness of handheld urinals. There were no published trials of male handheld urinals at the time. The single trial identified (32), involving a multi-centre cross-over evaluation of 13 female urinals, found that no single product suited all users. Many were successfully used when standing, crouching or seated at the edge of a bed/chair/wheelchair, but fewer were successful when seated back in a wheelchair, and only one was identified to be reasonably effective in a lying/semi-reclined position. Note, this study highlighted that there were fewer products to meet the needs of women with higher levels of dependence. Other work to develop and evaluate a novel, power-assisted female urinal that pumps urine into a holding reservoir highlighted mixed results in terms of reliability, size, weight, noise and aesthetics (33).

No new trials have been identified for inclusion in the current consultation. There are no new product reviews, nor any published reports of ongoing work to progress the power-assisted female urinal developed by Macaulay and colleagues (33). Most information available to inform users and healthcare professionals about this important product group continues to draw, primarily, on expert opinion (34).

2. SUMMARY

- Super-absorbent polymer can be added to urinals prior to use to absorb and solidify urine (27) (30) (35) (Level of Evidence 1).
- Experimentation is often required to identify the optimal urinal for an individual (27) (29) (30) (32) (35) (Level of Evidence 2).
- Cleaning of handheld urinals is an important consideration. Cleansing with soap and water may be appropriate between episodes of use by a single individual at home, but more robust methods that comply with manufacturer’s recommendations and local infection control policies will be necessary where users are multiple (29) (32) (35) (36) (Level of Evidence 2).
- Men with a retracted penis may find that urinals developed primarily with women in mind can work well for them if they are able to tuck their whole penis and scrotum inside the urinal during use (28) (Level of Evidence 3).
- The careful selection and adaptation of clothing can assist quick and easy use of urinals for both men and women (27) (28) (29) (30) (36) (Level of Evidence 3).
- Expanding the toileting devices available to those in acute care settings to include a wider range of handheld urinals suitable for use by both men and women has been recommended (30) (35) (Level of Evidence 3).

3. RECOMMENDATIONS

Recommendations relating to handheld urinals are summarised in Table D-2.

Table D-2: Recommendations relating to handheld urinals.

- Handheld urinals may usefully form one of a range of options available to both men and women to manage their toileting needs, enhancing the quality of life of both the user and (where relevant) their carer(s) (Grade of Recommendation C).
- Experimentation is often necessary to select the most appropriate urinal to meet individual needs and individual circumstances (Grade of Recommendation C).
- Different types of handheld urinals may be required by an individual in different situations (Grade of Recommendation C).

4. PRIORITIES FOR RESEARCH

- Evaluation of currently available male and female urinals to provide guidance to users, caregivers and healthcare professionals.
- Development of the range of female urinals, particularly to meet the needs of those who are less physically able, who are unable to move to the edge of a bed/chair/wheelchair and/or who need to use a urinal while supine.

E. COMMODES, MOBILE SHOWER-CHAIRS AND BEDPANS

Toileting is a fundamental aspect of personal or self-care. Using conventional toileting facilities is a complex undertaking requiring, for example, core stability, balance, strength, range of movement and cognitive, sensory and perceptual skills to transfer to and from the toilet, adjust clothing, grip and manipulate toilet paper and other menstrual and bowel/bladder management tools.

Gaining access to - and safely utilising - toileting facilities can represent a significant challenge for people with limited or impaired mobility and/or a range of other disabilities. A variety of strategies, assistive aids and equipment exist to facilitate ease of access and independence in toileting and to help maintain privacy and dignity: toilet seat raisers, toilet frames/surrounds, padded toilet seats, grab or support rails, bidets or personal cleansing/drying systems, bottom wipers, etc. (Table E-1), and adaptations to clothing...
and the physical lay-out of toileting facilities. Although there is a dearth of research examining the effectiveness of most of these options, occupational therapists are well placed to offer individual assessments (29) (37) (38) (39) (40).

### Table E-1: Main categories of assistive aids and equipment for toileting

<table>
<thead>
<tr>
<th>Category</th>
<th>Features</th>

</table>

Where it is not possible for an individual to gain timely and safe access to a toilet, conventional or adapted alternatives - such as commodes, mobile shower-chairs and bedpans - may be appropriate. In lieu of a toilet, commodes are static or mobile pieces of equipment that comprise a chair-like frame incorporating a toilet seat under a removable pan (disposable or washable) which is positioned to receive urine and faeces. Mobile shower-chairs (sometimes called sani-chairs) are also available. These are waterproof chairs on wheels that incorporate a toilet seat and are designed to be manoeuvred over the top of a conventional toilet once an individual is seated on them (41) (42). Bedpans are receptacles designed to be positioned beneath an individual who needs to void their bladder or empty their bowels while in bed, or perhaps while seated on a conventional chair. The design of some female handheld urinals may also make them suitable (for men or women) for collecting faeces (36).

Table E-2 lists the main factors influencing the appropriateness of a commode, shower-chair or bedpan as
a solution for individual needs, and Fig E-1 and Fig E-2 show examples of products in this category.

**Table E-2: The main factors influencing the appropriateness of a commode, shower-chair or bedpan as a solution for individual needs.**

- The physical characteristics of the individual such as size, weight, postural stability and functional capabilities.
- The mobility of the individual (including in bed) and approach to transfers (e.g. to commode or shower-chair).
- The cognitive status of the individual (e.g. capacity to recognise the purpose of the equipment).
- Availability of and access to brakes (where appropriate).
- Likely duration of individual episodes of use of the equipment.
- The level of assistance and / or supervision required to use the equipment safely and the burden that represents to any caregiver involved.
- User access to the perianal area for cleansing.
- Comfort and need for pressure relief during use.
- The environment in which the equipment will be used and its impact on privacy and dignity.
- The proximity of the area of use to waste disposal and storage facilities.
- Cleaning and maintenance requirements, responsible person and the burden that cleaning could represent.
- Personal preferences and aesthetics, particularly where equipment is to be used at home, and especially in ‘public’ areas of the home such as a lounge room.

1. EVIDENCE

The 5th International Consultation (31) highlighted the limited empirical research that had been undertaken to examine the effectiveness and use of commodes, shower-chairs and bedpans (43). Older work evaluated a range of commodes available at the time, highlighting concerns with the stability and - therefore - safety of some designs, and their limitations in terms of aesthetics and comfort (41) (44) (45) (46). The appearance of a commode and invisibility of its pan were highlighted as being particularly important in a home environment when masking the function of the chair may be important to both users and caregivers (41) (46) (47). Concerns were raised about the maintenance and cleanliness of commodes (48) (49) generally, and about the management of unpleasant odours, particularly in the home environment (47). Of particular note was the lack of guidance available on the effective cleaning of equipment and management of odours in the home environment, where responsibility for both typically falls to caregivers. The potential use of chemical toilets as an alternative was suggested (47).

Some research in the field has focused on considering the needs of people with spinal cord injuries (SCI) who use mobile shower-chairs, highlighting issues with pressure injury, user access to the perianal area, the ease and safety of rolling and turning the chair, cleaning it and falls from it (50). Evaluation of three chairs commonly used by those with SCI - including evaluation of seating pressures - was undertaken (51) (52) to inform the design and development of a more advanced alternative that is now commercially available (53).

The last consultation also noted that bedpans were not well described in the literature, although they could be broadly categorised into concave pans (rounded, triangular shaped with a curved base and sloping front to back), cut-away pans (rounded, triangular shaped with a flatter seat and rolled edges to provide handgrips) and shovel or ‘fracture’ pans (rectangular or wedge shaped with a flattened end that is positioned beneath the individual, and with a handle at the opposite end). Alongside issues around privacy and dignity, bedpans are generally considered problematic as they do not readily permit the user to assume positions that facilitate urination or defaecation, may cause pain, can be difficult to remove from beneath an individual and are therefore susceptible to spillage and causing skin damage. Furthermore, in the absence of lids, there is the risk of further spills, and they can be malodourous while transporting the content for disposal.

Only three new studies were identified for the current consultation, none of them focusing specifically on static commodes. In the first, Friesen et al (54) undertook an exploratory review to appraise the overall quality of evidence concerning mobile shower-commodes used by adults with SCI and to assess the available evidence in the areas of clinical assessment, design and performance testing. They identified no randomised control trials or systematic reviews of trials and reported that the overall strength of evidence was fair to poor, with case-control studies the highest level of evidence identified. The authors concluded that research is needed to understand how adults with SCI use their shower-chairs/commodes across a range of functional activities and that validated or standardised clinical assessments tools are required.

Subsequent work by the same Australian team interviewed adults with SCI and expert clinicians about how the designs and features of mobile shower-commodes affect selection and functional performance (42). Semi-structured interviews focussed around transfers, propelling, manoeuvring, bowel-care and showering were undertaken with seven adults who had been living with SCI for three or more years and eight expert clinicians working in the field for five or more years. The findings highlighted the complex array of sometimes competing factors that need to be accounted for in prescribing shower-chairs/commodes; for example, the need for large rear wheels to facilitate propulsion may complicate sliding transfers to and from the equipment. While folding frames permit portability, they compromise everyday use (e.g. they are incompatible with tilt-in-space features) and are paradoxically heavier than fixed frames. Also noteworthy was the importance of customised frames, seats and under-seat access to meet individual needs, and the challenges presented by the rapid rate of deterioration of padded seats combined with the lengthy delays often experienced in securing replacements.

Only one study was found evaluating hospitalised patient experiences related to metal bedpans (55). Semi-structured interviews were conducted, based on a German version of the standardised questionnaire (the Bedpan Ongemak Scaal®). The majority of participants (n=87) described the metal pan as hard, cold, uncomfortable and painful when they were left on the pan for an extended period. Pain was significantly more likely to be considered unacceptable by those in the ‘normal’ and ‘under-weight’ categories than by overweight users or those lying supine.

Participants reported fear of missing the pan whilst voiding and described embarrassment and worry about of smells and sounds. Finally, many reported having to wait a long time for the bedpan to be removed.

Recommendations emerging from the study include:

- Minimising time spent sitting on a bedpan and responding immediately to calls,
- Checking the user’s position to avoid pain, providing lumbar support as needed with a pillow for those unable to sit vertically and using pillows beneath the legs to help patients lift themselves onto pans with greater ease,
• Warming metal bedpans immediately prior to use, considering alternative models or applying a pressure care overlay,
• Asking mobile patients in shared rooms to leave the room while the other uses a bedpan,
• Ensuring toilet paper and wet wipes (for hands) are easily within reach, and offering to open a window or spray air-freshener following use of the bedpan.

2. SUMMARY

• A conventional or suitably adapted toilet is preferable to using a commode or bedpan wherever it is safely possible to do so (43) (56) (57) (Level of Evidence 3).
• Commodes or shower-chairs (where an individual can safely use them) are preferable to bedpans. Bedpans may position users poorly to urinate or defaecate and may cause pain (55) (Level of Evidence 3).
• Commode (and shower-chair) designs are criticised because they offer limited trunk support which, combined with lengthy periods of unsupervised use, may increase the risk of falls (56) (Level of Evidence 3).
• Shower-chairs may be preferable to static commodes in terms of facilitating access to a toilet, preserving privacy, dignity and the management of noise and odour (43) (56) (Level of Evidence 3).
• Shower-chair or commode stability must be assessed to ensure it is safe and appropriate for individual needs (29) (41) (44) (45) (46) (54) (Level of Evidence 3).
• Assessment of those with SCI should include review of current bowel-care routines, functional capacity to undertake bowel-care, postural stability and reach for intimate hygiene, transfers to and from the shower-chair/commode, pressure sores, skin integrity and interface pressure mapping (54) (Level of Evidence 3).
• Maintenance and cleaning of toileting equipment has been criticised (47) (48) (49) (Level of Evidence 3), although no guidance for cleaning, particularly in the home environment, is available.

3. RECOMMENDATIONS

Recommendations relating to commodes, mobile shower-chairs and bedpans are summarised in Table E-3.

2. SUMMARY

• Privacy and dignity during toileting are paramount, including the management of associated noise and odours (Grade of Recommendation C).
• Wherever safely possible, access to a conventional or adapted toilet should be offered, or facilitated via a shower-chair with due consideration given to preserving the safety and the modesty of the user during transportation (Grade of Recommendation C).
• The use of bedpans should be minimised to the greatest extent possible without unnecessarily resorting to invasive options such as catheterisation (Grade of Recommendation C).
• Full and careful assessment of individual needs, including mobility, transfers, postural stability, skin integrity, access to the perianal area, and safety must be undertaken before equipment is prescribed or used, and should be followed by regular reviews to assess on-going suitability (Grade of Recommendation C).
• Regardless of the equipment employed, users must have ready access to toilet paper and/or moist wipes and hand washing facilities, and/or appropriate adaptive devices or assistance to help them in this regard (Grade of Recommendation C).
• People should have safe and easy access to a direct method of calling for assistance when left alone for toileting on any piece of equipment (or indeed, on a toilet) (Grade of Recommendation C).
• Equipment should be cleaned after each use, and following local infection control policies in institutional environments, to maintain hygiene, aesthetics and to avoid odour, although there are no evidence-based published guidelines regarding frequency of cleaning or type of cleaning product (Grade of Recommendation C).
• Systems of regular on-going maintenance of equipment are important in whatever environment it is used (Grade of Recommendation C).

4. PRIORITIES FOR RESEARCH

• Evaluative studies of toilet seat raisers, toilet frames/surrounds, padded toilet seats, grab and support rails, bidets or personal cleansing/drying systems, bottom wipers, etc. to inform users, caregivers and healthcare professionals.
• Validated and standardised clinical assessment tools and outcome measures to guide the selection and determine the success of shower-
chairs/commodes for those with long-term needs, particularly adults with SCI (54).

- Evidence-based guidelines to inform the cleaning and maintenance of commodes, shower-chairs and bedpans in institutional and home environments.

### F. ABSORBENT PRODUCTS

Absorbent products (commonly known as pads) are available in a range of sizes and absorencies encompassing light through to very heavy for urinary and/or faecal incontinence. Most pads are bodyworn but some are used on the bed or chair. Broadly speaking, these can be divided into two main subgroups: suitable for light incontinence (usually smaller products) and suitable for moderate-heavy incontinence (usually larger products).

Incidental findings from product evaluations indicate that absorption capacity alone does not determine whether a user will choose to use a product. Some users may have frequent, low flow-rate loss of small volumes of urine (“dribble”), whilst others may be dry for days but then have a higher volume, higher flow-rate incontinence incident ("gush" or "flooding"). Both may prefer to use pads for light incontinence. Mobile and independent community-dwelling women of all levels of incontinence are reported to generally prefer small pads and are often willing to change them frequently rather than use larger products and change them less often (58). Conversely, dependent, immobile individuals may prefer the security of larger products despite relatively low urine volumes due to their dependence on others for pad changing.

Some studies have focused on the use of pads by men. Teunnissen and Lagro-Jansson (59) interviewed 56 men with UI of which only nine used absorbent pads. They concluded that men use pads less frequently than women, have little knowledge about purpose-built pads, are more likely to construct their own pads out of absorbent materials such as towels and are less satisfied with pads than women. Furthermore men may prefer other devices such as urinary sheaths (60) (Section G).

However, the findings of these studies about male and female product use and preferences may not be generalisable to all countries and cultures. In some countries, only limited ranges of absorbent products are available, predominantly adult diapers, with smaller pads less frequently available. Adult diapers are widely sold in supermarkets, prominently displayed, and may be viewed with less embarrassment than in countries where they are supplied primarily through health systems or pharmacies. In comparison, sheath systems may be harder to access and relatively more expensive. Climate (and consequently customary mode of dress) can affect the acceptability of sheaths and their attendant drainage bags.

Studies that have collected and weighed used pads to measure urine loss have found overlap between the quantities contained by pads from different subgroups; thus in a study of insert pads for moderate-heavy incontinence used by older people in residential care around 15% of insert pads for moderate-heavy incontinence contained less than 100g of urine (61) while in a study of older women with light incontinence living in the community about 10% of insert pads for light incontinence were found to contain more than 100g of urine (62).

Although the number of pads used per day might be a good measure of degree of urinary incontinence, this has not been found to be the case in nursing home residents in Norway (25). Pads were collected and weighed from residents in six homes, but a poor correlation was found between the number of pads used and the volume of urine measured over 48 hours. The authors concluded that this was due to pad changes being carried out at routine times by caregivers.

General guidelines on patient assessment for product selection are discussed in Section B. Aspects of assessment that are particularly important regarding absorbent pads are frequency / severity of leakage, day / night incontinence, sex (some products are designed for or are better for men / women than others), ability to change pad independently / need for carer, changing position (standing / lying), diapering facilities, individual priorities (e.g. need for discreetness), personal preference for design / materials (washable / disposable), lifestyle (at home / travel / work etc.). General guidelines on patient assessment for product selection are discussed in Section B.

Aspects of absorbent pad performance have been identified and prioritised (during interviews) by men and women taking part in a series of clinical trials (21). There was notable consistency across patient groups (light / heavy, men / women), with both indicating that the top priority was the ability of a product to hold urine without leakage, while discreetness, containment of odour, ability to stay in place, comfort when wet and ability to keep skin dry were important as well.

### 1. ABSORBENT PRODUCT CATEGORIES

Absorbent products may be classified into two broad categories - disposable (single-use) and washable (reusable) - with each category dividing into two subcategories: bodyworn products (worn by the user) or underpads (placed beneath the user). Within each sub-category are different design groups such as diapers and pull-ups which are sub-divided by size (to fit users of different sizes) and/or absorbency (to cater for different severities of incontinence). Some designs are further subdivided into those intended for men, for women or for children. This classification is shown in Table F-1.
### Table F-1: Classification of absorbent continence products

</tr>
</tbody>
</table>

* The products within a given design group may vary considerably in their features and their constituent materials.

**Bodyworn** absorbent products can be divided into four main design groups:

**Inserts** (sometimes called liners or, in the case of small pads, shields) are held in place by close-fitting underwear or separate stretch mesh briefs (Fig F-1). Many disposable inserts (Fig F-2 and Fig F-3) have an adhesive strip on the back to help secure them and may have an indicator that changes colour when the pad is wet. They may have longitudinal, elasticated standing gathers of hydrophobic material intended to impede lateral leakage of urine and faeces. They are sometimes rectangular but are usually shaped to fit the body. Elastication at the legs may also be used to enhance fit. Washable inserts (Fig F-4) are usually more simply designed than disposable inserts, with no elastication and are either shaped or a simple rectangle. Inserts are made in a wide range of sizes suitable for light through to very heavy urinary incontinence. For light faecal incontinence, the liner may be a small cotton gauze dressing placed against the anus and held in place by the cheeks of the buttocks (Fig F-5).

![Fig F-1: Mesh briefs with (a) and without (b) legs, for supporting disposable bodyworn pads.](image)

![Fig F-2: Small, disposable, unshaped (a) and shaped (b) insert pads for light incontinence.](image)

Fig F-4: Washable, shaped insert pads for light (a) and moderate / heavy (b) incontinence.

Fig F-5: Liner for light faecal incontinence.
(from www.continenceproductadvisor.org)

Disposable diapers (also called all-in-ones or briefs) (Figs F-6) usually have elasticated waist and legs and self-adhesive tabs (usually resealable), and often a wetness indicator and standing gathers. Modified diapers (T-shaped or belted briefs) fasten around the waist before the front is pulled into position and secured, enabling users to apply the diaper whilst standing (Fig F-7). Washable diapers are usually elasticated at the waist and legs and are fixed with
Velcro or press-studs (Fig F-8). Diapers are intended for moderate to very-heavy incontinence.

**Fig F-6: Disposable brief, closed (a) and open (b).**

**Fig F-7: Disposable T-shaped brief, closed (a) and open (b).**

**Fig F-8: Washable brief.**

**Pull-ups** are similar in construction to trainer pants for toddlers. The absorbent material is built into a pull-up pant and is either limited to the crotch area or distributed throughout the pants (Fig F-9, Fig F-10 and Fig F-11). Disposable pull-ups (Fig F-9) are usually elasticated throughout the pants for a close fit. Both disposable and washable pull-ups have versions for different levels of incontinence. Washable pull-ups for light incontinence are often known as pants with integral pad (Fig F-11).
**Homemade products** typically comprise terry-towelling squares which are folded into briefs, fastened with pins and covered with plastic pants as a waterproof barrier. Such pants may also be worn over more conventional designs in an attempt to reduce leakage and/or odour.

“Body” garments (like vests which have a crotch section which opens and closes with snap fasteners, much like those manufactured for babies) may be

---

**Fig F-9:** Disposable pull-ups for moderate / heavy incontinence for women (a), and for men (b).

**Fig F-10:** Washable pull-ups (unisex).

**Fig F-11:** Washable pants with integral pad for light incontinence: boxer style for men (a), y-front style for men (b), and for women (c).
helpful to hold pads in place and may reduce the rustling noise from plastic backing materials.

**Male pouches** (sometimes called shields, guards or leaves) are for lightly incontinent men and are designed to fit around the penis and sometimes the scrotum too (Fig F-12). All are worn with close-fitting underwear or stretch mesh briefs. An adhesive strip is often provided on the disposable versions to help hold them in place.

![Fig F-12: Disposable pouch (a) and leaf (b) for men](image)

**Underpad** absorbent products are usually simple rectangles of different sizes to be used on the bed or chair. Washable underpads may have a high friction backing or have ‘wings’ for tucking beneath the mattress to help keep them in place. Underpads vary widely in absorbency with less absorbent products being used as ‘back-up’ with bodyworn absorbents and more absorbent products being used as sole protection on the bed at night.

Availability of products will necessarily affect choice. However, even where only a single product type (e.g., adult diaper) is readily available, within that product type individual brands and/or absorbencies may be better suited to some users and circumstances than others. Clinicians and users are likely to manage incontinence more successfully if they become familiar with the relative advantages of different products: for example, cheaper products may be slightly less reliable than more expensive ones, but may be perfectly adequate for use at home, when more frequent changing is possible and affordable; more expensive products may provide better protection when out of the home; more absorbent night-time products may be suitable for travel as well as sleeping.

### 2. ABSORBENT PRODUCT MATERIALS

Absorbent products – disposable or washable – usually comprise three main layers: an absorbent core sandwiched between a water-proof backing beneath and a water-permeable coverstock (or topsheet) next to the wearer’s skin.

The main component in disposable absorbent cores is invariably some kind of fluffed wood pulp fibre, but most also contain powdered superabsorber in the crotch region (also referred to as superabsorbent polymer (SAP) or absorbent gelling material (AGM)). Superabsorbers hold much more urine – weight for weight – than fluff pulp and retain it far more tenaciously under pressure. They are usually based on cross-linked salts of polyacrylic acid whose chemistry can be varied according to the balance of properties such as absorption capacity and absorption speed desired. Some thermoplastic fibres are also sometimes included in absorbent cores to reduce core break-up and the collapse of the structure when wet. It is increasingly common for absorbent cores to comprise two or more layers, each designed to perform a different function. For example, an upper layer might comprise low absorbency fibres engineered to receive and distribute urine efficiently and maintain a dry layer next to the skin, while lower layers provide absorption capacity. Some disposable products have ‘breathable’ plastic backings designed to reduce skin occlusion.

Washable absorbent cores are usually made from a needlefelt or knitted fabric comprising rayon and/or polyester fibres. A variety of polymers are used for the water-proofing. In general, the thicker, stiffer materials are more durable (the durability of the plastic backing often determines the lifetime of the product) but less comfortable. Topsheets are usually made from either cotton – which is hydrophilic and intended to have good dry comfort – or polyester – which is hydrophobic and intended to have good wet comfort.

Concern for the environment and for controlling costs has led to an increase in the number of washable products available on the market. An important consideration in the comparison of washable and disposable designs is the relative environmental cost, particularly disposal (landfill) costs of disposable designs and energy costs associated with laundering the washables. A report on baby diapers concluded that...
there was no significant difference in environmental impact between three diaper systems (disposables, home and commercial laundered) although the types of impact did vary (63).

3. ABSORBENT PRODUCT CAPACITY AND USER REQUIREMENTS

Pads come in a range of absorbencies for different levels of incontinence and, understandably, purchasers wish to know how much urine pads will hold. But there is no simple answer: no pad has a volume of urine below which it is guaranteed not to leak; rather, the probability of success decreases as the volume of the urine increases. However, for higher absorbency pads performance falls away more slowly with increasing urine volume than it does for lower absorbency products.

Absorption capacity is a complex concept to communicate in sales literature and product packaging and so companies commonly quote a simple absorption capacity figure. Some use the volume of fluid a pad will hold in a laboratory test - usually international standard ISO 11948-1 (64) - but this figure can be very misleading. Although it correlates well with leakage performance for some groups of users (Section F.6.1.1), the volume of urine which a pad will hold when tested with ISO 11948-1 is enormous compared with how much it will hold in real use. For this reason, some companies prefer to quote a “working capacity”, which might be calculated as some proportion (companies vary in the proportion they use) of the capacity in the laboratory. However, this is still misleading as it implies that the pad will not leak until the working capacity is exceeded. A simple, valid and widely accepted solution to this problem has yet to be devised.

It is equally difficult to determine user needs concerning volume of urine their pads need to hold. Not only can different users leak widely differing volumes from each other but also an individual user may leak widely differing volumes on different occasions. This means that, like pad performance, users’ needs cannot be easily quantified. Published data describing users as ‘lightly incontinent’ place the median and 90th percentile urine volumes in used pads at about 15ml and 100ml, respectively (14). Similarly, those with moderate-heavy urinary incontinence have yielded corresponding figures of about 250ml and 600ml (14). Accordingly, in this chapter the material is divided – somewhat simplistically – into that which relates to light incontinence and that which relates to moderate-heavy.

Some products work better for users whose incontinence is towards the lighter or the heavier end of the spectrum and so, where necessary in the text and tables that follow, these distinctions are made by dividing light incontinence into “light LIGHT” and “heavy LIGHT”; and moderate-heavy incontinence into “light HEAVY” and heavy HEAVY”.

4. BODYWORN ABSORBENT PRODUCTS FOR WOMEN WITH LIGHT URINARY INCONTINENCE

There are four main product designs for women with light incontinence (Table F-2). In addition, menstrual pads are known to be frequently used for light urinary incontinence. The disposable pull-ups are relatively expensive, single-use items and seldom used for light incontinence except as ‘emergency’ items. Underpads are not commonly used for light incontinence.

In the most recent substantial study (2008), Fader et al (14) used a crossover randomised design to compare the most common product designs: disposable inserts, menstrual pads, washable pads with integral pad, and washable inserts. Three products were selected to represent each design and each product was tested for one week (three weeks for each design block, total 12 weeks). Product performance was characterised using a validated questionnaire to evaluate pad performance (leakage, discreetness etc.) with a five-point scale (very good – very poor) at the

4.1. Evidence

A small number of robust comparative evaluations of absorbent pads for women with light incontinence have been published, and one Cochrane review (65). Most studies are now rather old (2004 or earlier) and relate to products no longer available (18) (20) (66) (67). No studies of pads for women with light incontinence have been published since the 5th consultation (31).
end of each week of product testing. A pad change and leakage diary was used to record severity of leakage from individual used pads (three-point scale: a lot, a little, or no leakage), and numbers of laundry items and pads used were recorded to estimate costs. Skin health changes were recorded weekly. At a final interview preferences were ranked (with and without costs), acceptability of the design recorded (highly acceptable – totally unacceptable) and overall opinion marked on a visual analogue scale (VAS) of 0-100 points (worst design – best design). This VAS score was used to estimate cost-effectiveness.

Eighty-five women (mean age 60) completed the study and 8691 used pads were weighed. The disposable insert was significantly better than the other designs on most variables except for discreetness. For leakage prevention, overall acceptability and preference, disposable inserts were found to be significantly better than menstrual pads, which were better than washable pants with integral pad, which were better than washable inserts. There was no clear benefit for skin health using either washable or disposable designs. Most women preferred the disposable insert pad but some preferred the other cheaper designs (6/85 preferred menstrual pads; 13/85 preferred washable pants), both of which were >50% cheaper to use than disposable inserts. Washable inserts were significantly worse than the other designs (72/85 found them unacceptable). Overall there were generally more practical problems with washables, particularly when away from the home (Level of Evidence 1).

The authors concluded that allowing women to choose their preferred design of absorbent product (or combination of different designs for different circumstances) would be more cost-effective and provide better patient satisfaction than provision of disposable insert pads (the most expensive product) alone.

4.2. Summary

- Disposable inserts are more effective in terms of leakage and more acceptable than menstrual pads, washable pants and washable inserts (Level of Evidence 1).
- Menstrual pads are cheaper and washable pants cheaper still (on a per-use basis) and are acceptable to many, particularly those with lighter incontinence and particularly when used at home. They may also be more readily available in some regions than pads designed specifically for incontinence. (Level of Evidence 1)
- Washable inserts are not acceptable to most women with light urinary incontinence. (Level of Evidence 1)
- The user characteristics, priorities and contexts which favour or discourage the use of the different product designs are summarised in Fig F-16.

4.3. Recommendations

Recommendations relating to bodyworn absorbent products for women with light urinary incontinence are listed in Table F-3, while Table F-4 describes the user characteristics, priorities and contexts which favour or discourage the use of the different product designs.

Table F-3: Recommendations relating to bodyworn absorbent products for women with light urinary incontinence.

- Disposable inserts are recommended as the most effective and preferred absorbent product for women with light urinary incontinence (Grade of Recommendation B).
- Menstrual pads or washable pants may be sufficient for some patients with very light urinary incontinence and are cheaper (Grade of Recommendation B).
- Washable inserts are not recommended for women with light urinary incontinence (Grade of Recommendation B).
- Combinations / mixes of designs for different situations (e.g. disposable inserts for going out, washable pants with integral pad for staying at home) are likely to provide optimum management in terms of patient needs and cost-effectiveness, and product advice and provision (where purchased by institutions / services) should reflect this (Grade of Recommendation B).
- See also the general recommendations relating to pad selection in Table F-13 and to washable pads in Table F-14.

4.4. Priorities for research

- Because the performance of washables is generally poor (particularly for leakage) compared to disposables, the development of better washable products for women with light urinary incontinence is a priority.
- The use of combinations of designs for different situations needs to be evaluated.
Table F-4: User characteristics, priorities and contexts which favour or discourage the use of the different pad designs for females with light urinary incontinence.

5. BODYWORN ABSORBENT PRODUCTS FOR MEN WITH LIGHT URINARY INCONTINENCE

There are five main bodyworn absorbent product designs for men with light urinary incontinence (Table F-5). However, disposable and washable insert pads are often unappealing to men as they are frequently marketed specifically at women and bear a strong resemblance to menstrual pads. Anatomical differences are also likely to mean that they are less effective for men. Pouch, shield and leaf products (Figs F-11 and F6-12) are designed to be more suitable for men by containing the penis or penis and scrotum.

5.1. Evidence

Only one randomised trial has been published evaluating absorbent products for men with light urinary incontinence (68). Four main absorbent designs available in the UK in 2003 were compared: 6 pouches and 6 leaf products; 1 disposable insert pad and 1 washable pant with integral pouch chosen to represent their respective designs. Seventy men with light urinary incontinence completed the 14-week study. Outcomes were measured using product performance questionnaires after testing each product for a week and at the end of each design, pad leakage diaries and pad weight. ‘Overall opinion’ was used as the primary outcome variable.

Results showed:

- The performance of pouch designs was significantly worse than that of the leaf and insert designs. The most common problems with the pouch were staying in place and difficulties reinserting the penis in the pouch once the pouch was wet.
- The disposable insert was effective for leakage prevention and was substantially cheaper than the leaf designs.
- Products with the leaf designs had the best leakage scores, but one product was significantly better than the other. It was roughly triangular in
shape and slightly elasticated on the long edges to give shaping / cupping.

- The washable leaf was the least successful of the leaf designs.
- Washable pants with integral pad received polarised overall opinion scores (loved or hated) and scored well for staying place but poorly for leakage.

In a randomised trial – reported since the last consultation (31) - the performance of three continence devices (sheath drainage system, body-worn urinal (BWU), penile clamp) and absorbent pads was assessed by 56 men with persistent urinary incontinence (>1 year) post radical prostatectomy. Each device was tested for three weeks. The results for the non-pad products are reported in other sections (G, I and K). Pads were judged to be good for everyday activities and best for night-time use, most easy to use, comfortable when dry but most likely to leak and most uncomfortable when wet. However, there was a preference for having a mixture of products to meet daytime needs; around two-thirds of men elected to use a combination of pads and devices after testing. Men reported that pads and devices have different strengths, which make them particularly suited to certain circumstances and activities.

5.2. Recommendations

Recommendations relating to bodyworn absorbent products for men with light urinary incontinence are listed in Table F-6, while Table F-7 describes the user characteristics, priorities and contexts which favour or discourage the use of the different product designs.

5.3. Priorities for research

Although the performance of washables was generally poor (particularly for leakage) compared to disposables, some men would like to use washables. The development of better washable products is, therefore, a priority for men with light urinary incontinence.

6. BODYWORN ABSORBENT PRODUCTS FOR MEN AND WOMEN WITH MODERATE-HEAVY URINARY INCONTINENCE

There are at least 12 absorbent product designs for men and women with moderate-heavy urinary incontinence (Table F-8):

- Disposable bodyworn inserts and diapers (Figs F-3 and F-6).
- Modified diapers (T-shaped diapers, Fig F-7) can be applied when the wearer is standing.
- Pull-ups comprise an absorbent pad integrated into a disposable elasticated pant (Fig F-9).
- Washable counterparts are available but have a much smaller market. They are made from a variety of natural and synthetic fabrics.
- Disposable and washable bedpads and chair pads are used on the bed with or without the support of a bodyworn product. Chairpads are used either with or without a bodyworn product – if without, the individual must sit directly on the pad with no underpants on. Both practices place an underpad on display and mark the individual as being incontinent and are therefore to be discouraged.

6.1. Evidence

Although it was reported in the 5th International Consultation (31), two clinical studies of absorbent products for moderate-heavy incontinence conducted by Fader et al. (14) - one community based, the other in nursing homes - remain the most recent studies of reasonable size. In the community-based trial 85 moderate / heavily incontinent adults (urinary or urinary / faecal) living in their own homes (49 men and 36 women) were enrolled, and tested three (or two) products from each of five design categories (total of 14 test products): disposable inserts (with mesh pants); disposable diapers; disposable pull-ups; disposable T-shape diapers; and washable diapers. All products were provided in a daytime and a (mostly more absorbent) nighttime variant. Products were selected based on having similar scores for absorbency across the designs (Rothwell scores, (64) see below) and performance data from pilot studies. In the nursing-home-based trial 100 moderate / heavily incontinent adults (urinary or urinary / faecal) living in a total of 10 nursing homes (27 men and 73 women) evaluated one product from each of the four disposable design categories above. Products were selected on the basis of product performance from the community-based trial and, again, day and night-time variants were provided.

Product performance was characterised using validated questionnaires which asked the participants or caregivers to evaluate pad performance (leakage, ease of putting on, discreetness etc) using a five-point scale (very good – very poor) at the end of each test period. Pad weighing tests were also conducted along with perceived severity of pad leakage on a three-point scale (none, a little, a lot). Numbers of laundry items and pads used were recorded to estimate costs, and skin health changes were recorded by the participant or by the researchers. At the end of testing participants were interviewed and ranked their preferences (with and without costs), stated the acceptability of the design (highly acceptable – totally unacceptable) and recorded their overall opinion on a visual analogue scale (VAS) of 0-100 points (worst – best design). A pad changing experiment was conducted with 12 women from the nursing home based trial to determine any differences between product designs. Under idealised conditions the different designs were applied (by the same caregivers) in random order for each patient and the speed of pad changing was timed using a stop-watch.

Results (Community):

- Disposable inserts had worse leakage performance than the other designs for day and night.
- Disposable pull-ups were preferred over inserts for the daytime.
- T-shape diaper was not better overall than the traditional disposable diaper.
- Performance and preference findings differed between men and women, in part due to the larger leakage volumes experienced by the men.
- Pull-ups (the most expensive design) were better overall than the other designs for women during the day and night.
- Disposable diapers were better for leakage than disposable inserts (the cheapest), but women did not prefer them; for men, diapers were better both overall and for leakage and were the most cost-effective design.
- The two washable products based on cotton terry-towelling (one, a simple square, folded and pinned in a diaper shape and; the other, a diaper-like design - both worn with plastic pants) were better for leakage at night than the disposable designs, but less popular overall for daytime use. Only 25% of women found them acceptable, but over 60% of men found them highly acceptable at night.
- A washable product with a felt absorbent core and an integral plastic backing fixed by poppers performed significantly worse for leakage than the other two washables and was not included in the analysis.
- There were many practical problems dealing with washable products particularly when out of the house, but they were more acceptable at home.
- No firm conclusions could be drawn about the performance of designs for faecal incontinence and there was no firm evidence that there were differences in skin health problems between designs (Level of Evidence 1).

Results (Nursing home):

- The T-shape diaper was not easier or quicker to change than the diaper.
• Caregivers found pull-ups and inserts significantly easier and quicker to apply than the other designs (in the standing position).

• The ability of residents to stand was associated with staff preference for pull-ups or inserts.

Various older studies (2004 or older) have involved user trials of washable bodyworn products alone (22); disposable bodyworn products alone (69) (70); comparisons between disposable and washable bodyworn products (71) (72) (73) (74) (75) (76) (77) (78) (79); or between disposable and washable bedpads and bodyworns (24) (80) (81). The results from these studies are of limited value because of the many new products that have superseded them, but they do yield useful insights that apply to generic designs.

Since the last consultation (31), Fader et al. have published a study that used a “shopping experiment” to investigate the preferences of community-dwelling UK women and men with moderate-to-heavy urinary incontinence for four different designs of disposable pads (inserts, all-in-ones, belted/T-shaped and pull-ups) and towelling washable/reusable products, day and night (82). Participants tested each design and selected products they would prefer, given a range of different budgets. Inserts, most frequently supplied by the UK National Health Service, were ranked second to pull-ups by women and lowest by men. When faced with budget constraints, up to 40% of participants opted to 'mix-and-match' designs. Over 15 different combinations of products were selected by participants in this shopping experiment. Most (91%) stated a willingness to 'top-up' assigned budgets from income to secure preferred designs. Participants displayed diverse preferences and Fader et al. concluded that enabling user choice of absorbent product design through individual budgets could improve satisfaction of consumers and efficiency of allocation of limited resources.

6.1.1 Disposable absorbent products for urinary incontinence: development of international standards.

Because clinical evaluations are expensive and time-consuming, laboratory evaluation procedures are widespread. Few have been clinically validated but there is a clinically-validated International Standard (ISO 11948-1) relating to the leakage performance of disposable bodyworn pads for adults with moderate-heavy incontinence in institutions (64). It describes a simple method for measuring the absorption capacity of pads in the laboratory that was shown to correlate well with the leakage performance of 18 different products evaluated in an international multi-centre clinical study involving 112 heavily incontinent adults (83). The strength of the correlation between technical and clinical data depended on the exact parameters being compared, but typically r = 0.9 (Level of Evidence 2). This laboratory test (the Rothwell method) is now in common use in the UK, Sweden and other countries and provides a basis for selecting similar products with which to make direct comparisons (for cost purposes) or to select promising pads for inclusion in clinical trials.

The ability of ISO 11948-1 to predict the leakage performance of more recent bodyworn pads (138 diapers and inserts) for heavy incontinence was investigated by Cottenden et al. (84). Correlations were poorer than in the original 1993 study (r<0.87 compared with r<0.95) but still strong enough to make the method useful. For a given Rothwell capacity, the leakage performance of diapers was far superior to inserts, but no evidence was found for any other design feature of the test products (inserts and diapers) having a significant impact on their leakage performance (Level of Evidence 2).

Although leakage performance is a very important measure of pad effectiveness other factors are, of course, important too. Accordingly, it is helpful for users to systematically evaluate several products with similar leakage performance, as there can be wide variations between products on other variables such as fit and comfort.

6.2. Summary

• There is no single best product design (i.e. one design that is significantly better than all other designs for all users) (Level of Evidence 1).

• Different designs are better for men and women. In particular, men leak substantially higher volumes of urine than women (Level of Evidence 1).

• Disposable pull-ups or T-shaped diaper designs are not better overall than the cheaper diaper for men, indicating that the diaper is the most cost-effective design for men. For women pull-ups are better overall than the other designs (except for night-use in those living in nursing homes) (Level of Evidence 1).

• Unlike men, women in the community do not favour diapers over insert pads and of these cheaper designs, inserts may be preferred for women (Level of Evidence 1).

• Pads containing superabsorber leak less, are more comfortable, and keep the skin drier than those without (Level of Evidence 2).

• Leakage performance of inserts and diapers for heavy incontinence can be predicted with reasonable precision using an ISO laboratory tests (Level of evidence 2). ISO has very good repeatability and adequate reproducibility (Level of Evidence 2).

• Washable products are very varied in design, materials, and performance. Terry-towelling products (used with plastic pants) have good leakage performance but limited acceptability - confined mainly to some men at night (Level of Evidence 2).
• Leakage performance of inserts is worse than other designs, but they leak significantly less if they are held in place by mesh rather than ordinary pants (Level of Evidence 3).

• There is no firm evidence regarding the performance of different designs for faecal incontinence and no firm evidence that any design or type of material (washable or disposable) is better or worse for skin health (Level of Evidence 4).

6.3. Recommendations

Recommendations relating to bodyworn absorbent products for men and women with moderate-heavy urinary incontinence are summarised in Table F-9, while Table F-10 describes the user characteristics, priorities and contexts which favour or discourage the use of the different product designs.

Table F-9: Recommendations relating to bodyworn absorbent products for men and women with moderate-heavy urinary incontinence.

- Gender should be considered when products are prescribed / purchased for users. As men often have substantially higher incontinent urine volumes than women, men may require more products and / or more absorbent products than women (Grade of Recommendation B).

- Gender should also be considered when products are prescribed / purchased for users because men and women are likely to prefer different designs. Men generally prefer disposable diapers to inserts (Grade of Recommendation B).

- Women generally prefer disposable pull-ups to other designs, but these are expensive. Disposable inserts are a cost-effective alternative (Grade of Recommendation B).

- Caution is recommended if washable designs are being considered. Heavy bulk confines their use mainly to the night-time (where they may be particularly useful for users who lie on their side). They are unacceptable for most people during the daytime and for most women at any time and for this reason a blanket policy of health services providing washables alone is not recommended. If washables are being considered refer to points below (Grades of Recommendation B).

- Freedom from leakage: Where possible, international standard laboratory tests should be used to rank the likely leakage performance of different pads for heavy and light incontinence (Grade of Recommendation B). In general, diapers should be selected in preference to inserts to minimise leakage (Grade of Recommendation B).

- Carer application: When products are applied by a carer to a patient who can stand for pad changing, disposable inserts or pull-ups are easier and quicker to change than diapers or T-shaped diapers. If the patient is lying down (e.g. at night) pull-ups should be avoided (Grade of Recommendation B).

- Combinations of designs for different situations (e.g. disposable inserts for staying in, disposable pull-ups for going out, washable diapers at night) are likely to provide optimum management in terms of patient needs and cost-effectiveness (Grade of Recommendation B).

- See also the general recommendations relating to pad selection in Table F-13 and to washable pads in Table F-14.
Table F-10: User characteristics, priorities and contexts which favour or discourage the use of the different pad designs for adults with moderate – heavy urinary incontinence.

</tbody>
</table>

NB The content of this table is based on the referenced evidence cited in the chapter, but the unreferenced version provided for the lay public on the accompanying website (www.continenceproductadvisor.org) is reproduced here.

6.4. Priorities for research

- Comparison of absorbent products (disposable and washable) when used by caregiver-dependent users in the community.
- Development of more effective and acceptable disposable designs specifically for men.
- Development of more effective and aesthetically acceptable washable products, particularly for night-time use and for women.

7. DISPOSABLE UNDERPADS

The most recent publications on the use of bedpads were in 1994 (24) (80), probably reflecting their limited role in long-term management of incontinence. The presence of a disposable underpad on a chair discloses the fact that the user is incontinent. It also requires clothes to be pulled up (or absent) which poses a threat to a person’s dignity. In the bed, disposable underpads easily become displaced, folded and creased inhibiting both performance and comfort,
and may threaten skin health. Large disposable underpads with wings to tuck into the bed may have a role as bed protection ‘back-up’ to bodyworn pads. The main role of disposable underpads should be confined to temporary bed or chair protection such as during clinical procedures (e.g. enemata) or when using a urinal.

Trials comparing different disposable bedpads are few (24) (85) (86) and it is not possible to draw firm conclusions from them on the effectiveness of different product design features and materials.

Bedpads are generally supplied as non-sterile items and some case reports published between 1985 and 1997 suggest that recycled paper in bedpads could be a potential source of infection (87) (88) (89) (90). However, there are no recent studies and risk to patients appears to be minimal when products are used as directed.

7.1. Summary

No robust data are available on the effectiveness of current disposable bedpads or of their various design features or constituent materials. There is a possible risk of infection from bedpads made from recycled paper for immunocompromised users (Level of evidence 4). The leakage performance of bedpads (used alone or as back up to bodyworn pads) can be predicted with reasonable precision using clinically-validated laboratory tests (Level of Evidence 2).

7.2. Recommendations

Recommendations relating to disposable underpads are summarised in Table F-11.

Table F-11: Recommendations relating to disposable underpads.

- Disposable underpads should not be used for long-term management of UI or FI, but have a useful role as temporary protection for chairs and beds during clinical procedures (Grade of Recommendation C).
- Immunocompromised people should not use bedpads made from recycled paper because of the risk of infection (Grade of Recommendation B).

7.3. Priorities for research

Disposable underpads have a limited role in continence management but are known to be widely used. An exploration of patient views regarding their use may help demonstrate their limitations, particularly regarding skin health.

8. WASHABLE UNDERPADS

Aspects of assessment that are important regarding washable underpads are patient acceptability and preference, particularly with regard to willingness to be naked below the waist (if sole use intended) and availability of laundry and drying facilities.

Some evaluations have found significant differences between products relating to leakage performance and skin health but none of the products evaluated are now available (91) (92). Compared products always differed from one another in many respects making it impossible to draw reliable generic conclusions relating to current products. However, the choice of topsheet material and the presence or absence of features like tuck-in flaps and integral waterproofing appear to be, primarily, matters of personal preference.

In institutional settings, washable bedpads are commonly used by multiple patients and questions are often asked about the risk of cross-infection. Cottenden et al. (93) assessed the risk by determining the microbial content of 145 bedpads of five different designs after a night's use by incontinent adults, followed by laundring using a standard foul wash procedure which included heat disinfection at 71°C for three minutes. Laundering destroyed all known pathogenic organisms, although some commensal flora were isolated in small numbers. It was concluded that foul wash left beds safe for multiple patient reuse with no demonstrable risk of cross-infection.

8.1. Summary

The literature contains insufficient robust data on which to base guidelines for choosing between washable bedpads. Choice of topsheet material and the presence / absence of design features like tuck-in flaps and integral/separate water-proof backing appear to be, primarily, matters of personal preference (Level of evidence 3). Provided an approved foul wash procedure is used, the risk of cross-infection between different users of a bedpads is very low (Level of Evidence 2).

8.2. Recommendations

Recommendations relating to washable underpads are summarised in Table F-12.
Table F-12: Recommendations relating to washable underpads.

- If considering using washable underpads for sole use (i.e., without a bodyworn product), the patient will need to be naked below the waist. Patient consultation and approval will therefore be needed (Grade of Recommendation C).
- Personal preferences of users with regard to topsheet material, tuck-in flaps, and integral waterproof backing should be considered in making product selections (Grade of Recommendation C).
- Provided an adequate foul laundry wash cycle is used, the risk of cross-infection between successive users of washable bedpads is low and not a contra-indication for their use (Grade of Recommendation B).

8.3. Priorities for research

Research on these products is not seen as a high priority.

9. ABSORBENT PRODUCTS FOR CHILDREN WITH URINARY AND / OR FAECAL INCONTINENCE

Most children are expected to achieve daytime dryness by the age of three (94). However, some boys take longer to become dry and some (e.g., children with learning and physical disabilities) may never do so. These children usually require absorbent products to contain leakage.

Aspects of assessment that are particularly important regarding bodyworn products for children are presence of faecal incontinence, day / night incontinence, level of independence with toileting, and use of aids (e.g., callipers).

No studies of absorbent products have been published since the last consultation (31). The existing study was a comparison of diaper design with the newer pull-up design (95).

Findings indicated that generally, the diaper and pull-up products performed similarly. Overall, diapers were preferred for night-time use by the majority of parents. By contrast, 40% of parents preferred pull-ups for daytime use and these were found to be particularly appropriate for older children and those who were attempting independent toileting, provided they did not have faecal incontinence. Diapers were more suitable for children who were dependent on caregivers and / or had faecal incontinence, and wore callipers or adapted footwear. The authors recommended that both diapers and pull-ups be supplied for children, with pull-ups (which are about 50% more expensive than diapers) being provided for selected children during the daytime.

9.1. Summary and recommendations

Diapers and pull-ups meet different needs of children and both should be made available to children with disabilities, dependent on assessment (Level of Evidence 3 / Grade of Recommendation C).

9.2. Priorities for research

- Comparison of washable and disposable bodyworn products.
- What are the problems faced by parents / caregivers and children in managing continence with different product designs and materials?

10. ABSORBENT PRODUCTS FOR FAECAL INCONTINENCE

Most absorbent products are designed for urinary incontinence. No studies comparing available absorbent products for faecal incontinence were found. Bliss et al. (96) reported preliminary findings of a survey of the use and evaluation and suggested modifications of absorbent products for faecal incontinence by 188 community-living persons with the problem. Forty-five percent of persons used an absorbent product for FI. Ninety-eight percent of those with UI and FI used the same type of product for both. Suggested improvements in product designs included having better odour control, fit, and ability to stay in place; a clearer distinction between the front and back of a panti-liner or pad; adding wings for greater absorbency; and making them flushable, cooler feeling, wider and longer in the rear and more absorbent but less bulky. For mild faecal incontinence, especially when faeces remain between the buttocks without soiling underwear, persons have used a small disposable gauze surgical dressing placed between the buttocks. This product was more acceptable than a panti-liner or pad to some men (96) (Level of Evidence 2).

Recent work on odour relating to pad usage for FI is described in Section P, while management of FI using products other than pads is described in Section N.

10.1. Recommendations

- A disposable gauze dressing that can be placed between the buttocks may be acceptable for men with light faecal incontinence (Level of Recommendation C).

10.2. Research priorities

- Better designs of absorbent products are needed for light and moderate FI (with and without UI).

11. BROADER RECOMMENDATIONS

General recommendations on pad selection and recommendations relating to washable pads are summarised in Tables F-13 and F-14, respectively.
Table F-13: General recommendations on pad selection.

- **Individuality**: No one product works best for all testers: needs and priorities vary. Accordingly, users are advised to try a variety of products when possible (Grade of Recommendation B).

- **Brand differences**: Individual product brands within a design group often exhibit a wide range of performance and acceptability for individuals, and it cannot therefore be assumed that pads of different brands but broadly similar design will be equally acceptable or effective (Grade of Recommendation B).

- **Combinations of designs**: Absorbent products vary greatly in price and performance and suitability for individual needs. Users may therefore find combinations of designs preferable and cost-effective. For example, women might use pull-ups (expensive, but discreet and good for leakage) for going out, and inserts (cheap, less good for leakage) for staying at home. Men might use disposable diapers for daytime, and washable terry-towelling products for night-time (Grade of Recommendation B).

- **Freedom from leakage**: In general, pads containing superabsorber should be selected in preference to those without (Grade of Recommendation B). Nobody wants their pad to leak but compromises have to be made: the pad needed to contain a person’s most severe accident may be substantially more bulky and expensive than is needed most of the time. Some users choose to tolerate a higher risk of pad leakage in exchange for being able to use cheaper, smaller more discrete pads. Priorities for a given user should be investigated in making product selections (Grade of Recommendation B).

- **Comfort and skin health**: In general, pads containing superabsorber should be selected in preference to those without (Grade of Recommendation B). Shaped pads should usually be selected in preference to unshaped (Grade of Recommendation C).

- **Staying in place**: No product is effective if it slips from position. Inserts should be used with stretch (e.g. cotton / lycra) underwear or mesh pants (Grade of Recommendation B). Shaped pads are preferable to rectangular (Grade of Recommendation C).

- **Ease of putting on and taking off**: The ease of putting pads on and taking them off should be considered, especially for caregivers and for incontinent users with reduced mobility or dexterity (Grade of Recommendation C).

- **Aesthetics and discretion**: A possible preference for small, more discrete pads (even if they are more likely to leak) should be considered, especially for those wishing to wear close fitting clothing (Grade of Recommendation C). The possibility of plastic backing materials rustling noisily should be considered (Grade of Recommendation C).

- **Independence and lifestyle**: The ability of a user to change his / her own pad should be considered (Grade of Recommendation C): those able to change their own pad can often manage with a smaller (less absorbent) one than those reliant on a caregiver. Users who travel should consider in their choice of product(s) the practicalities of carrying a supply of pads, disposing of used ones, and dealing with laundry (Grade of Recommendation C).

- **Costs**: Cost issues should be approached with caution (Grade of Recommendation C). Expensive pads do not necessarily work better than cheaper ones. Cheaper pads do not necessarily save money. If pads leak more they may have to be changed more frequently and / or lead to higher laundry costs. More pad changes will mean increased caregiver workload. However, more absorbent pads will not necessarily reduce pad consumption rates: pads are often changed according to nursing unit or personal routine.
Table F-14: Recommendations relating to washable pads.

- **Laundry issues**: Access to good, reliable washing and drying facilities should be checked before washable products are introduced (Grade of Recommendation B). Laundry – especially of bedpads – can be heavy work, beyond the capability of frail incontinent people or their caregivers. The number of washable products needed per user depends on laundry turn-around times. Drying times for washables can be long and expensive, especially for bodyworns for heavy incontinence and for bedpads.

- **Personal preferences**: Personal preferences (of both users and caregivers) with regard to choosing between washable and disposable products should be taken into account carefully (Grade of Recommendation C). Some users prefer the chore of laundering washables to anxiety over when their next consignment of disposables will be delivered. Washables generally require less storage space than disposables. Discreet disposal of disposables can be a challenge. The possibility of using a mix of disposable and washable products should be considered (Grade of Recommendation C). Some users who choose disposables when at home prefer washables when travelling because of the space that disposables occupy in luggage and the possible inconvenience of disposal. Others use washables at home and disposables when away as they see the balance of disadvantages and advantages differently.

- **Personalisation of products**: In institutions, the chore of personalising washable products and sorting them after each laundry cycle should be considered before they are introduced (Grade of Recommendation C). Washable bodyworns are often personalised to particular users. In institutions this means marking products with users’ names and sorting them after laundry, an extra task for caregivers. Washable bedpads are not usually personalised.

- **Staining**: Washable products should not usually be used by those with faecal incontinence – beyond occasional light smearing – because of staining (Grade of Recommendation C). Skin sprays and ointments may also stain washables.

- **Costs**: Cost comparisons between washable and disposable products should be made with caution (Grade of Recommendation C). Key factors are: local arrangements (mostly laundry and transport costs); the durability of the products (which depends on how carefully they are used and the criteria for deciding when they should be replaced); the costs of ordering, transporting and disposing of disposables; and product purchase costs. Much of the cost of washables is encountered with the initial capital outlay for stock. This also represents a commitment to use the products for an extended period and so expensive mistakes can be made if it transpires that a better product was / has become available. It will usually be wise to experiment with samples of a variety of alternative products before committing to major purchases.

---

**G. EXTERNAL URINE COLLECTION DEVICES FOR MEN: URINARY SHEATHS**

Close-fitting penile sheaths (sometimes called condom catheters, uridomes, Texas catheters or external catheters) are male incontinence devices (no practical equivalent is currently available for women). The sheath fits over the penis much like a contraceptive condom and collects urine as it leaves the body. The sheath is normally connected at its outer end to a tube that leads to a urine drainage bag. Urine drains into the bag, which is usually worn on the thigh or calf, and is collected there until emptying is convenient. Sheaths come with a variety of design features and the main ones are listed in Table G-1, and illustrated in Fig G-1.
Table G-1: The main design features of sheaths.

- Materials: latex, silicone rubber or other synthetic polymers.
- **Size:** range of diameters (about 20-40 mm, in 5-10 mm increments) and lengths; most companies supply a measuring tool to ensure best fit; guide is placed at widest point of penis, typically about 20 mm from base (556).
- Adhesive: may be integral to the sheath (one-piece systems) or be a separate strip or spray (two-piece systems).
- Applicator: some sheaths are provided with an applicator with the aim of making application easier or to reduce manual contact with the penis.
- Anti-kinking / twisting features: these are intended to improve drainage by aiming to prevent the sheath from kinking or twisting at the distal end near the connection to the drainage bag tube.
- Anti-blow-off: some designs aim to reduce the likelihood of the sheath blowing off at high urine flow rates, as at the beginning of a void; for example, the distal end of the sheath may be thickened and bulbous to stop the internal walls sticking to one another between voids.
- Connections to the drainage bag: some designs aim to increase the ease and security of drainage bag connection; for example, a push ring or ridge at the end of the outlet tubing.
- Retracted penis: some sheaths are designed with or without specific features in order to accommodate a retracted penis; for example, a shorter sheath or a wider adhesive seal.
- Durability: varies according to manufacturer. 24 hours is a common recommendation but some are intended for extended wear.
- Transparency: some sheaths are made from transparent materials (e.g. silicone) which can allow for observation of penile skin condition along the shaft and glans.

---

**Fig G-1:** Sheath without integral adhesive, secured with external fixation (a), and a variety of sheaths showing anti-blow-off features and applicator (b).
The main factors that make sheaths (un)suitable for men are summarised in Table G-2.

**Table G-2: The main factors that make sheaths (un)suitable for men.**

<table>
<thead>
<tr>
<th>Sheaths are suitable for men with:</th>
<th>Sheaths are not advised for men with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Moderate to heavy urine loss.</td>
<td>• Confusion or psychological vulnerability. sensation through spinal cord injury or neuropathy (110) (557) (558).</td>
</tr>
<tr>
<td>• Urinary frequency and / or urgency.</td>
<td>• A retracted or very small penis (alternative products are available).</td>
</tr>
<tr>
<td>• Limited mobility.</td>
<td>(Sheaths can be used in combination with intermittent catheterisation.)</td>
</tr>
</tbody>
</table>

An effective urinary sheath is one that stays securely in place for an acceptable period, is leak-free, comfortable to wear, easy to apply and remove, avoids skin damage and channels the urine effectively into a urine drainage bag. Correct sizing and fastening are critical to product success. Users indicate that the foremost important quality of a penile sheath is security from leakage followed by comfort and ease of application and removal.

### 1. EVIDENCE

The 5th International Consultation (31) identified trials in which a sheath system was compared to alternative continence products: indwelling catheters (97), pads (60) or one sheath versus another (23) (98) (99) and the results from these studies are included in the summary section, below.

Since the last consultation two trials (15) (100) have been published. Macaulay and colleagues (15) conducted a cross-over trial comparing the performance of pads (usual continence management) with sheaths, bodyworn urinals and penile clamps. Fifty-six men tested each product for three-weeks. Quality of life was measured using the Kings Health Questionnaire (KHQ). Depending on their daily circumstances / activities, participants reported that each product had some advantages and disadvantages. Sheaths were good for extended periods when a pad change could be difficult, for maintaining skin dryness and continence, not smelling and convenient for storage and travel. The sheath and clamp were rated better than the pads or bodyworn urinal for ease of storage, carrying, odour and security. Pads were good for everyday activities and best for night-time use: easiest to use, comfortable when dry but most likely to leak and most uncomfortable when wet. Of note is that men preferred having a mixture of products to meet different needs and activities and, post-testing, around two-thirds of men were using a combination of pads compared to baseline. Of concern was that half of the men had previously tried a penile sheath system but only one of these had received assistance from a healthcare professional for fitting and follow-up.

The second non-randomised prospective trial assessed quality of life in individuals with spinal cord injury using either indwelling catheters, sheath drainage, or intermittent catheterisation (n=70) (100). Based on scores of the King’s Health Questionnaire (KHQ), men using an indwelling catheter or intermittent catheterisation scored lower on quality of life scores and role limitation and activity compared to those using a sheath system. However, because of the convenience sampling, the men using a condom catheter may have been higher functioning with a lower SCI than those using IC or indwelling catheters and results were not presented by level of injury.

A sheath product – which is secured to the glans is available. Manufacturer information suggests that the product is useful for men with a short or retracted penis for whom a standard sheath system is unsatisfactory. Apart from testimonials, there is as yet no published data evaluating the product and only one paper (101) that suggested the product could be a useful alternative to a conventional sheath.

Although many men use sheaths successfully, several case studies attest to the potential problems (Table G-3). It is of note that most such problems are preventable with proper sizing, continuous drainage, routine changing and appropriate skin care.

A review of findings relating to odour associated with sheath use is given in Section P.I.4.
Table G-3: Reported complications associated with sheath use.

<table>
<thead>
<tr>
<th>Complication</th>
<th>Prevention/Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contact dermatitis or allergy; balanitis, oedema (559) skin maceration from wet exposure (560)</td>
<td>Allergy to latex can develop over time; change product to silicone base; routinely check skin; ensure skin is dry before application of sheath and skin barrier; ensure sheath is correct size.</td>
</tr>
<tr>
<td>Compression, tourniquet effect; (561) (562) (563).</td>
<td>Use sheaths with caution in individuals with no penile sensation; avoid adhesive straps or use straps with stretch to allow for penis expansion/contraction; correct size is critical.</td>
</tr>
<tr>
<td>Skin irritation (564).</td>
<td>Ensure sheath does not become twisted near the distal end to avoid stagnation of urine and extended urine contact with penile skin; good genital hygiene.</td>
</tr>
<tr>
<td>Glans irritation/pressure ulcer</td>
<td>Ensure adequate space at end of sheath to prevent pressure on the glans.</td>
</tr>
<tr>
<td>UTI – range 40-63% (565) (566).</td>
<td>Ensure consistent drainage – if sheath twists it will block urine flow; at risk individuals – those with poor hygiene, cognitively impairment who may tug/twist sheath drainage tubing.</td>
</tr>
<tr>
<td>Hydronephrosis (567) (568).</td>
<td>Detrusor over activity risk factor for vesico-ureteral reflux; may require antimuscarinics &amp; intermittent catheterisation in addition to sheath drainage; warn users of the risks of acute urinary retention (AUR) when consuming large amounts of alcohol in a short time – individuals should be taught signs of AUR &amp; teaching of intermittent catheterisation if engaged in high fluid intake or recreational drugs.</td>
</tr>
<tr>
<td>Fibro-epithelial penile polyps (569) (570) (571).</td>
<td>Close skin observation by user or caregiver; good user education to aid in proactive skin health</td>
</tr>
<tr>
<td>Isolated gangrene (572).</td>
<td>Immunocompromised individuals are at high risk for infection related to condom use.</td>
</tr>
</tbody>
</table>

2. SUMMARY

- Sheaths are more comfortable than indwelling catheters and UTI incidence is similar (60) or somewhat lower in sheath users without dementia (97) (Level of Evidence 2).
- Men with moderate incontinence using a sheath rank QOL better with a sheath than when using an absorbent product (60) (Level of Evidence 2).
- Sheaths with integrated adhesive are preferred over those with an adhesive strip or applicator (23) (99) (Level of Evidence 2).
- Silicone sheaths are preferred over latex (23) (Level of Evidence 2).
- Men prefer a choice of continence products (pads, sheath, clamp) depending on activities and lifestyle (15) (Level of Evidence 2).

3. RECOMMENDATIONS

Recommendations regarding urinary sheaths are summarised in Table G-4.

- Product differences mean that men should try different products before making a final selection (Grade of Recommendation B).
- Men prefer access to a combination of continence products (sheath, pads, clamps), depending on activity (Grade of Recommendation B)
- Key performance characteristics are: security (ie ability to keep a leak-proof seal and channel urine to the drainage bag without leakage) and ease of application and removal of the sheath (Grade of Recommendation B).
- Sheath applicators may not make sheath application easier (Grade of Recommendation B).
- Sheaths with integral adhesive (one-piece systems) are preferred over (two-piece systems) (Grade of Recommendation C).
- Sheath users should be monitored for latex or adhesive allergies, skin health, tissue damage and UTI (Grade of Recommendation C).
- When possible the external sheath rather than indwelling urethral catheter should be the urinary collection device of choice. (Grade of recommendation B).
4. PRIORITIES FOR RESEARCH

- Evaluation of leg bag and sheath design features claimed to reduce twisting and kinking at the drainage bag connection site.
- Evaluation of products advertised as suitable for men with retracted penis.
- Studies to generate and validate procedures to help identify the type of sheath most likely to suit an individual.

H. URINE DRAINAGE BAGS AND ACCESSORIES

Urine drainage bags fall into two main categories. Bodyworn bags generally have a lower capacity (less than 500 ml) and are designed to be worn under clothing on the leg (often called leg-bags) or around the waist. They aim to provide discreet storage of urine and can be attached to either a catheter or a sheath. They are mainly used during the day and are secured to the leg or waist in a convenient position using a range of straps or other support devices. The popularity (or otherwise) of many features is generally a matter of personal preference.

Second, there are large capacity bags - commonly called night bags – which are designed to provide additional drainage capacity overnight or for people who are permanently in bed. They are usually held in position away from the body on either a floor-stand or a hanger which hooks onto the bed or chair frame. They may also be connected to a bodyworn bag to form a link system for overnight use.

Expert opinion found in best practice guidelines recommends positioning drainage bags so that they are off the floor, but data are insufficient to establish whether this practice reduces the incidence of bacteriuria. (102) (103) (104)

To prevent cross contamination, a closed drainage system is standard and, in the home, it is common to use vinegar, household detergent or diluted bleach (105) (106) (107) (108) (109) to clean drainage bags.

The main design features and variants of urine drainage bags are described in Table H-1 and illustrated in Fig H-1, and Fig H-2 shows a variety of tap designs.
### Table H-1: Drainage bag features

<table>

<td>Latex or cloth elastic straps.</td>
<td>Separate frame/stand or hooked on bed or wheel chair.</td>
</tr>
<tr>
<td><strong>Connecting tube</strong></td>
<td>Various lengths; can be cut to meet individual needs.</td>
<td>One length only; intended to maintain a closed link system.</td>
</tr>
<tr>
<td><strong>Drainage tap</strong></td>
<td>Flip valve, separate cap, screw cap.</td>
<td>As per leg bags.</td>
</tr>
<tr>
<td><strong>Sampling port</strong></td>
<td>If present, located in drainage tubing.</td>
<td>Located in drainage tubing.</td>
</tr>
<tr>
<td><strong>Comfort</strong></td>
<td>Cloth backed prevents skin irritation.</td>
<td>No specific comfort features.</td>
</tr>
<tr>
<td><strong>Discretion</strong></td>
<td>Internal welds reduce bulging and sound of urine on movement.</td>
<td>None are discreet; may be covered with cloth bag to disguise bag.</td>
</tr>
<tr>
<td><strong>Anti-kinking</strong></td>
<td>Connecting tube reduces kinking and twisting so that urine drainage is not obstructed.</td>
<td>Sturdy plastic tubing does not allow twisting at catheter site but may kink along drainage tubing.</td>
</tr>
<tr>
<td><strong>Anti-reflux valve</strong></td>
<td>Non-return flap valve to prevent urine reflux if bag is raised above bladder; may reduce risk of CAUTI.</td>
<td>As with leg bags.</td>
</tr>
<tr>
<td><strong>Linkage system</strong></td>
<td>Allows attachment of leg bag to night bag so maintain a closed system; may reduce risk of cross infection.</td>
<td></td>
</tr>
</tbody>
</table>

**Fig H-1:** A urine drainage bag shown worn on the calf (a), a discreet thigh urine drainage bag (b) and a shaped urine drainage bag for wheelchair use (c).
Urine drainage bags are suitable for those with:

- The visual acuity to see the tap/spigot, and the manual dexterity to open and shut it (110) (111).
- The ability to assess skin condition where straps and drainage bag contact the leg.

1. EVIDENCE

The last consultation (31) identified trials on: product (feature) evaluation (112) (113) (114) (115) (116) (117); drainage suspension systems (leg straps) (102) (103) (111) (118) (119) (120); and infection prevention (102) (103) (117) (120) (121), and the findings are included in the summary section, below.

Since the last consultation (31) there have been three new trials addressing: dependent drainage tubing loops (or airlocks) (Fig H-3) (122); specimen collection technique (123); and catheter securement (124). No updated guidelines on drainage tube management and no new trials evaluating aspects of body-worn or night drainage bags were found.

There has been a new focus on urinary catheter dependent loops which cause airlocks in the tubing and reduce or stop urine drainage (Fig H-3). The first study to present the theory and illustrate the potential threat to bladder emptying was by Schwab et al (122). Using a laboratory model bladder, the authors illustrated that the fluid-filled dependent loops generated back-pressure related to the difference in fluid meniscus heights and that this back pressure interfered with emptying. It was proposed that if the results obtained with a simulated bladder occur in actual bladders, retained urine volume would increase as meniscus height increased (i.e. dependent loop deeper). The increased back-pressure would rise to the point where the bladder could not empty. This work has drawn new attention to the importance of ensuring loops are minimised.

Wuthier (123) took the theory further, applying it to clinical practice, measuring pressures and positing that a dependent loop of more than 18 cm would cause an air-lock which could not be overcome by the typical bladder and would thus prevent urine flow into the drainage bag. Earlier work posited that urine drainage is suboptimal with a traditional Foley catheter design (125), but it was not clear if this related specifically to the catheter design or to the presence of dependent loops.

Two prevalence studies have been conducted on dependent loops. In a large academic US hospital, Danek (126) found that over 85% of catheterised patients had dependent loops containing urine. In another US study Wuthier and colleagues (123) found similar results in a cross sectional observational study; 87% of catheters had dependent loops with almost half having the potential for an air-lock and incomplete or absent bladder drainage. The clinical impact (or not) – particularly CAUTI – has not yet been reported.

Two recent prevalence studies highlighted a lack of understanding of best practice in catheter management. In the first, a survey of almost 400 nurses on
correct urine specimen collection in catheterised patients and appropriate reasons for obtaining a urine specimen from a catheterised patient revealed that over half answered incorrectly (127).

In the other, surveying indwelling catheter securement in a large academic hospital, only 18% of the patients had secured catheters despite products being available on the nursing unit (124). Unsecured catheters place the patient at risk for urethral and bladder neck trauma and pain; incorrectly obtaining a urine specimen from a catheterised patient may lead to a spurious UTI diagnosis.

2. SUMMARY

- Taps are sometimes difficult to open and may leak onto the fingers when the bag is emptied (112) (114) (Level of Evidence 2).
- Chafing between bag and skin is often reported (112) (114) (Level of Evidence 2).
- Bags with tubing that is flexible and can be cut to length to suit the individual are appreciated (112) (Level of Evidence 2).
- Discreet bags (that are not readily visible beneath clothing) are appreciated (112) (Level of Evidence 2).
- Designs in which the tap and outlet spouts are widely separated are most effective at preventing contamination of the hands with urine (113) (116) (Level of Evidence 2).
- There is insufficient evidence that pre-connected products reduce the incidence of bacteriuria (104) (Level of Evidence 2).
- There is no evidence that addition of antiseptic agents to drainage bags prevents the onset of bacteriuria (128) (Level of Evidence 2).
- Comfort and ease of applying straps to the leg is key to successful wear (111) (115) (118) (Level of Evidence 2).
- If there are dependent loops in the drainage tube, airlocks can compromise efficient bladder emptying (122) (123) (Level of Evidence 3).
- Most drainage bags (bodyworn and night bags) have an integrated anti-reflux valve but it is unclear whether they reduce the incidence of CAUTI (104) (117) (Level of Evidence 3).
- There is inadequate evidence to state that single use (104) or daily change of leg bags or drainage bags reduces bacteriuria or CAUTI. In practice, drainage bag changes ranged from every 3 days to more than 20 days (129) (130) (131) (Level of Evidence 3).
- An abdominal ‘belly bag’ drainage system may be more convenient, comfortable and less likely to cause discomfort than leg and night bags (119) (Level of Evidence 3).

3. RECOMMENDATIONS

Recommendations relating to urine drainage bags and accessories are summarised in Table H-2.

Table H-2: Recommendations relating to urine drainage bags and accessories.

- Taps should be easy to open and should not leak onto the fingers when the bag is emptied (Grade of Recommendation B).
- Care should be taken to avoid chafing between bag and skin (Grade of Recommendation B).
- Individual needs and personal preferences should determine the use of leg / suspension / attachments and position of where the bag is worn (115) (Grade of Recommendation C).
- Abdominal drainage bag (‘Belly Bag’) may be a convenient, comfortable option to a leg secured bag (119) (Grade of Recommendation C).
- Closed urinary drainage bag systems where the system is only broken to change the sterile bag according to manufacturer’s directions may reduce the onset of bacteriuria (Grade of Recommendation A).
- Drainage systems for night bags should be positioned off the floor to reduce the risk of cross infection (102) (103) (120) (Grade of Recommendation C).
- All facilities should enforce regular monitoring to practice to ensure adherence to evidence based guidelines on catheter/drainage bag management (Grade of Recommendation C).
- Catheter securement devices should be in place on the thigh or abdomen for all indwelling catheters (Grade of Recommendation C).
- Dependent catheter loops should be minimised to allow optimum urine drainage (Grade of Recommendation C).
- Guideline recommendation (EPIC 2) is that catheter bags are changed every 5-7 days (103) (Grade of Recommendation D).

4. PRIORITIES FOR RESEARCH

- Evaluation of a linked system with night bag/leg bag and the onset of bacteriuria compared to changing from day to night bag.
• Reviewing practice in home settings: is a closed catheter drainage system more effective at preventing symptomatic UTI than reusable non-sterile urinary drainage?
• Most effective and acceptable cleaning methods for non-sterile urinary drainage systems.
• Development of catheter tubing that prevents formation of dependent loops.

I. MALE BODYWORN URINALS AND DRIBBLE CONTAINERS

Products such as bodyworn urinals (BWU) and dribble containers (penile pouches) are an alternative to a sheath system (Fig I-1). They usually comprise a ring-shaped opening or cone-shaped component which is worn around the penis (and held firmly against the pubis by means of a belt and straps) and channels urine to an integral collection bag. There are two main designs: one-piece with the cone and flange as a single combined unit; or two-piece, where the cone and flange are separate and connect when in use. BWUs are more substantial collection devices than sheaths. They are designed to be washed and reused multiple times and to be worn over extended periods. They are less frequently used than sheaths but may be a good option for those with a retracted penis or who do not wish to wear a sheath. Dribble containers (penile pouches) involve holding a drainage bag or other container over the penis using a much lighter structure than the flanges used in bodyworn urinals. They are often disposable.

The more substantial designs should be fitted by a specialist: a good fit is crucial for comfort and to avoid leakage. It is also important that the wearer / carer understands how to use the device and the importance of skin care. The wearer / caregiver will need good manual dexterity to manage the device. Several urinals will be needed to use in rotation, allowing each to be properly washed and dried between periods of use.

The main factors that make bodyworn urinals (un)suitable for men, and the challenges to be addressed in using them effectively are summarised in Table I-1.

<tbody>
<tr>
<td>• Understand how to use the device and the importance of skin care.</td>
</tr>
<tr>
<td>• Have good manual dexterity to manage the device.</td>
</tr>
<tr>
<td>• Have fitting done by a specialist to ensure best leak-proof fit.</td>
</tr>
<tr>
<td>• Moderate to heavy urine loss.</td>
</tr>
<tr>
<td>• Urinary frequency and / or urgency.</td>
</tr>
<tr>
<td>• Limited mobility.</td>
</tr>
</tbody>
</table>

**1. EVIDENCE**

At the time of the 5th International Consultation (31), there were no trials evaluating bodyworn urinals or dribble containers. Since then, one trial has been published. Macaulay et al (15) conducted a randomised controlled trial that included BWUs. Fifty-six men compared (day and night, and for three weeks each): a BWU, sheath drainage, a penile clamp (daytime only), and the absorbent product they had regularly used before the trial. Outcome measures were overall opinion (rated on a 10-point visual analogue scale) for day or night use; product acceptability (not acceptable / poor / acceptable / good); advantages and disadvantages of the test products; revealed preferences (which products men used three months after the test).

The BWU was rated as “acceptable” by 48% of participants for daytime use at home, more comfortable when wet than pads, but worse than pads, sheaths or clamp in all other aspects including self-image. It was also described as leaking in certain postures, particularly when sitting as the penis can slip out of the flange. No significant differences in quality of life (measured by the King’s Health Questionnaire) were noted at the three month follow up. At the conclusion of the study, men were more informed on product choices and, although most (58%) were using a mix
of products at the three-month follow-up, few (22%) included a BWU in their mix.

2. RECOMMENDATION

Expert fitting and careful user selection is required to ensure effective and appropriate use of bodyworn urinals (Grade of Recommendation B).

3. PRIORITIES FOR RESEARCH

- Development and evaluation of leak-free, comfortable and aesthetically acceptable BWUs for men.
- Development and validation of a reliable instrument to measure the performance of different BWU designs and the impact on the quality of life of users.

J. MECHANICAL DEVICES FOR WOMEN WITH UI

Mechanical devices for women with urinary incontinence are designed to prevent urinary leakage, for women with stress urinary incontinence (SUI). There are three main categories:

**External urethral devices**: products that are applied over the urethra at the opening.

**Internal urethral devices**: products that are placed inside the urethra.

**Internal vaginal devices**: products that are inserted into the vagina.

The main factors that make mechanical devices (un)suitable for women are summarised in Table J-1.

**Table J-1: The main factors that make mechanical devices (un)suitable for women.**

<table>
<thead>
<tr>
<th>Mechanical devices may be suitable for women with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Stress urinary incontinence.</td>
</tr>
<tr>
<td>• Good hand control.</td>
</tr>
<tr>
<td>• Good memory and cognitive function.</td>
</tr>
<tr>
<td>• The ability to understand the concept of use (as opposed to a pad).</td>
</tr>
<tr>
<td>• A preference for preventing leakage over containing it.</td>
</tr>
</tbody>
</table>

They may be used in combination with other conservative management approaches such as PFMT.

1. EVIDENCE FROM THE 5TH INTERNATIONAL CONSULTATION (2013)

The published evidence on mechanical devices for women with UI is best introduced by reviewing each device category in turn.

1.1. External urethral devices

No female external urethral devices are currently on the market. This is as a result of varying effectiveness, local urethral / vulvar irritation and inconvenience, although side effects were relatively minor. Previously available brands included: Miniguard (Uromed Inc), FemAssist (InsightTM Medical Coro) and CapSure (CR Bard Inc).

1.2. Internal urethral devices

There are two different urethral inserts currently on the market (Fig J-1).
The first – the FemSoft (Fig J-1a) - has a soft, compressible, silicone chamber filled with mineral-oil. It is intended for day-time use during physical exercise and is self-inserted (using a separate insertion probe) and removed at user discretion. It is available in two lengths (3.5 cm and 4.5 cm). Before insertion, the proximal end of the cylinder is distended relative to the distal end but, as the user pushes the device (guided by the insertion probe) into the urethra, fluid transfers temporarily to the distal end, returning once the device is in place, so securing it. Side effects can include urethral irritation, UTI and device migration into the bladder. When successful, the Femsoft is an effective, safe and comfortable treatment for exercise incontinence (stress urinary incontinence) in women (Level of Evidence 3) (132).

The second device – the InFlow™ Intraurethral Valve-Pump (Fig J-1b and J-1c) - is intended for women with a chronic acontractile bladder who would otherwise use intermittent or indwelling catheterisation. The device consists of a short silicone urethral available in various lengths for specific fitting under local anaesthetic. It is maintained in position by distal proximal flanges. When the bladder is full, an inner turbine-like valve is activated by a hand held magnetic device and allows bladder emptying. When the handheld device is removed, the valve closes, maintaining continence. For selected women, the device can provide freedom from self or indwelling catheterisation and improve quality of life (133). Side effects are similar to those for an indwelling catheter: UTI, urethral irritation, encrustations and expulsion, although based on the few studies that have been done, these are infrequent. The key reason for withdrawing from use appears to be discomfort (134). Chen and colleagues recommend a trial period to allow the woman to assess tolerance, and regular support during initial use; if successful, on-going use will likely be of benefit. To date no long-term research is available on the adherence to the device nor the effects that it may have on bladder / urethral mucosa (135).

### 1.3. Internal vaginal devices

Support of the bladder neck with the aim of correcting urinary stress incontinence has been achieved, with varying success utilising traditional tampons, pessaries, contraceptive diaphragms and intravaginal devices. Follow up and patient teaching is important. Side effects of vaginal devices can include bleeding, extrusion, discharge, pain and urinary retention. It is recommended that women are followed-up at least every 6-12 months after the initial insertion and observation period (136). Several designs of intravaginal devices are available and are listed below.

a) **Tampon compared to pessaries**

- Both tampon and pessary provide protection against activity induced incontinence (137) (Level of Evidence 2).

b) **Diaphragm / pessaries**

- Diaphragms (138) (139) and pessaries (140) (141) have all been used successfully and are an alternative to surgery or whilst awaiting surgery (Level of Evidence 1). Pessaries are also a good option for specific patients. For detailed information on pessaries and prolapse, see Pessaries in Chapter 12 Adult Conservative Management.

c) **Vaginal devices designed specifically to support the bladder neck**

- The Rocket stress incontinence device is a simple surgical foam tampon-shaped cylinder with a withdraw string and supporting the bladder neck. Similar devices no longer marketed include: the Introl device, the Ladycon (Homecare Eneros, Norway), the Conveen Continence Tampon, and the Contrelle Activgard (originally called the Conveen Continence Guard). All provided some support to the bladder neck and were moderately effective (142) (143) (144).
d) Reusable vaginal hollow tampon (Contiform)

No reusable vaginal hollow tampons are currently marketed. Contiform was a hollow tampon-like device and an option for women with very mild incontinence (approximately 7 g on pad test) (145) (146).

e) Disposable vaginal devices

• Polyvinyl sponge has only one laboratory study (147) and no clinical research to verify its effectiveness study. In women with minor leakage the sponge reduced the leak to zero.

• The Tipi (ConTIPI Ltd, Israel) / Impressa (Kimberly Clark, USA) intravaginal device (Fig J-2) (has a resin core with support 'poles' covered with a soft nylon mesh that stretches between the arms of the poles to act as a suburethral sling. Based on limited research the device appears easy to use, well-tolerated and effective with side effects similar to other intravaginal devices: irritation, spotting, discomfort (148) (149).

Three new trials (150) (151) (152) and 6 reviews have been reported since the last consultation (31). New studies address the use of mechanical devices - such as intra-vaginal pessaries to manage Pelvic Organ Prolapse (POP) and coincidentally improve the symptoms. Secondary analysis of a previously published ATLAS study consider non-surgical treatments for SUI (153) (154). Secondary analysis of a previously published ATLAS study consider non-surgical treatments for SUI (155) (156)

Lone and colleagues (153) undertook a year-long prospective comparison of women choosing either vaginal pessaries (n=133) or surgery for POP (n=154) using validated ICIQ-VS and ICIQ-UI (SF) questionnaires a year post treatment. Exclusion criteria were women using pessaries solely for UI, those undergoing concomitant UI surgery or those who started in the pessary group but later opted for surgery. At one-year post enrolment, both groups had improved with no statistically significant difference between them concerning urinary or vaginal symptoms.

In a non-randomised trial comparing behavioural therapy or ring pessary (154), 83% of women who chose pessary reported QOL improvement at 1 year follow-up. All women had an improvement of prolapse symptoms and over 86% reported improved voiding symptoms. However, only 9.1% of the patients had improved SUI and 23.8% of the patients reported new onset of de novo SUI. The authors conclude that the ring pessary is an effective non-surgical treatment to alleviate symptoms associated with POP. The potential for de novo SUI and pessary management of POP should be noted and patients counselled accordingly.

The European Association of Urology guideline for assessment and nonsurgical management of UI does not routinely suggest intravaginal devices as treatment for incontinence [158]. An international panel of experts appraised evidence from existing systematic reviews and from independent literature searches, reviewed up to 2010. Key areas included surgery of uncomplicated SUI in women, surgery for complicated SUI in women, surgery for SUI for women with symptomatic mixed UI, men with SUI and surgical interventions for detrusor over activity. Surgery is typically considered for bothersome UI that does not improve with conservative therapy. Lucas and colleagues (157) conclude that there is a need for clarity in the surgical options offered to patients to ensure they can consider the most effective and safest procedures based upon the risks associated.

2. NEW EVIDENCE FOR THE CURRENT CONSULTATION

Three new trials (150) (151) (152) and 6 reviews have been reported since the last consultation (31). New studies address the use of mechanical devices - such as intra-vaginal pessaries to manage Pelvic Organ Prolapse (POP) and coincidentally improve the symptoms of SUI (153) (154). Secondary analysis of a previously published ATLAS study consider non-surgical treatments for SUI (155) (156)

Lone and colleagues (153) undertook a year-long prospective comparison of women choosing either vaginal pessaries (n=133) or surgery for POP (n=154) using validated ICIQ-VS and ICIQ-UI (SF) questionnaires a year post treatment. Exclusion criteria were women using pessaries solely for UI, those undergoing concomitant UI surgery or those who started in the pessary group but later opted for surgery. At one-year post enrolment, both groups had improved with no statistically significant difference between them concerning urinary or vaginal symptoms.

Kenton et al. (156) Shaffer et al. (155) both performed a planned secondary analysis of a multi-centre randomised trial from the original ATLAS trial (159). Schaffer et al. (155) determined success to be the same for continence pessary use, behavioural therapy or a combination of the two. The woman’s level of education, incontinence severity and menopause status predictors of success. Post-menopausal women were more likely to report improvement of continence than pre-menopausal women. Kenton et al. (156) conducted an analysis on the same dataset comparing behavioural therapy to vaginal pessary
use, focusing on changes in symptoms and HRQOL. Findings suggest no difference in pelvic floor symptom bother and HRQOL between the pessary and behaviour therapy arms in women undergoing conservative treatment for SUI. Therefore, individual preferences should be considered in the approach to the non-surgical treatment of SUI.

A novel intravesical attenuation device (VESAIR® Solace Therapeutics USA) was evaluated in a randomised controlled trial for the treatment of SUI (152). The device involves having a balloon inserted into the bladder via a delivery system and inflated; a one-way valve seals the device after being filled with 15cc air and 0.5cc AIRLOC®, a perfluorocarbon liquid that maintains buoyancy in the bladder which acts as a sponge and alters intra bladder spiking pressures. The balloon is removed cystoscopically. Participants were randomised 2:1 to treatment or sham procedure. Outcomes included a Stamey (score improvement of 1 or more points at 6 months) and a composite score combining data from pad test and patient impression of improvement. Withdrawal rate was high due to device malfunction, discomfort and the invasive nature of the procedure. Further evaluation is required before this device is made routinely available.

Ding and colleagues (151) conducted a prospective study of 81 women with advanced symptomatic POP (stages III and IV) who were fitted with a ring pessary with support. Primary outcome at 3 months was urinary flow measurements along with non-validated questionnaire pre- and post intervention to determine effectiveness. Of the 73 post-menopausal women, over half improved reported voiding symptoms, urinary urgency and SUI; 6 (14.3%) developed new onset SUI that could be managed with PFMT and 8 discontinued use due to discomfort and pressure, a desire for surgical treatment, extrusion of the pessary during daily activities or bothersome de novo SUI. Ding et al concluded that the ring pessary can help with POP and by consequence aid SUI symptoms.

A new intravaginal device for SUI management, not yet available on the market (B.BRAUN Medical SAS) has had safety, efficacy, tolerance and acceptability tested through a phase III multicentre randomised controlled trial. The device, made of a thermoplastic elastomer, was supplied in two sizes and, dependent upon acceptability of application or other factors such as discomfort, might be suggested to patients for consideration and acceptance of this device. The authors concluded that despite the small sample size, the 75NC007 intravaginal device is a safe and effective non-invasive treatment of SUI in women. Further systematic evaluation of this device is required with long-term follow up and objective measures of continence.

Lipp et al’s Cochrane review for mechanical devices (160) currently confirms that there is little evidence from controlled trials on which to judge whether device use is better than no treatment and large well conducted trials are required for clarification. There is also insufficient evidence to favour one device over another and little evidence to compare mechanical devices with other forms of treatment.

3. SUMMARY

Although many products have appeared on the market, few have stood the test of time: no external urethral devices - and only one intra-urethral device - are currently commercially available. Intravaginal devices such as pessaries remain a valuable adjunct to conservative management. Specifically:

- Intravaginal devices may be effective in SUI management when compared to behaviour therapy and represent a promising alternative or complementary non-surgical approach (150) (Level of Evidence 1).
- Improved continence is possible for women with SUI with intravaginal devices. The products appear safe to use with few reports of lower urinary tract issues (Level of Evidence 3).
- Efficacy appears to be higher in patients with minimal to moderate SUI leakage (Level of Evidence 3).
- Relatively high drop-out rates in monitored studies during which patient support is provided, indicates the need for proper patient selection and patient and provider education, but may also indicate limitations in product efficacy, difficulties in application or other factors such as discomfort (Level of Evidence 3).
- Women’s choice of continence products is dependent upon acceptability of application of the intra-urethral and intra vaginal devices (156) (Level of Evidence 3).

Some mechanical devices are effective, acceptable to a minority of women and relatively non-invasive (with the exception of intraurethral devices. They might be suggested to patients for consideration and acceptance of this device.
testing, particularly for short-term or occasional use. This recommendation is at the behest of health care professionals’ (HCP) noted in Bugge et al’s 2013 survey (161) considering contemporary practices.

4. RECOMMENDATIONS

Recommendations relating to mechanical devices for women with UI are summarised in Table J-2.

Table J-2: Recommendations relating to mechanical devices for women with UI.

- Internal vaginal support devices may be considered as a treatment option when managing women with SUI, dependent upon the availability of product, ease of insertion / removal, acceptance and cost (Grade of Recommendation C).
- Internal urethral devices may be considered for women with SUI, but they are invasive, costly and have had limited evaluation. They may be most appropriate for intermittent and occasional use (such as during vigorous exercise) (Grade of Recommendation C).

5. PRIORITIES FOR RESEARCH

- New devices - particularly invasive ones – must be evaluated by randomised trials including long-term follow-up.
- Evaluate the effects of mechanical devices for urinary incontinence on the urethra and / or bladder to determine their real value and safety.
- Comparison studies to other forms of conservative therapy, surgery and / or absorbent pads are mandatory.
- Assessment of cost effectiveness and effects on quality of life, when used intermittently or for particular activities.

K. MECHANICAL DEVICES FOR MEN WITH UI

Male mechanical devices (also called penile clamps or penile compression devices) are designed to prevent urine leakage by compressing the penile urethra using a clamp design or a peri-penile strap (Fig K-1).

For select men, mechanical devices offer a cost effective and convenient option for continence compared with a sheath and drainage bag or absorbent pads or for those who do not wish to undergo invasive incontinence surgery. However, there is potential for tissue damage and penile ischaemia and these devices should be used with caution. Clinical opinion is that the device should be released at least every two hours and is unsuitable for use overnight or when sleeping (15). Careful assessment is necessary for use of these devices and they should be fitted by a trained health professional and re-evaluated on a regular basis. The availability of online products means that men can purchase devices without assessment - healthcare professionals should be alert to the need for education of men on the safe use of these mechanical devices.

A penile compression device should be comfortable, easy to apply and remove and cause no untoward effects on skin or penile vessels. It should not be used for urgency incontinence. The main factors that may make mechanical devices (un)suitable for men are summarised in Table K-1.

Fig K-1: Mechanical devices for men

2356 | COMMITTEE 20. MANAGEMENT USING CONTINENCE PRODUCTS
Table K-1: The main factors that make mechanical devices (un)suitable for men.

**Mechanical devices may be suitable for men with:**
- Sufficient bladder capacity to allow about 2 h wear before needing to release the device.
- Mainly stress urinary incontinence.
- Cognitive ability to remember to release the device at regular intervals.
- Adequate hand function that the device can easily be opened and closed.
- Penile length to allow comfortable placement of the device on the shaft and not the glans.

**Mechanical devices are not suitable for men with:**
- Poor memory or reduced cognitive function.
- Overactive bladder.
- Penile skin irritation/dermatitis.
- No penile sensation or sensation of bladder fullness.

1. **EVIDENCE**

Although a range of devices is available, there has been little research on their safety and efficacy.

Only one trial (162) was identified for the last consultation (31); it evaluated the effect of three devices on mean urine loss, subjective opinion and cavernosal artery blood flow. The Cunningham clamp was the most successful device in terms of continence, ease of application and comfort but was also associated with the highest reduction of penile blood flow indicating a potential for ischaemia if the device was placed too tightly. When the clamp was placed in a comfortable position and tightness, it controlled leakage well but did not entirely eliminate it so that participants still wore a small continence pad.

Two new studies were found for the current consultation (15) (163). The first was a randomised, controlled trial (15) of 56 men with persistent incontinence post prostate cancer treatment. Men tested, for 3 weeks each, the Cunningham penile clamp, penile sheath and bodyworn urinal (BWU) and compared these to their usual product of continence pads. Significant differences in acceptability, comfort, effectiveness ease of use were found between products: the Cunningham clamp was good for short vigorous activities that increased abdominal pressure such as golf or swimming and was the least likely to leak. However, nearly all mean found the clamp uncomfortable or painful. Other products – sheath, pads, and bodyworn urinal – were also rated. Participants rated the sheath as effective for dryness and ‘good’ for extended use such as travel; the bodyworn urinal received the least positive reviews and did not stay in place well, particularly when the user was seated. Pads were positively rated for most activities and best for night-time use. Of note is that participants indicated a preference for having a mixture of products to meet daytime needs. This is an important trial as it is the first to systematically compare several different continence products for men.

A second trial with 16 men measured IIQ-7 scores pre and post use of the penile compression device (Dribblestop™) as well as subjective impressions of ease of use, comfort, activity levels and overall satisfaction (163). There was a significant improvement in IIQ-7 score; 14/16 participants found the device easy to use, allowing them to be more active and more confident and they would recommend the device to others.

2. **SUMMARY**

- Penile compression devices may be a valuable continence option for select men, particularly where activity may not only exacerbate incontinence but also preclude the use of bulky and / or absorbent products. (Level of Evidence 1).
- Men who used a compression device ranked them as easy to use and effective. (Level of Evidence 1).
- Some men found the Cunningham clamp uncomfortable or painful. (Level of Evidence 1).
- Male mechanical devices can partially control urinary leakage, but they may not eliminate it at comfortable levels of compression. However, they are likely to lead to reduced cavernosal artery blood flow and therefore care must be taken to ensure regular removal or release (Level of Evidence 2).

3. **RECOMMENDATIONS TABLE**

Recommendations relating to mechanical devices for men with UI are summarised in Table K-2.
Table K-2: Recommendations relating to mechanical devices for men with UI.

- Male mechanical devices may be considered for select men with stress urinary incontinence who are cognitively intact and aware of bladder filling, have normal genital sensation, intact penile skin and sufficient manual dexterity to open and close the device (Grade of Recommendation B).

- Devices should be fitted by a trained health professional and reviewed regularly (Grade of Recommendation C).

- Mechanical devices may be an option for short-term use when undertaking sport or other activities and as an adjunct to management with other continence products (Grade of Recommendation C).

4. PRIORITIES FOR RESEARCH

Further research is necessary on the length of time a device can remain in place, the amount of compression that is safe for penile vessels, and the effect on skin health and comfort when using the device. It is possible that one penile compression device will not meet the needs of all men and further design considerations may be warranted.

L. INDWELLING CATHETERS

Indwelling urinary catheters (Fig L-1a) are inserted into the bladder urethrally (UC) (Fig L-1b) or suprapubically (SPC). Table L-1 lists the contexts in which long-term catheterisation (> 30 days) is most commonly used.

Fig L-1: An indwelling catheter with balloon inflated (a) and in position in the urethra / bladder.
Table L-1: The contexts in which long-term indwelling catheterisation (> 30 days) is most commonly used.

- Bladder outlet obstruction (BOO) where patients are unsuitable for - or waiting for - surgical or medical relief.
- Chronic retention when intermittent catheterisation is not feasible.
- Continence care for debilitated, paralysed or comatose patients.
- Pressure ulcers at risk of urine contamination.
- Non-healing incontinence associated dermatitis.
- Intractable urinary incontinence where catheterisation enhances the patient’s quality of life when alternative non-invasive approaches are unsatisfactory or unsuccessful.

The older hospitalised person is at particular risk of having an unnecessary catheter or one remaining in situ for a prolonged period and/or being discharged without instruction for catheter care or date for removal (164). Common risk factors for catheters unnecessarily remaining in situ are listed in Table L-2.

Table L-2: Common risk factors for indwelling catheters unnecessarily remaining in situ.

- Absent or poor documentation on reason for catheter insertion.
- Extended hospital stays.
- Transfer from one clinical setting to another (573).
- No documented care plan for catheter removal (573) (574).
- Immobility, confusion / decline in function (170).

Several prevalence studies have indicated that about 9% of nursing home residents have a long-term indwelling catheter (range 7%- 38%) (165) (166) (167) (168) (169) (170). Duration of use can be for many years - in one US based study, mean use was 11.7 years (ranging in months from 1-589; median 8.8 years) (130) (171) (172). Lower use of catheters is recorded in centres with more proactive programmes related to prompted toileting and mobility.

It is understood that catheters should not be inserted as a continence measure until all other reasonable continence management/treatment strategies have been ruled out such as toileting, containment products and/or medication. In the evidence reviewed in the sections below, the primary focus is on the research related to long-term indwelling catheters (remaining in situ > 30 days).

The characteristics of the ideal catheter and ideal catheter material – according to expert opinion – are summarised in Table L-3, while Table L-4 outlines suitable materials, balloon size, catheter gauge and catheter length for different situations.

Table L-3: Characteristics of the ideal catheter and catheter material.

An effective indwelling catheter should have the following design characteristics:
- Be retained in the bladder effectively, yet easily removable without trauma to tissue.
- Have a soft ‘tip’ within the bladder to avoid pressure damage to the mucosa.
- Achieve effective drainage while minimising risk of bladder mucosa being ‘sucked’ into drainage channel.
- Conform to the shape of the urethra.

The ideal catheter material should:
- Be soft / flexible for comfort.
- Cause minimal tissue reaction or friction.
- Be sufficiently firm for easy insertion and maintenance of lumen patency in situ.
- Have elastic recoil so that an inflated balloon can deflate to almost its original size.
- Be resistant to colonisation by micro-organisms and to encrustation by mineral deposits.

### 1. EVIDENCE

An extensive body of literature was reviewed for the last (5th) consultation and the details can be found there (31). However, the findings from that review are included in the summary below (Section 2), along with more recent material.

Few randomised controlled trials have been conducted on either long or short term catheterisation since the last consultation (31). Most indwelling catheter research has focused on short-term catheters (< 14 days) in hospitalised patients with a particular focus on catheter-associated urinary tract infection (CAUTI). The trials that have been undertaken are typically small, with sample heterogeneity, imprecise outcomes and short term follow up. Most data are of Level of Evidence 4, based on clinical experience and expert opinion. Several Cochrane reviews relating to long-term catheter use attest to the low quality of studies which preclude drawing robust conclusions (See Appendix 2 for a listing).

Studies added for the current consultation can be usefully reviewed under the following headings:

a) Catheter characteristics and materials.
b) Catheter coatings and CAUTI.
c) Meatal cleansing.
d) Catheter encrustation.
e) Bladder calculi.
f) Catheter-related pain.
g) CAUTI.
h) Bladder cancer.
i) Management strategies.
j) Education of health care professionals.
k) Quality of life.
l) Cost.
m) Urinary catheters versus other strategies.

### a) Catheter characteristics and materials

Feneley and colleagues wrote in 2012: In an era that has witnessed outstanding technological advances in medical practice it is difficult to understand why we are still unable to perform the relatively simple task of draining urine from the bladder without producing infection and a range of associated complications (173). Efforts to improve the traditional Foley design include a novel spiral-shaped, drainage tubing which appears to optimise flow and minimise residual urine
and additional eyeholes (174) (175). Clinical testing is awaited.

b) Catheter coatings and CAUTI

Considerable laboratory work has been committed to finding a catheter coating that will prevent CAUTI or delay the onset in both acute and long-term care. To date and despite dedicated attempts to find options, there are no coated/impregnated catheters that will delay the onset of CAUTI in the long-term user. There may be modest benefit for those catheterised seven days or fewer.

- Silver Alloy: Two new trials comparing CAUTI with silver alloy versus standard catheter were found (176) (177). The first was a non-randomised retrospective review conducted in seven US acute care sites. Over the three months of data collection, a decrease in symptomatic CAUTI occurred when using both the US National Healthcare Safety Network surveillance definition and a clinical definition. In the most recent RCT in the UK (177) the authors found no difference in symptomatic UTI with silver alloy compared to standard catheters. One retrospective chart review suggested that silver alloy catheters post prostatectomy may increase risk of stricture, but a prospective study is required to determine this risk (178). Other randomised trials and a recent Cochrane review conclude that silver alloy catheters do not significantly reduce the incidence of CAUTI in acute care (179) (180) (181). Laboratory work has continued to modify silver coatings to increase antimicrobial activity (182).

- Antibiotic/antiseptic impregnated catheters: Earlier catheter studies on the effect of nitrofurazone (183) (184) (185) (186); minocycline and rifampicin (187); chlorhexidine, silver sulfadiazine, triclosan (188) (189) (190) (191) (192) have suggested benefit but outcome measures of bacteriuria vs CAUTI, heterogenous patient populations and small samples have limited the clinical impact of these findings. The largest randomised trial to date comparing nitrofural silicone, silver alloy coated latex or a PTFE standard catheter (n=7102 acute care short term catheter subjects) found that the nitrofural catheters had a small and not clinically meaningful decrease in CAUTI and were more uncomfortable than silver alloy or PTFE catheters. No significant decreases in symptomatic CAUTI occurred with silver alloy catheters compared to control (177). Laboratory work continues to show promise in antibiotic and antimicrobial catheters but findings have yet to be tested in clinical settings (193) (194) (195) (196) (197) (198).

- Other coatings or treatment undergoing laboratory testing: Zwitterionic molecules (in an anti-fouling coating) decreased biofilm development by 80% over seven days as compared with untreated catheters (199) (200). Laboratory testing also includes nanoparticle coatings on catheters (201) (202) coating with antimicrobial enzymes (203) (204), polydopamine peptide coating (205), the addition of plant extracts (206), the release of salicyclic acid (207), interference with bacterial signalling (208) (209), the use of bacteriophages to control colonising mixed species biofilms (210) (211) (212) and the application of low electrical currents to dislodge mature biofilms (213). Future opportunities for CAUTI control are promising based on the sophisticated laboratory work underway.

c) Meatal cleansing

An antiseptic solution is no more effective than sterile water in preventing the onset of bacteriuria (214) (215) (216). Meatal cleansing by simple washing with soap and water during routine bathing or showering is recommended (Level of Evidence 1) (103) (217) (218) (219). Effective handwashing by healthcare professionals, caregivers and patients, before and after handling catheters and drainage equipment, is generally accepted to be the most important component of any infection control strategy. Healthcare professionals and formal caregivers should also wear gloves.

d) Catheter encrustation

Catheter encrustations affect quality of life, nursing time and healthcare costs (220). Several approaches have been tested to reduce the problem including catheter maintenance solutions, (221) (222), fluid intake (223) (224) and catheter valves. Preventative strategies have largely failed but recent laboratory research, using advanced imaging techniques, has improved the understanding of crystalline biofilm formation which may aid in the development of anti-microbial materials, resistant to colonisation. (225)

Catheter encrustation (Fig L-2) occurs in up to 50% of LTC users, with resultant increased costs to services and patients (168) (226) (227) (228) (229). Mineral deposits - calcium phosphates and magnesium ammonium phosphate (struvite) - precipitate from the urine under alkaline conditions and cause blockage. In one trial prevalence of catheter blockage in a two month period was 11.08 per 1000 catheter-days’ use (220). During the 12 months of another trial (230), both treatment and control groups had a reduction in blockage (4.76 and 6.04 per 1000 catheter-days, respectively) but there were no statistically significant differences between groups.
Precipitation of different ionic species (ie Ca++, Mg++, and phosphates) is influenced by their ionic concentrations in the urine and by the presence of urea-splitting micro-organisms such as Proteus mirabilis (231) (232) (233) (234). The pH at which ions precipitate from the urine varies, not only for different ions, but also between individuals and at different times (235) (236). These factors contribute, at least in part, to individual susceptibility to catheter encrustation and time to blockage. 'Blockers' experience recurrent catheter blockage within a few days to a few weeks (226) and urine from recurrent blockers tends to have a very narrow 'safety margin' between 'voided' urinary pH and the pH at which crystallisation (or nucleation) occurs (232) (237). This margin is much wider in non-blockers (234).

Catheter maintenance solutions

Pursuit of a solution to managing catheter blockage is on-going and several catheter maintenance solutions are marketed (Table L-5). However, there is no evidence that any of the following are effective in preventing encrustation or blockage in the clinical setting:

- Washout / maintenance solutions (222) (238) (239).
- Catheter coating or material (229) (240) (241) (242) (243) (244) (245) (246) (247) (248) (249).
- Oral medication (250) (251).
- Balloon instillation (252) (253) (254).

Several solutions are marketed to decrease encrustations/increase catheter time in situ (Table L-5). However, to date there is no clinical evidence that catheter maintenance solutions are effective in improving catheter drainage (255). For patients who have blocking or encrusted catheters the key nursing procedure is to review the catheter integrity, observe for reduced flow or obvious encrustation and change the catheter before it blocks. A characteristic pattern of 'catheter life' can usually be identified with record-keeping of three or more catheter episodes (232) (237) (256). This may allow pro-active strategies of care designed to change the catheter before likely blockage.

Concerns have also been raised about a potential negative effect of washouts on the urothelium (221) (232) (237) (257) (258) (259) (260) (261). There is weak evidence that citric solutions (orange, lemon or lime juice) and / or water intake may change pH and mineral crystallisation (223) (262) (263). Table L-6 summarises the theory and evidence of research efforts on encrustation.

Table L-5: Catheter maintenance solutions.

<table>
<thead>
<tr>
<th>Solution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suby G or Solution G¹</td>
<td>3.23% citric acid solution, pH 4, containing magnesium oxide to minimise tissue irritation, aimed at reducing encrustation. Used where routine catheter maintenance is required to reduce build-up of encrustations.</td>
</tr>
<tr>
<td>Solution R¹</td>
<td>6% citric acid solution, pH 2, containing magnesium carbonate, aimed at dissolving encrustations. A stronger acid than Suby G and therefore not recommended for frequent, regular use.</td>
</tr>
<tr>
<td>RenacidinR²</td>
<td>A citric acid solution, pH 3.5-4.2, containing glucono-delta-lactone to minimise tissue irritation and magnesium carbonate, aimed at reducing encrustation.</td>
</tr>
<tr>
<td>Mandelic acid 1%¹</td>
<td>An acidic solution, pH 2, aimed at inhibiting the growth of urease-producers. A stronger acid which is not commonly used to reduce catheter encrustations.</td>
</tr>
<tr>
<td>Saline 0.9%¹,³</td>
<td>A neutral solution, pH 7, recommended for flushing of debris and small blood clots. Neutral pH solutions will not dissolve catheter encrustations.</td>
</tr>
<tr>
<td>Chlorhexidine 0.02%¹</td>
<td>An antiseptic solution aimed at preventing or reducing bacterial growth, in particular E. coli and Klebsiella species (but will not prevent biofilm formation on long-term catheters).</td>
</tr>
</tbody>
</table>

¹ Available in the UK pre-packed in a sterile delivery devices designed for instillation into a urinary catheter.
² RenacidinR is approved in the USA for kidney stone disintegration only. Although it may be effective in certain situations for persistent catheter blockers, there are no supporting studies.
³ Saline is widely available

**e) Bladder calculi**

Indwelling catheters (UC and SPC) are a known risk factor for bladder calculi formation compared to intermittent catheterisation (264) (265) (266) (267). This increased risk is independent of age, sex, level and degree of injury and the risk increases with duration of catheterisation so that by 5 to 10 years of continuous urethral or SP catheter use 33% to 46%, respectively, will have been treated for a bladder calculus (268). Any foreign object, like a retained piece of fluff from gauze, or pubic hair can cause a stone. Careful attention to hygiene and catheterisation technique could prevent this complication (269).

In a prospective cohort study of 66 SCI patients in Nigeria, encrustations and P. mirabilis were predictive of bladder stones; thus ultrasound was recommended for persons with these risks to identify and treat bladder calculi (270).

Symptoms of bladder calculi vary from unresponsive CAUTI to catheter bypassing, spasms and haematuria. Individuals who do not respond to appropriate treatment of CAUTI should have a urological referral.

**f) Catheter-related pain**

Catheterised individuals report discomfort, pain and restricted activities because of catheter related painful bladder spasms, position of the catheter/tubing or catheter changes (130) (271). In a prospective observational study of 116 patients post urological surgery, the type of surgery and catheterisation history predicted moderate to severe catheter-related bladder discomfort (198). In a sample of 202 long-term...
Indwelling catheter users, 23% reported catheter-related pain (other than during the catheterisation procedure) over the previous two months (220). Women complained about the pain because of sitting on the catheter or sores in the vaginal area. Bladder spasms, CAUTIs, blockage, and dislodgement can all contribute to catheter-associated pain, as well as insertion and removal procedures (272) (273) (274) (Level of Evidence 3).

If bladder spasm is the cause of pain a low dose of an anticholinergic medication may help (275). Attention to the catheter position and tubing is needed to prevent kinks or twists, to ensure that the catheter straps are not blocking urine flow and that the individual is not sitting on the tubing (276). Other approaches include treating constipation if present, ensuring that the catheter is the smallest size to provide adequate drainage, and ensuring that the catheter is secured and the drainage bag is well supported to prevent dragging on the catheter.

g) Catheter associated urinary tract infections (CAUTI).

Coatings on catheters are intended to control CAUTI but the problem is a challenge for both clinicians and researchers because of the complex nature of CAUTI development. The most common infecting organisms are Escherichia coli, Enterococcus spp, Candida plus other Gram-negative and Gram-positive isolates (277). Up to 40% of cultured specimens from long term catheters will show Proteus mirabilis as a key organism in biofilm production, catheter blockage and pH alteration because of urease production. Table L-7 highlights the progression of initial colonisation to adherent biofilm.

<table>
<thead>
<tr>
<th>Table L-7: Biofilm production from initial colonisation to adherent biofilm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Biofilms (282) (301) (589) (590) (591) (592) (593).</td>
</tr>
<tr>
<td>- Rapid colonisation of micro-organisms form a strongly adherent biofilm on catheter and drainage equipment surfaces.</td>
</tr>
<tr>
<td>- Biofilm formation begins by deposition of a conditioning layer of proteins, electrolytes and other organic molecules from the urine</td>
</tr>
<tr>
<td>- Micro-organisms attach to catheter surfaces &amp; divide to form micro-colonies, ultimately developing a complex three-dimensional structure, including fluid filled channels through which the biofilm members receive nutrients, diffuse waste and send chemical signals to each other</td>
</tr>
<tr>
<td>- Microorganisms growing as a biofilm are less susceptible to antimicrobial therapies than free-living organisms and are a major source of resistant, nosocomial pathogens</td>
</tr>
<tr>
<td>- Proteus mirabilis is a common biofilm isolate which secretes urease causing hydrolysis of urea to free ammonia, raises urine pH and promotes precipitation of calcium phosphate and magnesium ammonium phosphate (struvite) and catheter blockage.</td>
</tr>
</tbody>
</table>

Onset of CAUTI

- All individuals with indwelling urinary catheters will develop colonisation (asymptomatic bacteriuria) at 5-8% per day to 100% by day 30 (278) (279) (280) (Level of Evidence 1).

- Even short term antibiotic use in a catheterised patient may place them at risk of CAUTI (282) (283) (Level of Evidence 2).

- Most catheter users developing bacteriuria will remain asymptomatic and not require treatment (Level of Evidence 1).

- 24% of those developing bacteriuria will develop a symptomatic UTI without bacteraemia (284) (Level of Evidence 1).

- 4% with bacteriuria will develop bacteraemia a serious health care problem (284) (Level of Evidence 1).

Aetiology of CAUTI

Biofilm formation on the catheter surfaces begins as early as 24 hours after insertion. Microorganisms derive from the patient’s own colonic and perineal flora or from the hands of health-care personnel during catheter insertion or management (282) and gain access in two ways:

- Extraluminally during catheter insertion or via the periurethral space;
• Intraluminally following breaks in the closed system or contamination of urine in the drainage bag or break in closed system (within 32-48 hours v 72-168 hours respectively) (285).

Diagnosis of CAUTI

The generally accepted CAUTI definition is outlined in the U.S. National Healthcare Safety Network (NHSN) document (281). The criteria are guidelines for practice – individual patient presentation may differ. Further work is required on the most appropriate outcome measures and the corresponding patient reported symptoms of CAUTI, particularly in long term users.

Treatment of CAUTI

• Prophylactic antibiotics prior to re-catheterisation are not recommended (104) (286) (Level of Evidence 1).
• Routine use of prophylactic antibiotics or anti-septics in LTC patients is not supported and may favour the emergence of resistant organisms (104) (185) (287) (288) (Level of Evidence 1).
• Cranberry juice does not affect incidence of CAUTI in catheterised people (289) (Level of Evidence 1).
• Urine cultures should be obtained before initiating treatment to permit selection of specific therapy for the infecting organism; extensive use of broad spectrum therapy should be avoided (290) (Level of Evidence 2).
• Catheter should be replaced prior to collecting a urine sample for culture and sensitivity or prior to starting antibiotics in symptomatic patients (104) (291) (292) (293) (Level of Evidence 2).

Reducing the risk of CAUTI

Current evidence is weak regarding all aspects of CAUTI prevention in long term catheter users. Based on the existing research, none of the following factors have been shown to reduce the incidence of CAUTI:

• Pre-connected urine drainage bags (294).
• Perineal cleansing (294).
• Suprapubic versus urethral insertion (295) (296) (Level of Evidence 2).
• Silver alloy antimicrobial surfaces (297) (298).
• Catheter coatings to reduce protein absorption (299).
• Inflation of the balloon with a biocide solution, such as Triclosan (243) (252).
• Disruption of matrix or glycocalyx components with agents such as heparin (300).

• Numerous trials of oral antibiotics, antimicrobial bladder washes, drainage bag solutions and topical disinfectants all lead to the conclusion that bacteriuria and UTI may be suppressed temporarily at best, but resistant organisms are highly likely to emerge (301).

h) Bladder cancer

The reported incidence of squamous and transitional cell carcinoma associated with chronic indwelling catheterisation varies widely across studies (302) (303). In a US based study of 3,670 SCI subjects with indwelling catheters, the incidence of bladder cancer was 77/100,000 population vs 17/100,000 for the US general population (304) (Level of Evidence 3). Even SCI patients without an indwelling catheter may have a higher risk bladder cancer 15 times that of the general population and it is postulated that the neurogenic bladder may itself be a risk factor (305). The potential relationship between duration of catheterisation and cancer development could be studied further, particularly because patients change their form of bladder drainage which confounds the subgroup analysis in retrospective studies. Squamous cell cancer also was reported in two cases in persons with suprapubic catheters, which is believed to be uncommon and needs to be differentiated from granulomatous conditions which are common (306). Bladder calculi have been identified as an independent risk factor for bladder cancer by some authors (302).

Carcinoma within the cystostomy tract with SPC has also been reported (307) (308) (309). However, Hamid et al. (310) raise concerns over the interpretation of screening cystoscopy and biopsy in this population and note the importance of the distinguishing between histological changes and confirmed cancers when interpreting study results. Guidelines on catheter management includes a recommendation that patients with urethral catheters in place for 10 years or more should be screened annually for bladder cancer (311) (Grade of Recommendation C).

i) Catheter management strategies

In addition to CAUTI and encrustation, catheterisation is associated with several other complications: trauma due to malposition, leakage, calculi, false passage, haematuria, dislodgement, urethral strictures, hypersensitivity or anaphylaxis related to the catheter material (312) (313) (314). In a prospective surveillance project in a U.S. Veteran’s Administration hospital, genitourinary trauma was as common as CAUTI (315). In one group of 202 community-dwelling adults with long-term catheters the authors described catheter related problems: 31% with CAUTI, 24% blockage of the catheter, 12% accidental dislodgement, pain (23%), sediment (63%), bladder spasms (36%), or urine leakage (43%) (220). Many case reports describe catheter-related complications such as: urethral injury (316) (317) (318), intraperitoneal rupture of the bladder (319) (320), fistula (321), and iatro-
genic hypospadias (322). These complications consume nursing time, compromise quality of life, and are costly to the healthcare system.

Overall, complications can be reduced if systematic approaches are taken to catheter care. Guidelines and protocols for catheter-care practices have been developed by clinical experts and should be part of an institution’s care mandate. Research findings on topics such as meatal cleaning, lubrication, catheter securement, pain, and encrustations are discussed below.

Suprapubic versus urethral catheter insertion: Incidence of complications such as CAUTI, bladder calculi and encrustations do not differ between urethral or SP routes, but SPCs do offer easier access to catheter site, easier recatheterisation, and may be more comfortable for individuals. Table L-8 compares the two insertion approaches.

<table>
<thead>

<td>Urethral deformity/stricture</td>
<td>Haematuria of unknown origin, Bladder tumour Small contracted or fibrotic bladders Obesity if pannus covers SPC site; obesity makes catheter insertion more difficult or impossible because of the trocar length. Abdominal scarring from surgery or radiation</td>
</tr>
</tbody>
</table>

When changing a SPC, the new catheter should be inserted as quickly as possible as a delay of only a few minutes can result in partial obliteration of the tract (323) (324) and the tract will close completely within 24 hours. It is also possible to insert the new catheter too far into the bladder so it enters the ureter with resultant trauma with balloon inflation. Careful observation of the length of catheter external to the abdomen and the angle of protrusion prior to catheter change can help to ensure correct positioning of the new catheter (325). However, this is not always enough evidence to show correct positioning. A case presentation of a catheter which had “doubled-back” and showed the correct length suggests that imaging may occasionally be required to ensure correct placement. Dressings around the stoma site are not normally required unless there is excessive discharge, causing staining and / or sticking to clothing.
Maintaining effective catheter drainage

Use of urinary catheters is rarely completely trouble-free. Catheter drainage can be compromised by a variety of factors from simple causes such as kinked tubing or the position of the drainage bag, to bladder spasm, pressure of a constipated bowel on the adjacent urethra, suction of bladder mucosa into the catheter eye, or blockage by blood clots, mucus or encrustations. The algorithms in Fig L-2, Fig L-3 and Fig L-4 combine current evidence-based knowledge and expert opinion to provide some guidance on troubleshooting common problems. Further research is required to determine if dependent loops, which allow urine stasis, could contribute to CAUTI (126).
Urine does not drain

**Problem**

- Drainage bag 2/3 full?
  - N
  - Y: Empty the bag.

- Check position of drainage bag and tubing:
  - Is bag below the level of bladder?
  - Is tubing kinked or twisted?
  - Are dependent loops impeding urine flow?
  - Is catheter supported to prevent twisting/kinking?
  - N
  - Y: Adjust position of bag and/or drainage tube.

- Bladder mucosa obstructing catheter eyes (suction pressure)?
  - N
  - Y: Try to relieve blockage and ascertain cause:
    - "Milk" the catheter gently along its length.
    - Change the catheter, observe the nature of the blockage and any external deposits (cut the catheter open if necessary to view lumen).

- Catheter blocked by pressure from faecal loading in lower bowel?
  - N
  - Y: Change catheter and treat constipation.

- Catheter blocked by bladder calculi?
  - N
  - Y: Change catheter and perform cystoscopy and removal of stones.

- Unexplained problem? Change catheter and record details.

**Action**

- Raise the bag above the level of the bladder briefly to relieve suction pressure.

**Recurrent catheter encrustation and blockage:**

- Identify recurrent "blockers" by monitoring catheter changes for a characteristic pattern of "catheter life" (over a minimum of 3 catheters i.e. time to blockage) and by direct observation of encrustation.
- Plan to change catheter before likely blocking.

- Aim to extend "catheter life" where necessary by:
  - Using an all silicone catheter (larger lumen).
  - Encourage production of a dilute urine.

**Record problems, actions and outcomes.**

**Fig L-3: Troubleshooting long-term indwelling catheter problems: urine does not drain. (N = No; Y = Yes).**

(Always have a spare catheter available).
**Fig L-4: Troubleshooting long-term indwelling catheter problems: urinary bypassing.**

**Urinary bypassing**

**Problem**

- By-passing may be caused by the catheter being blocked.
- Are the catheter and balloon sizes correct? Large catheters and balloons (30ml) are associated with irritation and leakage.
- Urinary tract infection?
- Bladder irritation / spasm?

**Action**

- See algorithm in Fig L-2.
- Change catheter and / or balloon to a smaller size. 14-16 Ch is appropriate for most adults for long-term drainage.
- Check for signs and symptoms of systemic infection. Treat as required.
- Consider:
  - Concentrated urine: promote increased fluid intake to dilute urine.
  - Check for bladder calculi by X-ray or ultrasound. Refer if found.
  - Consider anticholinergic medication.
  - If persistent leakage occurs with SPC it may be necessary to consider surgical closure of the urethra. Refer to urology.

Record problems, actions and outcomes.
Catheter clamping prior to removal

Two new studies are conflicting on the value of clamping post operatively. In a non-randomised study of neurosurgical patients with a short term catheter (mean 2.6 days) the clamped group had a shorter time to urination, less residual and positive perceptions of their first void (Liu et al, 2015). In contrast, in a trial involving 60 stroke patients randomised to free drainage or timed clamping over 1, 2, or 3 days, there was no difference in time to first void, volumes, or residual, and clamping may have contributed to other problems like leakage or CAUTI. The authors recommended that an indwelling catheter be removed without attempts to recondition with clamping (326) and this approach is consistent with the findings from a recent systematic review (327).

Catheter valves

A catheter valve is a compact device used to control urine flow and is connected to the catheter outlet in place of a bag to allow a discreet alternative to conventional urine drainage bags. Valves are available in a variety of designs (Fig L-6) ranging from simple devices used for up to a week, to more complex forms which last longer and which may permit one-handed action. Most valve designs can be attached to a drainage bag at night to allow free drainage while the patient sleeps.
Suitable for: those who can manipulate the valve mechanism and empty the bladder regularly to avoid bladder distention and accompanying risks of reflux on the upper urinary tract.

Not suitable for: people with poor manual dexterity, low bladder capacity, detrusor overactivity, vesicoureteric reflux, renal impairment or cognitive impairment.

Evidence supporting the beneficial effects of catheter valves is derived from expert opinion and there is a paucity of research in this area. A lack of knowledge on valves may interfere with appropriate use; therefore, a full assessment is required to determine whether the person is a good candidate for a catheter valve using a systematic process, such as an algorithm (328).

There is no new research on catheter valves. Findings from studies reported in the 5th consultation (2013) indicate (329) (330) (331) (332):

- Catheter valves provide a well-accepted system of bladder emptying for those who can manipulate the valve mechanism and empty the bladder regularly to avoid overfilling (Level of Evidence 2).
- There is no evidence of increased risk of CAUTI, bladder spasms or discomfort compared to conventional drainage systems although there may be a higher incidence of nocturnal frequency and episodes of bypassing with valves. (Level of Evidence 2).
- Valves may promote maintenance of bladder tone and capacity (Level of Evidence 4).
- Preferred valve design should be easy to manipulate, leak-free, and inconspicuous (333). (Level of Evidence 3).
- An automatic valve system for LTC patients (334) may be helpful for patients who lack sufficient dexterity to manage a manual valve.

A catheter valve may facilitate periodic flushing but clinical evidence is currently lacking on reduction of encrustations and prolonging catheter life. Only one controlled laboratory study has explored the question (500), indicating that time to blockage with valves was extended by over 50% compared to controls. There is an opportunity for clinical research in this area.

**Catheter change frequency**

There is no research evidence to support specific change intervals for IUC or SPC. Thus protocols vary widely between facilities from monthly to several weeks if the catheter is trouble-free. There is inadequate evidence to state that CAUTI will be reduced when the catheter is changed every 4-6 weeks, rather than only when it blocks, or with planned changes of every two weeks (335).

**Lubrication**

Guidelines and clinical reports suggest that injury or discomfort may be minimised by using a sterile lubricant or anaesthetic gel (336) (337) for male catheterisation; few have considered the procedure for women or for supra-pubic catheterisation (338). Results are mixed on the benefit of lignocaine versus water based lubricant for female catheterisation: one trial demonstrated lignocaine gel group had a significantly lower median procedural pain score compared to the group receiving a water-based lubricating gel (339) whilst another trial found no difference between lubricants (340). In a small trial with infants, intraurethral the lidocaine resulted in less catheterisation distress than topical or topical and intraurethral water based lubricants (341).

The United Kingdom National Institute for Health and Care Excellence (NICE) guidelines on infection control (342) recommend: ‘an appropriate lubricant from a single-use container should be used during catheterisation to minimise trauma and infection’. Anaesthetic gels may be contraindicated in patients with damaged or bleeding urethral membranes and should be used with caution in those with cardiac conditions, hepatic insufficiency and epilepsy (343). Lubricants which contain chlorhexidine have been reported to trigger anaphylaxis in a small number of patients during catheter insertion and consequently a careful history is required to screen for sensitivities (344).

**Fluid intake**

Apart from catheter maintenance solutions, laboratory studies suggest that dilute urine or increased urinary citrate concentration from orange juice or other fruit juices could be beneficial (262) but randomised
clinical studies are needed to assess the benefit of fluid adjustments.

**Catheter Securement**

Catheter securement may prevent movement of - and tension on - the catheter and potentially reduce the incidence of urethral erosion, trauma and pain, prevent accidental dislodgement from traction (345), and possibly reduce the incidence of bacteriuria (346). Of note is that whilst securement is intuitively better care, it is not necessarily put into practice. Two studies highlight this: of 82 nurses (8 continence specialists), 98% recommended securement but only 4% were documented using it (347); in a one day point prevalence study in acute care, only 18% (8 of 44) of the catheters were secured (124).

Several securement devices are available ranging from:

- Adhesive devices (potential for skin irritation).
- Non-adhesive straps covered in fabric (can slip down with full urine bag).
- Holster styles (348).
- Adhesive tape such as silicone tape can be gentler than paper tape, based on a single trial with children (349). One case report in paediatrics demonstrated efficacy in using an adult leg bag to hold the catheter in place (350).

Choice will depend on individual’s usual activity, clothing, size of the thighs and the weight of the bag it would support. All need to be comfortable, easy to use, and gentle to the skin (351).

**Self-management**

Self-monitoring, a component of self-management, involves awareness of what to notice and related measurements or observations (352). Self-monitoring urine flow was found to be helpful in preventing or minimising catheter-related problems in a pilot study with 11 community-based individuals over a six months’ time period (172). In the follow up randomised trial (N=202), a self-management programme for long-term indwelling urinary catheter users was tested in an experimental design. The intervention consisted of a 3 day intake and output urinary diary, educational booklet, and three home visits by a study nurse (348). The outcomes of CAUTI, blockage, and accidental dislodgement were evaluated over the 12 months’ participation, measured in bimonthly phone call interviews, using a general estimating equation (GEE) and rates calculations. In the first six months of the study, blockage reports of occurrence (yes / no), but not frequencies of the event, were significantly lower in the experimental group than in the control group. No group differences were found for the full 12 months of the study or for other outcomes; however, examination of rates indicated that both groups improved over the 12 months’ study for all outcomes. Researchers believe that the self-monitoring through use of repeated interviews and of a catheter calendar for data collection in both groups contributed to overall self-care management improvements (230).

**j) Education of healthcare providers**

Despite the development of quality guidelines and the attention on CAUTI, knowledge and understanding of appropriate catheter care and risks of prolonged use remains suboptimal in many centres (353) (354) (355) (356) (357) (358). Educational approaches to research-based recommendations for catheter selection and minimising problems are welcomed by healthcare professionals and need to be made available in a variety of ways as part of on-going staff updates (359) (360) and as part of quality improvement/patient safety strategies.

**k) Quality of life and catheterisation**

Indwelling catheters can have both positive and negative effects on life quality. Users report reduced activities (361), embarrassment (271) (274), shame or stigma (171). Other concerns are loss of privacy (171) (273) (362) (363), end to sexual activity (364) (363) (365) (366), loss of manhood (367) and fear of odour and leakage (171) (366) (368) (369). Some indicate that care providers often dismiss their anxiety and concerns or do not provide enough information about sexuality or catheter care (363) (370) (Level of Evidence 3).

Positive benefits of catheterisation are also noted. In one qualitative study with 27 community dwelling adults, perspectives differed (371). Some who were no longer wet regarded the catheter positively, and several developed more self-reliance as they dealt with catheter problems. Others described the challenge of finding bathrooms and adjusted or limited their outings accordingly (Level of Evidence 2). Similar results were found in another qualitative study of 36 persons; changes in sexuality, behaviour, and self-esteem varied among individuals. Some said the catheter had no impact and others indicated it had profound effects on body image and sexuality. A suprapubic catheter was of benefit to some and the catheter position was important related to comfort, aesthetics, and body image (370).

The Consortium of Multiple Sclerosis Centres (372) oversaw a postal survey asking general questions about bladder and bowel management. Of the 9397 respondents, 12.8% used either intermittent or indwelling catheterisation. Fifty-three percent reported catheterisation having a positive impact. While the majority used intermittent catheterisation (64.7%), neither indwelling nor intermittent catheterisation appeared to affect QOL (373).

It is known that adherence to recommended bladder management post SCI is not always optimum for a variety of reasons (374). People sometimes switch from IC to an indwelling catheter -- despite the inherent problems with an indwelling catheter -- because of QOL issues (374). Many use different bladder drainage methods over time (172) (375). In one chart
review of people with SCI, 52% who were discharged using IC chose urethral catheterisation by 6 months citing discontinuation because of: the need to depend on caregivers, poor hand functioning, spasticity, incontinence (despite anticholinergic drugs) and toileting inconvenience (Level of Evidence 3). Problem solving by users for best catheter care is an area open for research. As part of a randomised clinical trial teaching self-management in 202 long-term indwelling catheter users, there were no group differences for QOL, though QOL improved somewhat during the 12 months participation in each group (230).

Practical aspects of living with the catheter, such as managing the drainage bag, can be significant (See Section H). In a small pilot study based on a postal questionnaire to LTC catheter users (n=59) (525) almost 25% of respondents stated that wearing a bag had a major negative affect on everyday living. Concealment was a key concern (89%) and visibility of the bag can be considered demeaning and declares a loss of bladder control (171) (273) and the fear of the bag leaking contributes to vulnerability. Even a short-term catheter can assault one’s dignity. In a study in post-operative short-term catheter use, people complained about feeling “on display” and objectified (362) (Level of Evidence 3).

Until recently, formal measurement of QOL has been limited because no validated instruments have been available. There are now two instruments measuring quality of life in people with indwelling urinary catheters, an earlier version (376) validated in two small samples and a robust measure recently available (26). The latter measure is preferred (Level of Evidence 3).

Guidelines

Guidelines for appropriate catheter use and prevention of catheter associated infections have been published by nursing groups (377) and by Centers for Disease Control in the US (281), NICE (378) in the UK and (279), NICE (376) in the UK and the European Association of Urology (379). The paucity of trial-based evidence has affected guideline development. For example, in the NICE ‘Guidelines for prevention of healthcare associated infections in primary and community care’ (342), of 29 recommendations relating to urinary catheterisation only six were directly based on Level 1 evidence. Twenty-one were grade D, being based on evidence from expert groups or clinical opinion.

Assessment Tools

In USA long-term care settings, all newly admitted Medicare/Medicaid funded residents must receive an assessment using a standardised form -- Minimum Data Set (MDS). A further assessment is triggered when / if a resident is newly incontinent and the Resident Assessment Instrument Minimum Data Set (RAI-MDS) is completed quarterly. Ideally, the instruments should prompt staff to enquire about whether a catheter is medically warranted or to develop an individualised catheter care plan (including the frequency of catheter changes and ongoing maintenance). The MDS and RAI are now used in a number of other countries, including Canada and Iceland. This assessment process is strengthened in the USA by its link to quality indicators. Specifically, long-term care facilities are required to use information from the residents’ comprehensive assessment to provide assurances that:

- Catheters are used for only medically valid reasons.
- Catheters are removed as soon as clinically warranted.
- Efforts are applied to restore or improve bladder function as much as possible.
- Efforts are made to prevent infection while the catheter is inserted (380).

Quality Indicators

Regulation accompanied by the use of evidence based quality indicators has a powerful influence on the quality of care. Quality indicators are defined as quantitative measures reflecting a professional care standard used as guides to monitor and evaluate the quality of patient care and support service activities. The ACOVE (Assessing Care of Vulnerable Elders) suite of quality indicators has been designed to measure the quality of care for that group (381). It incorporates one quality indicator to guide care related to catheter use.

“IF a VE has clinically significant urinary retention, and a long-term (> 1 month) urethral catheter is placed, THEN there should be documentation of justification for its use, BECAUSE treatment of certain underlying causes(s) of urinary retention (e.g., treatment of constipation or bladder outlet obstruction) may carry less risk than long-term urinary catheterisation” (381).

Patients themselves may also benefit from education to prevent unnecessary catheterisation. In one study of patients with short term catheters, 47% did not realise that catheters contributed to CAUTI, 89% thought catheters were not used too often, and—most importantly—68% preferred a catheter to a commode, bedpan or absorbent products (382).

Guidelines and assessment tools alone do not change practice. Further efforts should be directed to disseminating evidence-based education and the use of quality indicators and regulatory initiatives.

I) Cost benefit of different catheters

Few studies have been published on the cost benefits of different catheters. The focus of economic studies has been in acute care using models to predict a proportion of patients with bacteriuria who will develop symptomatic UTI or bacteraemia. One UK based decision-analytic cost effectiveness study was found, in
relation to a randomised trial over six weeks for short term catheterisation. The conclusion was that nitrofurazone coated catheters but not silver coated ones were more cost effective (383). In a companion study of costs associated with long-term catheters in Swedish nursing homes, catheter care costs were associated more with basic care than acute interventions; 90% of the cost was for personnel (229).

m) Urinary catheters versus other care strategies

Few studies have compared indwelling catheterisation with other strategies to manage urinary incontinence, not least because of the difficulties in recruiting to and conducting robust trials. Sheath systems are associated with fewer incidences of bacteriuria, symptomatic UTI or death than indwelling catheters (97). Participants reported that sheaths were more comfortable and less painful than indwelling catheters.

Preferences for different urinary incontinence treatments have been studied in long-term care (384). Most respondents preferred non-invasive strategies (containment products and prompted voiding) to invasive strategies such as indwelling catheterisation (385). Older adults stated they would choose a treatment based, in part, on feeling dry, being natural, not causing embarrassment, being easy, and not resulting in dependence.

2. SUMMARY

- Asymptomatic bacteriuria should NOT be treated with antibiotics; routine urine culture is unnecessary (unless urological instrumentation is planned) (Level of Evidence 1).
- Meatal cleansing of a catheterised individual by simple washing with soap and water (i.e. not with antimicrobial agents) during routine bathing or showering is recommended (Level of Evidence 1).
- A closed drainage system should be maintained to reduce risk of catheter-associated infection (Level of Evidence 2).
- Midnight versus morning removal of catheters may result in longer time to first void and larger first void and no difference in recatheterisation rate (Level of Evidence 2).
- Alpha blockers pre catheter removal after AUR may result in fewer re-catheterisations and improved voiding (Level of Evidence 2).
- Silver alloy coated catheters do not reduce the onset of CAUTI (Level of Evidence 1). Antimicrobial catheters can prevent bacteriuria during short-term catheterisation (<14 days) (Level of Evidence 1).
- Nitrofurazone coated catheters may reduce CAUTI risk, but are associated with discomfort. Potential toxicity and/or antimicrobial resistance is unknown (Level of Evidence 2).
- All currently available catheter materials are subject to bacterial biofilm formation (Level of Evidence 1).
- Recurrent urinary catheter blockage occurs in as many as 50% (range 24-50%) of all long-term catheterised patients (Level of Evidence 2).
- Recurrent urinary catheter blockage caused by encrustation occurs in 40-50% of all long-term catheterised patients (Level of Evidence 2).
- In the majority of individuals with a long-term indwelling catheter, a characteristic pattern of ‘catheter life’ can be identified (Level of Evidence 3).
- Evidence from in vitro models of the catheterised bladder indicates that: i) dilute urine; ii) high urine citrate content (> 1.5mg/mL) reduce risk of blockage (Level of Evidence 2).
- There is insufficient evidence from RCTs to assign an in vivo level of evidence for catheter washouts (Level of Evidence 2).
- Suprapubic catheterisation (SPC) is an appropriate alternative to urethral catheterisation (Level of Evidence 1).
- There is some evidence for a reduction in catheter-associated infection in SPC use during short-term catheterisation (Level of Evidence 2), compared to urethral catheter insertion. However, there is no corresponding evidence for long-term catheterisation (Level of Evidence 2).
- Patient comfort, quality of life and satisfaction with SPC is generally good compared to urethral catheters (Level of Evidence 1).
- Catheter valves provide a well-accepted system of bladder emptying for suitable patients who are able to manipulate the valve mechanism and empty the bladder regularly to avoid overfilling (Level of Evidence 2).
- There is no evidence of increased risk of urinary tract infection with valves compared to conventional drainage systems (Level of Evidence 2).

3. RECOMMENDATIONS

Recommendations relating to indwelling catheters are summarised in Table L-9.
Table L-9: Recommendations relating to indwelling catheters.

- Indwelling catheters should only be used after alternative management strategies have been considered and rejected as unsatisfactory (Grade of Recommendation A).
- Duration of catheterisation should be minimal (Grade of Recommendation A).
- A closed drainage system should be maintained to reduce risk of catheter-associated infection (Grade of Recommendation A).
- Meatal cleansing with plain soap and water (not with antimicrobial agents) is recommended (Grade of Recommendation A).
- Addition of disinfectants to drainage bags, bladder irrigation and antibiotic prophylaxis are NOT recommended as routine infection-control measure (Grade of Recommendation A).
- Silver-alloy catheters are not recommended for use in acute or long term care as they do not significantly reduce the incidence of CAUTI (Grade of Recommendation A).
- Routine urine culture in an asymptomatic patient is not recommended (Grade of Recommendation B).
- Catheter materials designed for long-term use (all-silicone, silicone or hydrogel-coating) should be used where a catheter is expected to be used long-term (i.e. >14days) (Grade of Recommendation B).
- If a long-term indwelling catheter is being considered, both SPC and UC should be considered, following appropriate risk assessment (Grade of Recommendation B).
- Routine washout solutions are NOT recommended to reduce encrustation or debris (Grade of Recommendation B).
- Preconnected urine drainage bags and catheters are NOT recommended as a means to prevent CAUTI (Grade of Recommendation C).
- UC and SPC catheters and drainage bags should be adequately supported to maintain patient comfort and prevent meatal or cystostomy tract damage from traction or abrasion (Grade of Recommendation C).
- Effective handwashing before and after handling catheters and drainage equipment may reduce the incidence of CAUTI (Grade of Recommendation C).
- In patients with recurrent catheter encrustation and blockage, systematic monitoring should be undertaken to identify a characteristic pattern of ‘catheter life’ and instigate pre-emptive catheter changes prior to likely blockage (Grade of Recommendation C).

4. PRIORITIES FOR RESEARCH

a) General

- Agreement on key outcome measures to permit comparisons between studies:
  - Standardised definition of UTI for catheterised individuals.
  - Asymptomatic bacteriuria in a catheterised patient and its clinical / research implications.
  - Standardised time frames for following patients.
  - Documentation of the use of antibiotics prior to and during a study eg preoperatively in surgery or commencement of antibiotics for other conditions during the study.
  - Patient follow-up to include post catheter removal.
  - Adherence to CONSORT guidelines (386).
  - Definition of recurrent blockage.
  - Consistent use of rates/1000 catheter days for blockage as well as CAUTI.
- Mixing study outcomes of asymptomatic bacteriuria and symptomatic urinary tract infection (CAUTI) limits meaningful comparisons and contributes to a lack in knowledge of effective ways to treat symptomatic CAUTI (387).
- Comparative studies of different patient groups eg. males and females, different age groups, patients at home and those in institutional care, including patients’ comfort, satisfaction and quality of life measures.
b) Indwelling catheters

- Address the barriers healthcare professionals face regarding optimum catheter management.
- Compare catheterisation techniques eg CIC, suprapubic and urethral catheters, on CAUTI and other risks or potential benefits.
- Review any detrimental effects on bladder tissue from persistent asymptomatic bacteriuria in long-term catheterised patients.
- Conduct laboratory and clinically based research of strategies to reduce recurrent catheter encrustation and blockage, including maintaining a dilute urine, increased level and acceptance of urinary citrate, role of acidic ‘catheter maintenance’ solutions.
- Further development of catheter materials resistant to microbial biofilm formation, new approaches to disruption of the biofilm, or alternatives to catheterisation.

b) Catheter valves

- Clinical investigation of effect of catheter valves on incidence and frequency of catheter encrustation and blockage.
- Cost-effectiveness studies of disposable versus re-useable valves.
- Studies designed to demonstrate if catheter valves promote maintenance of bladder tone and capacity.
- Further examination of combination management strategies such as valve during the day and free drainage overnight.
- Studies demonstrating the value of new designs in catheter valves, eg those operated by magnets for people lacking in hand dexterity.

M. INTERMITTENT CATHETERS

Intermittent catheterisation (IC) is the act of passing a catheter into the bladder to drain urine or maintain stricture patency via the urethra or a catheterisable channel such as a Mitrofanoff diversion. Urine is drained and the catheter removed until the next indicated time. IC avoids many problems associated with indwelling catheters but urinary tract infections (UTI) remain an issue for many IC users and most research, until recently, has focussed on UTI as an outcome. Intermittent catheterisation is a sterile technique in care settings and a clean procedure for community based individuals who self-catheterise or have a single caregiver providing bladder care. Policy varies by country on sterile single use catheters or reuse of catheters for IC. To date, there is an absence of evidence to support sterile single use catheters for community dwelling individuals with respect to prevention of UTI although users may report improved quality of life with single use. In this section, we provide an overview of the current literature on IC related UTI, quality of life and cost effectiveness.

The main factors that make intermittent catheterisation (un)suitable for people are listed in Table M-1.

Table M-1: The main factors that make intermittent catheterisation (un)suitable for people.

1. EVIDENCE

At the time of the 5th International Consultation (31), there were 25 published randomised controlled trials on some aspect of IC and 2 Cochrane reviews on the topic (388) (389). The first review focused on the effect that catheter design (uncoated or coated) and sterile or clean catheterisation technique had on the incidence of UTI; the authors concluded there was inadequate evidence to state that any type of catheter or method influenced the incidence of UTI in community dwelling IC users. The second review addressed policies related to IC, indwelling and suprapubic catheterisation. The authors concluded there was weak evidence to support prophylaxis in IC users and that antibiotic resistance was an issue. Findings from the
Since the last (5th) consultation (31) there have been five IC-related RCTs (390) (391) (392) (393) (394), five Cochrane reviews (394), (395) (396) (397) (398), three systematic reviews (399) (400) (401), one laboratory based study on catheter cleaning (402) and one on acceptability of a new cleaning method for catheters reused by a single IC user (403). Most research on IC continues to relate to catheter-associated urinary tract infection (CAUTI) and quality of life.

Short term (less than 14 days) studies focused on hospitalised individuals whereas long-term (using IC on an ongoing basis) studies are almost exclusively of patient groups with neurogenic bladder disorders. Small scale, comparable studies of new products are common and are often industry-sponsored.

One cost effectiveness study was found (404). Using a probabilistic decision analysis describing UTI over the lifetime of a spinal cord injured patient, those ‘assigned’ to single use hydrophilic coated catheters versus single use uncoated PVC catheters had 1.4 additional life years over a 35-year period compared to PVC catheter users.

a) Short-term bladder management

Less than 14 days: Zhang et al. (401) conducted a systematic review and meta-analysis to compare the rates of UTI and postoperative urinary retention (POUR) in individuals who had undergone total joint arthroplasty, randomised to either an indwelling urethral catheter or IC. Nine RCTs involving 1771 patients were included. All indwelling catheters were removed within 24-48 hours postoperatively. Rates of UTI were similar between groups and it was concluded that for patients at risk for POUR, indwelling catheterisation removed 24-48 hours postoperatively was the preferred option. For those low risk patients either indwelling catheterisation or IC could be appropriate or catheterisation following the surgery could be on an as needed basis.

Choice of catheter

Comparison of short-term (less than 14 days) urethral indwelling or urethral intermittent or suprapubic catheterisation in adults hospitalised for a wide range of reasons, from urology surgery to medical management was presented in a Cochrane review (395). The authors concluded that suprapubic catheters reduced both asymptomatic bacteriuria and symptomatic UTI and asymptomatic bacteriuria for indwelling urethral or IC inconclusive. The evidence was also inconclusive for advantages of suprapubic versus IC.

b) Long-term / continuing chronic bladder management

UTI prevention:

With respect to incidence of UTI and long-term IC, a recent Cochrane review compared one type of catheter design versus another, aseptic versus clean technique, single use versus multiple use catheters, self-catheterisation versus catheterisation by others, user preference and ease of use in both adults and children. Thirty-one trials met the inclusion criteria: 13 RCTs and 18 cross-over trials. The authors concluded that despite the number of trials there is still no convincing evidence that incidence of UTI is affected by any technique, coated or uncoated catheter or single or multiple use ‘clean’ catheters. The authors noted that current evidence is weak and trial design issues remain a significant issue. Since this review a cleaning method for multi-use catheters has been published (403) together with evidence of its efficacy (402). However, the method has not been tested in a randomised controlled trial.

In another Cochrane Review, (398) policies relating to antibiotic prophylaxis and IC were addressed. Eight trials met the inclusion criteria with all but one (Zegers 2011) at least 19 years old. The absence of recent research likely reflects the major practice change with respect to antibiotic resistance and prescribing recommendations of ‘as clinically indicated’ versus prophylaxis. Of the 8 studies, only one (405) favoured prophylaxis in children with spina bifida at higher risk: female, with vesico-ureteral reflux and high infection rates. The review authors concluded that implications of ongoing antibiotic use might outweigh limited benefit of prophylaxis.

In an attempt to evaluate whether IC is better than IUC, external (sheath) catheters are better than IUC or IC; or that IC is better than timed voiding. Jamison and colleagues reviewed over 400 studies involving individuals managing neurogenic bladder over the long-term (396). No trials were found that met the inclusion criteria so that currently it is not possible to draw any conclusions regarding clear benefit of IC over other methods in managing the neurogenic bladder.

Quality of life / patient preferences

Moving away from the clinical aspect, recent research focuses on IC users’ quality of life. Research in this area predominately explores catheter designs (e.g. different lengths, ‘ready to use’ presentation) with different materials such as PVC-free and catheters with coatings such as hydrophilic (406). Unsurprisingly, these studies are often industry-sponsored. Another trend in the literature is the focus on user groups with neurogenic bladder disorders and how IC can improve their quality of life. IC continues to be seen as the most commonly used procedure for those with incomplete bladder emptying and offers the ability to be self-caring, maintain independence and the opportunity to decide when and where to empty the bladder.

Other aspects that are evident in the literature are how long-term IC impacts on individual’s daily lives.
Apart from obstacles such as insufficient hand movement or being unable to sit, which can restrict some patients access to IC, worries, embarrassment (407) and psychological coping mechanisms (408) studies also report that patients find intermittent catheters unwieldy, difficult to use or to carry discreetly (390). As one study reports, moreover, the efficacy of CIC is often measured by the individual’s quality of life. A randomised, crossover, multicentre study evaluated discreet design compact catheters compared to standard catheters, which were used by those with neurogenic bladder dysfunction. Results found that 63% preferred the discreet compact hydrophilic coated intermittent catheter design as it contributed to a significant improvement in patient quality of life (390). Choice of product which offers discretion, ease of use and eliminates social anxiety is current user preference (408) (409).

Although there are several devices available to enable catheterisation by the individual - mirrors, catheter holders, and clothing retractors - it is of note that no published studies have explored IC users’ impressions of these devices. Fig M-1 shows a catheterisation aid.

![Fig M-1: A catheter holder / insertion aid (a) and an inflatable cushion with mirror, to be held between the knees and provide a better view of the urethral meatus when self-catheterising (b).](image)

**c) Self-management research**

One small trial has tested the feasibility and usability of a web-based intervention in a sample of people with spinal cord injury (N=34) using intermittent catheters (IC). Prior to the pilot with 30 individuals, the three-month intervention was pre-tested (N=4), and suggestions were given to refine the application, including modifying the web-based interactive urinary diary for mobile phone use. The single group pre-post study involved: a 23 page online educational booklet, links to ICI’s Catheter Products website and other related products, two phone calls with a study nurse in the first month and a follow up phone call at three months to revise goals and approaches. In addition discussion fora were provided, moderated by the study team and 2 peer advisors chosen from the pre-testing group (410) (411). Measures about self-efficacy and self-management of IC were developed and tested. The web-based application was well received, with the forum being used the least often yet well liked. Catheter related self-management was significantly improved with most comments about positive changes in fluid intake. Catheter self-efficacy and quality of life increased slightly and UTI decreased from the three months prior to the study (42% to 30%), but these changes were not significant. The intervention is ready to be tested in a larger study (412).

**2. SUMMARY**

- There remains insufficient evidence to state that one catheter product or catheterisation technique is better than another in the prevention of UTI in IC users (Level of Evidence 1).
- Soap and water combined with a 15 minute Milton soak (Milton method) renders catheters free of pathogenic organisms (Level of Evidence 1).
- Quality of life might be improved with use of compact portable IC catheters compared to standard length catheters or through single use catheters (particularly hydrophilic coated catheters. (Level of Evidence 2).
- Antibiotic prophylaxis may be beneficial for select individuals but must be weighed against the potential of antibiotic resistance (Level of Evidence 2).
- Intermittent catheterisation users find the Milton method (above) easy to use and of little burden (Level of Evidence 2)
- There are several catheter products on the market: uncoated PVC requiring added lubricant; gel coated; hydrophilic gel coated. Personal preference may determine use (Level of Evidence 4).
Aids such as clothing holders, mirrors or catheter holders may facilitate catheterisation (level of Evidence 4).

3. RECOMMENDATIONS

Recommendations relating to intermittent catheters are summarised in Table M-2.

Table M-2: Recommendations relating to intermittent catheters.

- Intermittent catheterisation (IC) is a treatment of choice for those with ongoing bladder emptying problems and residual urine > 100ml who are able to manage the technique (Grade of Recommendation A).
- IC technique can be taught to all ages of people with appropriate motivation and manual dexterity (or to a carer where this is acceptable to both parties). Appropriate education and ongoing support is needed (Grade of Recommendation C/D).
- Frequency of catheterisation needs to be based on individual need, to prevent over-filling of bladder (Grade of Recommendation C).
- An external lubricant or lubricant-coated catheter is recommended to minimise urethral trauma (Grade of Recommendation C).
- IC users may benefit from access to different catheters or catheter-packs for different purposes (eg ease of use may be particular important when at work or in public) (Grade of Recommendation C).

4. PRIORITIES FOR RESEARCH

- Testing of catheter cleaning methods by large groups to assess safe multi use of catheters.
- Ensure trials adhere to consistent definition of symptomatic urinary tract infection.
- Cost effectiveness studies should include patient acceptability/satisfaction with the procedure and or product.
- Health utility in various situations need to be considered, e.g., at home vs. away.
- Further development of self-management research in IC users in various populations in multiple sites.

N. PRODUCTS AND DEVICES FOR PREVENTING OR MANAGING FAECAL INCONTINENCE AND ITS SEQUELAE

1. INTRODUCTION

Anal plugs (to prevent faecal leakage) and peri-anal pouches, rectal catheters and absorbent pads (to contain it) may be used to manage faecal incontinence (FI) and its complications of skin damage and odour. Plugs, pouches and rectal catheters are discussed here while absorbent pads for managing FI are covered in Section F.10, and incontinence-related skin and odour problems in Sections O and P, respectively. Other approaches to conservative management of FI are addressed comprehensively in chapter 17 and in chapter 11.

Products and devices that redirect and / or store faeces have been used in individuals in institutions - such as hospitals and nursing homes - who are confined to bed and require assistance in incontinence management and toileting by caregivers due to acute or critical illness or functional disability (413) (414) (415) (416). These devices are often used to prevent or treat damage associated with FI or other wounds.

1.1. Anal Plugs

An anal plug (Fig N-1) consists of a removable, small cup-shaped piece of foam that is held in a collapsed position by a film for insertion. When the film comes in contact with the moist rectal mucosa, the plug opens to block the passage of faeces (417) (418). A plug is inserted like a suppository using a lubricant gel and can be removed by pulling on an attached string or expelled by raising intra-abdominal pressure and pushing as during normal defaecation. Table N-1 lists the main factors that make anal plugs (un)suitable for people.
Table N-1: The main factors that make anal plugs (un)suitable for people with FI.

Anal plugs are suitable for individuals who:

- Wish to prevent leakage for a specific period (during exercise or after an enema or rectal irrigation).
- Who have leakage associated with spina bifida, anorectal malformation, rectal sphincter injury.

Anal plugs are not suitable for individuals:

- With active disease of the bowel or rectum.
- Who have a SCI and are at risk of autonomic dysreflexia.
- For whom a device might disrupt an established bowel routine.

1.2. Rectal catheters and long and short rectal tubes

Rectal catheters drain liquid faeces through openings at their proximal end into a collection bag (Fig N-2). The catheters and collection bags are a closed system designed for extended use (US FDA approved for 29 days). Sometimes a balloon near the proximal tip is inflated to prevent faecal leakage around the catheter and to retard inadvertent expulsion of the tube during defaecation (419). Bowel management programs often include daily or more frequent saline irrigations through the rectal catheter to maintain liquid consistency of stool and catheter patency (420).
Table N-2 lists the main factors that rectal catheters / trumpets unsuitable for people with FI.

**Table N-2: The main factors that make rectal catheters / tubes unsuitable for people with FI.**

Rectal catheters / trumpets are not suitable for those with:

- Intestinal mucosal disease.
- Immunosuppression.
- Gastrointestinal bleeding or bleeding tendencies.
- Recent myocardial infarction or prostate surgery (419) (422).

Use of a rectal catheter with or without inflating the balloon is controversial because of concerns of ulcerating or perforating the rectum, damaging the anal sphincter, stimulating intestinal secretion worsening incontinence (419) (421) (422) (423).

1.3. Anal Pouch

An anal pouch consists of an external collection bag connected to a pliable wafer, which has an opening at its centre and an adhesive on the body side. The wafer adheres to the peri-anal skin (Fig N-3). The bag has a resealable port at its distal end through which faeces can be drained or connected to a larger, gravity drainage bag without the need to remove the wafer from the skin. Some pouches have a small folded flap that allows flatus to escape so that it doesn’t inflate and rupture the bag.

The pouch avoids the risks of rectal mucosal or sphincter damage associated with rectal catheters or small tubes. Disadvantages of the anal pouch are difficulty in applying it and maintaining its seal and potential skin damage from removing the wafer or from contact of faeces in the pouch with skin (424) (425).

2. EVIDENCE FROM THE 5TH INTERNATIONAL CONSULTATION (2013)

An anal plug can successfully prevent FI in individuals with a variety of aetiologies of FI, more so in adults than children (414) (426) (Level of Evidence 3). The self-reported effectiveness of the plug in adults ranged from 83% (564) to 38% (427). In one study of children, 32% were completely continent using an anal plug, and 13% reported "total failure" (426).
The most common concerns and problems associated with wearing an anal plug include discomfort and failure to retain the plug (Level of Evidence 3). Children seemed to experience less discomfort than adults.

The studies evaluating anal plugs had relatively small sample sizes unsupported by a power analyses and most had non-experimental designs.

Another type of experimental anal plug reported consists of a balloon at the end of a catheter inserted into the rectum and connected to a notification device (428). When faeces enter the rectum, a signal from a photo sensor on the catheter is sent to a pager which then notifies the person to inflate the balloon. Before a voluntary bowel movement, the balloon is deflated and the catheter is withdrawn and can be reinserted. A limitation of this plug is the need to deflate the balloon for 10-15 minutes every few hours to prevent ischemic bowel damage (Level of Evidence 4).

An experimental intra-anal stool bag is composed of a latex bag (20 cm non-extended, to 26 cm extended) that is inserted into the anus and an adhesive attachment applied peri-anally (429). There is a cut-out on the ventral urinary side of the adhesive wafer.

An intra-anal bag successfully collected faecal drainage 50% of the time in five elderly bedridden persons after a suppository was administered (429) (Level of Evidence 3). The internal anal bag has been primarily used when a bowel movement is induced using a suppository.

A rectal catheter system diverts faeces to a collection bag but requires liquid stool consistency and sometimes irrigation to remain patent. Few studies of rectal catheters measure their effectiveness in preventing faecal incontinence or seepage; most focus on preventing or healing skin/wound problems. However, seepage around the catheter does occur (413) (426) (Level of Evidence 3). For example, in a study of 29 paediatric patients, the mean number of daily FI episodes decreased approximately 30-50% (426). In a study of 29 adult patients, varying degrees of leakage around the rectal catheter were reported in 71% of 198 assessments; 35% of these leakages extended to pads on the bed or beyond (413). A rectal catheter system promotes healing of damaged perineal skin and wounds (413) (430) (431) (Level of Evidence 3/4). However, no standardised definitions or criteria for healing of skin damage were reported.

Cost savings based on decreased staff time and laundry costs are possible with the use of rectal catheter systems (424) (432) (Level of Evidence 3).

Non-blinded and non-independent endoscopic observations suggest the catheter does not cause rectal mucosal damage during the recommended length of use (≤ 29 d in the US) (413) (414) (432). There have been case reports of complications of rectal catheters including rectal or lower gastrointestinal bleeding and need for blood replacement, mucosal pressure necrosis, fistula, autonomic dysreflexia, and unwanted expulsion (433) (434) (435). (Level of Evidence 3).

A tube considerably shorter than a rectal catheter originally designed to provide an airway in the nasopharynx has been used as a rectal tube. Referred to as a rectal trumpet, the tube’s flange is inserted into the rectum and a collection bag is connected at its distal end (425). A rectal trumpet can successfully channel faeces to a collection bag and there is some evidence that it can enable damaged perianal skin to recover (425) but its safety has not been determined (Level of Evidence 3).

A possible advantage of the rectal trumpet over a rectal tube is that it is shorter and has less contact with the rectal mucosa, reducing the area of possible damage. Limitations of the smaller rectal tube are similar to those for the rectal catheter regarding risk of expulsion from forceful valsalva movements and dislodgement during repositioning of the patient and linen changes or from tugging on the collection bag (425).

An external perianal pouch (415) (421) is able to collect leaked stool (Level of Evidence 3) but adherence to the skin often fails. Another disadvantage of external perianal pouches is that the adhesive wafers used to adhere them to the skin can cause skin damage upon removal.

Studies of rectal catheters, small tubes, and anal pouches had non-experimental designs. In the prospective studies, sample sizes were relatively small (<50 subjects) and unsupported by a power analysis.

### 3. NEW EVIDENCE FOR THE CURRENT CONSULTATION

Four new papers inform the current consultation: a vaginal bowel system (436), a Cochrane Review of anal plugs (437), a subsequent single group evaluation of an anal insert (functioning similarly to an anal plug) (438), and a comparison trial of bowel catheter or trumpet with usual care (439), as well as some case reports of complications with rectal / anal devices.

#### 3.1. Vaginal Bowel system

A vaginal bowel-control system offers an alternate approach to preventing faecal incontinence (436) (Fig N-4). It is comprised of a vaginal insert and pressure-regulated pump. The vaginal insert consists of balloon on a silicone-coated stainless steel base that is situated posteriorly in the vagina and ventrally to the rectum. The wearer inflates the balloon insert to one of five preset pressures with the pump which then occludes the distal rectum preventing leakage of faeces.
The vaginal bowel-control system was evaluated in a month-long study of 61 middle-aged women who had faecal incontinence (but not of watery stools) at least four times in two weeks using a treatment group only design. Results of an intent-to-treat analysis showed that 78.7% of the women could be fitted with the device and had their faecal incontinence reduced by at least 50% (Level of Evidence 3). Using the device significantly improved QOL associated with FI. Nearly all users (96%) reported the device was comfortable or unnoticeable. Seventy-two percent of the original subjects used the vaginal bowel-control system for an additional two months with continued benefit.

There were 18 device-related adverse events (e.g., vaginal abrasions, erythema, irritation, ecchymosis, bruising) experienced by 23% subjects. Adverse symptoms included discomfort of having the device in the vagina, cramping, pelvic pain, and UI, frequency, and urgency occurred in 3-10% of women, which were all more common during the fitting period. Limitations of the vaginal bowel-control device are inability to be fitted with or to tolerate the adverse symptoms associated with the device.

### 3.2. Cochrane Review of anal plugs

A Cochrane review of the effectiveness of anal plugs in preventing FI published in 2012 (437) reached conclusions similar to those for the last International Consultation (31), namely that evidence suggests that anal plugs could be useful as a treatment or adjuvant treatment of FI in select individuals but that tolerance is difficult.

### 3.3. Anal insert

After the Cochrane review above, there was one study examining the effectiveness and tolerability of an anal insert (Fig N-5) using a non-randomised, single-group, open-label design (438). The anal insert made of soft silicone and has a thin spindle attached to a top and bottom disk. The inner top disk is available in two diameters and is intended to form a seal at the top of the anal canal. The bottom disk remains outside the anus to avoid displacement into the rectum and ease manual removal. It is single-use, inserted with an applicator, and can be also expelled with a bowel movement.

Of the 97 adult subjects enrolled, 73 used the anal insert for 12 weeks and 71 (73%) completed the entire protocol. Subjects reported FI on daily stool diaries for a 4-week baseline period, while using the anal insert 12 weeks, then without the insert for 4 additional weeks. Satisfaction with the insert was reported after 12 weeks of use.

Completers were mostly white females. The median daily frequency of FI decreased among completers from 0.9 (mean 1.1 ± 0.9) episodes/d at baseline to 0.2 (mean 0.3 ± 0.4) episodes/d at 12 weeks (p < 0.001). After the 4 weeks when the insert was no longer used, the median FI frequency increased to 0.5 episodes/d (mean 0.7 ± 0.7) but this frequency was also significantly lower than baseline FI frequency (p < 0.0001). Use of the anal insert resulted in a ≥50% reduction in FI frequency in 77% of the 73 completers.

The analysis of reduction in FI frequency was not intent to treat (ITT) and did not use repeated measures or longitudinal methods.

Safety of the anal insert was analysed using ITT. No serious adverse events and three moderate adverse events (faecal urgency, soreness, and bleeding haemorrhoids) in two subjects were reported. Unpleasant symptoms were a sense of faecal urgency (26% of 91 subjects), irritation (13%), pain (7%), and soreness in the anal area (6%). Displacement of the insert into the anal canal occurred in 24% of subjects which resolved with expulsion of the device during bowel movements.

Regarding satisfaction, 78% of the completers said they were very or extremely satisfied with the anal insert. The weekly mean and median experience scores of completers for overall experience, comfort, and ease of insertion were > 8 on a 10-point scale.
3.4. Comparison of bowel catheter and rectal trumpet

There was one study assessing effectiveness of a bowel catheter, rectal trumpet, or usual care. Usual care included an anal pouch in preventing or healing skin damage associated with FI (439). Critically-ill patients (n=59) who were incontinent of liquid faeces were randomly assigned to one of the treatments. Results showed that the usual care group had significantly lower (better) scores for dermatitis-like skin after treatment compared to baseline, and there were no significant differences in the incidence or healing of pressure ulcers among groups. A validated and reliable instrument for assessing incontinence associated skin damage (IASD), (the IASD instrument (440)) was used.

Although there was no significant difference in IASD scores between groups at baseline, authors seem to suggest that their random assignment was ineffective resulting in more patients with lower IASD scores in the groups receiving a rectal catheter or trumpet and that a few patients in these groups finished earlier than those in the usual care group. Other baseline characteristics among the groups were not further analysed for differences and the investigators did not report whether the location of skin damage was nearby the rectal catheter as others have noted (441), or the rectal trumpet or if the groups used the catheter/tubes developed IASD sooner than the usual care group.

3.5. Complications of rectal catheters

As the rectal catheter is used more in practice, there are additional reports of serious adverse events including gastrointestinal haemorrhage, (442), rectal bleeding (443), recto-urethral fistula, and anal ulcer erosion (444), and pressure ulceration and haemorrhage (445).

No recent studies evaluating anal plugs were found.

4. SUMMARY

The use of anal plugs to prevent faecal incontinence has been evaluated primarily by ambulatory, community-living individuals who need little to no assistance in managing FI and toileting. Both adults and children have used plugs.

An anal plug could be useful as a treatment or adjuvant treatment of FI in select individuals but tolerability is poor. (Level of Evidence 2)

A vaginal bowel-control system reduced FI and improves quality of life. Some users may experience vaginal irritation or abrasions. (Level of evidence 3)

An anal insert reduced frequency of FI and had been used by patients over 12 weeks. Symptoms of urgency, irritation, pain, as well as displacement into the rectum may reduce tolerability. (Level of Evidence 3)

Rectal catheters successfully divert faeces to a collection bag in acutely and critically-ill patients. They are primarily used to promote healing of perineal wounds but seepage around the catheters may result in perianal skin damage. (Level of Evidence 3/4)

As rectal catheters are used more in practice, adverse events such as haemorrhage, rectal bleeding and fistulae continue to be reported (Level of Evidence 3).

An external perianal pouch can collect stool that would leak from the rectum (Level of Evidence 3).

Use of an external perianal pouch and usual care including following recommended skin care guide-lines results in less incontinence associated skin damage than use of a rectal catheter or short rectal tube in critically-ill patients (Level of Evidence 3).

5. RECOMMENDATIONS

Recommendations relating to products for FI prevention and management are listed in Table N-3.

Table N-3: Recommendations relating to products for FI prevention and management.

- A vaginal bowel-control system can be tried to prevent FI. (Grade of Recommendation C).
- Anal plugs may be tried to decrease FI but many patients are likely to use them on a limited basis or reject them due to discomfort (Grade of Recommendation C).
- An anal insert is another option for reducing FI. Its tolerability to adults seems to be better than the anal plug but it is also associated with unpleasant symptoms and displacement into the rectum may occur. (Grade of Recommendation C)
- The use of a rectal trumpet (i.e. a nasopharyngeal tube inserted into the rectum) in patients with loose / liquid stool consistency offers an alternative to the rectal pouch when pouch adherence is a problem and it may preserve perianal skin integrity or facilitate healing (Grade of Recommendation C). The safety of the rectal trumpet has not been determined, but it suggests a lower risk than a standard, longer rectal tube due to its shorter length (Grade of Recommendation C).
- A bowel catheter can be used for diverting faeces in acutely and critically-ill patients unable to control bowel movements and at risk for skin damage or needing to heal wounds. Close monitoring of faecal seepage and integrity of perianal skin is recommended (Grade of Recommendation C).
- Due to potential diminished gastrointestinal perfusion in critically-ill patients and risks of bleeding,
caution in the use of bowel catheters and appropriate balloon inflation are recommended (Grade of Recommendation C).

- A standard rectal tube with and without an inflatable balloon for faecal diversion is indicated primarily for non-ambulatory patients with liquid stools (Grade of Recommendation C).

- An anal pouch attached to a drainage catheter can be used to contain/divert liquid stool. Because there is a risk of skin damage when removing the wafer adhering the pouch to the skin, it is not recommended in cases where skin is already damaged or the need for faecal diversion is less acute (e.g. where stool is more formed) (Grade of Recommendation C).

6. PRIORITIES FOR RESEARCH

- Additional evaluation of the vaginal bowel-control system, anal plugs, and the anal insert, using experimental designs, larger and adequately powered subject cohorts and valid/reliable objective measures over longer periods of use.

- Development of alternative devices to prevent FI, perhaps utilising wireless technology, intra-rectal plugs or pouches that inflate and deflate as needed, which have fewer safety risks, come in a variety of sizes for adults and children, and are comfortable, tolerable, and effective.

- Development and evaluation of an external anal pouch that is easy to apply and remove, better adheres to skin and, perhaps, even promotes healing of damaged skin to which it would be applied.

- More rigorous evaluation of rectal catheters and small tubes using experimental designs, larger and adequately powered subject cohorts, and valid/reliable measures

O. SKIN HEALTH

The skin of individuals suffering from incontinence will be regularly exposed to contact with urine and / or faeces. Associated skin damage is the main physical health consequence of urinary and faecal incontinence. Skin irritation within the pad occlusion area is usually termed diaper dermatitis in infants. In adults, the terminology of perineal dermatitis (PD) has commonly been used, but more recently it has been proposed that incontinence-associated dermatitis (IAD) is a better term because affected skin areas are not confined to the perineum (446). In 2007, an international consensus panel defined IAD as skin inflammation manifested as redness with or without blistering, erosion, or loss of skin barrier function that occurs because of chronically or repeated exposure of the skin to urine or faeces (447). (Fig O-1).

Fig O-1: Incontinence-associated dermatitis category 2 (Source: D. Beeckman, 2016)

Incontinence-associated dermatitis (IAD) is a common problem amongst absorbent product users. Prevalence varies between 5.6% and 50.0% and the incidence between 3.4 and 25.0% (446). Incontinence and subsequent skin breakdown have an influence on patients’ physical, psychological and social well-being. (448) (449). A wide range of products and procedures for the prevention and treatment of IAD in adults is available (450).

1. EVIDENCE

The findings from the 5th International Consultation (31) relating to incontinence and skin health have been included in the summary section, below.

A considerable amount of work has been done since the last consultation, as reported in the following sections.
1.1. Terminology

The terminology used in international literature to describe perineal skin breakdown caused by incontinence, is diverse (451) and the list below gives the main terms that have been used for incontinence-associated dermatitis (IAD) in adults (452):

- Diaper/napkin / nappy dermatitis.
- Diaper / napkin / nappy rash.
- Irritant dermatitis.
- Skin maceration.
- Moisture lesions.
- Incontinence lesions.
- Perineal dermatitis.
- Perineal rash.

In the USA the term incontinence-associated skin damage (IASD) is used instead of IAD as dermatitis is a medical diagnosis and most observations of this type of damage are not confirmed by a physician or nurse practitioner. Therefore, nurses in the USA are not allowed to chart IAD in the health record.

The WHO International Classification of Diseases (ICD-10) contains coding for diaper dermatitis but does not yet contain separate coding for IAD (446). Efforts are ongoing to add incontinence-associated dermatitis as an index term for irritant contact dermatitis due to incontinence (EQ72.83) in the new ICD-11 coding (available in 2017). Irritant contact dermatitis due to incontinence will be defined as irritant contact dermatitis from prolonged contact with urine or faeces as a result of incontinence. Also, a proposal has been made to change the index term "EP70.21 Primary irritant napkin dermatitis" to: "A type of irritant dermatitis from prolonged contact with urine or faeces due to incontinence."

1.2. Background

a) Pathophysiology

Recent studies and consensus documents present more insights into the pathophysiology of IAD. Previously IAD was considered to be a result of a disrupted skin barrier function and an increase in skin pH due to prolonged or repeated contact with urine and/or faeces (447). Comprehensive reviews of IAD literature until 2015 suggest a more complex aetiology of IAD (446) (451) (452) (456) (457). IAD develops as a consequence of recurrent chemical and physical irritation of the skin, which compromise the skin barrier function and increase the skin permeability. As a result, irritants and micro-organisms (e.g. Candida albicans) may more easily penetrate the skin to exacerbate inflammation and increase the risk of skin infection (446) (451) (452) (456) (457) (458).

Factors contributing to skin irritation and inflammation are: skin surface wetness, increased skin surface pH, digestive intestinal enzymes (lipases and proteases), enzymes produced by skin bacteria (urease, an enzyme that catalyses the hydrolysis of urea into carbon dioxide and ammonia), repeated skin cleansing activities, an occlusive perineal environment (e.g. due to diapers) and friction (452) (455) (459) (460). These factors act on various components of the outermost layer of the skin, the stratum corneum, which is responsible for the biomechanical barrier function of the skin (451) (457). The stratum corneum consists of corneocytes, embedded in lipids and joined together by proteins (like a structure of bricks and mortar in a wall) (461) (462).

With incontinence, overhydration of the stratum corneum occurs as water from urine and faeces is pulled into the corneocytes. Overhydration causes swelling of the corneocytes and disruption of the intercellular lipid bilayers. Lipases and proteases, present in faeces, break down the intercellular lipids and proteins (452) (457). As liquid faeces tends to contain more digestive enzymes, it is more damaging to the skin barrier (446). Urease, produced by skin bacteria, transforms urea (from urine) into ammonia, causing an increase in skin surface pH (452) (457). An increased skin surface pH leads to a decreased cohesion of the stratum corneum and a decreased recovery capacity of the skin barrier function (467). Repeated use of water, skin cleansing agents and rubbing with washcloths and towels leads to chemical as well as physical irritation. Friction and shear loads, mainly present in patients with limited ability to move in bed and chairs, diminish the strength of the skin barrier (468). Fig N-2 shows the progression and interrelated aspects from skin wetness to IAD.
b) Risk factors

Knowledge and awareness of risk factors is helpful to tailor IAD prevention and management to patients at risk. IAD prevalence studies highlight the risk factors listed in Table O-1.

This list of risk factors is not exhaustive as many other possible risk factors were not studied (in a large scale risk cohort study). A multivariate analysis of possible risk factors, performed by Kottner et al., could only explain 8% of variance in IAD prevalence (468).

Although an IAD risk assessment tool has been developed (469) and was used in one study (470), its usefulness in clinical practice has not been established. In clinical practice quantifying IAD risk with assessment tools, comparable to pressure ulcer risk assessment tools, is not advised as the predictive value of risk assessment scales varies per setting (as it is dependent on risk factors present and preventive measures taken) (471).

Table O-1: Risk factors for IAD.

- Incontinence: liquid stool is most irritating, followed by double incontinence, faecal incontinence and urinary incontinence (446) (468) (503) (504).
- Alkaline pH of urine, faeces and skin (493).
- Health status (critical illness, multi-morbidity) (502) (505).
- Fever (505).
- Diminished perfusion and oxygenation (505).
- Poor skin condition (e.g. steroid use/diabetes) (468) (502).
- Restricted mobility (468) (502) (506).
- Restricted activity (468) (502).
- Higher score on care dependency (468).
- Poor nutritional status (468) (502).
- Friction and shear (468) (505).
- Restricted cognitive awareness (502) (505).
c) Incontinence and pressure ulcers

A systematic review and meta-analysis identified incontinence and IAD as risk factors for pressure ulcer (also referred to as pressure injury) development (472). A possible explanation for this finding is that prolonged exposure to moisture and irritants contributes to an increase of the coefficient of friction and to changes in tissue stiffness. In addition, inflammation is associated with a local increase in skin temperature. As a consequence, the cutaneous resistance against tissue deformation is further diminished (473).

1.3. Clinical studies on the effectiveness of absorbent, diversion and containment products for preventing and treating incontinence-associated dermatitis in adults

Since the last consultation (31), three randomised controlled trials in adult patients were found. These trials investigated the effectiveness of an improved absorbent pad (474), indwelling faecal diversion systems (439) or faecal containment products (475).

In a cluster randomised controlled trial, Sugama et al. (474) tested the effectiveness of an improved absorbent pad with frontal absorbent material for the treatment of IAD in elderly women with urinary incontinence. The pad was designed to absorb urine in the frontal area to minimise exposure of the buttocks to urine, while preventing the absorbed urine from flowing back to the pad surface. Thirty women wore the improved absorbent pad during the day and the standard hospital pad at night (intervention group). Thirty women wore the standard hospital pad during day and night (control group). Within one week of follow-up, significantly more women from the intervention group (13/30, 43.3%) completely recovered from IAD, compared to the control group (4/30, 13.3%) (p=0.01). On the other hand, a similar proportion of women from the intervention group (13/30, 43.3%) and the control group (15/30, 50.0%) showed no change or even a deterioration of IAD. No significant differences in skin wetness (p=0.823) or skin pH (p=0.761) were found between groups. The fact that the improved absorbent pad was not worn at night could have influenced the results on skin wetness and skin pH (474). According to Kottner and Beeckman (457), skin barrier parameters, like skin wetness and skin pH are not necessarily directly related to clinical outcomes. (Level of Evidence 2)

Pittmann et al. (439) compared the effectiveness of three bowel management methods for prevention and treatment of IAD. A sample of 59 critically ill adults with faecal incontinence were randomly assigned to receiving a rectal catheter, a rectal trumpet or usual care. Care as usual consisted of: cleansing with premoistened wipes containing dimethicone or cleansing followed by application of a zinc oxide based ointment and/or application of an anal pouch. The use of rectal catheters, rectal trumpets and anal pouches is described in Section N. A significant reduction in IAD severity over time was only identified for usual care (p < 0.001). No adverse events occurred using the three bowel management methods. (Level of Evidence 2)

Denat et al. (475) studied the effectiveness of two external devices, used to contain faecal incontinence, for the prevention of IAD. Thirty bedridden patients from neurology and neurosurgery wards were randomly assigned to treatment with anal pouches (see Section N) or diapers. All patients had an indwelling urinary catheter. The perianal region was cleansed once daily and additionally if soiled. Significantly more patients using diapers (15/15, 100%) developed IAD, compared to patients using anal pouches (10/15 (66.7%) (p<0.04). In addition, the mean onset of IAD was significantly earlier in patients using diapers than in patients using anal pouches (p=0.011) (Level of Evidence 2).

All of these trials were of low to - at most - moderate quality due to small sample sizes with a lack of power (439) (474) (475) short follow-up periods (439) (474) (475) poor or unclear randomisation techniques (474) (475), unblinded outcome assessments (439) (475) and shortcomings in the reporting of statistics (e.g. no frequencies, standard deviations) (439).

1.4. Clinical studies on the effectiveness and cost-effectiveness of topical skin-care products and procedures for preventing and treating incontinence-associated dermatitis in adults

Since the last consultation (31), three new randomised controlled trials were found (476) (477) (478). These trials were identified as part of a Cochrane systematic review investigating the effectiveness of topical skin care products for preventing and treating incontinence-associated dermatitis (IAD) in adults (455).

Two trials tested the effectiveness of topical skin care products in adults (476) (477) and one the different frequencies of a structured skin care procedure (478). One study additionally investigated the cost of daily use of product (476).

a) Studies on the effectiveness of topical skin care products

Brunner et al. (476) compared the use of a cleansing/moisturising product followed by the application of a film forming skin product with the use of a disposable washcloth with cleansing, moisturising and skin protecting properties for the prevention of IAD. Sixty-four critical and acute care patients were randomised to receive one of the two skin care regimens. The number of participants who developed IAD did not differ significantly between the two trial groups: 7/31 participants (22.6%) in the two product group and 9/33 (27.3%) participants in the washcloth group developed IAD (Level of Evidence 2).
Buckley et al. (477) compared the effectiveness of two topical zinc-oxide based products in a structured skin care regime for the treatment of IAD: 142 hospitalised adults and older children were randomly assigned to receive either a 20% zinc oxide based ointment or a 40% zinc oxide based paste. Both skin care products were applied twice daily and after each incontinence episode. At each pad change, the IAD lesion was cleaned with normal saline, a polyhexanide wound cleaner, gaze pads and soft cloths. Significantly more participants from the group treated with the 20% zinc oxide based ointment were completely healed at day six (14/56, 25%) compared to the group treated with 40% zinc oxide based paste (5/65, 7.7%) (p = 0.009). Of note is that both products also differed in other active ingredients, such as menthol (20% zinc oxide product) or lanolin, petrolatum and cod liver oil (40% zinc oxide product). As a consequence, it is not clear which amount of zinc oxide is optimal or which ingredients are pivotal for the treatment of IAD. (Level of Evidence 2)

In a sample of 99 patients from a progressive care unit, Conley et al. (478) compared two frequencies of a structured skin care procedure for the prevention and treatment of IAD. The skin care procedure consisted of gently cleansing the skin with a skin cleanser, containing Aloe Vera mixed with water and a cleansing lotion, followed by patting the skin dry. If no erythema was observed, a product with silicone was applied. If erythema was present, a product with zinc oxide and menthol was applied. The skin care procedure was performed every six hours or every 12 hours. There were no significant group differences; 56.4% of the group receiving the skin care procedure every six hours and 60.0% of those receiving the skin care procedure every 12 hours had IAD during the study. (Level of Evidence 2)

b) Studies on the cost of daily use of product

Only one study evaluated cost of products. Brunner et al. (476), described in the paragraph above, noted the cost of daily use of product was significantly higher for the combined use of the skin cleanser and the film forming skin product ($6.59), compared to the use of the washcloth with cleansing, moisturising and skin protecting properties ($2.67) (p = 0.006) (Level of Evidence 2).

All of the above trials were of low to - at most - moderate quality due to small sample sizes (476) (477) (478), short follow-up periods (476) (477) (478), poor (478) or unclear (476) randomisation techniques, unblinded outcome assessments (476) (477) (478) and shortcomings in the reporting of statistics (e.g. no frequencies, standard deviations) (476) (478).

According to the authors of the Cochrane systematic review, very limited evidence exists on the effectiveness of skin care products for the prevention and treatment of IAD in adults (455). Soap and water performed poorly and the application of leave-on products (moisturisers, skin protectants or a combination) seems to be more effective than withholding these products. High quality confirmatory trials using standardised and comparable prevention and/or treatment regimens in different settings/regions are required. Furthermore, the authors recommend the development of a core outcome-set, including validated measurement tools to increase the comparability of trial results (455). In accordance with this recommendation, the IAD International Research Group has recently initiated to development of a core outcome set of well-defined IAD-related outcomes, which will include validated tools for outcome measurement (479).

1.5. IAD assessment and severity categorisation

The basic principles for skin assessment in patients with incontinence are presented in Table O-2.

<table>
<thead>
<tr>
<th>Who</th>
<th>Everyone with urinary and/or faecal incontinence (452).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frequency</td>
<td>At least once daily, more frequently in individuals at high risk of IAD (e.g. frequent episodes of incontinence, diarrhoea, multiple risk factors, see Section O-2b) (452).</td>
</tr>
<tr>
<td>Areas</td>
<td>Skin areas being exposed to urine and/or faeces: perineum, perigenital areas, buttocks, gluteal folds, thighs, lower back, lower abdomen, skin folds (groins, under large abdominal pannus, …) (452) (454).</td>
</tr>
<tr>
<td>Clinical signs of IAD</td>
<td>Maceration, erythema, presence of lesions (vesicles, bullae, papules, pustules, …), erosion or denudation, signs of fungal or bacterial skin infection (452).</td>
</tr>
</tbody>
</table>

Various tools have been developed for IAD severity assessment:

- Perineal Dermatitis Grading Scale (24) (480).
- IAD Assessment and Intervention Tool (IADIT) (481).
- Incontinence Associated Skin Damage and its Severity Instrument (IASD.D.2) (482) (440)
- Skin Assessment Tool (483).
- University College London / SCA Hygiene tool (484).

In 2015 Clark-O’Neill et al. (485) concluded that the existing instruments are too time-consuming and linguistically complex for use in routine clinical practice in nursing homes. The authors suggested to use a
simple classification tool, supported by photographs illustrating the severity categories (485).

The Incontinence Associated Skin Damage and its Severity Instrument (IASD.D.2) summarises IAD severity into a single score (range 0-56) using three categories of skin damage and the 14 body areas in which IASD can occur (440) (482). The instrument also shows images of the variation in colour manifestations of the different types of IASD severity to guide its use. However, it is not feasible to show all the different possible manifestations of IAD. The IASD.D.2 tool has been validated for reliability with light and dark skin (482). The tool is available on the University of Minnesota School of Nursing website (http://license.umn.edu/technologies/20150057_incontinence-associated-dermatitis-assessment-tool).

Beeckman et al. (486) have proposed an IAD severity categorisation tool (the Ghent Global IAD Categorization Tool (GLOBIAD)), consisting of four categories (Cat. 1A: persistent erythema without clinical signs of infection, Cat. 1B: persistent erythema with clinical signs of infection, Cat 2A: skin loss without clinical signs of infection, Cat. 2B: skin loss with clinical signs of infection), and supported by some example photographs (Fig O-3). It is comparable to the pressure ulcer classification system developed by the National and the European Pressure Ulcer Advisory Panels (NPUAP and EPUAP) (487) (482). Validation studies (451) have recently been completed, but are not yet published.
### Category 1: Persistent redness

#### 1A - Persistent redness without clinical signs of infection

**Critical criteria**
- Persistent redness
- A variety of tones of redness may be present.
- Patients with darker skin tones, the skin may be paler or darker than normal, or purple in colour.

**Additional criteria**
- Marked areas of discoloration from a previous (healed) skin defect
- Macrotelial skin
- Intact vesicles and bullae
- Skin may feel tense or swollen at palpation
- Burning, tingling, itching or pain may be present

#### 1B - Persistent redness with clinical signs of infection

**Critical criteria**
- Persistent redness
- A variety of tones of redness may be present.
- Patients with darker skin tones, the skin may be paler or darker than normal, or purple in colour.
- Signs of infection
- Such as vesicles or maculae or papules or nodules or pustules or bullae or other lesions
- White scaling or the surrounding skin or in the wound bed

**Additional criteria**
- Marked areas of discoloration from a previous (healed) skin defect
- Macrotelial skin
- Intact vesicles and bullae
- The skin may feel tense or swollen at palpation
- Burning, tingling, itching or pain may be present

### Category 2: Skin loss

#### 2A - Skin loss without clinical signs of infection

**Critical criteria**
- Skin loss
- Skin loss may present as skin erosions, denudation, excoriation, ulceration, open vesicles, or open bullae.
- The skin damage pattern may be diffuse.

**Additional criteria**
- Persistent redness
- A variety of tones of redness may be present.
- Patients with darker skin tones, the skin may be paler or darker than normal, or purple in colour.
- Macrotelial skin
- Intact vesicles and bullae
- Skin may feel tense or swollen at palpation
- Burning, tingling, itching or pain may be present

#### 2B - Skin loss with clinical signs of infection

**Critical criteria**
- Skin loss
- Skin loss may present as skin erosions, denudation, excoriation, ulceration, open vesicles, or open bullae.
- The skin damage pattern may be diffuse.
- Signs of infection
- Such as vesicles or maculae or papules or nodules or pustules or bullae or other lesions
- White scaling or the surrounding skin or in the wound bed

**Additional criteria**
- Marked areas of discoloration from a previous (healed) skin defect
- Macrotelial skin
- Intact vesicles and bullae
- The skin may feel tense or swollen at palpation
- Burning, tingling, itching or pain may be present

---

*Fig O-3: IAD Severity Categorisation Tool (452)*
The purposes of IAD assessment tools (440) (482) and the IAD Severity Categorisation Tool are (452):

- To promote the identification of IAD and enhance its correct identification and classification.
- To standardise record keeping.
- To provide a common description of IAD severity for the purpose of clinical practice, audit and research.

Given the difficulties in using pressure ulcer classification/staging tools (487) (488), however, the usefulness of IAD classification and such tools will need to be evaluated.

1.6. Differentiating IAD from pressure ulcers

Correct identification of IAD and pressure ulcers has significant implications for prevention, treatment and for reporting and benchmarking quality of care (451). Figure O-4 shows a pressure ulcer versus IAD. Table O-3 presents differences between pressure ulcers and IAD based on the 2005 European Pressure Ulcer Advisory Panel (EPUAP) position statement (488).

An e-learning training tool (PUCLAS3), aimed at supporting clinical teaching and learning about pressure ulcer classification and incontinence-associated dermatitis differentiation, has been developed and is available online (http://pucas3.ucvvgent.be/) (489). The scientific content is based on the EPUAP position statement and provides an overview of causative factors and typical wound-related characteristics (489). Additionally, an interactive web-based ‘serious game’ about IAD assessment and risk factors using currently available knowledge has been developed an educational aide. The educational game uses older adults in nursing homes as its exemplar and features the IASD.D.2 instrument; it is available online (vitalsims.com/iasd-access).

1.7. Products used to maintain or improve skin health in adults with incontinence

Skin care for incontinent patients includes following strategies (451) (452):

- Management of incontinence: to avoid or minimise contact from the skin with urine and/or faeces.
  - A structured skin care regimen, consisting of three strategies (Table O-4):
    - Skin cleansing: to remove irritants (urine, faeces, debris and microorganisms).
    - Skin moisturising: to repair or increase the integrity of the skin barrier.
    - Skin protecting: to avoid or minimise contact from the skin with urine and/or faeces.
    - Interventions for the prevention and treatment of IAD are similar. No specific products have yet been developed to promote skin barrier recovery after maceration (457).
Table O-4: Characteristics of products used for skin cleansing and for skin protection, and principle ingredients of products used for skin moisturising.

### Characteristics of products used for skin cleansing.

<table>
<thead>
<tr>
<th>Product</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water</td>
<td>• Contributes to overhydration of the stratum corneum (462).</td>
</tr>
<tr>
<td></td>
<td>• Performs poorly in the prevention and treatment of IAD (459).</td>
</tr>
<tr>
<td></td>
<td>• Plain water raises skin pH (496).</td>
</tr>
<tr>
<td>Soap</td>
<td>• Standard alkaline soap compromises skin surface pH (452).</td>
</tr>
<tr>
<td></td>
<td>• Performs poorly in the prevention and treatment of IAD (459).</td>
</tr>
<tr>
<td>Washcloths / towels</td>
<td>• May cause friction damage due to rubbing or scrubbing, especially when using rough washcloths or towels (492).</td>
</tr>
<tr>
<td>Skin cleanser</td>
<td>• Available as liquid solutions or lotions, in spray bottles, disposable washcloths or foam (599).</td>
</tr>
<tr>
<td></td>
<td>• Most should not be diluted (599).</td>
</tr>
<tr>
<td></td>
<td>• Most are ‘no-rinse’ and quick drying, eliminating friction caused by using towels (452).</td>
</tr>
<tr>
<td></td>
<td>• Avoids over-hydration caused by using water.</td>
</tr>
</tbody>
</table>

### Characteristics of products used for skin protection (452) (Skin protecting products often contain a mix of various skin protecting ingredients)

<table>
<thead>
<tr>
<th>Product</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Petrolatum-based</td>
<td>• Form an occlusive layer, increasing skin hydration.</td>

<td>• Transparent when applied thinly.</td>
</tr>
<tr>
<td>Zinc oxide-based</td>
<td>• Can be difficult and uncomfortable to remove (e.g. thick, viscous pastes).</td>
</tr>
<tr>
<td></td>
<td>• Opaque, needs to be removed for skin inspection.</td>
</tr>
<tr>
<td>Dimethicone-based</td>
<td>• Non-occlusive.</td>
</tr>
<tr>
<td></td>
<td>• Do not affect absorbency of incontinent products when used sparingly.</td>
</tr>
<tr>
<td></td>
<td>• Opaque or become transparent after application.</td>
</tr>
<tr>
<td>Acrylate terpolymers</td>
<td>• Form a transparent film on the skin allowing skin inspection.</td>
</tr>
<tr>
<td></td>
<td>• Do not require removal.</td>
</tr>
</tbody>
</table>

### Principle ingredients of products used for skin moisturising (452) (Moisturisers often contain a mix of emollients and humectants)

<table>
<thead>
<tr>
<th>Ingredient Type</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emollients (e.g. fat, waxes, oils)</td>
<td>• Reduce dryness, soften and smooth the skin</td>
</tr>
<tr>
<td></td>
<td>• Restore the intercellular lipid matrix</td>
</tr>
<tr>
<td>Humectants (e.g. glycerine, urea)</td>
<td>• Attract and retain water to promote skin hydration</td>
</tr>
</tbody>
</table>
a) Categorisation of products for the management of incontinence

Management of incontinence is the primary intervention in the prevention and treatment of IAD. Products for the management of incontinence can be divided into absorbent products and products for containment or diversion of urine or faeces and are discussed in Section N.

b) Categorisation of skin care products

Categorisation according to principle ingredient

Skin care products can theoretically be divided into three categories, based on the principle ingredient:

- Products for skin cleansing.
- Products for skin moisturising.
- Products for skin protection.

Table O-4 presents characteristics and recommendations for these three categories.

Categorisation according to product functioning

Skin care products usually contain a wide range of ingredients with different properties. The actual performance of products depends on the overall formulation, rather than on the principle ingredient (451). As a consequence, the function of a skin care product cannot always be clearly divided into moisturising or protecting.

Kottner et al. (457) proposed to categorise skin care products into:

- Skin cleansers: products used for removing irritants (urine, faeces, debris and microorganisms).
- Leave-on products: products with moisturising and/or skin protecting function.

c) Combination products

Skin care products may be combined into one product. For example: skin cleansers or skin protectants may also contain moisturising ingredients and disposable wipes may contain cleansing, moisturising as well as skin protecting ingredients (452).

Combination products may reduce clinician/caregiver time by reducing the number of steps. In addition these products may promote adherence to the skin care regimen (490) (491) (492).

Since the last consultation (31), one new randomised controlled trial investigating combination products was found (476). In this study, Brunner et al. (476) compared the use of a cleansing/moisturising product followed by the application of a film-forming skin product with the use of a disposable washcloth with cleansing, moisturising and skin protecting properties (493) (494). Development of absorbent products whose surface maintains an acidic pH (493) (495) and which acidify skin - even after absorbing alkaline fluid such as urine or faeces - aim to reduce IAD. Skin pH may need to be <6 to achieve benefit (495) but further clinical studies are needed.

d) Products used for managing skin infection

Candida albicans is most commonly responsible for secondary skin infections in patients with IAD. However, microbiological samples are recommended to ensure organism specific treatment (452).

Current recommendations are:

- Use antifungal creams or powders in combination with a skin protectant (e.g. acrylate terpolymer) (470).
- Do not use topical antimicrobial products as a routine (may promote antimicrobial resistance) (452).

e) Absorbent products and skin pH

Alkaline skin pH is a risk factor for IAD and standard absorbent products increase skin pH (493) (494). Development of absorbent products whose surface maintains an acidic pH (493) (495) and which acidify skin - even after absorbing alkaline fluid such as urine or faeces - aim to reduce IAD. Skin pH may need to be <6 to achieve benefit (495) but further clinical studies are needed.

2. SUMMARY

- A product that maintains a wet and occluded skin is likely to cause skin irritation and increases skin permeability to other irritants (e.g. from urine and faeces) (496) (497) (Level of Evidence 2).
- Moisture overhydrates skin and potentiates the effects of other irritants (498) (499) (500) (Level of Evidence 2).
- A wet skin is more susceptible to friction and abrasion injury (501) (Level of Evidence 2).
- Incontinence, diarrhoea, critical illness, hyperthermia, decreased activity and mobility, poor nutritional status, alkaline skin pH, poor skin condition, risk of friction and shear and restricted cognitive awareness are associated with a higher prevalence of incontinence-associated dermatitis (IAD) (446) (468) (495) (502) (503) (504) (505) (506) (507) (508) (509) (510) (511) (Level of Evidence 2).
- Faeces are more irritating than urine, but the combination of urine and faeces causes higher levels of irritation than urine and faeces alone (468) (512) (513) (514) (Level of Evidence 2).
- Faecal incontinence is a major risk factor for IAD development (507) (Level of Evidence 2).
- Incontinence and IAD are risk factors for pressure ulcer development (472) (510) (515) (516) (517) (Level of Evidence 2).

product ($6.59), compared to the use of the washcloth with cleansing, moisturising and skin protecting properties ($2.67) (p = 0.006) (Level of Evidence 2).
• Absorbent pads containing super absorbent polymers are associated with reduced skin moisture (24) (518) (519) (520) (Level of Evidence 2).

• Absorbent pads, which absorb urine in the frontal area and minimise exposure of the buttocks to urine, can promote IAD recovery (474) (Level of Evidence 2).

• Bodyworn absorbent products may raise interface pressure in the buttock region (521) (Level of Evidence 3).

• The use of anal pouches can reduce IAD incidence in bedridden patients with faecal incontinence and is associated with a later onset of IAD (475) (Level of Evidence 2).

• The use of topical preparations such as moisturisers or barrier products is associated with a lower incidence of IAD (455) (492) (522) (Level of Evidence 2).

• Alkaline skin pH negatively affects the skin barrier. Therefore, soap-based products with an alkaline pH – or absorbent pads that increase skin pH - negatively affect the skin barrier function and promote skin irritation (446) (486) (508) (509) (523) (Level of Evidence 3).

• Skin cleansers may be more cost-effective than soap and water (476) (490) (491) (511) (Level of Evidence 3) and may be better for skin health (522) (Level of Evidence 2).

• Barrier skin products may impede water penetration into the stratum corneum (524) (Level of Evidence 3).

• The use of a combination product for skin care can reduce the daily cost of product use (476) (Level of Evidence 2).

• Avoid the use of topical antimicrobial products as a routine (may promote antimicrobial resistance) (486) (Level of Evidence 4).

3. RECOMMENDATIONS

Recommendations relating to incontinence and skin health in adults are listed in Table O-5.

Table O-5: Recommendations relating to incontinence and skin health. (Source: D. Beeckman, 2016)

- Absorbent pads with super-absorbent polymers (SAP) are preferred to those without (24) (518) (519) (520) (Grade of Recommendation B).

- Absorbent pads should be changed when wet to minimise skin wetness and subsequently skin maceration and increase of the friction coefficient at the skin (451) (452) (457) (473) (Grade of Recommendation B).

- Absorbent pads or diapers - especially for users with faecal or double incontinence - should be changed as soon as possible after an episode of incontinence to prevent the development of dermatitis from proteolytic and lipolytic enzymatic activity (451) (452) (457) (Grade of Recommendation B).

- Skin should be cleansed daily and after each episode of faecal incontinence (451) (452) (457) (Grade of Recommendation C).

- A pH neutral skin cleanser is recommended (slightly acidic, similar to normal skin pH) skin care products, no-rinse cleansers or a premoistened wipe (446) (452) (508) (509) (523) (Grade of Recommendation B).

- Water and soap washing should be avoided. If the use of water could not be avoided, use only the amount of water needed. If soap is needed, choose a soap with a neutral pH (slightly acidic, similar to normal skin pH) (446) (452) (508) (509) (523) (Grade of Recommendation B).

- Skin cleansers with non-ionic surfactants (polyethylene glycol (PEG), acyl-polyglycoside (APG), polysorbats, octoxynols) should be chosen. Avoid skin cleansers with anionic surfactants (sodium laurylsulfate (SLS), sodium laureth sulfate, sodium sulphasuccinate, sodium stearate) (452) (Grade of Recommendation C).

- A gentle technique for washing and drying, with minimal or no friction and no rubbing/scrubbing should be used. Soft washcloths and towels or a disposable nonwoven cloth should be chosen (452) (Grade of Recommendation C).

- A balance should be found between removing irritants by cleansing and preventing irritation due to cleansing (452) (457) (Grade of Recommendation C).

- Application of leave-on skin products (such as moisturisers, skin protectants or a combination) seems to be more effective than withholding these products (455) (Grade of Recommendation B).

- Humectants (e.g. glycerine) should not be used if skin is overhydrated or macerated (452) (Grade of Recommendation C).

- Skin barrier products should be applied regularly, in appropriate quantity, to areas that potentially come in contact with urine and/or faeces (452) (457) (Grade of Recommendation C).

- General notes to the recommendations:

  - Based on the available evidence, it is not possible to recommend any specific skin cleanser, skin...
moisturiser or skin protectant over another (455) (459) (600) (601).

- The performance of each product depends on the overall formulation, rather than on the principle ingredient (452) (457).
- All products should be used according to the manufacturer’s instructions (452).
- Always check that the product does not contain any ingredient to which the patient is sensitive or allergic (e.g. preservatives, fragrances, perfumes) (452) (602).

4. PRIORITIES FOR RESEARCH

- Adequately powered controlled randomised trials that investigate the effectiveness of skin care products, skin care regimes and absorbent products to prevent or treat incontinence-associated dermatitis (IAD) are recommended.

- Controlled randomised trials should determine appropriate sample sizes using power analyses. Analyses need to be powered to distinguish effects on participants with faecal or double incontinence. Objective measures from instruments, standardised clinical assessments, and patient symptom ratings should be included.

- Laboratory-based studies on healthy volunteers are recommended to help select products and establish potential efficacy of products before undertaking RCTs in clinical settings.

- Further work is needed to examine the relationship between IAD and pressure ulcers, in particular the potential for their formation and/or methods to discriminate between them, including use of biomarkers and technology.

- Histopathological studies are needed to delineate more clearly the pathophysiological differences between the lesions diagnosed as IAD and those diagnosed as pressure ulcers, from a clinical pathological point of view.

- To enhance correct product selection and comparability in practice and research, the use of a standardised language and terminology in the description of skin care products is recommended. Particular attention should be paid to the description of the function of skin care products (e.g. moisturising and/or skin protecting) as well as the appropriateness of skin care products in patients with incontinence.

- There is a need for uniform, relevant and participant-important outcomes. The development of a core set of outcomes may improve the comparability across studies. Recently the IAD International Research Group has launched a project which aims to develop a core outcome set of well-defined IAD-related outcomes for clinical IAD research. This outcome set will also include validated tools for outcome measurement (479).

- Studies that investigate the effect of lowering skin pH via a variety of strategies (e.g., cleansers, protectants, absorbent products) in preventing and treating IAD are needed.

P. ODOUR CONTROL PRODUCTS

Fear of odour from leaked urine, stool or flatus is a major concern that preoccupies many people suffering from incontinence and is an issue raised in several studies that have explored patients’ experiences and opinions (4) (21) (525) (527) (528) (529) (530) (531) (532) (534) (535) (536) (537) (538). Chapter 16 (Section M) reviews the impact of FI and odour on quality of life. Recent studies (532) (533) (534) continue to show that individuals with UI or FI worry about odour emanating from leaked urine or faeces, as well as from flatus, and the stigma associated with “smelling bad” (533). The fear of odour plays a role in people’s affective and behavioural responses to incontinence. Concern about odour can interfere with social relationships, cause people to isolate themselves within the confines of their home or serve as a trigger to seek clinical care (527) (528) (529).

Understandably, some patients with incontinence place a high value on products that mask, control, reduce, or eliminate odour (538). According to one evaluation of different types of continence products for women with light incontinence ‘the ability of absorbent products to contain smell’ is the second most important factor when choosing a product, after the ‘ability to hold urine’ (21).

Additionally, caregivers are bothered by odour. Nurses caring for patients with diarrhoea during tube feeding rated odour as one of the most unpleasant aspect of caregiving (539). The odour associated with urine leakage is mainly due to the production of ammonia from urea by bacterial ureases, whereas factors that contribute to the odour of faeces and flatus include differing states of health and gastrointestinal function, diet composition, relative concentrations of volatile sulphur and hydrogen-containing gases and, possibly, short chain fatty acids or ammonia (540) (541) (542). Accordingly, there is a demand for products which will mask odour or, preferably, prevent it.
The evidence on products for incontinence odour reported in the 5th consultation (31) is summarised in Table P-1.

Table P-1: The main findings from the 5th International Consultation (31) relating to incontinence and odour.

- Fabrics that have been treated with anti-microbial agents - washable bedpads, carpets, chairs, clothing and bed linen - may be of benefit in reducing the odour associated with urine (Level of Evidence 4).
- Anti-microbial solutions to prevent odour of urine by destroying the bacteria responsible for the breakdown of urea may be used to wash products such as hand-held urinals or for treating urine spillage onto soft furnishings such as carpets (Level of Evidence 4).
- Applying scent to disposable bodyworn pads does little to reduce the odour associated with urine. (Level of Evidence 3).
- Products that are the most effective in reducing the odour associated with flatus are briefs made of activated charcoal fabric (95-99% absorbency), followed by charcoal activated pads worn inside underwear (55-77% absorbency), usual clothing (22%), and charcoal infused cushions (20% absorbency) (542). (Level of Evidence 3).
- Probiotic Lactobacillus plantarum was effective in reducing flatus by 50% in patients with IBS (543). (Level of Evidence 1).
- Over-the-counter α-galactosidase containing products, may reduce the production of malodorous gas among individuals experiencing stool leakage due to flatus (544) (545). (Level of Evidence 1).
- Ingesting activated charcoal may have little benefit in reduction of flatulence (541) (546). (Level of Evidence 1).

ICI reported that several companies supplied continence products that aimed to reduce the odour associated with UI by treating the fabric in washable bedpads, carpets, chairs, clothing or bed linen with an antimicrobial agent. However, it noted there were no robust published studies that had sought to evaluate products to reduce the odour of urine (Level of Evidence 4). In addition, the consultation cited one multicentre evaluation of different disposable pads for women with light UI (20), which reported applying scent to disposable bodyworn pads did not perform significantly better than other products in terms of odour (Level of Evidence 3).

Odour control products for FI as described in the report of the last consultation (31) are categorised as either oral ingestible products that aim to reduce the production of malodorous gas, or devices that aim to absorb the odour of gas.

The consultation described one trial that evaluated the extent to which the odour associated with flatus was reduced by the use of different types of continence products that were activated with charcoal (542). The devices included four different types of charcoal-activated pads worn inside conventional underwear; two types of charcoal-activated wearable briefs; and five types of charcoal-activated cushions upon which to sit. Six healthy adults tested each product. The products that were reported as being the most effective were the briefs (95-99% absorbency), followed by the pads (55-77%), usual clothing (22%), and cushions (20%) (Level of Evidence 3). The briefs appear to provide the greatest surface area for contact with malodorous rectal gas (Level of Evidence 3). The limited absorption of malodorous gas by clothing suggests that washing outer clothing as well as underwear is important to reduce odour (Level of Evidence 3).

Oral ingestible products that aim to reduce the production of malodorous gas include probiotics, the enzyme α-galactosidase, and oral charcoal mixtures.

a) Probiotics
In a randomised controlled trial (n=60 patients with irritable bowel disease), administration of Lactobacillus plantarum (5 x 107 cfu/ml) was associated with a significant reduction in pain and flatulence (543) (Level of Evidence 1).

b) Enzymes (α-galactosidase)
In a randomised crossover trial (n=19 healthy adults), treatment with 240 GaIU alpha-galactosidase was associated with less frequent flatulence events five hours after the test meal, but there was no different in bloating or pain (544) (Level of Evidence 1).

In a randomised controlled trial, administration of 1200 GaIU of α-galactosidase following a test meal of beans was associated with a significant reduction in the production of intestinal gas and the severity of flatulence in 8 healthy adults, but not 300 GaIU (545) (Level of Evidence 1).

c) Oral charcoal mixtures
Hall et al. (546) described a study in which 13 healthy adults were randomly administered in a double blind manner to three capsules of either 194mg of activated charcoal or placebo capsules immediately after a ‘bean meal’ and at 30 minute intervals for two hours after the meal. The researchers reported a significant reduction in the mean number of flatus events for
hills, and zinc by 71, 38, and 58% respectively, and by 86% by the combination of all three agents (547) (Level of Evidence 4).

In addition, the last consultation reported an in vitro study in which the flatus of 15 healthy adults who had been given 15g lactulose and had eaten a meal supplemented with beans, was treated with activated charcoal and then with zinc acetate (541). The researchers reported that treating the collected flatus with zinc acetate reduced sulphur gas content, but did not totally eliminate odour, while activated charcoal removed virtually all odour (Level of Evidence 4).

In summary, the last consultation noted that ingestion of the probiotic Lactobacillus plantarum was effective in reducing flatus by 50% in patients with irritable bowel disease (Level of Evidence 1). Over-the-counter α-galactosidase containing products, may reduce the amount of intestinal gas produced, which may in turn reduce the volume of odour, however it may not decrease its potency or perceived odour (Level of Evidence 1).

2. NEW EVIDENCE FOR THE CURRENT CONSULTATION

No new studies were found for the current consultation about products that aim to prevent, absorb, or control odour associated with UI, FI, or flatus. However, five publications on products for UI odour (60) (548) (549) (550) (551) and one about products for FI odour (552) not included in the previous review were added to the current review.

2.1. Products for urinary incontinence

The five products for UI that were studied included two about fabrics/materials treated with an antimicrobial agent (548) (549), two about penile sheaths (60) (550), and one concerning a reusable undergarment (551). Each is described in further detail below.

2.2. Fabric treated with an antimicrobial agent

Fukui et al (548) described an in vitro experiment comparing pads that were treated with either acrylonitrile copper sulfide or iron phthalocyanine. The authors claimed in vitro experiments showed that acrylonitrile copper sulfide cloth inhibited the growth of most bacteria causing urinary tract infection, and that iron-phthalocyanine cloth effectively eliminated bad-smelling gases. No clinical studies were found on evaluating this product.

In another in vitro study, suspensions of a range of bacterial, viral, fungal and yeast micro-organisms were applied to the products. N-halamine siloxane coatings were found to inactivate most antimicrobials and prevent odour caused by bacterial generation of ammonia on urine soaked fabrics (549). They claimed, HaloSheild, a patented product, developed by Medline Industries Inc. in partnership with Vanson HaloSource, can be applied to healthcare sheets and incontinence underpads but to date, no evaluation studies have been published.

2.3. Penile sheaths

According to the findings of two studies, penile sheaths may confer benefit in terms of reducing the odour associated with UI. In an industry funded RCT, 61 men with stable, moderate to severe UI and no concomitant FI compared Conveen Optima urisheaths’ to usual continence pad (60). In random order, the men wore their usual absorbent product or urisheaths, each for a 2-week period. The authors reported that all dimensions of participants’ quality of life using the King’s Health Questionnaire showed improvement. The men also rated the performance of the urisheaths significantly higher for efficacy, feeling of security, feeling of freedom, self-image, discretion, odour management and skin integrity, but not for ease of use, which was significantly higher with the absorbent product. Another earlier study also lends some support to the positive impact of penile sheaths on reducing the odour associated with UI: Lyder et al. (550) described a cohort study in which nursing staff from a Veteran Affairs Nursing Home were asked to rate the odour before and after one week of sheath use by 8 men with urinary and faecal incontinence who resided in different rooms. The authors reported that incontinence odour was markedly less in the rooms where sheaths were used. Limitations of the study were the unblinded nature of the evaluation and the lack of statistical power.

A broader review of findings on the use of penile sheaths is given in Section G.

2.4. Reusable undergarments

Gallo and Staskin (551) described the performance of reusable undergarments on odour control. They investigated patient satisfaction with a reusable undergarment called ‘HealthDri’ among 84 men and 42 women aged between 42-70 years of age with UI. Participants were given a minimum of one undergarment and asked to wear it as their primary method of incontinence containment for up to one month. Participants self-reported their satisfaction with the undergarment in 6 categories: (i) physical comfort, (ii) ability to keep skin dry, (iii) ability to prevent wet spots, (iv) discretion, (v) odour control, and (vi) confidence when wearing it compared to usual containment device). Among other findings, 80% rated the ability to control odour as adequate or excellent. No further studies on this undergarment were found.
2.5. Products for faecal incontinence odour

Community-dwelling people with FI (n=189) were surveyed about their use and evaluation of disposable bodyworn absorbent products for managing FI, including its odour (552). The survey was part of a clinical trial about the effects of dietary fibre on FI. Forty-five percent (86/189) used absorbent products, which included menstrual pads and products marketed for UI, but satisfaction rates concerning their usefulness for FI was generally low. When asked to rate the performance of the absorbent products they usually wore in terms of their effectiveness, odour control, comfort, fit and ability to stay in place, odour control had the lowest percentage of “good” ratings across all products. The authors concluded that odour control is the feature of an absorbent product that appears to need the greatest improvement for use in managing FI.

3. SUMMARY

- Odour control products have a key role to play in helping people with incontinence and caregivers retain their sense of adulthood, identity, independence, and engagement in social life (Level of Evidence 3).
- The clinical effectiveness of treating fabric-based continence products with antimicrobial agents to reduce the odour associated with urine is unclear (Level of Evidence 4).
- Compared with continence pads, penile sheaths may have greater ability to reduce the odour associated with urine leakage (Level of Evidence 2).
- Users of reusable undergarments reported being satisfied with the product’s ability to control the odour associated with UI (Level of Evidence 3).
- Users of disposable absorbent products reported being dissatisfied with products’ ability to control the odour associated with FI (Level of Evidence 3).
- Oral intake of probiotics (Lactobacillus plantarum, (5 x 10^7 cfu/ml)), enzymes (α-galactosidase), and oral charcoal mixtures, may reduce production of malodorous gas, but the effects of odour are unclear (Level of Evidence 1).
- Products or devices that are activated with charcoal can absorb odour associated with flatus, and charcoal activated wearable briefs are more effective than charcoal activated cushions or pads (Level of Evidence 3).

4. RECOMMENDATIONS

Recommendations relating to products for odour associated with incontinence are listed in Table P-2.

<table>
<thead>
<tr>
<th>Table P-2: Recommendations relating to incontinence and odour.</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Healthcare professionals must be sensitive to the fear and social consequences of odour (Grade of Recommendation A)</td>
</tr>
<tr>
<td>- Men with UI should be informed about different containment options and about the greater ability of penile sheaths to reduce the odour associated with urine leakage over absorbent pads (Grade of Recommendation B)</td>
</tr>
<tr>
<td>- Further research is required before recommending the use of fabrics and materials treated with anti-microbial agents to reduce the odour associated with UI (Grade of Recommendation D).</td>
</tr>
<tr>
<td>- Patients with UI should be offered the option of trialling a reusable undergarment to evaluate its ability to reduce the odour associated with UI (Grade of Recommendation D).</td>
</tr>
<tr>
<td>- Patients with FI should be informed about the limited ability of disposable absorbent products to reduce the odour associated with FI (Grade of Recommendation D).</td>
</tr>
<tr>
<td>- Odoriferous rectal gas may be better absorbed with body worn briefs containing activated charcoal rather than with separate pads or cushions (Grade of Recommendation C).</td>
</tr>
<tr>
<td>- Since some pads absorb up to 75% of gas, there may be value in offering patients who have smaller amounts of gas the opportunity to compare pads and briefs for themselves. (Grade of Recommendation C).</td>
</tr>
<tr>
<td>- Patients with irritable bowel syndrome may benefit from a trial of Probiotic Lactobacillus plantarum to reduce associated pain and flatulence (Grade of Recommendation C).</td>
</tr>
<tr>
<td>- For those persons experiencing stool leakage due to flatus, over-the-counter α-galactosidase containing products, which reduce the production of malodorous gas can be tried in an attempt to reduce FI frequency (Grade of Recommendation B).</td>
</tr>
<tr>
<td>- Washing of outer as well as under clothing after flatus is recommended to reduce odour due to absorption of gas by clothing (Grade of Recommendation C).</td>
</tr>
</tbody>
</table>

5. PRIORITIES FOR RESEARCH

- Development of an absorbent product that can eliminate, reduce or mask the odor of leaked urine and/or faeces while protecting the skin.
- Development of wearable undergarments and textile products (soft furnishings and bedding) for...
eliminating, reducing, or masking odour associated with urine, faeces and flatus.

- Investigation of whether probiotics or changes in dietary intake can eliminate or reduce the odour of flatulence or leaked faeces.

APPENDIX 1

The literature search to identify material for this chapter - additional to that reviewed for the last (5th) consultation (31) - was conducted as follows. MEDLINE and CINAHL databases were searched from 2008 – 2011 for English language publications. Detailed search strategies were developed for each electronic data-base searched. Consideration was given to variations in terms used and spellings of terms in different countries so that studies were not missed. Relevant abstracts were examined and then pertinent articles were retrieved and reviewed, and the reference lists searched for further studies. For product categories associated with little or no research literature, analysis relied on expert opinion from clinical practice papers.

The following main search terms were used: incontinence AND device*, toilet* AND facilities, female, male, urinal*, commode*, bedpan*, urine* AND sheath, condom AND catheter*, *, intermittent catheterisation, indwelling catheterisation, catheterisation, catheters, incontinence OR absorbent pad*, urinary AND catheter* (in title), urinary AND leg bag* OR legbag* OR drainage bag, faecal OR fecal AND incontinence AND plug OR pouch OR bag OR device, OR manage* system, incontinence OR perineal AND dermatitis OR inflammation OR skin damage, incontinence OR perineal OR diaper AND dermatitis OR inflammation OR skin damage OR skin lesion OR erythema OR rash OR erosion.

APPENDIX 2

Details of Cochrane reviews relating to long-term and short-term catheter use are described in Table Ap2-1.

Continenence promotion, education, and primary prevention involves informing and educating the public and health care professionals that urinary (UI) and faecal incontinence (FI), can be treated successfully in most cases, can always be managed, and can often be prevented. Other bladder disorders, with links to incontinence, such as bladder pain syndrome/interstitial cystitis (BPS/IC) and pelvic organ prolapse (POP), can also be treated and managed successfully and they are often included in continence awareness programmes.

The taboo for talking about disorders of the bladder and bowel is easing in most cultures. (1) Government funded initiatives have increased and practice guidelines have been developed. The multidisciplinary approach to clinical management and research is considered the most effective and impactful way to provide care and advance knowledge. Popular magazines, local and national papers, radio, and television, in most developed countries regularly cover health topics for men and women relating to UI, FI, BPS and POP. Many countries run national or local public awareness campaigns, often spearheaded by a national continence organisation and the internet is increasingly being viewed as a convenient source of health information for a growing number of consumers.

This chapter updates the 2013 International Consultation on Incontinence (ICI) chapter in these areas: primary prevention, continence awareness and promotion, help-seeking behaviour, models of care and service delivery and education along with the recommendations in each area. The majority of information available primarily relates to UI and less on FI, BPS/IC and POP. Since these conditions are prevalent but often ignored by sufferers and professionals, the first topic addresses population-based primary prevention research. Although there is evidence-based research to support strategies to promote continence in certain populations, further research is needed to substantiate the benefits of primary preventative strategies, including long term follow-up. The second section reviews continence awareness by discussing health promotion and help-seeking (care-seeking) behaviours (HSB) for these conditions. Progress continues to be made in the promotion of continence on a worldwide basis yet there is inadequate evidence for the rapid translation of awareness into behavioural change and using existing knowledge to trigger help-seeking behaviour. Information is provided about continence promotion programmes and advocacy through worldwide organisations. Although a great deal of published information on building public and health care professional awareness of incontinence, is available, there is minimal information about the impact of these efforts on changing healthcare policy and public and professional attitudes and knowledge about continence. The third section discusses service delivery and models of continence care. The committee highlights the work of the 2014 Multidisciplinary Continence Care Service group. The final topic addresses education of professionals in these areas (i.e., UI, FI, BPS/IC and POP) including the development and use of medical guidelines and care pathways. The committee found information about recent practice and research initiatives in all of these areas but found very little evidence-based research to support widespread dissemination and translation. An attempt was made to review current information of education of the public on these conditions. A listing of all guidelines released since 2007 on UI, FI, POP and BPS is provided.
1. BACKGROUND

According to the World Health Organisation primary prevention, “refers to actions aimed at avoiding the manifestation of a disease”. These actions include interventions to improve health by changing the impact of social and economic determinants on health, providing people information about how to reduce risks of disease and clinical preventive services, and community and individual-level interventions to reduce risks. Primary prevention of UI in adults is important because of its prevalence across the lifespan, its financial and societal costs, and impact on the quality of life (QoL) of affected adults. A consensus statement released in 2011 by a panel of experts, *A Healthy Bladder*, reinforced the ongoing need for primary prevention efforts to be addressed not only by healthcare professionals, but also by policymakers and funding bodies.

A driving force for developing primary prevention interventions for UI is epidemiological evidence of the global aging phenomenon. The World Health Organisation and the National Institute of Health in the United States (U.S.) estimated that there will be 1.5 billion people aged 65 years and over by 2050, representing 16% of the world’s population. The most rapid rate of growth of this age group will occur in less developed countries with 250% growth rate as compared to 71% in developed countries (https://www.nia.nih.gov/research/publication/global-health-and-aging/living-longer).

This rise in the number of older people is also expected to result in higher numbers of people living with increased burden from chronic non-communicable diseases that are associated with UI (i.e., diabetes, neurological disorders, and some cancers).

These global aging estimates have significant implications to healthcare utilization, costs for UI across the lifespan, and education of clinicians to treat these conditions. For example, estimates of lifetime risks for surgery for stress UI (SUI) in women is 20% by the age of 80 years (5) and the economic burden of urgency UI (UUI) is projected to increase by 25% by 2024. In the U.S., the prevalence of UI increased in six years from 35.8% to 38.6% in older adults who have complex medical problems, yet treatment rates remained low.

Previous research has identified multiple risk factors for UI and many of these factors may be modifiable including environmental, psychological and lifestyle and behavioural. Research has also found association between specific toileting behaviours and presence of lower urinary tract symptoms (LUTS), predominantly UI, in employed women, female nurses (13) (14) and women visiting a urogynaecology clinic. (15)

Recent research linked socioeconomic and health conditions in early childhood to impact on health later in life. (16) This includes intrapersonal factors such as reduced physical activity, obesity, smoking, exposure to stress, and development of mental health problems, i.e., depression. The origins of these factors appear to be complex and multi-level, that is, there are both intrapersonal and environmental mechanisms or intrapersonal and societal mechanisms leading to manifestation of negative health outcomes.

---

**Figure 1: Primary Prevention Model.**

© Palmer 2016
Since the Fifth ICI, there has been a heightened awareness that some social determinants are associated with the incidence and progression of UI. For example, research has observed a direct association between UI and obesity (17) and both UI and obesity are also associated with lower socioeconomic status. (18) UI has also been associated with depression in women in their 40s (19) and reduced physical activity. (20) In addition, racial disparities exist in patterns of UI, (21) primary prevention of UI in nursing home (NH) residents, (22) and women’s level of knowledge about UI and other urinary symptoms. (23) Some women are disproportionately affected by UI due to its impact on emotional and spiritual aspects of their lives. (24) Increasing screening may help initiate discussions between healthcare providers and adults about urinary symptoms and their prevention. Urologic health has been proposed as a priority during the well women visit. (25)

Use of an assessment questionnaire in primary care wellness visits with women 40 years and older increased discussion about UI and FI. (26) Thus the goal for the emphasis on reducing risk of UI is to reduce disease burden and improve QoL in both the short and long term.

Development of primary prevention interventions for individuals and populations remain in the nascent stage. (27) (28) Evidence based information or clinical guidelines for preventing incontinence are not widely available. (29) There are no systematic reviews of population-based primary prevention interventions. Efforts are underway to develop foundational knowledge about multi-level factors including individual, social, physical and environmental factors that will aid in the development and testing of interventions to prevent UI in women. (30) A primary prevention model was proposed that demonstrates the multi-stage approach to individual and population based education, case finding, intervention, embedded change, and outcomes, see Figure 1.

Professional organisations have developed events or organized information to heighten the public’s awareness of the importance of bladder health, such as the American Urogynecologic Society’s Bladder Health Week (http://www.augs.org/p/cm/ld/fid=708 ), designed to educate women about pelvic floor health; the International Continence Society’s (ICS) World Continence Week (https://www.ics.org/public/wcw); Continence Foundation of Australia public toilet map (https://toiletmap.gov.au/); and Canadian Continence Foundation factsheets and patient pamphlets (http://www.canadiancontinence.ca/EN/bladder-health-leakage-control-problems.php?EN/bladder-health.php). Efforts on the behalf of the Asia-Pacific Continence Board that represents countries in the Asia-Pacific rim and of the American Urological Association (AUA) are underway to designate November as Bladder Health Month (https://www.auanet.org/press-media/press_releases/article.cfm?articleNo=462). Evaluation of the effectiveness of these programmes is not available.

2. PREVENTION OF UI IN SPECIFIC POPULATIONS

2.1. Women During Pregnancy and Postpartum

A review of studies that were conducted to prevent UI during pregnancy and postpartum up to 2012 provided recommendations about UI prevention interventions. The authors who used the International Consultation on Urological Diseases steps for grading evidence made the following recommendations: advise to women to stop smoking before and during (Grade B), maintain normal weight before pregnancy (Grade B), aim to achieve normal weight post pregnancy (Grade B), advocate for occasional low intensity training during pregnancy (Grade B), avoid constipation during pregnancy (Grade B) and postpartum (Grade C), perform pelvic floor muscle (PFM) training during pregnancy and postpartum (Grade A), and use warm perineal packs during delivery (Grade B). The authors also noted that Cesarean section cannot be recommended (Grade D). (31)

Women in the second trimester of pregnancy were randomized into an intervention group (individually supervised PFM exercise intervention) and control group. Both groups received written information on how to perform PFM exercises. No differences were observed between the two groups at two and 12 months post-partum. (32) In a randomized, controlled trial (RCT) 70 pregnant women were randomized to an intervention group (supervised 6-week PFM exercise programme with instruction from a trained midwife) or control group (regular prenatal care). Fewer women in the intervention group developed SUI by the end of the study than did women in the control group (OR, 3.05, 95%CI, 1.07-8.70, p = 0.018). (33) Research is needed to increase the number of women willing to participate in PFM exercises. For example, in one study 95% of the women wanted professional information about these exercises but only one in three women were willing to participate in supervised PFM exercises postpartum. (34) Results from an online survey of 507 postpartum women who ran a minimum of once a week revealed that birth spacing of less than 2 years or having vaginal delivery increased odds of postpartum SUI (OR, 1.71 95%CI, 1.00-2.91). Women who had cesarean section delivery had increased odds of abdominal separation OR, 2.20 95%CI, 1.05-4.70.). During pregnancy, antenatal weight training decreased odds of SUI (OR, 0.46 95%CI,0.21-0.98). (35)

2.2. Men Post-prostatectomy

A meta-analysis of preoperative PFM exercises for UI after radical prostatectomy found that additional PFM exercises did not improve resolution of UI after radical prostatectomy at 3, 6, or 12 months. (36)
2.3. Community-dwelling Older Adults

Community based continence education workshops have been found to increase knowledge of continence issues and continence related QoL in older women. In a study of 51 women who attended a 2.5 hour workshop, there was an increase in continence knowledge that was sustained for three months after the workshop. (37) The authors concluded that learning self-management strategies were important to improve pelvic floor health and that education in a public forum may be beneficial for these patients. This questionnaire was developed in the U.S. and 92% of respondents were White and the median age was 69 years.

A multisite randomized controlled trial was conducted with women 55 years and over (N= 647) in which women were followed 3 months, 1, and 2 years after delivery of the intervention. The intervention consisted of bladder health information by either 2-hour face to face instruction or 20-minute DVD with the same information. Investigators found both methods equally effective. There was no change in self-reported UI at 2 years. (38) (39)

A continence questionnaire, the Continence Index, was developed to predict future UI in older women. Factors that emerged as the strongest predictors of UI included body mass index, sneezing, belief of developing future UI, difficulty in stopping urine stream, and remembering names. (40)

A cluster randomized trial was conducted in the United Kingdom (UK). Clustering was performed at the organisational level and women were 60 years or over who had UI at least weekly. The three interventions tested involved: continence education, self-management including a UI risk reduction tool, and a combination of education and self-management. A control group received information about memory loss, polypharmacy and osteoporosis. Women in the combined intervention group reported the highest rate of UI symptom improvement (66% versus 11% in control group). (41) A multi-national study to decrease stigma from UI and falls in older women has been reported in the literature; preliminary results are not available. (42)

3. PREVENTION OF FAECAL INCONTINENCE

Prevalence of FI in adult women and men is similar (median 8.1% range 2.3%-16.1% and 8.9% range 2.0%-20.7% respectively). (43) Dual incontinence was reported as more prevalent in women: 6% 95%CI, 5.0-7.1% versus 1.9% 95%CI, 1.4-2.7%. (44) FI prevalence increases with age (43) and is often under-reported. (44) Consultation for help with FI and physician screening are relatively low with many consumers unaware of available treatment and physicians reporting time as a barrier to screening. (45) Risk factors associated with FI are reported by Committee 16: FI: Conservative Treatment. Prevention of FI remains important, research is needed to determine the effectiveness of population-based interventions focusing on increasing awareness about risk factors for FI.

Summary

Primary prevention of urinary and fecal incontinence is in its nascent stage but changing global demographics are driving the need to develop effective primary prevention interventions across the human lifespan. Foundational evidence has demonstrated that modifiable risk factors exist across multiple levels: intrapersonal, environmental, and societal. High quality RCTs are needed in both men and women across the lifespan to develop evidence for the effectiveness of population and individual-level primary prevention intervention for UI and FI.

Levels of Evidence/Recommendations

- Pelvic floor muscle exercises can prevent UI in pregnant and postpartum women. (Level of Evidence: 1)
- Education designed for community-dwelling older women can prevent UI. (Level of Evidence: 1)
- No recent RCTs or case-control studies were located for prevention of FI. (Level of Evidence: 4)
- Pelvic floor muscle exercises should be provided to pregnant women. (Grade of Recommendations: A)
- Education to older women to prevent UI should be provided. (Grade of Recommendations: A)

III. CONTINENCE AWARENESS, PROMOTION AND ADVOCACY

Literature Search is found in Appendix 1.

1. BACKGROUND

According to the World Health Organisation, health promotion is, “the process of enabling people to increase control over, and to improve, their health. It moves beyond a focus on individual behaviour towards a wide range of social and environmental interventions” (http://www.who.int/topics/health_promotion/en/)

Efforts to promote awareness about incontinence and its treatment can be enhanced by adopting evidence-based theories and methods from the field of health promotion and by heightening awareness of the World Health Organisation social determinants of health. (46) Health promotion frameworks can be...
Consumer education is a critical component of effective continence promotion. Education of individuals with, or at risk of, UI and/or FI, their family members or informal caregivers, and healthcare professionals increases awareness about incontinence and the benefits of prevention and management. The goals of consumer education are elimination of stigma, promotion of help-seeking, and reduction of suffering. (47)

Using a quantitative descriptive design, Day et al (48) surveyed 50 community-dwelling women's knowledge about UI. Findings revealed that the women had poor knowledge, principally in relation to UI risk factors (38.8%), prevention (40.5%), treatment (39.4%) and management (49.4%), suggesting that women have unmet educational needs related to UI and indicating an area for improved consumer education. (48) According to a qualitative analysis of open ended questions from a survey of 1,458 women with UI in Washington State, women had a range of different interpretations and understanding about the causes of UI, with many believing it was a normal part of being female. (49)

An important aspect of continence promotion involves dispelling the pervasive myth that incontinence is an inevitable part of aging. Spencer (50) described a pre-post evaluation of an education programme for women with UI and found education alone was insufficient to alter women's beliefs. The researcher emphasized the need for more engagement about the topic, and to consider individualized learning needs. Clinicians play an important role in encouraging discussion and providing information about UI (51) and can empower an individual to make changes and set goals for UI self-management. (52)

Muller’s review of findings from several epidemiological surveys of community-dwelling adults with bladder control problems in the U.S. indicated that women look first to their doctors to serve as their primary pelvic health educators found that having a general practitioner (GP) was one of many factors that increased help seeking for UI. (53) Muller concluded that improved patient-doctor relationships and public education may foster healthcare seeking behaviour because the vast majority of women who had not sought healthcare for UI believed, at least in part, that there were no available treatments.

In a convenience sample survey of 360 women in Israel, researchers found that women who suffered from UI and those who were older generally had more knowledge about UI including causes and treatments. (54) Another small focus group study with African American and Latina women in the U.S. demonstrated general misconceptions about causes of pelvic floor disorders, symptom and treatments. (55) Participants were eager to gain more information, particularly to share with their daughters, and identified placing family demands before their own health needs as a barrier to seeking care. An online survey study of 1,092 adolescent and young women aged 19-30 years enrolled at a university in the U. S. revealed that those in the 25-30 year age cohort were more likely to have received information about UI, FI, and POP. (56)

Some countries governments provide support for continence promotion but much of the health promotion effort related to continence issues is undertaken by professional bodies, non-governmental continence organisations, and advocacy groups. The ICS provides information about peak bodies and advocacy organisations that are active in the area of health promotion, advocacy and represent the interests of people with, or at risk of, incontinence (http://www.ics.org/SiteLinks.aspx). Through the activities of these organisations and with the engagement of external stakeholders such as educational, health-care, and community service providers, these organisations aim to increase community awareness and understanding about incontinence, reduce social stigma, and raise public awareness about risk factors and options for managing incontinence.

Consumer knowledge about FI is also generally limited. Patel et al (57) conducted a content analysis of comments from 89 community-dwelling adults with FI to examine their continence literacy. The findings indicated that while many consumers had a significant emotional component to their experience of FI their knowledge about terms to use to describe their condition was often limited. (57) (58) (59) (60)

As part of a larger study that used a postal and internet survey conducted with members of a National Crohn’s and Colitis Support Group, Norton and Dibley (61) investigated factors that influenced help-seeking in people with inflammatory bowel disease (IBD) related FI, and their needs or desire for continence services. The most commonly cited reasons for not seeking help were: a lack of knowledge about from whom to seek help, how to seek help, and where to seek help.

2.1. Use of the Internet and Social Media

The internet is frequently searched for health information, and coverage of relevant health topics is growing. The benefits of acquiring health information via the internet include its wide accessibility, anonymity, and informality with eight in ten internet users in the U.S. looking online for health information. (62)

Amante et al (63) investigated access to care and use of the internet to search for health information using data from the 2011 National Health Interview Study (NHIS). Of 32,139 adult respondents, 43.55%
(13,997) reported searching the internet for health information. These authors suggested that a main reason for the widespread use of the internet to obtain health information was users did not consider their questions severe enough to warrant the effort or time to obtain routine, urgent, or emergent clinical attention.

Evaluations of internet based information about incontinence suggest the internet may prove to be a useful tool for consumer education and public health outreach particularly in light of the reluctance of those affected by stigmatized illnesses such as incontinence to seek treatment or to ask health care professionals for information. (64) (65) (66) For example, in a study of 208 people attending GP appointments in the UK conducted by Al-Shammary et al (64) the majority of people who used the internet felt able to discuss UI with their GPs or with the practice nurse, suggesting that information gleaned from the internet helped consumers make decisions about seeking help. Forty-five percent of respondents used the internet before consultation for the purpose of self-diagnosis. Mazloomdoost et al (65) evaluated the use of social networking and internet use as a source of information about pelvic floor disorders among women who presented to a clinical practice for female pelvic medicine and reconstructive surgery. The majority (75%) reported high internet use, with 53% using the internet or social networking to learn about their pelvic floor condition. Saiki and Cloyes (66) conducted a content analysis of publicly archived blog texts from 19 women living with UI. The findings revealed a focus on securing social connection and a place in the human community. Thus, blogging may offer women with UI a means by which they can safely disclose their condition and socially connect.

Some researchers have questioned the quality of continence information on the internet and social networks, and have suggested that validation is needed. (67) (68) (69) In 2001, Diering et al (70) evaluated the content, credibility, and function of 15 websites with UI content that had been developed by professional health care organisations for use by healthcare providers. The researchers concluded the internet served as a useful resource for ‘state-of-the-art’ knowledge about UI that health professionals can use to update their knowledge but also cautioned users to critically evaluate content. Using the World Health Organisation ‘Health on the Net’ (HON) principles, Saraswat et al (68) evaluated 150 websites using 17 commonly used terms for ‘female UI’ in English, French, German and Spanish, and compared website sponsors. The total number of websites for each term was variable, however ‘female sling surgery’, had the most websites (18 million), followed by ‘incontinence surgery’ (9.8 million). The most commonly encountered sponsors were physicians/surgeons (37%), followed by commercial sites (30%), government organisations or educational institutions (20%), and non-profit organisations (5%). The findings highlight the importance of assessing the quality and validity of internet health information, particularly as many websites also act as a platform for advertising. An evaluation by Dueñas-Garcia et al (67) of 13 patient-focused websites addressing treatment options for POP and stress UI also raised concern about the quality of information available to consumers. Using the DISCERN instrument, a validated instrument to assess the quality of written consumers health information relating to treatment options, the researchers reported available English-language professional websites written to inform patients about management choices for SUI and POP omit key components of quality patient information. (67)

Sajadi and Goldman’s (71) study to assess the quality of incontinence resources available among social networks, also showed that most websites providing UI information were not certified by an accrediting body. Using the term ‘incontinence’, the researchers searched for information on Facebook, Twitter, and YouTube, to evaluate its usefulness. Their conclusion was that while social networks have great potential for consumers with incontinence to connect with each other and find medically informative resources, there was insufficient useful UI content, especially from healthcare professionals and incontinence organisations. Social network sites are a key future source of information for consumers about incontinence, and medical professionals and societies should target these avenues to reach and educate consumers. Healthcare professionals, Continence organisations, and recognised advocacy organisations have a key role to play in assisting consumers to find reliable information about UI by providing details of reputable web sites and by playing a role in interpreting findings from high quality research and reframing them for consumption by the general public.

Although the internet has changed how many people access health information, internet access is far from universal, especially in developing nations, among older and poorer sections of society in developed nations, and among people with low levels of education and lower socioeconomic status. (72)

In both developing nations and in countries with limited health systems and dispersed populations, innovative methods are needed to disseminate information about incontinence, such as through community nursing infrastructures and lay health workers.

Summary

Based on survey and qualitative data regarding consumers’ understandings and knowledge of incontinence, the general public has limited knowledge about incontinence. The effectiveness of strategies to promote awareness about incontinence and its treatment can be enhanced by adopting evidence-based theories and methods from the field of health promotion, and should be underpinned by awareness of the social determinants of health. Consumers increasingly access the internet for health information but the
quality of information about incontinence may be variable. Clinicians and continence promotional bodies play an important role in helping consumers find high quality reliable information. The majority of publications on Continence Promotion and Programmes are qualitative or mixed methods designs and the Oxford Level of Evidence does not recognize.

Levels of Evidence/Recommendations

- Continence promotion is required to address broad gaps in knowledge about incontinence (Level of Evidence 3)
- Strategies to promote awareness about incontinence and its treatment can be strengthened by the use of evidence based theories and methods from the field of health promotion, including the social determinants of health (Level of Evidence 4)
- The internet represents an important source of information about incontinence, however the quality of information may be variable (Level of Evidence 3)

IV. HELP-SEEKING (CARE-SEEKING) BEHAVIOUR

Literature Search is found in Appendix 1.

1. BACKGROUND

Help-seeking for UI is not well-understood likely due to the lack of rigorous exploration of this behaviour. Despite increased awareness among healthcare providers and consumers of healthcare, a survey comparing help-seeking behaviours conducted sixteen years apart (1991 and 2007) revealed that there had been virtually no increase in the proportion of women seeking help for LUTS. (73)

A Model of Pathways to Treatment (74) offers a framework to explore the existing literature on the barriers and facilitators to seeking care and sex-differences in help-seeking. This model proposes four sequential time intervals in the process of receiving treatment: 1) appraisal, 2) help-seeking, 3) diagnostic, and 4) pre-treatment. During the first time interval the person detects bodily changes. These changes may be appraised as a normal change or abnormal, a symptom of an underlying condition. If the person decides the bodily change is abnormal, s/he is motivated to seek help from a healthcare provider for one of two reasons: 1) concern that the change is from a serious underlying condition; or 2) due to the consequences of the change. During this time interval, the person considers seeking help from a healthcare provider based on the outcomes of their appraisal of the symptoms and their self-management. Situational, contextual, and social factors can play a role during this phase in creating facilitators and barriers to seeking help. Once the person makes the first consultation from a healthcare provider, the diagnostic process begins, and afterwards, treatment is initiated.

For the purpose of this section, two time intervals are the focus of this section: 1) detection and appraisal of bodily changes related to UI; and 2) self-reported reasons to discuss symptoms with a healthcare provider. Using non-health professional and indirect resources (such as blogs, chat groups, and website) was considered to be self-management, not help-seeking behaviour.

The research questions are:

a) What factors act as barriers/facilitators to help-seeking for UI?

b) Do sex differences exist for help-seeking for UI?

2. FACTORS THAT ACT AS BARRIERS / FACILITATORS TO HELP-SEEKING

Since the 5th ICI edition, multiple descriptive studies were located noting that intrinsic and extrinsic factors can act as barriers/facilitators to help-seeking for UI. More information about help-seeking behaviours in women across the adult lifespan than for men was retrieved.

Intrinsic factors associated with barriers/facilitators:

Findings from a qualitative research study has described a process that takes place and influences decisions to seek treatment (or not), whereby adults affected by chronic, non-life-threatening conditions, weigh the perceived costs and benefits of treatment (in terms of discomfort and inconvenience as well as financially) against the effect of the condition on QoL. (75) In semi-structured interviews with 22 older people, three themes emerged: "being brushed aside," "putting up with it," and "something has to be done." (76) The authors noted that an important trigger for seeking help for incontinence was healthcare providers' confirmation of continence problems. Thus the role of healthcare professionals acting as facilitators to help-seeking care was emphasized.

An integrative literature review of help-seeking behaviours for UI symptoms among non-institutionalized women of all ages indicated that less than 38% of women sought help for their UI symptoms. (77) In women with UI, some (n=119, n=27.4%) said they did not report UI because it is a small or insignificant problem and that they can self-manage it. This perception can change over time with worsening of symptoms and increased continence pad use. For example, female patients from a urogynaecology practice with SUI reported that UI was perceived as a
problem about 4.7 ± 5.4 years after its onset. In this study, women waited an average of 13.28 ± 12.3 years to seek help. (78) In a population-based study, the rate of help-seeking was associated with increasing age (i.e., women over 70 years: 1.2 versus women between 50-59 years: 0.02). (79)

Fifty-eight men and women participating in the Boston Area Community Health Survey (BACH) also participated in focus groups about urinary symptoms, their attitudes and beliefs about the symptoms, and help-seeking behaviour. Worsening and longevity of symptoms, fears of underlying serious disorder, and increasing bother were reasons that prompted them to seek help. (80) Characteristics of women who sought help for UI participating in a longitudinal study in France included talking with others (i.e., family or friends) and having severe UI, mixed UI, weak social support, and neurologic disease. (81) Communication issues after women decided to seek treatment from physicians for UI was identified as a barrier to receiving care. This finding resulted from focus groups with an ethnically diverse sample of women in the U.S. The women also had expressed frustration with the level of information about UI and its treatment. (82)

## 3. KNOWLEDGE, ATTITUDES, AND BELIEFS ABOUT UI

Women’s knowledge, attitudes, and beliefs about UI have been long thought of as both barriers and facilitators to help-seeking behaviours. Many women believe UI is a normal part of aging (83) (84) (85) (86) and did not seek help for what they perceived as a non-problem. Other women who participated in a survey in Korea noted that they were embarrassed by being incontinent and did not seek help, but women who did not have UI said they would consult with a healthcare provider should they develop it. (83) In another study, women (61.9%) have also reported one reason for not seeking help for UI was that they hoped UI would spontaneously disappear (similar to findings by Buurman and Lagro-Janssen, (87) but interference with prayer and sexual, physical, and social activities were reasons to seek help. (88) Using the Theory of Planned Change, researchers found that help-seeking intention can be predicted. They also found that high perceived self-efficacy in managing UI or created emotional responses of embarrassment and shame. (89) Authors of a systematic review on perceptions about female UI however concluded that similarities existed among women from different racial and ethnic groups in terms of managing UI but their perceptions about UI differed. (90)

From the literature reviewed, knowledge deficits along with varying attitudes and beliefs that normalize UI or created emotional responses of embarrassment and shame. (89) About UI acted as barriers to help-seeking.

### Level of severity and bothersomeness of UI symptoms and consequences of symptoms

UI severity in women between 58-70 years was the main reason for reporting UI to a healthcare provider. (81) Women had greater odds of getting treatment for UI when their symptoms had become more frequent (adjusted OR, 3.16, 95% CI, 1.15–8.67) and bothersome (adjusted OR, 1.09, 95% CI, 1.01–1.18) in the prior year. (100) Another study found however, that bother from UI mediated the relationship between UI severity and help seeking behaviour. Thus women who perceived bother sought help for UI regardless of the level of severity. (101) Bother, as well as concern about a serious underlying condition, was also a reason to seek help for women between 45-65 years living in Iran while neglect, embarrassment, an assumption that UI was caused by aging, and economic issues acted as barriers to seeking help. (102) The literature revealed that more severe UI and bother from UI can act as facilitators to help-seeking.

It is difficult however to generalize findings among studies because different definitions for help-seeking and instruments were used, although it appears there
are common findings including age, type and severity of UI, and feelings of embarrassment are significantly related to barriers to seeking care. (103)

In a study conducted with men (N=1240), with a mean age 63.3±12.7 years, who sought help for LUTS at a urology clinic, subjects were asked by a physician before evaluation to select the most bothersome symptom. Nocturia accounted for 32.9% of initial complaints and it persisted in approximately 50% of men over time. (104)

Men over 50 years old (n=18) who had visited their GPs were asked to participate in semi-structured interviews about reasons they sought help with LUTS symptoms. The researchers found that men could be grouped into 3 categories: those who were concerned about cancer, those who found the symptoms a nuisance, and those who were prompted to seek help after seeing public information about LUTS. (105)

4. EXTRINSIC FACTORS THAT ACT AS BARRIERS/FACILITATORS TO HELP-SEEKING FOR UI

Women with low incomes (i.e., $30,000 USD annually) were less likely to discuss UI with a healthcare provider, even though they had health insurance, than women at higher income levels. (18) The authors of the study noted that other factors such as high co-payment and family and job responsibilities hindered making and attending healthcare appointments. (18) Costs of care and inconvenience created barriers for American Indian older women (average age 77.7 years ± 9 years) living in southwestern U.S. Inconvenience and fear, as measured by the Barriers to Incontinence Care Seeking Questionnaire (BICS-Q), created barriers for Latina women as compared to Caucasian and African American women, (106) indicating that cultural and social factors play a role in a woman’s decision and ability to seek care. El-Azab and colleagues (107) found that encouragement from husbands as well as having severe UI, and the desire to be able to pray, were associated with an increased likelihood of help-seeking behaviour in Middle Eastern women.

Social and cultural attitudes were cited as barriers to help-seeking (3) and this issue appeared to cross many cultures. For example, in one study, social rejection indicated higher level of intention to seek care among Chinese women (age range 40-65 years), (36) thus acting as a facilitator to help-seeking. The effect of stigma influenced attitudes towards help-seeking in women who were visiting at a health care centre who also responded to a survey. The researchers found that internalized stigma, social isolation, and internalized shame had a direct negative effects on help-seeking attitudes. (108) Other social factors lead women to hiding incontinence. Women reported fear of smelling like urine, fear of not being supported by those close to her, and being discriminated against were reasons not to seek help for UI. (109) Social factors however can facilitate help-seeking. Help-seeking for LUTS in Taiwan increased from 23.1% in 2000 to 38% in 2009. (110) The authors noted that the rapidly aging society and concerted efforts by the government and other organisations to increase awareness of LUTS were driving factors to this increase in help-seeking. Research ideas solicited from citizen juries composed of women who lived in New Zealand included research to make help-seeking and receiving treatment for UI easier for women. (111)

5. SEX DIFFERENCES FOR HELP-SEEKING BEHAVIOURS FOR UI

No studies that directly compared sex differences in help-seeking behaviours for UI were located. Teunissen and colleagues (112) interviewed 56 men and 314 women aged 60 years and older who were living independently in the community with “uncomplicated UI”. Men reported higher UI impact scores than women, despite their UI being less severe than that of women. The most important effect of UI reported by men was, “being out of control,” while most women considered, “feeling compelled to take several precautions” to be the most important consequence of UI.

To better understand the experience of the social context of UI, men and women participating in BACH, were recruited to participate in focus groups. Both men and women who had UI feared detection by others; men were concerned about being perceived as going to the toilet too frequently as compared to women in the same study who reported concerns about cleanliness and caring for her body. (113)

An internet survey administered to men and women aged 40 years and over in the U.S., the UK and Sweden, noted that of the men and women who reported LUTS, less than a third of respondents reported seeking treatment. (114) Eighty-three percent of men and 89% of women who had multiple symptoms including storage + voiding + post-micturition LUTS also had high rates of bother. Correlates for treatment seeking for both sexes included bother. Women, however, were more likely to report bother from storage symptoms and with combined symptoms (e.g., storage plus voiding or post micturition). In another study of men, 44% of those who reported having UI had sought help and of those, 57% sought help within 6 months of onset of symptoms. The authors noted that perhaps men reported these symptoms earlier than women because of higher level of bother and negative impact on QoL. (115) Secondary analyses of a dataset of adults between 20-94 years who had heart failure revealed sex and age differences. Younger men were more likely to report UI than younger women while the rate of help-seeking was similar between older men and women. (116)
Sex-differences in help-seeking behaviour can exist and research to determine the barriers and facilitators that are shared and differ between the sexes are needed to develop effective strategies to encourage early help-seeking for UI.

Summary

The lack of an accurate denominator to determine the rate of adults who have UI undermines efforts to determine the proportion of adults with UI who seek help from healthcare providers for it. UI affects health-related quality of life (HRQoL) and is associated with activity impairments when compared to continent adults. (117) thus eliminating and minimizing barriers and reinforcing factors that facilitate help-seeking across the lifespan and culture and are sex-specific should be a priority in UI research.

The literature reviewed supported the Model of Pathways to Treatment in that adults reported that they decided that bothersome or severe UI led them to seek help from a healthcare provider for UI symptoms and their consequences. Respondents to surveys also reported that extrinsic factors created significant barriers. Help-seeking is a complex behaviour with multiple factors including social and cultural ones, playing a role. Inclusion of qualitative methods to better understand how men and women who have UI think about and make meaning of bodily changes such as urinary leakage and how they think about the symptoms and their consequences is needed to create foundational research that will lead to help-seeking interventional research. Common terminology and validated instruments are essential to advance knowledge. Analyses that examine sex-differences in factors that act as barriers and facilitators to help-seeking are also needed.

Levels of Evidence/Recommendations

- No RCTs or case-control studies for help-seeking behaviour were located (Level of Evidence 4)
- Recommendation: No recommendation was possible based on the level of evidence provided by the available research.

V. CONTINENCE PROMOTION PROGRAMMES

Literature Search is found in Appendix 1.

1. BACKGROUND

Continence promotion programmes vary across countries and cultures, but all share the same aim of increasing awareness and understanding about incontinence. Efforts to raise awareness of continence issues need to consider the age, gender, and culture of target populations and the key health messages that are being delivered. It is necessary to consult with relevant groups when planning programmes in order to meet the needs of these groups and to enhance health seeking behaviours. Continence promotion programmes need to provide key health messages in the delivery of information about the risk factors and the management options for incontinence, and identify gaps in current information available to different target groups. Different populations likely have different informational needs.

Examples of successful campaigns include the community-based interactive continence promotion workshops conducted in pre-post evaluative study of 90 women in Canada, which were well-received by participants and which changed knowledge, attitudes, skills, and increased rates of help-seeking behaviours. (118) A similar study reported pre and post-evaluation findings from 50 women who attended a nurse-led educational workshop. Symptom and QOL scores significantly improved from baseline to 3 months (Pelvic Floor Impact Questionnaire: mean difference=14.2, p=0.005, 95%CI 4.7–23.8; Pelvic Floor Distress Inventory: mean difference=17.4, p<0.001, 95%CI 8.3–26.5). (37)

Newman (119) conducted a survey of 422 women in the U.S. in order to understand the current patient-professional relationship that could improve communication about continence issues. Respondents indicated they wanted more information about incontinence, and for healthcare professionals and organisations to supply this information to them.

2. CREATING PUBLIC AWARENESS

The use of the internet to find information about UI and its treatment was discussed earlier in this chapter. The internet can also be used to create public awareness. In addition to the internet, public awareness can be increased through print media, television and radio, telephones, and other mobile devices. (120) Specialised health publications developed for different groups in the population have the potential to offer valuable channels for dissemination of evidence-based continence advice. Media channels can also be engaged to disseminate information about incontinence. Journalists often use a “media hook,” i.e., an interesting story that will take priority over other news on the television, radio, or in the newspaper or magazines. In addition, having a spokesperson affected by incontinence or finding a celebrity willing to speak for the cause can help increase awareness. (59) These individuals can act as “influence leaders” or “ambassadors” for organisations.

Continence services play an important role in raising public awareness about incontinence. A study that evaluated health education and public awareness programmes in the UK from 1993 to 1996 in two
Health authorities found the availability of a continence service significantly increased information on how to deal with urinary symptoms. (121) This finding highlights the need for clinicians to provide health promotional information about incontinence as part of their service.

### 3. HEALTH LITERACY

Health literacy related to UI was considered an important component to the delivery of consumer education. The terms “continence” or “incontinence,” “interstitial cystitis,” or “painful bladder syndrome,” and “pelvic organ prolapse” may be poorly understood (122) and simpler terms may achieve greater public recognition across many languages and cultures. The use of “overactive bladder (OAB)” in advertising has increased reporting of the condition to primary care professionals in the U.S. Palmer and Newman (123) reported on a U.S. health promotion project to determine the needs of senior citizens concerning bladder control issues. Focus groups of older adults attending health seminars in urban, community and church settings were conducted. The primary objective of the project was to determine older adults’ understanding about general health and their beliefs about UI. The 82 participants were predominantly African-American women representing all socio-economic levels. These older adults expressed confusion when asked if “overactive bladder, bladder control issues, and UI” were the same condition. An evaluation of Australia’s National Continence Management Strategy in 2006 suggested that consumer education would be strengthened by identification of the most appropriate terminology within key messages to strengthen awareness raising strategies. (124) (125) For example, public education trials have shown improvements in understanding about terminology for prostate disease (108) and sexual health and sexual function. (126)

In the UK, campaigns and consumer literature often avoid clinical terms in favor of lay terms that focus on the need to use the toilet often, worrying that one may not make it to the toilet on time or have “leaking” of urine or feces. In the area of bowel disorders such as FI, people found it difficult to find the right words to discuss their symptoms. (60) The International Foundation for Functional Gastrointestinal Disorders (IFFGD) in the U.S. reported that people with FI will often report having diarrhea to their physician, but do not disclose symptoms of FI. Without the physician or nurse asking direct questions about the ability to control gas, liquid, or solid stool, FI may not be detected.

Lack of understanding about terminology and physiology may lead to difficulties with communication between patients and providers. A survey of 138 women attending continence clinics in the UK, Australia, and Italy found over 20% of women were unsure of the meaning of basic continence terminology commonly used by health care providers. (127) Terms tested in the study included “daytime frequency, nocturia, urgency, UIU, SUI, and hesitancy.” Two studies further highlighted confusion and lack of knowledge about LUTS. Smith and colleagues (128) conducted focus groups with women who experienced overactive bladder (OAB), and found high levels of misunderstanding about symptoms and physiology, and miscommunication between patients and providers. These findings were most pronounced among the older women who participated in this study. Senekjian and colleagues (122) corroborated these findings and recommended that public health campaigns about UI and other pelvic floor disorders should use terminology targeted to consumers who may have basic understanding.

Hougardy et al (129) reported a double-blind RCT in which 129 women in Belgium were randomized to receive an informational leaflet with explanatory information about urodynamic consultation or to a group that did not receive such information. No significant differences in overall satisfaction between groups were found regarding understanding the procedure and reducing patient anxiety.

By contrast, a pre-post survey of 151 women in Canada who had received both written and verbal information about urodynamic investigation prior to the procedure found that 78.1% felt they understood the indications for the testing. (130) Fewer felt they understood what the procedures would involve (68.2%) or that they had enough information about the tests (64.9%). Many women expressed anxiety or embarrassment about undergoing the procedure. A Swedish population-based study found that the distribution of a brochure on UI to the general public was well received and can be an efficient method to spread knowledge and encourage self-management. (131) Another study found that although recall about diagnosis information presented during an initial physician visit can be variable, the visit had enhanced understanding about available treatment options. (132)

### 4. PROGRAMME EVALUATION

Evaluating the effectiveness of health promotion programmes is a complex endeavor. Evaluation methods should be established a priori to implementation of the continence promotion programme. Evaluation should include both quantitative measurements and qualitative measures. According to the findings of a RCT of 145 family members regarding their satisfaction with an intervention to improve incontinence and mobility care for their relative in a NH, open-ended questions rather than “direct satisfaction” questions regarding continence care may elicit detailed and relevant information about the programme. (133) Health promotion evaluation methods include process evaluation, impact evaluation, and outcome evaluation.

Research-based evidence for the effectiveness of programmes aimed at raising awareness of conti-
nence issues or at improving help-seeking behaviours is rare. (134) A number of studies have considered the effectiveness of leaflets or brochures in raising awareness about UI and about treatment options. While the studies were generally supportive of this information, evidence was contradictory in some areas and far from conclusive. In a quasi-randomized controlled study of 1,175 participants, Wagg et al (135) reported that a self-help standard treatment leaflet was as effective as structured help from a continence nurse in reducing bothersome urinary symptoms in women. An Australian study evaluated whether an information leaflet influenced the help-seeking behaviours of 111 people with UI who had reported being bothered by UI, and who were from a broad cross section of patients from acute, subacute, and community settings. Of the 111 people who were able to be contacted, 44.1% indicated the leaflet had influenced their decision to seek help. (136) In a subsequent study using a similar design, O’Connell and Gaskin (137) evaluated the effects of an information leaflet on the health seeking behaviours of 55 people recruited from the waiting rooms of primary care practices in Australia. When interviewed two weeks later, 59% reported they had taken action to manage their UI, and 67.7% reported having done so as a result of the leaflet.

An early health promotion project called ‘Dry Expectations’ was developed and implemented in six ethnically diverse, predominantly minority, and inner city senior centres in the U.S. (138) The programme was designed for an older population. The project consisted of three phases: orientation and training of key staff members/peer educators at the centres (train-the-trainer model); educating seniors through four one-hour weekly sessions involving visual aids and completion of bladder records and quizzes; and follow up sessions with senior staff/peer educators to reinforce the previous training. The programme was very well received by the participants and approximately 80% felt they had more control over their bladder by the end of the last session.

Tuckett et al (139) synthesized evidence from intervention programmes or actions that provided information or attempted to raise awareness about men’s bladder and bowel health. The reviewers identified twelve RCTs and two before-and-after studies were identified. Because of the broad nature of the eligibility criteria, the studies addressed: (i) PFM exercises for prostate cancer, (ii) post micturition dribble, (iii) LUTS: (iv) evidence-based guidelines for the management of UI and/or FI. However, none provide specific outcome data to determine the relative effects of education or awareness raising activities. The reviewers concluded ‘there is little quantitative evidence for the effectiveness of interventions to improve men’s awareness of bladder and bowel health.” (139)

Levels of Evidence/Recommendations

- Continence promotion programmes need to accommodate varying levels of health literacy and access to health information in different populations (Level of Evidence: 4)
- Public health campaigns about incontinence and other pelvic floor disorders need to use terminology targeted to consumers’ understandings (Level of Evidence: 4)
- Satisfaction surveys about continence care could yield relevant and detailed information by using open-ended, rather than closed-ended questions (Level of Evidence: 1)
- Evidence for the use of leaflets or brochures in raising awareness about UI and different treatment options is inconclusive (Level of Evidence: 1).

VI. CONTINENCE ADVOCACY

Literature Search is found in Appendix 1.

1. BACKGROUND

Advocacy is defined as the act or process of defending or maintaining a cause or proposal. Advocacy, as it pertains to incontinence, involves assisting individuals to find necessary health care and treatment. Organisations composed of professional and public members promote continence advocacy as a core mission.

2. CONTINENCE ADVOCACY WORLDWIDE

A central goal of most continence advocacy organisations is raising public awareness and understanding about the types of incontinence, risk factors for incontinence, and available treatments, services, and management products. These organisations provide...
a public voice for an unheard consumer population in political and health-care governance, development, and planning processes. In recent years, consumers and clinicians have been involved in identifying and prioritizing important areas of research relating to incontinence in order to inform research development and funding decisions. (141) (111) In addition, through advocacy organisations, consumers of health care have become more closely involved and influential in the activities of clinical professional organisations.

Another major role adopted by many continence organisations is the direct provision of information support to those affected by incontinence and their caregivers. The types of information provided include information about symptoms, risk factors and associated conditions, treatments and management strategies, and availability of, and access to, health and social services. Such information is provided through a variety of sources, including consumer-oriented magazines, internet-based information resources, telephone support lines (often staffed by qualified nursing or counseling staff), and printed media such as leaflets and booklets on a wide variety of topics. Other innovative strategies have included outreach work through travelling information roadshows and events. (142) Organisations also provided emotional support to people with incontinence by putting them in touch with others similarly affected either through direct contact at meetings or through internet discussion forums.

Continence organisations reviewed varied in scale and in nature, from small consumer or clinician groups that focus on quite specific bladder symptoms or conditions, to large and well-funded national organisations that address bladder problems as a peak body. Often the founding and development of such organisations resulted from the dedication of a small group of consumers, clinicians, or both, that worked to promote awareness and understanding of incontinence among the public and healthcare providers and to provide optimal services and support to those affected. These organisations represented a wide diversity of models, including consumer-led, company-sponsored, consumer-only, professionals-only, and organisations which have deliberately set about trying to bring together all relevant stakeholders in a relatively democratic model. Globally, these organisations played a dynamic role in building both public and professional awareness of this underserved and underreported condition.

Funding

The degree of funding available inevitably affected the level and scope of work. In some countries, such as Australia and to a lesser degree New Zealand, continence support organisations have government support for their work. In other countries such as the U.S. and UK, financial support generally came from charitable donations from individuals and foundations, or through the support of the pharmaceutical industry and continence products manufacturers. Most continence organisations believe that more funding from any source will improve advocacy work but there is no evidence to support this.

Summary

Advocacy is necessary for people who have incontinence and many organisations have advocacy as their mission. A wide range of models of continence advocacy, including collaborative models that bring consumers and different groups of health professionals together, existed. Little research regarding formalized evaluation on the effectiveness of these organizations was located.

Levels of Evidence/Recommendations

- Evidence for the impact of continence advocacy worldwide was based on opinion (Level of Evidence: 4)
- Worldwide Advocacy (Grade of Recommendation: None)

VII. MODELS OF CARE, DELIVERY AND ACCESSING CARE

Literature Search is found in Appendix 1.

1. BACKGROUND

A large cross-sectional community mail survey of women with UI in France, Germany, Spain, and the UK found that many women preferred to be treated for UI by their primary care providers, despite easy access to specialized services. (143) Appropriately trained continence nurses and physical therapists appeared able to provide quality UI care for women. In other studies, women were satisfied with care provided by continence nurses. (144) (145) (146) In the U.S., the health care of older adults who experience UI and FI was provided by PCPs. Drennan and colleagues (147) interviewed thirty-two caregivers about their strategies for managing older adults with UI and dementia. They recommended that professionals, especially those in primary care, should be more proactive in questioning patients about UI and toileting habits to identify counter-productive and harmful strategies. Need exists to consider specialist roles, responsibilities, and protocols to guide appropriate referrals and ensure good collaboration.

Implementation of integrated service mandates can be challenging due to infrastructure limitations and other barriers. To oversee all these problems, a study aimed to provide an evidence-based specifica-
tion for the procurement and organisation of continence care was conducted. Evidence was gathered through a systematic literature review and semi-structured interviews resulting in the Optimal Continence Service Specification (OCSS). (148)

2. NEED FOR SERVICES

No published studies directly compared the effectiveness of specific delivery systems for continence care. Although the Optimal Continence Service Specification (OCSS) produced guidance to service delivery, evaluation of effectiveness of services remains under-investigated.

Knowledge and attitudes about UI and care may influence consumer choices regarding services. Some studies suggest that as QoL worsens, care-seeking increases. (149) In some cultures, particularly those where living with extended family is more common, UI may be viewed as a family issue rather than a disorder affecting just one family member. (150) Family support was often seen as an important component when dealing with UI. (151)

In some studies, many women preferred to take an active role in their own UI care. For example, a survey of 265 Norwegian women with UI, O'Donnell and Hunskaar (152) found that 60% of women wanted to be actively involved in their UI care decisions, compared to only 38% for their general health care needs. (153) This finding may also have been influenced by the context of care and educational level of the woman (152) or associated with the desire for adequate clinical information rather than for active treatment decision-making. (154)

3. MODELS OF CARE

Continence care was defined by the Canadian Continence Foundation as “all measures directed toward the prevention, improvement and or management of UI” (http://www.canadiancontinence.ca/pdf/en_dec2000vol_1.pdf). A report on continence care services worldwide noted that services were scattered, inconsistent and considerable discrepancies exist in their funding. The report concluded that accessible (and affordable) continence care and multidisciplinary teamwork were needed. (155)

In response to this report, a modular service specification was designed, the OCSS. (148) The modules were: 1) case detection, 2) specialist assessment and treatment, 3) case coordination, 4) caregiver support, 5) community-based support, 6) use of containment products, and 7) use of technology (Figure-2). The key recommendations are detailed in Table-1.

### Table-1: Optimal Continence Services Specification Recommendations

1. Ensure ease of access by the establishment of robust referral pathways from detection of incontinence through to appropriate assessment and treatment;
2. Shift the responsibility of basic continence care away from PCPs to continence nurse specialists (CNSs) in primary care where available, where CNSs are unavailable, train existing healthcare professionals such as primary care-based nurse practitioners, community nurses, physician’s assistants or, in developing countries, local community healthcare workers, to provide evidence-based continence care;
3. Where possible, use a case coordinator to ensure collaborative working, especially to help delay or prevent admission of patients to permanent care settings; given the general trend to more integrated clinical pathways, in particular concerning patients with multiple comorbidities, it is necessary to strike a balance between specialization and holistic case management approaches;
4. Promote use of self-management tools and techniques; provision of information on the use of containment products;
5. Emphasize shared decision making between healthcare provider and patient/caregiver; and educational campaigns on the nature of the illness and treatment strategies;
6. Integrate specialists with other parts of the care pathway and ensure they play a key role in quality governance, training and the dissemination of best practice;
7. Use a comprehensive assessment of user, product, and usage related factors to assess the needs of patients and caregivers with regards to containment products. This process should be standardized, valid and easily reproducible. The final decision regarding choice of product should remain with the end-user: the patient and/or their informal or professional caregiver;
8. Use of technology should be integral to the delivery of continence care. Technology should enable self-care and connect patients, caregivers and enable providers to monitor progress and troubleshoot problems;
9. For payers: in order to provide the highest quality continence care, ensure care standards are incentivized. This can be achieved through stipulating the achievement of targets on certain outcome and operational
measures, careful use of quality-related financial incentives, emphasis on clinical governance and optimal pricing that is most strongly correlated to the true cost of providing a service;

10. Establish accredited programmes of training for:
   - Nurses wanting to become CNSs and
   - Other health or social care professionals such as social workers wishing to improve their competence in delivering continence care.

There are many factors that can persuade health care planners about the importance of adequate investment in community continence services. For instance, in the UK in 2015 NHS England launched a national policy document entitled Excellence in Continence Care which provided a framework for commissioners and health care providers to develop continence services that reduce health related harm and costs, were commissioned for dignity and value and ensures that appropriate outcomes were measured. (https://England.nhs.uk. Search for excellence in continence care).

The provision of continence care and services in each country depended on the organisation and infrastructure of its health services. Because UI is prevalent and affects men and women of all ages who receive medical care from a variety of health care providers (e.g., PCP, family physician, geriatrician, gynaecologist, nurse practitioners), there will seldom be one point of entry to continence care. A major barrier to facilitating continence services models was the lack of studies that compared effectiveness of specific continence care delivery systems. A range of existing service delivery models were located in the literature and described below.

3.1. Single Specialist

This service, the most common model in developed countries, was led by a consultant or specialist physician (i.e., urologist, gynaecologist or urogynaecologist). It focused on a “urodynamic unit” that provided medical or surgical treatment with a nurse continence advisor or continence nurse specialist acting as an integrated part of the service.
3.2. Nurse Specialist or Advisor

Examples of nurse-directed models of incontinence care were described in the literature. Farrell and colleagues (156) studied a step-wise care delivery model that included continence advisor and nurses. This model was effective as the traditional medical model. In Australia, New Zealand and the UK, a national network of Continence Nurse Advisors (CNAs) or Continence Nurses liaise, integrate services, and guide individuals through the referral route most appropriate to meet their needs. The efficacy of Continence Nurse Practitioners (CNPs) in the UK was reported by Matharu and associates (157) who studied 450 women over 40 years of age who underwent urodynamic studies in the UK after seeing a trained CNP. In women diagnosed with bladder overactivity, the CNP prescribed medications to 79% of patients and PFM training to 64.8% of the women. In those with urodynamic SUI, 88% had appropriately been prescribed PFM training. Nurses assessed and assigned women to appropriate conservative treatments, resulting in shortening waiting times for urodynamic and specialist assessment.

Choi (83) performed a case-controlled intervention study with primary care patients (male and female) who had LUTS in China. An intervention group (N=360) received a nurse-led continence care programme and a control group (N=360) received usual care by their PCPs. Outcome measures included symptom severity, HRQOL, self-efficacy, global health, and self-reported health service utilization at 12-months. The intervention group had significant improvements in LUTS severity and HRQOL, although improvements in the amount of urine leakage were not significantly different between the two groups. A higher proportion of intervention group (as compared to control group) reported increased self-efficacy (43.48% vs. 66.83%), improved global health condition (17.74% vs. 41.5%), having doctor consultation (18.5% vs. 8.06), having medication due to LUTS (26.50% vs. 11.29%) and having non-drug therapy due to LUTS (59.5% vs. 9.68%).

Despite evidence for active intervention, emphasis often remains on urine containment and passive UI management rather than on active therapy. An audit of the continence services in the UK revealed that rationing of pads and absorbent products was widespread, with most patients limited to four pads per day. (158) In addition, 59% of the continence services surveyed provided pads for children under the age of four, which was outside of the published national guidelines. These findings indicated need for improved implementation of continence services, especially in relation with rationing and use of pads and products.

There is a long history for the efficacy of specialist NCA in the delivery of community continence care. (159) (160) (161) (162) In the U.S., urology nurses have been trained as “teachers” to successfully implement behaviour modification programmes to groups. (163) Nurse providers played an important role in the evaluation and management of POP, a condition which is often associated with concomitant UI. (164)

Lee (165) reported findings from a study investigating the introduction of nurse consultants (NC) in Hong Kong. The study focused on a range of patient outcomes including UI. A total of 280 patients, 140 in each cohort under NC or non-NC care, participated in the study. The study showed that patients under NC care had favourable patient health and service outcomes compared with those under non-NC care. The NC cohort also reported a high level of patient satisfaction.

Holtzer-Goor (166) conducted a study investigating cost-effectiveness of inclusion of a nurse specialist in the treatment of UI in primary care in the Netherlands. A decision analytic model was developed comparing the current care pathway for UI in the Netherlands with the pathway as described in the OCSS. (148) The new care strategy was operationalised as the appointment of a continence nurse specialist (NS) located with the GP. With the new care strategy, a QALY gain of 0.005 per patient was achieved while saving €402 per patient over a 3-year period. Although no health gains were achieved in both groups, the authors concluded that a NS in the GP practice would likely reduce UI, improve QoL, and reduce costs.

3.3. Multidisciplinary Resource and Referral Centre

Multidisciplinary clinics, as service models, have been shown to provide comprehensive continence care. The Continence Foundation of Australia (CFA), funded by the Australian Government, employed CNAs to answer the National Continence Helpline and to provide advice to consumers and health professionals, including referral advice. (167) Evaluation of this service indicated availability and uptake of information, as well as increased traffic to the Bladder and Bowel website and the National Public Toilet Map. There had also been a general increase in the number of consumers seeking help for their incontinence.

Multidisciplinary services should initially focus on a step-wise approach to evaluation and management. This need not be limited to tertiary level centres, but can be incorporated into care in local communities when providers with expertise are available. (168)

3.4. Primary Care

Although most primary care practitioners recognize that UI is common, only a minority had an organized plan for its evaluation and management, and few PCPs reported feeling very comfortable dealing with UI. Over 70% of GPs in Canada felt fairly confident in managing UI. (169) Most family physicians referred patients for specialist care, with few referrals to com-
community services. Respondents thought that continence services were scarce, with long waiting times, and that such services were generally overstretched. They also believed that although high-quality continence care was a personal priority, it was not a priority focus for their practice partnerships or networks. In terms of the highest ranked areas for improvement in UI management were: increased awareness and understanding among physicians (ranked first by 28.5% of respondents), followed by dedicated incontinence clinics or nurses for referral (17.7%) and improving patient awareness and understanding (12.0%).

Early attempts by the U.S. Agency for Health Care Policy and Research, now known as the Agency for Healthcare Research and Quality (AHRQ), to use physician group interventions to raise awareness through UI guidelines failed to improve screening and management rates in the primary care setting. (170) Yazdany (171) prospectively randomized patient charts (n=88) to carry a chart-alert sticker (e.g., “Do you leak urine?”) that reminded resident physicians to ask about UI in their general gynaecology clinics. Overall, resident physicians’ inquiry rate about UI increased from 4% to 34%.

Quality of primary care delivered by nurses was found to be similar to physicians, with nurses providing more health advice and achieving higher levels of patient satisfaction compared to doctors. (144) A RCT in the Netherlands compared usual care for UI in GP clinics to those that included a nurse specialist. (172) Short-term outcomes revealed better continence rates in those patients seen in clinics that involved care by the nurse practitioners. The results were not sustained at the one-year follow-up with both groups having equivalent continence outcomes. A focus group analysis with the nurse practitioners revealed that they felt competent to provide the needed services and appreciated by patients. (174) In addition, nurses thought they added value to the practice, particularly since many of the GPs were seen as lacking interest in UI.

The first point of contact for persons with UI is usually the primary care practitioner but ongoing management requires a care delivery model (see Figure-2) based on a chronic care approach that has been used successfully in other chronic conditions (e.g., diabetes, CHF, asthma). (175)

### 4. OTHER SERVICE MODELS

In a structured literature review, Chin and colleagues found that primary care clinics for continence led by nurses and allied health professionals were common across the world. (176) Although there were a number of differences that were culture specific, there were also a number of key factors that predicted quality care across all cultures. These included identification and recruitment of appropriate patients, improving access to care, enhancing engagement with primary care providers, using small teams with adequate training, developing structured referral lines, and working to employ evidence-based practices including guidelines and treatment protocols.

Group intervention models for delivering first-line treatment for UI has long been found feasible (41) (177) (178) (179) and these models may be an equally effective and potentially cost-saving approach. (180) Another study has shown that non-medical lay instructors can be taught how to instruct patients in proper PFM exercises. (181) This train-the-trainer model may be useful to help disseminate behavioural therapy on a more widespread basis.

Internet based services are becoming available. Bjork (182) conducted telephone interviews amongst 21 women with SUI who participated in a RCT study comparing two treatment programmes based on instructions for PFM training. One programme was internet-based and included email support by an urotherapist; the other programme was delivered by post. Neither programme had face-to-face contact. A supportive patient-provider relationship was developed in the internet-based programme, despite the lack of face-to-face contact which has promise in increasing access to care and empowering women.

### 4.1. Setting Specific Models

Continence promotion, education, and treatment may occur in a variety of clinical settings, particularly in relation to other associated clinical conditions. For example, UI occurs commonly after acute stroke. Rehabilitation nurses who work with post-stroke patients could play an important role in continence care, however research shows this may not happen regularly. Heart failure is another common clinical condition, particularly among older adults, that is associated with UI. A study of 182 heart failure patients with at least monthly UI revealed that 83% had not asked for help with their incontinence symptoms and 64% were interested in learning more. (183) Many patients, particularly those with concomitant diabetes, were contemplating changing their behaviours and seeking care for UI. These findings indicate that this group may be receptive to education and interventions that improve urinary symptoms.

A multinational qualitative study examined data from focus groups of rehabilitation nurses in the UK, Sweden and China. (184) They found that only a superficial assessment of continence was routinely performed by most nurses in this setting. The authors noted a focus on containment and social continence although process models of practice were seen in all countries. In line with these findings is the conclusion of Edwards (185) who investigated patients aged 65 years and older with a fragility fracture as a result of a fall. Of 3184 patients, 63% (2009) were assessed for urinary continence following a hip fracture and 41% (817) of these identified a problem. Twenty-one percent (1187) of 5642 patients with non-hip fragility fractures were assessed and a problem was found in 27% (316). Hip fracture patients were more likely...
(p=0.0001) to receive a continence assessment and have problems detected. Only about half of those with problems had any intervention or a referral to a continence service. Admission to hospital for non-hip fracture patients was a strong predictor of being assessed (p=0.0001). Edwards concluded rates of assessment and action for those who fall and have continence problems are low despite current national guidelines.

Acute care, where older adults comprised the largest segment of the population being admitted to it, was reviewed. This setting provides care to manage short-term, but urgent, health problems and UI was prevalent. A prospective cohort study of 577 patients (mean age 82 +/- 6.9 years) admitted to general medical wards of three acute care hospitals in Brisbane, Australia, found UI rates of 43.8% (243/555) premorbid, 36.7% (176/479) during admission, and 35.3% (187/530) at discharge. (186) Moreover, of 438 patients at the time of discharge, 38 (12.8%) had new onset UI. One group of patients with a high risk for developing UI in hospital are female hip fracture patients. In an older study, secondary analyses of data from 6,516 hospitalised women with a fractured hip revealed 21% became incontinent during hospitalisation. (187) Similar findings were reported for elderly patients admitted to hospitals in Israel, (188) Switzerland, (189) and Italy. (190)

Zisberg and colleagues (188) conducted a prospective cohort study of 352 patients aged 70 and older who were continent prior to admission to an acute care hospital. They found, 17.1% developed UI during their hospitalization, and in a multivariate analysis, the use of a urinary catheter or diaper were associated with the development of UI (4.26 95% CI 1.53-11.83 and 2.62 95% CI 1.17-5.87 respectively). Zurcher and colleagues (189) surveyed 78 elderly inhabitants in a Swiss hospital and found 41 (51%) screened positive for UI, yet only 10 (24%) of nursing records documented the presence of UI. Moreover, the use of absorbent pads was the only intervention documented. The number of patients who declined to be asked about their continence status was minimal (n=5).

Other research on UI in acute care drew attention to an overreliance on continence aids, and inadequate attention to identifying and addressing potentially contributing factors. For example, Ostaszkiewicz and colleagues (191) conducted a point-prevalence survey of 447 hospitalised older adults in acute and sub-acute care settings in Australia and found 60% with a continence product or device, however, 50 (41%) patients with an absorbent pad denied having experienced UI or FI in the preceding 24 hours. By contrast, 113 patients (16%) who reported UI or FI in the same period had no continence product or device.

4.2. Elder Services (Long Term Care or Nursing Homes)

Long term care for frail elderly persons is provided in a variety of types of institutional settings throughout the world. Continence care in these settings is dependent upon many factors, including: type of resident care need (those requiring long-term skilled and personal care, short-term rehabilitation, post-hospitalization care); physical environment; the organisational culture and leadership commitment to providing high quality care; the number, education, and motivation of direct care staff; access to physicians with interest in and understanding of continence care; and financial and regulatory incentives to provide appropriate continence care.

Despite UI being a quality indicator in U.S. NHs, significant barriers to translating research on prompted voiding and other interventions into practice existed. (192) This issue is especially concerning given the current and future growth in the frail elderly population. Available evidence indicated that the focus was too often on containment and use of pads or absorbent products compared to active continence promotion or treatment. A Cochrane review supported this finding, and noted that none of the studies reviewed focused on attempts to maintain continence in facility residents. (193) A systematic review of systematic reviews on the most frequently used behavioural interventions used in long-term care indicated limited evidence for short-term effectiveness. (194) Barriers for improving continence care were considered multi-level and included: lack of knowledge about UI, beliefs about UI, high work load, low commitment from co-workers, and lack of institutional support. (195) Multiple strategies were seen as necessary in order for quality improvement in continence care to occur. These included creating a sense of urgency about the problem and a sense of solidarity among co-workers and facility administration. Managerial oversight and communication about the evidence of performance before and after the quality improvement program, and use of evidence to make decisions about how to modify the programme were considered essential to programmatic success. (192)

Little evidence was available to determine how older adults who received the interventions perceive and respond to them. (196) Higher registered nurse to patient ratio was identified as a facilitator or better continence care. (197)

An innovative model described the development of individualized continence profiles for use with NH residents (198) that could help NH staff identify residents who may benefit from various forms of assessment and interventions. Another model previously worked to involve NH residents more actively in their fluid intake and continence care. After a 12-week intervention, overall hydration status improved and time spent in saturated incontinence absorbent products decreased significantly in a cohort of 153 NH residents who participated in the intervention. (199) Distance learning techniques were successfully used to teach and implement programmes and strategies for management of UI in NH. (200)
5. MODELS IN DEVELOPING NATIONS

Continence services are a relative luxury, to which countries with a low per capita income are unlikely to devote scarce resources, especially while other population health issues have precedence.

The potential demand for UI services in developing nations far outstrips the resources that are available. The provision of services will depend on dedicated healthcare professionals with support by government or industry, and by a local continence organisation to educate a new generation of service providers who will carry the services to remote communities. Increased use of advanced communication technologies can help to disseminate continence promotion materials among nurses and other health professionals worldwide. (201)

Summary

A range of service delivery models exist; single specialist, nurse specialist or advisor, multidisciplinary resource and referral centre, primary care and other models (acute or subacute care, elder services at home or in long term care and models in developing countries). Within this spectrum the evidence supports nurse-led community services leading to higher health-related QoL and in some instances higher cure rates. The multidisciplinary referral settings are reporting also favorable outcomes. There remains discrepancy between availability of guidelines for different healthcare delivery settings and actual daily practice. The Optimum Continence Service Specification has shown that within a 3-year period, this model of care can be cost-effective, especially when societal costs are taking into account. Further research on cost-effectiveness and patient-level effectiveness of models of continence care in a variety of healthcare delivery settings is urgently needed.

Levels of Evidence/Recommendations

- Effectiveness of service delivery models. (Level of Evidence: 4)
- A care delivery model should be based on the principles as described in the Optimum Continence Service Specification. (Grade of Recommendations: C)
- Increased emphasis is needed on non-physician models of care (nursing, nurse practitioner, continence advisor, physiotherapy, physician assistants, etc.). (Grade of Recommendations: C)
- Despite the proliferation of guidelines, there is increasing evidence that practicing clinicians and nurses (in the community, acute care, and in long term care) are not consistently following them. Implementation models should be developed on how to translate guidelines into practice. (Grade of Recommendations: C)

VIII. EDUCATION

1. BACKGROUND

Professional education regarding continence occurs in a wide variety of settings ranging from undergraduate education in medicine, nursing, physiotherapy and other related disciplines, through the full continuum of graduate education and ongoing professional education. This includes both formal education incorporated into established curricula or clinical experiences, and informal types of education such as on-the-job training and point-of-care instruction. Education may be directed toward generalists or specialists and will differ based on the topic of interest and the target learners. The focus of educational topics can range from evaluation and care of individual patients or clinical conditions, to population health and health policy. Examples of clinical education could include surgical skills training for surgical residents and fellows, community and ambulatory care, bedside, or operating room care for nurses, or biofeedback training for physical therapists. This section reviews professional education on continence from a broad perspective across disciplines and specialties.

2. MEDICAL EDUCATION

2.1. Generalists (family physicians/general practitioners/primary care physicians)

Physicians (general, primary care, and family physicians) traditionally have been viewed as having a gate-keeping role in continence provision since they are often the most likely first point of contact when adults seek professional help for their incontinence. Most physicians have received little education or formal training about incontinence, fail to screen for it, and view the likelihood of successful treatment as low, leading to most physicians avoiding the topic with patients. At the same time, there are no data confirming the benefits of screening as a method to reduce the burden of suffering from UI. An earlier postal survey noted that only 18% of respondents said providers asked them to complete a questionnaire about bladder control during routine office visits, and a majority (69%) felt it would be very helpful in prompting discussion if their physician or health care professional provided a form for them to check off symptoms of incontinence. (119)

Traditionally, UI and FI formed a very small part of the undergraduate medical curriculum. Education on UI has been fragmented across different organ systems,
with training scattered among gynaecology, urology, and geriatric medicine. Bladder and pelvic floor anatomy is poorly covered in preclinical training and relevant physiology is rarely mentioned. One study found that exposure to issues of pelvic floor dysfunction in women was extremely limited in medical education, with more than 80% of medical students receiving no formal training in this area during the first two years of training. (202) A national survey of medical school Deans in the UK in 2008 found that information on UI was included as part of education on geriatric syndromes in essentially all schools, although the response rate to the survey was 61%. (203)

A survey of programme directors for internal medicine residency training programmes in the U.S. was conducted to determine whether they believed their residents should master thirteen core competencies. (204) Although almost all believed it was an important goal, there was a large discrepancy among programme directors whether residents actually achieved this level of learning.

There is very little available literature on knowledge among family doctors on FI. A study explored GPs awareness of surgical treatment options for FI. (205) A postal questionnaire was mailed to 1,100 GPs in the Yorkshire region in the UK, and a response rate of 48.5% was achieved. The questionnaire assessed basic knowledge of FI and treatment options. Overall knowledge was poor, with the majority unaware of available investigations, treatments, and specialist centres. The authors recommended better communication between specialist centres and GPs, as well as continuing medical education (CME) programme implementation.

Several studies examined physician attitudes about diagnosis and management of UI and associated conditions. In one survey of 55 PCPs in the U.S., most indicated that they understood UI and that it was a common condition among patients in their practice. (206) Although 56% of these physicians felt comfortable asking about UI, only 19% felt comfortable making a correct diagnosis, and only 11% felt comfortable providing actual treatment for UI to their patients. These providers thought that differentiating types of incontinence was difficult (59%) and that managing UI was difficult (69%). Lack of familiarity with screening tools and treatment algorithms were also cited as barriers. Time did not appear to be the driving factor with only 26% reporting that time was a major limitation.

In a similar survey study of family practitioners in Canada, 24.1% reported receiving no training in UI management beyond their residency. (169) Although 53.8% reported proactively discussing UI with their patients, and 70% felt confident managing the condition, the majority still referred their patients to specialist providers. They did not tend to refer for community-based services due to perceptions about lack of available resources and long wait times. Case-based curricular materials have been shown to be effective in urology residency education. (207) One Canadian study surveyed urology residents in training, and found that there was a desire for more structured education in patient-provider communication skills. (208) In another project, training about UI was included with a number of other geriatric syndromes.

(209) Those internal medical residents who received the information via internet-based methods had better overall test results than those who completed paper-based training. A recent survey of residency programme directors in paediatrics in the U.S. found the vast majority (85%) did not require clinical experience in paediatric urology although 65% did have some didactic education. (210)

Some models of physician education have incorporated training on UI into modules on quality care. For example, the Assessing Care of Vulnerable Elders (ACOVE) project in the U.S. includes UI as one of the target conditions. A recent study investigated implementation of this information into community-based physician education within practice groups. (211) These authors found that dissemination of this information was better received by PCPs, and some intended to make changes in their practice related to this new knowledge. Similar studies have also found that PCPs specifically educated about UI assessment and interventions were more likely to recommend care for UI to their patients. (212) (213) Collaborative practice by physicians and nurse practitioners yielded better overall outcomes for the ACOVE quality assurance measures, including those for UI. (214)

2.2. Specialist Physician

There was little new published evidence on medical specialist training in the form of effective training interventions. Specialist training in incontinence is not always adequate. Both UI and FI still may be perceived as exclusive to “super-specialists,” potentially alienating colleagues.

Even among subspecialists, training may not be ideal. Marsh and colleagues (215) surveyed 100 gynaecologists and urologists in the UK and found widespread inconsistent and inappropriate diagnosis of BPS/IC. A survey of general gynaecologists showed a wide variation in comfort dealing with issues related to UI and prolapse. (216) Most felt comfortable with basic surgical procedures for UI and straightforward anterior and posterior prolapse, but less comfortable with complex clinical scenarios including apical prolapse and treatment of UI after prior failed procedures. Of note, newer graduates and younger surgeons tended to have a much more limited repertoire of surgical options that they used in their practice. Another study of recent general gynaecology residency graduates found most performed midurethral slings for incontinence and felt comfortable doing basic anterior and posterior repairs for prolapse, however, few actually did other more complex urogynaecological procedures in practice. (217)
Some gynaecology programmes include education on basic cystoscopy to detect for potential intraoperative injuries during hysterectomy or other pelvic surgery. However, not all graduates intended to use this diagnostic tool, with higher rates reported by urology fellows compared to general gynaecologists. (218) An initiative to train community gynaecologists in this technique was located. (219)

Structured training and curricula have been developed for a variety of surgical procedures used to treat UI and POP. (220) Inclusion of this training in residency will lead to increased numbers of physicians who are qualified to offer this type of care to patients suffering from UI. A variety of models have been developed to help teach some basic skills such as cystoscopy or methods for grading the degree of POP. One option includes the use of cadaver labs. (221) Others options have used inanimate objects to replicate the female pelvis and teach basic anatomic concepts. (222) (223)

In the U.S., subspecialty certification in Female Pelvic Medicine and Reconstructive Surgery (FPMRS) began in 2013. This certification is offered through joint sponsorship by the American Board of Urology and The American Board of Obstetrics and Gynecology. During the first three years, candidates who met strict criteria were allowed to take the certification examination without necessarily having completed a formal fellowship training experience. However, starting in 2016, only candidates who have completed a fellowship approved by the Accreditation Council on Graduate Medical Education (ACGME) will be eligible for FPMRS certification. All successful candidates will require ongoing maintenance of certification (MOC). Audits of surgical logs among those completing FPMRS certification show they tended to be doing more complex surgical cases for UI and POP compared to their general urology colleagues undergoing general urology recertification. (224) (225)

Continued emphasis on quality education for specialist physicians is needed worldwide. (226) Many current and recent FPMRS fellows indicated in survey research that they are interested in gaining experience in global healthcare, and potentially incorporating international work into their practice. (227)

In addition to the FPMRS fellowship and certification pathway, there are also unaccredited fellowship opportunities in women’s health. Most of these are offered collaboratively through academic departments of internal medicine, family medicine and obstetrics and gynaecology. These programmes provided the opportunity to gain specialized training in the nonsurgical aspects of women’s health care including UI and associated conditions. However, knowledge about these opportunities for professionals was generally low, and the programmes lacked formal accreditation. (228)

A study of gynaecologists in Germany found that most considered their specific post-graduate training in urologic issues and urogynaecology to have been inadequate. The vast majority of general gynaecologists in this study referred their patients with voiding or incontinence issues to subspecialists in urology or urogynaecology.

Duty hour limitations have been imposed on residency training in the U.S., Europe, and many other regions. There has been concern that this could have a detrimental effect, particularly on surgical specialist education. (229) (230) However, although one survey demonstrated obstetrics and gynaecology residents performed substantially fewer numbers of some types of surgical procedures, those for UI and POP did not appear to be negatively affected. (231) Similar studies have shown no appreciable decrease in surgical case volume among urology residents. (232) (233)

Approximately 10% of graduating urology residents did not currently meet the nationally recommended standard for surgical case experience for male urethral reconstruction, penile operations, or surgery for male UI. (234)

Linking education on UI to geriatrics may be limiting for some specialists. A recent survey of surgicaltrainees in the UK demonstrated that in general, they felt inadequately prepared to provide care for older adults with complex clinical geriatrics issues. (235) Script concordance models have been developed to assess clinical reasoning skills related to care for UI in older adults. (236) A recent study using script concordance found that compared to expert surgeons, general gynaecologists who had large practice volume for procedures related to incontinence and prolapse did better than new residency graduates and those who had been in practice the longest. (237) Ongoing education and utilisation of evidence-based training with incorporation of guidelines have been suggested as a strategy to maintain high quality standards of treatment, particularly for surgical care of UI. (238)

Due to an ever expanding geriatric population, there is a recognized need for expansion in the workforce among urology, reconstructive surgery, and other specialties that provide care for UI and associated conditions. (239) (240) (241) There is a particular need for expansion of the workforce in academic urology to accommodate increased education of specialists, including those in FPMRS. (242) This is true in Europe as well as in the U.S. (243) However, funding for graduate medical education including faculty expansion is an important barrier to expanding the educational pool in fields like urology, particularly in the U.S. (244)

Urology and gynaecology residency training opportunities have been expanding worldwide including in developing nations in Asia, Africa and the Middle East. (245) (246) (247) There has also been an increase in efforts to improve education about diagnosis and treatment of genitourinary fistulae. (248)
Increased training and utilization of nurse practitioners, physician assistants, and other advanced practice providers in urology and gynaecology has been incorporated in some clinical practices, particularly in the U.S. (249) This may be a particularly effective method to address workforce shortages in some areas. Development of specific educational programs and competencies for these types of providers will also be important for these types of practitioners. (250)

3. NURSING EDUCATION

Literature Search is found in Appendix 1.

Nurses play a significant role in the area of incontinence since they are the largest single group of health care professionals around the world and they are often the first to become aware that a person is experiencing incontinence. There have been a number of recent studies that explore the use of new innovative methods of education provision for nurses.

The continence education process should start at an undergraduate level and continue through updates or enhanced learning post qualification. McClurg et al (251) undertook a survey of all UK Higher Education Institute's to establish the amount of undergraduate continence related education within relevant health care programmes including adult, mental health, learning disabilities and children's nursing, midwifery, occupational therapy, and physiotherapy. The mean number of hours was 4.7, with adult nurses receiving the most education totaling 7.3 hours. However, 41 out of 294 responders reported no continence related education in their undergraduate programme.

3.1. Generalist Nurses

Innovative methods of improving knowledge among nurses have undergone recent evaluation. An important study undertaken by Cheater and colleagues (252) added to the debate by examining the value of audit and feedback, and educational outreach, which in the past has often focused on doctors' behaviours rather than nurses'. In this study, the researchers undertook a cluster-randomized trial to evaluate 194 nurses in 157 family practices with 1,078 patients with a diagnosis of UI. They found that when compared to educational materials alone, there were no improvements in care for either educational outreach or audit and feedback (all groups did improve, but differences between groups were not significant).

Ostaszkiewicz (253) described a nursing leadership model to enhance continence care in older adults. Evaluation of the programme suggested improved management and assessment of incontinence for individuals sustained after a two-year period. Leadership programmes have proved effective in a number of areas in nursing provision. Within these more recent studies, the use of innovative methods of knowledge transfer and education are beginning to be adopted, and such methods used in other areas of professional education may be well suited to UI and FI.

Education related to UI may often be linked to training about other concomitant disorders or conditions. For example, training on prevention and treatment of pressure ulcers or dermatitis may include significant components related to UI. (254) (256) (257) Training about improved mobility and care following a stroke in the geriatric population has also shown this educational link. (258) (259) These findings can facilitate efforts to disseminate information about continence care and promotion to a wider audience of nurses who have direct patient contact.

Although advanced practice registered nurses (APRNs) have sufficient knowledge and positive attitudes about treating UI in women, many have difficulty applying them into practice in the clinical setting. (260) These authors suggested that increased exposure to these topics in clinical experiences during training for graduate nurses is needed.

Programmes have focused on nurse education for continence care in specific settings, such as the NH. (261) Competency-based UI education with use of case examples has been used successfully in the training of generalist nurses. (262) Experiential activities have also been used with good results. (263) Interprofessional, simulation training has also been shown to be effective for teaching continence assessments in geriatric medicine. (264)

3.2. Specialist Nurses

Educational courses on incontinence are available for nurses in the UK, U.S., Europe and Australia, and have appeared in Asia, notably Hong Kong and Singapore. These courses vary from two to four weeks of face to face didactic courses to distance learning courses lasting 12 months that lead to a post-basic nursing certificate and, in some cases, post-graduate degrees.

In the UK, education programmes are documented at the Association for Continence Advice website (http://www.aca.uk.com/education_modules.php) and comprise information on 1 day courses, as well as diploma courses, degree modules and masters level study. Such databases of courses offer an excellent overview for students and providers. Likewise, the Continence Foundation of Australia (http://www.continence.org.au/pages/continence-courses.html) provides nurses access to information and links to educational organisations that provide a variety of programmes which focus on or incorporate both UI and FI content in the curriculum. Many can be continued through to post-graduate tertiary education. A number of these programmes can be undertaken externally and therefore are popular with nurses in rural and remote areas, as well as nursing students practicing in other countries. Clinical support complements the theoretical components. Lack of funding was a barrier to access to education with up to 71% of specialist nurses in the UK reporting that
they were unable to access funding or study leave from their employers for these courses. Many nurses were self-funding or accessing education through professional associations (All Party Parliamentary group. (2013), Continence Care Services England 2013, Survey Report, www.appgcontinence.org.uk).

Internationally, inconsistency in the provision of specialist education to prepare nurses to practice as experts in the field of incontinence existed. Innovative internet-based learning programmes incorporating modern information and communication technology (e-learning) may offer one way of providing standardized programmes of study to practitioners.

A Minimum Standards in Continence Care has been developed by the UK Continence Society to set required standards and a competency framework for education and training of all health care professionals (HCPs) to ensure that they have attained the training requirements to work within their designated role. (265) However, without standardized education, these recommendations can be difficult to implement and monitor.

Beitz and Snaporis (266) described an innovative online learning programme which included continence nursing. As with physicians, it was unlikely that improving nursing knowledge alone will translate into improved clinical practice or into the ultimate goal of improved patient outcomes. De Gagne et al (267) have demonstrated how e-learning UI educational courses in South Korea were useful to support nurses in isolated and rural areas who had limited resources.

Improved education of school-based nurses regarding normal bowel and bladder habits of children may have helped to improve paediatric continence and promote healthy elimination patterns. (268) Although 61% of school nurses surveyed reported they had never received training on the topic, many (43%) had been asked to provide information to their teacher colleagues.

In the U.S., there were no academic or clinical proficiency requirements to be considered a continence nurse practitioner or specialist. (269) In 1993, the Wound Ostomy Continence Nurses (WOCN) Society developed the first certification programme for continence care nurses in the U.S. This nursing organization published a position statement on the role of continence nurses (270) and core curricula for continence management (http://www.wocn.org/, accessed December 8, 2016). The Society of Urologic Nurses and Associates (SUNA) certified different educational levels of nurses in the area of urology and in urodynamic testing. This organization published the Scope and Standards of Practice with Competencies of the Urologic Registered Nurse and Advanced Practice Registered Nurse that includes care of the urologic patient with UI and POP. The norm is that most “continence” nurses in the U.S. obtain their knowledge and skill through self-motivated activities.

To date, most of the focus on UI education has been at the baccalaureate and advanced degree levels while some discussion has focused on whether specialty training in wound, ostomy, and continence nursing should be at the doctoral level. In the U.S., the new Doctor of Nursing Practice (DNP) degree may help to fill this training gap. (272)

A study of 231 vulnerable elders with complex disease and enrolled in a 'Special Needs Plan' in the U.S. showed the benefit from a nurse care management programme with nurse practitioners in addition to physician care, as opposed to those who received care from a physician alone. (213) This model has continued to develop and requires further evaluation.

Albers-Heitner and colleagues. (273) evaluated the cost-effectiveness of involving UI nurse specialists in primary care compared to care-as-usual by GPs. From 2005 until 2008, an economic evaluation was performed alongside a pragmatic multicentre RCT that compared patients with UI receiving care by nurse specialists with patients receiving care-as-usual by GPs in the Netherlands. One hundred eighty-six adult patients with SUI, UUI, or mixed UI were randomly allocated to the intervention and 198 to care-as-usual; they were followed for 1 year.

Main outcome measures were ‘QALYs’ (Quality Adjusted Life Years based on societal preferences for health outcomes), the EuroQol-5D, ‘QALYpatient’ (based on patient preferences for health outcomes) (EuroQol VAS), and ‘Incontinence Severity weighted Life Year’ (ISLY) based on patient-reported severity and impact of UI (ICIQ-UI SF). Health care resource use, patient and family costs, and productivity costs were assessed. Compared to care-as-usual, nurse specialist involvement yielded slightly more favorable cost-effectiveness results. Based on these results, the authors recommended adopting the nurse specialist intervention in primary care.

One area of specialist nursing that has limited research into outcomes of continence care and education is midwifery. There are a large number of women that develop bladder and bowel issues throughout pregnancy and postpartum yet no available evidence was located on the impact that midwives can have on early detection, intervention, or prevention.

3.3. Nursing Assistants

A cross-sectional study via postal survey to gather self-reported data from nurses and NAs in NHs was conducted in Taiwan. (274) Results indicated UI-related knowledge scale and practice behaviours differed significantly in both groups. The authors recommended that enhancing staff competence in incontinence care was needed in both levels of nursing to improve NH residents with UI. Educational efforts, particularly in the NH setting, must involve not only professional nurses, but NAs and other staff, as well. Blekken et al (275) have recently reported on a pilot
study to trial methodology prior to a cluster RCT on the feasibility, acceptability and adherence of two educational programmes for care staff concerning NH patients’ FI.

### 4. OTHER ALLIED HEALTH PROFESSIONALS

#### 4.1. Physiotherapists or Physical Therapists

Physiotherapists (PTs) have long played a part in continence care and the management of UI. In some countries, patient self-referral to specialised PTs has become commonplace. Physiotherapist’s involvement in UI appeared to be either on the basis of individual interest or through association with women’s hospitals or obstetric departments, rather than as part of a general physiotherapy practice. (276) As such, they tend to be highly motivated and enthusiastic.

Generalist PTs have been encouraged to be more aware of the risk factors for incontinence in males and females, to identify patients with risk factors and to assist them in seeking further advice or treatment. Throughout the world national physical therapy organisations have established continence physiotherapy sub-groups. (277) The International Organisation of Physical Therapists in Women’s Health represents over 20 member countries with PTs practicing continence and women’s health physiotherapy and offers professional development programmes. A number of specialist continence PTs also treated men and children. Universities in many countries offer short courses or post-graduate continence education programmes to PTs that may range from post-graduate degree courses to Masters and PhD programmes. (278)

The Scope of Practice for continence PTs may include PFM training, bladder training, management of sexual dysfunction, ano-rectal dysfunction and treatment of pelvic pain syndromes, FI and male continence issues.

Regulatory issues mentioned were often linked not only to quality of care, but also to reimbursement for clinical care and services. Reimbursement policies for services frequently determine which professionals are able to provide continence care. In the Netherlands, for example, the government paid for up to 14 visits to a physiotherapist for incontinence therapy. In the U.S., patient’s visits to a physiotherapist were typically restricted by the need for referral and cost. In some countries, physiotherapists had to prove a certain level of specialist education to ensure full insurance reimbursement.

#### 4.2. Pharmacists

In Australia, pharmacists have been avid consumers of continence education programmes. In 2004, the Pharmacy Guild launched an educational and promotional programme for their members with appropriate outcome evaluation measures. The public sees pharmacists as important and approachable sources of health information, especially information on medicines that may cause or exacerbate UI and FI. Many retail pharmacies displayed health promotion literature on a range of subjects, including UI. Pharmacists may also advise the consumer on appropriate continence products. Educational seminars for pharmacists were reported to be generally well received. There were a growing number of CME programmes for pharmacists on the internet, either through new products or through sites such as www.worldwide-learn.com.

**Summary**

Although there are a wide variety of educational programmes available across disciplines and specialties, overall education on continence and associated topics lags well behind other clinical topics in most professional educational settings. Many health care providers do not receive formal education on UI, FI, or other continence-related topics as part of their general education. These topics are included in some general practice education settings, but most often these are limited to the graduate level of instruction such as graduate nursing programmes, medical and surgical residency or fellowship. There is an ongoing need to continue to expand and evaluate educational offerings on topics related to continence and bladder and bowel health across all levels of training and for both generalist and specialist professionals.

**Levels of Evidence/Recommendations**

Professional education of UI, FI and POP is not evident based on the materials reviewed. (Levels of Evidence: 3-4)

- There is a need for research on both educational content and methodology across all disciplines, particularly as the emphasis on primary care education increases and the opportunities for exposure to targeted content decreases
- There is a need to identify the extent to which education, particularly at the undergraduate level, translates to actual practice in clinical settings
- There is a need for research on content development and delivery to teach and assess basic clinical skills including those that every professional should acquire (e.g., History gathering and physical examination, development of care plans, urinary catheter placement) as well as specialized skills (e.g., surgical technique, urodynamic assessment, pessary placement)
- There remains a need for research on educational methodology and modes of instruction for
continence care including active-learning experiences, modular education, self-directed learning, distance-learning, online learning.

- (Grade of Recommendations: D)

### 5. IMPACT OF CLINICAL GUIDELINES

Literature Search is found in Appendix 1.

In the past several years, there has been an explosion in the rate of development and publication of clinical guidelines for UI and associated conditions. Since the last ICI, at least 20 different guidelines or consensus recommendations have been published regarding UI and associated conditions (see Table 2). Many of these have been developed by professional organisations focused on urologic, gynaecologic, geriatric, or related fields. Some have been created and disseminated on behalf of national governing bodies. Several older guidelines have recently been updated using evidence-based methodology.

Most of the guidelines target physician practice, although some do include recommendations specific to PTs, nurses, or other health care professionals. Different guidelines focus on specific clinical areas, and some are gender specific. Some only examine issues related to either the assessment or the treatment of UI. Some of the treatment-centred guidelines are specific for either surgical therapy or conservative therapy. Others look at clinical conditions in specific patient populations including those with underlying neurologic disorders, women with POP, or patients who have previously undergone surgical treatment for UI. There can be some confusion, particularly when guidelines present conflicting or even contradictory recommendations about specific issues of evaluation or management. Table 1 lists the published guidelines from 2007 through 2016.

Since the last ICI, there has been extensive expansion of development and dissemination of guidelines, practice recommendations, and structured treatment programmes for UI and FI focused on both general UI, (265) (279) (280) (281) (282) (283) (284) general FI, (285) (286) (287) (288) geriatric UI, (289) and specific underlying conditions that can influence continence. Some examples include OAB and neurogenic detrusor overactivity, (290) (291) (292) urinary urgency and incontinence in men, (293) UI associated with various neurological conditions, (294) (295) treatment of post-stroke incontinence, (296) (297) (298) normal pressure hydrocephalus, (299) Parkinson disease, (300) (301) multiple sclerosis, (302) (303) prevention of pressure ulcers, (304) UI associated dermatitis (305) and urinary catheter management. (306)

Within the realm of obstetrics and gynaecology, there are new guidelines on the management of third and fourth degree perineal tears during vaginal delivery, (307) (308) instrumental delivery techniques, (309) and terminology for native tissue repairs for POP. (310) In paediatrics, there are new guidelines on evaluation and treatment for congenital conditions affecting the bladder and bowel, (311) (312) use of urodynamics in evaluation of UI in children, treatment of daytime incontinence, (313) and constipation. (314)

Guidelines have also been developed regarding diagnostic and therapeutic options in order to define best-practice. This includes urodynamics, (315) (316) (317) clinical assessment methods and nonsurgical therapies for UI, (318) (319) service specifications for care, (320) pelvic floor physiotherapy, (321) biofeedback for FI, (322) various surgical procedures for UI, (323) laparoscopic and robotic single site surgeries, (326) sacral neuromodulation, (327) and vaginal oestrogen use. (328) Several survey instruments designed to screen for UI have also been developed, tested, and reported recently. This includes a symptom screening tool for UI due to OAB. (332) and a brief self-administered screening tool. (333) Population studies using screening instruments have shown high prevalence rates of UI (41%) with 72% of women reporting at least moderate to severe symptoms, and 73% reporting at least 2 years duration of symptoms. (84)

Guidelines have also been developed for different care settings. In the U.S., the Centres for Medicare and Medicaid Services (CMS) issued F-Tag 315 in 2005. This guideline provides recommendations for bladder management in the long-term care setting. DuBeau et al (334) assessed the knowledge and attitudes of NH staff (including directors of nursing and NH surveyors) following revised U.S. government guidelines on continence care (Tag F315 - http://www.cms.hhs.gov/transmittals/downloads/R8SOM.pdf). They used a questionnaire in a convenience sample of 558 staff attending workshops. The authors reported striking deficiencies in knowledge amongst staff and identified managerial structures as barriers to guideline implementation. They suggested such barriers need to be overcome in order to improve the quality of continence care. Nursing journals have published recommendations on ways to enhance implementation and compliance with the U.S. government regulatory guidelines. (305)

Some guidelines have focused on education rather than on care delivery. The International Urogynaecological Association (IUGA) issued a set of guidelines specific for training in the area of female pelvic medicine and reconstructive pelvic surgery. (335) Other professional organisations have issued similar information under the headings of 'consensus statements,’ recommendations,’ and ‘curricula.’

Many of the published guidelines focus on younger, healthy, community dwelling adults.

Guidelines for evaluation and treatment of UI and FI in children and the geriatric population or those with significant comorbidity need to be developed. These will need to take into account issues such as cognitive impairment, which can influence continence status in older adults. (336) Fung, (337) in a study in a large academic Veterans Affairs medical centre in the U.S., used guidelines to develop condition-specific computerized templates to serve as guides for clinicians to ask questions and perform elements of a physical exam for two specific medical conditions: UI and falls. This study demonstrated that a set of templates can be developed within an existing electronic health record system that can be used to prompt a clinician to obtain elements of a history and to perform physical examination.
The UK’s National Institute for Health and Care Excellence (NICE) (2013) national guideline on UI in women [National Institute for Health and Care Excellence (NICE), 2013] recommends that invasive treatment for OAB and/or SUI symptoms should only be offered after evaluation from a multidisciplinary team.

5.2. Audits and Assessments of Guidelines

A number of published studies have examined the degree to which clinicians actually follow published guidelines. Many of these have focused on primary care providers.

A postal survey of Dutch GPs found that most adhered to guidelines when making the diagnosis of UI. (172) However, implementation of other measures and treatments were less robust. At least 25% reported difficulty adhering to the guideline due to lack of time, staff, diagnostic tools, competency in care delivery, and perceived low motivation on the part of patients. Others have questioned the utility of this specific guideline when viewed from the perspective of urologists. (338) They proposed future research to determine if recommendations for referral to specialists are adequate and if they will be implemented in a manner that will benefit patients. Another study with Dutch GPs identified therapeutic nihilism among the physicians and low motivation on the part of patients as major barriers to guideline implementation. (112) Other barriers included lack of time, difficulty explaining therapeutic options, limitations in patient mobility, and increased patient comorbidities.

A survey of primary care clinicians in the UK revealed that 56.8% agreed or strongly agreed that the 2006 NICE guideline on UI in women reflected their current practice. (339) However, more than half of clinicians indicated that they had not changed their practice to be fully compliant with the guideline. In another study, GPs in the UK identified knowledge limitations, time constraints, and access to resources on UI as important barriers to better implementation of the guidelines. (340) (341) Survey data revealed wide variation in opinions regarding specific recommendations in the NICE guidelines for evaluation and treatment female UI. (342) Recent data on compliance with the NICE recommendations for evaluation of LUTS in men in the UK found that the majority did not receive management according to the guidelines, (343) especially for older men compared to young men.

Adherence to the new NICE guideline for FI also appeared to be less than ideal. In a study of more than 5,350 cases, no documented focused history was taken in more than one-third of hospitals, one-half of primary care clinics, and three-quarters of care homes. (344) Less than half of all subjects had a documented plan for care for an identified bowel-related cause for clinical FI. The effect of FI on QoL was poorly documented, particularly in hospital settings.

Adherence to guideline recommendations may also be less than optimal among specialist providers. Ismail (345) examined records of women undergoing sling surgery for treatment of SUI at an academic medical centre in the UK. Only 45.3% of the patients had documentation in the medical record that they had previously tried conservative therapies. Documentation of underlying risk factors was highly variable. A similar study among urologists in Spain showed that compliance with guideline recommendations was less than ideal. (346)

Attitudes and adherence to new guidelines such as preoperative use and utility of urodynamics for UI (347) and evaluation and treatment of paediatric constipation (348) have been variable. Even adherence to recommended nomenclature for some pelvic floor conditions has been less than optimal. (349)

Studies have also examined the degree of awareness and adherence to guidelines among specific patient populations. Ismail (345) reported on the results of a survey of 223 women in the UK who had recently delivered their first child. According to the NICE guideline, these women should have been taught PFM exercises in the antenatal period. Although 95% reported awareness of the importance of the exercises, many did not have accurate information and only a small minority actually practiced them.

Adherence to guidelines for geriatric syndromes which influence continence status is also not particularly strong. For example, there are multiple barriers that can influence UI management in home health care settings. (350) A study of the national guidelines in the UK and Wales for older adults who have suffered a fall demonstrated that only 63% of 3,184 patients who fell and suffered a hip fracture, and only 21% of those with a fragility fracture not associated with a fall were assessed for concomitant UI. (185) Only half of those identified as having a UI problem were actually referred to a continence centre or provided any type of intervention.

Guideline recommendations are not without controversy. In a retrospective database analysis of 6,276 women, Agur et al (351) noted that of women believed to have pure SUI based history alone, at least 25% were found to have other forms of voiding dysfunction based on urodynamics. They concluded that the recommendation in the NICE guideline to avoid urodynamics testing in women with pure SUI symptoms might be unwise and could miss other important findings, which could influence care.

There are even more limited data on whether adherence to guidelines actually leads to substantive changes in measurable continence outcomes. (352) In cases where organized services were available, overall quality outcomes were better compared to areas where these services were not offered. (353)

An audit of the NICE guideline in the UK revealed that patient age may be associated with differential imple-
momentation of guideline recommendations for UI evaluation and treatment. (354) In this study, data from 7,846 women treated at either acute hospitals or primary care trusts in the UK, revealed that elderly women were significantly less likely to receive guideline compliant care compared to younger women. Actual levels of adherence by the care providers varied widely depending on the specific recommendation being evaluated. Levels of guideline adherence also appeared to differ between specialists providing care in acute hospital settings compared to GPs in the primary care trusts. In response to this finding, an editorial analysis asked rhetorically if lack of adherence to published guidelines for UI may actually represent a form of ageism on behalf of clinical providers and patients. (355)

### Summary

Overtime, there has been a dramatic increase in the development and dissemination of guidelines, consensus statements and best practice recommendations. These are generally created and disseminated by professional organisations focused on both primary and specialty care. Methodology varies based on the sponsoring organisation, but most follow established principles using evidence-based techniques. There has been increased interest in the development and use of guidelines over recent years. Since the last ICI, there has been a substantial increase in both general guidelines regarding UI and FI, and in those targeting specific clinical situations such as UI or FI associated with neurological disorders, following childbirth, or after treatment for fistula or other conditions. Methods of dissemination are variable, and clinician awareness of guidelines can be a challenge. It can also be difficult to make clinical choices in cases where different guidelines may provide conflicting recommendations. Data from audits also indicated that clinical practitioners do not always adhere to guidelines. Future work will need to continue to assess existing and new guidelines, methods of guideline dissemination, ways to improve awareness of guidelines, and techniques to continually improve practice.

### Levels of Evidence/Recommendations

Effectiveness of guidelines in clinical practice. (Levels of evidence: 3 to 4)

- There is a need to continue to evaluate the quality and relevance of existing clinical guidelines, particularly in the context of updating these materials or creating new guidelines based on emerging evidence.
- There is a need for additional research on guideline dissemination, awareness and adoption among clinicians.

- There is a need for assessment of multiple guidelines on similar topics to determine the extent to which they agree or conflict on specific points, and ways to resolve these differences to guide professional practice.
- There is a continued need for evaluation research to explore impact of guidelines on clinical care both at individual and population levels. This evaluation strategy needs to include impact on a wide range of outcomes, including incidence and prevalence of disease, treatment outcomes, prevention efforts, costs, and health care policy. (Grade of Recommendations: C)

### IX. PUBLIC EDUCATION

**Literature Search is found in Appendix 1.**

#### 1. BACKGROUND

Education of the lay public and patients is a crucial part of overall efforts in education and continence promotion. In the creation and discussion about this section, the committee recognized that a number of different terms are often used interchangeably when referring to this population. These terms include public education, layperson education, patient education, client education, consumer education, etc. These terms can have important distinctions depending on the perspective of those involved. For example, ‘patients’ may indicate those receiving care or suffering from a particular condition such as UI. The term ‘clients’ implies that people are receiving some type of services from a professional provider. And the term ‘consumer’ implies that the person is using either goods or services related to their UI. For simplicity, the term ‘public education’ will be used to summarize the information in this section.

Patient education consists of healthcare professionals teaching patients about their disease and offering therapeutic instruction, particularly information about self-management strategies, drugs, adaptation of their dosage and side-effects. (356) Patient education regarding normal and abnormal bladder function has been found to be helpful in the establishment of healthy bladder habits. (357)

However, there was very little evidence to highlight the benefit of patient education for people with bladder and bowel conditions and the difference it may make to their outcomes. Most patient education studies found did not meet the quality criteria for inclusion. There are also inherent issues with generalisability of data as there are no standardised methods, techniques, or delivery for patient education or even any agreement on the content on education.

There have been several studies assessing patients level of knowledge regarding specific treatments e.g. bladder retraining, PFM training, etc, however almost all of these are conference abstracts that have not...
been developed into full peer reviewed papers. Brown et al (358) assessed women’s knowledge of vaginal pessaries. Few patients had heard about pessaries from any source other than a physician or other health care provider and patients who indicated they would decline pessary use reported a lower level of education. Educational efforts alone may not be adequately sufficient to yield successful outcomes. Another study showed that intensive education about UI related to radical prostatectomy for cancer did not lead to better continence outcomes following surgery. (359) According to findings from a focus group study, obtaining information from people who have UI and their carers may have usefulness in helping these individuals in developing self-management tools women could use on their own in the future. (52)

The Prolapse and Incontinence Knowledge Questionnaire (PIKQ) was developed and validated by Shah et al (360) as a reliable method of assessing patient knowledge of UI and POP. In several of the studies reviewed assessing education given to female patients was used pre and post intervention to assess gain in knowledge.

Recently there has been a substantial increase in publications related to public education for incontinence. These have broadly focused on several areas including knowledge and perceptions about incontinence and associated conditions, development and dissemination of public education or programmatic efforts related to continence, and the availability and quality of social media and electronic applications for public education on continence and related topics.

A survey of visitors to a public education website with information on UI collected self-reported data from 374 people and found that 13% had not spoken with a healthcare provider about their UI symptoms, and 75% were not using any type of active approach to address their symptoms. (361) A systematic review of published studies examined perceptions of both patients and staff about factors facilitating or serving as barriers to uptake of behavioural therapies. (196) It reported that the main patient factors identified to help enhance adoption of these treatments included having realistic goals and expectations and gaining a sense of control. For care staff, a sense of teamwork and experience with success were enabling factors. Barriers for patients included fear of accidents and experience with success were enabling factors. (362) Education. Educational efforts alone may not be adequate to yield successful outcomes. Another study showed that intensive education about UI related to radical prostatectomy for cancer did not lead to better continence outcomes following surgery. (359)

Studies on perceptions about UI and future health have shown mixed results. One study of 786 people in Spain identified that 50% felt their UI was normal for their age, and 71.5% expected it to worsen with time and increasing age. (363) However, 80% also expected improvement with treatment. People used a variety of coping strategies, and this increased with increasing UI severity.

Innovations in public education treatment programmes for UI and associated conditions incorporated technology applications. (364) Delivery of a PFM programme via the internet was found to be more effective at one year among those with initial short term improvement in symptoms, increasing age, and among those who continued regular PFM exercises. (365) Other researchers have shown a mobile app was effective in helping train women with SUI about PFM exercise, and could be useful to enhance education about the condition. (366) Another study of 41 women demonstrated that an avatar based online educational programme was effective in improving health related quality.

### Summary

Public education directed toward patients, clients and consumers is an important part of the overall spectrum of information and dissemination of continence promotion. This can take many forms ranging from the provision of health information between health care providers and individual patients to public service announcements and other mass media communications. Although there has been a recent increase in public education efforts, research in this area is still in its relative infancy.

### Levels of Evidence/Recommendations

Effectiveness of public education efforts through various channels including individual education, public media and mass communications (Levels of Evidence 3 to 4)

- There is a need for additional focused research on methods to enhance patient and public education about UI, FI, and POP, both at an individual and broader public level.
- Research is needed to examine methods to improve efficiency of public education including group training, mass marketing and other techniques.
- The role of technology in public education for continence promotion should be examined in more depth.

(Grade of Recommendations: C)

### X. CONCLUSIONS

Continence promotion involves many different components including primary prevention strategies, health care advocacy, and methods of encouraging help-seeking behaviours. It also includes development of models to enhance provision of and access to health care in a wide variety of settings ranging...
from community programmes, to facility-based and institutional programmes, to widespread governmental initiatives. Education, of both health care providers and the public remains a cornerstone of successful continence promotion. Although there has been an increase in attention to these topics in recent years, additional work will be needed to actively advance our knowledge and to foster future progress.

**APPENDIX 1. LITERATURE SEARCH**

The literature search to identify material for this chapter, additional to that reviewed for the last (5th) consultation, was conducted as follows:

**Primary Prevention:** Online databases Pub Med, Cinahl, Pynchin, and Medline were searched, with focus on literature published in and after 2010. Search terms used (aware* OR educat* OR promot* OR instruct* OR interven* OR teach* OR learn* OR lifestyle OR behav* OR change*) AND prevent* AND (incontinent* OR continent* OR continence*) NOT continental Sort by: Relevance Filters: Publication date from 2011/01/01; Adult: 19+ years

BIOSIS: You searched for: TOPIC: (((health* OR care OR help) AND (acceptance OR accepting OR accept OR seek OR seeks OR seeker OR seeking)) OR TOPIC: ("help-seeking" OR "care-seeking") Refined by: TOPIC: (incontinence OR incontinent OR continence OR continent) AND TOPIC: (adult* OR man OR woman OR men OR women) AND PUBLICATION YEARS: (2015 OR 2014 OR 2013 OR 2012 OR 2011 OR 2010 ) Timespan: All years. I. INTRODUCTION

The average lifespan of a woman is now over 80 years, and rising for all almost all Organisation for Economic Co-operation and Development (OECD) countries (1). This is good news, but it raises a number of fiscal questions for governments and health care systems. Older adults are at greater risk for a range of health conditions, including urinary incontinence (UI), overactive bladder (OAB), pelvic organ prolapse (POP), and faecal incontinence (FI). We also face the aging baby boomers and many countries are still recovering from the 2008 recession. The growing demand for health care, coupled with a desire to contain health care costs, has resulted in a heightened interest in maximizing value. Economic tools are useful for understanding value in health care, defined as outcomes gained for unit of money spent. By enumerating the costs and benefits, payers can make informed decisions about treatment options in order to maximise a population’s health.

The management of UI, OAB, POP, and FI has evolved over the past decade, driven in part due to advances in treatment, but also in part to a greater willingness among patients to talk to their clinician about their issues (2). Stress incontinence can be readily cured by a variety of conservative and surgical options, but benefits can erode over time. Similarly, drug and device companies have developed new treatments for overactive bladder, but these may require prolonged administration with longstanding treatment costs. Conservative measures such as bladder training, also require patient adherence to achieve success.

The news from the Economics Committee is mixed. On one hand, economic evaluations of existing treatments are increasingly the focus of studies. The bad news is that these analyses are not readily transparent and thus new studies often create more confusion and uncertainty. In this chapter we summarize economic methods frequently used in health care. We then present a critical analysis of recent publications. Throughout this chapter, we focus on the economics of UI, POP, and FI, and thus we have organized the chapter accordingly.

II. BACKGROUND

1. HEALTH CARE PRODUCTION

When a person with incontinence (and to some extent prolapse) decides to seek medical care, they will have already incurred some costs, related to pads or laundry, and to managing the condition at home. He or she will then have a basic consultation, tests will probably be ordered, and a treatment may be initiated. These are the costs of treatment. The incontinence may increase the risk of a urinary tract infection, or the person may slip and fall on the way to the toilet. These are the costs associated with treating the consequences of incontinence (3, 4).

Self-management costs, treatment costs and consequence-related costs vary a great deal across and within countries. Part of this variation reflects inherent differences in the price of inputs, such as labour, needed to produce medical care. It also reflects the different ways that governments regulate health care (5). These contextual differences affect every economic analysis and places the burden on researchers to describe explicitly where, when, and how the economic data were obtained so that the results are interpretable. The regulatory context also affects patients, whether that is in access to care or in their costs of health care goods and services.

Health care costs are incurred when resources are used to produce goods or services. The production cost for most health care products is often not well understood because there is no market. More often there is a “charge” stated on a bill, or the total amount paid by a third party, whether that is the government
or an insurance company. Costs, charges and payments are not equivalent and are often substantially different for the same good or service. For example, hospital accounting systems in the US focus on billing and payments. The charges listed on the bill usually overstate costs, on average by a factor of three, and charges are rarely paid in full by the payer. For example, in a study of the costs of surgery for female faecal incontinence in the US (6), hospital “charges” were defined as the amount on the hospital bill, but the hospital “costs” were defined as the amount that the hospital actually received in payment. Only after understanding this definition can one make sense of the fact that hospital “charges” for FI surgery rose from $48 million to $57 million over 3 years, but the hospital “costs” increased only slightly from $23 to $24.5 million over the same 3 years (6).

Many health care systems use accounting software to track inputs (labour and capital) and then estimate the cost of care. Yet again, there is considerable variation in how these systems are employed and the validity of the results. Consequently, many researchers prefer to use payments as the estimate for cost, when available. Researchers have developed imperfect methods for adjusting charges with a hospital-specific ratio of costs to charges to better estimate costs (7). Charges, however, are not always available. Integrated health care systems, including Canada and the U.K, do not routinely generate bills, and in these circumstances, researchers have developed methods for generating pseudo-bills and cost estimates (8-10).

When researchers need to estimate the cost, they can choose from a range of approaches from “gross costing” to “micro costing” (11). These terms are similar to the phrases “top-down” and “bottom-up.” Accounting and billing systems use activity based micro-costing methods, whereby detailed estimates of time and products (inputs) are combined with unit costs to estimate total costs. Micro-costing (or “bottom-up”) is challenging to perform because a single inpatient stay or outpatient procedure might have hundreds or thousands of inputs. For example, Morris et al. (12) performed over 3621 observations to determine expenditure on urinary faecal or mixed incontinence in a one month study of 29 patients in a sub-acute care facility. Even when there are a limited number of inputs, the cost can vary by location or the time of purchase if input prices fluctuate.

At the other end of the spectrum, gross cost methods (“top-down”) identify a limited number of important characteristics such as the Health Care Resource Group (HRGs) in the U.K., Diagnosis Related Groups (DRGs) in the U.S. or Australia, and length of stay. However, gross costing lacks precision; this can be problematic if the study seeks to understand the cost of close substitutes. For example, in Australia the DRG for Tension Free Vaginal Tape and Colposuspension is the same, even though the production costs differ.

Accounting systems typically only reflect the resources used by the provider to produce care. These systems do not usually track patient costs, such as co-payments or travel costs. If researchers want to estimate societal costs, which are often of most interest (11, 13), one must include patient-incurred costs. This distinction is important for urinary incontinence, since most patients incur the costs for routine care (e.g., pads and protection). In the year 2000, routine care costs in the U.S. were $1347 per person for urinary incontinence and $1554 for people with OAB (14).

Thus, the perspective can dramatically affect the conclusions. For example, a study from the US analysed Medicare claims for the treatment of urinary incontinence among women aged 65 or older for 3 years (1992, 1995, 1998) including outpatient, inpatient and emergency department visits (15). Such Medicare claims nearly doubled over the time frame, from $128 million to $234 million, largely due to increased numbers of women treated by office visits and ambulatory (day only) surgery for items such as collagen injections. When the per capita changes were analysed, and inflation was considered, costs had actually declined by 15%. However, the editorial comment following this article points out that Medicare claims have a payer’s perspective, do not quantitate pad usage, and did not, until recently, track pharmaceuticals. Since we know that overactive bladder is more common as age increases, medical treatment is likely to be increasingly important in the over 65 age group, so that the conclusion of a 15% drop in per capita Medicare expenditure is not likely to be valid representation of costs in general. The editors pointed out that the article was mainly representative of patients with stress incontinence as a result. Such methodological issues are important.

In the example described above, the “perspective” was that of Medicare claims. In other words, Medicare was the “payer”, not the patient. This highlights the fact that costs can be evaluated from several different perspectives. The four most commonly used perspectives are: 1) overall society costs, which includes all aspects of care and treatment (which this committee recommends), 2) the payer, such as Medicare, 3) the provider, such as a hospital or managed care plan, and 4) the patient.

In general, health economists prefer the use of a societal perspective (11, 13). This facilitates comparisons across illnesses and across different countries. More focused analyses are sometimes also done to consider other perspectives, but this is usually clear in most papers.

### 2. INTERNATIONAL ISSUES

Patients often incur considerable costs paying for routine care products and treatments. However, the proportion of costs incurred by patients varies from
country to country. For example, in Sweden, the national health insurance covers routine care products. In the UK, age-dependent patient subsidies are available for pads. In Germany and Spain, pad costs are reimbursed if prescribed by a doctor (16). In Australia, low-income patients can apply for a subsidy to reimburse most of their routine care products, but wealthier patients must pay all the costs. In the US, such products are rarely covered by insurance (16).

Coverage for treatment also varies across countries. In the UK, most patients use the National Health Service (NHS) so that all office visits, tests, outpatient visits and surgical treatments are free to the patient. Pharmacotherapy does attract a small out-of-pocket payment per prescription. In Australia, about 70% of patients only have government insurance, similar to the UK NHS, but 40% of patients also have private insurance providing more generous coverage. In the US, adults over age 65 and those with a disability are covered by the Medicare program. This provides coverage for inpatient, outpatient and pharmacotherapy, although patients are generally responsible for sizable co-payments and nursing home care is capped. Those not covered by Medicare often have private insurance or Medicaid (a health insurance program for people with low incomes).

In the Netherlands, all legal residents are obliged to purchase a basic health policy (the purchase of a complementary policy covering extra health services remains voluntary). The government establishes what is in the basic package and under what conditions people are entitled to care.

Nursing home coverage is another area where there is widespread variation in costs, quality and coverage. In the US, Medicaid is the primary payer for long term care, but because the programme is for low-income adults, many people have to spend most of their assets before they qualify. Many of the high quality programmes do not accept Medicaid, because Medicaid payments are too low, thus the US has differentiated markets by quality. In Australia, low-income patients who have no private superannuation (pension fund) can receive the “old age pension” which covers long-term care, albeit in lower-calibre facilities than would be chosen by those who could afford better (similar to the Netherlands system). In Japan, generous long-term benefits are provided to long term institutional residents, so that out of pocket payments are reduced.

3. COSTS RELATIVE TO TIME

3.1. Inflation

Costs change over time and researchers need to account for this variation in their analysis. The easiest way is to present the costs relative to a specific year (e.g., 2012). Costs borne in past years should be inflated. In many countries, the governments publish inflation indices. In the US, inflation is represented in the Consumer Price Index (e.g., www.stats.bls.gov).

In the UK, the Health Service Cost Index or the Retail Price Index, published by the NHS Executive, Leeds, UK, can be used to adjust the costs of health care services (www.statistics.uk.gov).

Caution is needed because general inflation relates to the cost of a consistent set of goods over time, e.g., over time, the goods must be of the same quality, and thus the costs observed five years ago can be observed today. If so, then the inflation index is informative. However, medical goods change rapidly, as does their quality. For example re-usable laparoscopic equipment has been replaced by disposable equipment, and newer drugs have emerged. This makes it difficult to determine whether any change in price is due to inflation or due to changes in quality. Consequently, many researchers recommend against using price indices that are developed specifically for medicine because these do not take quality into account. General consumer price indices are usually preferred for inflation adjustment.

3.2. Discounting

We choose to invest in health care now to reduce the probability of costlier problems in the future. Cancer prevention is the prototypical example, where we invest in cancer screening now with the hope that if we have cancer, we will find it earlier and it will lead to fewer serious problems. Economic analyses must include these future costs. Discount rates, typically of 3-4% per annum, are used to estimate the net present value of future costs. By examining future costs and benefits, we can work to ensure that prevention efforts add value.

Cost-effectiveness models for incontinence must consider future costs. Drug treatments, for example, incur future costs. People have time preferences for money and future costs should be discounted to represent present value. There is some debate about the appropriate discount rate (17-19), but most international studies use a discount rate of 3-4% per annum (20).

3.3. Efficacy over Time

Economic models need to adjust for future changes in costs and efficacy. Surgery has a large up-front cost, and may at first appear more cost effective than pharmacotherapies, but often surgical efficacy wanes over time. For example, in Adang et al. (20) dynamic graciloplasty is portrayed as having a stable success rate over time in the treatment of faecal incontinence. In fact, we now know that dynamic graciloplasty has a very poor success rate over 10 years, so that the estimated data from Adang et al. are not accurate.

In summary, health care costs vary across countries and over time. This variation needs to be taken into account in the economic analysis. Sensitivity analyses are often useful because they enable us to investigate how different assumptions and input parameters can influence the results. As we describe in the

In summary, health care costs vary across countries and over time. This variation needs to be taken into account in the economic analysis. Sensitivity analyses are often useful because they enable us to investigate how different assumptions and input parameters can influence the results. As we describe in the
4. TYPES OF ECONOMIC ANALYSIS

4.1. Cost Effectiveness Analysis

A typology of economic models for health and medicine has emerged. With the exception of cost of illness studies, these economic models are designed to provide information about a choice (or set of choices). The current gold standard is cost-effectiveness analysis, in which the benefits and costs are compared in an incremental cost-effectiveness ratio (ICER). The ICER can be depicted as

\[
\text{ICER} = \frac{\text{Average Cost}_A - \text{Average Cost}_B}{\text{Average QALY}_A - \text{Average QALY}_B}
\]

The subscripts A and B are used to denote alternative treatment choices and QALY represents quality adjusted life years. It is easiest to consider two choices, but the following framework generalizes to more than two. If there are more than two treatment options, then each pair-wise comparison needs to be calculated to identify the optimal choice.

Historically, CEA was a generic term in which any outcome could be used, while cost-utility analysis (CUA) was reserved for when outcomes were measured using quality adjusted life years (QALYs). Over the past decade, CEA and CUA have become synonymous. Hereafter, we use the term CEA to imply outcomes measured in QALYs. Well-known texts discuss standard techniques for conducting a CEA (11, 13).

QALYs reflect quantity and quality of life. The quality adjustment is based on utilities. The power of CEA is that it can capture all potential benefits of an intervention and allow comparisons across health conditions, thereby promoting allocative efficiency.

4.2. Cost Benefit Analysis (CBA)

A CBA measures outcomes in money. When outcomes are valued as a currency, the optimal choice can be easily found by addition and subtraction (i.e. the end result is not a ratio). However, it is difficult to monetize health outcomes, and many researchers and policymakers are averse to placing a monetary value on life. CBA is widely used in many fields, such as environmental economics, but rarely used in health.

One approach for measuring outcomes in money is by asking patients what is the most they would be willing to pay. This approach, known as contingent valuation, has attracted some attention, including work in urinary incontinence (21).

4.3. Cost Minimization Analysis (CMA)

CMA assumes the outcomes are equivalent and only focuses on the costs. CMA has been argued as appropriate when considering patent versus the equivalent generic drugs. In practice, rarely are CMA conducted because treatments are rarely equivalent.

4.4. Cost Consequence Analysis (CCA)

In this analysis, outcomes are measured by assessing whether a treatment changes health care utilization (i.e. hospitalization averted or emergency visit averted). These analyses alone are incomplete and can be misleading. However, when combined with a CEA, they can provide information on the mechanisms underlying changes in costs. Often researchers hypothesize that a new treatment will increase appropriate utilization or decrease inappropriate utilization; this analysis can be helpful in this regard.

4.5. Cost of Illness (COI)

COI studies describe the costs related to a condition for a given population over a period of time (e.g., year). All COI studies include health care costs related to the condition. The inclusion of lost productivity (i.e. employment effects) varies and is more controversial. While some studies have attempted to place a cost on pain and suffering, such calculations are now discouraged. COI studies are not designed to inform decision makers about how to allocate scarce resources for treating conditions.

4.6. Summary

There are a number of economic tools that are commonly used in health care. Most new treatments offer additional benefits at an additional cost. The CBA and CEA were designed to determine how much money it costs to improve outcomes. Although the CEA is the preferred method, accurately measuring utilities can be challenging. We will discuss these issues in more depth because different methods for utility elicitation can have a very profound effect on the interpretation of the CEA.

5. MEASURING OUTCOMES

5.1. Introduction

The book by Gold and colleagues (11) is often used as guidelines for conducting CEA in health. The authors recommend using QALYs as the outcome in the CEA. However, this book also notes that analysts could use a clinical outcome measure. For incontinence, clinical outcome measures include 24-hour pad test, a voiding diary, or urodynamics. These outcomes are attractive for clinicians because they often use these measures in clinical practice. Clinical outcomes can be very valuable in identifying when a treatment is efficacious. However, using clinical outcomes in a CEA can yield results that are limited in
scope and potentially biased. A treatment might have improved a person’s quality of life, but had little effect on the clinical outcome measure. The converse is also possible. Moreover, a CEA with one clinical outcome measure is not comparable to another CEA using a different clinical outcome measure. A clear advantage of QALYs is that they are generalizable across conditions.

5.2. Health Status and Quality of Life Measures

There are a number of frequently used and highly regarded general health status measures, such as the SF-36, which describe a person’s current health state. Instruments that assess how a person perceives or feels about their health state are called health related quality of life (QOL) measures. Some of these measures are generic while others are disease-specific. A number of disease specific quality of life measures exist for OAB and incontinence, such as the Incontinence Quality of Life questionnaire (I-QOL) (22). These measures describe a person’s quality of life specific to incontinence. Generic and disease specific quality of life measures are difficult to include in an economic evaluation because they were not designed for that purpose. In the past decade, there has been considerable effort placed on developing mapping algorithms that enable researcher to use the SF-36 or I-QOL and then “map” these scores onto a preference based valuation scale for CEA models (23-25).

5.3. Utility Measurement

As noted above, QALYs denote the relationship between the value of a given health state and the length of time a person lives in that health state. The value of a given health state is measured in utilities, which represent the preference for a given health state relative to other health states.

To understand utilities, consider the following: most people would prefer to be healthy over a given time rather than suffer constant urinary or faecal incontinence. Utility measurement refers to valuing these preferences on a perfect health-death scale with end points of 1.00 and 0.00, where 1.00 is perfect quality of life (best imaginable) and 0.00 is death equivalent quality of life. For example, the measured utility for urinary incontinence may be 0.60. If treatment improves this to 0.70, then the value of the treatment is 0.70 - 0.60 = 0.10. If this utility gain is maintained over time, say for 10 years, then the gain is 0.10 x 10 = 1.00 QALY. Because utilities are measured on an absolute scale (perfect health to death), they can be used across different health states and therefore can be used to compare the effect of interventions in different health fields, or different interventions within the same field. For example, the QALYs gained from treatment for incontinence could be compared with those gained from treatment for depression. Where treatment costs (including costs to the patient) are known, the treatment providing the lowest incremental cost-per-QALY gained is preferred as this ensures society gains the greatest benefit from the health care dollar.

Direct and indirect methods have been used to elicit utilities (26). The most common direct elicitation methods for valuation include time trade off (TTO), standard gamble (SG), and the visual analog scale (VAS). For description of these methods, see our previous chapter in this ICI series (27). Indirect utility elicitation is frequently used in clinical research because it is easy. Most indirect measures rely on multi-attribute utility (MAU) instruments, which decomposes health related quality of life into health domains (e.g., mobility and emotions). Respondents provide estimates for each attribute, which are then ‘valued’ based on pre-defined weights and summarized into a single utility score. The most commonly used MAU instrument is the EQ-5D.

- EQ-5D was developed by the Euroqol team from 7 European countries (28, 29). It has 5 items measuring Mobility, Self-care, Usual Activities, Pain/Discomfort and Anxiety/Depression. The upper bound is 1.00, lower bound is ~0.59; a negative value represents a health state that is worse than death. This instrument is widely in many languages and it is very brief. It is currently the most widely used utility measure in urinary incontinence.

- Quality of Well-Being Scale (QWB) has three dimensions (Mobility, Physical Activity, and Social Activity), with 3–5 levels each, and 27 illness symptoms (30). The QWB requires trained interview administration (15–35 minutes), although a shorter version is available; a self-report version is under development. The upper bound is 1.00, lower bound is 0.00

- Health Utilities Index (HUI) uses 12 items that measure 8 domains (Vision, Hearing, Speech, Ambulation, Dexterity, Emotion, Cognition and Pain). The upper bound is 1.00, lower bound is ~0.36 (31).

- 15D is a generic, comprehensive, standardized, self-administered measure of HRQOL that can be used both as a profile and single index score measure (32). The 15D was created in Finland. It has 15 items measuring Mobility, Vision, Hearing, Breathing, Sleeping, Eating, Speech, Elimination, Usual Activities, Mental Function, Discomfort & Symptoms, Depression, Distress, Vitality and Sexual Function (28). The upper bound is 1.00, lower bound is 0.11. The 15D has been used in urinary incontinence studies (33-36).

- Assessment of Quality of Life (AQoL) includes five dimensions: Illness (not used in utility computation), Independent Living, Social Relationships, Physical Senses and Psychological Well-being (37). The upper bound of the utility score is 1.00, and the lower bound is –0.04.

BACKGROUND | 2485
• Rosser Index has two dimensions measuring disability and distress, and measured 29 health states (38). The upper bound is 1.00, and the lower boundary –1.49.

• Mapping algorithms. Scientists have developed algorithms to map health status and quality of life instruments to utilities. Perhaps the best known is the SF-6D, which maps the SF-36 or SF-12 to a utility score (23). The SF-6D measures physical functioning, bodily pain, mental health, physical role, emotional role, social functioning, and vitality. The bounds for the SF-6D are 1.00, and 0.30 for the worst possible health. There have also been new mapping algorithms for mapping the I-QOL to utilities using AQoL and EQ-5D weights (24, 39). There is also a mapping of the King’s Health Questionnaire to utility weights, and the OAB-q questionnaire (40, 41). While these mapped algorithms have shown responsiveness, a significant difference does not imply a meaningful difference. For example, a 10 point increase from baseline has been suggested to represent a minimally important difference on the OAB-q (42).

• Proxy report. People with incontinence may not be cognitively able to complete a MAU or go through a utility elicitation process. Some of the MAUs, such as the HUI, have been validated for use with proxies. Although not always possible, if proxies are expected then proxies should be gathered for all cases, even those patients who complete the utility measure themselves, so that the method is applied in a standard, consistent fashion.

6. DECISION ANALYSIS

Decision analysis is a quantitative probabilistic tool for resolving problems when there is uncertainty with regards to treatment options. For example, Albo and colleagues (43) compared Burch colposuspension to fascial sling for stress incontinence. They concluded that the fascial sling yielded a higher rate of successful treatment, measured as a composite outcome, but also resulted in greater morbidity. Even in well-designed multi-site clinical trials, the results may be ambiguous. Decision analysis may be used to overcome this ambiguity.

Decision analysis can be boiled down into five steps. The first step involves identifying the structure of the problem and this requires the listing of all decision alternatives, all clinical outcomes, and a sequence of events. After completing step one, step two involves assigning probabilities to all chance events (e.g., death). Step three involves quantifying the benefits (e.g., QALYs) for all outcomes. The fourth step involves the mathematical calculation of expected utility for each strategy (or this can be taken from published data). Step four will often identify the preferred strategy. The final step involves conducting sensitivity analysis to check that the model is robust across a range of clinically meaningful possibilities.

Every decision model involves some assumptions. Frequently, assumptions are needed to incorporate clinical trial data in the model. For example, a common assumption is that the effect shown in a clinical trial is generalizable to the broader population—treating women with TVT will result in effects like those seen in Lier and colleague’s paper(35) (discussed later in the chapter). Some assumptions may seem trivial, but it is best to delineate each assumption along the way. Published decision analysis should include a table of assumptions along with other data inputs; frequently this is the first table in the decision analysis.

The clinical question and the structure of the problem (step 1) should provide guidance on the decision model. Frequently decision trees are used because they are simple and address the question at hand. Decision trees are so named because they look like a tree with a trunk, branches and leaves.

6.1. Decision Tree

In a decision tree, there is a distinction between a decision node and a chance node. A decision node is a point where a choice is made by the decision maker (typically a physician or patient). For example, for a woman with stress incontinence, the choice to operate (yes or no) would be represented with a decision node. A choice must have at least two options and more than two choices are permitted. However, each choice must be mutually exclusive. A patient cannot choose both operation and no operation. A chance node is a point where chance determines fate. For example, the decision maker chooses to operate or not operate, and hopefully the treatment is successful, but treatment success or failure is a chance node. Not only must chance nodes be mutually exclusive, but they must also be collectively exhaustive (one of the chances must happen and the sum of probabilities for all of the chances must add to 100%).

\[1.20 \times 0.90 + 2 = 3.8\]
In addition to chance and decision nodes, there are terminal nodes. These nodes are the final outcome for the pathway taken. Figure 1 shows a hypothetical decision tree for treating a patient with stress incontinence. In this hypothetical situation, we structure the model to have two options: surgery or drugs. The choice under examination is surgery versus medical management. Surgery carries some risks—a small probability of operative death, for example, in the case of clam cystoplasty for refractory detrusor overactivity. The decision nodes are represented by squares while chance nodes are represented by circles. The terminal nodes are cure, no cure, operative death or non-adherence, which is the same as no cure. This is a hypothetical decision model, and most decision models are much more complex. Clearly this model could be expanded to include behavioural treatment and each decision node could be expanded to consider all relevant alternatives (autologous sling, Burch colposuspension, tension-free vaginal tape, trans-obturator tape).

For the next step in the decision model, one must include probabilities at each chance node. We must identify the probability that the disease is cured after operation. Researchers should review the published literature to find this probability and ideally some information about the distribution around this probability (e.g., probability= 58% with a 95% CI 51-68%).

After including probabilities, one must place values next to the terminal nodes. These values must be a single outcome and QALYs are preferred, although life years (unadjusted for quality) are used for some diseases. With outcomes and probabilities, one can then “run” the decision tree. Because there is one decision node with two options, we will be computing expected values for the two options. Running the model involves starting at each end node and working left or backwards. The expected value for the surgical survival node is 3.8 QALYs (see Figure 2).

The expected value for the surgical operative death node is 0. When we combined a 10% chance of operative death (0 QALYs) and a 90% chance of survival (3.8 QALYs), we find the expected value of surgery is 3.42 (Figure 3). If we do the calculation for the lower branch, we get the expected value for drug therapy is 3.76 QALYs. Because 3.76 >3.42, we would recommend surgery over drugs IF the sensitivity analysis shows this result to be robust. The decision tree in the example focuses on QALYs for UI treatment and it ignores cost differences, but it could be easily modified to include cost information.

6.2. Markov Model

The decision tree, as shown above, assumes the chance of having an event is constant over time. Our knowledge about urinary incontinence suggests otherwise. A person, for example, could get surgery for stress incontinence, but over time, we need to include the potential for surgical failure. Markov models are preferred for incorporating changes in health states over time. At their core, Markov models are mathematical techniques, derived from matrix algebra, that describe the transitions a cohort of patients make among a number of mutually exclusive health states over time. The model works by making calculations for each period of time (i.e. cycle). Figure 4 shows a very basic four-state Markov model. At each time, a person has to be in one (and only one) of the states. The model works by making calculations for each period of time (i.e. cycle). Figure 4 shows a very basic four-state Markov model. At each time, a person has to be in one (and only one) of the states. But with each change in time (cycle), the person can move to another state, shown with arrows, depending on the possible states and a probability. If the person dies, they are shown to enter the death state. The person cannot leave this state.
Some aspects of the Markov model construction are similar to a decision tree. Setting up the model is quite similar. One must identify the health states and the transition probabilities. What is quite different is that one must determine the cycle length—the rate at which you allow people to change states. The cycle length should be a clinically meaningful period of time and this choice is also frequently affected by the availability of data. There may be publications showing annual failure rates for surgery and so one could choose an annual cycle.

For a Markov model, one needs to know the value for each state. Again, QALYs is the preferred metric. When the model runs, the program tracks the amount of time each person spends in each state. Transitions to other states are handled by transition probabilities (i.e., the likelihood of cure or failure). Decisions, such as the decision to change from one treatment to another, can affect transition probability. Models can use cohort simulations where a large hypothetical cohort of patients is run through the model. This does not provide information on the distribution of expected values. Monte Carlo simulations run each patient through the model a large number of times (e.g., $10^4$). In doing so, this provides a distribution and variance information on patients.

With Markov models, sensitivity analyses remain a crucial step to test the robustness of the model. Recent advances in sensitivity analyses and in the graphical presentation of data general require the use of specific software. Although some people program Markov models into a spreadsheet, such as Excel, specialized software such as TreeAge, can streamline decision analysis and provide many advanced features that would be very difficult in Excel.

6.3. Summary

Decision trees and Markov models are decision models are two of the more common types of models used in decision analysis. Over the past decade, there has been considerable discussion on how to best present results from decision models. Readers will probably encounter cost effectiveness acceptability curves (CEACs), which are designed to present CEA results for decision makers. According to Fenwick and Byford (44),

“Care must be taken when interpreting the information provided by a CEAC. A CEAC simply presents the probability that an intervention is cost-effective compared with the alternative for a range of values of λ. That is, the probability that the ICER falls below the maximum acceptable ratio. Statements concerning CEACs should be restricted to the uncertainty of the estimate of cost-effectiveness. The information from a CEAC should not, in general, be used to make statements about the implementation of the intervention.”

As implied by Fenwick and Byford (44), questions of implementation introduce other issues, such as the underlying production function, that must be addressed separately. It does not generally hold that statements about cost-effectiveness under ideal situations will necessary hold across a range of implementation scenarios.

Another critical point raised by Fenwick and Byford (44), is the need to include uncertainty. The past decade has also seen an increasing number of incontinence-related papers presenting ICERs without any information on the underlying uncertainty. Some papers reported no significant difference in cost and no significant difference in outcome; they then compute the ICER and despite not including uncertainty they conclude that one treatment is more cost-effective than the other. Scientists must do a better job providing information on uncertainty with the ICER. An example of a CEAC is shown in Figure 5.

7. WITHIN TRIAL ANALYSIS

Clinical trials increasingly measure costs and benefits as secondary end points. In the analysis, the marginal
difference in costs can be computed as well as the marginal difference in outcomes. If one treatment yields significant improvements in outcomes at a significantly lower cost, then it is dominant and an ICER is not necessary. The ICER is computed when one treatment is more effective and more expensive. Computing an ICER is straightforward, however, is necessary to also compute the confidence interval. An ICER without a confidence interval is as useless as an odds ratio or hazard ratio without a confidence interval. Bootstrapping is frequently used to estimate the confidence interval. The International Society for Pharmacoeconomics and Outcomes Research (ISPOR) has issued guidance on within trial analysis (45).

8. BOOTSTRAPPING

Bootstrapping is a resampling method that enables researchers to estimate parameters based on the observed data. Bootstrapping is particularly useful when estimating a confident interval for an ICER. The ICER involves dividing the mean difference in costs by the mean difference in utilities. Statistical software can easily determine whether two samples have different mean costs or different mean utilities (e.g., t-test). Bootstrapping is one way to calculate the confidence interval around the ratio of these two differences. Bootstrapping involves randomly drawing cases from the sample and replacing the case back in the sample. Resampling is done until the original sample size is met. The same process is then done again and again, typically 4000 times. Thus, by resampling, the analyst can calculate the ICER 4000 times, thereby providing a distribution around the ICER.

9. BUDGET IMPACT ANALYSIS

Providers and payers often have questions that are not directly addressed by a CEA based on a societal perspective. Budget impact analysis (BIA) was developed to inform a decision maker on how alternative technology will affect their budget. A BIA will often focus on the decision maker’s costs and over a short time frame (e.g., 1-3 years). Other parameters in the model, such as patient characteristics or input costs, can also be tailored specifically for the decision maker. Making decision based solely on a BIA can lead to suboptimal societal results (46). Hence, scientists advocate that a BIA be done in conjunction with a CEA so that decision makers are informed about the broader social implications of their decision. ISPOR (www.ispor.org) has published guidelines for conducting a BIA (47).

10. KEY STEPS IN A CEA

This section highlights ten key issues that must be addressed in a CEA. These ten principles, summarized below, comprise an appropriate minimum standard for performing and reporting CEA. The principles were identified from guidelines established by the Panel on Cost-Effectiveness in Health and Medicine convened by the United States Public
The Research Question must be clearly stated. All CEAs must compare at least two different treatments or interventions. One of these should include the current standard practices. For example when comparing surgeries for stress incontinence, one of the comparators should be a longstanding method, avoid comparing two new methods side by side.

The Time Frame over which costs and benefits are measured should be long enough to capture the economic impact of an intervention and future health outcomes. Pharmacology studies of 12 weeks duration give very little real economic information, and surgical complications/ failures seldom emerge in less than 1-2 years.

Perspective: The choice of perspective should be clear. Total society perspective (all payers) is the gold standard. Other perspectives, such as the payer or patient perspective, may be useful but must be stated clearly.

Probabilities are needed for each “chance” event, such as chance of cure or chance of an adverse event. The best sources of probabilities come from meta-analyses of randomized clinical trials, or if not available use data from individual clinical trials.

Costs: Units of expense and unit costs should be described in detail. Information on the source (e.g., charges, payments) and year of the cost data should be presented. If the costs were inflated and/or converted from another currency, then this must be described.

Outcome Measure: Measures of effectiveness depend on the type and objectives of analysis. Quality adjusted life years are the gold standard, as described previously in this chapter.

Analytic Model: Each intervention being assessed must be described and possible courses of events identified, including the expected course of disease, treatments, complications, and outcomes. This may be performed using a spreadsheet/ clinical trial path, or Decision Tree, or Markov Model.

Discounting: Discounting is necessary to calculate the present value of money and health states that will occur in the future. Future costs and utilities should be discounted to present value; 3% per year is a recommended starting point.

Incremental Analysis: The purpose of a CEA is to describe the relative value of one health care strategy compared to another. An incremental cost-effectiveness ratio (ICER) is the incremental cost divided by the incremental effectiveness of intervention A compared to intervention B, and is calculated as follows.

\[ \text{ICER} = \frac{\text{Avg. Cost}_A - \text{Avg. Cost}_B}{\text{Avg. Utility}_A - \text{Avg. Utility}_B} \]

Averages should be used rather than other measures of central tendency, such as medians, because it is important to include the effect of outliers. The leverage of the outliers should be tested in a sensitivity analysis.

Sensitivity Analysis and Uncertainty: A sensitivity analysis should allow the reader to understand whether the conclusion of the analysis would hold true if either the Costs or the Probabilities (of cure or complications) were to vary substantially. Probabilistic sensitivity analysis with Monte Carlo simulation is the preferred approach and is required by some journals.

III. SUMMARY OF RECENT ECONOMIC ANALYSES

This section reviews recent literature on the economics of UI, FI and POP. Among modelling studies, we find that very few studies estimate lifetime costs and benefits. When comparing treatments that have very different initial treatment costs, this can create a bias towards treatments that have lower initial costs (behavioural or pharmacological treatment), as opposed to treatments that are initially expensive (surgical).

In the last edition of this chapter, we found a number of studies that computed the ICER and then claimed that one treatment was cost-effective without presenting any information on uncertainty. An ICER without uncertainty is akin to an odds-ratio without a confidence region. We are pleased to see an increasing number of studies including probabilistic sensitivity analysis.

1. BEHAVIOURAL THERAPIES

A number of medical and surgical treatments for urinary incontinence exist with evidence supporting short-term efficacy. While some women opt for these approaches, many prefer conservative/ behavioural therapy, at least as a first-line treatment, because it is non-invasive and there are virtually no adverse side effects. Conservative/ behavioural therapy, (hereafter referred to as behavioural therapy) covers a class of techniques for preventing incontinent episodes through behaviour change. The most common behavioural treatment is pelvic floor training (with or without biofeedback). Behavioural approaches also include cognitive behaviour training techniques to reduce the likelihood of an accident. There is considerable variation in behavioural techniques and their use of professional staff. Some modalities use intensive, one-on-one clinician-led training with direct verbal feedback often involving physical examination of the pelvic floor, while other options are more focused on...
group training or self-care techniques. The level of intensity is important as it not only affects the efficacy, but it also affects the cost of the intervention, with more intensive interventions generally being more effective and more expensive than less intensive options.

Since the last edition, we found seven new published articles evaluating economic aspects of behavioural techniques (48-56). There is strong evidence that behavioural programs are more expensive than usual care. The more intensive programs cost approximately $150 to $344 (2015 USD). However, it remains unclear if behavioural programs provide value in part because there is heterogeneous adherence to these treatments. Some of these studies reporting improvements in pad tests, pads used per week, post void residual, functional impairment measure, and the ICIQ (see Arnold et al., (49)). However, effects were not robust when measured with generic quality of life measures, such as the EQ-5D. This raises questions whether these generic instruments are sensitive to small but important changes.

Future research should consider coupling disease-specific end points with the EQ-5D. Future research should also consider strategies to provide the least expensive interventions as a first-line treatment followed by more intensive options for non-responders. This is a proven way to allocate limited resources. Behavioural economic programs, which create incentives to adhere, may also be useful given the heterogeneous adherence to these treatments.

2. SURGERY FOR STRESS INCONTINENCE

Our review of the literature identified 35 new papers related to the economics of surgery for stress incontinence. We note a couple of challenges in comparing studies. First, most studies lacked end point data beyond 12 month on costs or effectiveness. The randomized trial by Boyers et al (57) tracked end points for 12 months; the longest follow-up was 3-years in the Markov model conducted by Sand et al. (58).

Second, many studies compared alternative surgical treatments. For example, Ciftci et al. (59) compared commercially purchased slings versus hand-made slings, while Laudano et al. (60) compared tension free vaginal tape (TVT) versus colposuspension. Thus, in general, given the follow-up time frame and the restricted set of treatment comparisons, it makes it very difficult to make statements about the cost-effectiveness of surgical treatments compared to pharmacotherapy or behavioural treatment.

Among the 35 studies, not all address questions that were directly relevant for our review. Feng et al. (61) looked at the use of pre-operative urodynamic testing for sling surgery and concluded that there are times when it is overused and other times when it is underused, both of which could affect the cost and effectiveness of care. Subak et al. (62) tracked women who had colposuspension and sling surgery and found that self-management costs decreased 72% ($625 per woman year) and that savings was correlated with decreasing UI frequency. Finally, we excluded some studies from further review because they dealt with issues of surgical timing (cf. Chernansk et al. (63) and Richardson et al. (64)).

Among the relevant studies, Richardson et al. (65) compared mid-urethral sling (MUS) surgery to PFMT and a pessary in a decision tree. They created their tree based on published information. They concluded that surgery was more expensive and more effective, yielding an ICER of $32,132 / QALY. They varied input parameters in one-way and two-way sensitivity analyses. They noted that surgery remains cost-effective at less than $50,000/QALY until the adherence to PFMT and pessary > 40.5% and 43.5%, respectively. The 1-year model was computed based on cure rate of 90.8% for the MUS. We see two limitations with this study. First, a longer follow-up time could be important, especially if the effectiveness of MUS changes after one year. Second, a Monte Carlo simulation would have provided considerable more information on the level of uncertainty around these cost-effectiveness thresholds.

Boyers et al. (57) conducted a randomized trial to assess the costs and effectiveness of a single-incision mini sling to standard mid-urethral sling (MUS). These two types of slings are what economists call close-substitutes, and the potential cost saving for the mini-sling is related to having local anaesthesia versus general anaesthesia. As one might expect with close substitutes, there were no significant differences in quality of life outcomes, as measured with the King’s Health Questionnaire (mean difference: -0.003; 95% CI: -0.008 to +0.002). They also found no significant differences in costs, unless they included costs related to lost productivity (returning to work...
earlier with the mini sling). While the authors calculate the ICER, they did not produce confidence intervals around the ICER. Thus, their conclusion that the mini-sling is cost-effective is not warranted. Rather, it is likely that such an analysis would have produced an ICER with very wide confidence intervals, suggesting little confidence that one treatment is more cost-effective than the other.

Kunkle et al. (66) used a decision tree to assess the cost-effectiveness of mid-urethral sling versus bulking agents for women without urethral hypermobility. They used published data when available and assessed uncertainty with a Monte Carlo simulation. They concluded that MUS was not cost-effective as a first-line treatment for women without urethral hypermobility. They further note that “when MUS costs less than $5132, it becomes a cost-effective first-line treatment, and when it costs less than $2035, it is cost saving.” Unfortunately, only costs and effects through 1 year were included. Bulking agents generally have a limited lifetime, so a longer time frame is critical, creating concerns that the conclusion is flawed.

In prior Committee reports, we reviewed many studies comparing invasive surgeries (Burch colposuspension) to less invasive surgeries (slings). Interestingly, that question seems to be largely answered, with authors typically citing Manca (67). In contrast, this time our review identified a number of studies comparing the costs of close substitutes (e.g., a commercial sling versus a hand-made sling) (59, 68). Although we can observe different prices for the treatment, these differences tend to be obscured by natural variation in practice patterns. So while a hand-made sling may be less expensive than a commercial sling, these cost differences tend to be quite small and are not easily observable when costs of care are summarized over time (e.g., cost per discharge).

Unfortunately, we found a number of articles that presented weak evidence, made unwarranted conclusions, were unclear in presentation, or made errors in calculations. One notable error identified in more than one study is the order of operation in calculating the ICER. The numerator of the ICER is the mean difference in the QALYs between the treatments. The denominator is the mean difference in the QALYs between the treatments. These mean differences must be calculated prior to dividing costs by QALYs. It is incorrect to divide the cost of treatment A by its QALYs and then divide the cost of treatment B by its QALYs. These ratios cannot be directly compared (see Figure 6).

### 3. SURGERY FOR URGE INCONTINENCE AND REFRACTORY OAB

There are two primary treatments for urge urinary incontinence and refractory OAB: sacral nerve stimulation (SNS) and Botulinum Toxin A. Since the previous Committee report, two additional papers were published comparing cost-effectiveness of SNS to Botulinum Toxin injection (69, 70), and to oral medical treatment (70). In addition, two publications looked at economics aspects of different SNS test phases (71, 72).

Aboseif et al. (73) retrospectively reviewed the US costs related to SNS for a period extending from one year pre- to one year post-implantation. In a heterogeneous group of patients, also including patients with urinary retention and chronic pelvic pain, a one-year SNS treatment reduced outpatient doctor visits and diagnostic and therapeutic procedure costs 92%, along with a 30% reduction in drug costs (73). This, however, did not include the costs of the neuromodulation implant itself, nor the surgical implantation costs. QALYs were not ascertained.

Because there is no standard protocol for Botulinum Toxin A injection, a different protocol using 200 units every 14 months was evaluated in the Arlandis study, which proved cost-effective on the ICER < € 30000/QALY threshold (74). The data are consistent with a cost-effectiveness analysis in Canada and Italy (69, 70). A Markov model was used to estimate long-term costs and outcomes. Sacral neuromodulation, injection with Botulinum toxin and optimal medical therapy were included in the analysis. Hassouna et al. (70) estimated cost effectiveness over a 10-year period and demonstrated that SNS became cost-effective compared to Botulinum toxin injection at 5 years. In the Italian study, SNS became cost-effective from the third year onwards, with ICER of 21258.72 €/QALY, and was economically dominant at year 10 (69). At long-term follow up, the most influential variables appeared to be the frequency of Botulinum toxin injections, IPG longevity (reflecting the quality of lead placement, e.g., the closer the lead is placed to the nerve, the lower amplitudes are necessary for the effect) and hospitalisation costs for both procedures.

The Canadian study also compared to SNS to optimal medical therapy. In Canada SNS was cost-effective at the 2-year period and dominant at 5 and 10 years. The incremental cost of SNS was -$2233 and -$11447 at 5 and 10 years respectively, with added QALYs of 0.94 and 1.76 compared to optimal medical therapy.

In summary, the different mid- to long-term cost-effectiveness analyses support a therapeutic pathway starting with SNS compared to Botulinum toxin injection (69, 70, 74, 75). Reducing need for hospitalisation (e.g., local instead of general anaesthesia) and optimal lead placement (e.g., less need for revision, lower amplitude for stimulation) appear important influencing factors.

Kantartzis and colleagues (72) analysed different options for SNS in a cost-effectiveness decision analysis model: unilateral PNE, bilateral PNE, unilateral permanent lead test, bilateral permanent lead test and full implant with test phase. No intermittent treatment was used as reference case. Full implant with
test phase appeared the most expensive ($31,824) with effectiveness of 4.113 QALYs. However unilateral and bilateral test with permanent electrodes had lower costs ($6,038 and $7,702, respectively) and appeared more effective (4.201 and 4.321 QALYs, respectively), making these the preferred strategies. This was because the pulse generator is the most expensive part of the treatment procedure. The base parameters in the model were success rate of unilateral and bilateral tests with permanent electrode (67% and 87%) (SDW4). However, a single institution analysis in the US reported a success rate of 90% for stage I and showed that with these numbers a single stage implant would be cost-effective over staged procedure, according to specific reimbursement data (71). Break-even point was found at 68.6% success, based on Blue Cross/Blue Shield reimbursement and at 95% success rate for Medicare. The cut-off level is different for different reimbursement systems and thus most likely different for different countries. However it would be interesting to conduct such strategy in different countries and settings to obtain the individual cut-off level.

4. PHARMACOTHERAPY

Although pharmaceutical companies must show that a new drug is safe and efficacious prior to approval and marketing, the requirement for evidence of cost-effectiveness (i.e. whether the new drug is cost-effective compared to another treatment), varies from country to country.

The U.S. Food and Drug Administration does not require economic data in its review of a new drug. Instead it leaves economic questions to the purchasers (e.g., insurance companies, government purchasers or individuals), similar to the Netherlands. In the UK, however, the National Institute for Health and Clinical Excellence (NICE) requires economic review. Although there is not a strict threshold, they have denied approvals for new drugs that have an incremental cost effectiveness ratio greater than £30,000 per QALY. However, there is some pressure to reduce this threshold (76). In Australia, manufacturers must prove cost-effectiveness, but there is no explicit threshold to be listed on the Pharmaceutical Benefit Scheme (whereby patients pay a subsidized cost for the drug). However, only therapeutic efficacy and safety must be shown for it to be available in Australia as a non-subsidized “private” prescription. Many purchasers (as in Australia) have formularies, or lists of medications that they are willing to pay for, and the economic evaluation is frequently part of the request to place the new drug on the formulary.

In the next sections, we review the literature since the prior Committee publication in 2012 on the economics of drugs for incontinence and overactive bladder.

4.1. Stress Incontinence

We identified no cost-effectiveness articles for stress urinary incontinence (SUI) in the past 5 years since the prior ICI report in 2012. This is consistent with the lack of available pharmacological therapies for stress incontinence. (NOTE: Duloxetine did not receive US FDA approval for SUI. It is approved by the European Medicines Agency, an Agency of the European Union, for depression, anxiety and diabetic peripheral neuropathy.)

4.2. Urge Incontinence and OAB

There are several commonly used pharmacological treatments for overactive bladder and urgency urinary incontinence, including oxybutynin (Ditropan) as a tablet or as Oxytrol patches; tolterodine (Detrol), darifenacn (Enablex), trospium (Sanctura), solifenacin (Vesicare), fesoterodine (Toviaz), and more recently introduced mirabegron (Myrbetriq). There have been few CEA/CUAs on medications since the prior ICI report and most have been funded or performed by drug developers, creating potential conflicts of interest. Other common limitations include using an incontinence-specific utility measure, limited time frame and limited comparison treatments. While industry-funded studies often include experts in performing CEA and sound methods, they must be interpreted carefully for the possibility of bias. For example selection of assumptions included in the models or analyses like probability of events (e.g., drug response, likelihood of transitioning to a different treatment strategy, probability of side effects or adverse events), timeframe, costs and perspective. Each of these parameters can dramatically affect the analysis and the outcome.

Several analyses presented incremental analyses compared to no treatment, rather than to the next least costly treatment which makes the intervention appear more cost-effective (lower “ICER”). Most analyses that include sensitivity analyses find that the analysis is most sensitive to utilities. This can be dramatically affected by choice of measure and availability of primary data (vs. other assumptions). In the past five years, researchers have developed mapped algorithms that link scores on the I-QOL to the AQOL analysis is most sensitive to utilities. This can be dramatically affected by choice of measure and availability of primary data (vs. other assumptions). In the past five years, researchers have developed mapped algorithms that link scores on the I-QOL to the AQOL

SUMMARY OF RECENT ECONOMIC ANALYSES | 2493
pared to other medicines. Wielage and colleagues looking at the cost-effectiveness of mirabegron compared to tolterodine, considered a proxy for treatment effectiveness. While both studies showed that solifenacin was cost-effective compared to a comparator drug by current thresholds, analyses were sensitive to utility values and drug effectiveness and should be interpreted with care.

Nilsson et al. (79) developed a decision model to compare the class of newer anticholinergic drugs (i.e. solifenacin, tolterodine, fesoterodine, darifenacin, oxybutynin patch), to oxybutynin immediate-release, and to no treatment (placebo effect) over a 1 year time period in Sweden. Data from the Swedish Prescribed Drug Registry provided primary data on utilization, and current economic analysis methodology, has the potential to improve our understanding of new therapies and better guide patient care and resource allocation.

Mirabegron, a β3-agonist, is a newer OAB medication that should not increase anticholinergic burden or the risk of dementia. There have been a few studies looking at the cost-effectiveness of mirabegron compared to other medicines. Wielage and colleagues (80) developed a Markov model in the US, while CEA models for Mirabegron were also submitted to NICE for UK review (81, 82). CEA reviewed the models and published a lengthy review (83). Despite the concerns raised in the NICE review, Mirabegron appears to hold promise as a new treatment for OAB and urge incontinence.

The cost-effectiveness of percutaneous tibial nerve stimulation (PTNS) versus extended release tolterodine for the treatment of OAB over a 1-year timeframe was assessed using modelling (84). Percutaneous tibial nerve stimulation therapy included 12 sessions over 3 months followed by maintenance therapy. The primary outcome was the ICER, with less than $50,000 per QALY gained considered cost-effective. One-way sensitivity analyses and Monte Carlo simulation assessed the robustness of the model. The analyses showed that PTNS added significant cost to the management of OAB with modest improvement in quality of life. For every 100 patients treated with PTNS the costs increased by $303,480 and resulted in an additional 4.3 quality adjusted life-years gained compared to tolterodine ER. The ICER was $70,754 per QALY gained. The ICER was most affected by utility for incontinence and probability of continuing PTNS beyond 12 months. In Monte Carlo analyses, PTNS was cost-effective only 21% of the time. The investigators concluded that PTNS was not cost-effective for treating OAB compared to tolterodine ER. However, in clinical practice, PTNS is usually employed for patients who failed pharmacotherapy.

A multi-site randomized, controlled trial, the Anticholinergic versus Botulinum Toxin, Comparison Trial for the Treatment of Bothersome Urinary Incontinence (ABC) is being conducted in the US and includes a within-trial cost-effectiveness analysis (85). This trial compares the change in UUI episodes over 6 months, tolerability and cost effectiveness between women receiving daily anticholinergic therapy plus a single intra-detrusor injection of saline versus a single intra-detrusor injection of 100 U of Botulinum toxin A plus daily oral placebo tablets. They will collect primary data on direct and indirect costs and utilities (using the OAB-Q and SF-12) to estimate QALY and calculate ICER. This type of CEA, that uses primary data and current economic analysis methodology, has the potential to improve our understanding of new therapies and better guide patient care and resource allocation.

Data were inconsistent on the cost compared to cost saving of treating UUI/OAB with medication. A cross-sectional study using data from an internet-based questionnaire of a nationwide sample of 75,000 adults (US National Health and Wellness Survey) evaluated the impact of treating urge and mixed UI on healthcare resource utilization, productivity, activity impairment and associated costs (86). UUI/MUI respondents were categorized as OAB treatment users or non-treatment users (who never used treatment and whose condition reportedly interfered with life activities or was difficult to manage). Outcome measures included healthcare utilization and Work Productivity and Activity Impairment questionnaire-based scores. Direct and indirect costs were estimated using labour and medical expenditure data sources ($2008). Treatment (vs. non-treatment)
users were more likely to be female (81% vs. 70%), older (mean = 63 vs. 53) and reporting more moderate-to-severe OAB (71% vs. 53%; all p < 0.05). Adjusting for covariates, treatment users had significantly lower activity impairment, more provider visits and higher total direct costs ($27,291 vs. $21,493) per year. Thus, treatment for UUI/MUI may help with symptom management and lessen activity impairment but has higher costs compared to never users.

A case-control study with case defined as diagnosis of OAB, ≥1 UI episode per day and prescribed anticholinergic therapy and control as no OAB matched in a 1:3 ratio based on sex, age, and observation time, used retrospective medical and pharmacy claims data to analyse patient comorbidities, as well as track health care resource utilization (HRU) and direct payer costs ($2013) (87). OAB was significantly

![Figure 7]

Proportions of Males and Females with Each of the Six ADL Disability Types by Age Group (a) Males; (b) Females

Note: N =18,801.

*Figure 7*
associated with increased HRU rates of hospital admissions, outpatient visits, prescriptions filled, and diagnostic tests performed. After adjustment for covariates, total health care cost was 33% higher for OAB cases than non-OAB controls, resulting in an increased cost of $2,821 per year. OAB patients who initiate anticholinergic therapy use significantly more health care resources than patients without OAB.

In contrast, a third study performed by a pharmaceutical company concluded that OAB treatment was cost-saving compared to no OAB pharmacotherapy in vulnerable elderly OAB patients. Costs of treating OAB with fesoterodine compared to no OAB pharmacotherapy from the US payer perspective was assessed using a decision analytic cost model (88). Vulnerable elderly OAB patients were defined as age ≥65 years with 2-15 UUI episodes/day and at risk of deteriorating health by a score of ≥3 on the Vulnerable Elders Survey (VES)-13. Fesoterodine treatment response was defined as no UUI episodes over 1 year. OAB-related costs included OAB drug costs, healthcare resource use (inpatient hospitalization, outpatient visits, and physician office visits), and OAB-related co-morbidities (falls/fractures, urinary tract infections, depression, and nursing home admissions; $2013). Treating OAB patients could save $1616 per patient vs. no OAB pharmacotherapy. In univariate sensitivity, results were most sensitive to changes in fesoterodine efficacy followed by annual costs of inpatient hospitalization. Some of the reasons for this conflicting finding may be that the analysis did not include cognitive impairment, assumed a low prevalence of UUI (13.5%), used a high probability treatment response (51% no UI episodes at week 12).

OAB medication adherence may be an important factor in decreasing absenteeism. A retrospective claims database of 27 large US employers was used to evaluate employee urinary antispasmodic (UA) medication persistence and adherence, the impact of salary and co-payments on adherence, and the impact of UA adherence on medical, pharmacy, sick leave, short- and long-term disability, workers’ compensations, and adherence were assessed controlling for demographics, job-related factors, co-payments, and pre-index employee benefit utilization. Increased co-payments and co-payments as a percentage of salary were associated with lower adherence. Employees with ≥80% adherence had lower medical, sick leave, and short-term disability and higher overall drug costs than employees with less than 80% adherence, although the effects could be related to an omitted variable. Thus, there is some weak evidence to suggest a potential economic benefit to employers from increased UA adherence.

A retrospective study of 3094 actively working patients initiating first treatment with antimuscarinics (fesoterodine, solifenacin or tolterodine) from 31 primary care centres was done in Spain (90). The comparison of fesoterodine versus solifenacin and tolterodine showed a higher adherence (medication possession ratio; 90% vs. 87% and 86%, respectively), higher treatment persistence (40% vs. 35% and 34%), fewer days of sick leave (5 vs. 10 and 9 days) and costs corrected for covariates (€371 vs. €703 and €693 in €2014; all p < 0.05). While it is not clear how sick leave and productivity were assessed, the results suggest that initiating treatment with fesoterodine to treat OAB (compared with solifenacin or tolterodine) had fewer days of sick leave, resulting in lower costs due to lost productivity.

5. INCONTINENCE COSTS RELATED TO NURSING HOMES

The economics of incontinence and nursing homes focus on two separate, but related issues: 1) the cost of nursing home admissions attributable to incontinence, and 2) the cost of treating incontinence that develops while in the nursing home.

Additional nursing home admissions cost is often a major component in the total cost of urinary incontinence. In a 2001 study (15) the cost estimate was $2.4 billion in 1995 dollars. In a 2004 study (14), the cost estimate was $4.0 billion in 2000 dollars. In a 2006 study (91), the attributable fraction (AF) statistics from published data was shown to be $6.0 billion in 2004 dollars. The Attributable Fraction (AF) statistics are obtained by using incontinence prevalence rates for those admitted to nursing homes, as compared to those who were not admitted to nursing homes. The research supporting the AF statistics is not consistent. While Thom et al. (92) found a relationship between UI and nursing home admission, more recent studies have found otherwise. Holroyd-Leduc et al. (93) conducted a population-based prospective cohort study (from 1993-1995) in over 6,500 elderly (>age70) patients. After adjusting for confounders, UI was not an independent predictor for death, nursing home admission, or functional decline.

A recent, noteworthy study by Fong et al. (94) found that additional limitations on activities of daily living were associated with nursing home admission. There was a noticeable increase in nursing home admissions after 3 ADLs. Interestingly, bathing was the most critical factor (not toileting). While toileting/ incontinence has a role in nursing home admissions, it is less important than bathing (see Figure 7). Economic models may have overstated this attributable fraction and more conservative cost estimates are now warranted.

Once a person is admitted to a nursing home, labour costs are a major component of caring for incontinent patients. These costs are studied via time/motion observation, correlated with severity and type of incontinence. In 49 long-term care facilities in North Carolina, US, it was found that the incremental labour...
Pelvic organ prolapse (POP) is prevalent, with 3-6% of middle-aged and older women reporting symptomatic and/or bothersome POP (97, 98). Surgeries for POP are also common, with the lifetime cumulative risk POP surgery was 12.6% (95% CI 12.4-12.7) by age 80 years in the US. The age-specific annual risk for POP increases progressively until ages 71 and 73 years when the annual risk is estimated as 4.3 per 1,000 women (99). The annual economic costs of pelvic organ prolapse surgeries are substantial and similar to other surgical interventions for women (breast cancer, gynecologic cancer, urinary incontinence).

Several newer surgical approaches for POP have become commonly used in the past 5 years, including laparoscopic sacrocolpopexy, robotic sacrocolpopexy, and vaginal mesh. These new modalities may include very costly capital investment in equipment (such as robotic systems), use expensive disposables, in-use, use costly mesh kit products, take longer operative time, and/or be associated with adverse events and future procedures. They may also be associated with shorter hospital stay and more rapid recovery. Therefore, cost-effectiveness is well suited for these modalities and there have been several economic analyses in the past 5 years.

Similar to other surgical procedures, costs for prolapse surgery are largely driven by length of stay (LOS) and less affected by operative time and equipment. A single site study with one surgeon described costs, operative times, and LOS for 91 open and 73 robotic consecutive sacrocolpopexies (101). Direct costs were determined with their hospital procurement database and robot costs and maintenance were included. Median operative times for open and robotic approaches were 166 and 212 minutes (P < 0.001), respectively, and length of stay was 3 versus 2 days (P < 0.001). The median cost for the open and robotic procedures was $7,804 and $6,668 (P = 0.002), respectively. Thus robotic sacrocolpopexy takes slightly longer to perform but costs less than the open procedure in total due to higher LOS costs.

A retrospective cross-sectional and longitudinal study from the 2001 to 2011 US National Inpatient Sample included women undergoing inpatient prolapse repairs (102). In multivariate analyses, African Americans had 9% (95% CI 5%, 13%) longer LOS compared with Caucasians and the uninsured had 15% (95% CI, 1%, 30%) longer LOS compared with those privately insured. Comorbidities associated with 20% increase in LOS and costs were congestive heart failure, pulmonary circulation disorders, metastatic cancer, weight loss, coagulopathy, electrolyte/fluid imbalance, and blood loss/deficiency anaemia (P < 0.001). Over the 10 years of the study, mean LOS declined from 2.4 days (95% CI: 2.4, 2.5) to 1.8 days (95% CI: 1.7, 1.9; P < 0.001), yet mean total cost increased from $6233 (95% CI: $5859, $6607) to $9035 (95% CI: $8632, $9438; P < 0.001). Paradoxically, inpatient surgical costs for prolapse increased despite decreasing LOS. With the study design, the reason for this finding could not be elucidated.

Two cost-minimization studies compared robot-assisted vs. open sacrocolpopexy(103) and laparoscopic sacral colpopexy (LSC) vs. total vaginal mesh (104) In the first study, direct costs over 30 days from the hospital perspective at a single site in the US were included (103) Operative time was similar for robotic and open surgery (226 versus 221 minutes, respectively) but postoperative LOS was less for robotic vs. open (1.0 versus 3.3 days, p <0.001). This study observed 10% cost savings for robot-assisted versus open sacrocolpopexy ($10,178 versus $11,307), with the largest drivers of cost identified as the number of institutional robotic cases done annually, LOS and cost per hospitalization day in the postoperative period. The second study used primary cost data from a randomized trial of LSC versus TVM and included prices from privately- and publicly-conducted procedures in Australia and women’s opportunity cost of time form the societal perspective (104). In this trial, there were no differences in outcomes at 2 years on two POP QOL measures, suggesting that cost-minimization analysis may be an appropriate study design. Mean total economic costs were significantly lower in the laparoscopic group compared with total vaginal mesh ($4013; 95% CI, 3108, 4918; similar for public and private models). Labour costs were significantly greater for laparoscopic but were offset by lower consumable, inpatient, opportunity, and reoperation costs compared with total vaginal mesh. Therefore, laparoscopic sacrocolpopexy has lower economic cost than total vaginal mesh.

A meta-analysis and systematic review (105, 106) nicely summarized several CEA s comparing robot-
assisted to laparoscopic sacrocolpopexy. Overall, the studies show that robot-assisted was costlier than laparoscopic with similar clinical outcomes. The first study included studies that directly compared the outcomes of robot-assisted and laparoscopic with a sample size in each group more than 15, and the follow-up duration longer than 3 months (105). Seven studies (4 retrospective, 2 randomized clinical trials, 1 prospective study) with data on 264 robot-assisted and 267 laparoscopic procedures were included. The mean operative time was longer in the robot-assisted group (246 vs 206 minutes; P<0.001) and the estimated blood loss, incidence of intraoperative/postoperative complications and in the two groups were not statistically different. The costs of robot-assisted were significantly higher than laparoscopic in each of three studies (P<0.01 for all). Thus, the clinical outcomes of prolapse surgery were similar with robot-assisted and laparoscopic, but robot-assisted was more costly.

A systematic review included only randomized controlled trials (2 trials, n = 156) comparing laparoscopic and robot-assisted sacrocolpopexy (heterogeneity between the two studies precluded a meta-analysis) (106). In one trial (Paraiso), laparoscopic was faster than robot-assisted sacrocolpopexy (199±46 vs. 265±50 min; p <0.001) (107), yet no difference was found in the second trial (ACCESS; 225±62.3 vs. 246.5±51.3 min; p = .11) (108). Costs for using the robot were significantly higher in both studies, however, in the ACCESS trial, only when purchase and maintenance of the robot was included (laparoscopic $11,573±3191 vs. robot-assisted $19,616±3135; p <.001). In the Paraiso study, robot-assisted was more expensive even without considering those costs (laparoscopic US$ 14,342±2941 vs. robot-assisted 16,278±3326; p = 0.008). Both studies observed longer operating time and higher pain scores through 1 month in the robotic groups. There were no differences in anatomical outcomes, pelvic floor function, or quality of life. In these small, randomized studies, robotic surgery significantly increased cost compared to the conventional laparoscopic sacrocolpopexy with no improvement in outcome.

For the surgical correction of apical prolapse, the abdominal approach is associated with better outcomes; however, it is more expensive than the transvaginal approach. A decision-analytic model was developed to assess the cost-effectiveness of abdominal sacral colpopexy (ASC) vs. sacrospinous ligament fixation (SSLF) to determine if the improved outcomes of ASC justify the increased expense (109). The model included post-operative SUI with possible mid-urethral sling placement, prolapse recurrence with possible re-operation, and post-operative dyspareunia. Cost-effectiveness was defined as an ICER of less than $50,000 per QALY. At the baseline, ASC is more expensive than SSLF ($13,988 vs $11,950; $2013) and more effective (QALY 1.53 vs 1.45) with an ICER of $24,574/QALY at 2 years. ASC was not cost-effective if the rate of post-operative stress incontinence was above 36% after ASC or below 28% after SSLF, the rate of recurrent prolapse was above 15% after ASC or below 4% after SSLF, or the rate of post-operative dyspareunia was above 59% after ASC or below 19% after SSLF. In this study, abdominal sacral colpopexy was a cost-effective alternative compared with sacrospinous ligament fixation. Of note, is that SSLF can be considered a cost-effective alternative as the post-operative outcomes of SSLF improve.

To assess the cost-effectiveness of a mesh-augmented anterior vaginal wall repair compared with a non-mesh fascial plication repair, Jacklin and Duckett (110) used a 5-year timeframe from the UK National Health Service perspective (£2008-9) with data derived from systematic reviews and recent publications, and utilities assumed to be similar to those for urinary incontinence. In the base case, the ICER for mesh-augmented anterior repairs was £15 million per QALY. Sensitivity analysis found no plausible model inputs that could make a mesh repair cost-effective by conventional criteria because of the extra costs associated with the price of the mesh, treating mesh erosion and low difference in reoperation rate for mesh anterior wall repairs. A few studies explored pre-operative evaluation or prophylactic procedures with prolapse repair surgery. Richardson et al. (111) used decision analysis modelling to compare the cost-effectiveness of mid urethral sling to prevent occult stress urinary incontinence in women undergoing abdominal sacrocolpopexy. They evaluated 3 treatment approaches (1) abdominal sacrocolpopexy alone with deferred option for mid urethral sling, 2) abdominal sacrocolpopexy with concomitant mid urethral sling and 3) preoperative urodynamic study for selective mid urethral sling) over 1-year ($2010 US Medicare reimbursement). Utilities were from general HRQOL in population-based studies, but assumed a large impact of SUI (0.71 compared to 0.93 with no SUI) that may have biased the analysis toward the sling intervention. They found that universally performing mid urethral sling at abdominal sacrocolpopexy was the most cost-effective approach compared to abdominal sacrocervical repair alone (ICER $2,867 per QALY). Universal mid urethral sling dominated the preoperative urodynamic study strategy (less costly and more effective). The cost-effectiveness of abdominal sacrocolpopexy plus mid urethral sling was robust to sensitivity analysis with a cost-effectiveness ratio consistently below $20,000 per QALY. This study concluded that universal concomitant mid urethral sling is the most cost-effective prophylaxis strategy for occult stress urinary incontinence in women undergoing abdominal sacrocolpopexy and preoperative urodynamic study is not cost-effective. A retrospective study of mid-urethral sling at a single site assessed the value of preoperative assessment (electrocardiogram, chest x-ray, basic metabolic panel, complete blood count, coagulation studies and...
urinals) in 101 women (112). They evaluated appropriateness of tests based on guidelines from the American Academy of Family Physicians and additional costs of inappropriate tests ($2014 US Medicare reimbursement). Overall 76% of coagulation profiles, 73% of complete blood counts, 47% of basic metabolic panels, 39% of chest x-rays and 21% of electrocardiograms ordered did not have an appropriate clinical indication, with 6-22% under-ordering of appropriate tests. The estimated total from overused tests was $18 per patient. At this site, preoperative testing was both over- and under-used in women undergoing sling surgery leading to increased health care costs.

Two studies examined endometrial evaluation prior to prolapse surgery (113). A decision analytic model was used to compare the cost-effectiveness of endometrial biopsy, transvaginal ultrasound and no screening for endometrial cancer in asymptomatic, postmenopausal women prior to uterine morcellation in minimally invasive supracervical hysterectomy and sacral colpopexy for pelvic organ prolapse treatment. The cost per-patient was $8800, $9023, and $9112 over 5 years for no screening, endometrial biopsy, and transvaginal ultrasound, respectively ($2012 US dollars) with 0.39 and 0.38 days of life saved for endometrial biopsy and transvaginal ultrasound, respectively, compared to no screening. The ICER was $207,348 for endometrial biopsy (dominated transvaginal ultrasound) compared with no screening. The analysis was robust to sensitivity analyses. Another decision analysis evaluated the cost-utility of preoperative endometrial evaluation before Le Fort colpopoiesis in asymptomatic women ($2012 US Medicare costs) (114). From a health plan perspective and willingness-to-pay thresholds of $50,000 and $100,000, no evaluation was superior to both biopsy and ultrasound. At a 64% probability of cancer, biopsy is more cost-effective than no evaluation and ultrasound. Thus, pre-operative screening for endometrial cancer is likely not cost effective in asymptomatic, postmenopausal women.

Thus, by standard thresholds, abdominal sacral colpopexy (ASC) may be cost-effective compared to sacropinous ligament fixation (SSLF) and performing a mid-urethral sling with ASC may be cost-effective compared to ASC alone. Mesh-augmented anterior vaginal wall repair was not cost-effective compared with a non-mesh fascial plication repair and pre-operative screening for endometrial cancer before prolapse surgery is likely not cost effective in asymptomatic, postmenopausal women.

7.1. Cost of Illness

Faecal incontinence is a debilitating condition associated with significant impairment in quality of life. Even minor symptoms can lead to deterioration in general health, physical functioning, and emotional well-being. Social isolation can occur for fear of having accidents, leading to a loss of productivity and ability to perform activities of daily living (115, 116). The costs associated with treating faecal incontinence vary based on the population studied. For instance, the non-surgical costs of managing faecal incontinence is higher in nursing home residents when compared to the adult working population although in the latter group, lost productivity, may account for a greater proportion of total costs (117). There is significant variation in costs (across countries and providers) making it difficult to extrapolate the results of cost-effectiveness studies to a local health care system.

Early studies assessing the cost of faecal incontinence focused on inpatients with faecal incontinence (118), patients with self-reported faecal incontinence (119), and patients with obstetric injury(120). All of these studies collected data retrospectively from databases and lacked a validated measure of severity.

Deutekom et al. (116) collected prospective data from 253 Dutch patients with faecal incontinence to assess the direct medical and non-medical costs of treatment from a societal perspective. Severity of incontinence was measured using the St Mark’s continence score but QALYs were obtained and therefore the relationship between cost, severity and quality of life was not explored. However, the study did produce novel data on the proportion of absenteeism, productivity loss and need for paid and unpaid care for patients with faecal incontinence, from the perspective of a Netherlands population. Lost productivity occurred in 15.4% of patients who worked, with absenteeism due to symptoms of incontinence occurring in 1.7%. The cost of non-surgical treatment was estimated to be €2169 per patient per year. Costs associated with lost productivity were found to account for more than half the total costs associated with the management of faecal incontinence.

In 2012, Xu et al. (121) performed a patient survey to collect self-reported data regarding the sociodemographic characteristics, clinical symptoms and utilization of medical and nonmedical resources for faecal incontinence. Patients were identified from outpatient records at a single tertiary care centre and mailed questionnaires. The results therefore relate to a self-selected cohort of patients that may have had more severe symptoms of faecal incontinence than compared to the general population. Unit costs were based on US Medicare reimbursement rates, national average medication cost and estimates from other relevant sources (e.g., continence pad cost). Analysis included medical and non-medical costs and lost productivity. The analysis was conducted from a societal perspective. The mean cost per person for the conservative management of faecal incontinence was $4110 per year (median $1594; IQR $517-5164). Medical costs accounted for $2353 per year (median $1176; IQR $294-2438), non-medical cost $209 per year (median $75; IQR $17-$262) and lost-productivity cost $1549 per year (median $0; IQR $0-813).
There was a correlation between the severity of faecal incontinence and medical costs.

7.2. Prevention

Surgery for anal fistulae often results in damage to the anal sphincters and subsequent impairment of continence. The clinical outcomes of two sphincter-preserving treatments, anal fistula plug and endo-anal advancement flap, was studied by Adamina et al. in 2010 (122). The primary end point was fistula healing, defined by absence of need for further drainage, abscess formation and an external fistula opening on physical examination at six-months follow-up. Only patients with anal fistula of cryptoglandular origin were studied.

A micro-costing analysis of treatment costs was performed with adjustments for inflation and sensitivity analysis were performed. Non-medical costs and lost productivity costs were not assessed. The primary end point, healed fistula, was found to be lower than in the majority of published studies on the two techniques adopted. As cost-effectiveness was based on healing and complication rates, with no direct measurement of faecal incontinence the cost-effectiveness for adopting each surgical strategy to prevent episodes of FI remains unclear. The study concluded adopting a strategy of anal fistula use saved $1,588 per healed fistula.

Tan et al. (123) studied the cost-effectiveness of primary sphincter repair versus delayed sphincter repair for anal sphincter injury, in the prevention of faecal incontinence. Clinical data were identified from a literature review of studies published between 1976 and 2006 that described at least one of the measured outcomes (probability of functional success/failure and quality of life). A decision tree analysis over a ten-year horizon was constructed with QALYs derived from the SF-6D (23). The study concluded that primary sphincter repair was the most cost-effective strategy being associated with a gain of 5.72 QALYs for a cost of £2750 compared with delayed sphincter repair, which yielded a QALY gain of 3.73 for a cost of £2667.

Langill et al. (124) conducted an industry-sponsored study to examine the costs of managing faecal incontinence using a faecal management system (Flexiseal, Convatec, USA) compared with traditional methods (absorbable pads, cleansers etc.) in the intensive care unit. The use of a faecal management system was associated with lower daily material costs, nursing time for managing faecal incontinence, and annual cost savings when compared to patients managed traditionally. A further study by Pittman et al. (125) also reported saving medical costs from the use of a bowel management system when compared to traditional care with greater clinician satisfaction with the device.

7.3. Treatment

Recent cost-effectiveness analyses have primarily focused on sacral nerve stimulation (SNS) as a first-line surgical treatment for patients with faecal incontinence.

7.3.1 SNS Versus Conservative Treatments

Dudding et al. (126) assessed the cost-effectiveness of SNS versus maximal conservative treatment from a societal perspective over a seven-year time horizon. Data collected prospectively on consecutive patients undergoing two-stage SNS, under general anaesthetic, at a single UK institution, over a ten-year period were entered into a Markov decision model. Clinical effectiveness was measured by reductions of incontinence episodes measured by repeat bowel habit diaries. Medical and lost productivity costs were estimated using the UK national tariff and health resource group (HRG) codes and data previously published by Deutokem and colleagues (116). No data on caregiver costs were collected. Cost effectiveness was measured as ICER with the QALY calculation derived from the SF-6D (127). Sensitivity analysis was performed to assess robustness of the model and rates were discounted by 3.5%. The ICER for SNS was £25,070 per QALY gained. This equates to £1038 more per year to treat patients with SNS for a median reduction in 286 incontinent episodes (£3.63 per episode reduced). However, this calculation was based on a self-selected group of patients undergoing SNS that had all failed to benefit from conservative treatment. The ICER of £25,070 per QALY gained was within the £30,000 per QALY threshold recommended by the UK National Institute of Clinical Excellence as an effective use of UK NHS funding with proper justification. When lost-productivity costs were also considered the ICER decreased to £12,959 per QALY gained. The cost-effectiveness of SNS is likely to deteriorate over a longer time-horizon due to battery depletion and the need to remove and re-implant a new pulse generator.

Brosa et al. (128) assessed the clinical and cost effectiveness of sacral nerve stimulation versus maximum conservative treatment from a hospital perspective. Only patients with an intact anal sphincter, including those that had previous repair, were included. All procedures were performed under local anaesthetic. Despite a high failure rate of peripheral nerve evaluation, in patients with an anatomically intact anal sphincter, SNS appeared cost effective when compared with maximal conservative treatments. SNS had a cost of €16,181 per QALY gained; for those with a deficient sphincter, SNS cost €22,195 per QALY gained. Both ICERs were within the €30,000 threshold accepted in Spain. The greatest cost associated with SNS was related to the high upfront cost of the permanent device. The authors proposed that the cost-effectiveness of SNS is improved by performing the procedure under local anaesthetic. While the results are largely consistent with Dudding’s work (126), this study has some limitation worth noting.
Costs were evaluated over a five-year time horizon, but future costs were not discounted. In addition, a detailed description of the Markov model used was not provided and it is unclear how the QALY values were determined. Finally, there was potential conflict of interest as two of the authors worked for Medtronic (device manufacturer for 'InterStim' sacral neuromodulation equipment), and "four authors received an unrestricted grant from Medtronic".

The relationship between the Markov model developed in the above paper by Brosa et al. (128), and a patient cohort study published by a similar group of authors (129) also from Spain in the same year, is unclear. In the paper from Munoz-Duyos et al. (129) only patients with an intact anal sphincter, including those that had previous anal sphincter repair, were included. Patient-level cost data were given for 57 temporary evaluations all performed under local anaesthetic in 47 patients, giving a success rate of 61%. This success rate is lower than most published studies of sacral nerve stimulation. Permanent SNS devices were implanted in 29 patients, who were followed for a median of 3 years. The study was reported on an intention to treat basis over a five-year time horizon. Only treatment costs were evaluated. The actual Markov model was not provided. Costs were not discounted. No sensitivity analysis was performed. It is unclear how the QALY were determined, as no QALY tests were administered, and data arising from calculating QALYs from SF36 were quoted as being derived from the paper by Brosa et al. (128). Thus it appears that this report from Munoz-Duyos was perhaps related to or overlapped with the Brosa paper (128, 129).

Mitchell et al. (130) performed a cohort analysis of age and sex matched patients undergoing temporary single electrode helical wire placement under general (GA) and local anaesthesia (LA). Although not statistically significant, a greater proportion of patients had success in the GA group (77% versus 64%). Sample size was limited (n=111), limiting the precision of the estimated result. A £130 cost saving was found with the local anaesthetic procedure (general anaesthetic £743 versus local anaesthetic £613). However, as this cost was not correlated with clinical effectiveness the conclusion of the study, that temporary wire insertion under local anaesthetic is more cost effective is unjustifiable.

Dudding and Nugent (131) compared the use of a permanent quadripolar electrode for temporary testing as part of a staged implant versus the helical wire electrode as part of a two-stage procedure. Estimates of top-down cost, clinical outcome and complication rate related to temporary, staged and permanent sacral nerve stimulation was calculated using published data from multiple sources. These data were then used to formulate a basic decision analysis model. It was concluded that on an intention-to-treat basis, by adopting a staged implant strategy, a saving of £27.78 per patient can be made over a two-stage procedure.

7.3.2 SNS Versus Other Treatments for Faecal Incontinence

Three recent studies have assessed the cost-effectiveness of sacral nerve stimulation in comparison with other surgical treatments. First, Indinnimeo et al. (132) used a decision analysis model to compare a surgical treatment pathway for faecal incontinence with and without sacral nerve stimulation. Data were obtained from published studies and from "expert" panel consensus. Readers should note that one of the authors worked for Medtronic Italia and that some data on SNS were taken from a review in which the majority of patients were implanted using an open surgical rather than percutaneous technique. Treatment success was defined as the cessation of the patient to seek further treatment due to a satisfactory reduction of incontinent episodes with the therapy. Cost-effectiveness was based on medical costs, discounted by 3% over a five-year time horizon. Sensitivity analyses were performed to assess robustness of the model. The cost of test sacral nerve stimulation was disproportionately high (£6,430) in relation to the alternative therapies and calculations based on this rate may not be applicable in other health systems. The ICER was £28,285 for those with sphincter defects and £38,662 those with intact sphincters which the authors cite as being within the £40,000 acceptability threshold of the Italian NHS. Multiple flaws in the model, however, lead to uncertainty in the validity of these estimations. First, treatment success was based on published outcome at 6-month follow-up and it was assumed that loss in efficacy over time for each treatment was equal. Second, it was also assumed that all patients with a structurally deficient anal sphincter, defined as damage up to 120 degrees in radial extent affecting the partial or full length of the internal and/or external anal sphincter, should undergo sphincter repair. Pre-operative sphincter function was not considered. In practice, only patients with full-length defects and adequate residual muscle bulk and function would be considered for repair. Those with partial length defects or isolated internal anal sphincter defects are not usually considered for sphincteroplasty. Importantly, indications for sphincter repair or dynamic graciloplasty are end-stage faecal incontinence in the presence of a substantial muscular and/or neural defect of the anal sphincter. The assumption of the model that all patients, including those with an intact anal sphincter, would undergo dynamic graciloplasty or artificial bowel sphincter, sometimes as a first-line treatment is unrealistic and does not reflect current clinical practice. Finally, the use of sacral nerve stimulation is likely underestimated with the total number of patients being treated with SNS calculated as 86 to 115 patients per year over a five year period in a population of 48 million. Colostomy was assumed to achieve 100% continence, however, in practice some patients with weak sphincters remain incontinent of mucus requiring continued pad usage and ongoing distress.

Leroi et al. (133) performed a multi-centre cohort study comparing clinical outcome and cost of sacral
nerve stimulation versus alternative surgical or conservative treatments for faecal and dual incontinence. Alternative treatments were only considered once a trial of temporary sacral nerve stimulation had failed. Clinical efficacy was measured by prospective collection of continence scores over a two-year time-horizon. There was a considerable drop-out rate in the non-implanted groups (47%). Medical and non-medical costs were calculated by a top-down method from the French National Rate 2004/2005 and prospective collection of individual patient data from the initial medical consultation. Whilst the method states that lost-productivity costs were also calculated it is unclear on how this was achieved and whether they were included in the analysis. QALYs were derived from SF-6D (127). Costs were not discounted but a sensitivity analysis was performed. The median cost of treatment in those patients undergoing SNS was €14,973 over two-years compared to a median cost of €9648 in those patients undergoing alternative treatments. SNS was found to offer a marked health benefit but not found to be cost effective with an ICER of €90,082 per patient year of >50% improved continence. The cost per QALY was not estimated. The complicated design of this study, lack of clear description of the cost-effectiveness parameters, short time horizon and high loss to follow-up leads to questionable validity of the results. In addition, the St Mark's continence score was used to assess clinical effectiveness and this tool may not be sensitive enough to detect all changes in health state. Alternative treatments were only considered once a patient had failed a trial of SNS. However, nearly one-half of patients undergoing "alternative treatment" continued with conservative measures or had no treatment, with resultant significant bias of cost reduction toward the non-implanted group. In addition, the complication rate associated with SNS implantation was higher than other published studies with pain experienced in 78% of patients and an infection rate of 5%.

Van Wunnik et al. (134) examined the cost-effectiveness of adding sacral nerve stimulation into the surgical treatment pathway of those patients undergoing neosphincter procedures for faecal incontinence. A Markov-type model was developed that compared two groups of patients, all of whom were assumed to have failed optimal conservative treatment. In the first group protocol, SNM-, patients underwent either dynamic graciloplasty (DG; 50%) or insertion of an artificial bowel sphincter (ABS; 50%). In the second group protocol, SNM+, the majority of patients underwent sacral nerve stimulation as the first-line surgical treatment with remainder undergoing either dynamic graciloplasty (10%) or insertion of an artificial bowel sphincter (10%). Modelling for treatment success and failure and revisional surgery was performed with failures in the sacral nerve stimulation group (before or after revisional surgery) progressing to the next treatment line of dynamic graciloplasty, colostomy or no further treatment (faecal incontinence with no colostomy and occasional colonic irrigation). No modelling of SNS to ABS was performed. For those patients undergoing a first-line neosphincter procedure the next treatment line was colostomy or no further treatment. The complex model was run for five-cycles allowing the proportion of the cohort in each health state to be obtained and associated with a cost and utility score for each strategy. Medical costs were based on a random subset of 25 patients per treatment method collected from a local prospective faecal incontinence database using prices for 2009 and indexing for 2010. QALY assessment was derived from the EQ-5D questionnaire (135). Extensive sensitivity analysis was performed.

The strategy of adopting SNS prior to consideration of ABS and DG (SNM+) was found to be more cost-effective than the strategy of progressing direct to a neosphincter procedure without considering neurostimulation (SNM-). Dominance was seen both in terms of clinical effectiveness and lower cost). The cost per QALY also favoured the use of sacral nerve stimulation with the SNM+ group yielding a cost per QALY of €3912 versus €5471 in the SNM- group. In terms of QALYs, the SNM+ and SNM- groups were comparable, perhaps reflecting the fact that the model placed some patients of the SNM+ group direct to a neo-sphincter procedure, and that in all treatment pathways the devices used have significant initial costs (an implantable pulse generator for SNS and DG and an implantable sphincter device for ABS). Despite this, the use of SNS was justified in the treatment pathway for patients with faecal incontinence being more effective than DG and ABS for lower costs, mainly related to fewer short and long-term complications.

Until 2013 there was insufficient evidence to recommend the use of injectable bulking agents in routine clinical practice. However recent evidence regarding the medium-term outcomes of newer bulking agents have led to the inclusion as a comparative treatment option in cost-effective analyses (136-138). Likewise, the use of percutaneous tibial nerve stimulation for the treatment of faecal incontinence has increased in recent years based on reported evidence from a number of small case series. When compared to sacral nerve stimulation, the medical costs of percutaneous tibial nerve stimulation are cheaper (£5916 ($9465) versus £19320 ($30924)) when measured over a ten-year horizon (139). However, in the absence of cost-effectiveness analysis the relevance of these relative savings is unclear. The publication of a recent multi-centre, double-blinded, randomized trial that reported no significant clinical benefit of percutaneous tibial nerve stimulation for faecal incontinence when compared to sham therapy puts further doubt on the clinical effectiveness of percutaneous tibial nerve stimulation (140).

In 2014, Bernstein et al. (141) published a cost-effectiveness study comparing Non-Animal Stabilized Hyaluronic acid and Dextranomer Co-polymer (NASHA-
Dx), sacral nerve stimulation and conservative measures in the treatment of faecal incontinence. A Markov model was constructed based on outcomes obtained from the published literature, expert opinion and a survey of practicing physicians (undertaken at the 23rd International Colorectal Disease Symposium, Fort Lauderdale, Florida, 2012). This information was deemed to reflect US practice at the time of the study.

Options for the analysis were to continue to receive conservative treatments, undergo NASHA-Dx or undergo SNS over a three-year time horizon with no cross-over between treatment groups. Costs were considered from the perspective of the US health care payer and based on patient self-reported data derived from the single institution study previously published by Xu et al. (121). Discounting was 3% per annum. Lost productivity costs were not included. Behavioural therapy, in the form of biofeedback, was included as a downstream treatment option for those who had failed to benefit from the primary treatment. Measured end points included incontinence free days and QALYs. Results demonstrated that SNS was superior to NASHA-Dx and conservative treatment with the greatest number of incontinence free-days (515 vs 268 vs 129 days respectively). However, SNS was deemed to be not cost-effective due to an ICER of $103,066 per QALY gained when compared to conservative treatment and of $244,509 per QALY gained when compared to NASHA-Dx. NASHA-Dx was shown to be cost-effective with an ICER of $37,036 per QALY gained when compared with conservative treatments. Budget impact analysis concluded that NASHA-Dx was significantly less expensive to the health care system than SNS for patients who are candidates for either treatment.

The study was based on costs from the US health care system, which has higher direct costs when compared to health systems from other countries. Recent meta-analysis has questioned the benefit of biofeedback in the management of faecal incontinence (142) and therefore the addition of this therapy to the treatment pathway of those patients who had failed primary therapy may not represent current or future clinical practice. In addition to this, the analysis was based on a three-year time horizon and thus favoured the NASHA-Dx strategy. Of the five published studies used to determine clinical effectiveness for NASHA-Dx, two reported on the same group of patients with short-term and three-year follow-up. The other studies only reported median-term follow-up (one study 24-month follow-up and two studies 12-month follow-up).

In the study with longest term follow-up published by Melligren et al. (138), 112 of 136 patients who had undergone NASHA-Dx were followed up at 36 months. Ninety seven (87%) of these patients had undergone greater than two injections of NASHA-Dx. It is not clear whether the requirement for multiple injections was factored into the cost analysis by Bernstein et al., although not all patients require multiple injections. Studies reporting the outcomes from treatment with alternative injectable bulking agents have demonstrated that alternative injectable agents lose efficacy in the long-term (143) and therefore NASHA-Dx may be found to be less cost-effective when considered over a longer time horizon, especially if further treatments are required.

In late 2015, Pochopien et al. (144) reported on a patient-level simulation model comparing two sub-populations, differentiated by the presence or absence of a surgically repairable sphincter defect. Medtronic sponsored the study and authors included Medtronic employees and members of an independent consultancy group. The isolated, sequential and summative clinical and economic effects of sacral nerve stimulation against alternative treatments of anal sphincteroplasty, NASHA-Dx and percutaneous tibial nerve stimulation were modelled with a lifetime horizon from the perspective of the UK National Health service. Clinical effectiveness, resource consumption and effect of treatment on quality of life were obtained from a systematic literature review with direct medical costs derived from the 2015/16 UK National tariff and National Institute of Clinical Excellence costing report 2007. Extensive sensitivity analyses and discounting at 3.5% for cost and outcome were included.

Sacral nerve stimulation was found to be cost-effective when considered as part of a sequence of interventions for treating faecal incontinence. The analysis supported the use of SNS in patients with an intact sphincter who have failed to gain sufficient benefit from NASHA-Dx. A strategy of NASHA/Dx followed by SNS was found to be more cost-effective than percutaneous tibial nerve stimulation followed by SNS in patients with no sphincter damage, generating savings of £2,522 per patient and 0.011 additional QALYs. In patients with anal sphincter disruption amenable to sphincteroplasty, anal sphincter repair followed by SNS was found to be more cost-effective than anal sphincter repair alone. This strategy generated an additional 0.209 QALYs with an ICER of £13,482 per QALY gained. In almost all comparisons incremental cost-utility ratio for SNS was within the £30,000 per QALY threshold recommended by NICE as an effective use of UK National Health Service resources.

IV. SUMMARY AND FUTURE RESEARCH PRIORITIES

In the years since the last ICI, some high-quality economic analyses have been published. One driver for these studies is the requirement for CEA data from NICE along with detailed critiques. This is pushing for greater standardization among trials as well as higher overall quality.

There were some new papers comparing onabotulinumtoxinA and sacral nerve stimulation. There were also a number of new papers related to OAB medical treatment, including new models published to support

SUMMARY AND FUTURE RESEARCH PRIORITIES | 2503
the approval of mirabegron in the US (2012) and the EU/UK (2013).

The Committee notes that evidence regarding cost effectiveness of outpatient therapies for stress incontinence remains limited, aside from the recent economic study of obesity treatment for this condition. However, the economic analysis of therapy for overactive bladder syndrome requires greater effort, to encompass longer time frames and wider use of QALYs that can yield cost utility analysis (CEA). The Committee was disappointed to find that most of the recent economic studies of anticholinergic therapy did not include collection of raw QALY data.

In the last 4 years, the implementation of Sacral Nerve Stimulation for refractory detrusor overactivity has been the subject of several economic analyses, which are indeed important. However, the Committee reiterates the need to collect primary data for QALY outcomes in future studies of this technique.

In the field of prolapse, it is not yet known whether any currently available QALYs are sensitive to treatment benefit, so that CEA may still not be feasible in this area. The recent POPPY study is to be commended for including patient-level cost data and quality of life information about conservative treatment (145).

As regards faecal incontinence, it is encouraging to see economic analyses of Sacral Nerve Stimulation. However, more data about long-term cost effectiveness in faecal incontinence are urgently needed.

As regards methodology, researchers need to consider carefully how they construct the model parameters for Decision Tree Analysis and Markov Models, so that “real life” assumptions are made. The gold standard remains Cost Effectiveness Analysis in parallel with Randomized Controlled Trials, and we urge all clinicians to consider cost and QALYs as important outcome measures.

Finally, the committee encourages researchers to provide information on the uncertainty around an ICER. A solitary ICER is hard to interpret, much like an odds-ratio without a confidence interval.

APPENDIX – SEARCH STRATEGIES

We performed a comprehensive computerized medical literature search (PubMed) for the years 2007-June 2016 to identify all economic, health-related quality of life and cost-effectiveness analyses published on urinary incontinence, faecal incontinence or pelvic organ prolapse. Our initial search strategy was very broad and meant to be very sensitive but not specific. We performed a search for the following Medical Subject Headings (MeSH) and keywords: cost-effectiveness analysis, health care costs, quality-adjusted life years, costs and cost analysis, sick-

REFERENCES 2540
I. INTRODUCTION

The goal of this chapter is to highlight challenges in the research focus in this consultation, as well as to facilitate production of high-impact, high-quality research. This chapter highlights issues related to research concerning prevention, improved aetiological understanding, precise and personalised diagnosis and treatment. In addition, the chapter provides general recommendations for optimal research in areas of interest for this consultation, including progress and research challenges in the field of urinary incontinence. Finally, we present specific recommendations applicable to research for certain types of treatments and certain subgroups patients.

The report endorses consistent use of the methodology and approved terminology that will facilitate research and communication about research in the areas of this consultation. Recognised published guidelines produced by the International Continence Society (ICS) (1-15) and other major professional societies (16-18) are useful examples of standardised terminology that advances communication in research.

In general, the Oxford Centre for Evidence-based Medicine Levels of Evidence and Grades of Recommendation (http://www.cebm.net/levels_of_evidence.asp) are not easily applied to research methodology, challenges and priorities. Therefore, the Research Committee of this consultation used the following categories.

- **High**: Supported by strong evidence (multiple strong publications)
- **Medium**: Supported by moderate evidence (limited/moderate level publications)
- **Low**: Expert/Panel opinion.

1.1. Defining the Research Question

Effective engagement in research requires the investigator to carefully define the research question. The investigator(s) should take a deliberate approach to formulate the specific research question(s), based on a careful review of related clinical research and relevant studies that are well designed and clinically relevant. The research reviews provided by the Cochrane Incontinence Group (http://healthsci.otago.ac.nz/dsm/wch/obstetrics/cure) provide an excellent starting point for most major incontinence topics. Based on a thorough literature review, the investigator can then clearly describe the primary research question(s), summarise the background information, and formulate the rationale, objectives and hypotheses for the study. Once this is clearly laid out, preferably in writing, the research team should then carefully assess whether the research question can be feasibly answered. It is far better to change direction at this point if it seems likely that the sample size cannot be obtained or that the research question cannot be answered with the resources available than it is to waste resources on an unfinished study. Ultimately, the investigator(s) should formulate the simplest study design that will provide the highest quality of evidence to test the given hypothesis in a cost and time-efficient manner. Whenever possible, basic or translational research should occur as part of the clinical research study in order to advance discovering of underlying mechanisms or pathophysiology. This balance between breadth and depth greatly increases the yield of the research effort. (19)

2. RESEARCH ETHICS

Ethical concerns about the performance of medical research became increasingly important in the 20th Century, highlighted by the atrocities of the Second World War and by several highly publicised studies. One of the most prominent of these was the Tuskegee study of syphilis conducted by the United

INTRODUCTION | 2515
States Public Health Service from 1932-1972. In this study, the investigators recruited poor, uneducated, African-American share-croppers from the rural south to participate in a long-term study to evaluate the natural history of untreated syphilis. Participants with syphilis were not told about their disease and treatment was withheld long after the development of highly effective antibiotic cures in the 1940s. The study is frequently cited for multiple ethical lapses including the failure to inform patients of their disease, the use of coercive incentives (free health care), and the intentional recruitment of uneducated, often illiterate subjects.

Stanley Milgram, a psychologist at Yale University, authored another important study that helped shape our current ethical approach to research. Milgram wanted to understand why people often blindly follow authority even in the face of morally repulsive commands. He set up an experiment in which a subject was told by an authoritative figure (part of the study) to administer shocks at progressively higher levels to individuals concealed behind a screen when they provided incorrect answers to simple memory questions. In the experiment, the individual behind the screen was actually part of the study and no actual shocks were administered. However, the subject (administering shocks) did not know this. In the end, 65% of the subjects were persuaded to administer potentially lethal shocks, even when presented with feedback of anguishing screams and simulated unconsciousness. The study has been cited so frequently, not because it answered important questions about human nature in the face of authority, but because of the unintended emotional effects on subjects, of whom many experienced long-lasting psychological trauma.

One of the greatest steps forward in modern history of research ethics came about through the publication of the 1979 Belmont Report on “Ethical Principles and Guidelines for the Protection of Human Subjects of Research” (26). These principles, including Respect for Persons, Beneficence, and Justice, are essential for ethical research and are briefly reviewed as follows:

- **Respect for Persons** recognises the voluntary nature of research participation and includes informed consent without undue influence.

- **Beneficence** requires investigators to maximise benefits and reduce risks to the subject. The primary concern of the investigator should be the safety of the research participant and careful consideration of the risk/benefit ratio; this includes an ongoing responsibility to monitor research and medical literature as the research proceeds. The investigator needs to critically consider within the expert medical community if there is clinical equipoise for the proposed interventions in their trial. Is one treatment no better than another? Are the research risks reasonable in relation to anticipated benefits? It is the responsibility of the investigator to ensure risks are minimized and potential benefits enhanced as well as that the knowledge gained outweighs the risks. Of note, invalid research cannot be ethical no matter how favourable the risk–benefit ratio for study participants.

- **Justice** requires that the benefits and risks be distributed fairly and not focus on individuals with limited access to health care, prisoners, or those with cognitive impairments. Justice is of particular concern in Phase I testing of pharmaceutical agents and in early investigation of surgical devices/implants. Payment offered for participation in such drug trials may be extremely attractive, and even coercive, to poor and disenfranchised subjects. Early device studies may target countries with lax regulatory environments, even if there is little intent to market the device in the country in which testing occurs.

At a minimum, an ethical research study should meet the following criteria:

- the study should well planned, scientifically sound with clearly defined aims;
- clinical research should be prospectively registered whenever possible;
- the study should be feasible with a realistic chance for completion;
- there should be a reasonable assumption that new knowledge will be provided at the end of the study; and
- there should be an expectation that the results will be published to advance scientific knowledge.

Ethical Approval: An appropriate ethical board, such as an Institutional Review Board (IRB) must approved human subject research protocols; however, IRB approval should only be regarded as a minimal ethical standard for research. Ultimately it is responsibility of the investigator to ensure the research is ethically acceptable, and the investigator must take responsibility for all aspects of the research, ensuring that the work is done rigorously and with the highest integrity. In the process of IRB approval, submitted research protocols are peer-reviewed by a multidisciplinary team that may include members of the scientific community, clinicians, pharmacists, the public/patient groups, the legal profession, and individuals who can provide an ethical perspective. Each member of this team reviews the protocol from their particular perspective in order to provide the most comprehensive safeguarding of subject health and well-being.

Informed Research Consent: Informed consent is an ethical cornerstone of human subject research. Informed research consent must contain three elements: 1) it must be voluntary, 2) it must provide a full disclosure of relevant information including risks, benefits, and alternatives, and 3) it must be presented to an individual or surrogate who has clear decision-
making capacity. Ethically, informed consent is based on the principle of autonomy in that the patient is given full authority to make a medical decision about his or her own body. The informed consent document should be written using terms that are meaningful to potential participants.\textsuperscript{(32,33)}

Specific requirements for informed consent vary depending on institutional regulations as well as the type of study and its inherent risk. However, some general requirements include name of the investigators and contact numbers and a detailed description of any planned intervention and known side effects. The document should include a statement that the individual may decline participation with no subsequent consequence to any ongoing medical care and whether or not remuneration is provided. Additionally, there should be a statement about payment for medical care required during the course of the study if there is an adverse event associated with the intervention. When relevant, the document should include a lay description of randomisation understanding that the patient will be randomly assigned to treatment.\textsuperscript{(32,33)}

Required Disclosures and Conflicts of Interest: Investigators who are involved in development and/or testing drugs or devices developed by industry have the obligation to disclosure relationships with industry and financial disclosures related to supplemental personal income. It is acceptable for investigators to receive contracted financial support to perform research and a principled partnership between industry and investigators has known benefits.\textsuperscript{(34)} Financial conflict of interest policies have been developed due to ethical concerns about potential biases that may influence trial design, conduct, over interpretation of positive results or not publishing negative results.\textsuperscript{(31,35)} It is strongly preferred that investigators engaged in research with industry sponsors have a research contract and/or receive funds through or through an appropriate entity with research oversight capabilities. Disclosure and transparency of these relationships help maintain scientific integrity and preserve public trust in the scientific process.\textsuperscript{(34)} An investigator’s institution may have additional disclosure requirements for conflicts of interest (including, but not limited to, conflicts in finances or conflicts of commitment); investigators must be aware of all relevant regulations affecting their research. This is a rapidly evolving area and investigators are encouraged to clearly understand and disclose such relationships. Online resources with detailed regulatory requirements are available through multiple research sponsors; a sample is included from the U.S. National Institutes of Health.\textsuperscript{(36)}

Resolving ethical dilemmas: When available, ethics committees from hospital and/or institutional entities may be helpful to address challenging ethical dilemmas in research. The primary investigator maintains the sole responsibility to maintain the highest ethical standards for all aspect of research conducted under his or her name. When resolving an ethical research dilemma, it may be helpful to consider this pragmatic, simple test: “Imagine what you are preparing to do will be reported the next day on the front page of your local newspaper. If you are comfortable having colleagues, friends, and family know what you did, chances are you acted in an ethically responsible manner”.

3. SCIENTIFIC INTEGRITY, RIGOR AND REPRODUCIBILITY IN BIOMEDICAL RESEARCH

In order to address and emphasise the issues of rigor and reproducibility in biomedical research, the U.S National Institutes of Health (NIH) convened a joint workshop in 2014 in collaboration with the Nature Publishing Group and Science.\textsuperscript{(37)} Invites to the workshop were journal editors from the top 30 journals that most frequently published work from NIH-funded investigators. The group was able to produce detailed guidelines on areas from statistical analysis, transparency in reporting, data and material sharing, and consideration of refutations. The group also addressed the need to establish best practice guidelines from several key research techniques that are highly subject to bias, mistakes, and shortcomings. These areas include image-based data (i.e. immunohistochemistry or western blots) which can be manipulated or post-processed using commercially available image processing software and biological materials which must be described with adequate detail necessary for unique identification (i.e. antibodies, cell lines, and animals).

II. RESEARCH AREAS OF INTEREST FOR THIS CONSULTATION

Over the years, there have been efforts to document the broader impact of urinary incontinence—beyond episodes of incontinence recorded on diaries or measuring the amount of urine on a pad after a prescribed set of provocative manoeuvres. Multiple measurement tools were developed to determine quality of life impact, bother and family impact of urinary incontinence. Some studies were on incontinence without distinction of type incontinence while some studies were limited to SUI or UUI and some included SUI, UUI and mixed UI.

Despite evidence showing associations of UI with obesity, diabetes, cardiovascular conditions, depression and musculoskeletal conditions, research in the evaluation and treatment of UI more narrowly focused on UI as a “quality of life” condition. UI is an important medical condition with tremendous quality of life impact for the person and family members. A narrow “quality of life” focus may be limiting. An expanded...
approach should policies that impact research dollars and programmes/policies that could lead to improved continence care. For example, UI is clearly associated with decreased physical activity. Recommendations for all priority health conditions include increasing or maintaining physical activity. UI may be a preventable and treatable barrier to maintaining and increasing physical activity and thus should be on the treatment algorithm for prevention and treatment of obesity, DM, cardiovascular disease, falls and fractures.

An expanded research focus should start with inclusion of UI (and other LUTS) questions in prevention and treatment studies for the priority medical conditions. A research priority must be to assess the effect of UI on prevention or treatment of priority conditions in addition, an expanded research agenda should identify and address UI proactively in order to improves the outcomes of the priority medical conditions. Thus, collaborative, multi- and inter-disciplinary research must occur; researchers in urinary incontinence must work with researchers focused on other key areas, including obesity, DM, cardiovascular and falls and fracture researchers.

Our expanded research focus should also include improved personalisation of prevention and treatments. It is possible that current treatment options would meet most people’s needs if our research broadened our perspective about causes and contributing factors to UI. Research that provides a framework for systematically addressing all of the modifiable factors to individualise therapy for each patient, taking into account the patient’s community setting, beliefs, values, preferences and cognitive abilities. A particular treatment may be more effective if it were delivered in a context or method that worked better for that individual patient. For example, we have extensive experience with RCT for all forms of incontinence treatment and understand the degree of efficacy in a study population. However, there is limited experience in trying to understand why persons are responders and non-responders to the intervention. There may be significant contribution of factors unrelated to the lower urinary tract/pelvic floor to treatment outcome that, if understood, could lead to better tailoring of treatment regimens.

While most current UI treatments involve some degree of behaviour change which is instituted and maintained by self-care or self-management, treatment plans are generally implemented in a “protocol-driven”, “one size fits” all manner. Research to understand phenotypes that predict treatment response may result in better treatment outcomes.

2. GENOMICS, PROTEOMICS, TRANSCRIPTOMICS, METABOLOMICS – THE “OMICS” TECHNOLOGIES AND INCONTINENCE

The awkward term “omics” refers to several technologies that attempt to measure the totality of biological molecules of a class at once, across a whole cell, or tissue. “Oomics” studies have the potential for comprehensive assessment of a biological system, and the integration of “omics” technologies is known as systems biology. The earliest true “omics” studies were in genomics, the measurement of all common genetic variation, and proteomics, the measurement of expression of all proteins. The use of the “omics” suffix has now been expanded to include all kinds of biological molecules and subtypes of molecules, but the most common additional applications include transcriptomics, the measurement of total gene expression, and metabolomics, the measurement of all metabolites. These technologies share remarkable promise in leading us towards personalised and tai-
loured therapies, but the misapplication of these technologies also reveals a number of shared pitfalls. Here we review each of the major technologies briefly, and then consider how they can or should be applied to the study of incontinence.

2.1. Genomics

Of the “omics” technologies, arguably the most mature is the genome wide association study or GWAS. GWAS has revolutionised the study of the genetics of common diseases. In a GWAS hundreds of thousands of variants, distributed across the entire genome, are genotyped to find genetic regions or loci associated with a trait. The first successful GWAS, identified a single susceptibility locus for macular degeneration (40), but since that time the field has grown to include hundreds of new primary studies per year, and thousands of associated publications (Figure 1).

The exemplar conditions, amenable to a GWAS approach, are those studied in the landmark Wellcome Trust Case Control Consortium study (41) (type 1 diabetes, type 2 diabetes, coronary heart disease, hypertension, bipolar disorder, rheumatoid arthritis, Crohn’s disease). Like incontinence, these conditions are all both common, and complex, with a combination of genetic, environmental, and lifestyle risk factors.

The combination of multiple aetiological factors underlying complex diseases has tended to complicate the discovery of risk variants for these conditions. The ‘common disease common variant’ (CDCV) hypothesis suggests that common variants will explain most of the genetic susceptibility for common diseases. As the Human Genome Project was being completed, the original formulation of this hypothesis suggested that genetic susceptibility would be explained by just a few common variants with moderate effect sizes. (42, 43) However, we now know that for the majority of common diseases, the common susceptibility variants, at least as identified using GWAS, have typically small (0.7 > Odds Ratio < 1.3) or very small effect sizes (0.85 > Odds Ratio < 1.15). (44, 45) Despite inclusion of more than 150,000 individuals in the largest obesity GWAS consortium, a large majority of current identified statistically significant risk SNPs for obesity, are associated with OR of only 1.01-1.15. For most common diseases, rather than being just a few common variants responsible for genetic susceptibility, there may be hundreds each with tiny and interacting effects, many of which will always remain out of reach of detection by conventional GWAS.

Despite the successful discoveries made using GWAS, the whole field has attracted criticism, perhaps because expectations for GWAS in the early 2000’s were not met. (46, 47) A first major limitation is that a GWAS cannot fully explain the observed heritability of complex conditions. (45) The classic example is height, a condition with 80% heritability, and less than 10% of phenotypic variance is accounted for by known variants. (46) The missing heritability problem may arise from overestimation of formal heritability in twin studies, or from failure to detect signals from multitude of rare or common risk variants with small effects, or from a number of other epigenetic or epistatic effects. Regardless, even with large sample sizes GWAS is currently not able to uncover the full genetic architecture of a condition.

The second major limitation is that GWAS has had very mixed success at identifying causal variants. (47) Many SNPs identified in GWAS are intergenic, but even identification of genic SNPs may not directly help to uncover the underlying biology. As the causal variants altering a gene’s expression, or a protein’s structure are unlikely to be directly genotyped, one approach is to densely genotype or sequence a GWAS identified risk locus, in a process called fine mapping. (48)

While some new genetic risk loci have recently been identified for incontinence in conference abstracts, the only published GWAS for incontinence to date, with a modest sample size by the standards of the field, did not identify any replicated risk loci. (49) This situation is likely to change as the size of incontinence GWAS consortia grows.

2.2. Transcriptomics

The original measurements of total gene expression were performed using cDNA microarrays. These allow efficient simultaneous measurement of active mRNA expression for all known and putative genes and transcripts in a cell or tissue at any given moment. This has had broad applications that largely overlap and complement GWAS, including at the most general level providing insight into biological mechanisms, identification of subgroups of diseases, and in some cases prediction of disease outcome or treatment response. Although this technique has
been widely applied to investigation of bladder carcinomas (50) the difficulty of sampling healthy bladder tissue has limited its application in functional urology. A number of studies have assessed whole genome expression in cultured human detrusor smooth muscle cells (51, 52) or in cultured human urothelial cells (53, 54), which both likely differ systematically from such tissues in vivo. The technique has been successfully applied to urine sediment, which may over-represent senescent or apoptotic cells. (55) Transcriptome data from healthy portions of the bladder for patients undergoing cystectomy has also been measured either using microarrays (56) (n=2) or more recently RNA sequencing (57) (n=2), with the latter experiment now publically available. (58) RNAseq has numerous advantages over microarray, including that it can capture expression of unknown mRNAs, and their variants, whereas microarrays are limited to detection of known sequences. To our knowledge RNAseq has not been used in functional urology.

Only two studies have applied whole genome arrays to benign bladder biopsies. Gamper and colleagues first demonstrated the feasibility of the technique, taking three to four large biopsies (20 mm3) from healthy and unhealthy regions of the bladder for patients with interstitial cystitis (n=11). (59) Tseng and colleagues extended this work, extracting sufficient RNA from single biopsies from women with interstitial cystitis (n=10). (60) Both experiments focused on differential expression associated with ulcerated and non-ulcerated areas of the bladder in interstitial cystitis, providing limited generalisable information for other bladder conditions. A single conference abstract has been presented employing these methods for incontinence, but at the present time no publications have been reported.

2.3. Proteomics and Metabolomics

The proteome includes all the expressed proteins in a cell or tissue, whereas the metabolome generally included only the smaller molecules less than 1 kDa in size. Proteomics and metabolomics have special interest for biomarker discovery, and particularly with reference to incontinence, for biomarker discovery in urine. Many existing biomarkers in both urology and gynecology are themselves proteins (e.g. PSA and CA125). Both proteomics and metabolomics employ a range of different spectroscopy techniques. Mass spectrometry has been perhaps the most widely used method, but different techniques have demonstrated different disadvantages, with no single method providing a complete and reliable assessment of either the entire proteome or metabolome. Although there are only around 20,000 human protein-coding genes, there are predicted to be more than 250,000 human proteins, as each gene may code for multiple protein products. In contrast there are only around 5,000 small metabolites, but the diversity of molecules within this class, including small proteins, lipids and carbohydrates poses enormous challenges for their identification. Both proteomics and metabolomics have been widely employed in urological oncology, and over the last two years studies for functional urological conditions have also been reported as conference abstracts. To our knowledge, at the present time no studies using these technologies for incontinence or LUTS have been published however.

2.4. Caution in “omics” Research

Incontinence is an archetypical example of a common complex disease, with multiple subtypes and an array of complex potential causes. It has a wide range of environmental and life style risk factors, that might obscure attempts to identify meaningful biological differences. Stress and urgency incontinence overlap much more commonly than expected by chance, suggesting that they might have common environmental or genetic risk factors (61), but it is not a trivial problem to correctly assign women as having stress, urgency, or mixed incontinence either on the basis of symptoms (62) or laboratory testing. (63) Thus any “omics” study of incontinence faces substantial problems with case ascertainment, and potential problems with misclassification bias, which might further obscure biological signals. Although these technologies can be applied to any common trait, they been most successful for conditions with tightly defined pathology. Incontinence as a whole certainly does not have a single clear pathology, and even the subtypes have multiple potential causes. (64)

The common pitfalls of clinical research described above tend to be magnified in “omics” research. Two particular problems need to be planned for in the design of all “omics” studies, both relating to the lack of specific hypothesis. Unlike most conventional clinical or basic research, driven by a defined hypothesis, “omics” research seeks simply to identify differences in any of a large number of molecules between cases and controls, or between different experimental conditions. For some ‘omics technologies formal consensus has been reached regarding adjustment of significance to account for the huge number of simultaneous measurements. In human genomics, a p value of 5 is accepted as significant, corresponding to the predicted number of independent genetic loci. In other “omics” fields different adjustments are considered, including the very conservative Bonferroni correction, and the more liberal False Discovery Rate method, which controls the significance threshold, such that a typical 10% of “significant” results are accepted as due to type 1 error. For all “omics” studies very careful consideration of sample size is needed at planning stage to account for loss of power from multiple comparisons.

The related problem is of a need for external replication of “omics” results. Not only is there a risk of false positive results, but the problem of winner’s curse will also tend to magnify apparent effect sizes for the top “hits” from “omics” studies. (65, 66) GWAS the current default is for a two-stage design with a discovery process using whole genome SNP arrays, and replication in independent samples, using either new arrays,
III. BASIC SCIENCE RESEARCH

1. USE OF LABORATORY ANIMALS FOR RESEARCH

Drawing from the human ethical oversight construct, the development and implementation of a similar process to ensure animal welfare is now common practice and required at all research institutions conducting research with animals. Animal use and welfare was under no federal regulation prior to 1966. Starting in 1961, a group of veterinarians working in research institutions began meeting in Chicago to formulate the first guidelines governing animal care. A Guide for the Care and Use of Laboratory Animals was prepared by this group and supported by the NIH. However, there was no U.S. federal law governing animal welfare and the use of cats and dogs for research was increasing, often supplied by local animal dealers. A major article, with photographs, published in Life magazine highlighted animal abuse, theft and neglect by these dealers galvanizing passage of the Laboratory Animal Welfare Act by Congress in 1966. In 1986 the term IACUC was coined in the Animal Welfare Act where the composition of each institutions IACUC committee was delineated. Each IACUC must ensure the use of animals for research is performed in a humane manner compliant with federal guidelines and regulations.

IV. TRANSLATIONAL RESEARCH (BENCH TO BEDSIDE)

Definition: Translational research is the process of turning observations in the laboratory, clinic and community into interventions that improve the health of individuals and the public — from diagnostics and therapeutics to medical procedures and behavioural changes.

Translational research is a critically important link between the bench and the bedside. Without effective translation, we lose the benefits of costly and innovative biomedical research. Current impediments to support translational research include a severe lack of translational funding and the resources to facilitate a very complex translational medicine pathway. Unfortunately, only about 2 percent of the current US federal funding goes to translational research. The translation of basic biological discoveries into clinical applications that improve human health is an intricate process that involves a series of complex steps: the discovery of basic information about the pathogenesis of a disease; an assessment of whether that information has the potential to lead to a clinical advance; development of candidate diagnostics, devices or therapeutics; optimisation of the candidates in preclinical settings; regulatory assessment of the data to determine use for human use; testing in human clinical trials; application for approval for widespread clinical use; and ultimately, the assessment of approved diagnostics, devices, and therapeutics during widespread use in real-world settings. Initiatives to integrate the public and private sectors led to the formation of the National Center for Advancing Translational Sciences (NCATS) at the US National Institutes of Health in 2012. NCATS research projects and initiatives focus on addressing scientific and technical challenges to reduce, remove, or bypass bottlenecks in the development of new treatments and tests that will ultimately improve human health. The aim of NCATS is to catalyse the scientific community to propose implementation projects including therapeutic target validation, chemistry, virtual drug design, preclinical toxicology, biomarkers, efficacy testing, phase zero clinical trials, drug rescue and repurposing, novel clinical trial design and post-marketing research. With translational research, the focus is on the result, not the process. Translational research recognises that knowledge exists to change lives, but it must be tested, confirmed and applied.

V. CLINICAL RESEARCH

Definition

Many definitions for “clinical research” have been proposed. The National Institutes of Health (NIH) currently defines clinical research as research with human subjects that is:

1.1. Patient-orientated Research

Research conducted with human subjects (or on material of human origin such as tissues, specimens, and cognitive phenomena) for which an investigator (or colleague) directly interacts with human subjects. Excluded from this definition are in vitro studies that utilize human tissues that cannot be linked to a living individual. It includes: (a) mechanisms of human disease, (b) therapeutic interventions, (c) clinical trials, or (d) development of new technologies.

1.2. Epidemiological and Behavioural studies

1.3. Outcomes Research and Health Services Research

Patient-orientated research encompasses many study designs, from cross-sectional questionnaire studies to large-scale clinical trials. The NIH defines a clinical trial as, “A research study in which one or more human subjects are prospectively assigned to
one or more interventions (which may include placebo or other control) to evaluate the effects of those interventions on health-related biomedical or behavioral outcomes.” Clinical trials of an experimental intervention may be done in a small group of people to determine a safe dosage range and identify side effects (Phase I), in a larger population to determine efficacy and further evaluate safety (Phase II), in a very large population to compare effectiveness with other standard or experimental interventions and to collect information that will allow the interventions to be used safely (Phase III), and to monitor the effectiveness and safety of the approved intervention in the general population after it has been marketed (Phase IV).

Challenges

Conducting clinical research is challenging. An Institute of Medicine workshop identified several key challenges as follows(74):  

- Prioritising of clinical research questions  
- The divide between clinical research and clinical practice  
- Globalisation of clinical trials  
- The cost of clinical trials  
- Narrow incentives for physician participation in clinical research  
- Shrinking clinical research workforce  
- Need to navigate administrative and regulatory requirements  
- Recruitment and retention of patients

The next section focuses on some challenges that are of particular relevance to studies of urinary incontinence and pelvic organ prolapse.

### 2. INCLUSION AND EXCLUSION CRITERIA

Inclusion criteria are often narrow; while results derived from a homogenous pool of participants is more likely to demonstrate a difference from an experimental intervention, the results also may be biased and applicable only in this homogeneous population(76), making translation to the practicing clinician difficult. Narrow inclusion criteria also may hamper the ability to meet recruitment goals. But, while broad inclusion criteria yield more generalisable results, these may also make it harder to attribute statistical significance to the intervention under study.

In general, it is important to limit exclusion criteria to those that reduce risk to potential participants, and, especially in longer-term studies, to those factors that could hamper the potential for follow-up. It is important to include individuals in whom the treatment would likely be used once widespread. For example, in testing a new drug for urgency incontinence, that is excreted by the kidneys, it is important to exclude people with high serum creatinine levels, but equally important to include older individuals with multiple comorbidities in specific studies, as these are also likely to benefit from a drug for urgency incontinence once released.

Additionally, inclusion criteria related to the condition of study must be considered in concert with the consideration of the primary outcome measure. If an inclusion measure defines “disease”, it is essential that the outcome measure does not include this same measure or cut-point as “success”. For example, if a surgical trial comparing two treatments for pelvic organ prolapse defines prolapse as >/= stage II and excludes from enrolment only women with </= Stage I prolapse) and the primary outcome measure defines successful treatment as prolapse at or above the hymen, then women enrolled with maximal prolapse at points 0 or -1 may be considered successfully treated when in fact, their condition has not changed. It is also important to note that a given condition, such as stress urinary incontinence, will be present or absent depending on which outcome measure is used to define it. Avoid using one outcome measure to exclude women from a study and then a different outcome measure defining the same condition as the primary outcome measure.

### 3. BLINDING (MASKING)

While blinding of participants, health care providers and the research team is feasible in pharmaceutical trials (though not without problems), it may not be possible in trials of some surgical procedures, behavioral or physical therapies, or health care delivery methods. In these studies, the only possible blinded person is often the assessor. It may be advantageous for the clinical staff to be aware of the assignment to allow them to monitor the health and safety of individuals, since the potential effects of the treatment (side effects) will often be known in advance. Single blinding ameliorates biased reporting of symptoms and/or side effects by participants. However, clinical staff can influence data collection and change other aspects of participants’ care when they know which study treatment subjects are receiving.

It should be noted that blinding is not impossible in all surgical trials and should be considered when possible. For example, in a trial comparing mid-urethral slings versus no treatment in continent women undergoing vaginal surgery for pelvic organ prolapse, surgeons made superficial suprapubic incisions in women randomly assigned to sham treatment and the incisions were dressed in the same way as the actual incisions in the group assigned to tension-free vaginal tape.(76) At 12 months, only 10% of participants assigned to TVT were sure of their treatment group and 94% of these were correct, while 11% of participants assigned to sham treatment were sure of their treatment; 47% were correct. Of the remainder
who reported no treatment knowledge, 33% in both
groups correctly guessed their treatment assignment.

4. RANDOMISATION

Stratified randomisation ensures equal distribution of
subjects with a particular characteristic in each group
when blocking is employed within strata. This is par-
ticularly important if certain participant characteristics
are likely to influence the outcome. For example, in
incontinence research, variables such as prior failure
of therapy, degree of pelvic organ prolapse or sever-
ity of incontinence might be considered important
even to stratify at randomisation, because unequal
distribution of variables important to the outcome may
create headaches during the data analysis.

5. PARTICIPANT SAFETY

Ensuring participant safety is paramount. An inde-
pendent data safety monitor (DSM) or data safety
monitoring board (DSMB) is important to evaluate the
study on an ongoing basis to determine early evi-
dence of significant harm or benefit. Depending
on the size, complexity, and risks of a trial, the DSMB
is comprised of experts needed to monitor interim
data to ensure the safety of the participants. The
DSMB should be established prior to initiation of the
trial. In addition to reviewing results of the study for
safety monitoring they may evaluate interim analyses
to ensure that a treatment is not producing unac-
ceptable levels of side effects and/or efficacy. A
priori stopping rules or boundaries are established to
assess if the study should continue or be terminated
due to futility (that is, no conclusion will be drawn due
to low enrollment, few outcome events, or high drop-
out rates etc.), reaching an endpoint, or identifying in-
creased risks. Guidelines for stopping the study
should be agreed upon, prior to the start of the trial.
Interim analyses (in particular those based on effi-
cacy) will have implications for the study power. Spe-
cialist statistical advice and support will be essential
to address these issues. Investigators must not be
aware of the results of interim analyses, however,
since this may cause bias by influencing how vigor-
ously any given patient is recruited into or followed up
in the study, and most importantly, runs the risk of a
type II error (i.e. mistakenly concluding benefit when
there is none). Nevertheless, emergency procedures
for unblinding a patient’s allocation are required in
case of a severe side effect or concomitant serious
illness where knowledge of treatment assignment is
essential for patient management and safety.

6. ANALYSIS

High quality data management is key to providing
valid and ethical research results. The analytical
plan should be consistent with study aims and the a
priori analytical plan should be included at the time of
the protocol entry into a clinical trials registration sys-
tem. Currently, high tier journals will often request the
statistical analysis plan and protocol at the time of the
review of the report. This section will not contain any
technical details of statistical methods, which are
available in standard texts. Instead we note some particular problems faced by research with
longer-term follow-up in incontinence and pelvic or-
gan prolapse.

The gold standard in analysing randomised trials is
by intention-to-treat, according to the group to which
subjects were randomised, regardless of the extent of
compliance with the intended treatment. Appreciable
loss to follow-up in a trial (which is not the same as
adherence with intended treatment, lack of efficacy,
or the observation of adverse events) may present serious problems both in terms of generalizability of
the findings to the wider population and, in the case
of differential loss to follow-up across treatment
groups, to the validity of the comparisons. Results
should always be accompanied by a full and clear de-
scription of how the analysis handled deviations from
intended treatment and missing outcome measures.
For example, in a randomised trial comparing surgery
and a urethral plug for urinary incontinence, in which
participants are followed for 5 years and outcomes
collected using patient-reported outcomes, how
should data from participants that crossed over from
one group to the other be handled? It is more likely
that participants in the urethral plug group, over the
course of time, will request surgery than the opposite;
if no adjustment is made, the two interventions may
have the same effectiveness when analyzed by inten-
tion-to-treat methods. Decisions in this regard re-
quire substantial thought. The discussion should in-
clude how missing outcome data may have affected
the conclusions. Sensitivity analyses can be used
to test the exclusion of, or assumptions about, miss-
ing values; practical examples of such analyses are
becoming more common.

7. TRAINING AND CERTIFICATION

Little training is needed to administer a pill. The same
is not true for surgical, behavioural and physiotherapy
interventions. Competence varies widely and a learn-
ing curve can be substantial. However, surgical or
clinical expertise is rarely reported in clinical research
studies. For example, in a systematic review of 99
studies of open spine surgery, only 10% described
surgical skill or experience, which raises the question
of expertise bias in interpreting studies’ results. In
addition to the actual intervention, other study proce-
dures can also be impacted by inconsistent experi-
ence. The Urinary Incontinence Treatment Network
demonstrated that multi-centre urodynamic studies
require not only the development of specific proce-
dures and interpretation guidelines, but also continu-
ous quality improvement efforts.
8. CHALLENGES IN CONDUCTING TRIALS IN DEVELOPING COUNTRIES

Conduct of clinical trials in developing countries presents ethical, organizational, cultural and infrastructural challenges to researchers, pharmaceutical companies, sponsors and regulatory bodies. A balance between managing these challenges while yet conducting the trials is important so that research can be encouraged and supported in order to bring maximum public health benefits to these communities, often underrepresented in research. Difficulties, as outlined by authors of an investigator-initiated trial, include “obtaining valid informed consent, ethical compensation mechanisms for extremely poor populations, poor health infrastructure and considerable socio-economic and cultural divides”. Other challenges include appropriate translation of study measures, access to care at the conclusion of the trial, administrative bottlenecks, equitable investigator (as well as participant) compensation, difficulty obtaining skilled researchers, and regulatory bodies with different standards from those of developed countries.

9. TRIAL REGISTRATION AND DATA SHARING

The International Committee of Medical Journal Editors (ICMJE) initiated a policy in 2005 requiring investigators to enter information about trial design into an accepted clinical trials registry at or before the time of first patient enrolment. This requirement, adapted by many journals, aims to restrict the practices of selective publication and selective reporting of research outcomes, as well as to prevent unnecessary duplication of research effort. The ICMJE accepts registration in any registry that is a primary register of the WHO International Clinical Trials Registry Platform (ICTRP) or in ClinicalTrials.gov. The ICMJE encourages registration of research with non-trial designs, such as observational studies, but does not require it at this time. The ICMJE also encourages posting of clinical trial results in clinical trial registries but does not require it; such posting is not considered prior publication if the results are limited to a brief abstract or tables.

Standards recommended by ICMJE are frequently adapted by medical journals and therefore play a major role in guiding research conduct. Thus, it is of interest to note that at the time of this writing, the ICMJE posted proposed requirements for sharing clinical trial data and is inviting public feedback. In an editorial, the Committee notes that “there is an ethical obligation to responsibly share data generated by interventional clinical trials because participants have put themselves at risk”.

The ICMJE recommendation continues: “As a condition of consideration for publication of a clinical trial report in our member journals, the ICMJE proposes to require authors to share with others the de-identified individual-patient data (IPD) underlying the results presented in the article (including tables, figures, and appendices or supplementary material) no later than 6 months after publication.” The proposal also requires that authors outline a detailed plan for data sharing at the time of clinical trial registration. While the outcome of this proposal isn’t known at the time of this report, it is clear that the tides are turning and data sharing is now viewed as more and more important, not only by journal editors, but by funding bodies (which often have specific requirements to this regard), investigators and research participants. Nuances of data sharing should be considered in planning clinical trials (for example, in the consent process, participants must be asked to provide consent to have de-identified data shared publicly). Investigators should stay abreast of changes in this rapidly evolving area.

Many funding agencies around the world require publications resulting from such funding to be deposited in an open repository, so that they are freely available to all. In general, authors submit the postprint (the manuscript after peer review and acceptance but before copy-editing, formatting or other journal-specific tasks) to a repository accessible online without charge. A large number of journals now assist the author by automatically depositing the published content into a repository such as PubMed Central. Some publishers will delay the release of their articles for a set time after publication, generally six to twelve months.

10. REPORTING RESEARCH RESULTS

The investigator has an ethical responsibility to take responsibility for all aspects of the research, ensuring that the work is done rigorously and to maintain the integrity of the research. Investigators should adhere to published standards in reporting their research results, in order to maximise quality and transparency. Further, most journals require this. Adherence to these guidelines and the use of flow diagrams in particular is associated with improved quality in reporting of RCTs. The "Enhancing the QUAlity and Transparency Of health Research" (EQUATOR) Network project (www.equator-network.org) provides a continuously updated platform of the many different guidelines now available for reporting the design, methods and results of different study types. The most commonly used guidelines for clinical research are listed below:

- Consolidated Standards of Reporting Trials (CONSORT):
- for randomized clinical trials
- Strengthen the Reporting of Observational Studies in Epidemiology (STROBE) —of note, these guidelines do not pertain only to prospective cohort studies, as sometimes assumed, but also to cross-sectional, case-control and retrospective studies.
• Standards for Reporting of Diagnostic Accuracy (STARD) (95): for studies about the accuracy of diagnostic tests.

• Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (96): for systematic reviews.

• Standards for Quality Improvement Reporting Excellence (SQUIRE) (97): for studies about quality improvement in health care.

• Standard protocol items for clinical trials (SPIRIT) - this is an excellent resource in planning a clinical trial. (98)

To improve guidelines adherence, a checklist accompanies each guideline. It is crucial that the reporting guidelines be considered during the planning phase of the study in order to ensure that all key elements are collected as required.

Most of the guidelines contain additional separate items for certain types of studies. In this section, we use the CONSORT guidelines as an example. CONSORT includes additional guidelines for reporting parallel group randomised trials, pragmatic trials, non-inferiority and equivalence trials, and cluster randomised designs. (99-103) The statement includes a checklist of items that covers a comprehensive set of characteristics of a clinical trial. These include clear statements about the objectives of the trial, intended study population, planned comparisons and justification for any subgroup or covariate analyses. The method and unit of randomisation should be stated. For all trials, specifications for the sample size calculation (primary outcomes, target differences, etc.) should be stated and justified. In addition, the precision actually obtained in a study must be presented. This requires confidence intervals as well as the observed p-values, at least for primary outcomes but preferably for all outcomes. The principal confidence intervals should be for comparisons between the groups, rather than for differences in the outcomes within the trial groups. (82,104) Results should include a trial flow diagram, with numbers and reasons for the exclusion of eligible subjects, the number randomised and subsequent losses to follow-up. (105) Protocol deviations should be described and explained. (106) Harms of the trial should be described for each treatment group. Finally, the discussion should include a brief summary of the trial’s findings, possible explanations for the results, interpretation of the findings in light of the literature, limitations of the trial including internal and external validity, and the clinical and research implications of the study. (107) Some guidelines also include specific information that must be included in publication abstracts. These are particularly important to follow, given that many readers rely solely on the abstract for their interpretation of a study.

11. RECOMMENDATIONS ON STUDY CONDUCT AND STATISTICAL METHODS

• The role of quality RCTs as providing the strongest level of evidence in incontinence research should be fully acknowledged by researchers, journal reviewers, and editors. HIGH

• Careful attention to the planning and design of all research, especially RCTs, is of the utmost importance. HIGH

• Appropriate expertise in biostatistics and clinical trial design should be employed at the design phase of a RCT and thereafter on an ongoing basis. HIGH

• The design, conduct, analysis and presentation of research should be fully in accordance with the applicable research guidelines. HIGH

12. SPECIAL CONCERNS FOR SPECIFIC STUDIES

12.1. Systematic Reviews

Systematic review remains perhaps the most formalised part of epidemiology, with a wealth of available guidance for the correct conduct and reporting of reviews (96,108-112), and the creation of recommendations based on the evidence. (110) Without transparent reporting of systematic reviews, it is difficult for editors and readers to judge the quality of a review. One fundamental step that is frequently overlooked is prospective registration of the review protocol in a database such as PROSPERO. The types of studies included should be pre-specified, along with all planned outcomes and analyses.

Searches should encompass a range of sources, perhaps including Medline, EMBASE and CINAHL. Importantly, as many studies never reach publication efforts should be made to search the grey literature. It is almost always helpful to directly contact primary study authors, for clarifications, additional information about methodology, and even additional data or analyses where necessary.

The screening and data extraction process should be planned in advance, and all reviewers should be trained to use the data forms, to achieve a high level of consensus. All screening and data extraction should be performed independently and in duplicate. Reference lists should be hand searched for all included articles, applying the same standardised screening process, as this can pick up additional relevant studies.

Statistical methods are equally formalized for meta-analysis. Fixed effects models [Mantel-Haenszel weighting (113)] should be used for meta-analyses with
only two studies, or for three or more studies and low heterogeneity, but otherwise random effects models [Dersimonian and Laird weighting\cite{109}] should be used. Assessments of risk of bias in primary studies, and for the meta-analysis as a whole\cite{111}, are important particularly when formalising recommendations based on the pooled evidence, and should follow the most relevant scheme for the types of studies included.\cite{112}

12.2. Quality Improvement Studies

The SQUIRE (2.0) guidelines facilitate performance, analysis, and publication of quality improvement.\cite{97} SQUIRE 2.0 is the inclusion of a glossary of key terms to help standardise definitions and clarify the use/misuses of commonly employed phrases in the quality improvement literature. Terms such as “intervention,” “opportunity costs,” “process,” and “systems” are clearly defined. The guidelines also present information about context (interpreting the work within its own unique environment), and studying the intervention (evaluating the generalisability of the intervention as opposed to simply performing or doing it). The guidelines are presented in a printable 18-item table as opposed to simply performing or doing it). The guidelines are presented in a printable 18-item table that takes potential quality improvement investigators through a step-by-step process for performing and publishing their work from abstract to conclusion.

12.3. Observational Studies Using Routinely Collected Health Data

Observational studies using routinely collected health data obtained for clinical and administrative purposes (often referred to as “database studies”) are increasingly common, given the increased availability of health administrative data, disease registries, electronic health record data repositories, public health reporting data, etc. The major advantage of these studies, that the data are already collected, often on millions of people, is also the major drawback: Because the data were collected without a specific a priori research goal in mind, the database may lack key information needed. Further, the information collected, especially in administrative data collected for billing purposes, may not be accurate; validation is often required. However, the potential of such databases to enable efficient and cost-effective research is substantial.

The REporting of studies Conducted using Observational Routinely-collected health Data (RECORD) Statement is an excellent resource for investigators planning and reporting such studies.\cite{114} Below we summarize, based on this statement, some of the key recommendations for investigators planning studies using routinely collected health data. Further detail is available in the full report.

- Clearly state the methods used to identify study subjects, including whether identification is based on single codes, algorithms (combinations of records or codes), linkage between databases, or free-text fields.
- Provide a complete list of codes and algorithms used to classify exposures, outcomes, confounders, and effect modifiers.
- Describe data cleaning methods at different stages of the study (for example, how were missing data and repeated measures handled?)
- Clearly define how the final study population was derived.
- Consider potential sources of bias: “(1) codes or algorithms to identify study populations, outcomes, confounders, or effect modifiers (misclassification bias); (2) missing variables (unmeasured confounding); (3) missing data; and (4) changes in eligibility over time.”\cite{114}

Unmeasured confounding is particularly problematic in these types of studies. The fact that an outcome was assessed in a very large population cannot make up for the absence of an important potential confounder in the database. The investigator is better off looking elsewhere to answer the research question at hand. Another problem frequently arising in studies using large databases are changes in composition of the database population or coding practices over time. Such changes challenge the integrity of temporal comparisons using the dataset. Finally, some journals require that the author attest to the reliability and validity of key variables used in a database before they will consider publication of these studies.

12.4. Behavioural and Physiotherapy Trials

Terminology: The lack of consistent terminology severely hampers our ability to build a body of literature about conservative interventions. The terms “behavioural therapy”, “lifestyle intervention”, “conservative treatment”, “non-surgical treatment”, “physiotherapy”, “biofeedback”, and pelvic floor muscle exercise” are often used interchangeably and incorrectly to describe both the same, and different interventions. While such therapies are discussed elsewhere in this consultation, we here advance this committee’s opinion about appropriate terminology, consistent with the most recently updated terminology manuscript.\cite{115}

Behavioural interventions: According to Oxford Advanced American Dictionary the term ‘behavioural’ is “the way someone behaves, especially towards other people”, and behavioural science is the study of human behaviour. We recommend that behavioural science be limited to studies that evaluate how people do or do not behave as desired.

Lifestyle modification interventions: Lifestyle modification interventions for UI are discussed elsewhere in this consultation and have traditionally in-
cluded diet modification, intake of caffeine and carbonated soft drinks, fluid restriction, weight loss, smoking cessation and advice of increasing general physical activity level. Behavioural science can be used to understand how and why people change lifestyle to, for example, adhere to exercise and weight loss programs, but it should not be used as term to replace specific therapies such as physiotherapy or pelvic floor muscle training.

**Physiotherapy:** Physiotherapy refers to assessment, prevention and treatment given by an authorised physiotherapist (ICS physiotherapy committee www.icsoffice.org). It involves “using knowledge and skills unique to physiotherapists” and, “is the service only provided by, or under the direction and supervision of a physiotherapist” (WCPT 1999). This implies that the term physiotherapy should only be used in trials where the professional providing the intervention is a physiotherapist. We recommend describing the actual intervention instead of using the term physiotherapy: eg pelvic floor muscle training with or without biofeedback, electrical stimulation, pelvic floor muscle training with vaginal cones or resistance device etc. This accurately describes the intervention and is neutral towards profession. Publications should report the actual profession of the interventionist (e.g., physiotherapist, general practitioner, urogynaecologist, urologist, midwife, nurse, fitness instructor), rather than using the vague term, “therapist”.

**Biofeedback:** Biofeedback encompasses “a group of experimental procedures where an external sensor is used to give an indication on bodily processes, usually in the purpose of changing the measured quality.” Biofeedback equipment was developed within the area of psychology, mainly for measurement of sweating, heart rate and blood pressure under different forms of stress. Today, a variety of biofeedback apparatuses are commonly used in clinical practice to assist with PFMT, and the biofeedback can be either visual, auditory or both. In many textbooks the term “biofeedback” has been used to classify a method as different from PFMT. However, biofeedback is not a treatment on its own. It is an adjunct to training. For example, it may measure the response from a single PFM contraction or provide visual feedback during attempts to relax the muscles. Hence, a more precise terminology is PFM training or relaxation with or without biofeedback.

In addition to traditional biofeedback apparatuses, other instruments can offer valuable feedback. Vaginal and anal surface EMG, urethral, vaginal or anal squeeze pressure measurements, ultrasound and MRI can all be used to make the patients more aware of muscle function, and to enhance and motivate patients’ effort during training.

**Conservative interventions/treatments:** Conservative interventions include all of the above, and this term includes everything except medication and surgery. As several studies have found that more than 30% of women with pelvic floor dysfunction are not able to perform a correct PFM contraction at the first consultation, it is mandatory to report how ability to perform a correct contraction was assessed before commencing an exercise trial. Also in electrical stimulation research one should report in which way response to the stimulation was assessed. Although there is level A, grade 1 evidence for some of the conservative interventions such as PFMT for SUI, a variety of new conservative methods to treat the condition are frequently suggested in clinical practice and in the literature. These new methods are often presented as being effective, but are usually a hypothesis based on theories, data from small experimental laboratory studies/ small clinical series, or associations found in large epidemiological studies. If the clinicians like the approach, it soon enters clinical practice and textbooks without any further critical testing. A model for how new therapies ideally should enter clinical practice has been proposed. In this model the new idea should go through at least the 4 first stages before they enter practice:

- Clinical observation and laboratory studies
- Clinical exploration
- Pilot studies
- Randomised controlled trials
- Refinement, e.g. dose-response issues
- Active dissemination of the method if it has proven to be effective

It is important that the patients participating in the 3 first stages before the RCT are given full information that they are participating in an experimental treatment, and that the clinician does not know if this new approach is effective. The patients also need to be informed if there are other proven effective treatments available.

12.5. Reporting of Trial Characteristics

In addition to reporting the specific type of intervention (e.g. PFMT with biofeedback compared to PFMT alone or electrical stimulation) and the profession administering the intervention, the intervention needs to be described in such detail that other investigators can reproduce the intervention. This includes:

- Ability to perform a correct PFM contraction.
- Frequency: number of home training sessions and supervised training sessions (e.g. every day, 3 times/week)
- Number of repetitions and sets (e.g. 12 sets x 3 times/ day)
- Duration: length of each training session (e.g. 20 minutes), and duration of the total training period (e.g., 3 months, 6 months)
• Intensity: In exercise science, this is usually reported as % of one repetition maximum for strength training. In pelvic floor muscle training it is often described as attempts to reach maximum contractions or utilising submaximal contractions. Another description of intensity is the holding time in seconds, e.g.: 6-8 sec

• Adherence: the degree to which participants follow the prescribed protocol, usually reported as a percentage of the total possible.

Educational material provided, such as DVDs, brochures and booklets should be described.

Assessment: All devices used for assessments (e.g. manometers, dynamometers, ultrasound and EMG) must be described in detail, and their responsiveness (ability to detect small changes), reliability and validity should be reported. (124)

12.6. Adherence vs Effectiveness

It is important to note that adherence is not the same as the effectiveness of a programme, as it is possible to have high adherence, but still little effect of training. (125) Hence, when reporting the effect of conservative interventions it is ideal to measure also the exposure variable that the treatment is expected to change (e.g. muscle strength, ability to relax etc). This variable should not be confused with the primary or secondary outcomes of the intervention (e.g. leakage measured with pad testing, number of leakage episodes or QoL).

In many areas of conservative interventions there are high quality RCTs, systematic reviews and meta-analysis showing statistically significant and clinically relevant differences between the intervention and the untreated control group or other interventions. Of conservative therapies, PFMT for SUI/MUI has the strongest evidence to support its use; further, the more intensive the programme (more supervision, higher dosage of training) the better the effect. Therefore, when comparing new methods and innovations with established PFMT, it is important to compare the new intervention with the current best evidence, meaning the effective arm of the reported RCTs. Unfortunately, it is common to compare new methods with an ineffective training protocol, thereby overestimating the effect of the new method and claiming that it is equal to or better than “the old method”. When comparing different methods the dosage also needs to be the same in both treatment arms, e.g. when comparing PFMT with and without biofeedback, the number of supervised sessions, length of the sessions, frequency of home treatment and duration of the intervention must be the same.

12.7. Adverse Events and Cost

There are few adverse effects or complications reported after conservative interventions, but they do exist, e.g. in electrostimulation (126), and adverse effects or lack of adverse effect, and inconvenience to the patients should be reported. Although seldom harmful, conservative treatments are time consuming and can be costly for participants and paying parties because of the need for close follow up during the interventions. Cost effectiveness studies are crucial to fully understand where conservative therapies fit in the treatment armamentarium.

12.8. Outcome Measures

The need for use of responsive, reliable and valid outcome measures in research is covered elsewhere in this chapter. The RCTs published in conservative treatment have applied a huge variety of outcome measures, making systematic reviews and meta-analysis difficult or impossible to conduct. Therefore, in future research it is important to use established and recommended outcome measures. In addition to description and use of responsive, reliable and valid primary and secondary outcome measures, future studies should include description and assessment of adherence to the intervention protocol, measurement of the independent variable (the intervention; e.g. strength training, relaxation training) and measurement of the possible underlining mechanisms of how the treatment works. It is usually not possible to blind the participants or those providing the intervention, but the assessors of outcome should always be blinded to group allocation.

12.9. Specific and Non-specific Effects

There have been some concerns that the effect of conservative treatments can be attributed to non-specific effects such as the extra attention of the therapist. The role of the therapist is to educate, motivate and empower the patient to be able to perform the actual program, secure high adherence, and minimize participant drop out. In patient reported outcomes and reports on quality of life it may be difficult to separate the effect of the attention and the actual effect. However, the effect of the attention is less likely to affect outcomes such as muscle strength, urodynamic assessments, pad testing and morphological changes measured by ultrasound and MRI. Investigators blinded to treatment allocation should conduct all assessments in order to minimize bias. The logistics of this should be addressed during the planning phase of the study. In a high quality RCT, Dumoulin et al address the problem of attention in physiotherapy research. (127) Women with persistent UI, three months after childbirth were randomised to either two different training regimens or a control group receiving relaxation massage for the back and limbs for the same amount of time as the supervised training groups. 70% were cured on pad testing in both treatment groups while there was no effect on urine loss in the relaxation massage group. Participants in the massage control group had improvement in disease specific quality of life.
12.10. Power Calculations and Number of Participants

Some of the RCTs on conservative treatments are flawed by small sample sizes, this being especially evident in electrostimulation studies and may account for negative effects caused by type II errors. It is important that future studies use results of previous published studies to make appropriate power calculations that incorporate estimates of drop outs and loss to follow-up to decide the optimal number of participants needed. Recruiting large numbers of participants may come at the expense of the rigor of the intervention. Weak interventions (e.g. non-optimal training dosages or suboptimal electrostimulation parameters) are unlikely to be effective and do not yield the true effect of an intervention. In meta-analyses, adding RCTs with large sample sizes but weak and ineffective interventions can dilute the effect of smaller RCTs with higher methodological and interventional quality.

12.11. Long-term Studies

To date there are no quality criteria for how to report long term follow-up studies or how to conduct meta-analyses of long term studies. Challenges in long term follow-up studies include cross over to the more effective treatment after cessation of the original RCT, co-interventions during the follow-up period, recurrent events (e.g. new pregnancy), competing events (other diseases leading to incontinence) and loss to follow up. For conservative interventions it is expected that any training effect will diminish over time if no maintenance training is conducted or the pre- or co-contraction of the pelvic floor muscles has not reached an automatic level during the original trial. In order to control for as many of the above mentioned factors as possible, it is recommended that the long term follow up study should be planned together with the original RCT. Loss to follow-up and adherence to the protocol during the follow-up period must be reported.

13. RECOMMENDATIONS FOR CONSERVATIVE TREATMENT TRIALS

- Use correct terminology to describe the intervention. HIGH
- Report details of ability to perform correct contraction, dose-response issues and adherence. HIGH
- Use recommended outcome measures with high responsiveness, reliability and validity. HIGH
- Compare new methods with the best available intervention. HIGH
- Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions. HIGH
- For long-term follow-up studies report cross-over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up

14. EXPERIMENTAL DEVICES AND MATERIALS

Surgical research presents unique challenges to efforts at optimising patient care. It is important to create a pathway for real advances while simultaneously protecting patient safety. When new procedures are substantially different from prior operations there should be a broad based preliminary exploration leading to a comparative trial if warranted. At the same time, many minor modifications of surgical procedures are inappropriate for randomised trials and if required, surgical progress would be slowed.

It has been argued that the first patient in whom a procedure is performed should be randomised. Alternatively, it has been suggested that case series for new procedures are allowed until the procedure finds its intended use and to avoid doing studies while those performing the procedures are on the "learning curve". Typically, new surgical procedures for incontinence have been reported as case series. Not only do surgical case series provide the lowest level of evidence for treatment effects, case series may be "harmful". An accumulation of "positive" case series may present a premature certainty about benefits of a procedure and make it even more difficult to perform randomised trials. Influential members of the surgical community may endorse a new procedure and if the procedure is considered better it may be difficult to get surgeons and patients to randomise or a trial may appear to be unethical with a "proven" procedure.

Therefore, devices often are widely adopted by clinicians based on anecdotal data, marketing, or small case series. This raises a unique problem for trials in this area: 1) Surgeon buy-in can be difficult to obtain as some surgeons ("early adopters") may perceive that the newest therapy is best and thus be unwilling to randomise patients to receive the traditional therapy, 2) Other surgeons ("late adopters") may perceive that the data available do not support use of the newest therapy and thus be unwilling to randomise patients, 3) Patients may be unwilling to be randomised to traditional therapy because they are influenced by marketing forces propelling the newest devices to the forefront, and 4) Device companies frequently modify their materials or technique recommendations; therefore, by the end of the 3-5 years it typically takes to complete the earliest outcome assessment for a surgical randomised trial, the device tested is no longer the same as the device used in the
trial. Thus, the results may be discounted as being no longer applicable.

An important area of concern in surgical and device studies is patient recruitment procedures. The protocol should detail the procedure for selection of consecutive patients who meet the inclusion criteria. All situations in which a patient meets the inclusion/exclusion criteria but is not offered enrolment by the investigator should be documented. The number of patients who decline enrolment should be stated, along with the reasons. It is vital that clinician researchers do not "cherry pick" from their patients, that is, that they do not limit recruitment to those patients considered to have the greatest chance of cure or lowest chance of risk. The study population should be as generalizable as possible. There should be a complete accounting of all participants in the study including the reasons for subject withdrawal.

Participants must be well informed about what is known and not known about devices or procedures being tested. They should not be led to assume that because a device is on the market, it is "safe and effective", as gaining knowledge about this is the purpose of the trial.

**15. SURGICAL STUDIES**

Cross-sectional studies of surgical procedures by type can provide estimates of prevalence, variation by age, race, and region as well as morbidity and mortality. This type of information raises important health policy questions regarding physician practices, patient preferences for incontinence treatment, and differential access to and the utilisation of care. Observational studies can provide important information about effectiveness and complications of surgical procedures, and also are very helpful in designing and selecting potential randomised clinical trials.

The randomised controlled trial is the accepted "gold standard" for research of treatment effects. In all surgical specialties, there has been growing concern regarding the limited number of randomised controlled trials for surgical procedures, poor methodological standards in those that have been performed, and a perception that surgeons are reluctant to rigorously test new surgical interventions.

The body of literature of surgical randomised trials in pelvic floor disorders is increasing. Modern trials are beginning to overcome historical limitations including insufficient sample sizes, lack of blinding of the participants and/or individuals assessing the outcomes, short follow-up, inclusion of limited number of surgeons only, poor description of the technique, and lack of standardised outcome measures. Multi-centre treatment networks appear effective in overcoming some of these limitations. Differential drop out after randomisation (or for cohort studies, after the intervention) can introduce bias. Randomisation can occur in the operating room after the patient was anaesthetised, reducing this risk.

For studies of specific surgical procedures, the technique should be described in such detail that it could easily be reproduced in another study. Standardisation of the procedure may vary depending on the research question. Surgical trials using a small number of highly skilled surgeons are analogous to medical trials where only compliant patients are randomised, reflecting efficacy of the procedure in an ideal setting. It may be more generalisable to a mixture of skill level among surgeons in the community, and so reflect effectiveness of the procedure in usual practice.

Masking (blinding) of participants as to their assigned intervention and those assessing the outcome is particularly important for surgical trials for incontinence because there may be enthusiasm by the patient or surgeon for a new procedure, many outcomes are based on the patient’s own assessments such as symptom and quality of life scores, and the intervention is primarily for improvement of symptoms.

Organizations and treatment networks have been established to address many issues related to surgical interventions. Examples include the UK National Institute of Clinical Excellence (NICE www.nice.org.uk), the Australian Safety and Efficacy Register of New Interventions (ASERNIP-S www.surgeons.org/asernip-s). The NICE and ASERNIP-S provide systematic reviews of new operations, assessment of effectiveness, and recommendations that the technique has sufficient data for widespread use, or that the techniques appear unsafe, or that further audit/research are required before its widespread usage.

**16. RECOMMENDATIONS FOR SURGICAL AND DEVICE TRIALS**

- The safety and serious side effects of new operations must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicentre cohort studies when RCTs are not practical. HIGH
- Safety and serious side effects of incontinence devices must be completely defined with adequate follow-up, especially for use of implantable devices and biologic materials, so that risks can be weighed against efficacy. HIGH
- Valid informed research consent is required in all trials of research surgical interventions; this research consent is separate from the main surgical consent. HIGH
- Reports of successful treatment should be limited to subjects with a minimum (not mean) of
one-year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated. HIGH

- Whenever possible, randomisation for surgical trials should occur at the time of surgery to minimise drop-outs and switch of proceduremony.

- Long-term follow-up of RCT cohorts in an observational cohort is recommended HIGH

17. PHARMACOTHERAPY TRIALS

Although many RCTs have been published in recent years on pharmacotherapy for urinary incontinence, a great deal more remains to be learned. The trials have almost all been limited to 8-12 weeks of treatment giving very little information about long-term safety and efficacy of drug therapy. Inclusion criteria are often stringent, such that the study population of healthy middle-aged people bears little resemblance to the patients for whom providers wish to prescribe medication. There is less than adequate information about special patient groups—men, children, neurogenic patients, and especially the frail elderly. Because incontinence creates such an impact on the older population, good studies to define the utility and safety of drug therapy are greatly needed in this group.

An issue of special relevance in trials of pharmacological agents (although germane to other treatment modalities) is the controversy regarding placebos in clinical trials. Regardless of whether a drug is effective or not, simply giving a drug to a patient may produce a beneficial response. To assess if a drug has an effect over and above the placebo response, it is usually tested against an inactive substance (placebo). In incontinence studies, the placebo effect may be quite large, anywhere from 30-50% in recent published studies. To account for this, investigators and regulators have generally demanded a placebo arm in most clinical trials of medication. While this may be acceptable to participants for short trials, it is neither ethical nor feasible to withhold treatment for longer periods of time. Further, clinicians and patients generally want to know how a new drug compares with established treatment.

Masking, while desired in all types of trials, is especially important in pharmacological trials. Further, it is feasible to do in such trials (as opposed to surgical or conservative interventions, in which masking may not always be possible) and thus should be prioritized. However, the identical appearance of two pills does not guarantee that participants will be unaware of group assignment. Side effects common with anticholinergic therapy, such as dry mouth, may unmask participants. Studies should assess the degree to which masking was successfully maintained.

18. RECOMMENDATIONS FOR PHARMACOTHERAPY TRIALS

- As effective drug therapy is available for most forms of incontinence, active drug comparator arms are recommended for most trials. HIGH

- Very little is known about the safety, efficacy and tolerability of drug therapy beyond 12-week trials. A concerted effort is needed to create this type of information base. Long-term follow-up of RCT cohorts in an observational cohort is recommended HIGH

19. COST ANALYSIS

Economic and health policy outcomes are gaining increasing importance, as policy makers deliberate the values of different therapies. The financial burden on the health care system, the patient and patient’s family of various treatment options makes cost an important outcome to measure. We recommend that cost analyses be planned with clinical studies whenever possible. Costs may be influenced by economic and political factors that are subject to change at any time; however, when basic units of work, time, and resources are carefully defined, models of costs remain useful even if market forces change in an unforeseen manner.

In health and medicine, economic analyses are descriptive and/or comparative. Descriptive data include the socioeconomic cost caused by the disease and its current treatment, whereas comparative data provide an economic evaluation of different treatment strategies and interventions where costs are compared to health outcomes.

There are several relevant types of cost analysis, some of which require a high level of expertise to conduct:

- Cost of illness analysis (COI) typically quantifies the burden of medical expenses (direct costs) and the resulting value of lost productivity (indirect costs) attributable to a specific condition such as an illness or injury.$^{145,146}$

- Cost effectiveness analysis (CEA) measures the costs and consequences of two or more diagnostic or treatment pathways related to a single common effect or health outcome. It then summarizes the results in ratios that demonstrate the cost of achieving a unit of health effect for different types of patients and for variations of the intervention.$^{147,148}$

- Cost utility analysis (CUA) is a form of cost effectiveness analysis in which particular attention is paid to the quality of health outcome related to treatment. In CUA, health effects are expressed in terms of quality-adjusted life years.
A QALY is a measure of health outcome that assigns to a given period of time a weighting that corresponds to the health-related quality of life during that period, and then aggregates these weights across time periods. The QALY is important because it considers both quantity and quality of life.

Cost benefit analysis estimates the net social benefit of an intervention by comparing the benefit of the intervention with the cost, with all benefits and costs measured in dollars. Health outcomes are converted into monetary values using "willingness to pay" (the value an individual would pay for reduction in illness severity) or "risk of death" or "human capital" methods (an individual’s value to society based on productivity or future wages).

Cost analysis should be incorporated into clinical studies whenever possible. Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a potentially important variable, or to change during the intervention and follow up. Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a potentially important variable, or to change during the intervention and follow up. Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. Synchronous pressure-flow studies are generally desirable and should be included whenever feasible. Several pressure-flow nomograms have been proposed to diagnose obstruction in men. It is important to specify which if any nomogram is being used; the ICS nomogram is recommended.

Recommendations for Research in Men

Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a potentially important variable, or to change during the intervention and follow up. Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. Synchronous pressure-flow studies are generally desirable and should be included whenever feasible. Several pressure-flow nomograms have been proposed to diagnose obstruction in men. It is important to specify which if any nomogram is being used; the ICS nomogram is recommended.

Participants should be stratified by prostate size at randomisation when size is considered to be a potentially important determinant of treatment outcome. Clinical evaluations of different male UI products, including strengths, limitations and efficacy in clinically relevant subgroups.

a) Hormonal effects:

Our knowledge of hormonal influences on the lower tract remains limited. Randomised clinical trials and prospective cohort studies have demonstrated that hormone replacement therapy (HRT) does not improve or may worsen incontinence. It therefore seems appropriate that information about menstrual and hormonal status should be an integral part of the
baseline history. New studies designed to examine the influence of hormones on incontinence (if considered ethical by an appropriate review board) should include details of hormonal status (premenopausal, postmenopausal without HRT, post-menopausal with HRT), the route and type of HRT (oestrogen only, combined sequential, combined continuous), and whether or not oophorectomy has been performed.

b) Obstetric History:
The influence of vaginal childbirth on the structure and function of the female pelvis is the focus of much recent and ongoing research but the complex interactions remain incompletely understood. While it is clear that childbirth, and particularly vaginal childbirth increases the risk of incontinence and pelvic organ prolapse, the potential effect of further childbirth on previous or current treatments of incontinence (especially surgery) has yet to be determined.

Potentially confounding variables include: number and route of deliveries (vaginal/Cesarean), use of forceps or vacuum, infant birthweight and head circumference, duration of second stage of labour, use of episiotomy and any vaginal or perineal trauma, and epidural anaesthesia. The importance of these variables will depend upon the specific study design; for randomised studies the allocation process should balance these between groups, but consideration should be given to stratifying or minimising the randomization against one or more of these important factors, depending on the exact intervention. For epidemiological or observational research each of these factors should be collected and included in univariate and multivariate analyses.

c) Pelvic Organ Prolapse:
The effect of pelvic organ prolapse on lower urinary tract function remains poorly understood. Pelvic organ prolapse may potentially affect lower urinary tract function by obstruction of the urethral outflow, and thereby mask sphincter weakness (so called “occult” stress incontinence). Emerging evidence suggests that prolapse may contribute to the symptoms of OAB and correction of the prolapse may modulate these symptoms. Thus, it is important to include assessment of pelvic organ prolapse in incontinence research on women. A validated assessment method for prolapse should be used to identify the stage of prolapse; the Pelvic Organ Prolapse Quantification System (POP-Q)\(^9\) is recommended. Research protocols should be developed, either excluding women with prolapse severity beyond a specified stage, or the analysis plan should include stratification for stage of prolapse in randomisation, and adjustment for prolapse stage in any analysis. For larger studies where regression analyses are planned, stage of prolapse should be considered a mandatory factor for inclusion. Prolapse should be graded at the same time as the outcome assessment for incontinence and LUTS is performed.

Recommendations for Research in Women

- Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. HIGH
- High quality, symptom and bother scores (e.g., ICIQ-FLUTS, KHQ, PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes HIGH
- Standardised assessment of pelvic organ prolapse (by POPQ) should be performed before treatment and at the time of other outcome assessments in all research where prolapse and continence outcomes are being assessed. HIGH
- Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests. HIGH
- Assessment of the impact of treatment on sexual function should be performed with other outcome assessment when appropriate. MEDIUM

21.3. Frail older and Disabled Men and Women

There are a number of unique and pertinent research issues for this population.

In the frail elderly, important variables include:

- Demographic information: Advancing age, white race, and women (156-159) are associated with an increase risk of incontinence and each of these variables should be adjusted for in most analyses.
- Medical Conditions: Medical conditions related and unrelated to the lower urinary tract have been shown to increase the risk of incontinence in older women and are especially important to assess in the frail older population.\(^158,160-162\) Prior hysterectomy has also been suggested as a potential risk factor for incontinence in older women.\(^163,164\)
- Medication Inventory: Certain medications may exacerbate incontinence and therefore a complete medication inventory is essential.\(^162,164-166\)
- Physical function: Mobility is often impaired in the frail elderly and impacts urinary control\(^167\), therefore mobility should be assessed using validated instruments such as the Bartel Orcats or ADL scales.\(^167,168\) Data on walking aids or wheelchairs, gait speed, and manual dexterity may also be collected.

CLINICAL RESEARCH | 2533
Cognitive function: Cognitive function impairment and/or dementia increase the risk of incontinence. The Mini-Mental Status Scale Examination (170) assesses global cognitive function, and the Confusion Assessment Method (CAM) (159) is a standardized assessment for delirium. A battery of neuropsychological tests to measure subtle impairments in cognitive function include the Buschke Selective Reminding Test (verbal learning and memory) (171), the Digit Symbol (incidental memory, visual scanning and motor speed) (172), and the Trails A (attention and visual) (173).

Outcome measures should be selected for applicability to the frail elderly. Commonly used self-reported measures of frequency of urinary symptoms, severity, or level of bother may not be possible in the cognitively impaired frail elderly patient. Similarly, voiding diaries that have been shown to be valid and reliable in assessing urinary frequency, nocturia, and incontinence episodes by type (140,173-175) may not be feasible or reliable. Motivated and trained staff, caregivers, or family members may be able to adequately collect diary data; however, this has not been validated.

In nursing home or inpatient settings, wet checks by staff at set intervals have been used in a number of studies. There are limitations to the measurement including visually determining what is "wet" because of new absorbent materials and staff reports not always being reliable or valid, due to underreporting (176,177). To overcome the limitation of defining wetness and underreporting, 24-hour pad weighing tests (178,179) may be used. Pad weighing tests and wet checks are feasible and can provide important outcome data if staff is well trained and checks are often (18). New outcome measures specific to the frail older population such as increased socialization or decreased caregiver burden need to be developed.

21.4. Children and Adolescents

The conduct of clinical research in children is no more difficult than in adults, as parents and caregivers are often motivated and eager to participate. Four overriding issues separate paediatric research from the general recommendations. First, developmental physiology and psychology varies widely within the group referred to as children undergo many different stages: newborns, infants, toddlers, preschoolers, school age children, adolescents and young adults. They not only differ from older adults, but also undergo rapid developmental changes within a short time. Because children are growing, any treatment, especially pharmacological and surgical therapy, may affect them profoundly in the long term. On the other hand, treatment in children can be more effective than in adults precisely due to this developmental flexibility. A specific aspect is the close interaction between the developing central nervous system and peripheral organs such as the bladder. In addition, the interaction between the urinary and gastro-intestinal system plays a special role in this age group. Second, compliance with therapy requires the inclusion of parents, as children and even adolescents depend on caregivers to administer treatment in most studies. Third, reporting of symptoms and outcomes requires the assessment by both parents (proxy) and children. Symptoms reported by a caregiver may not be interpreted in the same way as the child, which is important to consider. Finally, the issue of informed consent is complex with children, but this has been settled by legal requirements in most countries.

Urinary incontinence in children falls into four main categories: organic, i.e. neurogenic (myelomeningocele and other less common neurogenic aetiologies) or structural; nocturnal enuresis, which can be either mono-symptomatic or polysymptomatic; non-organic daytime urinary incontinence, including detrusor overactivity, voiding postponement and dysfunctional voiding without neurological disease. This issue of age groups is most crucial in children with myelomeningocele. These children are often on medication beginning at a very young age and continuing for many years; the long-term safety of medications in children must be established in all age groups. We recommend that clinical studies have long-term (five years or more), open label extension arms to monitor safety, particularly focusing on normal growth and development and the effects on treatment of liver and central nervous system function. Therapy for other causes of incontinence in children tends to start at a later age, i.e. the definitional age of incontinence (5 years).

Assessment of compliance with therapy is always difficult, and can also be so with children. Compliance with voiding diaries, a significant issue in the adult population, has to be monitored to achieve reliable results. The social and family interactions between the child and parent or caregiver, as well as own behavioral issues and disorders, can influence the accuracy of data collection and treatment compliance, both positively and negatively.

Outcome measures have been developed in children as in adults. Validated, age-specific symptom and disease-specific quality of life instruments are available for most chronic disease for the paediatric population, as well as generic instruments. Early efforts in this area have been reported for dysfunctional voiding and daytime incontinence. Invasive urodynamics can be used when deemed appropriate (specifically in the neurogenic population), but is usually not required in non-organic incontinence.

21.5. Neurogenic Populations

Neurogenic lower urinary tract dysfunction (NLUTD) is defined as a bladder disorder secondary to a known neurological lesion, disease or condition. This broad definition includes a very heterogeneous constellation of neurological disorders and syndromes making the clinical diagnosis of NGB difficult in many cases.
Classification of NLUTD has three primary aims—to aid in discriminating or identifying an unknown underlying neurological disease process, to characterise the nature of the dysfunction so as to develop a treatment plan, and to assess the risk of secondary effects (e.g. on the upper tract) which may influence the necessity and aggressiveness of treatment. The latter two are clearly relevant to research in neurogenic incontinence and must be reflected in study design and patient description.

It is difficult to find a classification system for NLUTD that serves both clinical and research demands that is satisfactory for each of the three aims. The published NLUTD classification systems have been reviewed in detail in textbooks. Both the disease process and the site of the neurological lesion(s) are relevant in the study of NLUTD, yet even this information is inadequate to predict the functional lower urinary tract deficits for an individual patient. There is no one method that meets the broad needs of classification in this group. Typical or classic cases are often well described but it is especially difficult to describe mixed and incomplete lesions. Historically, classification systems oversimplify or become extremely complex to apply in routine clinical practice.

A new classification system has been proposed by Powell to better define the neurogenic lesion or condition affecting lower urinary tract function and thereby help direct treatment. The SALE (Stratify by Anatomical Location and Etiology) classification system for NLUTD is based on seven categories (six anatomical/aetiological and one future biomarker), each having a neurological defect (upholds basic definition) in a distinct anatomical location. The system incorporates the presence or absence of bowel dysfunction and autonomic dysreflexia. The proposed classification divisions which would benefit research stratification including supra-pontine, pontine, supra-classification divisions which would benefit research function and autonomic dysreflexia. The proposed corporates the presence or absence of bowel dysfunction (dys) in a distinct anatomic location. The system in- having a neurological defect (upholds basic defini-atomical/aetiological and one future biomarker), each tem for NLUTD is based on seven categories (six an- evant in the study of NLUTD, yet even this information is inadequate to predict the functional lower urinary tract deficits for an individual patient. • European Association of Urology (EAU): “Guidelines on Neurogenic Lower Urinary Tract Dysfunction” P(183)

• United Kingdom: National Institute for Health and Clinical Excellence (NICE) “Urinary Incontinence in Neurological Disease: management of lower urinary tract dysfunction in neurological disease”(184)

• U.S. Veteran’s Health Administration Handbook on Spinal Cord Injury and Disorders (SCI/D) Systems of Care(185)

• American Urological Association (AUA) and Society for Urodynamics Female Pelvic Medicine and Reconstructive Urology (SUFU): Guidelines for Urodynamics(186)

• The Consortium for Spinal cord Medicine “Bladder Management in Adults with Spinal Cord Injury”(187)

A comprehensive review of these guidelines is beyond the scope for this chapter; however, key areas included renal function testing, imaging, cystoscopy, and urodynamics. The most aggressive surveillance protocol came from the EAU guidelines that recommended yearly renal function testing, imaging every 6 months, and urodynamics at least every 1-2 years. The NICE guidelines recommended ultrasound surveillance every 1-2 years, consideration of urodynamics for high risk patients, and that surveillance cystoscopy should not be performed. The variability in these guidelines, which are derived mainly from poorly done observational studies and are consensus based, speaks to a pressing research need for the ICI to encourage long-term evidence based studies on outcomes in patients with NLUTD and how these are affected by different forms of surveillance and management.

Measuring quality of life outcomes in the NLUTD population has often lagged behind other lower urinary tract disorders due to the heterogeneity of the neurological conditions that are often grouped together (i.e. spinal cord injury with multiple sclerosis). Several patient-reported outcome measures (PROMs) have been specifically designed for measuring the quality of life in patients with neurogenic bladder. Costa and associates described the Qualiveen in 2001 to measure the quality of life in patients with spinal cord injury and it has been validated and is available in English, French, Dutch, Spanish and Italian. Clark and Welk contributed an excellent review of 16 PROMs for assessment of quality of life and symptoms in neurogenic bladder patients (189). Selection of the appropriate PROM for measuring quality of life outcomes is essential for clinicians and researchers working with the NLUTD population.

The following summary highlights recommendations for research in the key areas of this Consultation.

22. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY NEUROLOGICAL URINARY AND FAECAL INCONTINENCE

22.1. Pathophysiology of NLUTD

• An area of high priority for research is the development of a more directly informative classification system which would include anatomical location and etiology in association with corresponding urinary, faecal and neurological symptoms, information from clinical neurophysiological testing and urodynamic abnormalities as well as prognostic biomarkers

• As such, the classification would describe a patient suffering from NLUTD and simultaneously inform about the most appropriate treatment, follow-up regimen, and long-term prognosis

22.2. Diagnostics

• Studies to establish neurological populations and absolute indications for the use of invasive urodynamics in NLUTD as a primary assessment tool and as specialized assessment tool. Also, establish its best application for follow-up of treatment modalities HIGH

• Research to establish what is ‘urodynamic safety’ in NLUTD, preferably by population studied HIGH

• Identify clinical predictors of urodynamic findings in NLUTD MEDIUM

• To further develop patient reported outcome measures in NLUTD HIGH

• Further research into neuroimaging and its association with clinical neurourological practice HIGH

• Further development and standardisation is needed for the use of electrosensation test to become established as a clinical test LOW

• Research to produce high level evidence to define UTI’s in neurological patients HIGH

• Need more evidence for the use of prophylactic antibiotics to reduce symptomatic urinary tract infections after invasive UDS LOW

22.3. Management of NLUTD

• Research into mechanisms and prognosis of the development of bladder cancer in patients with NLUTD HIGH

• It is currently not possible to state whether any IC method or catheter type is advantageous due
to the poor quality of available studies. Further research on the topic is strongly recommended HIGH

22.4. Pharmacotherapy for NLUTD

- Further research is needed to establish the efficacy and safety of the newer antimuscarinics in NLUTD, long-term outcomes and safety, the efficacy and safety of mirabegron in NLUTD, as well as combination treatments HIGH
- Oral and intravesical cannabinoid agonists have shown promising results either in clinical or preclinical studies, and should be further investigated for optimal balance between efficacy and safety in NLUTD MEDIUM
- Further research needed on pharmacotherapy for detrusor-sphincter dyssynergia, sphincter deficiency and detrusor underactivity HIGH

22.5. Minimally Invasive Treatments – Botulinum Toxin A

- Further research is needed on long-term outcomes and safety, administration techniques, the bio-equivalence of the various preparations, the concomitant use of anticholinergic drugs or β3-agonists, mechanisms of action, and wider effects HIGH
- Future research should also focus on PROs and patient satisfaction, tolerability issues, alternative techniques of application, ways to minimise post-treatment voiding dysfunction in patients who void freely HIGH
- Larger studies in select patient populations are also recommended HIGH

22.6. Electrical Neuromodulation

- Further studies on chronic pudendal nerve stimulation must be carried out to identify the best stimulation parameters and to verify the long term results
- The thalamus may be a promising target for the development of new therapies for lower urinary tract dysfunction. Further investigation on this matter is needed before its potential role can be elaborated.
- IVES is a viable option to induce/improve bladder sensation and to enhance the micturition reflex in patients with incomplete central or peripheral nerve damage, but corroborating controlled evidence is needed
- Research to establish indications for sacral neuromodulation in the care of DSD in neurological urinary dysfunction.

22.7. Surgery for NLUTD

- Published data is inadequate to support a recommendation on the use of bladder neck incision in patients with inadequate bladder emptying due to DBND, either as a first-line procedure or as a complementary approach to DBND recognised following permanent urethral stenting. Further studies are needed
- Bladder augmentation using biomaterials or tissue engineering is promising, but the preliminary results need to be confirmed by larger studies

22.8. Specific Neurological Conditions

Requirement for robust epidemiological research, insight into mechanisms, studies on utility of diagnostic tests, assessment of urinary tract risk factors, and randomized trials to assess benefits and harms of therapy for specific neurological diseases. Urinary and faecal incontinence both suffer from limited high quality research, and faecal incontinence in particular.

Priority Research Topics Include:

- Systematic cataloguing of the specific brain centres pertinent to lower urinary tract control, and how they are at risk in given neurological diseases
- How medications for LUTS may influence specific neurological diseases or associated dysfunctions (e.g. blood pressure control)
- The clinical relevance of functional brain imaging to clinical management
- Indicators of neurological presentation or progression that may be first evident in urological clinics

23. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY FAECAL INCONTINENCE

- Collect data on faecal incontinence whenever practical as part of research on urinary incontinence
- Develop techniques for diagnosing faecal incontinence and its aetiologies using new and available diagnostic technologies
- Develop user-friendly measures and instruments for quantifying the severity of faecal incontinence and other components of anal incontinence separately and in total
- Investigate the epidemiology of the different types and subtypes of bowel and anal incontinence
- Well designed and adequately powered studies are needed to evaluate faecal incontinence treatment modalities currently available including:
24. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS)

- Broadened the research scope to improve symptom-based classification to identify the degree of bladder and non-bladder symptoms.
- Develop a simple, non-invasive diagnostic test for BPS
- Research that focuses identify bladder-specific pathology, a bladder pain syndrome-specific biomarker
- Establish patient databases in different regions and conduct longitudinal follow-up to understand the natural history of the disease and to examine the differences in disease natural history among regions.
- Develop a practical multi-disciplinary care model and test it in various settings.
- Develop an easy-to-use tool for non-specialists to readily identify co-morbid conditions that may impact on the need for additional consultation and suggest specific treatment pathways.

25. RECOMMENDATIONS FOR RESEARCH IN POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

Significant further research is required in most areas of the surgical management of prolapse including but not limited to:

- Uterine prolapse and its various treatment options
- Surgery for recurrent prolapse
- Identifying risk factors for recurrent prolapse
- Re-evaluation of prolapse quality of life questionnaires to ensure they are sensitive to change
- The utilisation and incorporation of tissue engineering in pelvic organ prolapse surgery
- Impact of POP surgery on bladder overactivity.
- Impact of POP surgery on urinary voiding dysfunction
- Impact of rectocele repair on symptoms of obstructed defaecation and faecal incontinence

26. RECOMMENDATIONS FOR RESEARCH IN CHILDREN AND ADOLESCENTS

- Long-term follow-up is of critical importance in the paediatric population in order to ascertain the effect of a treatment on normal growth and development. HIGH
- Research is needed to develop standardized outcome measures including validated, age-specific symptom and disease-specific quality of life outcome measures. MEDIUM
- Research of problems specific to different age groups is needed. Especially, incontinence in preschool children and in adolescents is needed. HIGH
- The transition and transfer from paediatric to adult care should be studied and evidence-based recommendations should be formulated. HIGH
- The specific incontinence problems of young adults aged 18-21 years need more attention in research. MEDIUM
- Incontinence in children and adults with special needs is a neglected part of research and clinical care. These include individuals with intellectual disability, specific syndromes, autism spectrum and other disorders. HIGH
- The interaction between brain and bladder and/or gut needs to be studied with new functional and structural imaging techniques of the CNS. HIGH
• Treatment studies of daytime urinary incontinence, including pharmacotherapy and urotherapy, are needed. HIGH

• The correlates of sleep in children with nocturnal enuresis needs to be elucidated in more detail. HIGH

• Life span, longitudinal epidemiological studies from childhood to adulthood in a prospective design are required to procure representative data. HIGH

27. RECOMMENDATIONS FOR RESEARCH IMPROVEMENT IN BASIC SCIENTIFIC RESEARCH

Integrate data from reductionist experiments to inform the formulation of better systems-based approaches in the investigation of the pathology of the lower urinary tract (LUT), the genital tract (GT) and the lower gastro-intestinal tract (LGIT).

Encourage greater emphasis on basic research to characterise tissues receiving relatively little attention: ie the lower gastrointestinal tract; the bladder neck and urethra; the ureter, pelvic floor musculature.

Generate research programmes for foetal and neonatal research in LUT and LGIT function.

Use genome-wide bioinformatics and population health surveys to generate testable hypotheses regarding the physiological and pathophysiological functions of the LUT, GT and LGIT.

Generate improved experimental approaches to investigate the pathophysiology of the LUT and LGIT by:

• the development of animal models that accurately describe human pathological conditions, including the greater use of large-animal models

• the better use of reverse translational approaches for linking animal models to the human disease.

• the use of human tissue from well-characterised patient groups.

• the development of emerging areas such as: tissue engineering; proteomics and metabolomics

• increased collaborations between biological, physical and mathematical sciences.

Develop centres of excellence or consortia of excellence in LUT, GT and GIT research

• integrate expertise from university departments, academic medical units and industry

• encourage translational approaches to research.

• develop inter-institutional research-training programmes to allow new researchers the opportunity to better interact and exchange ideas.

Additional emphasis on the importance of research to medical trainees and science graduates through:

• establishing research training as a core component of postgraduate clinical development

• increased access to support funds, especially scholarships and personal awards

• organisation of focused multidisciplinary research meetings, either stand-alone or as dedicated sessions during national and international conferences

• greater interaction between medical centres and Higher Education Institutions (HEIs).

• allowing researchers-in-training better access to international meetings through reduced registration charges and improved travel grants.

• inclusion in clinical meetings of point-counterpoint session(s) with both basic science and clinical viewpoints.

• development of research fora for exchange of ideas between active researchers and industry.

• lobbying research-funding organisations about the medical and social importance of LUT and LGIT disorders.

Increase emphasis on research into LUT and LGIT in HEIs through:

• greater representation on grant-funding agencies

• encouragement of submission to high impact-factor journals and recognition of research published in specialty journals

• more integrated teaching and training opportunities.

VI. CONCLUSIONS

The 2016 Consultation examined and classified available data in order to determine the level of evidence that supports our research for individual with urinary incontinence and closely related disorders, including pelvic organ prolapse. In order to meaningfully advance research in the focus area of this consultation, investigators are strongly encouraged to begin with a clear, relevant and impactful research question. Careful design, conduct and analysis of the research study is paramount. Prompt dissemination with appropriate data sharing is strongly recommended in order to benefit affected individuals and the broader research community working in this field.

INTRODUCTION
The 6th International Consultation on Incontinence met between September 13-15th 2016 in Tokyo and was organised by the International Consultation on Urological Diseases and the International Continence Society (ICS), in order to develop consensus statements and recommendations for the diagnosis, evaluation and treatment of urinary incontinence, faecal incontinence, pelvic organ prolapse and bladder pain syndrome.

The consensus statements are evidence based following a thorough review of the available literature and the global subjective opinion of recognised experts serving on focused committees. The individual committee reports were developed and peer reviewed by open presentation and comment. The Scientific Committee, consisting of the Chairs of all the committees then refined the final consensus statements. These consensus statements published in 2017 will be periodically reevaluated in the light of clinical experience, technological progress and research.

7. **RECOMMENDATIONS FOR TRANSLATIONAL AND CLINICAL RESEARCH**  
8. **INTERNATIONAL CONSULTATION ON INCONTINENCE MODULAR QUESTIONNAIRE (ICIQ): QUESTIONNAIRES AND BLADDER DIARY**
The consultation agreed to use the current International Continence Society definitions (ICS) for lower urinary tract dysfunction (LUTD) including incontinence, except where stated. These definitions were published in the journal *Neurourology and Urodynamics* (2002; 21:167-178 and 2006; 25: and can be viewed on the ICS website: www.ics.org

The following ICS definitions are relevant:

1. **LOWER URINARY TRACT SYMPTOMS (LUTS)**

LUTS are divided into storage and voiding symptoms.

Urinary incontinence is a storage symptom and defined as the complaint of any involuntary loss of urine. This definition is suitable for epidemiological studies, but when the prevalence of bothersome incontinence is sought, the previous ICS definition of an "Involuntary loss of urine that is a social or hygienic problem", can be useful.

Urinary incontinence may be further defined according to the patient’s symptoms

- **Urgency Urinary Incontinence** is the complaint of involuntary leakage accompanied by or immediately preceded by urgency.
- **Stress Urinary Incontinence** is the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing.
- **Mixed Urinary Incontinence** is the complaint of involuntary leakage associated with urgency, and also with effort, exertion, sneezing and coughing.
- **Nocturnal Enuresis** is any involuntary loss of urine occurring during sleep.
- **Post-micturition dribble** and **continuous urinary leakage** denotes other symptomatic forms of incontinence.

**Overactive bladder** is characterised by the storage symptoms of urgency with or without urgency incontinence, usually with frequency and nocturia.

2. **URODYNAMIC DIAGNOSIS**

**Detrusor Overactivity** is a urodynamic observation characterised by involuntary detrusor contractions during the filling phase, which may be spontaneous or provoked.

Detrusor overactivity is divided into:

- **Idiopathic Detrusor Overactivity**, defined as overactivity when there is no clear cause
- **Neurogenic Detrusor Overactivity** is defined as overactivity due to a relevant neurological condition.

**Urodynamic stress incontinence** is noted during filling cystometry, and is defined as the involuntary leakage of urine during increased abdominal pressure, in the absence of a detrusor contraction.

3. **BLADDER PAIN SYNDROME**

Bladder pain syndrome is defined by ESSIC as chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent desire to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.

4. **PELVIC ORGAN PROLAPSE**

- **Urogenital prolapse** is defined as the symptomatic descent of one or more of: the anterior vaginal wall, the posterior vaginal wall, and the apex of the vagina (cervix/uterus) or vault (cuff) after hysterectomy. Urogenital prolapse is measured using the POP-Q system.
- **Rectal prolapse** is defined as circumferential full thickness rectal protrusion beyond the anal margin.

5. **ANAL INCONTINENCE**

Anal incontinence defined as "any involuntary loss of faecal material and/or flatus and/or mucus" and may be divided into:

- **Faecal incontinence**, any involuntary loss of faecal material
- **Flatus incontinence**, any involuntary loss of gas (flatus)
- **Mucus incontinence**, any involuntary loss of mucus only (not faeces)

* At the time of this consultation, these definitions are not included in the current ICS terminology.
The following phrases are used to classify diagnostic tests and studies:

- **A highly recommended test** is a test that should be done on every patient.
- **A recommended test** is a test of proven value in the evaluation of most patients and its use is strongly encouraged during evaluation.
- **An optional test** is a test of proven value in the evaluation of selected patients; its use is left to the clinical judgement of the physician.
- **A not recommended test** is a test of no proven value.

This section primarily discusses the Evaluation of Urinary Incontinence with or without Pelvic Organ Prolapse (POP) and Faecal Incontinence.

The recommendations are intended to apply to children and adults, including healthy persons over the age of 65.

These conditions are highly prevalent but often not reported by patients. Therefore, the Consultation strongly recommends case finding, particularly in high risk groups.

### A. HIGHLY RECOMMENDED TESTS DURING INITIAL EVALUATION

The main recommendations for this consultation have been abstracted from the extensive work of the 23 committees of the 6th International Consultation on Incontinence (ICI, 2016).

Each committee has written a report that reviews and evaluates the published scientific work in each field of interest in order to give Evidence Based recommendations. Each report ends with detailed recommendations and suggestions for a programme of research.

The main recommendations should be read in conjunction with the management algorithms for children, men, women, the frail older person, neurogenic patients, bladder pain, pelvic organ prolapse, and anal incontinence.

The initial evaluation should be undertaken, by a clinician, in patients presenting with symptoms/ signs suggestive of these conditions.
• Lifestyle: including exercise, smoking and the amount and type of fluid and food intake.

1.4. Other Treatment Planning Issues:
• Desire for treatment and the extent of treatment that is acceptable
• Patient goals and expectations of treatment
• Patient support systems (including caregivers).

• Cognitive function: all individuals need to be assessed for their ability to fully describe their symptoms, symptom bother and quality of life impact, and their preferences and goals for care. They must be able to understand proposed management plans and to discuss, where appropriate, alternative treatment options. In some groups of patients, formal testing is essential e.g. cognitive function testing for individuals for whom the clinician has concerns regarding memory deficits and/or inattention or confusion, and depression screening for individuals for whom the clinician has concerns about abnormal affect. Proxy respondents, such as family and caregivers, may be used to discuss the patient’s history, goals of care, and treatment for individuals with dementia, but only if the individual is incapable of accurate reporting or weighing treatment decisions.

2. PHYSICAL EXAMINATION

The more complicated the history and the more extensive and/or invasive the proposed therapy, the more complete the examination needs to be. Depending on the patient’s symptoms and their severity, there are a number of components in the examination of patients with incontinence and/or pelvic organ prolapse.

Physical examination should be performed regardless of whether the patient is a child, a woman, a man, someone with neurological disease or a frail elderly person.

2.1. General status:
• Mental status
• Obesity (BMI)
• Physical dexterity and mobility

2.2. Abdominal/flank examination: for masses, bladder distention, relevant surgical scars

2.3. Pelvic examination:
• Examination of the perineum and external genitalia including tissue quality and sensation.
• Vaginal (half-speculum/Sims) examination for pelvic organ prolapse (POP), which should be done in the vertical position
• Bimanual pelvic and anorectal examination for pelvic mass,
• Digital rectal examination to assess pelvic floor muscle function and the function of internal and external anal sphincter as well as puborectalis muscle.
• Stress test for urinary incontinence.

2.4. Neurological testing (see chapter on assessment)

3. URINALYSIS

In patients with LUTS, the possibility of a urinary tract infection should be evaluated, with appropriate testing (ranging from dipstick to urine microscopy and culture when indicated as UTI is a readily detected, and easily treatable cause of LUTS,

Conclusion

For simple treatments, particularly non-invasive and inexpensive therapies, management may start without the need for the further investigations listed below.

B. RECOMMENDED FURTHER ASSESSMENT PRIOR TO, OR DURING, SPECIALIST ASSESSMENT

The tests below are recommended when the appropriate indication(s) is present. Some recommended tests become highly recommended in specific situations.

This section should also be read in conjunction with the relevant committee reports.

1. FURTHER SYMPTOM AND HEALTH-RELATED QOL ASSESSMENT

1.1. Bladder Diary

In patients with urinary symptoms the use of a bladder diary (examples in Annex 1) is highly recommended to document the frequency of micturition, the volumes of urine voided, incontinence episodes and the use of incontinence pads.

1.2. Questionnaires

The use of the highest quality questionnaires (GoRA, where available) is recommended for the assessment of the patient’s perspective of symptoms of incontinence and their impact on quality of life.
The ICIQ is highly recommended (GoR A) for the basic evaluation of the patient’s perspective of urinary incontinence, with other GoR A questionnaires recommended for more detailed assessment. Further development is required in the areas of pelvic organ prolapse, bladder pain syndrome, and for specific patient groups, as only GoR B questionnaires are currently available (see Assessment Chapter).

2. RENAL FUNCTION ASSESSMENT

Standard biochemical tests for renal function are recommended in patients with urinary incontinence when there is the possibility of renal impairment.

3. UROFLOWMETRY

Uroflowmetry with the measurement of post void residual urine is recommended as a screening test for symptoms suggestive of urinary voiding dysfunction or physical signs of POP or bladder distension. Uroflowmetry should be part of the initial assessment if the result is likely to influence management eg in older men with possible prostatic obstruction.

4. ESTIMATION OF POST VOID RESIDUAL URINE (PVR)

In patients with suspected voiding dysfunction, PVR should be part of the initial assessment if the result is likely to influence management, for example, in neurological patients.

5. IMAGING

Although routine imaging is not recommended, imaging of the lower urinary tract and pelvis is highly recommended in those with urinary symptoms whose initial evaluation indicates a possible co-existing lower tract or pelvic pathology. Initial imaging may be by ultrasound, or plain X-ray.

Imaging of the upper urinary tract is highly recommended in specific situations. These include:

- Haematuria,
- Neurogenic urinary incontinence e.g. myelodysplasia, spinal cord trauma,
- Incontinence associated with significant post-void residual,
- Co-existing renal disease such as pyelonephritis or reflux, or loin/kidney pain,
- Severe pelvic organ prolapse, not being treated
- Suspected extra-urethral urinary incontinence,
- Children with incontinence and UTIs, where indicated

Urodynamic studies which show evidence of poor bladder compliance or high pressure detrusor overactivity.

6. INVESTIGATIONS IN FAECAL INCONTINENCE AND RECTAL PROLAPSE

- Endoanal US or MRI prior to anal sphincter surgery is highly recommended, even when obvious anatomic defects are not evident.
- Defaecating proctography or dynamic MRI is recommended in suspected rectal prolapse which cannot be adequately confirmed by physical examination.
- Anorectal manometry is useful to assess resting and squeeze anal pressures. The resting and squeeze pressures represent the function of the internal and external anal sphincter, respectively.

7. ENDOSCOPY

Although routine cysto-urethroscopy is not recommended, LUT endoscopy is highly recommended:

- When initial testing is abnormal, e.g. haematuria and suggests other pathologies,
- When pain or discomfort feature in the patient’s LUTS, these may suggest an intravesical lesion
- When appropriate in the evaluation of vesicovaginal fistula and extra-urethral urinary incontinence (in childbirth fistulae, endoscopy is often unnecessary).

In anorectal conditions, proctoscopy or flexible sigmoidoscopy should routinely be performed in the evaluation of patients with faecal incontinence. Colonoscopy, air contrast barium enema or CT colography is highly recommended in the presence of unexplained change in bowel habit, rectal bleeding or other alarm symptoms or signs (see Basic Assessment chapter).

8. URODYNAMIC TESTING

8.1. Urodynamic (multi channel pressure subtracted cystometry) evaluation is recommended

- When the results may change management, such as prior to most invasive treatments for UI and POP,
- After treatment failure, if more information is needed in order to plan further therapy,
• As part of both initial and long-term surveillance programmes in some types of neurogenic lower urinary tract dysfunction,

• In “complicated incontinence” (for details please see relevant subcommittee reports).

8.2. The aims of urodynamic evaluation are often diagnostic, but may also relate to prognostic factors, direct management or assess response to prior therapy, and also:

• To reproduce the patient’s symptoms and correlate these with urodynamic findings

• To assess bladder sensation

• To detect detrusor overactivity

• To assess urethral competence during filling

• To determine detrusor function during voiding

• To assess outlet function during voiding

• To assess residual urine

9. SMALL BOWEL FOLLOW-THROUGH, CT ENTOGRAPHY OR CAPSULE ENDOSCOPY

These tests are recommended in those with faecal incontinence and the presence of unexplained diarrhoea or when Crohn’s disease is suspected.

C. FURTHER DIAGNOSTIC TESTS TO BE USED AS APPROPRIATE

1. ADDITIONAL URODYNAMIC TESTING

Video-urodynamics may be useful in the management of UI in children, in patients who fail surgery and in some neurogenic patients, to obtain additional anatomical information. Either X-ray or US imaging can be used depending on the needs of the individual patient.

If a more detailed estimate of urethral function is required, then the following optional tests may give useful information:

• Urethral pressure profilometry

• Abdominal leak point pressures

• Video-urodynamics

• Electromyography of pelvic floor or urethral sphincter

If initial urodynamics have failed to demonstrate the cause for the patient’s incontinence then the following tests are optional:

• Repeated routine urodynamics or video-urodynamics

• Ambulatory urodynamics

2. PAD TESTING

Pad testing is an optional test for the routine evaluation of urinary incontinence and, if carried out, a 24 hr test is suggested.

3. NEUROPHYSIOLOGICAL TESTING AND IMAGING

The information gained by clinical examination and urodynamic testing may be enhanced by neurophysiological testing of striated muscle and nervous pathways.

Appropriately trained personnel should perform these tests. The following neuro-physiological tests can be considered in patients with peripheral lesions prior to treatment for lower urinary tract or anorectal dysfunction.

• Concentric needle EMG

• Sacral reflex responses to electrical stimulation of penile or clitoral nerves.

Imaging of the nervous system (and neighbouring structures, including spine, the abdominal cavity and pelvis) by MRI or CT, may confirm suspected involvement of the nervous system, and the nature of the cause.

4. FURTHER IMAGING

Cysto-urethrography, US, CT and MRI may have an indication:

• Suspected pelvic floor dysfunction

• Failed surgery, such as recurrent posterior vaginal wall prolapse or failed sling surgery

• Suspected fixed urethra

5. CYSTO-URETHROSCOPY

This is an optional test in patients with complicated, persistent or recurrent UI (e.g. after failed SUI surgery)
6. ANORECTAL PHYSIOLOGY TESTING

Endocoil MRI has high accuracy for detecting anal sphincter injury but is second line after endoanal ultrasound. Patients with faecal incontinence may benefit from assessment with MRI, particularly those with anorectal malformations and/or previous anal sphincter surgery.

Defaecography may be useful and is recommended in patients with faecal incontinence, who have failed conservative therapies, and are possible candidates for laparoscopic ventral rectopexy.
3. MANAGEMENT CONSENSUS STATEMENTS

The consensus statements are derived from the detailed work in the committee reports on the management of incontinence in children, men, women, the frail elderly and neurological patients, as well as those with obstetric fistula, pelvic organ prolapse, bladder pain syndrome, and faecal incontinence. The management of incontinence is presented in algorithm form with accompanying notes.

The chapters analyze the evidence and give it a level of evidence (LoE) and this generates a GoR of recommendation (GoR).

The Consultation recognises that no algorithm can be applied to every patient and each patient's management must be individualised.

There are algorithms for

I. Urinary Incontinence in Children
II. Urinary Incontinence in Men
III. Urinary Incontinence in Women
IV. Fistulae
V. Pelvic Organ Prolapse
VI. Urinary Incontinence in Neurological Patients
VII. Bladder Pain Syndrome
VIII. Faecal Incontinence in Adults
IX. Urinary and faecal Incontinence in frail Older Men and Women

These algorithms are divided into two for groups I to III, VII and X. The two parts, initial management and specialised management require a little further explanation.

Although the management algorithms are designed for patients whose predominant problem is incontinence, there are many other patients in whom the algorithms may be useful such as those patients with urgency and frequency, so-called *OAB dry

Management definitions

Management may be divided into

- Conservative, all methods that are non-medical and non-surgical, some of which do not target the disease process
- Medical (pharmacological) therapy
- Surgical therapy
- Conservative therapy includes
  - Lifestyle interventions e.g. weight loss
  - Bladder training
  - Pelvic floor muscle training (PFMT)
  - Containment products e.g. pads
  - Dependent continence strategies eg regular toileting

Consensus does not exist as to the use of the term “behavioural therapy” as some state that this term only includes bladder training and PFMT, whilst others consider that all conservative management contains a behavioural element, for example wearing and changing pads constitutes a change in behaviour. Hence the consultations recommendations list the elements of conservative management as relevant are intended for use by all clinicians including health care assistants/aides, nurses, physiotherapists, generalist doctors and family doctors as well as by specialists such as urologists, geriatricians and gynaecologists.

The consultation has attempted to phrase the recommendations in the basic algorithms in such a way that they may be readily used by clinicians in all countries of the world, both in the developing and the developed world.

The algorithms for initial management are intended for use by all clinicians including health care assistants/aides, nurses, physiotherapists, generalist doctors and family doctors as well as by specialists such as urologists, geriatricians and gynaecologists.

The specialised algorithms are intended for use by specialists. The specialised algorithms, as well as the initial management algorithms are based on evidence where possible, and on the expert opinion of the 400 healthcare professionals who took part in the Consultation. In this consultation, committees ascribed levels of evidence to the published work on the
subject and devised GoRs of recommendation to inform patient management.

It should be noted that these algorithms, dated April 2017, represent the Consultation consensus at that time. Our knowledge, developing from both a research base and because of evolving expert opinion, will inevitably change with time and relate to the unique context of individual patients seeking care. The Consultation does not wish those using the algorithms to believe they are “carved in tablets of stone”: there will be changes both in the relatively short term and in the long term.

1. ESSENTIAL COMPONENTS OF BASIC ASSESSMENT

Each algorithm contains a core of recommendations in addition to a number of essential components of basic assessment listed in sections I to III.

- General assessment
- Symptom assessment
- Assessment of quality of life impact
- Assessment of the desire for treatment
- Physical examination
- Urinalysis

2. JOINT DECISION MAKING

The patient’s desires and goals for treatment: Treatment is a matter for discussion and joint decision making between the patient and his or her health care advisors. This process of consultation includes the specific need to assess whether or not the patient wishes to receive treatment and, if so, what treatments he or she would favour. Implicit in this statement is the assumption that the health care provider will give an appropriate explanation of the patient’s problem and the alternative lines of management, and the potential benefits and risks of treatment. The assumption that patients almost always wish to have treatment is flawed, and the need to incorporate patient values and preferences is paramount.

In each algorithm, treatments are listed in order of simplicity, the least invasive being listed first. This order does not imply a scale of efficacy or cost, two factors which need to be considered in choosing the sequence of therapy. The order is likewise not meant to imply a suggested sequence of therapy, which should be determined jointly by the treating health care provider and the patient, considering all the relevant factors listed above.

In the initial management algorithms, treatment is empirically based, whilst the specialised management algorithms usually rely on precise diagnosis from urodynamics and other testing.

The assumption is made that patients will be reassessed at an appropriate time to evaluate their progress.

3. USE OF CONTINENCE PRODUCTS

The possible role of continence products to prevent, contain and/or manage bladder and/or bowel leakage should be considered at each stage of patient assessment and treatment, to maintain dignity and social functioning, and/or to support self-management or care by others.

Consider temporary use of continence products:

- While treatment is awaited.
- In addition to treatment; for example using pads and/or urinals when taking anti-muscarinics or carrying out pelvic floor exercises, until sufficient improvement is achieved.

Consider permanent use of continence products:

- When treatment is not chosen or not suitable for the individual
- When treatment does not achieve (complete) cure
- For intermittent use; for example when the patient has a cough, or needs to travel without reliable toilet access
- For continuous use if incontinence is unpredictable and/or frequent or if complications related to incontinence (e.g. skin breakdown) are imminent or present

Consider offering a mixture of continence products (disposable/washable; absorbent/non-absorbent) to optimise effectiveness and to reduce costs; e.g. different products for day and night; or for staying at home and for going out/travel/specific activities.

Further guidance on management with continence products is given in Chapter 20 and at the ICI/ICS supported website:

www.continenceproductadvisor.org

At the foot of each of the treatment algorithms below, the phrase “Consider CONTINENCE PRODUCTS for temporary support during treatment”, emphasizes the importance of continence products for many sufferers of incontinence.
I. URINARY INCONTINENCE IN CHILDREN

A. INITIAL MANAGEMENT

Children present specific management problems for a variety of reasons: assessment requires help from their parents and caregivers; consent to treatment may be problematic; and cooperation in both assessment and treatment may be difficult.

1. INITIAL ASSESSMENT SHOULD INVOLVE A DETAILED INVESTIGATION OF VOIDING AND BOWEL HABITS USING BLADDER/BOWEL DIARIES AND STRUCTURED AND VALIDATED QUESTIONNAIRES.

The child’s social environment and general and behavioural development should also be formally assessed and recorded. Physical examination should be done to detect a palpable bladder, faecal loading and exclude anatomic and neurogenical causes. Urine analysis and culture is sufficient to exclude the presence of infection. If possible, the child should be observed voiding.

- Referrals for specialist treatment are recommended for children who have complicated incontinence associated with:
  - Recurrent and febrile urinary infection
  - Voiding symptoms or evidence of poor bladder emptying
  - Urinary tract anomalies
  - Previous pelvic surgery
  - Neuropathy or neuropathic origin
  - Bowel dysfunction not responsive to treatment

- Comorbid behavioural (e.g. ADHD and ODD) and emotional disorders.
- Initial treatment is recommended for the remaining patients who have:
  - Nocturnal enuresis without other symptoms (monosymptomatic enuresis).
  - Daytime symptoms of frequency, urgency, voiding postponement, straining, interrupted voiding, urgency incontinence with or without nighttime wetting.

2. TREATMENT

- Initial treatment for mono-symptomatic nocturnal enuresis should include:
  - Parental and child counselling and motivation
  - Review of bladder diary with attention to night-time polyuria
  - Age appropriate education and demystification or explanation

- A choice between either bed wetting alarm (GoR A) or anti-diuretic hormone analogues of desmopressin (GoR A). It may be a parental and child choice if advantages and disadvantages are well explained.

- Daytime incontinence should be managed holistically including:
  - Counselling, timed voiding, behaviour modification and bowel management when necessary (GoR B);
  - Antimuscarinics may be used if the child has OAB symptoms (GoR A)
INITIAL MANAGEMENT OF URINARY INCONTINENCE IN CHILDREN

HISTORY / SYMPTOM ASSESSMENT

Nocturnal enuresis (monosymptomatic)
Daytime ± Nighttime wetting ± Urgency / frequency

CLINICAL ASSESSMENT

General assessment (see relevant chapter)
- Physical examination: abdominal, perineal, ext. genitalia, back/spine, neurological
- Assess bowel function → if constipated, treat and reassess
- Urinalysis ± Urine culture → if infected, treat and reassess
- Assess post-void residual urine by abdominal examination (optional: by ultrasound)

PRESUMED DIAGNOSIS

Monosymptomatic Nocturnal Enuresis
Urgency Incontinence
Recurrent Infection
Dysfunctional Voiding
Any other abnormality detected e.g. Post void residual

TREATMENT*

- Explanation/education
- Enuresis Diary
- Alarm (A)
- Desmopressin (A)

- Explanation/education
- Fluid/voiding regimen (A)
- Bladder training (B)
- Antimuscarinics (A)
- Alarm (bed wetting) (B)

Failure
Failure

SPECIALISED MANAGEMENT

“Complicated” Incontinence associated with:
- Urinary tract anomaly
- Neuropathy
- Pelvic surgery
- Voiding (emptying) symptoms
- Recurrent urinary infection
- Bowel dysfunction not responsive to treatment
- Comorbid behavioural and emotional disorders

* Consider CONTINENCE PRODUCTS for temporary support during treatment
I. URINARY INCONTINENCE IN CHILDREN

B. SPECIALISED MANAGEMENT

- **Two groups of children** with “complicated” incontinence should have specialist management from the outset (Fig. 2).

  - Children whose incontinence is due to, or associated with, **urinary tract anomalies** and **neuropathy**.
  - Children **without** urinary tract anomalies, but with **recurrent febrile infection** and, proven or suspected, **lower urinary tract dysfunction**.

- **Children who fail the basic treatment**, but who have neither neurogenic nor anatomical problems, should also receive specialist management.

Children with comorbid behavioural and emotional disorders require referral to mental health services, as compliance and treatment outcomes are lower.

Assessment and treatment should follow evidence-based practice guidelines.

### 1. ASSESSMENT

- As part of further assessment, the measurement of **urine flow** (in children old enough), together with the **ultrasound estimate of residual urine** and appearance of the bladder wall and rectum are highly recommended. An evaluation of the **upper urinary tracts with ultrasound** is also highly recommended. Those who do not improve **with treatment** and have neither neurogenic nor anatomical problems **should be reassessed** using bladder diaries, symptom questionnaires, urinalysis, uroflowmetry and residual urine determination.

  **If there are recurrent and febrile infections**, upper tract imaging and possibly a VCUG should be considered. However, endoscopy is rarely indicated.

- **Urodynamics should be considered**:

  - If the type and severity of lower tract dysfunction **cannot be explained by clinical findings** or in the presence of possible relevant neuropathy or urinary tract anomalies. (GoR B)

### 2. TREATMENT

The treatment of incontinence associated with **urinary tract anomalies** is complex and cannot easily be dealt with in an algorithm. In many children **more than one pathology** demands treatment. If there are **complex congenital abnormalities present**, the treatment is mostly surgical and it should be individualised according to the type and severity of the problem (please see Children’s Committee Report).

Care should be given by specialist children’s nurses and therapists.

- **Initial treatment should be non-surgical.**
  - **For stress urinary incontinence** (SUI): pelvic floor muscle training (GoR C).
  - **For OAB symptoms**: fluid/voiding regimens and antimuscarinics (GoR A).
  - **For voiding dysfunction**: timed voiding, voiding re-education, pelvic floor muscle relaxation (+/- biofeedback), alpha-blocker therapy, and intermittent catheterisation (when PVR >30% of bladder capacity) (GoR A/B).
  - **For bowel dysfunction**: high fibre diet and laxatives as appropriate, and transanal irrigation in severe cases (GoR A).
The child’s progress should be assessed and, if quality of life is still significantly impaired, or if the upper urinary tracts are at risk, surgical treatment is likely to be necessary.

- If surgical treatment is required, then urodynamic studies are recommended to confirm the diagnosis.
- For USI, colposuspension, sling surgery, bulking agent injection and AUS may be considered (GoR B).
- For DO/poor compliance, botulinum toxin (for DO, and off-label) and bladder augmentation may be performed (GoR B).
- If the child cannot do IC then a Mitrofanoff channel may be needed (GoR A).
SPECIALISED MANAGEMENT OF URINARY INCONTINENCE IN CHILDREN

EXPERT HISTORY & PHYSICAL EXAMINATION

CLINICAL ASSESSMENT

DIAGNOSIS

TREATMENT*

Incontinence without suspicion of urinary tract anomaly

Consider:
- Micturating cystogram (B)
- Renal nuclear medicine scan (B)
- if abnormal --> Urodynamics (A)
- Cystourethroscopy (B)
- Spinal imaging (A)

Incontinence with suspicion of urinary tract anomaly

Medicine scan

Urodynamic Stress Incontinence

- Pelvic floor muscle training (A)

Detrusor Overactivity / Poor Compliance

- Fluid/voiding regime (A)
- Antimuscarinics (A)
- Bowel management including transanal irrigation (A)

Dysfunctional voiding

- Timed voiding (B)
- Pelvic floor relaxation ± biofeedback. (A)
- Pharmacotherapy
- Antimuscarinics (B)
- α-blockers (B)
- Intermittent cath. (B)
- Bowel management including transanal irrigation (A)
- SNS (B)

Failure

Anatomical Causes of Urinary Incontinence

- Correct anomaly (see: surgical treatment in children) (A)

Failure

Failure

Failure

Failure

- Colposuspension (B)
- AUS (B)
- Sling (B)
- Bulking agent injection (C)

- Botulinum toxin (B)
- Bladder augmentation (B)
- SNS (B)

- Mitrofanoff if IC fails (A)

* Consider CONTINENCE PRODUCTS for temporary support during treatment
II. URINARY INCONTINENCE IN MEN

A. INITIAL MANAGEMENT

1. INITIAL ASSESSMENT SHOULD IDENTIFY:

- **“Complicated” incontinence group**
  Those with pain or with haematuria, recurrent infection, suspected or proven poor bladder emptying (for example due to bladder outlet obstruction), or incontinence following pelvic irradiation or radical surgery, are recommended for specialised management.

- Poor bladder emptying may be suspected from symptoms, physical examination or if imaging has been performed by X-ray or ultrasound after voiding.

- **Four other main groups** of men should be identified by initial assessment as being suitable for initial management.
  - Those with post-micturition dribble alone,
  - Those with overactive bladder (OAB) symptoms: urgency with or without urgency incontinence, together with frequency and nocturia
  - Those with stress urinary incontinence (most often post-prostatectomy),
  - Those with mixed urinary urgency and stress incontinence (most often post-prostatectomy)

2. MANAGEMENT

- For men with post-micturition dribble, this requires no assessment and can usually be treated by teaching the man how to do a strong pelvic floor muscle contraction after voiding, or manual compression of the bulbous urethra directly after micturition. (GoR B)

- For men with **stress, urgency or mixed** urgency / stress incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, scheduled voiding regimens, behavioural therapies and medication. In particular:
  - Lifestyle interventions (eg weight loss GoR B)
  - Supervised pelvic floor muscle training for men with post radical prostatectomy SUI accelerates recovery time(GoR B)
  - Scheduled voiding regimen for OAB (GoR C)
  - Antimuscarinic/beta 3 agonist drugs for OAB symptoms with or without urgency incontinence (GoR B) if the patient has no evidence of significant post-void residual urine
  - \(\alpha\)-adrenergic antagonists (a-blockers) can be added if it is thought that there may also be bladder outlet obstruction. (GoR C)

- Should initial treatment be unsuccessful after a reasonable time (for example, 8-12 weeks), specialist advice is highly recommended.

Clinicians are likely to wish to treat the most bothersome symptom first in men with symptoms of mixed incontinence.
INITIAL MANAGEMENT OF URINARY INCONTINENCE IN MEN

HISTORY
- Post-micturition dribble

CLINICAL ASSESSMENT
- Incontinence on exertion (usually post-prostatectomy)
- Incontinence with mixed symptoms
- Urgency / frequency, with or without urgency incontinence

PRESUMED DIAGNOSIS
- General assessment (see relevant chapter)
- Urinary symptom assessment and symptom score (including bladder diary or frequency-volume chart and questionnaire)
- Assess quality of life and desire for treatment
- Physical examination: abdominal, rectal, sacral, neurological
- Assessment of pelvic floor muscle function
- Assess post-void residual urine

MANAGEMENT*
- Urethral milking (B)
- Pelvic floor muscle contraction (B)

STRESS INCONTINENCE
presumed due to sphincteric incompetence
- STRESS INCONTINENCE
Treat most bothersome symptom first

MIXED INCONTINENCE
Treat most bothersome symptom first

URGENCY INCONTINENCE
presumed due to detrusor overactivity

DISCUSS TREATMENT OPTIONS WITH THE PATIENT
- Lifestyle interventions
- Pelvic floor muscle training ± biofeedback (B)
- Scheduled voiding/bladder training in OAB (C)
- Antimuscarinics/beta 3 agonist for OAB ± urgency incontinence (B)
- α-adrenergic antagonists (if suspected bladder outlet obstruction)

“Complicated” Incontinence:
- Recurrent or “total” incontinence
- Incontinence associated with:
  - Pain
  - Haematuria
  - Recurrent infection
  - Prostate irradiation
  - Radical pelvic surgery

any other abnormality detected e.g. significant post void residual

SPECIALISED MANAGEMENT

Failure

* Consider CONTINENCE PRODUCTS for temporary support during treatment
The specialist may first reinstitute initial management if it is felt that previous therapy had been inadequate.

1. ASSESSMENT

   - Patients with “complicated” incontinence referred directly to specialised management, are likely to require additional testing, such as cytology, cystourethoscopy and urinary tract imaging.

   If additional testing is normal then those individuals can be treated for incontinence by the initial or specialised management options as appropriate.

   If symptoms suggestive of detrusor overactivity, or of sphincter incompetence persist, then urodynamic studies are advisable in order to arrive at a precise diagnosis, prior to invasive treatment.

2. TREATMENT

   When basic management has been unsuccessful and if the patient’s incontinence markedly disrupts his quality of life then invasive therapies should be considered.

   - **For sphincter incompetence** the recommended option is the artificial urinary sphincter (GoR B). Other options, such as a male sling, may be considered (GoR C).

   - **For refractory idiopathic detrusor overactivity**, (with intractable overactive bladder symptoms) the recommended therapies are: Botulinum toxin A (GoR B), and SNS (GoR C).

   - When incontinence has been shown to be associated with poor bladder emptying due to detrusor underactivity, it is recommended that effective means are used to ensure bladder emptying, for example, intermittent catheterisation (GoR B/C).

   - If incontinence is associated with bladder outlet obstruction, then consideration should be given to surgical treatment to relieve obstruction (GoR B). α-blockers and/or 5α-reductase inhibitors would be an optional treatment (GoR C).

   - There is increased evidence for the safety of antimuscarinics for overactive bladder symptoms in men, chiefly in combination with an α-blocker (GoR B).
SPECIALISED MANAGEMENT OF URINARY INCONTINENCE IN MEN

HISTORY/SYMPTOM ASSESSMENT

- Post-prostatectomy incontinence
- Incontinence with urgency / frequency

“Complicated” Incontinence:
- Recurrent incontinence
- Incontinence associated with:
  - Prostate or pelvic irradiation
  - Radical pelvic surgery

CLINICAL ASSESSMENT

- Consider urodynamics and imaging of the urinary tract
- Urethrocystoscopy (if indicated)

DIAGNOSIS

STRESS INCONTINENCE due to sphincteric incompetence

- Treat major component first

MIXED INCONTINENCE

- with coexisting bladder outlet obstruction

URGENCY INCONTINENCE due to detrusor overactivity (during filling)

- with coexisting underactive detrusor (during voiding)

TREATMENT*

- If initial therapy fails:
  - Artificial urinary sphincter (B)
  - Male sling (C) (see chapter 13)
  - $\alpha$-blockers, 5aRI (C)
  - Correct anatomic bladder outlet obstruction (C)
  - Antimuscarinics/beta 3 agonists (B)
  - Botulinum toxin A
  - SNS (B)

- Interim catheterisation
- Antimuscarinics / beta 3 agonists

- Correct anomaly
- Treat pathology

* Consider CONTINENCE PRODUCTS for temporary support during treatment
III. URINARY INCONTINENCE IN WOMEN

A. INITIAL MANAGEMENT

1. INITIAL ASSESSMENT SHOULD IDENTIFY:

- **“Complicated” incontinence group.** Those with pain or haematuria, recurrent infections, suspected or proven voiding problems, significant pelvic organ prolapse or who have persistent incontinence or recurrent incontinence after pelvic irradiation, radical pelvic surgery, previous incontinence surgery, or who have a suspected fistula, should be referred to a specialist.

- **Three other main groups** of patients should be identified by initial assessment.
  - Women with **stress incontinence** on physical activity
  - Women with **urgency, frequency** with or without urgency incontinence: overactive bladder (OAB)
  - Those women with **mixed** urgency and stress incontinence

Abdominal, pelvic and perineal examinations should be a routine part of physical examination. Women should be asked to perform a “stress test” (cough and strain to detect leakage likely to be due to sphincter incompetence). Any pelvic organ prolapse or urogenital atrophy should be assessed. Vaginal or rectal examination allows the assessment of voluntary pelvic floor muscle function, an important step prior to the teaching of pelvic floor muscle training.

2. TREATMENT

- For women with **stress, urgency or mixed** urinary incontinence, initial treatment should include appropriate lifestyle advice, pelvic floor muscle training, PFMT), scheduled voiding regimes, behavioural therapies and medication. In particular:
  - **Advice** on caffeine reduction for OAB (GoR B) and weight reduction (GoR A).
  - Supervised pelvic floor muscle training (GoR A), supervised vaginal cones training for women with stress incontinence (GoR B).
  - Supervised bladder training (GoR A) for OAB.
  - **If oestrogen deficiency** and/or **UTI** is found, the patient should be treated at initial assessment and then reassessed after using vaginal oestrogens for a suitable period (GoR B).
  - **Antimuscarinics/beta 3 agonist** for OAB symptoms with or without urgency incontinence (GoR A); duloxetine* may be considered for stress urinary incontinence (GoR B)

PFMT should be based on sound muscle training principles such as specificity, overload progression, correct contraction confirmed prior to training and use of “the Knack” for 12 weeks before reassessment and possible specialist referral.

Clinicians are likely to wish to treat the **most bothersome symptom first** in women with symptoms of mixed incontinence. (GoR C).

- Some women with significant pelvic organ prolapse can be treated by vaginal devices that treat both incontinence and prolapse (incontinence rings and dishes).

*Duloxetine is not approved for use in United States. In Europe it is approved for use in severe stress incontinence (see committee report on pharmacological management for information regarding efficacy, adverse events, and ‘black box’ warning by the Food and Drug Administration of the United States).
INITIAL MANAGEMENT OF URINARY INCONTINENCE IN WOMEN

HISTORY
- Incontinence on physical activity
- Incontinence with mixed symptoms
- Incontinence / frequency with urgency

CLINICAL ASSESSMENT
- General assessment (see relevant chapter)
- Urinary symptom assessment (including bladder diary and questionnaire)
- Assess quality of life and desire for treatment
- Physical examination: abdominal, pelvic and perineal
- Cough test to demonstrate stress incontinence if appropriate
- Urinalysis ± urine culture -> if infected, treat and reassess if appropriate
- Assess oestrogen status and treat as appropriate
- Assess pelvic floor muscle function
- Assess post-void residual urine

PRESUMED DIAGNOSIS
- STRESS INCONTINENCE: presumed due to sphincteric incompetence
- MIXED INCONTINENCE: treat most bothersome symptom first
- OAB with or without URGENCY INCONTINENCE: presumed due to detrusor overactivity

MANAGEMENT*
- Life style interventions.
- Pelvic floor muscle training for SUI, MUI, or OAB (A)
- Bladder retraining for OAB (A)
- Antimuscarinics/beta 3 agonist OAB ± urgency incontinence (A) or Duloxetine** for SUI (B)
- Other adjuncts, such as electrical stimulation
- Vaginal devices eg cones (B)

** Subject to local regulatory approval (see black box warning).

“Complicated” Incontinence:
- Recurrent incontinence
- Incontinence associated with:
  - Pain
  - Haematuria
  - Recurrent infection
  - Significant voiding symptoms
  - Pelvic irradiation
  - Radical pelvic surgery
  - Suspected fistula

If other abnormality found e.g.
- Significant post void residual
- Significant pelvic organ prolapse
- Pelvic mass

SPECIALISED MANAGEMENT

* Consider CONTINENCE PRODUCTS for temporary support during treatment
III. URINARY INCONTINENCE IN WOMEN

A. SPECIALISED MANAGEMENT

1. ASSESSMENT

Women who have “complicated” incontinence (see initial algorithm) may need to have additional tests such as cytology, urodynamics, cystourethroscopy or urinary tract imaging. If these tests are normal then they should be treated for incontinence by the initial or specialised management options as appropriate.

- Those women with persistent symptoms despite initial management and whose quality of life is impaired are likely to request further treatment. If initial management has been given an adequate trial then interventional therapy may be desired. When the results of urodynamic testing may change management, we highly recommend testing prior to intervention in order to diagnose the incontinence type and, therefore, inform the management plan. Urethral function testing by urethral pressure profile or leak point pressure is optional.

- Systematic assessment for pelvic organ prolapse is highly recommended and the POP-Q method should be used in research studies. Women with co-existing pelvic organ prolapse should have their prolapse treated as appropriate.

2. TREATMENT

• If stress incontinence is confirmed then the treatment options that are recommended for patients include the full range of non-surgical treatments, as well as colposuspension procedures, (GoR A) and bladder neck/sub-urethral sling operations (GoR A). All of these procedures have potential risks and associated complications which should be discussed with the individual. The correction of symptomatic pelvic organ prolapse may be desirable at the same time. For selected patients injectable bulking agents (GoR B) and the artificial urinary sphincter (GoR C) can be considered.

• Refractory urgency incontinence (overactive bladder) secondary to idiopathic detrusor overactivity may be treated by botulinum toxin A (GoR A), sacral nerve stimulation (GoR B) or bladder augmentation/intestinal cystoplasty (GoR D).

• Those patients with voiding dysfunction leading to significant post-void residual urine (for example, >30% of total bladder capacity) may have bladder outlet obstruction or detrusor underactivity. Prolapse is a common reversible cause, of voiding dysfunction.
# Specialised Management of Urinary Incontinence in Women

## History/Symptom Assessment

- Incontinence on physical activity
- Incontinence with mixed symptoms
- Incontinence with urgency / frequency

## Clinical Assessment

- Assess for pelvic organ mobility / prolapse
- Consider imaging of the UT/ pelvic floor
- Urodynamics (see notes)

## Diagnosis

### Urodynamic Stress Incontinence (USI)

- Treat most bothersome symptom first

### Mixed Incontinence USI/DOI

- Treat most bothersome symptom first

### Detrusor Overactivity Incontinence (DOI)

- Correct anatomic bladder outlet obstruction (e.g. genito-urinary prolapse)
- Intermittent catheterisation

### Incontinence associated with poor bladder emptying

- Bladder outlet obstruction
- Underactive detrusor

## Treatment*

**Note procedures in increasing level of invasiveness**

### Stress incontinence surgery

- Bulking agents (B)
- Tapes and slings (A)
- Colposuspension (A)

If initial therapy fails**:

### Botulinum toxin (A)

- Sacral Nerve Stimulation (B)
- Bladder augmentation (D)

If initial therapy fails**: Consider CONTINENCE PRODUCTS for temporary support during treatment

### Consider:

- Urethrocystoscopy
- Further imaging
- Urodynamics

### Complicated Incontinence:

- Recurrent incontinence
- Incontinence associated with:
  - Pain
  - Haematuria
  - Recurrent infection
  - Voiding symptoms
  - Pelvic irradiation
  - Radical pelvic surgery
  - Suspected fistula

### Consider:

- Urethrocystoscopy
- Further imaging
- Urodynamics

### Lower Urinary Tract Anomaly / Pathology

- Correct anomaly
- Treat pathology

** Note procedures in increasing level of invasiveness

* Consider CONTINENCE PRODUCTS for temporary support during treatment
In the developing world fistulae occur as a consequence of poor perinatal care. Despite vast surgical experience in some centres, published research is of low quality.

In the developed world, iatrogenic urogenital fistulae are known complications of pelvic surgery and oncological treatments such as radiotherapy, chemotherapy or a combination of both. In the oncological context, fistulae may also occur as a result of primary or recurrent malignancy. The development of fistula following radiotherapy for primary treatment should trigger a search for evidence of tumour recurrence (GoR D). The use of neoadjuvant or adjuvant therapies is likely to be associated with a greater risk of fistula development than the primary treatment alone.

The most common non-obstetric causes of fistulae involving the gastro-intestinal tract are diverticular disease, Crohn's disease, malignancy and radiotherapy.

### 1. INITIAL ASSESSMENT

Early detection of fistulae could be improved by examining all women after their delivery, or prevented by Caesarian section for women who suffer prolonged labour and who are at risk of developing an obstetric fistula. Associated pathologies should be actively searched for and should be taken into account in the treatment plan: all components of the 'obstructed labour injury complex' should be examined. Prevention by better health education, and by avoiding harmful practices must be encouraged.

Classification of fistulae is recommended. Although many classification systems exist, the committee recommends the use of the Goh, WHO or Tafesse classification systems (GoR B)

The formal classification of the fistula should be done under anaesthesia when the patient is on the operation table, just before surgery.

- Leakage of stool, urine, or possibly both is the hallmark sign of a fistula. The leakage is usually painless, may be intermittent if it is position dependent, or may be constant.
- CT and cystoscopy appear more consistent in the confirmation and location of possible intestino-vesical fistulae, than other investigations (GoR C)

### 2. MANAGEMENT OF NEW AND ESTABLISHED VVF

Management of VVF depends on whether the fistula is diagnosed within a few weeks of its occurrence or whether the woman presents late with an established fistula.

Early fistulae are those which are not re-epithelialised, and ischaemic and necrotic tissue can be present at the time of examination. There is evidence that early catheter care will result in the cure of a significant minority of VVFs. (GoR C)

Established fistulae are re-epithelialised and show no oedema, ischaemic changes or inflammation. These fistulae and those that fail catheter treatment should be treated surgically by an experienced surgeon. (GoR C)

### 3. TREATMENT

If catheter drainage fails, then fistula repair will be necessary. There are certain principles behind fistula repair:

- Necrotic tissue must be removed prior to fistula repair.
- Fistula repair must only be undertaken by a properly trained surgeon.
- Adequate post-operative care is essential.

- Level 3 evidence indicates that the routine use of cystoscopy with dye testing at gynaecological surgery has high sensitivity, specificity and negative predictive value in the detection of ureteric injury, although false positive tests do occur. (GoR C)
- Ureteric injury or fistula may be suspected in patients following pelvic surgery if a fluid leak or pelvi-calyceal dilatation occurs postoperatively. (GoR D)
- Uretero-arterial fistula may be suspected in patients presenting with haematuria with a history of relevant pelvic surgery and indwelling ureteric stent. (GoR D)
- Elevated levels of creatinine in drainage fluid following pelvic surgery are suggestive of urine leaking due to a urinary tract injury. (GoR D)
Proper follow-up should be arranged.

In principle, most fistulae can be dealt with by the vaginal approach, but an abdominal approach may be needed in some cases (e.g. concomitant reconstructive procedures e.g. ureteral reimplantation or bladder augmentation). (GoR C)

A tension-free single layer closure of the bladder wall and closure of the vaginal wall in a separate layer is advocated. A Martius flap in primary fistula repair is not recommended.

When reporting on outcome after fistula repair, authors should make a clear distinction between fistula closure rates and post-operative incontinence rates and the time at which the follow-up was organised.

Prevention of post-operative stress incontinence must be added to the surgical procedure if the urethral closing mechanism is involved. This can be done by a good repair of the pubocervical fascia and refixation or by adding a sling procedure.

Attention should be given as appropriate to skin care, nutrition, rehabilitation, counselling and support prior to and following fistula repair. (GoR D)

There is no proven benefit to delayed repair of vesicovaginal fistulae; the timing of repair should be tailored to the individual patient and surgeon requirements, but can be undertaken as soon as any oedema, inflammation, tissue necrosis, and infection have resolved. (GoR B)

There are no high quality data to indicate greater cure rates for any one technique as compared to others; level 3 evidence indicates similar success rates for vaginal and abdominal, and for transvesical and transperitoneal approaches. (GoR C)

A variety of interpositional grafts can be used in either abdominal or vaginal procedures, although there is little evidence to support their use in any specific setting. (GoR C)

Conventional and robotically-assisted laparoscopic approaches have both been shown to be feasible in selected cases; the indications for, or optimal patient for these techniques is not yet clear. (GoR C)

A period of continuous bladder drainage is crucial to successful fistula repair; there are no high level data to support any particular type, route, or duration of catheterisation. Current practice suggests, 10-14 days for simple and/or post-surgical fistulae; 14-21 days for complex and/or post-radiation fistulae. (GoR D)

Whilst diversion is used more widely in radiation-associated fistulae of all types as compared to non-radiated fistulae, there is low-level evidence that repair procedures can achieve successful fistula closure and continence in appropriately selected cases. (GoR C)

Where urinary and/or faecal diversions are required, attempts should be made to avoid using irradiated tissues wherever possible, and to minimise the potential for anastomotic complications. (GoR C)

There is low-level evidence to support the use of interposition grafts when repair of radiation-associated fistulae is undertaken. (GoR C)

### 4. MANAGEMENT OF THE COMPLICATIONS OF VVF

The complications of vesico-vaginal fistulae are many but include:

- Persistence or recurrence of urinary incontinence
- Persistence of lower urinary tract symptoms or occurrence of new lower urinary tract symptoms, including overactive bladder
- Urinary tract infections
- Upper urinary tract symptoms, including loin pain
- Dyspareunia and sexual dysfunction
- Infertility
- Neurological symptoms
- Psychological problems and mental illness
**MANAGEMENT OF VESICOVAGINAL FISTULA**

**HISTORY**
- Leakage of urine from vagina / perineum

**CLINICAL ASSESSMENT**
- Clinical examination
- Urethro-cystoscopy
- Imaging (X-ray/CT/MRI, US)
- Evaluate upper urinary tract

**PRESUMED DIAGNOSIS**
- Recent VVF
  - Consider Catheter, evaluate weekly
  - Healed
  - Persistent leakage

- Established VVF

**MANAGEMENT***
- Primary simple
  - Vaginal repair
  - Consider timing
- Primary complex
  - Surgical repair
  - Consider timing
  - Consider interposition material
- Recurrence
  - If small, consider catheter, evaluate weekly
  - Surgical repair
  - Consider timing
  - Consider interposition material
- Post-irradiation
  - Surgical repair
  - 6-12 months
  - Consider interposition material

**Assess fistula closure & assess continence status**

* Consider CONTINENCE PRODUCTS for temporary support during treatment
1. MANAGEMENT OF FISTULAE INVOLVING BOWEL

- There is limited evidence to support a non-surgical or conservative surgical approach in colo-vesical fistulae where there are minimal symptoms or evidence of limited bowel involvement. (GoR C)

- A one-stage approach to surgery for intestino-vesical fistulae is appropriate in many cases, but should be limited to those patients whose nutritional state is good, and where there is no evidence of additional intra-abdominal pathology (e.g. severe inflammation, radiation injury, advanced malignancy, intestinal obstruction) or major co-morbidity. (GoR B)

- A laparoscopic/robotic approach to one-stage management is feasible, although there is no high level evidence to allow comparison of outcomes with open surgery. (GoR D)

2. MANAGEMENT OF URETERIC FISTULAE

- Surgeons undertaking complex pelvic surgery should be competent at identifying, preserving and repairing the ureter. (GoR D)

- Ureteric stents are not required as prophylaxis against injury during routine gynaecological surgery, while their role in more extensive surgery remains to be established. (GoR B)

- Most upper urinary tract fistulae should be initially managed by conservative or endoluminal techniques where such expertise and facilities exist. (GoR B)

- Persistent ureterovaginal fistulae should be repaired by an abdominal approach using open, laparoscopic or robotic techniques according to availability and competence. (GoR D)

- For patients with ureteric fistulae associated with advanced pelvic cancer and poor performance status, palliation by nephrostomy tube diversion and endoluminal distal ureteric occlusion is an option. (GoR C)

3. MANAGEMENT OF URETHRO-VAGINAL FISTULAE

Recommendations

- Urethrovaginal fistulae are preferably treated by a vaginal approach. (GoR C)

- A variety of autologous tissue interposition techniques have been described, but their value remains uncertain. (GoR C)

- Urethrovaginal fistulae repair may be complicated by stress incontinence, urethral stricture and urethral shortening necessitating long-term follow-up. (GoR C)
MANAGEMENT OF IATROGENIC URETERIC FISTULAE

**HISTORY**
Extra-urethral vaginal urinary leakage and/or signs of ureteric obstruction

**CLINICAL ASSESSMENT**
Clinical examination Urethro-cystoscopy Imaging (Xray/CT/ MRI, US)
Evaluate upper urinary tract obstruction

**PRESUMED DIAGNOSIS**
Ureterovaginal fistula

**MANAGEMENT***
Endoluminal technique (stenting, nephrostomy) for at least 6 weeks
Unable to stent (initially)...
Re-evaluate for fistula closure, ureteric obstruction
Persisting fistula or ureteric obstruction
Healed
Ureteric reimplantation (open, laparoscopic or robotic)
Long-term follow-up for stricture and hydropephrosis

* Consider CONTINENCE PRODUCTS for temporary support during treatment
1. INTRODUCTION

Pelvic organ prolapse includes vaginal and rectal prolapse. Treatment of pelvic organ prolapse is generally reserved for symptomatic prolapse. Clinicians should recognise that coexistent pelvic floor symptoms are frequently present and that these symptoms may or may not be related to the prolapse. Women with prolapse require a careful and detailed initial assessment not only of the prolapse but associated bladder, bowel and sexual function.

2. ASSESSMENT

Symptom assessment preferably with a validated pelvic floor questionnaire that assesses bladder, bowel, vaginal and sexual function and bothersomeness is required. (Grade C).

Physical examination should:

- Report the most distal site of vaginal descent in relation to a fixed point such as the hymen and include an assessment of the anterior posterior and apical vagina. While standardised reporting utilising tools such as the Pelvic Organ Prolapse Quantification (POP-Q) are encouraged. The system used to measure the extent of the prolapse should be documented.
- Be undertaken in the standing position to evaluate the full extent of the prolapse.
- Determine if coexistent pelvic pathology is present on careful bimanual examination. Cytological screening of the cervix should be undertaken if required.
- The prolapse should be reduced to document the presence of occult stress urinary incontinence (see chapter for prolapse and urinary incontinence pathway).
- Assess pelvic floor muscle function (see chapter for full review).
- Determine if epithelial/mucosal ulceration is present.
- Evaluate anal sphincter tone and or the presence of rectal prolapse in those with bowel symptoms (refer to chapter for pelvic organ prolapse and bowel symptom pathway).

When examination findings of the extent of the prolapse are not consistent with the history the examination can be repeated in a few weeks’ time. (GoR C).

Post void residual should be measured; while most elevated post-void residual urines (150mls) resolve with treatment of the prolapse, a specialist consultation is required.

3. MANAGEMENT

Observation is appropriate when medically safe (GoR C).

Lifestyle interventions include weight loss, treating constipation, avoiding straining at stool and heavy lifting (GoR C).

Pelvic floor muscle training:

- Reduces associated pelvic floor symptoms (GoR A).
- May reduce the symptom of vaginal bulge (GoR C).
- Does not reduce extent of prolapse on examination based on POP-Q stage (GoR B).

Vaginal Pessary: when successfully fitted

- May reduce prolapse symptoms (GoR B)
- Need to be regularly reviewed (GoR C)
- Have high rates of discontinuation (GoR C)

Local Oestrogens are recommended in those with hypo-oestrogenic symptoms and in those with urethral prolapse or vaginal ulceration (GoR B)

Reconstructive surgery is reserved for those with symptomatic prolapse and is aimed at correcting the vaginal topography and functional pathology. Please see text for full recommendations.

Obliterative surgery is an important and effective treatment option in those who are happy to sacrifice coital activity. (GoR C)
MANAGEMENT OF PELVIC ORGAN PROLAPSE
(INCLUDING UROGENITAL PROLAPSE AND RECTAL PROLAPSE)

**HISTORY**
- Bothersome pelvic organ prolapse

**CLINICAL ASSESSMENT**
- **Symptoms Screening**: assess bothersomeness, frequency and severity of urinary, ano-rectal, genital and sexual symptoms
  - **Urinary**: PVR, cough stress test, urinalysis.
  - **Physical Examination**: Sufficient to determine the site and severity of prolapse and detect other significant findings
    - Selective use of urodynamics when results would alter planned treatment.
    - Selective use of upper tract imaging when observation is planned
  - **Ano-Rectal**: Endoscopy, lower GI tract imaging

**DIAGNOSIS**
- **UROGENITAL PROLAPSE WITH OR WITHOUT OTHER PELVIC SYMPTOMS**
  - Observation
  - Lifestyle interventions
  - Pelvic floor muscle training
  - Pessary
  - Reconstructive surgery
  - Obliterative surgery

- **RECTAL PROLAPSE WITH OR WITHOUT OTHER PELVIC SYMPTOMS**
  - Observation
  - Lifestyle interventions
  - Transperineal surgery
  - Transabdominal surgery

- **Complex or recurrent prolapse**
  - Investigation by specialist

**MANAGEMENT***
- *Consider CONTINENCE PRODUCTS for temporary support during treatment*
The pelvic organ prolapse (POP) surgery pathway was designed to provide an evidence-based guide for both clinicians and women for the surgical management of pelvic organ prolapse. Within the pathway, green lines highlight the preferred option and yellow lines indicate reasonable options.

An early option in the treatment pathway for women not wanting to preserve sexual function is obliterative surgery (colpocleisis) which is an efficacious intervention that has low morbidity (LoE 3).

The majority of women will enter the reconstructive pathway. Apical suspension procedures should be considered in all cases with 10-year re-operation rates for prolapse being significantly reduced if apical suspensions are performed concomitantly with both anterior and posterior colporrhaphy as compared to those performed without apical support.

In those undergoing anterior and posterior colporrhaphy, the evidence is supportive of traditional native tissue suture plications (LoE 1). In the anterior compartment, permanent mesh could be considered for recurrent cases when the patient understands the risk benefit profile for these interventions and that the data for their use is scant. Evidence is not supportive of biological grafts in the anterior compartment (LoE 2).

In the posterior compartment, fascial plication is superior to site-specific native tissue repair (LoE 2) and levatorplasty should be avoided due to higher rates of dyspareunia (LoE 3). Data are not supportive of biological or permanent mesh grafts. Posterior colporrhaphy is superior to transanal repair of rectocele (LoE 1) and there is no data to support ventral rectopexy with or without vaginal graft for rectocele.

With recognition of the importance of apical vaginal support in minimising the risk of subsequent recurrence, the pathway separates those with post-hysterectomy (vault) prolapse from those with uterine prolapse.

Data are supportive of sacral colpopexy as the preferred intervention for vault prolapse with superior anatomical and functional outcomes when compared to a variety of vaginal based interventions with and without transvaginal mesh (LoE 1). This preference is highlighted by a green preferred option arrow in the management pathway. In recognition that not all patients are suitable for sacral colpopexy, a yellow reasonable option is included for vaginal based apical support (uterosacral or sacrospinous colpopexy). Both uterosacral and sacrospinous colpopexy are equally effective vaginal options (LoE 1) and utilisation of transvaginal permanent mesh apical support is not supported by the data (LoE 1).

When performing sacral colpopexy, the laparoscopic approach is preferred with reduced peri-operative morbidity and cost when compared to both the open or robotic approach (LoE 2). The yellow reasonable option pathway exists for both open and robotic options in recognition of the longer learning curve associated with the laparoscopic approach (LoE 3).

Apical support in those with uterine prolapse can be performed abdominally or vaginally and includes options for both uterine preservation (hysteropexy) and hysterectomy, with not insignificant relative contraindications for uterine preservation listed in Table 6. In post-menopausal women undergoing hysterectomy, bilateral salpingo-oophorectomy (BSO) significantly reduces the rate of ovarian cancer without increased morbidity. In those retaining ovaries at hysterectomy, bilateral salpingectomy also reduces rate of subsequent ovarian cancer.

Vaginal hysteropexy is equally effective as vaginal hysterectomy with apical suspensions and is associated with reduced blood loss and operating time as compared to hysterectomy (LoE 1). Vaginal hysterectomy with apical support has a lower re-operation for prolapse than abdominal sacrohysteropexy (LoE 1). Sacrohysteropexy has a higher re-operation for prolapse than sacral colpopexy with hysterectomy; however, sacral colpopexy with hysterectomy is not recommended due to the high rate of mesh exposure (LoE 2). Supra-cervical hysterectomy at sacral colpopexy reduces the rate of mesh exposure associated with hysterectomy and sacral colpopexy; however, in a single retrospective study, recurrent prolapse was more common in the supracervical hysterectomy group. Although these data is not complete, vaginal based hysterectomy and hysteropexy with apical support should generally be considered as preferred options for uterine prolapse with sacral colpopexy reserved for vault prolapse.

Those undergoing prolapse surgery with stress urinary incontinence (SUI) and occult SUI should generally have continence surgery performed at the time of prolapse surgery (LoE 1). Those with prolapse without SUI or occult SUI should not undergo continence surgery at time of prolapse surgery (LoE 1).

Based largely upon expert opinion (LoE 3) those with prolapse without bowel symptoms and those with impaired defaecation with rectocele should undergo prolapse surgery as per the above pathway. Those with POP and impaired defaecation without rectocele, and those with faecal incontinence require colorectal assessment. If
rectal prolapse exists, these patients may benefit from combined colorectal and gynaecological interventions. Those with significant constipation and prolapse should be approached cautiously and may benefit from gastroenterology assessment prior to entering the POP surgery pathway.

Those undergoing POP surgery generally have improved sexual function post-operatively but a small number undergoing any POP surgery will experience painful intercourse post-operatively that may require subsequent intervention (LoE 1).
Consider CONTINENCE PRODUCTS for temporary support during treatment.
VI. URINARY INCONTINENCE IN NEUROLOGICAL PATIENTS

A. INITIAL MANAGEMENT

1. STRONG GENERAL RECOMMENDATIONS

- Patients with known neurological disease often need evaluation to exclude bladder dysfunction, not only if symptoms occur, but as a standard assessment as neurogenic bladder has a high prevalence in the particular disease (for prevalence figures see chapter).
- A possible neurological cause of “idiopathic” incontinence should always be considered. Diagnostic steps to evaluate this include basic assessments, such as history and physical examination, urodynamics and specialised tests.
- Incontinence in neurological patients does not necessarily relate to the neurologic pathology. Other diseases such as prostate pathology, pelvic organ prolapse, might have an influence. These factors should be evaluated as potential primary or contributory causes.
- Extensive diagnostic evaluation is often useful and necessary to tailor an individual treatment based on complete neurofunctional data. This may not be needed in every patient e.g. patients with suprapontine lesions or in patients where treatment will consist merely of bladder drainage when the person is frail or has limited life expectancy.
- There is often a need to manage both bladder and bowel dysfunction simultaneously.

2. INITIAL ASSESSMENT

- The management of neurological urinary incontinence depends on an understanding of the likely mechanisms producing incontinence. This can in turn depend on the site and extent of the nervous system abnormality.
- Under current classifications, neurogenic incontinence patients can be divided into four groups. History and physical examination are important in helping distinguish these groups:
  - peripheral lesions (as after major pelvic surgery) including those with lesions of the cauda equina (eg. lumbar disc prolapse);
  - sacral spinal cord lesions involving the sacral micturition centre
  - suprasacral spinal cord lesions (suprasacral infrapontine spinal cord lesions);
  - central lesions of the brain or brain stem (stroke, Parkinson’s disease).
- Assessment should be made using Questionnaires, urinalysis, bladder diary, uroflowmetry with assessment of PVR, and imaging of the urinary tract (ultrasoundography); all provide basic data for the initial assessment of the NLUTD.
- Invasive urodynamics should be used as part of the initial assessment in select patient populations (SCI, meningomyelocele)
- Due to increasing data on organ cross-sensitisation and the debilitating effect of faecal incontinence on QOL, a history of bowel function should be also included.

3. INITIAL TREATMENT

- Patients with peripheral nerve lesions (e.g. denervation after pelvic surgery) and patients with spinal cord lesions (e.g. traumatic spinal cord lesions) should receive specialised urological management (GoR A).
- Initial treatment for patients with incontinence due to suprapontine pathology, like stroke; need to be assessed for degree of mobility and ability to cooperate.
- Initial recommended treatments are behaviour therapy (GoR C) and antimuscarinic drugs for presumed detrusor overactivity (GoR A). If incontinence persists and if operative procedures are not indicated then continence products (GoR B) or catheters (GoR C) may be necessary on a long-term basis. These can also be necessary in non-cooperative or less mobile patients.

Pharmacological detrusor relaxation and/or antibiotics may be useful in cases of persistent bypass leakage and/or recurrent UTI (patients with continuous drainage) In all cases, bowel management should complement management of NLUTD.
# Initial Management of Neurogenic Urinary Incontinence

## History, Level of Lesion
- **Peripheral nerve lesion** (e.g. radical pelvic surgery).
- **Sacral cord/cauda equina lesion** (e.g. lumbar disc prolapse).
- **Suprasacral infrapontine and pontine lesions** (e.g. trauma, multiple system atrophy).
- **Suprapontine cerebral lesion** (e.g. Parkinson’s disease, stroke, multiple sclerosis).

## Clinical Assessment
- Further history (bowel, sexual function, fertility issues).
- General assessment including of home circumstances.
- Urinary diary and symptom score.
- Assessment of functional ability, quality of life and desire for treatment.
- Physical examination: assessment of sensation in lumbosacral dermatomes, anal tone and voluntary contraction of anal sphincter, bulbocavernous and anal reflexes, gait, mobility, contractures, hand function.
- Urine analysis + culture (if infected: treat as necessary).
- Urinary tract imaging, serum creatinine: if abnormal to specialist management.
- Post void residual (PVR) assessment by abdominal examination or optional by ultrasound.
- Invasive UDS in select patient populations (e.g. spinal cord injury, meningomyelocele).

This assessment will give basic information, but does not yield precise neurourological diagnosis.

## Presumed Diagnosis
- **Stress urinary incontinence due to sphincter incompetence with negligible PVR**
- **Urinary incontinence due to detrusor overactivity**
- **Urinary incontinence associated with poor bladder emptying (significant PVR)**
- **With negligible PVR**

## Management*
- **Behavioural modification (C)**
- **External appliances (B)**
- **Intermittent catheterisation** **with or without antimuscarinics (A)**
- **Continence products (B)**
- **Indwelling catheter (C)**

Depending on cooperation and mobility: 
- Behavioural modification, (C)
- Antimuscarinics (A)/beta 3 agonists (D)
- Continence products (B)
- Indwelling catheter (C)

## Specialised Management
- Failure
- Failure

---

* Consider CONTINENCE PRODUCTS for temporary support during treatment

** Some patients omit IC through personal choice or inability to self catheterise

*** Add complimentary bowel management in all cases
VI. URINARY INCONTINENCE IN NEUROLOGICAL PATIENTS

B. SPECIALISED MANAGEMENT

1. ASSESSMENT

- Most patients with neurogenic urinary incontinence require specialised assessment: Invasive urodynamic studies should be used with videourodynamic if available when surgical interventions are planned or when the “bladder may be unsafe”.

- Upper tract imaging is needed in some patients and more detailed renal function studies will be desirable if the upper tract is considered in danger: high bladder pressure, upper urinary tract dilation, recurrent or chronic upper tract infection, (major) stones, (major) reflux.

- In patients with peripheral lesions, clinical neurophysiological testing may be helpful for better definition of the lesion.

2. TREATMENT

For specialised management, conservative treatment is the mainstay (GoR A). Management of neurogenic urinary incontinence has several options. The algorithm details the recommended options for different types of neurological dysfunction of the lower urinary tract. The dysfunction does not necessarily correspond to one type/level of neurological lesion and is defined best by urodynamic studies. One should always ascertain that the management ensures a safe lower urinary tract (storage at low pressure and complete emptying).

Both urinary and bowel function should be assessed together if both systems are affected, as symptoms and treatment of one system can influence the other, and vice versa (GoR A).

As therapeutic approaches can differ in various neurological diseases, the most prevalent diseases are discussed separately in the chapter.

3. TREATMENT MODALITIES (OFTEN IN COMBINATION)

- **Conservative**
  - Intermittent catheterisation (GoR A)
  - Behavioural treatment (GoR C)
  - Timed voiding (GoR C)
  - Continence products (GoR B)
  - Antimuscarinics (GoR A)
  - Alpha-1-adrenergic blockers (GoR C)
  - Oral cannabinoid agonists (MS) (GoR C)
  - Beta-3-agonist alone or as an add-on to AM (GoR D)
  - Bladder expression (GoR B)
  - Triggered voiding (GoR C)
  - Indwelling catheter (GoR C)

- **Minimally invasive treatments**
  - Botulinum toxin for: sphincter (C) detrusor (A)
  - Intravesical electrical stimulation (C)
  - PTNS/TTNS (C)
  - SNM (stable disease only) (C)
- Artificial sphincter (A)
- Bladder neck sling (B)
- Sub-urethral tapes (D)
- Bulking agents (D)
- Bladder neck closure (D)

- Stents intraurethral (B)
- TUI sphincter (B)
- Sacral deafferentation (B)
- Sacral anterior root stimulator (B)
- Enterocystoplasty (B)
SPECIALISED MANAGEMENT OF NEUROGENIC URINARY INCONTINENCE

LEVEL AND EXTENT OF LESION, HISTORY AND CLINICAL ASSESSMENT

Peripheral nerve lesion (e.g. radical pelvic surgery) conus cauda equina lesion (e.g. lumbar disc prolapse)

Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)

Suprapontine cerebral lesion (e.g. Parkinson’s disease, stroke, multiple sclerosis)

SPECIALISED ASSESSMENT

- Urodynamic testing (preferably videourodynamic).
- Urinary tract imaging

DIAGNOSIS

Urodynamic Stress Incontinence due to sphincter incompetence

Incontinence associated with poor bladder emptying due to detrusor underactivity / sphincter overactivity

UI due to detrusor overactivity

- With DSD
- No DSD

CONSERVATIVE TREATMENT

- Timed voiding (C)
- External appliance (B)

- Artificial sphincter (A)
- Bladder neck (autologous) sling (B)
- Bulking agents (D)
- Bladder neck closure (D) (Synthetic midurethral tapes D)**

- Stents intraurethral (B)
- TUI sphincter (B)
- BTX-A to sphincter ** (C)
- IVES (C)

- BTX-A to detrusor + IC (A)
- SDAF + IC (B)
- SDAF +/- SaRS (B)

- Behavioural (C)
- IC + AM (A)
- Triggered voiding (C)
- Indwelling cath. + AM (C)
- Continence products + AM (B)

STOMA/DIVERSION MAY BE AN OPTION IN SELECTED CASES

- AM antimuscarinics
- SDAF sacral deafferentation
- SARS sacral anterior root stimulation
- IC intermittent catheterisation
- PVR postvoid residual
- TUI transurethral incision
- DSD Detrusor-sphincter dyssynergia
- IDC indwelling catheter
- BTX-A Botulinum toxin A
- IVES intravesical electrical stimulation

** if urethral hypermobility is the cause of USI; the long-term risks of tapes in the neurogenic population are undefined
* If IC not possible or after sphincter relaxation procedures and with adequate UDS controls
**Intravesical botulinum injections undertaken according to national licensing. Sphincteric botulinum injections are not currently licensed.
* Consider CONTINENCE PRODUCTS for temporary support during treatment
VII. BLADDER PAIN SYNDROME

Definition

Bladder Pain Syndrome (BPS): in the absence of a universally agreed definition, the International Society for the Study of Interstitial Cystitis – ESSIC definition is given (1).

ESSIC: Chronic pelvic pain, pressure or discomfort of greater than 6 months duration perceived to be related to the urinary bladder accompanied by at least one other urinary symptom like persistent desire to void or urinary frequency. Confusable diseases as the cause of the symptoms must be excluded.

There are no published data as to what duration of symptoms indicates that early spontaneous resolution of symptoms is unlikely. While ESSIC arbitrarily uses a 6 month duration, the American Urological Association Guideline suggests that a 6 week history is long enough to initiate diagnosis and treatment of BPS (2). Without further data, the Consultation cannot make a recommendation and believes that it is up to the discretion of the physician and patient as to the proper interval between symptom onset and evaluation and diagnosis of a chronic condition.

1. NOMENCLATURE

The scientific committee of the International Consultation voted to use the term “bladder pain syndrome” for the disorder that has been commonly referred to as interstitial cystitis (IC). The term painful bladder syndrome was dropped from the lexicon. The term IC implies an inflammation within the wall of the urinary bladder, involving gaps or spaces in the bladder tissue. This does not accurately describe the majority of patients with this syndrome. Painful Bladder Syndrome, as defined by the International Continence Society, is too restrictive for the clinical syndrome.

Properly defined, the term Bladder Pain Syndrome appears to fit in well with the taxonomy of the International Association for the Study of Pain (IASP) (see below), and focuses on the actual symptom complex rather than what appears to be long-held misconception of the underlying pathology.

Bladder Pain Syndrome (XXIII-2) (per IASP)

Bladder pain syndrome is the occurrence of persistent or recurrent pain perceived in the urinary bladder region, accompanied by at least one other symptom, such as pain worsening with bladder filling and day-time and/or night-time urinary frequency. There is no proven infection or other obvious local pathology. Bladder pain syndrome is often associated with negative cognitive, and behavioural, sexual, or emotional consequences, as well as with symptoms suggestive of lower urinary tract and sexual dysfunction.

The Consultation believes that, based on the pathology and endoscopic finding characteristics of the Hunner lesion, the epidemiological pattern that distinguishes it from bladder pain syndrome, the clinical response to local treatment of the lesion by resection, fulguration, or steroid injection, the response to cyclosporine, and the

Figure 1
absence of reports in the literature that non-Hunner patients go on to develop Hunner lesions (ie, the finding of a Hunner lesion does not represent a continuum in the natural history of bladder pain syndrome), that the presence of a Hunner lesion should be considered a distinct disease. It therefore should drop out of the bladder pain syndrome construct, much like we do not consider other painful conditions like radiation cystitis, ketamine cystitis, or urinary tract infection a part of bladder pain syndrome.

The Consultation concludes that it would be reasonable to designate the Hunner lesion in symptomatic patients with the term “interstitial cystitis”, thus indicating a true interstitial inflammation. It would be defined much as Hunner defined it 100 years ago, and harmonise the largely Asian, European, and North American concepts of interstitial cystitis. The Consultation will continue to refer to the symptom complex as “bladder pain syndrome”. Hunner lesion will be considered a distinct phenotype, but in the future may be classified as a separate disorder entirely, albeit with local symptoms that are difficult to differentiate from bladder pain syndrome in the absence of endoscopy. In other words, we may be coming full circle in the historical perspective Figure 1.

2. HISTORY / INITIAL ASSESSMENT

Males or females whose symptoms meet the requirements of the definition of bladder pain syndrome should be evaluated. The presence of commonly associated disorders including irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia in the presence of the cardinal symptoms of bladder pain syndrome also suggests the diagnosis. Abnormal gynaecological findings in women and well-characterised, confusable diseases that may explain the symptoms must be ruled out.

The initial assessment consists of a bladder diary or frequency/volume chart, focused physical examination, urinalysis, and urine culture. In the absence of confusable disorders (uncomplicated disease), a diagnosis can be made and treatment instituted. Urine cytology, cystoscopy, and urodynamic evaluation are recommended if clinically indicated and/or the diagnosis is in doubt (complicated disease). Patients with urinary infection should be treated and reassessed. Those with recurrent urinary infection, abnormal urinary cytology, and microscopic or gross haematuria are evaluated with appropriate imaging and endoscopic procedures, and only if the findings are unable to explain the symptoms, are they diagnosed with BPS. GoR C

3. INITIAL TREATMENT

- Patient education, (GoR B)
- Dietary manipulation, (GoR B)
- Nonprescription analgesics,
- Stress reduction,
- Pelvic floor relaxation techniques comprise the initial treatment of BPS. In the patient with findings suggesting pelvic floor dysfunction, pelvic floor physical therapy with myofascial trigger point release and intravaginal Thiele massage is often an effective therapeutic intervention. The treatment of pain needs to be addressed directly, and in some instances referral to an anesthesia/pain centre can be an appropriate early step in conjunction with ongoing treatment of the syndrome. (GoR A)

When conservative therapy fails or symptoms are severe and conservative management is unlikely to succeed,

- Oral medication (GoR B) or
- Intravesical treatment can be prescribed. It is recommended to initiate a single form of therapy and observe results, adding other modalities or substituting other modalities as indicated by the degree of response or lack of response to treatment. (GoR B)

4. SECONDARY ASSESSMENT

If initial oral or intravesical therapy fails, or before beginning such therapy based on clinician judgment, it is reasonable to consider further evaluation which can include urodynamics, pelvic imaging, and cystoscopy with bladder distention and possible bladder biopsy under anaesthesia.

- Findings of detrusor overactivity suggest a trial of antimuscarinic or beta-3-agonist therapy.
- The presence of a Hunner lesion suggests therapy with transurethral resection, fulguration of the lesion, or direct steroid injection into the lesion. (GoR B)
• Bladder distention itself can have therapeutic benefit in 30-50% of patients, though benefits rarely persist for longer than a few months. (GoR C)

5. REFRACTORY BPS

Those patients with persistent, unacceptable symptoms despite oral and/or intravesical therapy are candidates for more aggressive treatment modalities. Many of these are best administered within the context of a clinical trial if possible. These may include

• Sacral nerve stimulation, (GoR B)
• Intradetrusor botulinum toxin, (GoR B)
• Oral cyclosporine A (GoR C), or
• Clinical trials of newly described pharmacological management techniques. At this point, most patients will benefit from the expertise of an anaesthesia pain clinic.

The last step in treatment is usually some type of surgical intervention aimed at increasing the functional capacity of the bladder or diverting the urinary stream.

• Urinary diversion with or without cystectomy has been used as a last resort with good results in selected patients. Cystectomy and urethrectomy do not appear to add any additional efficacy to diversion alone.

Augmentation or substitution cystoplasty seems less effective and more prone to recurrence of chronic pain in small reported series (GoR C)
BLADDER PAIN SYNDROME

SYMPTOMS
Pain, pressure or discomfort perceived to be related to the bladder with at least one other urinary symptom (e.g. frequency, nocturia)

BASIC ASSESSMENT
History
- Bladder diary or frequency/volume chart
- Focused physical examination
- Urinalysis, culture

“Complicated” BPS:
- Incontinence
- Urinary infection
- Haematuria
- Gynaecologic signs/symptoms

Consider CONTINENCE PRODUCTS for temporary support during treatment

1ST LINE RX
“Uncomplicated BPS” Conservative Therapy
- Stress reduction (B)
- Patient education (B)
- Dietary manipulation (B)
- Nonprescription analgesics
- Pelvic floor relaxation
- Pelvic floor physical therapy (A)
- Consult if associated disease

TREAT AS INDICATED

URINARY INFECTION
Test and reassess

Normal
Abnormal

Consider Urine cytology
- Further imaging
- Endoscopy
- Urodynamics
- Laparoscopy

Consider CONTINENCE PRODUCTS for temporary support during treatment
BPS REQUIRING MORE ACTIVE INTERVENTION

2ND LINE TREATMENT
(no hierarchy implied)
Consider oral and or intravesical therapies; (B)
Consider physical therapy; (A)
Consider cystoscopy with hydrodistention under anaesthesia and treatment of any Hunner lesion (B)

3RD LINE TREATMENT
Consider, if not done previously:
Cystoscopy under anaesthesia with bladder hydrodistension fulguration, resection or steroid injection of Hunner lesion (B)

4TH LINE TREATMENT
(no hierarchy implied)
Sacral Nerve stimulation (B)
Intra-detrusor botulinum toxin (B)
Cyclosporine A (C)
Consider new treatment trials

5TH LINE TREATMENT
Consider:
Diversion with or without cystectomy (C)
Substitution cystoplasty

Improved with acceptable quality of life:
Follow and support

Note: The only FDA approved therapies are DMSO and pentosan polysulfate.
Consider CONTINENCE PRODUCTS for temporary support during treatment.

- Pain management is a primary consideration at every step of the algorithm
- Patient enrollment in appropriate research trial is a reasonable option at any point
- Evidence supporting SNS, cyclosporine A, and botulinum toxin for BPS remains limited. These interventions are appropriate only for practitioners with experience in treating BPS and who are willing to provide long-term care post-intervention
VIII. FAECAL INCONTINENCE IN ADULT PATIENTS

ASSESSMENT AND MANAGEMENT

1. INITIAL CLINICAL ASSESSMENT

Adult patients with faecal incontinence present with a variety of symptom complexes. As many people are reluctant to admit to having faecal incontinence, it is important to proactively enquire about it, especially in known high risk groups (such as older community-living individuals, post partum women who might have had an obstetric injury and patients with loose stools).

History will include symptoms such as loose stools and urgency, the type and severity of bowel incontinence, systemic disorders, neurological disorders, and ano-rectal surgeries (e.g., haemorrhoidectomy), obstetric history for women, medications, diet, chronic straining, cognitive status, and effects of symptoms on quality of life.

2. INITIAL INTERVENTIONS

- Assessing the type of bowel incontinence may help identify an aetiology. Types of bowel incontinence: Anal incontinence is the involuntary loss of faeces and/or flatus and/or mucus). Faecal incontinence is the involuntary loss of faeces. Flatus incontinence is the involuntary loss of rectal gas, which may indicate rectal sensory impairment and/or anal sphincter dysfunction. Mucus incontinence is the involuntary loss of mucus only (See Figure 1).
  - Some subtypes of faecal incontinence are urgency faecal incontinence, which is the involuntary loss of faeces due to an inability to defer defaecation, once the desire is perceived, for long enough to reach a toilet. Urgency faecal incontinence is often a symptom of external anal sphincter dysfunction. The symptom of urgency does not necessarily result in urgency faecal incontinence. Functional faecal incontinence is due to limitations in mobility or toileting ability or delayed assistance. Passive faecal incontinence, incontinence without forewarning, is typically related to internal anal sphincter dysfunction or poor closure of the external sphincter due to rectal prolapse or stage III/IV haemorrhoids.

- Physical examination will include anal inspection, abdominal palpitation, a brief neurological examination, digital rectal examination and usually procto-sigmoidoscopy or colonoscopy.

- Further diagnostic testing needs to be considered if the patient has symptoms such as an unexplained change in bowel habit, weight loss, anaemia, rectal bleeding, severe or nocturnal diarrhoea, or an abdominal or pelvic mass and bowel pathology when organic conditions such as cancer, inflammatory bowel disease (IBD), a recto-vaginal fistula, full thickness rectal prolapse, or cloacal deformity are suspected. Condition specific management is indicated for these patients.

- Reversible factors (such as inadequate access to toilets and side effects of medications resulting in loose stools) should be assessed and addressed at the outset.

Some initial management can often be performed in primary care. After environmental factors and local or systemic pathology have been excluded, initial interventions include:

- Discussion of options and goals of management with the patient
- Provision of patient or caregiver information and education (GoR A)
- Adjustment of diet and fluid advice, fibre intake (GoR A)
- Establishing a regular bowel habit (GoR C) or urgency training if relevant (GoR C)
- Anti-diarrhoeal medication can help if stools are loose (GoR B)
- Use of continence products including various types and sizes of absorbent pads, briefs, etc., to contain leaked faeces and prevent skin damage
- Provide advice on practical coping skills when incontinence occurs (GoR C)
### 3. SECONDARY INTERVENTIONS

- If initial interventions fail to improve symptoms after 8-12 weeks, consideration should be given to referral to an incontinence specialist (e.g., gastroenterologist, continence nurse, advisor physiotherapist, or colorectal surgeon) for other interventions or further assessment.
- Pelvic floor muscle training (PFMT) – contraction of pelvic floor muscles, multiple times per day to improve strength of contraction and increase awareness of anorectal muscle function. (GoR C)
- Biofeedback therapy – behavioural treatment designed to enhance the strength of sphincter contraction and improve rectal sensation using specialised equipment. Biofeedback therapy can be combined with PFMT to improve strength. (GoR B)
- Transanal Irrigation to maximise bowel emptying and minimise faecal incontinence primarily in patients with incomplete elimination, passive faecal incontinence, or faecal incontinence with defaecation difficulty. (GoR C)

### 4. SECONDARY ASSESSMENT

- A variety of anorectal investigations, including manometry, anal ultrasound, and possibly MRI, defaecography, and neurophysiological testing can help to define structural or functional abnormalities of anorectal function and guide management if initial and/or secondary interventions are ineffective

### 5. TERTIARY REFERRAL, SURGICAL OR MULTI-DISCIPLINARY CONSULTATION

- Faecal incontinence that fails to respond to initial and secondary management requires specialised consultation by a gastroenterologist, colorectal surgeon, urogynaecologist, and/or a multi-disciplinary team
Identification
Active case finding or patient presents with faecal incontinence (C)

Initial Clinical Assessment
• History (C)
• Physical exam (C)
• Medication and diet review (C)
• Assessment of impact on quality of life (C)
• Proctosigmoidoscopy and/or colonoscopy as needed (C)

Address Reversible Factors
Toilet access, medication side effects, loose stools, etc. (C)

Secondary Interventions
• PFMT +/- (B)
• Biofeedback (A)
• Incontinence products such as an anal plug or insert (B)

Secondary Assessment
• Manometry and/or Ultrasound (B/C)
• Possible additional test
• MRI (C)
• Defaecography (B/C)
• Neuro-physiology testing (C/D)

Condition Specific Assessment and Management
For cancer, IBD, impaction, full thickness rectal prolapse, recto-vaginal fistula, cloacal deformity (C)

Incontinence Specialist (C)

Initial Interventions
• Discussion of options and patient’s goals of management (B/C)
• Education of patient and/or caregiver (B/C)
• Diet and eating pattern modifications (B), and dietary fibre supplements (A)
• Medications (loperamide) (B)
• Bowel habit training (C)
• Transanal irrigation (C)
• Incontinence products such as pads for containment (B)
• Practical advice for coping (locating toilets, carrying cleansing kits, etc.) (C)

Tertiary
Referral, surgical and/or multi-discipline consult (C)

* Consider CONTINENCE PRODUCTS for temporary support during treatment
VIII. FAECAL INCONTINENCE IN ADULT PATIENTS

SURGERY FOR FAECAL INCONTINENCE

1. PATIENT ASSESSMENT

- The reader is referred to the relevant chapter sections in “Dynamic Testing” and “Conservative Treatment for Faecal Incontinence.” In general, patients referred for surgical management of faecal incontinence must either have failed conservative therapy or not be candidates for conservative therapy due to severe anatomic or neurological dysfunction.

- Prior to surgical management of faecal incontinence, the integrity of the anal sphincter complex should be assessed. This assessment is best performed with endoanal ultrasound, though pelvic MRI may also be useful. Ancillary tests include anal manometry, electromyography, and defaecography.

- If the patient has persisting faecal incontinence, he or she should undergo repeat assessment, including endoanal ultrasound.

2. SPECIALISED MANAGEMENT

- The surgical approach is influenced by the presence and magnitude of an anatomical anal sphincter defect. If no defect is present, or if the sphincter defect is minimal, options include SNS and biomaterial injection therapy.

- Acute anal sphincter repair is usually required following obstetric or direct trauma. End to end or overlapping repair may be performed. When possible the internal anal sphincter should be separately repaired. (GoR C)

- Patients with rectal prolapse, rectovaginal fistula or cloacal deformity often have associated faecal incontinence. Initial therapy should be directed at correction of the anatomical abnormality. (GoR C)

- For patients with moderate sphincter defects, sphincteroplasty, SNS or biomaterial injection therapy can each be considered. For patients with large sphincter defects (>120 degrees), sphincteroplasty is likely to be the best option, though a PNE trial for SNS can be considered. (GoR C)

- Patients with sphincter defects of greater than 180° or major perineal tissue loss require individualised treatment. In some cases, initial reconstruction can be performed. Should incontinence persist, alternatives include stimulated muscle transposition (usually graciloplasty) artificial anal sphincter implantation, or SNS. (GoR C)

3. SALVAGE MANAGEMENT

- For patients who remain incontinent following sphincteroplasty, repeat endoanal ultrasound should be undertaken to reassess the status of the repair. If no defect is present, or if the sphincter defect is minimal, options include SNS and biomaterial injection therapy. If there is a large persisting sphincter defect, repeat sphincteroplasty can be considered. (GoR C)

- Patients who have failed SNS can be considered for biomaterial injection therapy or sphincteroplasty if a sphincter defect is present. Other alternatives include stimulated graciloplasty and implantation of an artificial anal sphincter. (GoR C)

- Patients who fail surgical therapy for faecal incontinence, or who do not wish to undergo extensive pelvic reconstruction, should consider placement of an end sigmoid colostomy. (GoR C) While this procedure does not restore continence, it does restore substantial bowel control and appears to improve social function and quality of life. Novel therapies can also be considered under protocol: PTNS, the magnetic anal sphincter, SECCATM, vaginal pessary (EclipseTM) and sling procedures. (GoR D)

4. SPECIAL SITUATIONS

- Individuals with congenital abnormalities may be amenable to surgical repair. Often this will involve both laparoscopic abdominal and perineal approaches. Poor functional outcomes may be treated by an Antegrade Continence Enema (ACE) procedure or colostomy. Patients with cauda equina type neurological disorders, either congenital or acquired, should be considered for an ACE procedure or colostomy. (GoR C)

IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

A. INITIAL MANAGEMENT

Patients with known neurological disease may present with symptoms related to neurological bowel dysfunction, such as: difficulty in defaecation, constipation and faecal incontinence which disturb their activities of daily living and impair quality of life. Many have permanent impairments and functional limitations and disabilities, which are due to neurological deficits and complications.

1. INITIAL ASSESSMENT

- The history should include:
  - Neurological diagnosis and functional level
  - Previous and present lower gastrointestinal (LGIT) function and disorders
  - Severity of neurogenic bowel dysfunction
  - Current bowel care and management including diet, fluid intake, medications affecting bowel functions
  - Co-morbidity / complication e.g., urinary incontinence, autonomic dysreflexia, pressure ulcers, sexual dysfunction
  - Patient’s satisfaction, needs, restrictions and quality of life
  - Environmental factors and barriers and facilitators to independent bowel management.

- Physical examination:
  - Cognitive function; motor, sensory and sacral reflexes – voluntary anal sphincter contraction, deep perianal sensation, anal tone, anal and bulbocavernous reflexes
  - Spasticity of the lower limbs
  - Abdominal palpation for faecal loading and rectal examination

- Functional assessment:
  - Hand and arm use, fine hand use, mobility – maintaining body position, transfer and walking ability.

- Environmental factors assessment:
  - toilet accessibility; devices for bowel care and mobility; caregiver support and attitude;

2. BASIC INVESTIGATIONS

Stool examination, plain abdominal X-Ray

3. INITIAL TREATMENTS

- Patient education and goals-setting to achieve complete defaecation on a regular basis and faecal continence based on right time, right place, right trigger and right consistency
- Adequate fibre diet and fluid intake; appropriate trigger according to preservation of sacral (ano-rectal) reflex – digital rectal stimulation (GoR C); suppository and enema (GoR B); if no anorectal reflex, manual evacuation (GoR B); abdominal massage (GoR C) can also be helpful
- Prescribe medications – stool softener, laxative, prokinetic agents, anti-diarrhoeal drugs as necessary
- Assistive techniques may be necessary for
  - Defaecation – transanal irrigation (GoR A)
  - For incontinence – anal plug (GoR C)

The algorithm does not apply to management in acute neurological patients that need regular bowel emptying.
INITIAL MANAGEMENT OF NEUROGENIC FAECAL INCONTINENCE

**HISTORY, LEVEL OF LESION**
- Sacral cord/cauda equina lesion (e.g. lumbar disc prolapse). Peripheral nerve lesion (e.g. radical pelvic surgery)
- Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)
- Suprapontine lesions (e.g. Parkinson’s)

**CLINICAL ASSESSMENT**
- History taking including diagnosis, pre-morbid bowel function and sensation and their disorders, current bowel and bladder programme, co-morbid diseases/disorders, QOL and needs
- Physical & neurological examination including cognitive function, voluntary anal contraction, perianal sensation, sacral reflexes, digital rectal examination, abdominal palpation for faecal impaction
- Functional assessment including hand and arm use, fine hand use, balance, transfer and walking
- Environmental factors assessment including toilet accessibility, assistive device, caregivers’ support and attitude
- Basic investigation: stool exam, plain film abdomen in selected patients (diarrhoea, impaction not felt on rectal examination)

This assessment will give basic information but does not permit a precise diagnosis of neurogenic bowel dysfunction

**PRESUMED DIAGNOSIS**
- Incontinence due to sphincter incompetence
- Incontinence due to lack of cognitive function, sensory awareness disorders, unable to control by voluntary anal contraction
- "false incontinence" due to faecal impaction

**TREATMENT**
- Manual evacuation
- Assistive device – anal plug
- Mini-enema, transanal irrigation
- Suppository
- Biofeedback
- Digital rectal stimulation
- Chemical stimulant, suppository, mini-enema, stool softener, laxative, prokinetics, and
  Transanal irrigation could be given by patient/caregiver; biofeedback by patient
- Faecal disimpaction:
  Oral PEG plus enemas or transanal irrigation

**NECESSARY IN ALL**
- Patient education, adequate fibre diet and fluid intake; regular bowel care, preferably ± 3 times a week

**SPECIALISED MANAGEMENT PREFERABLE FOR MORE "TAILORED" TREATMENT**

* Consider CONTINENCE PRODUCTS for temporary support during treatment
IX. FAECAL INCONTINENCE IN NEUROLOGICAL PATIENTS

B. SPECIALISED MANAGEMENT

1. ASSESSMENT

- Some patients with neurogenic faecal incontinence will need specialised assessment, especially if initial management is unsuccessful to look for comorbidity and certainly before performing invasive treatment.
- Do not assume that all symptoms are due to neuropathy, e.g. women with neurological pathology might have had childbirth injury to the sphincter.
- Special investigations: manometry, endoanal ultrasound, (dynamic) MRI, (needle) EMG. These specific bowel functional tests and electro-diagnostic tests must be considered optional, as their value in neurological pathology is not sufficiently demonstrated so far.

2. TREATMENTS

- Conservative treatment for neurological faecal incontinence is also the mainstay for specialised management, (GoR C).
- Management of neurological incontinence does not include very extensive treatment modalities and many conservative interventions are still empirical.
- Transanal irrigation (GoR B).
- Electrical stimulation sphincter, (GoR C).
- Percutaneous neuromodulation and sacral nerve stimulation: further research is required (GoR D).
  - Surgical management of neurogenic faecal incontinence has different options which need a very strict patient selection
  - Antegrade Continence Enema ACE (GoR C).
  - Artificial bowel sphincter or FENIX procedure (GoR C).
  - Sacral Anterior Root Stimulation SARS (GoR C).
  - Botulinum Toxin (GoR C).
  - Neuromodulation (GoR C).
  - It is recommended that urinary and bowel function are assessed simultaneously if both systems are affected, as symptoms and treatment of one system can influence the other and vice versa (GoR A).
  - As the therapeutic approach can differ in different neurological diseases, the most prevalent diseases are discussed separately in the chapter.
SPECIALISED MANAGEMENT OF NEUROGENIC FAECAL INCONTINENCE

**PRIMARY ASSESSMENT, HISTORY, LEVEL AND EXTENT OF LESION, CLINICAL ASSESSMENT**

- Sacral cord/cauda equina lesion (e.g. lumbar disc prolapse). Peripheral nerve lesion (e.g. radical pelvic surgery)
- Suprasacral infrapontine and pontine lesion (e.g. trauma, multiple sclerosis)
- Suprapontine lesions (e.g. Parkinson’s)

**SPECIALISED ASSESSMENT**

- Functional bowel testing / functional imaging
- Consider neurophysiological testing and anorectal manometry.

**DIAGNOSIS**

- Faecal Incontinence through loss of bowel sensation, sphincter deficiency or severe rectal prolapse

**CONSERVATIVE TREATMENT**

- Transanal irrigation (B)
- Electrical stimulation of sphincter (C), Percutaneous neuromodulation: further studies

**SURGICAL TREATMENT**

- ACE (C)
- Artificial bowel sphincter or FENIX procedure (C)
- SARS (C)
- Botulinum Toxin for anal sphincter spasticity (C)
- Neuromodulation (C)

**STOMA/DIVERSION MAY BE AN OPTION IN SELECTED CASES**

* Consider CONTINENCE PRODUCTS for temporary support during treatment
X. URINARY AND FAECAL INCONTINENCE IN FRAIL OLDER MEN AND WOMEN

- There is no reason to suspect why interventions which have proven efficacy in the community dwelling elderly should not also be effective in frail older people. Clinicians should, however, take due regard of the practicality, potential benefits and dangers of employing any single intervention in this population.

- Frail older people do require a different approach addressing the potential role of co-morbid disease, current medications (prescribed, over the counter and/or naturopathic), and functional and cognitive impairment in urinary and faecal incontinence.

- The extent of the investigation and management should take into account the degree of bother to the older person and/or caregiver, the goals for care, the degree that the older person is able to undertake any intervention and the overall prognosis and life expectancy.

- Effective management to meet the goals of care should be possible for most frail older people.

1. HISTORY AND SYMPTOM ASSESSMENT

- Active case finding for urinary and faecal incontinence should be done in all frail older people (GoR A).

- History should include comorbid conditions and medications that could cause or worsen incontinence.

- Physical examination should include a rectal examination for faecal loading or impaction (GoR C), functional assessment (mobility, transfers, manual dexterity, dressing and undressing ability, ability to toilet) (GoR A), a screening test for depression (GoR B), and cognitive assessment (to assist in planning and management, (GoR C)).

- The mnemonic DIPPERS (see urinary and faecal incontinence algorithms) covers some of these comorbid conditions. Note that urogenital atrophy does not, in itself, cause urinary incontinence and should not be treated for this purpose (GoR B).

- The patient and / or caregiver should be asked about the degree of bother of urinary incontinence and/or faecal incontinence(GoR B); goals for urinary and faecal incontinence care (dryness, decrease in specific symptoms, quality of life, reduction of comorbidity, lesser care burden) (GoR B); and likely cooperation with management (GoR C).

- Evaluation for bowel “alarm” symptoms (rectal bleeding, positive blood screening from stool studies, obstructive symptoms, recent onset of constipation, weight loss, and a change in stool calibre) will need more extensive evaluation (GoR A)

- Urinalysis is recommended for all patients, primarily to screen for haematuria (GoR C).

- Treatment of otherwise asymptomatic bacteriuria/pyuria is not beneficial (GoR C), and it may cause harm by increasing the risk of antibiotic resistance and severe adverse effects. e.g., Clostridium difficile colitis (GoR C).

- Stool studies may not be needed in all patients with faecal incontinence. Patients with diarrhoea, especially those with more acute onset diarrhoea, may need to be tested for infectious causes of their diarrhoea. Other stool studies could involve testing for malabsorption syndromes.

- The utility of the Clinical Stress test in this population is uncertain (GoR D).

- Wet checks can assess urinary incontinence frequency in long-term care residents (GoR C).

- A post voiding residual volume (PVR) test is impractical in many care settings and there is no consensus for the definition of what constitutes a “high” PVR in any population. A PVR measurement is not recommended in the routine initial assessment of frail older people with urinary incontinence.

- However, there is compelling clinical experiential evidence for PVR testing in selected frail older people with: diabetes mellitus (especially long standing); prior urinary retention or high PVR; recurrent UTIs; medications that impair bladder emptying (e.g., opiates); severe constipation; persistent or worsening urgency urinary incontinence despite antimuscarinic/beta-3-agonist treatment; or prior urodynamics showing detrusor underactivity and/or bladder outlet obstruction (GoR C). Treatment of contributing comorbidity may reduce PVR. Trial with catheter may be considered for PVR > 200-500 ml if the PVR is felt to contribute to UI or urinary frequency (GoR C).
Nocturia Assessment of frail elders with bothersome nocturia should identify potential underlying causes including nocturnal polyuria (by bladder diary/frequency-volume chart or wet checks; oedema on examination) (GoR C), primary sleep problems (e.g., sleep apnoea); and low voided volumes (e.g., from high PVR).

Stool impaction/loading. If suspected on digital rectal examination, an abdominal x-ray may be necessary to further evaluate the degree and location of impaction/loading in frail older adults.

2. CLINICAL DIAGNOSIS

The most common types of Urinary Incontinence in frail older people are urgency, stress, and mixed urinary incontinence. Frail older people with urgency urinary incontinence also may have detrusor underactivity during voiding with a high PVR but without outlet obstruction. There is no evidence that antimuscarinics are less effective or cause retention in this situation (GoR D).

The most common types of faecal incontinence in frail older people are related to urgency and passive leakage. Passive leakage can refer to leakage, seepage and staining following bowel movements that are not associated with faecal urgency and may also occur with faecal impaction. Because constipation and impaction often contribute to faecal incontinence in older adults, these are considered separately in the algorithm.

3. INITIAL MANAGEMENT

Initial treatment should be individualised and influenced by goals of care, treatment preferences and estimated remaining life expectancy, as well as the most likely clinical diagnosis (GoR C). In some frail older persons the only possible outcome may be containment; management with continence products, especially for people with minimal mobility (require assistance of > 2 people to transfer), advanced dementia (unable to state their name), and/or nocturnal urinary and faecal incontinence.

Conservative and behavioural therapy for UI includes lifestyle changes (GoR C), bladder training for more fit alert persons (GoR B), and prompted voiding for frailter, more impaired older people (GoR A).

For the select cognitively intact older person with UI or FI, pelvic floor muscle therapy can be considered, but there are few studies (GoR C). Antimuscarinics may be added to conservative therapy of urgency UI (GoR A-C, depending on agent).

4. ONGOING MANAGEMENT AND REASSESSMENT

Optimal urinary and faecal incontinence management is usually possible with the above approaches. If initial management fails to achieve the desired goals, the next steps are reassessment and treatment of contributing comorbidity and/or functional impairment.

5. SPECIALISED MANAGEMENT

If frail older people have either other significant factors (e.g., pain, haematuria, bowel "alarm" symptoms), UI or FI symptoms that cannot be classified as urgency, stress, or mixed or overflow or other complicated comorbidity which the primary clinician cannot address (e.g. dementia, functional impairment), then specialist referral should be considered. Referral may also be appropriate when there is been insufficient response to initial management. The type of specialist will depend on local resources and the reason for referral: surgical specialists (urologists, gynecologists, colorectal surgeons), gastroenterologists, geriatricians or physical therapist (functional and cognitive impairment); or continence nurse specialists (homebound patients). Referral decisions should consider goals of care, patient/caregiver desire for invasive therapy and estimated remaining life expectancy.
Age *per se* is not a contraindication to UI or FI surgery (GoR C), but before surgery is considered, all patients should have:

- Evaluation and treatment for any comorbidity, medications, and cognitive or functional impairments contributing to UI that could compromise surgical outcome (e.g., dementia that precludes patient ability to use artificial sphincter) (GoR C).
- Adequate trial of conservative therapy, including pharmacological therapies where relevant (GoR C).
- Discussion (including the caregiver) to ensure that the anticipated surgical outcome is consistent with goals of care in the context of the patient’s remaining life expectancy (GoR C).
- Urodynamic testing or anorectal manometry, because clinical diagnosis may be inaccurate (GoR B).
- Preoperative assessment and perioperative care to establish risk of, and to minimise the risk of common geriatric post-operative complications such as delirium and infection (GoR A), dehydration and falls (GoR C).
**MANAGEMENT OF URINARY INCONTINENCE IN FRAIL OLDER MEN & WOMEN**

**HISTORY/ SYMPTOM ASSESSMENT**
- Delirium
- Infection
- Pharmaceuticals
- Psychological
- Excess urine output
- Reduced mobility
- Stool impaction (and their factors)

4. RECOMMENDATIONS FOR FURTHER RESEARCH IN EPIDEMIOLOGY

1. Longitudinal study designs are needed to: (i) estimate the incidence and remission rates of urinary incontinence (UI) anal incontinence (AI) and pelvic organ prolapse (POP) and to (ii) describe the natural course of these conditions and (iii) to investigate risk factors and possible protective factors. In addition, similar studies regarding other lower urinary tract symptoms (LUTS) should be initiated.

2. Although there is now more information regarding prevalence, incidence, and other epidemiological data in developing countries, further information is still needed. It is recommended that fundamental research regarding prevalence, incidence and other epidemiological data in developing countries should be encouraged, and tailored to the cultural, economic and social environment of the population under study.

3. Some potential risk and protective factors deserve more attention. For example, the role of pregnancy and childbirth in the development of UI, AI and POP must be studied in a fashion that links population-based methods to clinical assessment of pregnancy, delivery and birth trauma and follows women over many years. Such a design is necessary because the effect of pregnancy and childbirth may become clear only years later when the woman is older and because the woman will not then be able to report the exact nature of the tear, episiotomy, etc.

4. There should be more emphasis on the associations between UI, AI and POP and specific diseases like stroke, diabetes, and psychiatric diseases.

5. The variation of disease occurrence in groups of different racial origin yet similar environmental exposures, lend support to the presumed genetic influence on the causation of UI, AI and POP. This again provides circumstantial evidence for a genetic contribution to pelvic floor muscle disorders since most of these studies have been unable to control for heritability in relation to the complex interaction of environmental factors.

The aetiology of UI, AI and POP is widely recognised to be multifactorial, yet the complex interaction between genetic predisposition and environmental influences is poorly understood. Genetic components require further investigation. Twin studies provide a possible means of studying the relative importance of genetic predisposition and environmental factors. By comparing monozygotic female twins with identical genotype, and dizygotic female twins who, on average, share 50 percent of their segregating genes, the relative proportions of phenotypic variance resulting from genetic and environmental factors can be estimated. A genetic influence is suggested if monzygotic twins are more concordant for the disease than dizygotic twins whereas evidence for environmental effects comes from monozygotic twins who are discordant for the disease.
The following proposals for research come from the Committees’ work in reviewing the current literature on Basic Science:

1. Integrate data from reductionist experiments to inform the formulation of better systems-based approaches in the investigation of the pathology of the lower urinary tract (LUT), the genital tract (GT) and the lower gastro-intestinal tract (LGIT).

2. Encourage greater emphasis on basic research to characterise tissues receiving relatively little attention: ie the lower gastrointestinal tract; the bladder neck and urethra; the ureter, pelvic floor musculature.

3. Generate research programmes for fetal and neonatal research in LUT and LGIT function.

4. Use genome-wide bioinformatic and population health surveys to generate testable hypotheses regarding the physiological and pathophysiological functions of the LUT, GT and LGIT.

5. Generate improved experimental approaches to investigate the pathophysiology of the LUT and LGIT by:
   - The development of animal models that accurately describe human pathological conditions, including the greater use of large-animal models
   - The better use of reverse translational approaches for linking animal models to the human disease.
   - The use of human tissue from well-characterised patient groups.
   - The development of emerging areas such as: tissue engineering; proteomics and metabolomics
   - Increased collaborations between biological, physical and mathematical sciences.

6. Develop centres of excellence or consortia of excellence in LUT, GT and GI research
   - Integrate expertise from university departments, academic medical units and industry
   - Encourage translational approaches to research.
   - Develop inter-institutional research-training programmes to allow new researchers the opportunity to better interact and exchange ideas.

7. Bring about a greater emphasis on the importance of research to medical trainees and science graduates through:
   - Establishing research training as a core component of postgraduate clinical development
   - Increased access to support funds, especially scholarships and personal awards
   - Organisation of focused multidisciplinary research meetings, either stand-alone or as dedicated sessions during national and international conferences
   - Greater interaction between medical centres and Higher Education Institutions (HEIs).
   - Allowing researchers-in-training better access to international meetings through reduced registration charges and improved travel grants.
   - Inclusion in clinical meetings of point-counterpoint session(s) with both basic science and clinical viewpoints.
   - Development of research forums for exchange of ideas between active researchers and industry.
   - Lobbying research-funding organisations about the medical and social importance of LUT and LGIT disorders.

8. Increase emphasis on research into LUT and LGIT in HEIs through:
   - Greater representation on grant-funding agencies
   - Encouragement of submission to high impact factor journals and recognition of research published in specialty journals
   - More integrated teaching and training opportunities
6. RECOMMENDATIONS FOR PRIMARY PREVENTION, CONTINENCE PROMOTION, MODELS OF CARE AND EDUCATION

Primary prevention, continence promotion and advocacy, models of care and education involves informing and educating the public and health care professionals that UI and FI are not inevitable, but are treatable or at least manageable. Other bladder disorders such as BPS/IC and POP can also be treated successfully. The committee found information about recent practice and research initiatives in all of these areas but evidence-based research only on primary prevention of UI. Continence promotion and advocacy, and professional and non-professional education, require prioritisation by public health professionals, educationalists, clinicians and researchers to reduce the burden that UI, FI, BPS/IC and POP places on society, healthcare systems, caregivers, and above all, affected adults. As to models of care, the evidence supports nurse-led community services as leading to higher health-related QoL and in some instances, higher cure rates. The multidisciplinary referral settings are also reporting favourable outcomes.

1. PRIMARY PREVENTION

- Pelvic floor muscle exercises can prevent UI in pregnant and postpartum women. (Level of Evidence: 1)
- Education designed for community-dwelling older women can prevent UI. (Level of Evidence: 1)
- No recent RCTs or case-control studies were located for prevention of FI. (Level of Evidence: 4)
- Pelvic floor muscle exercises should be provided for pregnant women. (GoR A)
- Education of older women to prevent UI should be provided. (GoR A)
- Continence promotion is required to address broad gaps in knowledge about incontinence (GoR C)
- Strategies to promote awareness about incontinence and its treatment can be strengthened by the use of evidence based theories and methods from the field of health promotion, including the social determinants of health (GoR D)
- The Internet represents an important source of information about incontinence, however the quality of information is variable (GoR C)
- For help-seeking behaviour, no RCTs or case-control studies were located (Level of Evidence 4)
- Continence promotion programmes need to accommodate varying levels of health literacy and access to health information in different populations (Level of Evidence: 4)
- Public health campaigns about incontinence and other pelvic floor disorders need to use terminology targeted to consumers’ understandings (Level of Evidence: 4)
- Satisfaction surveys about continence care could yield relevant and detailed information by using open-ended, rather than closed-ended questions (Level of Evidence: 1)
- Evidence for the use of leaflets or brochures in raising awareness about UI and different treatment options is inconclusive (Level of Evidence: 1).
- Evidence for the impact of continence advocacy worldwide was based on opinion (Level of Evidence: 1)
- Recommendation for help-seeking behaviour: No recommendation was possible based on the level of evidence provided by the available research.
- Worldwide Advocacy (GoR D)
2. MODELS OF CARE

- Effectiveness of service delivery models. (Level of Evidence: 4)
- A care delivery model should be based on the principles as described in the Optimum Continence Service Specification. (GoR C)
- Increased emphasis is needed on non-physician models of care. (GoR C)
- Despite the proliferation of guidelines, there is increasing evidence that practicing clinicians and nurses are not consistently following them. Implementation models should be developed on how to translate guidelines into practice. (GoR C)

3. EDUCATION

- Professional education of UI, FI, BPS/IC, and POP is not evident as determined by materials reviewed. (Levels of Evidence: 3-4)
- Effectiveness of guidelines in clinical practice has not been determined. (Levels of evidence: 3 to 4).
- There is a continued need for evaluation research to explore impact of guidelines on clinical care both at individual and population levels. This evaluation strategy needs to include impact on a wide range of outcomes, including incidence and prevalence of disease, treatment outcomes, prevention efforts, costs, and health care policy. (GoR: C)
- Effectiveness of public education efforts through various channels including education, public media and mass communications (Levels of Evidence 3-4)
- There is a need for additional focused research on methods to enhance patient and public about pelvic disorders, both at an individual and broader public level. (GoR C)
- The role of technology in public education for continence promotion should be examined in more depth. (GoR C)
7. RECOMMENDATIONS FOR TRANSLATIONAL AND CLINICAL RESEARCH

A. RECOMMENDATIONS ON STUDY CONDUCT AND STATISTICAL METHODS

The role of quality RCTs as providing the strongest level of evidence in incontinence research should be fully acknowledged by researchers, journal reviewers, and editors. (GoR A)

Careful attention to the planning and design of all research, especially RCTs, is of the utmost importance. (GoR A)

Appropriate expertise in biostatistics and clinical trial design should be employed at the design phase of a RCT and thereafter on an ongoing basis. For Phase 4, phase 5, and implementation trials, health economists should be included in trial design to support questions of value (cost-effectiveness). (GoR A)

The design, conduct, analysis and presentation of RCTs must be fully in accordance with the CONSORT Statement. (GoR A)

The design, conduct, analysis and presentation of observational studies should follow STROBE guidelines. (GoR A)

The design, conduct, analysis and presentation of meta-analyses should follow QUORUM guidelines. (GoR A)

Reporting studies of diagnostic tests, including urodynamics, should follow the STARD statement guidelines. (GoR A)

B. RECOMMENDATIONS ON RESEARCH CONDUCT

1. RECOMMENDATIONS FOR CONSERVATIVE TREATMENT TRIALS

Use correct terminology to describe the intervention. (GoR A)

Report details of ability to perform correct contraction, dose-response issues and adherence. (GoR A)

Use recommended outcome measures with high responsiveness, reliability and validity. (GoR A)

Compare new methods with the best available intervention. (GoR A)

Use power calculation in planning of the study. Avoid large sample sizes and weak (ineffective dosages) interventions. (GoR A)

For long-term follow-up studies report cross-over, co-interventions, recurrent and competing events, adherence in the follow-up period and loss to follow-up. (GoR A)

2. RECOMMENDATIONS FOR SURGICAL AND DEVICE TRIALS

- The safety and serious side effects of new operations must be completely defined with adequate follow-up so that risks can be weighed against efficacy. At a minimum, this requires more use of large scale, independent, prospective, multicentre cohort studies when RCTs are not practical. (GoR A)

- Safety and serious side effects of incontinence devices must be completely defined with adequate follow-up, especially for use of implantable devices and biological materials, so that risks can be weighed against efficacy. (GoR A)

- Valid informed research consent is required in all trials of surgical interventions, which is separate from the consent for surgery. (GoR A)

- We recommend ongoing research into the usefulness of pre- and post-operative predictive testing (such as urodynamics, ultrasound, MRI, etc) in surgical trials. (GoR A)

- Reports of successful treatment should be limited to subjects with a minimum (not mean) of one-year follow-up and should include a patient perspective measure. Specific assumptions about subjects lost to follow-up should be stated. (GoR A)
Randomisation for surgical trials should occur at the time of surgery to minimise drop-outs and switch of procedure (GoR A)

Long-term follow-up of RCT cohorts in an observational cohort is recommended (GoR A)

3. RECOMMENDATIONS ON COST ANALYSIS IN INCONTINENCE

Cost analysis should be incorporated into clinical studies whenever possible (137). (GoR A)

Cost analysis should describe the perspective of the analysis and analyses using the societal perspective and the payer perspective are useful. (GoR A)

C. RECOMMENDATIONS FOR SPECIFIC PATIENT GROUPS

1. MEN AND WOMEN WITH LUTS

1.1. Men with LUTS

Measurement of prostate size should be performed before and after treatment (at the same time as continence outcome measures where possible) whenever prostate size is considered to be a variable, or to change during the intervention and follow up. (GoR A)

Maximum free flow rate and measurement of post-void residual urine should be recorded pre-treatment and the effect of therapy on these parameters should be documented simultaneously with assessment of the primary outcome variables. (GoR A)

Participants should be stratified by prostate size at randomisation when size is considered to be a potentially important determinant of treatment outcome. (GoR C)

1.2. Women with LUTS

Specific information about menopausal status, hysterectomy, parity/obstetric history, and hormonal status should be included in baseline clinical trial data and controlled for in specified analyses in the research protocol. (GoR A)

High quality, symptom and bother scores (e.g., ICIQ-FLUTS, ICIQ-SF, ICIQ-QoL(KHO), PISQ, ICIQ-FLUTSsex) validated in women should be employed when assessing outcomes. (GoR A)

Standardised assessment of pelvic organ prolapse should be performed before treatment and at the time of other outcome assessments in all research where prolapse and continence outcomes are being assessed. (GoR A)

Criteria for cure/improvement/failure from incontinence treatment should be defined in the protocol based on patient perception as well as objective and semi-objective instruments such as validated questionnaires, diaries and pad tests. (GoR A)

Assessment of the impact of treatment on sexual function should be performed with other outcome assessment when appropriate. (GoR B)

2. CHILDREN

Long-term follow-up is of critical importance in the paediatric population in order to ascertain the effect of a treatment on normal growth and development. (GoR A)

Research is needed to develop standardised outcome measures including validated, age-specific symptom and disease-specific quality of life outcome measures. (GoR B)

3. NEUROGENIC POPULATIONS

Detailed urodynamic studies are recommended for classification of neurogenic lower urinary tract disorders in research studies because the nature of the lower tract dysfunction cannot be accurately predicted from clinical data. Videourodynamic studies are preferred but are not mandatory. (GoR C)

An area of high priority for research is the development of a classification system to define neurogenic disorders. Relevant features could include the underlying diagnosis, the symptoms, a precise documentation of the neuromuscular lesion by clinical neurophysiologic testing, and the nature of the urodynamic abnormality. (GoR C)

4. POPULATIONS AFFECTED BY BLADDER PAIN SYNDROME (INCLUDING INTERSTITIAL CYSTITIS)

Broader entry criteria should be used to reflect the full spectrum of the BPS/IC patient population. (GoR B)

The primary endpoint of BPS/IC trials should be patient driven and the Global Response Assessment is recommended. A wide spectrum of secondary endpoints will be useful in defining the effect of treatments. (GoR B)
5. POPULATIONS AFFECTED BY PELVIC ORGAN PROLAPSE

- A validated standardised assessment of prolapse (eg POP-Q) should be used for baseline and outcome assessments. (GoR A)
- Complete reporting of outcomes including a validated assessment of anatomy, functional status, and complications is essential. (GoR A)
- Complications/adverse events (especially for mesh) must be explicitly and completely reported in any research. (GoR A)
- Long term outcomes (> 2 years) of intervention studies are needed. (GoR A)

D. RECOMMENDATIONS FOR ETHICS IN RESEARCH

The GoR for this section is A.

Continuity in clinical direction from design through authorship is mandatory. Investigators should be involved in the planning stage and a publications committee should be named at the beginning of the clinical trial. The Uniform Requirements for Manuscripts Submitted to Biomedical Journals, from the International Committee of Medical Journal Editors should be followed. Authorship requires:

- Substantial contributions to conception and design or acquisition of data or analysis and interpretation of data,
  - Drafting the article or revising it critically for important intellectual content,
  - Final approval of the version to be published
- Authors should provide a description of what each contributed and editors should publish that information.
- Authors should have access to all raw data from clinical trials, not simply selected tables

Clinical trial results should be published regardless of outcome. The sponsor should have the right to review manuscripts for a limited period of time prior to publication but the manuscript is the intellectual property of its authors, not the sponsor.

- All authors should be able to accept responsibility for the published work and all potential conflicts of interest should be fully disclosed
The scientific committee which met at the end of the 1st ICI in 1998 supported the idea that a universally applicable questionnaire should be developed, that could be widely applied both in clinical practice and research and should reflect the patients’ perspective of their situation.

The hope was expressed that such a questionnaire would be used in different settings and studies and would allow cross-comparisons, for example, between a drug and an operation used for the same condition, in the same way that the IPSS (International Prostate Symptoms Score) has been used.

An ICIQ Advisory Board was formed to steer the development of the ICIQ and met for the first time in 1999. The project’s early progress was discussed with the Board and a decision made to extend the concept further and to develop the ICIQ Modular Questionnaire to include assessment of urinary, bowel and vaginal symptoms(1). The first module to be developed was the ICIQ Short Form Questionnaire for urinary incontinence: the ICIQ-UI Short Form (2) (Fig 1). The ICIQ-UI Short Form is now widely used globally and since 2004 its use or further development has been reported in almost 100 publications.

Given the intention to produce an internationally applicable questionnaire, requests were made for translations of the ICIQ-UI Short Form at an early stage, for which the Advisory Board developed a protocol for the production of translations of its modules. The ICIQ modules have been translated into over 40 languages to date across the various modules.

Since the fifth consultation a further two modules have been published and are available for use: the ICIQ Bladder Diary (3,4) and ICIQ-LTCqol(5). The bladder diary is the first fully validated bladder diary, which notably incorporated patient and clinician input during its development. The ICIQ-LTCqol questionnaire provides an assessment of symptoms, impact and bother associated with indwelling catheter use. This brings the total number of available modules to sixteen.

With increasing demand for electronic versions of questionnaires, a study has been conducted by the ICIQ group to evaluate the equivalence of the ICIQ’s psychometric properties in alternative formats (6). With equivalence demonstrated, app development for the eICIQ is underway.

www.ICIQ.net provides details of the validation status of the modules under development for urinary symptoms, bowel symptoms and vaginal symptoms and provides information regarding the content of existing modules. Information regarding production of translations and the ICIQ development protocol is also available for those interested in potential collaborations to continue development of the project.
Many people leak urine some of the time. We are trying to find out how many people leak urine, and how much this bothers them. We would be grateful if you could answer the following questions, thinking about how you have been, on average, over the PAST FOUR WEEKS.

1  Please write in your date of birth:  

2  Are you (tick one):  

   Female ☐  Male ☐  

3  How often do you leak urine? (Tick one box)  

   never ☐  0  
   about once a week or less often ☐  1  
   two or three times a week ☐  2  
   about once a day ☐  3  
   several times a day ☐  4  
   all the time ☐  5  

4  We would like to know how much urine you think leaks. How much urine do you *usually* leak (whether you wear protection or not)? (Tick one box)  

   none ☐  0  
   a small amount ☐  2  
   a moderate amount ☐  4  
   a large amount ☐  6  

5  Overall, how much does leaking urine interfere with your everyday life?  

   Please ring a number between 0 (not at all) and 10 (a great deal)  

   0  1  2  3  4  5  6  7  8  9  10  

   not at all a great deal  

   ICIQ score: sum scores 3*4+5 ☐  ☐  

6  When does urine leak? *(Please tick all that apply to you)*  

   never – urine does not leak ☐  
   leaks before you can get to the toilet ☐  
   leaks when you cough or sneeze ☐  
   leaks when you are asleep ☐  
   leaks when you are physically active/exercising ☐  
   leaks when you have finished urinating and are dressed ☐  
   leaks for no obvious reason ☐  
   leaks all the time ☐  

Thank you very much for answering these questions.

*Figure 1: ICIQ-UI Short Form*
The ICS defines three types of Bladder Charts and Diaries which can be used to collect data:

**MICTURITION TIME CHART**
- times of voiding and
- incontinence episodes

**FREQUENCY VOLUME CHART**
- times of voiding with voided volumes measured,
- incontinence episodes and number of changes of incontinence pads or clothing

**BLADDER DIARIES**
- the information above, but also
- assessments of urgency,
- degree of leakage (slight, moderate or large) and descriptions of factors leading to symptoms such as stress leakage, eg. running to catch a bus. It is important to assess the individual’s fluid intake, remembering that fluid intake includes fluids drunk plus the water content of foods eaten. It is often necessary to explain to a patient with LUTS that it may be important to change the timing of a meal and the type of food eaten, particularly in the evenings, in order to avoid troublesome nocturia.

The recent development and publication of the ICIQ Bladder Diary provides the first fully validated bladder diary that incorporated patient, clinician and statistical

</table>
input during its development (3,4). This rigorous de-
velopment methodology has ensured the provision of
a psychometrically robust tool that reflects the key is-
sues from a patient’s and clinical perspective to ena-
ble the gathering of required information to treat pa-
tients with LUTS (Fig 1). The diary is intended to be a
standalone tool that provides instructions and an ex-
ample to guide completion. The diary is intended for
completion over three days and fits onto two sides of
A4 to optimise administration and completion. Data
collected are:

- Fluid intake
- Urine output
- Leakage episodes
- Time of sleep and waking
- Pads used
- Optional bladder sensation scale

The bladder sensation scale is intended to be an in-
terchangeable variable that can be replaced with a
more pertinent measure for an intended use, for ex-
ample, a pain scale. It is advised that any scale used
in this manner should be validated.

INSTRUCTIONS FOR USING THE BLADDER
DIARY

This diary helps you and us to understand why you
get trouble with your bladder. The diary is a very im-
portant part of the tests we do, so that we can try to
improve you symptoms. On the chart you need to rec-
ord:

9. When you get out of bed in the morning, show
   this on the diary by writing ‘GOT OUT OF BED’.
10. During the day please enter at the correct time
    the drinks you have during the day, eg. 8.00am
    – two cups of coffee (total 400 ml).
11. The time you pass your urine, eg. 7.30am. Do
    this every time you pass urine throughout the day
    and night.
12. Each time you pass urine, collect the urine in a
    measuring jug and record the amount (in mls or
    fluid ozs) next to the time you passed the urine,
    eg. 1.30pm/320ml.
13. Each time you pass your urine, please write
down how urgent was the need to pass urine:
    ‘O’ means it was not urgent.
    + means I had to go within 10 minutes.
    ++ means I had to stop what I was doing and go
to the toilet.
14. If you leak urine, show this by writing an ‘W’ on
    the diary at the time you leaked.
15. If you have a leak, please add ‘P’ if you have to
    change a pad and ‘C’ if you have to change your
    underclothes or even outer clothes. So if you leak
    and need to change a pad, please write ‘WP’ at
    the time you leaked.
16. If you have a leakage please write in the column
called ‘Comments’ whether you leaked a small
amount or a large amount and what you were do-
ing when you leaked, eg. ‘leaked small amount
when I sneezed three times’.
17. Each time you change a pad or change clothes,
    please write in the ‘Comments’ column.
18. When you go to bed at the end of the day show
    it on the diary - write ‘Went to Bed’.
ICIQ-BLADDER DIARY (12/13)

Please complete this 3 day bladder diary. Enter the following in each column against the time. You can change the specified times if you need to. In the time column, please write BED when you went to bed and WOKE when you woke up.

**Drinks:** Write the amount you had to drink and the type of drink.

**Urine output:** Enter the amount of urine you passed in millilitres (mls) in the urine output column, day and night. Any measuring jug will do. If you passed urine but couldn’t measure it, put a tick in this column. If you leaked urine at any time write LEAK here.

**Bladder sensation:** Write a description of how your bladder felt when you went to the toilet using these codes

- **0:** If you had no sensation of needing to pass urine, but passed urine for “social reasons”, for example, just before going out, or unsure where the next toilet is.

- **1:** If you had a normal desire to pass urine and no urgency. “Urgency” is different from normal bladder feelings and is the sudden compelling desire to pass urine which is difficult to defer, or a sudden feeling that you need to pass urine and if you don’t you will have an accident.

- **2:** If you had urgency but it had passed away before you went to the toilet.

- **3:** If you had urgency but managed to get to the toilet, still with urgency, but did not leak urine.

- **4:** If you had urgency and could not get to the toilet in time so you leaked urine.

**Pads:** If you put on or change a pad put a tick in the pads column.

Here is an example of how to complete the diary:

</table>

**Bladder sensation codes**

0 - No sensation of needing to pass urine, but passed urine for “social reasons”
1 - Normal desire to pass urine and no urgency
2 - Urgency but it had passed away before you went to the toilet
3 - Urgency but managed to get to the toilet, still with urgency, but did not leak urine
4 - Urgency and could not get to the toilet in time so you leaked urine
